# P R E F A C E.

**U**TILITY ought to be the principal intention of every publication. Wherever this intention does not plainly appear, neither the books nor their authors have the smallest claim to the approbation of mankind.

To diffuse the knowledge of Science, is the professed design of the following work. What methods, it may be asked, have the compilers employed to accomplish this design? Not to mention original articles, they have had recourse to the best books upon almost every subject, extracted the useful parts, and rejected whatever appeared trifling or less interesting. Instead of dismembering the Sciences, by attempting to treat them intelligibly under a multitude of technical terms, they have digested the principles of every science in the form of systems or distinct treatises, and explained the terms as they occur in the order of the alphabet, with references to the sciences to which they belong.

As this plan differs from that of all the Dictionaries of Arts and Sciences hitherto published, the compilers think it necessary to mention what they imagine gives it a superiority over the common method. A few words will answer this purpose. Whoever has had occasion to consult Chambers, Owen, &c. or even the voluminous French *Encyclopedie*, will have discovered the folly of attempting to communicate science under the various technical terms arranged in an alphabetical order. Such an attempt is repugnant to the very idea of science, which is a connected series of conclusions deduced from self-evident or previously discovered principles. It is well if a man be capable of comprehending the principles and relations of the different parts of science, when laid before him in one uninterrupted chain. But where is the man who can learn the principles of any science from a Dictionary compiled upon the plan hitherto adopted? We will, however, venture to affirm, that any man of ordinary parts, may, if he chuses, learn the principles of Agriculture, of Astronomy, of Botany, of Chemistry, &c. &c. from the *ENCYCLOPEDIA BRITANNICA*.

IN the execution of this extensive and multifarious undertaking, the Compilers laboured under many disadvantages, partly arising from the nature of the work, and partly owing to the following circumstance.

THE Editors, though fully sensible of the propriety of adopting the present plan, were not aware of the length of time necessary for the execution, but engaged to begin the publication too early. However, by the remonstrances of the Compilers, the publication was delayed for twelve months. Still time was wanted. But the subscribers pushed the Editors, and they at last persuaded the Compilers to consent to the publication. If time had been allowed, the Compilers designed to have completed the sciences before proceeding to the technical terms; and by that means to have guarded against omissions, and made all the references from the terms to the sciences more particular. The consequence was unavoidable. All the references to any science that occur in the alphabet previous to the name of the science itself, are general: those that follow are particular; pointing out, not only the name of the science, but the number of the page.

WE must further acknowledge, that, in some instances, we have deviated from the general plan; but, we hope, not without reason. For example, under the words BOTANY and NATURAL HISTORY, it would have been an endless, and perhaps an useless task, to have given the generic distinctions of every plant, and of every animal. These are to be found under the names of the plants and animals themselves. The same observation may be made with respect to *Mineralogy*, *Materia Medica*, *Pathology*, *Physiology*, and *Therapeutics*. These are so interwoven with *Anatomy*, *Botany*, *Chemistry*, and *Medicine*, that, in a work of this kind, it was almost impossible, without many unnecessary repetitions, to treat them as distinct sciences. Indeed, properly speaking, they are not sciences, but parts or accessories of sciences, which, by the dexterity of teachers and authors, have been long exhibited under that form.

WITH regard to errors in general, whether falling under the denomination of mental, typographical, or accidental, we are conscious of being able to point out a greater number than any critic whatever. Men who are acquainted with the innumerable difficulties attending the execution of a work of such an extensive nature will make proper allowances. To these we appeal, and shall rest satisfied with the judgment they pronounce.

IN order to give some idea of the materials of which this Dictionary is composed, we shall conclude the preface with a list of the principal authors made use of in the compilation.

# Encyclopædia Britannica;

OR, A NEW AND COMPLETE

## D I C T I O N A R Y

O F

## A R T S and S C I E N C E S.

A B

A B A

**A**A, the name of several rivers in different parts of the world, viz. 1. of one in Solagne, in France; 2. of one in French Flanders; 3. of three in Switzerland; 4. of five in the Low Countries; 5. of five in Westphalia; 6. of one in Livonia.

**AABAM**, a term, among alchemists, for lead.

**AACH**, the name of a town and river in Swabia. It is also a name sometimes given to Aix-la-chapelle.

**AADE**, the name of two rivers, one in the country of the Grisons in Switzerland, and the other in Dutch Brabant.

**AAHUS**, a small town and district in Westphalia.

**AAM**, a Dutch measure for liquids, containing about 63 lb. avoirdupois.

**AAMA**, a province in Barbary, very little known.

**AAR**, the name of two rivers, one in Westphalia, and one in Switzerland. It is likewise the name of a small island in the Baltic sea.

**AARSEO**, a town in Africa, situated near the mouth of the river Mina.

**AATTER**, or **ATTER**, a province of Arabia Felix, situated on the Red-sea.---N. B. All other places which begin with a double A, but more generally with a single one, will be inserted according to the last orthography.

**AB**, the eleventh month of the civil year of the Hebrews. It corresponds to part of our June and July, and consists of 30 days. On the first of this month the Jews commemorate the death of Aaron by a fast: they fast also on the ninth, because on that day both the temple of Solomon and that erected after the captivity were burnt. The same day is also remarkable for the publication of Adrian's edict, prohibiting the Jews to look back, even when at a distance, upon Jerusalem, or to

Vol. I. No. 1.

lament its desolation. The lamp of the sanctuary, in the time of Ahaz, was extinguished on the night of the 18th, for which reason the Jews fast that day. See *ASTRONOMY, Of the division of time.*

**AB**, in the Syriac kalendar, is the name of the last summer-month.

**ABACATUAIA**, in ichthyology, a barbarous name of the zeus vomer, a fish belonging to the thoracic order of Linnæus. See *ZEUS.*

**ABACAY**, a barbarous name of a species of the psittacus, or parrot. See *PSITTACUS.*

**ABACH**, a town in Bavaria, situated on the Danube, a little above Ratibon.

**ABACISCUS**. See *ABACUS.*

**ABACOA**, a term, among ancient writers, for arithmetic. **ABACOO**, the name of one of the Bahama islands.

See *BAHAMA.*

**ABACOT**, the name of an ancient cap of state worn by the kings of England, the upper part whereof was in the form of a double crown.

**ABACTORES**, or **ABACTORS**, a term for such as carry off or drive away a whole herd of cattle by stealth.

**ABACTUS**, an obsolete term, among physicians, for a miscarriage procured by art.

**ABACUS**, a table strewed over with dust or sand, upon which the ancient mathematicians drew their figures, It also signified a cupboard, or buffet.

**ABACUS**, in architecture, signifies the superior part or member of the capital of a column, and serves as a kind of crowning to both. It was originally intended to represent a square tile covering a basket. The form of the abacus is not the same in all orders: in the Tuscan, Doric, and Ionic, it is generally square; but in the Corinthian and Composite, its four sides are arched inwards, and embellished in the middle with

A

some

some ornament, as a rose or other flower. Scamozzi uses *abacus* for a concave moulding on the capital of the Tuscan pedestal; and Palladio calls the plinth above the echinus, or boustin, in the Tuscan and Doric orders, by the same name. See plate I. fig. 1. and ARCHITECTURE.

**ABACUS** is also the name of an ancient instrument for facilitating operations in arithmetic. It is variously contrived. That chiefly used in Europe is made by drawing any number of parallel lines at the distance of two diameters of one of the counters used in the calculation. A counter placed on the lowest line, signifies 1; on the 2d, 10; on the 3d, 100; on the 4th, 1000, &c. In the intermediate spaces, the same counters are estimated at one half of the value of the line immediately superior, viz. between the 1st and 2d, 5; between the 2d and 3d, 50, &c. See plate I. fig. 2. A B, where the same number, 1768 for example, is represented under both by different dispositions of the counters.

**ABACUS harmonicus**, among musicians, the arrangement of the keys of a musical instrument.

**ABACUS logarithmicus**, a right-angled triangle, whose sides forming the right angle contain the numbers from 1 to 60, and its area the facts of every two of the numbers perpendicularly opposite. This is also called a canon of sexagesimals.

**ABACUS Pythagoricus**, the multiplication-table, or any table of numbers that facilitates operations in arithmetic.

**ABADAN**, a town of Persia, situated near the mouth of the Tygris.

**ABADDON**, from *abad*, to destroy; a name given by St John, in the Revelations, to the king of the locusts.

**ABADIR**, a title which the Carthaginians gave to gods of the first order. In the Roman mythology, it is the name of a stone which Saturn swallowed, believing it to be his new-born son Jupiter: hence it became the object of religious worship.

**ABÆRE**, a town in the deserts of Arabia.

**ABAFI**, a sea-term, signifying *towards the stern*: for instance, *abafi the mizzen-mast*, implies, that the object is between the mizzen-mast and the stern.

**ABAI**, in botany, a synonyme of the calycanthus præcox, a genus of plants belonging to the icofandria polygynia class of Linnæus. See CALYCANTHUS.

**ABAISSÉ**. See ABASED.

**ABALIENATION**. See ALIENATION.

**ABANBO**, a river of Ethiopia which falls into the Nile.

**ABANCAI**, or **ABANCAYS**, a town and river of Peru, in the district of Lima.

**ABANO**, a small town in Italy, subject to Venice, and situated five miles south-west of Padua.

**ABAPTISTON**, or **ANABAPTISTON**, an obsolete term for the surgical instrument called a *trepan*. See SURGERY, and *Trepan*.

**ABARCA**, a shoe made of raw hides, formerly worn by the peasants in Spain.

**ABARTICULATION**, in anatomy, a species of articulation which is now termed *diarthrosis*. See ANATOMY, Part I. and *Diarthrosis*.

**ABAS**, a weight used in Persia for weighing pearls. It is 1-8th less than the European carat.

**ABASCIA**, the country of the Alcas. See ALCAS.

**ABAISED**, *Abaisse*, in heraldry, an epithet applied to the wings of eagles, &c. when the tip looks downwards to the point of the shield, or when the wings are shut; the natural way of bearing them being extended.

**ABASING**, in the sea-language, signifies the same as striking.

**ABASSI**, or **ABASSIS**, a silver coin current in Persia, equivalent in value to a French livre, or tenpence half-penny Sterling. It took its name from Schaw Abas II. king of Persia, under whom it was struck.

**ABATAMENTUM**, in law, is an entry to lands by interposition, i. e. when a person dies seized, and another who has no right enters before the heir.

**ABATE**, from *abatre*, to destroy; a term used by the writers of the common law, both in an active and neutral sense; as, to *abate* a castle, is to destroy or beat it down; to *abate* a writ, is, by some exception to render it null and void.

**ABATE**, in the manage, implies the performance of any downward motion properly. Hence a horse is said to *abate*, or take down his curvets, when he puts both his hind-legs to the ground at once, and observes the same exactness in all the times.

**ABATEMENT**, in heraldry, implies something added to a coat of arms in order to lessen its dignity, and point out some imperfection or stain in the character of the wearer.

**ABATEMENT**, in law. See ABATE.

**ABATEMENT**, in commerce, signifies an allowance or discount in the price of certain commodities, in consideration of prompt payment; a diminution in the stipulated quantity or quality of goods, or some such circumstance.

**ABATEMENT**, in the customs, an allowance made upon the duty of goods, when the quantum damaged is determined by the judgment of two merchants upon oath, and ascertained by a certificate from the surveyor and land-waiver.

**ABATIS**, an ancient term for an officer of the stables.

**ABATOR**, in law, a term applied to a person who enters to a house or lands, void by the death of the last possessor, before the true heir.

**ABAVO**, in botany, a synonyme of the adanfonia, a shrub belonging to the monadelphica polyandria of Linnæus. See ADANSONIA.

**ABAYANCE**. See ABEYANCE.

**ABB**, a term, among clothiers, applied to the yarn of a weaver's warp. They also say *Abb-wool* in the same sense.

**ABBA**, in the Syriac and Chaldee languages, literally signifies a *father*; and figuratively, a superior, reputed as a father in respect of age, dignity, or affection. It is also a Jewish title of honour given to some of the class called Tanaites.

**ABBAT**. See ABBOT.

**ABBATIS**. See ABATIS.

**ABBEFORD**, a sea-port town in Norway, in 58. 44. N. lat.

**ABBESS**, the superior of an abbey or convent of nuns, over whom he has the same authority as the abbots over the monks. Their sex indeed hinders them from performing

- forming the spiritual-functions; but in the 12th century there were abesses in Spain who gave benedictions, and confessed people of both sexes.
- ABBEVILLE**, a large city of Piccardy in France, lying 90 miles north of Paris, in 50. 7. N. lat. and 2. o. E. long.
- ABBEY**, a religious house, governed by an abbot, where persons retire from the world, to spend their time in solitude and devotion. By the invention of masses for the living and the dead, dispensations, jubilees, indulgences, &c. the abbies procured such large privileges, exemptions, and donations, that, when these houses were totally abolished in England by Henry VIII. to the number of 190, an yearly revenue of L. 2,853,000 reverted to the crown.
- ABBEY-BOYLE**, a town in the county of Roscommon in Ireland.
- ABBOT**, the superior of an abbey or convent of monks. In the first ages of Christianity, the abbots were plain disinterested men, and lived contented with the government of their monasteries, which were generally erected in the most solitary parts: but being called from their deserts to oppose the heresies in the church, they soon began to entertain sentiments of ambition, and endeavoured to shake off their dependency on the bishops. Hence arose the distinctions of *mitred abbots*, *croziered abbots*, *ecumenical abbots*, *cardinal abbots*, &c. The principal distinction which subsists at present among abbots, is that of *regular* and *commendatory*; the former of which take the vow, and wear the habit of the order; the latter are seculars, though they are obliged to take orders at the proper age. Before the Reformation in England, there were abbots elective and representative; some mitred, and others not. The mitred abbots were invested with episcopal authority within their own limits, independent of the bishop; but the others were subject to the diocesan in all spiritual government. The mitred abbots were Lords of parliament, of which number Sir Edward Coke reckons 27, who sat in parliament, besides two Lords Priors.
- ABBREVIATE** of *adjudications*, in Scots law, an abstract or abridgment of a decret of adjudication, which is recorded in a register kept for that purpose. See *SCOTS LAW*, title, *Adjudications*.
- ABBREVIATION**, or **ABBREVIATURE**, implies the substitution of a syllable, letter, or character, for a whole word.
- ABBREVIATOR**, a person who abridges any large book into a narrower compass.
- ABBREVIATORS**, a college of 72 persons in the chancery of Rome, who draw up the pope's briefs, and reduce petitions into proper form.
- ABBREVOIR**, a term in masonry, expressive of certain indentures made in the joints or beds of stones, which being filled with the cement or mortar, bind them firmer together.
- ABBROCHMENT**. See **ABROCHMENT**.
- ABBUTTALS**, signify the buttings or boundings of land towards any point. Limits were anciently distinguished by artificial hillocks, which were called *boten-*
- times*, and hence *butting*. In a description of the site of land, the sides on the breadth are more properly *adjacentes*, and those terminating the length are *abbuttantes*; which, in old surveys, were sometimes expressed by *capitare*, to head; whence abbuttals are now called *head lands*.
- ABCASSES**, a people or country in Asia, situate between Circassia, the Black-sea, and Mingrelia.
- ABCDARIA**, in botany, a synonyme of the verbessina acmella. See **VERBESINA**.
- ABCDARY**, or **ABCDARIAN**, an epithet applied to compositions, whose parts are disposed in an alphabetical order.
- ABDALS**, or *servants of God*, in the Eastern countries; furious enthusiasts, who frequently run about the streets, destroying all who differ from them in religious opinions.
- ABDELAVI**, in botany, a name used by Arabian writers for a species of cucumis. See **CUCUMIS**.
- ABDEST**, a term used for the legal purifications by water, practised among the Mahometans and Persians before they begin their religious ceremonies.
- ABDICARIAN proposition**, in logic, the same with a negative one. See **LOGIC**, and *Proposition*.
- ABDICATION**, the action of renouncing or giving up an office.
- ABDOMEN**, in anatomy, is that part of the trunk of the body which lies between the thorax and the bottom of the pelvis. See **ANATOMY**, part VI.
- ABDUCTION**, a form of reasoning among logicians, which consists in drawing conclusions from certain and undeniable propositions. See **LOGIC**.
- ABDUCTION**, in surgery, a species of fracture wherein the broken parts of the bone recede from each other. See **SURGERY**, *Of fractures*.
- ABDUCTOR**, in anatomy, the name of several muscles which serve to open or draw back the parts to which they are fixed. See **ANATOMY**, Part VI.
- ABEL-TREE**, or **ABELE-TREE**, an obsolete name for a species of the poplar. See **POPULUS**.
- ABELIANS**, **ABELOITES**, or **ABELONIANS**, a sect of heretics that sprung up near Hippo in Africa during the reign of Arcadius. They had one distinguishing and extraordinary tenet, which was to marry, but never to consummate.
- ABELMOSCH**, or **ABELMUSCH**, in botany, the trivial name of a species of the hibiscus. See **HIBISCUS**.
- ABENSBURG**, or **ABENSPERG**, a small town in Bavaria, on the river Abenz, near the Danube.
- ABERBROTHOCK**, one of the royal boroughs of Scotland, situated in the county of Angus; about 40 miles north of Edinburgh. Its west long. is 2. 20. and N. lat. 56. 30. There was formerly one of the richest monasteries in Scotland in this town. It was founded by King William of Scotland about the year 1170, in honour of Thomas Becket Archbishop of Canterbury, with whom he is said to have been intimately acquainted. This monastery received considerable donations from Gilchrist Earl of Angus, and Gilbred his son. It was possessed by the monks of St Bennet. The inhabitants of Aberbrothock, for the sake

fake of their monastery, were made denisons of all England (London excepted) by King John.

**ABERDEEN**, the name of two cities in Scotland, called the *Old* and *New Towns*, situated on the German Ocean, in 1 45. W. lon. and 57. 11. N. lat.

The old town lies about a mile to the north of the new, at the mouth of the river Don, over which is a fine bridge, of a single arch, which rests at both sides on two rocks. The old town was formerly the seat of the bishop, and had a large cathedral church, commonly called *St Machers*. This cathedral had anciently two rows of stone pillars across the church, and three turrets; the steeple, which was the largest of these turrets, rested upon an arch, supported by four pillars. In this cathedral there was a fine library; but about the year 1560 it was almost totally destroyed.

But the capital building is the King's-college, on the south side of the town, which is a large and stately fabric. The steeple is vaulted with a double cross arch, above which is an imperial crown, supported by eight stone pillars, and closed with a globe and two gilded crosses. In the year 1631 this steeple was thrown down by a storm, but was soon after rebuilt in a more stately form. This college was founded by Bishop El phinston in the year 1500; but James IV. claimed the patronage of it, and it has since been called the *King's College*. This college, and the Marishall-college in the new town, form one university, called the *University of King Charles*.

The new town is the capital of the shire of Aberdeen. For largeness, trade, and beauty, it greatly exceeds any town in the North. It stands upon a hill or rising ground. The buildings are generally four stories high, and have, for the most part, gardens behind them, which gives it a beautiful appearance. On the high street is a large church, which formerly belonged to the Franciscans. This church was begun by Bp William Elphinston, and finished by Gavinus Dunbar, Bishop of Aberdeen, about the 1500. Bp Dunbar is said likewise to have built the bridge over the Dee, which consists of seven arches. The chief public building in the new town is the Marishall-college, founded by George Keith Earl of Marshell, in the year 1593; but has since been greatly augmented with additional buildings. In both the Marishall and King's-college the languages, mathematics, natural philosophy, divinity, &c. are taught by very able professors.

**ABERDOUR**, a small town in Fifeshire, Scotland, on the frith of Forth, about ten miles N. W. of Edinburgh.

**ABERGAVENY**, in Monmouthshire, England, a well-built town, lying 142 miles W. by N. of London, in 51. 50. N. lat. and 30. 5. W. lon. This town consists of about 500 houses, has a weekly market on the Tuesdays, and another on the Fridays; and three fairs for horses, sheep, and black cattle.

**ABERMURDER**, an old law-term for murder, proved in a judicial manner, which could not be atoned for with money.

**ABERRATION**, in astronomy, a small apparent motion of the fixed stars, first discovered by Dr Bradley

and Mr Mollineux, and found to be owing to the progressive motion of light, and the earth's annual motion in its orbit. If a lucid object be fixed, and the eye of the observer moving along in any other direction than that of a straight line from the eye to the object, it is plain, that the object must have an apparent motion, greater or less, according to the velocity with which the eye is moved, and the distance of the object from the eye. See *ASTRONOMY*.

**ABERRATION**, in optics, a deviation of the rays of light which prevents their uniting in the same focal point, and is occasioned by their being refracted by a spherical lens, or reflected by a spherical speculum. See *OPTICS*.

**ABERYSWITH**, a market-town in Wales, lying 199 miles W. S. W. of London, in 52. 30. N. lat. and 40 15 W. long.

**ABESTA**, the name of one of the sacred books of the Persian magi, which they ascribe to their great founder Zoroaster. The abesta is a commentary on two others of their religious books called *Zend* and *Pazind*; the three together including the whole system of the Ignicold, or worshippers of fire.

**ABESTON**, a blundering way of writing Abestus. See *ABESTUS*.

**ABETTOR**, a law-term, implying one who encourages another to the performance of some criminal action, or who is art and part in the performance itself. Treason is the only crime in which abettors are excluded by law, every individual concerned being considered as a principal. It is the same with *art and part* in the Scots law.

**ABEVACUATION**, in medicine, a gentle evacuation. See *EVACUATION*.

**ABEX**, the name of a large tract of land, lying along the west coast of the Red-sea, south of Egypt, subject to the Ottoman Porte.

**ABEYANCE**, in law, the expectancy of an estate. Thus if lands be leased to one person for life, with reversion to another for years, the remainder for years is an abeyance till the death of the lessee.

**ABHEL**, in botany, an obsolete name of the fabina or favin. See *JUNIPER* and *SABINA*.

**ABIB**, signifying an ear of corn, a name given by the Jews to the first month of their ecclesiastical year, afterwards called *Nisan*. It commenced at the vernal equinox, and, according to the course of the moon, by which their months were regulated, answered to the latter part of our March, and beginning of April.

**ABIDING** by a writing, in Scots law: When a person founds upon a writing alleged to be false, he may be obliged to declare judicially, whether he will stand or abide by it as a true deed. As to the consequences of abiding by, or passing from, a false deed, see *SCOTS LAW*, title, *Crimes*.

**ABIES**, the fir-tree, in botany, belongs to the monœcia monadelphica class of Linnæus. For its characters, see *PINUS*, of which it is a species.

**ABIGEAT**, an old law-term, denoting the crime of stealing cattle by droves or herds. This crime was more severely punished than *furtum*, the delinquent being

being often condemned to the mines, banishment, and sometimes capitally.

**ABIGEATUS**, or **ABACTUS**, among physicians, signifies a miscarriage effected by art.

**ABIGES**, a term in the Roman law, applied to one who had been guilty of the crime **ABIGER**; which see.

**ABILITY**, a term in law, denoting a power of doing certain actions in the acquisition or transferring of property.

**ABINGDON**, a town of Berkshire, England, seated on the Thames, about 55 miles W. of London, and gives title of Earl to the noble family of Bertie.

**AB-INTESTATE**, in the civil law, is applied to a person who inherits the right of one who died intestate, or without making a will. See **INTESTATE**.

**ABISHERING**, a term found in old law books, denoting a liberty or freedom from all americiaments, and a right to exact forfeitures of others.

**ABIT**, or **ABOIT**, obsolete terms for ceruse or white lead. See **CERUSE** and **CHEMISTRY**.

**ABJURATION**, in our ancient customs, implied an oath, taken by a person guilty of felony, and who had fled to a place of sanctuary, whereby he solemnly engaged to leave the kingdom for ever.

**ABJURATION**, is now used to signify the renouncing, disclaiming, and denying, upon oath, the Pretender to have any kind of right to the crown of these kingdoms.

**ABJURATION of heresy**, the solemn recantation of any doctrine as false and wicked.

**ABLAC**, a small river in Swabia, which falls into the Danube not far from Furstenburg.

**ABLACTATION**, the weaning a child from the breast. See **WEANING**.

**ABLACTATION**, in gardening, signifies grafting by approach. See **GRAFTING** and **GARDENING**.

**ABLACQUEATION**, an old term in gardening, signifies the operations of removing the earth and baring the roots of trees in winter, to expose them more freely to the air, rain, snows, &c.

**ABLATIVE**, is the 6th case in Latin grammar, and peculiar to that language. It is opposed to the dative, which expresses the action of *giving*, and the ablative that of *taking away*.

**ABLAY**, or **ABLAI**, a country of Great Tartary, whose inhabitants, called *Bocharis*, are vassals of the Russians. It lies to the east of the Irtsi, and extends 500 leagues along the southern frontiers of Siberia.

**ABLECTI**, in Roman antiquity, a select body of soldiers chosen from among those called **EXTRAORDINARI**, which see.

**ABLEGMINA**, among the ancient Romans, signified those parts in the entrails of victims which were sprinkled with flour, and burnt upon the altar, in sacrificing to the gods.

**ABLET**, or **ABLEN**, an obsolete name of the fish called *Cyprinus*. See **CYPRINUS**.

**ABLUMENTS**, in medicine, are the same with diluters.

**ABLUTION**, a ceremony used by the ancient Romans before they began the sacrifice, which consisted in washing the body. They very probably learned this ceremony from the Jews, as have also the Mahometans, who still practise it with the utmost strictness.

VOL. I. No. 1.

**ABLUTION**, among chemists, the sweetening any matter impregnated with salts, by repeatedly washing it with pure water. See **CHEMISTRY**.

**ABLUTION**, with physicians, is either the washing of any external part by bathing, or of the stomach and intestines by diluting liquors.

**ABO**, a city of Sweden, capital of Finland, seated at the mouth of the river Aurojoks on the gulph of Bothnia, 24. o. N. E. of Stockholm, in lat. 60. 30. N. and long. 21. 30. E.

**ABOARD**, signifies any part on the deck or inside of a ship; hence any person who goes on the deck, or into the apartments of a ship, is said to go aboard.

**ABOLITION**, implies the act of annulling, destroying, making void, or reducing to nothing. In law, it signifies the repealing any law or statute.

**ABOLLA**, the name of a military garment worn by the Greeks and Romans.

**ABOMASUS**, **ABOMASUM**, or **ABOMASIUS**, names of the fourth stomach of ruminating animals. The first stomach is called *venter*, the second *reticulum*, the third *omasus*, and the fourth *abomasus*. The third stomach, omasis, is endued with the singular quality of curdling milk. But the truth is, the stomachs of almost all animals, whether they ruminate or not, will produce the same effect, though not perhaps in an equal degree, as the stomachs of calves or lambs. See **MILK**, **RUNNET**.

**ABOMINATION**, a term used in scripture to express idols, idolatry, &c.

**ABORIGINES**, an epithet applied to the original or first inhabitants of any country, but particularly used to signify the ancient inhabitants of Latium, or country now called *Campagna di Roma*, when *Aeneas* with his Trojans came into Italy.

**ABORTION**, in midwifery, the birth of a fœtus before it has acquired a sufficient degree of perfection to enable it to perform respiration and the other vital functions. See **MIDWIFERY**, title, *Of abortions*.

**ABORTION**, among gardeners, signifies such fruits as, being produced too early, never arrive at maturity.

**ABORTIVE**, in a general sense, implies any thing which comes before its proper time, or miscarries in the execution.

**ABOY**, a small town in Ireland, in the province of Leinster.

**ABRA**, a silver coin of Poland, in value nearly equivalent to an English shilling.

**ABRACADABRA**, a magical word or spell, which being written as many times as the word contains letters, and omitting the last letter of the former every time, was, in the ages of ignorance and superstition, worn about the neck, as an antidote against agues and several other diseases.

**ABRAHAM'S balm**, in botany. See **CANNABIS**.

**ABRAHAMITES**, an order of monks exterminated for idolatry by Theophilus in the ninth century. Also the name of another sect of heretics who had adopted the errors of Paulus. See **PAULICIANS**.

**ABRAMIS**, an obsolete name for the fish cyprinus. See **CYPRINUS**.

B

ABRASA,

ABRASA, in surgery, ulcers, where the skin is so tender and lax as to render them subject to abrasion.

ABRASION, in medicine, the corroding of any part by acrid humours or medicines.

ABRAUM, an obsolete name of a certain species of clay, called by some authors *Adamic earth*, on account of its red colour.

ABRASAX, or ABRAXAS, a mystical term found in the ancient theology and philosophy of Basilides's followers.

ABRAX, an antique stone with the word *abrasax* engraved on it. They are of various sizes, and most of them as old as the third century.

ABREAST, a sea-term. In an attack, pursuit, or retreat at sea, the squadrons or divisions of a fleet are often obliged to vary their dispositions, and at the same time observe a proper regularity, by sailing in right or curved lines: when they sail at a proper distance from each other, and are all equally forward, they are then said to have formed the line *abreast*.

ABRENUNCIATION. See RENUNCIATION.

ABRIDGEMENT, in literature, a term signifying the reduction of a book into a smaller compass.—The art of conveying much sentiment in few words, is the happiest talent an author can be possessed of. This talent is peculiarly necessary in the present state of literature; for many writers have acquired the dexterity of spreading a few critical thoughts over several hundred pages. When an author hits upon a thought that pleases him, he is apt to dwell upon it, to view it in different lights, to force it in improperly, or upon the slightest relations. Though this may be pleasant to the writer, it tires and vexes the reader. There is another great source of diffusion in composition. It is a capital object with an author, whatever be the subject, to give vent to all his best thoughts. When he finds a proper place for any of them, he is peculiarly happy. But, rather than sacrifice a thought he is fond of, he forces it in by way of digression, or superfluous illustration. If none of these expedients answer his purpose, he has recourse to the margin, a very convenient apartment for all manner of pedantry and impertinence. There is not an author, however correct, but is more or less faulty in this respect. An abridger, however, is not subject to these temptations. The thoughts are not his own; he views them in a cooler and less affectionate manner; he discovers an impropriety in some, a vanity in others, and a want of utility in many. His business, therefore, is to retrench superfluities, digressions, quotations, pedantry, &c. and to lay before the public only what is really useful. This is by no means an easy employment: To abridge some books, requires talents equal, if not superior, to those of the author. The facts, manner, spirit, and reasoning, must be preserved; nothing essential, either in argument or illustration, ought to be omitted. The difficulty of the task is the principal reason why we have so few good abridgements: Wynne's abridgement of Locke's Essay on the Human Understanding is, perhaps, the only unexceptionable one in our language.

These observations relate solely to such abridgements as are designed for the public. But,

When a person wants to set down the substance of any book, a shorter and less laborious method may be followed. It would be foreign to our plan to give examples of abridgements for the public: But, as it may be useful, especially to young people, to know how to abridge books for their own use, after giving a few directions, we shall exhibit an example or two, to shew with what ease it may be done.

Read the book carefully; endeavour to learn the principal view of the author; attend to the arguments employed: When you have done so, you will generally find, that what the author uses as new or additional arguments, are in reality only collateral ones, or extensions of the principal argument. Take a piece of paper, or a common-place book, put down what the author wants to prove, subjoin the argument or arguments, and you have the substance of the book in a few lines. For example,

In the Essay on Miracles, Mr Hume's design is to prove, That miracles which have not been the immediate objects of our senses, cannot reasonably be believed upon the testimony of others.

Now, his argument, (for there happens to be but one), is,

“ That experience, which in some things is variable, in others uniform, is our *only* guide in reasoning concerning matters of fact. A variable experience gives rise to probability only; an uniform experience amounts to a proof. Our belief of any fact from the testimony of eye-witnesses, is derived from no other principle than our experience in the veracity of human testimony. If the fact attested be miraculous, here arises a contest of two opposite experiences, or proof against proof. Now, a miracle is a violation of the laws of nature; and as a firm and unalterable experience has established these laws, the proof against a miracle, from the very nature of the fact, is as complete as any argument from experience can possibly be imagined; and if so, it is an undeniable consequence, that it cannot be surmounted by any proof whatever derived from human testimony.”

In Dr Campbell's Dissertation on Miracles, the author's principal aim is to shew the fallacy of Mr Hume's argument; which he has done most successfully by another single argument, as follows:

“ The evidence arising from human testimony is not solely derived from experience: on the contrary, testimony hath a natural influence on belief antecedent to experience. The early and unlimited assent given to testimony by children gradually contracts as they advance in life: it is, therefore, more consonant to truth, to say, that our *diffidence* in testimony is the result of experience, than that our *faith* in it has this foundation. Besides, the uniformity of experience, in favour of any fact, is not a proof against its being reversed in a particular instance. The evidence arising from the single testimony of a man of known veracity will go far to  
“ establish

“ establish a belief in its being actually reversed: If  
 “ his testimony be confirmed by a few others of the  
 “ same character, we cannot withhold our assent to  
 “ the truth of it. Now, though the operations of nature  
 “ are governed by uniform laws, and though we  
 “ have not the testimony of our senses in favour of  
 “ any violation of them, still, if, in particular instances,  
 “ we have the testimony of *thousands* of our fellow-  
 “ low-creatures, and those too men of strict integrity,  
 “ swayed by no motives of ambition or interest,  
 “ and governed by the principles of common sense,  
 “ That they were actually eye-witnesses of these vio-  
 “ lations, the constitution of our nature obliges us to  
 “ believe them.”

These two examples contain the substance of about 400 pages.—Making private abridgements of this kind has many advantages; it engages us to read with accuracy and attention; it fixes the subject in our minds; and, if we should happen to forget, instead of reading the books again, by glancing a few lines, we are not only in possession of the chief arguments, but recall in a good measure the author's method and manner.

Abridging is peculiarly useful in taking the substance of what is delivered by Professors, &c. It is impossible, even with the assistance of short-hand, to take down, *verbatim*, what is said by a public speaker. Besides, although it were practicable, such a talent would be of little use. Every public speaker has circumlocutions, redundancies, lumber, which deserve not to be copied. All that is really useful may be comprehended in a short compass. If the plan of the discourse, and arguments employed in support of the different branches be taken down, you have the whole. These you may afterwards extend in the form of a discourse dressed in your own language. This would not only be a more rational employment, but would likewise be an excellent method of improving young men in composition, an object too little attended to in all our universities. Besides, it would be more for the honour of professors; as it would prevent at least such immense loads of disjointed and unintelligible rubbish from being handed about by the name of such a man's lectures.

**ABRIDGEMENT**, in law, signifies the making a declaration or plaint shorter by leaving out something

**ABRIDGEMENT**, in arithmetic. See **ARITHMETIC**, *Of vulgar fractions*

**ABRIDGEMENT**, in algebra. See **ALGEBRA**, *Of equations*

**AEROBANIA**, a town and district in Transylvania.

**ABROCHMENT**, an old law term which signifies forestalling. See **FORESTALLING**.

**ABROGATION**, signifies annulling, making void, or repealing a law.

**ABROLKOS**, the name of certain shelves, or banks of sand, about 20 leagues from the coast of Brazil.

**ABRON**, a river of France which falls into the Loire not far from Nevers

**ABRONO**. See **ABRUGI**.

**ABROTANOIDES**, the name of a species of coral called

*porus*. It is also a synonyme of the artemisia. See **ARTEMISIA**.

**ABROTANOIDES**, a wine mentioned by Dioscorides, impregnated with futhernwood.

**ABROTANUM**, in botany, a synonyme of several plants. See **ARTEMISIA**, **FILAGO**, **SANTOLINA**.

**ABRUPTION**, in surgery. See **ABDUCTION**.

**ABRUS**, in botany, the trivial name of the glycine. See **GLYCINE**.

**ABRUZZO**, in geography, the name of two provinces belonging to the K. of Naples, on the gulph of Venice, distinguished by Nearer and Farther Abruzzo, from their position with respect to Naples.

**ABSCEDENTIA**, in surgery, a term applied to decayed parts of the body, which, in a morbid state, are separated from the sound, or lose that union which was preserved in a natural state.

**ABSCCESS**, in medicine and surgery, an imposthume, or any tumor or cavity containing purulent matter. See **SURGERY**, title, *Of tumours or abscesses*.

**ABSCHARON**, a town in Asia, situated on the western shore of the Caspian sea.

**ABSCISSE**, in mathematics. See **CONIC SECTIONS**, **ABSCISSION**, a figure in rhetoric, whereby the speaker stops short in the middle of his discourse, leaving the audience to make the inference.

**ABSCISSION**, in surgery, the same with amputation.

**ABSCONSA**, a dark lantern used by the monks at the ceremony of burying their dead.

**ABSENCE**, in Scots law: When a person cited before a court does not appear, and judgment is pronounced, that judgment is said to be *in absence*. No person can be tried criminally in absence. See **LAW**, title, *Sentences and their execution*.

**ABSINTHIATED medicines**, such as are impregnated with absinthium or wormwood.

**ABSINTHIUM**, in botany, the trivial name of the common wormwood or artemisia. It is also a synonyme of the tanacetum incanum, the fenecio incanum, the anthemis montana, the achillæa ægyptiaca, and of the parthenium hysterophorus. See **ARTEMISIA**, &c.

**ABSIS**, in astronomy, the same with **AP SIS**, which see.

**ABSOLUTE**, in a general sense, denotes a thing's being independent of, or unconnected with, any other; it is also used to express freedom from all limitation.

**ABSOLUTE government**, is that wherein the prince, unlimited by the laws, is left solely to his own will. See **GOVERNMENT**.

**ABSOLUTE gravity**, in physics, is the whole force by which a body is urged downwards. See **MECHANICS**.

**ABSOLUTE**, in metaphysics, denotes a being that possesses independent existence.

**ABSOLUTION**, in general, is the pardoning or forgiving a guilty person.

**ABSOLUTION**, in civil law, is a sentence whereby the party accused is declared innocent of the crime laid to his charge.

**ABSOLUTION**, in the canon law, is a juridical act whereby the ecclesiastical officers remit or forgive the penitent offender, or declare him restored to the privileges of innocence in consideration of his repentance.

**ABSORBENT**

**ABSORBENT medicines**, testaceous powders, as chalk, crabs-eyes, &c. which are taken inwardly for drying up or absorbing any acrid or redundant humours in the stomach or intestines. They are likewise applied outwardly to ulcers or sores with the same intention.

**ABSORBENT vessels**, in anatomy, a name given promiscuously to the lacteal vessels, lymphatics, and inhalent arteries. See ANATOMY.

**ABSORBENT vessels**, is also a name used for the small fibrous roots of plants.

**ABSORPTION**, in the animal economy, is the act whereby the absorbent vessels imbibe the juices, &c.

**ABSTEMIOUS**, an epithet applied to persons very temperate in eating and drinking. It is likewise applied to those who could not partake of the eucharist on account of their aversion to wine.

**ABSTENTUS**, in law, an heir who is with-held by his tutor from entering upon his inheritance.

**ABSTERGENT medicines**, those employed for resolving obstructions, concretions, &c. such as soap, &c.

**ABSTINENCE**, the refraining from something we have a propensity to. It commonly imports a spare diet.

**ABSTINENTS**, in church history, a sort of people in the ancient church who carried their abstinence and mortification very far. They have been classed with heretics, though we have no certain account of their particular opinions.

**ABSTRACT idea**, in metaphysics, is a partial idea of a complex object, limited to one or more of the component parts or properties, laying aside or abstracting from the rest. Thus, in viewing an object with the eye, or recollecting it in the mind, we can easily abstract from some of its parts or properties, and attach ourselves to others: we can attend to the redness of a cherry, without regard to its figure, taste, or consistence. See ABSTRACTION, METAPHYSICS.

**ABSTRACT terms**, words that are used to express abstract ideas. Thus beauty, ugliness, whiteness, roundness, life, death, are abstract terms.

**ABSTRACT mathematic**, sometimes denominated *pure mathematics*, treat of magnitude or quantity absolutely and generally considered, without regard to any particular species of magnitude.

**ABSTRACT numbers**, such as have no particular application.

**ABSTRACT**, is also a term in literature to signify a concise, yet general view or analysis of some larger work. It differs from an abridgment, in being shorter and more superficial; and from an extract, as this last is a copy of some part or passage of it.

**ABSTRACTION**, the operation of the mind when occupied by abstract ideas. A large oak fixes our attention, and abstracts us from the firubs that surround it. In the same manner, a beautiful woman in a crowd, abstracts our thoughts, and engrosses our attention solely to herself. These are examples of real abstraction: when these, or any others of a similar kind, are recalled to the mind, after the objects themselves are removed from our sight, they form what is called *abstract ideas*, or the mind is said to be employed in abstract ideas. But the power of abstraction is not confined to ob-

jects that are separable in reality as well as mentally: the size, the figure, the colour of a tree are inseparably connected, and cannot exist independent of each other; and yet we can mentally confine our observations to any one of these properties, neglecting or abstracting from the rest.

**ABSTRACTION**, in chemistry, the evaporating or drawing off the menstrum from any subject.

**ABSTRACTITIOUS**, an obsolete term, among chemists, for a vegetable spirit obtained without fermentation.

**ABSTRUSE**, a term applied to any thing that is hard to be understood, whether the obscurity arises from the difficulty of the subject, or the confused manner of the writer.

**ABSURD**, an epithet for any thing that contradicts an apparent truth.

**ABSURDITY**, the name of an absurd action or sentiment.

**ABSUS**, in botany, the trivial name of a species of the castia.

**ABSINTHIUM**. See ABSINTHIUM.

**ABUAI**, one of the Philippine isles. See PHILIPPINE.

**ABUCCO**, **ABOCCO**, or **ABOCCI**, a weight used in the kingdom of Pegu, equal to 12 $\frac{1}{2}$  teccalis; two abuccos make an agiro; and two agiri make half a biza, which is equal to 2 lb. 5 oz. of the heavy weight of Venice.

**ABUKESO**. See ASLANI.

**ABUNA**, the title of the Archbishop or Metropolitan of Abyssinia.

**ABUNDANT numbers**, such whose aliquot parts added together exceed the number itself; as 20, the aliquot parts of which are, 1, 2, 4, 5, 10, and make 22.

**ABUSAN**, an island on the coast of Africa, in 35 35. N lat dependent on the province of Garet, in the kingdom of Fez.

**ABUSE**, implies the perverting of any thing from its original intention.

**ABUTIGE**, a town in Upper Egypt, famous for producing the best opium.

**ABUTTALS**. See ABUTTALS.

**ABUTILON**, in botany, the trivial name of several species of the fida. See SIDA. Abutilon is also a synonyme of the melochia tomentosa, and melochia depressa, two American plants of the monadelphia pentandria class. It is likewise a synonyme of the lavatera, malva, and hibiscus.

**ABYSS**, in a general sense, signifies any unfathomable gulph. It is also the name of a vast cavern filled with water, supposed to exist near the centre of the earth.

**ABYSS**, in scripture, is sometimes used for hell.

**ABYSS**, in antiquity, a name given to the temple of Proserpine,

**ABYSS**, among alchemists, signifies the receptacle of the seminal matter, and sometimes the seminal matter itself.

**ABYSSINIA**, a kingdom of Africa, bounded on the N. by that of Sennar, or Nubia; on the E. partly by the Red sea, and partly by Danacala; on the W. by Gorham and Gingiro; and on the S. by Alaba and Ommo-Zaidi. It was formerly of greater extent

extent than it is at present, because several provinces have revolted, and the Turks have made encroachments to the east. The land is fertile in many places, and the air is very hot, except in the rainy season, and then it is very temperate. For four months in the year, greater rains fall there than perhaps in any other part of the world, which occasion the swelling of the river Nile, that has its source in this country. It contains mines of all sorts of metal, except tin; but the inhabitants make no great advantage thereof. The fields are watered by several streams, except in the mountainous parts. The emperor, or king, is called *Negus*; and he has been commonly taken for Prester John. His authority is absolute, and he often dwells with his whole court in tents. However, Abyssinia is not without cities, as some pretend; for Gondar is a large place, where the king commonly resides when he is not in the field. The inhabitants are black, or very near it; but they are not so ugly as the negroes. They make profession of the Christian religion, but it has a mixture of Judaism. The habit of persons of quality is a silken vest, with a sort of scarf; but the common people wear nothing but a pair of drawers.

**ABYSSINIAN church**, that established in the empire of Abyssinia. It is a branch of the Copts or Jacobites; a sect of heretics, who admit but one nature in Jesus Christ.

**ACACALOTL**, the Brazilian name of a species of the *Corvus*. See *CORVUS*.

**ACACIA**, in botany, a synonyme of the poinciana, genista, mimosa, robinia, guaiacum, &c. See these articles.

**ACACIA**, in the materia medica, the inspissated juice of the unripe fruit of the acacia. This juice is brought from Egypt in roundish pieces, wrapt up in thin bladders, and is used as a mild astringent.

**ACACIA germanica**. See *PRUNA*.

**ACACIA**, among antiquaries, something resembling a roll or bag, seen on medals, as in the hands of several consuls and emperors. Some take it to represent a handkerchief rolled up, wherewith they made signals at the games; others a roll of petitions or memorials; and some a purple bag full of earth, to remind them of their mortality.

**ACACIANS**, in ecclesiastical history, the name of several sects of heretics; some of whom maintained, that the Son was only a similar, not the same, substance with the Father; and others, that he was not only a distinct, but a dissimilar substance. Two of these sects had their denomination from Acacius bishop of Cæsarea, who lived in the fourth century, and changed his opinions, so as, at different times, to be head of both. Another was named from Acacius patriarch of Constantinople, who lived in the close of the fifth century.

**ACADEMIC**, **ACADEMICIAN**, or **ACADEMIST**, a member of an academy. See *ACADEMY* in the modern sense.

**ACADEMICS**, or **ACADEMISTS**, a denomination given to the cultivators of a species of philosophy originally derived from Socrates, and afterwards illustrated

and enforced by Plato, who taught in a grove near Athens, consecrated to the memory of Academus an Athenian hero; from which circumstance this philosophy received the name of *academical*. Before the days of Plato, philosophy had, in a great measure, fallen into contempt. The contradictory systems and hypotheses that had successively been urged upon the world, were become so numerous, that, from a view of this inconsistency and uncertainty of human opinions, many were led to conclude, that truth lay beyond the reach of our comprehension. Absolute and universal scepticism was the natural consequence of this conclusion. In order to remedy this abuse of philosophy and of the human faculties, Plato laid hold of the principles of the academical philosophy, and, in his *Phædo*, reasons in the following manner: "If we are unable to discover truth, (says he), it must be owing to two circumstances; either there is no truth in the nature of things, or the mind, from a defect in its powers, is not able to apprehend it. Upon the latter supposition, all the uncertainty and fluctuation in the opinions and judgments of mankind admit of an easy solution: Let us therefore be modest, and ascribe our errors to the real weakness of our own minds, and not to the nature of things themselves. Truth is often difficult of access: in order to come at it, we must proceed with caution and diffidence, carefully examining every step; and after all our labour, we will frequently find our greatest efforts disappointed, and be obliged to confess our ignorance and weakness."

Labour and caution in our researches, in opposition to rash and hasty decisions, were the distinguishing characteristics of the disciples of the ancient academy. A philosopher possessed of these principles, will be slow in his progress, but will seldom fall into errors, or have occasion to alter his opinion after it is once formed. Vanity and precipitance are the great sources of scepticism: hurried on by these, instead of attending to the cool and deliberate principles recommended by the academy, several of our modern philosophers have plunged themselves into an absurd and ridiculous kind of scepticism. They pretend to discredit things that are plain, simple, and easily comprehended; but give pre-emptory and decisive judgments upon subjects that evidently exceed the limits of our capacity. Of these Berkley and Hume are the most considerable. Berkley denied the existence of every thing, excepting his own ideas. Mr Hume has gone a step further, and questioned even the existence of ideas; but at the same time has not hesitated to give determined opinions with regard to eternity, providence, and a future state, miraculous interpositions of the Deity, &c. subjects far above the reach of our faculties. In his essay on the academical or sceptical philosophy, he has confuted two very opposite species of philosophy. After the days of Plato, indeed, the principles of the first academy were grossly corrupted by Aristotle, Carneades, &c. This might lead Mr Hume into the notion that the *academical* and *sceptical* philosophy were synonymous terms. But no principles can be of a more opposite nature than

than those which were inculcated by the old academy of Socrates and Plato, and the sceptical notions which were propagated by Arcefilas, Carneades, and the other disciples of the succeeding academics.

**ACADEMY**, in antiquity, a garden or villa, situated within a mile of Athens, where Plato and his followers held their philosophical conferences. It took its name from one Academicus, or Ecademus, a citizen of Athens, who was the original owner of it, and made it a kind of gymnasium: he lived in the time of Thefeus. Cimon embellished it with fountains, trees, and walks; but Sylla, during the siege of Athens, employed these very trees in making battering-engines against the city. Cicero too had his villa, or place of retirement, near Puzzuoli, which he also named an academy, where he composed his *Academical questions*, and his book *De natura deorum*.

**ACADEMY**, among the moderns, is most commonly used to signify a society of learned men, established for the improvement of any art or science. Charlemagne was the first that established an academy in Europe. Most nations have since followed his example; but Italy has by far the greatest number. In the cities of Piedmont, Ferrara, and Milan, Jarekius reckons 550. We have but few in Britain. In England those of note are, the Royal Society, the Antiquarian Society, Society for the encouragement of arts, and the Academy of Painting; in Scotland, the Edinburgh Society, College of Physicians, and Musical Society; all which see in their proper places.

The French have several academies; as, the Royal Academy of Sciences, for the improvement of physics, mathematics, and chemistry. It was first instituted in 1666, by the assistance of Mr Colbert, comptroller-general of the finances, but was not confirmed by the French king till the year 1696, who, by a regulation dated the 26th of January, new-modelled and put it on a better footing. According to this regulation, the academy was to be composed of ten honorary academicians, eight strangers associates, twenty pensionaries fellows, twenty elves or scholars, and twelve French associates; these were to be divided into six classes, viz. geometricians, astronomers, mechanics, anatomists, chemists, and botanists; the honorary academicians to be all inhabitants of France, the pensionaries and elves all to reside at Paris.

In the year 1716, the duke of Orleans, then regent, made an alteration in their constitution, augmenting the number of honoraries and associates to twelve, admitting regulars among such associates, suppressing the class of elves, and establishing in lieu thereof a new class of twelve adjuncts to the six several kinds of science cultivated by the academy; and, lastly, appointing a vice-president, to be chosen yearly by the king out of the honorary members, and a director and sub-director out of the pensionaries.

The academies of Florence and Bologne, of Montpellier and Bourdeaux, of Leipzig and Berlin, and of late those of Peterburg and Seville, were formed upon the same model with the Royal Academy of Sciences.

**French ACADEMY**, a society of forty, established for improving the French language.

This academy was founded by Cardinal Richlieu, and confirmed by the edit of Lewis XIII. in 1635. They have compiled a dictionary, intitled, *Le Dictionnaire de l'academie Françoise*. This work was begun in 1637, and finished in 1694. They have a director and chancellor, who are drawn by lot every three months, and a secretary who is perpetual. They meet at the old Louvre, on the Mondays, Thursdays, and Saturdays, all the year round, and hold an extraordinary meeting at the reception of a new member, and on St Lewis's day, when the prizes of eloquence and poetry are adjudged.

**Royal ACADEMY of Painting and Sculpture**. This society was founded about the year 1648. The members were at first about twenty-five in number, viz. twelve officers, called *ancients*, eleven private members, and two syndics; but at present it consists of forty painters and sculptors. There are four perpetual rectors, nominated by the king; a director and chancellor; a secretary, who keeps the register, and countersigns the dispatches; a treasurer, twelve professors, adjuncts to the rectors and professors, six counsellors, a professor for the part of anatomy that belongs to painting and sculpture, and another for geometry and perspective.

There is also an academy of painting, sculpture, &c. at Rome, established by Lewis XIV. wherein those who have won the annual prize at Paris, are entitled to be three years entertained for their further improvement.

**ACADEMY of Medals and Inscriptions**, called also *The academy of belles lettres*, was erected by Lewis XIV. for the study and explanation of ancient monuments, and to perpetuate the remembrance of great events, by medals, relievos, inscriptions, &c. The plan of this academy was formed by Mr Colbert, and established in 1663. In its first institution it consisted only of four or five members; but in 1701, they were increased to forty, viz. ten honoraries, ten pensionaries, ten associates, and ten novices or elves, under the direction of a president and vice-president, who are annually appointed by the king.

Their chief employment has been upon the medallic history of the reign of Lewis their founder. But the learned are indebted to this academy for many volumes of essays on other parts of history, published under the title of *Memoirs*, &c.

**ACADEMY of Architecture**, established about the end of the year 1671 by Mr Colbert, consisted at first only of six architects; but their number is since considerably increased.

**ACADEMY of Politics**, is composed of six persons, who meet at the Louvre, in the chamber where the papers relating to foreign affairs are lodged. But as the kings of France are unwilling to trust any, except their ministers, with the inspection of foreign affairs, this academy is of little use to the public.

**Royal ACADEMY of Dancing** was established by the King of France in 1661. It consists of thirteen able dancing-masters,

masters, who meet once a-month; and two of the academists teach by turns the art of dancing, ancient and modern.

The French have also academies in most of their great cities, as, the Academy of Sciences at Montpellier, that of the Lanternists at Thoulouse; besides others at Nîmes, Arles, Angiers, Lyons, Caen in Normandy, &c.; and the Chirurgical Academy at Paris is a modern institution for the general improvement of the art, and to compile and publish the ancient and modern history of it.

*Royal Spanish* ACADEMY at Madrid, has for its object the cultivation of the Castilian tongue, and was established in 1714 by the Duke d'Escalona, with the approbation of the King of Spain. It consists of twenty-four academists, including the director and secretary.

In Portugal, John V. founded an historical academy at Lisbon, in the year 1720, for collecting and ascertaining the history of his own dominions. It consists of fifty members, a director, four censors, and a secretary.

In Germany, they have the *Academy of Naturæ Curiosæ*, otherwise called the *Leopoldine Academy*, founded in 1652 by Jo. Laur. Bausch a physician, and, in 1670, taken under the protection of the Emperor Leopold. The design of this society was to promote medical knowledge. They began in 1684 to publish their observations, under the title of *Ephemérides*; which publication has been continued annually, with some interruptions, and under different titles. This academy consists of a president, two adjuncts or secretaries, and colleagues or members without limitation.

*Berlin* ACADEMY, was founded by Frederick I. the late King of Prussia, in the year 1700. It has for its objects the improvement of natural knowledge, and the belles lettres. The charter of this society was amended in 1710, and by it the president is to be nominated by the king. The members are divided into four classes; 1. for physic, medicine, and chemistry; 2. for mathematics, astronomy, and mechanics; 3. for the German language, and the history of the country; 4. for Oriental learning, particularly what relates to the propagation of the gospel among infidels. The great promoter of this foundation was the celebrated Mr Leibnitz.

*Russian* ACADEMY was founded by Czar Peter the Great, at Petersburgh, upon the plan of the Academy of Sciences at Paris; besides which, they take in the Russian language.

ACADEMY is also a term for schools and other seminaries of learning among the Jews, where their rabbins and doctors instructed their youth in the Hebrew language, and explained to them the Talmud, and the secrets of the Cabbala: Those of Tiberias and Babylon have been the most noted.

ACADEMY is often used with us to denote a kind of collegiate school, where youth are instructed in arts and sciences. There is one at Portsmouth for teaching navigation, drawing, &c.; another at Woolwich, for fortification, gunnery, &c.

ACADEMY is likewise a name given to a riding-school, where young gentlemen are taught to ride the great horse, &c. and the ground allotted for it is usually called the *Menage*.

ACADEMY *figure*, a drawing of a naked man or woman, taken from the life, which is usually done on paper with red or black chalk, and sometimes with pastils or crayons.

ACADIE, or ACADIA, in geography, a name formerly given to Nova Scotia, one of our American colonies. See NOVA SCOTIA.

ACÆNA, in antiquity, a Grecian measure of length, being a ten feet rod, used in measuring their lands.

ACALABA. See ACAJOU.

ACAJA, in botany, a synonyme of the *Spondias lutea*, an American tree. See SPONDIAS.

ACAJOU, in botany, a synonyme of the *Anacardium occidentale*, or cashew-nut-tree. See ANACARDIUM.

ACALEPTIC, in ancient prosody, a complete verse.

ACALIS, in botany, an obsolete name of the *Ceratonia*. See CERATONIA.

ACALYPHA, in botany, a genus of plants belonging to the monocæia monadelphia class. There are only four species of this plant; the *acalypha virginica*, which is a native of Ceylon; the *virgata*, *indica*, and *australis*, all natives of America. Sir Hans Sloane ranks this plant with the nettle, under the name of *urtica minor iners spicata*.

ACAMATOS, a word used to express the best shape of the human body.

ACAMBOU, a kingdom on the coast of Guinea in Africa.

ACAMEEH, among some of the old chemists, the scoræ of silver; as also a superfluity of the humidum radicale.

ACANACEOUS *plants*, such as are armed with prickles.

ACANAPHORA, in botany, an obsolete name of the *centaurea jacea*, or knapweed. See CENTAUREA.

ACANES, in geography. See ARANIS.

ACANGIS, that is, *ravagers* or *adventurers*; a name which the Turks give their hussars or light-troops, who are generally sent out in detachments to procure intelligence, harass the enemy, or ravage the country.

ACANNY, an inland country on the gold coast of Guinea in Africa, which affords the best gold, and is great plenty. There is a town or village of the same name, W. long. o. 5. lat. 8. 30.

ACANTHA, in botany, the prickle of any plant.

ACANTHA, in zoology, a term for the spine or prickly fins of fishes.

ACANTHA, in anatomy, an obsolete term for the spinal processes of the back.

ACANTHABOLUS, in surgery, an instrument for pulling thorns, or the like, out of the skin.

ACANTHACEOUS, among ancient botanists, an epithet given to thistles and other prickly plants.

ACANTHE, in botany, an obsolete name for the *Cynara* or artichok. See CYNARA.

ACANTHIAS, in ichthyology, the trivial name of a species of *Squalus*. See SQUALUS.

- ACANTHINE, any thing resembling or belonging to the herb acanthus. Acanthine garments, among the ancients, are said to be made of the down of thistles; others think they were garments embroidered in imitation of the acanthus.
- ACANTHIUM, in botany, the trivial name of a species of onopordium. See ONOPORDIUM.
- ACANTHOIDES, in botany, a synonyme of the carlina, or carline-thistle. See CARLINA.
- ACANTHOPTERYGIUS *fishes*, a term used by Linnaeus and others for those fishes whose back-fins are hard, ossaceous, and prickly.
- ACANTHUS, bears-breach, or brank-urine, in botany, a genus of plants belonging to the didynamia angiospermia class. There are only five species of this plant, all of which are natives either of Italy or the Indies. For its figure, which is extremely beautiful, see plate I. fig. 3. The leaves of the acanthus are famous for having given rise to the capital of the Corinthian order of architecture.
- ACANTHUS is likewise used by Theophrastus as a synonyme of the acacia.
- ACANTHUS, in architecture, an ornament representing the leaves of the acanthus, used in the capitals of the Corinthian and Composite orders. See ARCHITECTURE.
- ACANUS, in botany, a synonyme of the carduus scaberrimus of Linnaeus. See CARDUUS.
- ACAPATLI, the American name of the piper longum, or long pepper. See PIPER.
- ACAPNON, in botany, an obsolete name of the origanum or marjoram. See ORIGANUM.
- ACAPULCO, in geography, a sea-port town in North America, in 19. 0. W. long. 17. 3. N. lat. situated in the province of Mexico, on a fine bay of the South-sea, from whence a ship sails annually to Manilla in the Philippine islands.
- ACARA, in ichthyology, an obsolete name of the perca chrysoptera. See PERCA.
- ACARA-AYA, in ichthyology, an obsolete name of a species of the cyprinus or carp. See CYPRINUS.
- ACARA-PEBA, in ichthyology, an obsolete name of the sparus. See SPARUS.
- ACARA-PINIMA, in ichthyology, an obsolete name of the sparus cantharus. See SPARUS.
- ACARA-PITAMBA, in ichthyology, an obsolete name of a species of the mugil. See MUGIL.
- ACARAI, a town in Paraguay in South America, built by the Jesuits in 1624, 116. 40. long. 26. 0. S. lat.
- ACARI. See ACARUS.
- ACARICOBIA, in botany, a synonyme of the hydrocotyle umbellata. See HYDROCOOTYLE.
- ACARNA, in botany, a synonyme of the carduus cufabonæ, of the enicus, of the carlina lanata, corymbosa, racemosa, and cancellata. Acarna is also used by Vaillant as a term for cynaraccephalous or artichoke-headed plants.
- ACARNAN, an obsolete name of the sparus erythrinus. See SPARUS.
- ACARON, the name of the god of flies. The Ekronites called him *Baalzobub*.
- ACARUS, a genus of insects belonging to the order of aptera, or such as have no wings. The acarus has 8 legs, 2 eyes, one on each side of the head, and two jointed tentacula like feet. See plate I. fig. 4. There are thirty-one species of the acarus. 1. The elephantinus, is about the size of a white lupia seed, has a depressed orbicular livid body, thickest at the edges, with three furrows on each side of the belly, and a black oval trifid spot at the base or end of the body. It is a native of India. 2. The ægyptius, is of an oval shape, yellowish colour, and a white edge or margin. It is a native of the East. 3. The redivivus is plain and oval, with an oval spot at the base. It lives on oxen and dogs. 4. The americanus, is reddish and oval, with the scutellum and joints of the feet white. It is a native of America. 5. The sanguifugus. The hinder part of the abdomen is crenated, the scutellum is oval and yellowish, and the beak is trifid. It is a native of America, and sticks so fast on the legs of travellers, sucking their blood, that they can hardly be extracted. 6. The ricinus is globular, and has a round spot at the base; the feelers are clubbed. It inhabits the bodies of dogs and oxen. 7. The cancrioides, with nippers like a crab, and an oval depressed belly. It is found in the shady places of Europe. 8. The scorpioides, with crab-like nippers, a cylindrical belly, and a small pendulous head. It is of a yellowish colour; and its bite is venomous. It is a native of America. 9. The crassipes has the second pair of legs shaped like those of a crab, and is a native of Europe. 10. The passerinus has the third pair of legs remarkably thicker than the rest. It infests several species of sparrows. 11. The motatorius has the first pair of legs very long and nimble, and frequents the woods. 12. The aphidioides has the first pair of feet longest, and two small horns at the hinder part of the belly. It is a native of Europe. 13. The coleoptratus is black, and the sides are a little crustaceous. It is a native of Europe. 14. The telurus is of a greenish yellow colour. It has a small sting or weapon, with which it wounds the leaves of plants, and occasions them to fold backward. They are very frequently to be met with in the autumn, inclosed in the folded leaves of the lime-tree. 15. The siro has lob-like sides; the four hinder feet are longest; the head and thighs are of an iron colour, and the belly is bristly. It inhabits the farinaceous plants of Europe and America. 16. The exulcerans has very long fetaceous legs, but the two first are short. It inhabits the scabies. 17. The geniculatus, is black, and the joints of the thighs are globular. 18. The aquaticus has a depressed red belly, and the hinder part of it obtuse. It inhabits the fresh waters of Europe. 19. The holosericeus has the same characters with the former, only it does not live in water. 20. The baccharum, has a red distended belly, and lives on gooseberries, &c. 21. The muscorum, is of a yellowish red colour, and the hinder legs are long and thread-like. It inhabits mosses. 22. The batatas, is of a blood-colour, and a little rough; the fore pair of legs are as long as the body.

body. It inhabits the potatoes of Surinam. 23. The gymnopterorum, is reddish, with two scarlet spots on each side. It inhabits bees, &c. 24. The coleopterorum, is reddish, with a white anus. It inhabits the scarabæus. 25. The rupestris, is yellowish, with a double coloured line on the back. It is a native of Europe. 26. The longicornis, is red, and the feelers are longer than the snout. It is a native of Europe. 27. The littoralis, is of a tawny yellowish colour, and has blood-red legs. It frequents the shores of Europe. 28. The fungorum is of a yellowish colour, and has a globular clammy belly. It inhabits the mushroom. 29. The scaber, is ash-coloured, and depressed; the sides are scurfy. It is a native of Europe. 30. The falcinus, is red, with two yellow lines on the back; it is forked before. It dwells on the willows. 31. The croceus, is yellow, with a reddish spot on each side of the breast.

ACATALECTIC, a term, in the ancient poetry, for such verses as have all their feet or syllables, in contradistinction to those that have a syllable too few.

ACATALEPSY, signifies the impossibility of comprehending any thing.

ACATALIS, a name given by the ancients to the juniper-berry.

ACATASTATOS, with physicians, signifies the irregular paroxysms of a disease.

ACATERY, or ACCATRY, an officer of the king's household, designed for a check betwixt the clerks of the kitchen and the purveyors.

ACATHARSIA, an impurity of the blood or humours.

ACATHISTUS, in an ecclesiastical sense, a solemn hymn anciently sung in the Greek church on the Saturday of the fifth week of Lent, in honour of the Virgin, for having thrice delivered Constantinople from the invasions of the barbarous nations.

ACATIUM, in antiquity, a kind of boat used in military affairs, and was a species of the *naves actuariæ*. See *ACTUARIÆ NAVES*.

ACATSIA-VALLI, in botany, a synonyme of the *cas-ficha filiformis*. See *CASSITHA*.

ACAULIS, in botany, signifies plants that have no caulis or stem.

ACCALIA, in antiquity, solemn feasts held in honour of Acca Laurentia, nurse to Romulus. They were otherwise called *Laurentalia*.—To the same Acca is also ascribed the institution of the *fratres arvales*.

ACCAPITARE, in law, the act of becoming vassal of a lord, or of yielding him homage and obedience. See *VASSAL* and *HOMAGE*.

ACCAPITUM, signifies the money paid by a vassal upon his admission to a feud.

ACCAPITUM, in our ancient law, was used also to express the relief due to the chief lord. See *RELIEF*.

ACCEDAS *ad curiam*, in the English law, a writ lying, where a man has received, or fears false judgment, in an inferior court; it lies also for justice delayed, and is a species of the writ *recordare*.

ACCEDONES. See *ACCEDNONES*.

ACCELERATED, implies, in a general sense, quick-

ened, continually increasing. Thus, *accelerated motion* is a motion continually increasing. See *MACHANICS*.

ACCELERATION, an increase of velocity in the motion of a body; it is opposed to retardation, which is a diminution of motion.

ACCELERATION, is also a term used by ancient astronomers, with whom it signified the difference between the revolution of the primum mobile, and that of the sun, computed to be three minutes and fifty-six seconds.

ACCELERATOR, in anatomy, the name of two muscles of the penis, which serve for ejecting the urine or semen. See *ANATOMY*, Part VI.

ACCIDENTES, a lower order of ministers in the Romish church, whose office is to light and trim the candles.

ACCENDONES, in Roman antiquity, a sort of gladiators, whose office was to excite and animate the combatants during the engagement. See *GLADIATOR*.

ACCENSI, among the ancient Romans, a kind of supernumerary soldiers, who served to fill the places of those who were killed or disabled by their wounds.

ACCENSI *srenses*, among the Romans, an inferior order of officers, who attended the magistrates in the manner of our ulthers, sergeants, or tipstaffs.

ACCENSION, in chemistry, the action of setting a body on fire: thus the accension of tinder is effected by striking fire with flint and steel.

ACCENT, or accenting, in reading or speaking: When we raise the tone higher in sounding any particular word or syllable, that word or syllable is said to be accented, or graced with an accent. In hexameters there is a capital accent in every line, easily distinguishable from the rest by a good ear. Thus,

*Nec bene promeritis capitâr, nec tangitur ira.*

Accents either in prose or poetry have a double effect: They contribute to the melody, by giving it air and spirit; they contribute not less to the sense, by distinguishing words of importance from others. Accenting is entirely confined to long syllables; for a short syllable is not capable of an accent. Every word in an hexameter line that has a long syllable may be accented, unless the sense interpose, which rejects the accenting a word that makes no figure by its signification. But, notwithstanding this circumstance, there is constantly one accent in every line which makes a greater figure than any of the rest. Thus,

*Smooth flow the waves, the zephyrs gently play,  
Belinda smil'd, and all the world was gay.*

In order to facilitate the reading of dead languages, grammarians have adopted various characters for distinguishing the accents belonging to particular syllables; such as the acute, marked thus, (´), the grave thus ( ` ), and the circumflex thus ( ^ ), or ( ^ ), &c. The acute denotes that the voice is to be raised; the grave, that it is to be lowered or flattened; and the circumflex, that the syllable is to be lengthened or dwelt upon.

- ACCENT**, in music, is a certain modulation of sounds to express a passion, whether by the voice or instruments. See **MUSIC**.
- ACCENTER**, in music, one of the three fingers in a trio, *viz.* the person who sings the highest part. See **TRIO**.
- ACCEPTANCE**, in Scots law, denotes either a person's admitting his subscription to a bill or draught, by which he subjects himself to the payment of it; or accepting or agreeing to offers made in bargaining, by which the bargain is concluded.
- ACCEPTANCE**, in the church of Rome, is put for receiving the Pope's constitutions.
- ACCEPTANCE**, in commerce, is the subscribing, signing, and making one's self debtor for the sum contained in a bill of exchange, or other obligation. See **BILLS**.
- ACCEPTATION**, in grammar, the sense or meaning wherein any word is taken.
- ACCEPTER**, or **ACCEPTOR**, the person who accepts a bill of exchange, &c.
- ACCEPTION**, the same with acceptance.
- ACCEPTILATION**, among civilians, an acquittance or discharge given by the creditor to the debtor without the payment of any value.
- ACCESS**, the approach of one person or thing to another. It is also used by physicians for the beginning of a paroxysm.
- ACCESSARY**, or **ACCESSORY**, in law. See **ACCESSORY**.
- ACCESSIBLE**, something that may be approached, or that access may be had to. Thus we say, Such a place is accessible on one side, &c.
- ACCESSION**, in Scots law, is a method of acquiring property, by which, in things that have a close connexion or dependence upon one another, the property of the principal thing draws after it the property of the accessory. Thus, the owner of a cow becomes likewise the owner of the calf. See **LAW**, title, *Division of rights*. It sometimes likewise signifies consent or acquiescence.
- ACCESSION**, among physicians, is used for a paroxysm of a disease; among politicians, it signifies a prince's succeeding to the government upon the death of his predecessor.
- ACCESSORY**, in Scots law, is the subject acquired by accession; or, in crimes, it signifies the person by whose assistance, advice, or command, the crime was committed: In this latter sense, it is the same with accomplice, art and part, &c. See **LAW**, title, *Crimes*.
- ACCESSORY nerve**. See **ANATOMY**, Part V.
- ACCB**, a name given by some authors to lead.
- ACCIDENT**, in a general sense, denotes any casual event.
- ACCIDENT**, in logic, signifies secondary qualities, or such as do not essentially belong to any subject.
- ACCIDENT**, in grammar. See **GRAMMAR**.
- ACCIDENT**, in heraldry, an additional point or mark in a coat of arms, which may be either omitted or retained without altering the essence of the armour; such as, *abatements, differences, and tincture*.
- ACCIDENT**, among physicians, an obsolete term for a symptom.
- ACCIDENTS**, in astrology, the most remarkable occurrences in a man's life.
- Absolute ACCIDENT**, in the Romish church, an accident which may possibly subsist, at least miraculously, without a subject; which is unintelligible jargon.
- ACCIDENTAL**, something that happens by accident, or a mode that is not essential to its subject.
- ACCIDENTAL point**, in perspective. See **PERSPECTIVE**.
- ACCIDENTAL dignities and debilities**, in astrology, certain casual dispositions of the planets, whereby they are supposed to be either strengthened or weakened.
- ACCIPENSER**, in ichthyology, a genus of fishes belonging to the Amphibia Nantes of Linnaeus. The accipenser has a single linear nostril: the mouth is in the under part of the head, and contains no teeth; the cirri are below the snout, and before the mouth. There are four species of this genus, *viz.* 1. The sturio, or sturgeon, with 4 cirri, and 11 squamous protuberances on the back. It inhabits the European seas. This fish was so greatly esteemed in the time of Severus, that he ordered it to be carried to his feasts by servants crowned with garlands, and trumpets playing before. See **PLATE I.** fig. 5. 2. The ruthenus has 4 cirri, and 15 squamous protuberances. It is a native of Russia. 3. The huso has 4 cirri; the body is naked, *i. e.* has no prickles or protuberances. The skin of the huso is so tough and strong, that it is employed for ropes in carts and other wheel-carriages. Hinglars is also made of the skin of this fish, and its eggs are sometimes made into pickles. It inhabits the Danube, and the rivers of Russia. See **PLATE I.** fig. 6. 4. The plecostomus, which is distinguished from the other three by having only 2 cirri. It is a native of Surinam. The whole four species are viviparous.
- ACCIPENSISUS**. See **ACCIPENSER**.
- ACCIPITER**, the name of Linnaeus's first order of birds. The birds belonging to this order have crooked beaks. This order comprehends only four genera, *viz.* The vultur, falco, strix, and lanus. See **VULTUR**, &c.
- ACCIPITRINA**, an obsolete name of the hierachium or hawkweed. See **HIERACHIUM**.
- ACCISMUS**, in antiquity, signifies a feigned refusal of what one earnestly desires.
- ACCISMUS**, in rhetoric, is accounted a species of irony. See **IRONY**.
- ACCLAMATION**, any expression of joy, or applause, whereby the public testifies its approbation.
- ACCLAMATION** is also used, in a bad sense, for expressions of detestation.
- ACCLAMATION**, in rhetoric, a figure, the same with **EPIPHONEMA**, which see.
- ACCLAMATION medals**, among antiquaries, such as represent the people expressing their joy in the posture of acclamation.
- ACCLIVUS**, in anatomy, a synonyme of the oblique ascendens muscle. See **ANATOMY**, Part II.
- ACCLIVITY**, the rise or ascent of a hill, in opposition to the declivity or descent of it. Some writers

ters in fortification use it for the *talus* of a rampart.

**ACCLOYED**, in farriery, signifies pricked. Thus a horse's foot pricked in shoeing, is said to be *accloyed*.

**ACCOLA**, among the Romans, signified that a person lived near some place.

**ACCOLADE**, in antiquity, one of the forms of conferring knighthood, in which the prince laid his arms about the neck of the young knight, embraced him, and, some say, gave him a blow on the cheek, neck, or shoulder, in imitation of the form of manumission among the Romans.

**ACCOLEE**, sometimes synonymous with **ACCOLADE**, which see.—It is also used in divers senses in heraldry: Sometimes it is applied to two things joined; at other times, to animals with crowns, or collars about their necks, as the lion in the Ogilvy's arms; and lastly to kews, battons, maces, swords, &c. placed saltier-wise behind the shield.

**ACCOMMODATION**, making two or more things agree with one another.—Among divines, it is applying what is originally said of one person, or thing, to another: Thus the words of Isaiah to the Jews of his time, are, by our Saviour, accommodated to his contemporaries, and by St Paul to his.—In law, it signifies the amicable issue of a debate, which is effected sometimes by mediation of friends, sometimes by submission, and sometimes by a division of the subject in debate.

**ACCOMPAGNAGE**, a term in the silk manufactures, signifying a fine woof of the same colour with the gilding, helping to enrich the ground under which it passes, and to hinder it from striking cross the gilding itself, which would diminish its gloss and lustre. All rich stuffs, the warps whereof are of a colour different from the gilding, should be accompanied.

**ACCOMPANIMENT**, something attending or added as a circumstance to another, either by way of ornament, or for the sake of symmetry. See **CIRCUMSTANCE**.

**ACCOMPANIMENT**, in music, these parts that are added to render the harmony more full and complete, as an instrument accompanying a voice. Among the moderns, the accompaniment frequently plays a different melody from the song it accompanies; but authors are not agreed whether it was so among the ancients. See **MUSIC**.

**ACCOMPANIMENT**, in painting, denotes such objects as are added, either by way of ornament, or probability, as dogs, guns, game, &c. in a hunting piece. See **PAINTING**.

**ACCOMPANIMENT**, in heraldry, any thing added to a shield by way of ornament; as the belt, mantling, supporters, &c. It is also applied to several bearings about a principal one; as a saltier, bend, fess, chevron, &c.

**ACCOMPLICE**, in law. See **ACCESSORY**.

**ACCOMPLISHMENT**, the entire execution or fulfilling of any thing.

**ACCOMPLISHMENT**, is also used for any mental or personal endowment.

**ACCOMPT**. See **ACCOUNT**.

**ACCOMPTANT**. See **ACCOUNTANT**.

**ACCORD**, in music. See **CONCORD**.

**ACCORD**, in law, an accommodation between parties at variance, by means of an offer made by the one, and accepted by the other.

**ACCORD**, in painting, is the harmony that reigns among the lights and shades of a picture.

**ACCORNED**, in heraldry: When any figure of an animal, in an escutcheon, has horns of a different colour from those of the real animal, then it is said to be *accorned*.

**ACCOUNT**, or **ACCOMPT**, in a general sense, a computation or reckoning of any thing by numbers. Collectively, it is used to express the books which merchants, traders, bankers, &c. use for recording their transactions in business. See **BOOK-KEEPING**.

**ACCOUNT in company**, is an account betwixt partners relating to the transactions of their joint concern. See **BOOK-KEEPING**.

**ACCOUNT of sales**, is an account given by one merchant to another, or by a factor to his principal, of the disposal, charges, commission, and nett proceeds of certain merchandises sent for the proper or company account of him that consigned them to such factor or vender. See **BOOK-KEEPING**.

**ACCOUNT current,—of goods**. See **BOOK-KEEPING**.

**ACCOUNT in bank**, a fund which it is common for merchants or others to furnish themselves with in the cash of a bank, to be in readiness for the payment of bills of exchange, purchases, &c.

**Auditing an ACCOUNT**, is the examining and passing an account by an officer appointed for the purpose. See **AUDITOR**.

**Chamber of ACCOUNTS**, in the French polity, is a sovereign court of great antiquity, which takes cognizance of, and registers the accounts of the king's revenue. It is nearly the same with the English *Court of EXCHEQUER*; which see.

**ACCOUNT in the remembrancer's office**, in the exchequer, is the state of any branch of the king's revenue; as the account of the mint, of the wardrobe, of the army, navy, &c.

**ACCOUNT**, in law, the action that lies against a person who is accountable by office to another, but refuses to render the account.

**ACCOUNT**, is also taken sometimes, in a particular sense, for the computation of time; as we say, The Julian account, the Gregorian account, &c. in which sense it is equivalent to *style*.

**ACCOUNT** is also used in sundry mercantile forms of expression for advantage, hazard, loss, &c.

**ACCOUNTABLE**, a term used to denote a person's being liable to render an account for any thing.

**ACCOUNTANT**, or **ACCOMPTANT**, in the most general sense, is a person skilled in accounts. In a more restricted sense, it is applied to a person, or officer, appointed to keep the accounts of a public company, or office, as the South-sea, the India company, the bank, the excise, &c.

**ACCOUNTANTSHIP**, the art of keeping and balancing accounts. See **BOOK-KEEPING**.

ACCOUNT-

**ACCOUNTANT-GENERAL**, a new officer in the court of Chancery appointed by act of parliament to receive all moneys lodged in court instead of the masters, and convey the same to the bank of England for security.

**ACCOUNTING-HOUSE**, counting-house, or computing-house, is a house, or office, set apart by a merchant, or trading-company, for transacting their business, as well as keeping their books, accounts, vouchers, &c.

**ACCOUTREMENT**, an old term, applied to the furniture of a soldier, knight, or gentleman.

**ACCRETION**, in physics, the increase, or growth, of an organical body, by the accession of new parts.

**ACCRETION**, among civilians, the property acquired in a vague or unoccupied thing, by its adhering to or following another already occupied; thus, if a legacy be left to two persons, one of whom dies before the testator, the legacy devolves to the survivor by right of accretion.

**ACCROCHE**, in heraldry, denotes a thing's being hooked with another.

**ACCROCHING**, in old law-books, is encroaching upon, or usurping another man's right.

**ACCRUE**, in law, any thing that is connected to another as an appendage.

**ACCUBATION**, in antiquity, the posture used by the Greeks and Romans at table. The body was extended, and the head resting on a pillow, or on the elbow.

The Romans at their meals made use of a low round table, around which two or three couches were placed in proportion to the number of guests; and hence it was called *biclinium*, or *triclinium*. These were covered with a sort of bed-cloaths, and furnished with quilts and pillows for leaning on. The guests reclined on the left side, the first at the head of the bed, with his feet behind the back of the second, &c. Before they came to table, they changed their cloaths, for what they called the *canatoria vestes*, the dining garment, and pulled off their shoes to keep the couch clean.

**ACCUBITOR**, an ancient officer of the emperors of Constantinople, whose business was to lie near the emperor. He was the head of the youths of the bed-chamber, and had the *bedicularius* and *procurator* under him.

**ACCUMULATION**, in a general sense, the act of heaping or amassing things together. Among lawyers it is used in speaking of the concurrence of several titles to the same thing, or of several circumstances to the same proof.

**ACCUMULATION of degrees**, in an university, is the taking several of them together, or at smaller intervals than usual, or than is allowed by the rules of the university.

**ACCURATE**. See **EXACTNESS**.

**ACCURSED**, denotes something that lies under a curse, or is detestable. It is likewise used for an excommunicated person.

**ACCUSATION**, in law, the charging any person with a criminal action, either in one's own name, or that

of the public. It differs little from impeachment or indictment.

**ACCUSATIVE**. See **GRAMMAR**.

**AC-DENGLISH**, a name given to the Archipelago by the Turks.

**ACE**, a term among gamesters, signifying a card or die marked with a single point.

**ACENTETUM**, or **ACENTETA**, names used by the ancients for the purest rock crystal. See **CRYSTAL**.

**ACEPHALI**, or **ACEPHALITÆ**, a name given, in ecclesiastical history, to several sects that were destitute of any head or leader; as also, to such bishops as were exempted from the jurisdiction of a patriarch.

**ACEPHALOUS**, in our ancient law-books, an appellation given to such persons as held nothing of any superior.

**ACEPHALUS**, without a head.

**ACEPHALUS**, an obsolete term for the tenia, or tapeworm. See **TENIA**.

**ACEPHALUS**, is also used to express a verse defective in the beginning.

**ACER**, in botany, the maple or sycamore tree, a genus of the polygamia diœcia class. There are ten species of this genus. The calix of the female is quinquefid, the corolla pentapetalous, the stamina eight, one pistil, and two seed-capsules. The calix of the male is also quinquefid, the corolla pentapetalous, and the stamina eight. There are only two species of the acer which are reckoned natives of England, *viz.* the pseudo-platanus, and the campestre.

**ACERB**, a sour rough atringency of taste, such as that of unripe fruit. See **ASTRINGENT**.

**ACERENZA**. See **CIRENZA**.

**ACERIDES**, signifies a plaster without any wax in its composition.

**ACERINA**, an obsolete name of a species of the perch, a fish of the thoracic order. See **PERCA**.

**ACERNO**, a town of Italy, in the kingdom of Naples, with a bishop's see. It is 17 miles S. W. of Conza, and 12 N. E. of Salerno, long. 14. 23. lat. 40. 55.

**ACERRA**, in antiquity, an altar erected, among the Romans, near the gate of a person deceased, on which his friends daily offered incense, till his burial.—The Chinese have still a custom like this; they erect an altar to the deceased in a room hung with mourning, and place an image of the dead person on the altar, to which every one that approaches it bows four times, and offers oblations and perfumes.

**ACERRA**, in geography, a town of Italy in the kingdom of Naples, and in the terra di Lavoro. It stands on the river Agno, 7 miles N. E. of Naples, and 20 S. W. of Benevento, lon. 14. 23. lat. 40. 55.

**ACERRÆ**, the pots wherein incense was burnt.

**ACERSECOMES**, long-haired, a name of Apollo, because he was usually painted so.

**ACESTIDES**, in foundry, a name given by the ancients to the chimneys of their furnaces wherein bras was made.

**ACETABULUM**, in antiquity, a little vase or cup used at table to serve up saucers or seasoning. It also denotes

Fig. 1. Abacus

Fig. 2. Abacus or Counting Board

Fig. 4. Acarus

Fig. 5. Accipenser sturio or Sturgeon

Fig. 6. Accipenser huso or Jinglap Fish

Fig. 3. Acanthus

*Fig. 1. ACHILLEA NOBILIS or  
Purple-Fansy leaved Yarrow*

*Fig. 2.  
ACONITUM PYRENAICUM  
or  
Yellow Pyrenean Aconite*

notes a Roman measure, both for liquid and dry things, equal to a cyathus and a half.

**ACETABULUM**, in anatomy, a cavity in any bone for receiving the protuberant head of another, and thereby forming that species of articulation called *enarthrosis*. See **ANATOMY**, Part I.

**ACETABULUM**, in botany, the trivial name of a species of the peziza, or cup-peziza, a fungus belonging to the cryptogamia fungi of Linnæus. It has got the name of *acetabulum* from the resemblance its leaves bear to a cup. See **PEZIZA**.

**ACETARY**, Nehemiah Grew, in his anatomy of plants, applies this term to a pulpy substance in certain fruits, *e. g.* the pear, which is inclosed in a congeries of small calculus bodies towards the base of the fruit, and is always of an acid taste. See **AGRICULTURE**, Sect. I.

**ACETIFICATION**, a term used by chemists for the making of vinegar.

**ACETOSA**, in botany, a synonyme of the rumex, or sorrel. See **RUMEX**.

**ACETOSE**, or **ACTOUS**, an epithet applied to such substances as are sour, or partake of the nature of vinegar.

**ACETUM**, vinegar, the vegetable acid of the chemists. See **CHEMISTRY**, title, *Of acids*.

**ACETUM distillatum**, in chemistry, distilled vinegar.

**ACETUM spurium**, in chemistry, a distilled vinegar, rectified by the help of verdigrease.

**ACETUM radicum**. Boerhaave thinks the *tartarus regeneratus* is the *acetum radicum* of the old chemists.

**ACGHIA-SARAI**, a town on the north shore of the Caspian sea.

**ACH**, or **ACHE**, in medicine, a term used for any feverish pain, as head-ach, tooth-ach, &c. See **MEDICINE**.

**ACHA**, a barbarous name of a species of the tetrao, a bird of the order of gallinæ. See **TETRAO**.

**ACHÆINUS**. See **ACHÆINUS**.

**ACHAIA**, a province of Turkey in Europe, now called *Livadia*, of which Athens was anciently the capital, at present named *Saithines* or *Setines*. See **LIVADIA**.

**ACHALACTLI**, in ornithology, a barbarous name of the columba cyanocephala. See **COLUMBA**.

**ACHAM**, a country in the E. Indies, bounded on the N. by Bouton, on the E. by China, on the S. by Ava, and on the W. by Patan and Jesta in Bengal. It is very little known to the Europeans.

**ACHANE**, in Persian antiquity, a corn-measure, equal to forty-five Attic medianni. See **MEDIMNI**.

**ACHANDES**. See **REMORA**.

**ACHAOVA**, in botany, an obsolete name of the marum matricaria, &c. See **MARUM**.

**ACHASSES**, a river of Languedoc in France.

**ACHAT**, in the law-French, signifies a contract or bargain, especially by way of purchase.

**ACHAT**. See **AGAT**.

**ACHATOR**, in the old law-books, is used for **PURVEYOR**, which fee.

**ACHBALUC-MANGI**, a town in the northern confines of China.

**ACHE**, in medicine. See **ACH**.

**ACHECAMBEY**, one of the Bahama islands. See **BAHAMA**.

**ACHELO**, a town near the Euxine sea.

**AGHEN**, or **ACHEM**, a capital town of a kingdom of the same name, in the N. part of the island of Sumatra, in the E. Indies. It extends as far as the line.

The inhabitants are generally very superstitious. It has for a considerable time been a noted place for trade; and was formerly governed by a queen; but in 1700, a Saïd, or Preacher, found means to usurp the government. Its principal produce is gold dust, which is exceeding good. They punish theft very severely; yet robbery and murder are very frequent among them. This town is seated by the side of a river, and the king's palace is in the middle of the town, and is well fortified. It is 450 miles N. W. of Malua, and 1000 S. E. of Fort St George, 95.55. E. long. 5. 30. lat.

**ACHERNER**, in astronomy, a star of the first magnitude in the southern extremity of the constellation Eridanus. See **ERIDANUS**, and **ASTRONOMY**.

**ACHETA**, an obsolete name of the gryllus or cricket. See **GRYLLUS**.

**ACHLAR**, a Malayan word, signifying a sort of fruit or roots pickled with vinegar and spice. See **BAMBOE**.

**ACHËNUS**, a name given by the ancients to the cervus or stag. See **CERVUS**.

**ACHILLÆA**, in botany, a genus of plants belonging to the syngenesia polygamia superflua class. Of this genus there are 21 species, only two of which are natives of Britain, *viz.* the achillea millefolium, or common yarrow, (see Plate II. fig. 1.) and the achillæa ptarmica, or sneezewort.

**ACHILLÆA**, a name frequently given by the ancients to the gum called dragons blood. See **DRACONS-BLOOD**.

**ACHILLEID**, **ACHILLEIS**, a celebrated poem of Statius, in which that author proposed to deliver the whole life and exploits of Achilles; but being prevented by death, he has only treated of the infancy and education of his hero.

*Tendo* **ACHILLIS**. See **ANATOMY**, Part II.

**ACHIMENES**, in botany, a synonyme of the columnea scandens, a genus of the didynamia angiospermia class. See **COLUMNEA**.

**ACHIOTE**. See **ACHIOTTE**.

**ACHIOTTE**, a name given to the drug *achiote*.

**ACHIOTTE**, an American drug, used in dying and in chocolate. It is produced from the mitella

chocolate. It is produced from the mitella choco, a tree which grows in North America. Betwixt the small filaments or leaves of this tree, little grains of a vermilion colour are found, which the Indians make into cakes, and send in this form to Europe; it is supposed to promote urine.

**ACHIROPOETOS**, a name given, by ancient writers, to certain pictures of Christ and the Virgin supposed to have been miraculously made without hands.

- ACHLAR, a river in America, called *Araxis* by the ancients.
- ACHLIS. See MACHLIS.
- ACHLYS, in medicine, a dimness of sight, arising from any fear remaining after an ulcer in the cornea. It is also used for the disorder called a *suppuration of the uterus*.
- ACHMETSCHET, a town of the peninsula of the Crimea, the residence of the sultan Galga, who is eldest son of the Khan of Tartary, 31. 20. long. 45. 0. lat.
- ACHONRY, a small town of Ireland in the province of Connaught, and county of Sligo, seated on the river Shannon.
- ACHOR, in medicine, small ulcers on the face which discharge a viscid humour. See MEDICINE.
- ACHRAS, in botany, a genus of the hexandria monogynia class. It bears a fruit not unlike the pear. There are only three species of the achras, *viz.* the mimosa, the sapota, and the falcifolia, all natives of America.
- ACHRONICAL, ACHRONYCAL, or ACRONYCHAL. See ACRONICAL.
- ACHYR, a strong town and castle of the Ukrain, subject to the Russians since 1667. It stands on the river Uorklo near the frontiers of Russia, 127 miles W. of Kiow, 36. 0. long. 49. 32. lat.
- ACHYRANTES, in botany, a genus of the pentandria monogynia class. There are seven species of the achyrantes, most of them natives of the Indies.
- ACHYRANTHA, in botany, the triviale name of a species of the illecebrum. See ILLECEBRUM.
- ACHYRONIA, in botany, an obsolete name of a genus of the diadelphia decandria class.
- ACHYROPHORUS, in botany, a synonyme of the *seriola*. See SERIOLA.
- ACIA, a term in the Roman surgery, about the meaning of which physicians and commentators are greatly divided; some taking it for the needle, and others for the thread.
- ACICULÆ, the small spikes or prickles of the hedgehog, *echinus marinus*, &c.
- ACIDS, substances which give a sour, sharp, or tart taste. Among the chemists, the acid salts are distinguished into the nitrous, vitriolic, muriatic, and vegetable. See CHEMISTRY, title, *Of acids*.
- ACIDS, in the materia medica, are such medicines as possess an acid quality; such as vinegar, spirit of vitriol, &c. These being powerful antiseptics, are esteemed good in all putrid and malignant diseases, and, by their cooling virtue, are no less efficacious in feverish and inflammatory cases.
- ACIDITY, that quality which renders bodies acid.
- ACIDOTON, in botany, is both a synonyme and the triviale name of a species of the *adcha*. See ADELIA.
- ACIDULÆ, a term for water or any substance impregnated with an acid.
- ACIDULATED, a name given to medicines that have an acid in their composition.
- ACIERNO, a town in the Hither Principality, in the kingdom of Naples, with a bishop's see. It is 15 miles E. of Salerno, 37. 0. E. long. 40. 52. lat.
- ACINAIES, in antiquity, a kind of cutlafs, or scimitar, in use among the Persians.
- ACINARIA, in botany, a synonyme of the *fucus acinarius*, belonging to the cryptogamia *algæ* of Linnæus. See FUCUS.
- ACINI, in botany, a synonyme of the *thymus alpinus*. See THYMUS.
- ACINIFORMIS *tunica*, in anatomy. See UVEA.
- ACINODENDRION, in botany, the triviale name of a species of the *melastoma*. See MELASTOMA.
- ACINODENDRUM, in botany, a synonyme of two species of the *melastoma*.
- ACINOIDES, in botany, the triviale name of a species of the *ziziphora*. See ZIZIPHORA.
- ACINOS, in botany, a synonyme of a species of the *cunila*. See CUNILA.
- ACINUS, in botany, signifies grapes or berries growing in clusters.
- ACINOTHERA, in botany, both a synonyme and the triviale name of a species of the *rhexia*. See RHEXIA.
- ACITLI, in ornithology, the American name of the *colymbus cristatus*, a bird of the order of anseres. See COLYMBUS.
- ACKNOWLEDGMENT, in a general sense, is a person's owning or confessing a thing; but, more particularly, is the expression of gratitude for a favour.
- ACKNOWLEDGMENT-MONEY, a certain sum paid by tenants in several parts of England, on the death of their landlords, as an acknowledgment of their new lords.
- ACLIDES, in Roman antiquity, a kind of missile weapon, with a thong affixed to it, whereby to draw it back. Most authors describe it as a sort of dart or javelin; but Scaliger makes it roundish or globular, with a slender wooden stem to poise it by.
- ACLOWA, in botany, a barbarous name of a species of *colutea*. It is used by the natives of Guinea to cure the itch. See COLUTEA.
- ACME, or ACKME, the top or height of any thing. It is usually applied to the maturity of an animal just before it begins to decline; and physicians have used it to express the utmost violence or crisis of a disease.
- ACMELLA, in botany, the triviale name of a species of the *verbesina*. See VERBESINA.
- ACNIDA, in botany, a genus of the diœcia pentandria class. There is only one species of it, *viz.* the *acnida canadica*. It is a native of Virginia.
- ACNUA, in Roman antiquity, signified a certain measure of land, near about the English rood, or fourth part of an acre. See ROOD.
- ACOBA, a small town of Portugal in the province of Estremadura.
- ACOEMETÆ, or ACOEMETI, in church history, or men who lived without sleep; a set of monks who chaunted the divine service night and day in their places of worship. They divided themselves into three bodies, who alternately succeeded one another, so that their churches were never silent. This practice they founded upon the precept, *Pray without ceasing*. They flourished in the east about the middle of the fifth century. There are a kind of *acometi* still subsisting in  
the

- Roman church, *viz.* the religious of the holy sacrament, who keep up a perpetual adoration, some one or other of them praying before the holy sacrament, day and night.
- ACOLASTRE**, a small river of France in the Nivernois.
- ACOLCHICHI**, in ornithology, a barbarous name of the phœnicopterus, a bird of the order of grallæ. See **PHœNICOPTERUS**.
- ACOLIN**, an obsolete name of a species of the tetrao, of the order of gallinæ. See **TETRAO**.
- ACOLIN**, in geography, a river of France which takes its rise in the Bourbonnois.
- ACOLUTHI**, a term applied to persons who were firm and steady in their opinions, and particularly to the stoics, who were remarkably tenacious of their resolutions and principles.
- In church-history, the term *acolythus*, or *acolythiff*, is peculiarly applied to candidates for the ministry who continually attend the bishops.
- ACOLYTHIA**, in the Greek church, denotes the office or order of divine service; or the prayers, ceremonies, hymns, &c. whereof the Greek service is composed.
- ACOMA**, a town of N. America, in New-Mexico, seated on a high mountain, with a strong castle. It is the capital of the province, and was taken by the Spaniards in 1596, 108. 35. W. long. 35. o. lat.
- ACOMAC**, a county of Virginia, in N. America, being a peninsula, bounded on the N. by Maryland; on the E. and S. by the ocean, and on the W. by the bay of Chese-peak. Cape Charles is at the entrance of the bay, being the most southern promontory of this county.
- ACONE**, a species of whet-stone. See **Cos**.
- ACONITUM**, in botany, a genus of the polyandria trigynia. There are seven species of the aconitum. 1. The lycostomum, is a native of Lapland, Switzerland, and other hilly countries of Europe. 2. The uncinatum, is a native of Philadelphia. 3. The variegatum grows on the Italian and Bohemian mountains. 4. The napellus, is a native of Switzerland, Bavaria, and France. 5. The Pyrenaicum, is a native of Siberia, Tartary, and the Pyrenæan mountains. See plate II. fig. 2. 6. The cammarum, and, 7. The anthora, are both natives of Taurus and the Pyrenæan mountains. The English name of the aconitum is *wolfbane* or *wonkshead*. Each species is highly acrid, and extremely dangerous when taken into the stomach, as it generally occasions convulsions, and frequently a mortification in that organ.
- ACONTIAS**, in zoology, an obsolete name of the anguis jaculus, or dart-snake, belonging to the order of amphibia serpentes. See **ANGUIS**.
- ACONTIAS**, is also a name applied by some writers to a kind of comet or meteor, whose head appears roundish or oblong, and its tail long and slender, like a dart or arrow.
- ACONTIUM**, in ancient writers, a kind of Grecian dart or javelin, somewhat resembling the Roman pilum.
- ACOPA**, in botany, an obsolete name of a species of the trifolium. See **TRIFOLIUM**.
- ACOPA**, also signifies medicines for refreshing the body after great fatigue.
- ACOPAM**. See **ACOPA**.
- ACOPIS**, a kind of fossil, mentioned by Pliny.
- ACOPUM**, among ancient physicians, a topical medicine composed of warm and emollient ingredients for allaying the sense of weariness.
- ACORES**, in geography. See **AZORES**.
- ACORN**, the fruit of the oak-tree. See **QUERCUS**.
- ACORUM**, in botany, a fynonime of the acorus. See **ACORUS**.
- ACORUS**, in botany, the sweet-smelling flag or calamus, a genus of the hexandria monogynia class. It is a native of this as well as other European countries. There are three varieties of this genus, *viz.* the acorus calamus; the vulgaris, or aromaticus of the shops; and the verus, which chiefly grows in the Indies.
- ACORUS**, in mat. med. a name sometimes given to the great galangal. See **GALANGAL**.
- ACORUS**, in botany, is likewise a fynonime of the iris pseudacorus. See **IRIS**.
- ACOUSMATICI**, sometimes also called *Acoustici*, in Grecian antiquity, such disciples of Pythagoras as had not completed their five years probation. See **Pythagorean philosophy**.
- ACOUSTIC**, in general, denotes any thing that relates to the ear, or the sense of hearing.
- ACOUSTIC duct**, in anatomy, the same with meatus auditorius, or the external passage of the ear. See **ANATOMY**, Part VI.
- ACOUSTIC instrument**, an instrument made in the form of a horn, perforated at the small end, to assist hearing.
- ACOUSTIC nerve**, the same with the auditory nerve. See **ANATOMY**, Part V. and *Auditory nerve*.
- ACOUSTICS**, with physicians, medicines for curing deafness.
- ACQS**, a town at the foot of the Pyrenæan mountains in the government of Foix in France. It takes its name from the hot waters in these parts; 1. 25. E. long. 43. o. lat.
- ACQUA**, a town in the Grand Duchy of Tuscany, where there are warm baths, 12. 5. E. long. 43. 45. lat.
- ACQUA-CHE-TAVELLA**, a celebrated fountain of Italy, in Calabria-citerior, a province of Naples. It is near the mouth of the river Crata, and the ruins commonly called *Sihari ruinata*. It has been said to beautify those who washed in it.
- ACQUAPENDENTE**, a pretty large town of Italy, in the territory of the church, and patrimony of St Peter, with a bishop's see. It is seated on a mountain, near the river Paglia, 10 miles W. of Orvieto, and 57 N. by W. of Rome, 11. 53. E. long. 42. 43. lat.
- ACQUARIA**, a small town of Italy, in Frigiana, a district of Modcna, which is remarkable for its medicinal waters. It is 12 mil. s. south of the city of Modcna, 11. 17. E. long. 4. 24. lat.
- ACQUAVIVA**, a small town in the Terra di Bari, a province in the kingdom of Naples, 17. 25. E. long. 41. 10. lat.

**ACQUEST**, or **ACQUIST**, in law, signifies goods got by purchase or donation. See **CONQUEST**.

**ACQUI**, a town of Italy, in the Dutchy of Montferat, with a bishop's see, and commodious baths. It was taken by the Spaniards in 1745, and retaken by the Piedmontese in 1746; but after this, it was taken again and dismantled by the French, who afterwards forsook it. It is seated on the river Bormio, 25 miles N. W. of Genoa, and 30 S. of Casal, 8. 30. E. long. 44. 40. lat.

**ACQUIESCENCE**, in commerce, is the consent that a person gives to the determination given either by arbitration, or by a consul.

**ACQUIETANDIS pleiis**, in the English law, is a writ that lies for a surety, against a creditor, who refuses to acquit the complainant after the debt is paid.

**ACQUIETANTIA de sibirii et hundredis**, in England, signifies the privilege of being free from suit and service in shires and hundreds.

**ACQUISITION**, in general, denotes the obtaining or procuring something. Among lawyers, it is used for the right or title to an estate got by purchase or donation.

**ACQUITARE**, in ancient law-books, signifies to discharge or pay off the debts of a person deceased.

**ACQUITTAL**, a discharge, deliverance, or setting of a person free from the guilt or suspicion of an offence.

**ACQUITTANCE**, a release or discharge in writing for a sum of money.

**ACRA**, a town of Africa, on the coast of Guinea, where the English, Dutch, and Danes, have strong forts, and each fort its particular village, o. 2. W. long. 5. o. lat.

**ACRASIA**, among physicians, signifies the predominancy of one quality over another.

**ACRE**, or **ACRA**, a sea-port town in Syria. It was formerly called *Ptolemais*, and is a bishop's see. It was very famous in the time of the crusades, and underwent several sieges both by the Christians and Saracens. It is now an inconsiderable town, being entirely supported by its harbour, which is frequented by ships of several nations. It is 20 miles S. of Tyre, and 37 N. of Jerusalem, 39. 25. E. long. 32. 40. lat.

**ACRE**, in the Mogul's dominions, the same with lack, and signifies the sum of 100,000 rupees; the rupee is of the value of the French crown of 3 livres, or 30 sols of Holland; an 100 lacks of rupees make a crown in Indostan, or 10,000,000 rupees; the pound Sterling is about 8 rupees; according to which proportion, a lack of rupees amounts to 12,500 pounds Sterling.

**ACRE**, a measure of land used in several provinces of France, particularly in Normandy. It is larger or less according to the different places; but commonly contains 160 perches.

*The Acre of woods in France*, consists of four roods, called *vergés*; the rood is 40 perches, the perch 24 feet, the foot 12 inches, the inch 12 lines.

**ACRE**, the universal measure of land in Britain. An acre in England contains 4 square roods, a rood 40

perches or poles of 16 $\frac{1}{2}$  feet each by statute. Yet this measure does not prevail in all parts of England, as the length of the pole varies in different counties, and is called *customary measure*, the difference running from the 16 $\frac{1}{2}$  feet to 28. The acre is also divided into 10 square chains, of 22 yards each, that is 4840 square yards. An acre in Scotland contains 4 square roods; 1 square rood is 40 square fells; 1 square fall, 36 square ells; 1 square ell, 9 square feet, and 73 square inches; 1 square foot, 144 square inches. The Scots acre is also divided into 10 square chains; the measuring chain should be 24 ells in length, divided into 100 links, each link 8 $\frac{1}{2}$  $\frac{1}{4}$  inches; and so 1 square chain will contain 10,000 square links.

The English statute acre is about 3 roods and 6 fells standard measure of Scotland.

**ACREME**, in old law-books, signifies ten acres of land.

**ACRIBEA**, signifies great accuracy.

**ACRID**, a name for any thing that is of a sharp or pungent taste.

**ACRIDOPHAGI**, signifies *locust-eaters*. It has been much disputed whether the inhabitants of Arabia, Ethiopia, &c. ever eat locusts. We shall give the substance of what Hasselquist says on this subject, who travelled in Syria and Egypt so late as the year 1752. This ingenious gentleman, who travelled with a view to improve natural history, informs us, that he asked Franks, and many other people who had lived long in these countries, whether they had ever heard that the inhabitants of Arabia and Ethiopia, &c. used locusts as food. They answered that they had. He likewise asked the same question of Armenians, Coptes, and Syrians, who lived in Arabia, and had travelled in Syria and near the Red-sea; some of whom said they heard of such a practice, and others that they had often seen the people eat these insects. He at last obtained complete satisfaction on this head from a learned sheik at Cairo, who had lived six years in Mecca. This gentleman told him, in presence of M. le Grand, the principal French interpreter at Cairo, and others, that a famine frequently rages at Mecca when there is a scarcity of corn in Egypt, which obliges the inhabitants to live upon coarser food than ordinary: That when corn is scarce, the Arabians grind the locusts in hand-mills, or stone mortars, and bake them into cakes, and use these cakes in place of bread: That he has frequently seen locusts used by the Arabians, even when there was no scarcity of corn; but then they boil them, stew them with butter, and make them into a kind of fricassée, which he says is not disagreeably tasted; for he had sometimes tasted these locust-fricassées out of curiosity. From this account, we may see the folly of that dispute among divines about the nature of St John's food in the wilderness. Some of them say that locusts were the fruits of certain trees, others that they were a kind of birds, &c.; but those who adhered to the literal meaning of the text were at least the most orthodox, although their arguments were perhaps not so strong as they might have been, had they had an opportunity of quoting such an author as Hasselquist.

ACRIFOLIUM, in botany, a sharp or prickly leaf.

ACRIMONY, that quality in bodies which renders them acrid to the taste.

ACRIVIOLA, in botany, a synonyme of a species of tropeolum or Indian cress. See TROPÆOLUM.

ACROAMATIC, or ACROATIC, in general, denotes a thing sublime, profound, or abstruse. Aristotle's lectures to his favourite disciples and intimate friends bore this denomination, in opposition to his exoteric lectures, or those accommodated to a popular audience.

ACROBATIC, or ACROBATICUM, in Grecian antiquity, an engine whereby the people were raised aloft, that they might see further, or with greater advantage. It was much the fame with the scanorium of the Latins.

ACROCHIRISMUS, in Grecian antiquity, a kind of gymnastic exercise, performed with the fists, without closing at all.

ACROCHORDON, a painful wart, which is very prominent and pendulous.

ACROCORION, in botany, an obsolete name of the crocus. See CROCUS.

ACROMATIC, or ACHROMATIC, in optics, a term applied to a particular kind of telescope, the most perfect of the refracting kind. See OPTICS and TELESCOPE.

ACROMION, in anatomy, the upper part of the scapula. See ANATOMY, Part I.

ACROMONOGRAMMATICUM, in poetry, a kind of poem, wherein every subsequent verse begins with the letter wherewith the immediately preceding one terminated.

ACRON, a territory on the gold coast of Guinea in Africa, bordering on the Faatyncean country. The Dutch have a fort here, called *Fort Patience*. The inhabitants apply themselves principally to husbandry. They are a very ignorant people, and go naked like the rest of the negroes.

ACRON, among ancient botanists, signifies the top or flower of plants of the thistle kind.

ACRONICAL, ACHRONICAL, or ACHRONICAL, in astronomy, is a term applied to the rising of a star, when the sun is set in the evening; but has been promiscuously used to express a star's rising at sunset, or setting at sunrise.

ACROSPIRE, a vulgar term for what the botanists call the *plume*. See AGRICULTURE, *Of vegetation*.

ACROSPIRED, in malt-making, is the grain's shooting both at the root and blade end. See MALT.

ACROSTIC, ACROSTICUM, in poetry, a poem disposed in such a manner, that the initial letters of the verses make some person's name, title, motto, &c.

ACROSTICUM, in botany, a genus of the cryptogamia filices, of which there are 20 species, but only three of them are natives of Britain, viz. the septentrionale, or horned fern; the ilvensis, or hairy fern; and the thelypteris, or marsh fern.

ACROSTOLIUM, in ancient naval architecture, the extreme part of the ornament used on the prows of their ships, which was sometimes in the shape of a

buckler, helmet, animal, &c.; but more frequently circular, or spiral. It was usual to tear them from the prows of vanquished vessels, and fix them to the conquerors, as a signal of victory.

ACROTELEUTIC, among ecclesiastic writers, an appellation given to any thing added to the end of a psalm, as the Gloria Patri or doxology.

ACROTERRI, a town in the island of Santorin, that lies in the sea of Candia, 25. 26. E. long. 36. 25. 1st.

ACROTERRIA, in architecture, small pedestals, usually without bases, anciently placed at the middle and the two extremes of pediments or frontispieces, serving to support the statues, &c. It also signifies the figures placed as ornaments on the tops of churches, and the sharp pinnacles that stand in ranges about flat buildings with rails and ballusters.

Among ancient physicians, it signified the larger extremities of the body, as the head, hands, and feet. It has also been used for the tips of the fingers, and sometimes for the eminences or processes of bones.

ACRITHYMIA, in surgery, a large tumour resembling a wart, though sometimes flat and depressed.

See SURGERY, title, *Of tumours*.

ACSOR, a town in the river Nile in Egypt, famed for its earthen ware.

ACSU, a town in Asiatic Tartary, situated in 40. 30. N. lat.

ACT, in general, denotes the exertion of power; and differs from power, as the effect from the cause.

Act, among lawyers, is an instrument in writing for declaring or justifying the truth of any thing. In which sense, records, decrees, sentences, reports, certificates, &c. are called *Acts*.

Acts, also denote the deliberations and resolutions of an assembly, senate, or convocation, as, Acts of parliament, &c.

Act of *saith, aut da se*, in the Romish church, is a sort of jail delivery, for the punishment of heretics, and the absolution of those who are found to be innocent. The culprits are first led to church, where their sentence, either of condemnation or absolution, is pronounced, and the guilty are delivered over to the secular power, with an earnest intercession for them, that no blood may be shed. But if they persist in their supposed errors, they are burnt alive. See INQUISITION.

Acts, in dramatic poetry, are the parts or divisions into which tragedies and comedies are generally split. Dramatic compositions usually consist of five acts. But this division is not essentially necessary, but may be varied according to the humour of the author, or the nature of the subject. See DRAMA.

Act of *grace*. See GRACE.

ACTÆA, in botany, a genus of the polyandria monogynia class. There are three species of this plant, viz. the actæa piccata, or bone-berries, which is a native of Britain; the racemosa, which is a native of America; and the cimicifuga, which is a native of Siberia.

ACTIAN *games*, in Roman antiquity, were solemn games

games instituted by Augustus, in memory of his victory over Marc Anthony at Actium, held every fifth year, and celebrated in honour of Apollo, since called *Actium*. Hence Actian years, an era commencing from the battle of Actium, called the *Æra of Augustus*.

**ACTION**, in a general sense. See **ACT**.

**ACTION**, in mechanics, the motion produced by the impulse of one body upon another. See **MECHANICS**.

**ACTION**, in ethics, denotes the external signs or expressions of the sentiments of a moral agent. See **ETHICS**, **METAPHYSICS**.

**ACTION**, in poetry, the same with the subject or fable. Critics generally distinguish two kinds, the principal and the incidental. The principal action is what is generally called the *fable*; and the incidental an *episode*. See **DRAMA**.

**ACTION**, in oratory, is the outward deportment of the orator, or the accommodation of his countenance, voice, and gesture, to the subject of which he is treating. See **ELOQUENCE**.

**ACTION**, in a theatrical sense, is much the same with action in oratory; the one adapts his action to an assumed character, the other is supposed to feel in reality what he expresses.

**ACTION**, in painting and sculpture, is the posture of a statue or picture, serving to express some passion, &c.

**ACTION**, among physicians. See **MOTIONS**.

**ACTION**, in commerce, is a term used abroad for a part or share in a company's stock or capital.

**ACTION**, in Scots law, is a demand made before a judge for obtaining what we are legally intitled to demand, and is more commonly known by the name of law-suit or process. See **LAW**, title, *Actions*.

**ACTIONARY**, or **ACTIONIST**, a proprietor of stock in a trading company.

**ACTIONS**, among merchants, sometimes signify moveable effects; and we say the merchant's creditors have seized on all his actions, when we mean that they have taken possession of all his active debts.

**ACTIVE**, denotes something that communicates action or motion to another; in which acceptation it stands opposed to passive.

**ACTIVE**, in grammar, is applied to such words as express action; and is therefore opposed to passive. The active performs the action, as the passive receives it.

**ACTIVE principles**, in chemistry, such as are supposed to act without any assistance from others; as mercury, sulphur, &c. See **CHEMISTRY**.

**ACTIVITY**, in general, denotes the power of acting, or the active faculty. See **ACTIVE**.

*Sphere of ACTIVITY*, the whole space in which the virtue, power, or influence of any object is exerted.

**ACTIUS**, in mythology, a surname of Apollo, from Actium, where he was worshipped.

**ACTOR**, in general, signifies a person who acts or performs something.

**ACTOR**, in the drama, is a person who represents some part or character upon the theatre. The drama in its original only consisted of a simple chorus, who

sung hymns in honour of Bacchus; so that the primitive actors were only singers and musicians. Theſpis was the first who introduced a *persona*, or actor, to ease the chorus, by reciting the adventures of some of their heroes. Æschylus introduced a second, and changed the ancient recitatus into dialogues. Sophocles added a third, in order to represent the variety of incidents in a more natural manner. And here the Greeks stopped; at least we do not find, in any of their tragedies, above three persons in the same scene, though, in their comedies, they took a greater liberty. The ancient actors were masked, which must have been a great disadvantage to their action, as they were thereby deprived of all the variety of expression the countenance is capable of. Actors were as much honoured at Athens, as they were despised at Rome. The French have, in this particular, adopted the manner of the Romans, and the English that of the Athenians. See **DRAMA**.

**ACTORUM tabule**, in antiquity, were tables instituted by Servius Tullius, in which the births of children were registered. They were kept in the treasury of Saturnus.

**ACTRESS**, a woman who performs a part upon the stage. Women actors were unknown to the ancients.

**ACTUAL**, something that is real and effective, or that exists truly and absolutely.

**ACTUARIÆ naves**, a kind of ships among the Romans, chiefly designed for swift sailing.

**ACTUARIUS**, or **ACTARIUS**, a notary or officer appointed to write the acts or proceedings of a court, or the like. In the Eastern empire, the actuarii were properly officers who kept the military accounts, received the corn from the *subscriptores*, or store-keepers, and delivered it to the soldiers.

**ACTUATE**, to bring into act, to put a thing in motion, or to stir up a person to action.

**ACTUS**, in ancient architecture, a measure in length equal to 120 Roman feet. In ancient agriculture, the word signified the length of one furrow, or the distance a plough goes before it turns.

**ACTUS minimus**, was a quantity of land 120 feet in length, and four in breadth.

**ACTUS major**, or **ACTUS quadratus**, a piece of ground in the square form, whose side was equal to 120 feet, equal to half the jugerum.

**ACTUS intervencialis**, a space of ground four feet in breadth, left between the lands as a path or way.

**ACUANITES**, or **ACUANITÆ**, a branch of those ancient heretics who bore the general name of Manichees. This branch took their distinguishing title from Acua, a disciple of Thomas.

**ACUBENE**, in astronomy, the Arabic name of a star of the fourth magnitude, in the southern forceps of Cancer; by Bayer marked A. See **ASTRONOMY** and **CANCER**.

**ACUHYTLI**, a barbarous name of a species of serpent. **ACUTION**. See **ACUTION**.

**ACULEATE**, or **ACULEATI**, a term applied to any plant or animal armed with prickles.

**ACULEATUS**, in ichthyology, a synonyme of the gasterosteus or stickle-back. See **GASTEROSTEUS**.

**ACULEI**, the prickles of animals or of plants.

**ACULEOSA**, in botany, a synonyme of the *gorteria ciliaris* and the *roella ciliata*. See **GORTERIA**, **ROELLA**.

**ACULER**, in the menage, is used for the motion of a horse, when, in working upon volts, he does not go far enough forward at every time or motion, so that his shoulders embrace or take in too little ground, and his croupe comes too near the centre of the volt. Horses are naturally inclined to this fault in making demi-volts.

**ACUMEN**, in the ancient music, a sound produced by the intention or raising of the voice.

**ACUMINA**, in antiquity, a kind of military omen, most generally supposed to have been taken from the points or edges of darts, swords, or other weapons.

**ACUMULO**, a small town in Abruzzo Ulterior, a province of the kingdom of Naples, 17. 15. long. 39. 30. lat.

**ACUPUNCTURE**, the name of a surgical operation among the Chinese and Japanese, which is performed by pricking the part affected with a silver needle. They employ this operation in head-achs, lethargies, convulsions, colics, &c.

**ACUS**, in ichthyology, the trivial name of a species of *syngnathus*. See **SYNGNATHUS**.

**ACUTE**, as applied to angles, triangles, cones, &c. See these articles.

**ACUTE accent**, in grammar. See **ACCENT**.

**ACUTE**, in music, signifies a tone that is sharp, shrill, or high, in respect of some other, and is opposed to grave.

**ACUTE diseases**, such as come suddenly to a crisis. This term is used for all diseases which do not fall under the head of chronic diseases.

**ACUTITION**, among physicians, the sharpening or increasing the force of any medicine.

**ACYROLOGIA**, signifies an improper word, phrase, or expression.

**AD**, a Latin preposition, originally signifying *to*, and frequently used in composition both with and without the *d*, to express the relation of one thing to another.

**Ad bestias**, in antiquity, is the punishment of criminals condemned to be thrown to wild beasts.

**Ad hominem**, in logic, a kind of argument drawn from the principles or prejudices of these with whom we argue.

**Ad ludos**, in antiquity, a sentence upon criminals among the Romans, whereby they were condemned to entertain the people either by fighting with wild beasts, or with one another, and thus executing justice upon themselves.

**Ad metalla**, in antiquity, the punishment of such criminals as were condemned to the mines, among the Romans; and therefore called *Metallioi*.

**Ad quiddities**, among schoolmen. See **QUIDDITIES**.

**Ad valorem**, a term chiefly used in speaking of the duties or customs paid for certain goods: The duties on

some articles are paid by the number, weight, measure, tale, &c. and others are paid *ad valorem*, that is, according to their value.

**ADA**, a large town of Asia, inhabited chiefly by Armenians.

**ADACA-MANGEN**, in botany, a synonyme of the *sphæranthus*. See **SPHÆRANTHUS**.

**ADAGE**, a proverb, or short sentence, containing some wise observation or popular saying.

**ADAGIO**, in music, an Italian adverb, signifying *softly*, *leisurely*; and is used to denote the slowest of all times, except the grave.

**ADAJA**, a river in Spain which falls into the Duro.

**ADALIDES**, in the Spanish policy, are officers of justice for matters touching the military forces, especially on expeditions.

**ADAMANT**, a name sometimes given to the diamond. See **DIAMOND**. It is likewise applied to the scoria of gold, the magnet, &c.

**ADAMANTIC**, in church history, a name given to the followers of Origen, surnamed *Adamantius*.

**ADAMBOE**, in botany, a synonyme of the *ipomoea campanulata*, an Indian plant, belonging to the pentandria monogynia class. See **IPOMOEA**.

**ADAMI pomum**, or *Adam's apple*, in botany, an obsolete name of a species of the citrus or orange. See **CITRUS**.

**ADAMI pomum**, in anatomy, the convex part of the first cartilage of the larynx. See **ANATOMY**, Part VI.

**ADAMIC earth**, a name given to common red clay, alluding to that species of earth of which the first man is supposed to have been made.

**ADAMITES**, in church history, a name sometimes used for the descendants of Adam by Seth, who are more usually called *Sehtites*. But the name *Adamites* is more particularly used, by ecclesiastical writers, for a sect of ancient heretics, who took upon them to imitate the nakedness of Adam, and pretended to be re-inflated in his original innocence.

**ADAMSHIDE**, a district of the circle of Rastenburg, belonging to the King of Prussia, which, with Dombrooken, was bought, in 1737, for 42,000 dollars.

**ADAM'S peak**, a high mountain of the E. Indies, in the island of Ceylon, on the top of which they believe the first man was created; and there is the shape of a man's foot, cut out of the rock, about five or six feet in length, which they pretend is the print of his foot, 80. 50. E. long. 55. lat.

**ADANA**, an ancient town of Natolia, with a bishop's see. It stands on the river Choquen, 25 miles N. E. of Tarsus, 36. 25. long. 38. 10. lat.

**ADANSONIA**, in botany, a genus of the monadelphia polyandria class. It is a native of Senegal and Egypt.

**ADAOUS**, or *Adows*, a people of Guinea in Africa. **ADAPTERS**, in chemistry, machines for fitting a recipient to the capital. See **CHEMISTRY**.

**ADAR**, the name of a Hebrew month, answering to the end of February and beginning of March, the 12th of their sacred, and 6th of their civil year. On the

7th day of it, the Jews keep a fast for the death of Moses; on the 13th, they have the fast of Esther; and on the 14th, they celebrate the feast of Purim, for their deliverance from Haman's conspiracy.

**ADARCE**, a kind of concreted salts found on reeds and other vegetables, and applied by the ancients as a remedy in several cutaneous diseases.

**ADARCON**, in Jewish antiquity, a gold coin mentioned in scripture, about the value of which authors are not agreed.

**ADARF**, a small town of Ireland, in the county of Limerick.

**ADARME**, in Commerce, a small weight in Spain, which is also used at Buenos-Aires, and in all Spanish America. It is the 16th part of an ounce, which at Paris is called the *demigros*. But the Spanish ounce is seven per cent. lighter than that of Paris. Stephens renders it in English by *A dram*.

**AD ARTICULATION**, in anatomy, the same with diarthrosis. See **DIARTHROSIS**.

**ADATAIS**, **ADATIS**, or **ADATYS**, in commerce, a muslin or cotton-cloth, very fine and clear, of which the piece is ten French ells long, and three quarters broad. It comes from the E. Indies; and the finest is made at Bengal. See **MUSTIN**.

**ADCHER**, in the materia medica, a name given by some to the *Schoenanth*. See **SCOENANTH**.

**ADCORDABLES denarii**, in ancient law-books, is money paid by the vassal to his lord, in the nature of a fine, upon selling or exchanging a feud.

**ADCRESCENTES**, among the Romans, denoted a kind of soldiery, entered in the army, but not yet put on duty; from these the standing forces were recruited. See **ACCENSI**.

**ADDA**, in geography, a river of Switzerland and Italy, which rises in mount Braulio, in the country of the Grisons, and passing through the Valteline, traverses the lake Como and the Milanese, and falls into the Po, near Cremona.

**ADDACE**, in natural history, a name the Africans give to the common antelope. See **GAZELLA**.

**ADDEPHAGIA**, in medicine, a term used by some physicians, for gluttony, or a voracious appetite.

**ADDER**, in zoology, a vulgar name for the **VIPER**; which see.

**ADDERS-TONGUE**, in botany, the English name of the ophioglossum. See **OPHIOGLOSSUM**.

**ADDER-WORT**, in botany, the English name of the polygonum bistata. See **POLYGONUM**.

**ADDEXTRATORES**, in the court of Rome, the pope's mitre-bearers, so called according to Ducange, because they walk at the pope's right-hand, when he rides to visit the churches.

**ADDICE**, or **ADZE**, a kind of crooked ax used by ship-wrights, carpenters, coopers, &c.

**ADDICTI**, in antiquity, a kind of slaves, among the Romans, adjudged to serve some creditor whom they could not otherwise satisfy, and whose slaves they became till they could pay, or work out the debt.

**ADDICTION**, among the Romans, was the making over goods to another, either by sale, or by legal sen-

tence; the goods so delivered were called *bona addicta*. Debtors were sometimes delivered over in the same manner; and thence called *servi addicti*.

**ADDICTIO in diem**, among the Romans, the adjudging a thing to a person for a certain price, unless by such a day the owner, or some other, give more for it.

**ADDITAMENT**, a term sometimes used by chemists and physicians for the addition of any new ingredient to increase the strength of a menstruum or composition.

**ADDITION**, is the joining together or uniting two or more things, or augmenting a thing by the accession of others thereto.

**ADDITION**, in ARITHMETIC, ALGEBRA, LOGARITHMS, &c. see these articles.

**ADDITION of ratios**, a term sometimes used for composition of ratios.

**ADDITION**, in music, a dot marked on the right side of a note, signifying that it is to be sounded or lengthened half as much more as it would have been without such mark.

**ADDITION**, in law, is that title or designation which is given to a man, over and above his proper name and surname, to shew of what estate, degree, occupation, or place he is.

**ADDITIONS**, in heraldry, some things added to a coat of arms, as marks of honour; and therefore directly opposite to abatements. Among additions we reckon **BORDURE**, **QUARTER**, **CANTON**, **GYRON**, **PILE**, &c. See these articles.

**ADDITION**, in distillery, a general name given to such things as are added to the wash or liquor while fermenting, to increase the vinosity and quantity of the spirit, or give it a particular relish.

**ADDITIVE**, in general, something to be added. Thus, mathematicians speak of *additive ratios*, astronomers of *additive equations*, &c.

**ADDOU**, one of the Maldivian islands.

**ADDRESS**, a term often used to express the skill and propriety with which an affair is conducted or managed.

*An ADDRESS*, in a particular acceptation, is a congratulation, petition, or remonstrance, presented to a superior, especially to the king.

**ADDUCENT muscles**, or **ADDUCTORS**. See **ADDUCTOR**.

**ADDUCTION**, in anatomy, the motion or action of the adducted muscles.

**ADDUCTOR**, in anatomy, the names of all muscles which pull one part of the body towards another. See **ANATOMY**, Part II.

**ADEA**, in geography, a province of Annian, on the eastern coast of Africa, called also *Adel*.

**ADEB**, a large and uncertain Egyptian weight, used chiefly for rice.

**ADEL**, or **ADEA**, in geography, a kingdom of Africa, called also *Zeila*, from its capital town. It lies on the S. coast of the strait of Babelmandel. There is seldom any rain here, and yet the country is fruitful, it being well watered with rivers. It abounds with wheat,

*Fig. 1. ADONIS APPENINA*

*Fig. 2. ALAUDA or Lark*

*A. Bell's Sculp.*

PLATE III  
A. N. 1. 1800. 1801. 1802.

- wheat, millet, frankincense, and pepper. Their religion is the Mahometan.
- ADEL-fish**, an obsolete name of the *salmo albus*, belonging to the order of abdoinales. See **SALMO**.
- ADEL-ODAGAM**, in botany, a synonyme of the *justicia* bivalvis. See **JUSTICIA**.
- ADELIA**, in botany, a genus of the diœcia monadelphia class. Of this genus there are three species; the *bernardia*, a native of America; and the *ricinella* and *acidoton*, both natives of Jamaica.
- ADELPHIANI**, in church history, a sect of ancient heretics, so called from their leader *Adelphius*. They keep the sabbath as a fast.
- ADELSCALC**, in antiquity, a servant of the king; from the German, *adel*, noble, and *scale*, a servant. They seem to have been the same with *royal thanes* among the Saxons, and the *ministri regis* in ancient charters.
- ADELSPERG**, a small town of Germany, in lower Carniola.
- ADEMPITION**, in law, is the revocation of a donation, or grant, either directly by a deed or writ, or indirectly by another wise disposing of the subject of it. See **RESCISSIO**.
- ADEN**, formerly a rich and considerable town of Arabia the Happy. It is seated by the sea-side, a little eastward of the straits of Bebelmandel.
- ADENANTHERA**, in botany, a genus of the decandria monogynia class. There are only two species of this plant, the *pavonina* and the *faleataria*, both natives of India.
- ADENBURG**, or **ALDENBURG**, in geography, a town of Westphalia, and in the dutchy of Burg, subject to the Elector Palatine. It is 12 miles N. E. of Cologne, and 17 W. of Bonn, 7. 25. E. long. 51. 2. lat.
- ADENDUM**, a small town of Africa, in the kingdom of Fez.
- ADENOGRAPHY**, that part of anatomy which treats of the glandular parts.
- ADENOIDES**, in anatomy. See **PROSTATES**.
- ADENOLOGY**. See **ADENOGRAPHY**.
- ADENOS**, a kind of cotton otherwise called *marine cotton*. It comes from Aleppo by the way of Marseilles, where it pays 20 per cent. duty, according to the tariff of the year 1766. Its valuation, according to the same tariff, is 76 livres 16 sols.
- ADENOSE abscess**, a term sometimes used for a hard tumour resembling a gland.
- ADEONA**, in mythology, the name of a goddess invoked by the Romans when they set out upon a journey.
- ADEPHAGIA**, in mythology, the goddess of gluttony, to whom the Sicilians paid religious worship.
- ADEPS**, in anatomy, the fat found in the abdomen. It also signifies animal-fat of any kind.
- ADEPTES**, a term among alchemists for those who pretended to have found out the panacea or philosophers-stone.
- ADEQUATE**, something equal to or exactly corresponding with another.
- ADEQUATE idea**, signifies a distinct or perfect conception of all the qualities of any object.
- ADERBERG**, a town of Pomerania, situate on the Oder.
- ADERBIGAN**, a province of Persia, bounded on the N. by Armenia Proper, on the S. by Irac-Agemi, on the E. by Ghilan, and on the W. by Curdistan. The principal town is Tauris, from 42. to 48. long. from 36. to 39. lat.
- ADERNO**; a small place in the Val di Demona in the kingdom of Sicily, 15. 25. E. long. 28. 5. lat.
- ADESSENARIANS**, **ADESSENARI**, in church-history, a sect of Christians, who hold the real presence of Christ's body in the eucharist, though not by way of transubstantiation. They differ considerably as to this presence, some holding that the body of Christ is in the bread; others, that it is about the bread; and others, that it is under the bread.
- ADEFECTED equation**. See **ALGEBRA**.
- ADFIILIATION**, a Gothic custom, whereby the children of a former marriage are put upon the same footing with those of the second. This is also called *unio prolium*, and still retained in some parts of Germany.
- ADHATODA**, in botany, a synonyme of a species of *ruelia*, *acanthus*, and of two species of *justicia*.
- Action of ADHERENCE**, in Scots law, an action competent to a husband or wife, to compel either party to adhere, in case of desertion. See **LAW**, title, *Marriage*.
- ADHERGAT**, a town of Syria, near the frontiers of Arabia.
- ADHESION**, implies the sticking or adhering of two bodies together.
- ADHESION**, in logic, signifies tenaciousness to an argument, without regard to any evidence of its truth.
- ADHESION**, in anatomy, a term for one part sticking to another, which in a natural state are separate.
- ADHOA**, in ancient customs. See **RELIEF**.
- ADJA**, or **ADGA**, a town of Guinea on the coast of Fantin.
- ADJACENT**, an appellation given to such things as are situate near, or adjoining to each other.
- ADIANTHUM**, in botany, a genus of the cryptogamia filices, of which there are 19 species, and only two of them natives of Britain, *viz.* the *adiantum capillus veneris*, or true maiden-hair, and the *trapeziforme*, or shining maiden-hair.
- ADIAPHORISTS**, **ADIAPHORISTE**, or **ADIAPHORITES**, in church-history, a name importing lukewarmness, given, in the sixteenth century, to the moderate Lutherans, who embraced the opinions of Melancthon, whose disposition was vastly more pacific than that of Luther.
- ADJAZZO**, in geography, a handsome town and castle of Corsica in the Mediterranean, with a bishop's see, and a good harbour. It is populous, and fertile in wine. Some call it *Agaccio*. It is 27 miles S. W. of Corte, 8. 53. E. long. 41. 54. lat.
- ADJECTIVE**, in grammar, when joined to a substantive, imports some quality, or accident, or circumstance belonging to that substantive.
- ADIGE**, in geography, a river in Italy, which taking

its rise S. of the lake Glace, among the Alps, runs S. by Trent, then E. by Verona in the territory of Venice, and falls into the gulph of Venice, N. of the mouth of the Po.

**ADJOURNMENT**; the word imports putting off something to another day or time.

**ADIPOSE**, a term used by anatomists for any cell, membrane, &c. that is remarkable for its fatness.

**ADVIRBEITSAN**, in geography, a province of Persia, in Asia, and part of the ancient Media. It is bounded on the N. by the province of Shirvan, on the S. by Irac-Agemi and Curdistan, on the E. by Gilan and the Caspian sea, and on the W. by Turcomania.

**ADIT**, in general, signifies the passage to, or entrance of any thing, as the adit of a mine, &c.

**ADJUDICATION**, in Scots law, the name of that action by which a creditor attaches the heritable estate of his debtor, or his debtor's heir, in order to appropriate it to himself, either in payment or security of his debt; or, that action by which the holder of an heritable right, labouring under any defect in point of form, may supply that defect. See *Law*, title, *Comproisings and adjudications*.

**ADJUNCT**, something added or joined to another. In rhetoric and grammar, they signify certain words or things added to others, to amplify or augment the force of the discourse.

**ADJUTANT**, in the military art, is an officer whose business it is to assist the major. Each battalion of foot and regiment of horse has an adjutant, who receives the orders every night from the brigade-major; which, after carrying them to the colonel, he delivers out to the serjeants. When detachments are to be made, he gives the number to be furnished by each company or troop, and assigns the hour and place of rendezvous. He also places the guards, receives and distributes the ammunition to the companies, &c. and by the major's orders, regulates the prices of bread, beer, and other provisions.—The word is sometimes used by the French for an *aid-du-camp*.

**ADJUTANTS-general**, among the Jesuits, a select number of fathers, residing with the general of the order, each of whom has a province or country assigned him, as England, Holland, &c. and their business is to inform the father-general of state-occurrences in such countries.

**ADJUTORIUM**, a term used by physicians for any medicine in a prescription but the capital one.

**ADJUTORIUM**, in anatomy, the same with the humerus or shoulder-blade. See *HUMERUS*.

**ADLE-EGGS**, such as have not received an impregnation from the semen of the cock.

**ADLOCUTION**, in Roman antiquity, is chiefly understood of speeches made by Roman generals, to their armies, to animate them with courage, before a battle.

**ADMINICLES**, in Scots law, signifies any writing or deed referred to by a party in an action of law, for proving his allegiances or assertions.

**ADMINICLES**, among antiquarians, the ornaments where-with Juno is represented on medals.

**ADMINICULATOR**, an ancient officer of the church, whose business it was to attend to, and defend the cause of widows, orphans, and others destitute of help.

**ADMINISTRATION**, in general, the government, direction, or management of affairs, and particularly the exercise of distributive justice; among ecclesiastics it is often used to express the giving or dispensing the sacraments, &c.

**ADMINISTRATION**, is also the name given by the Spaniards in Peru, to the staple magazine, or warehouse, established at Callao, a small town on the S. Sea, which is the port of Lima, the capital of that part of S. America, and particularly of Peru. The foreign ships, which have leave to trade along that coast, are obliged to unload here, paying 13 per cent. of the price they sell for, if the cargo be entire, and even 16 per cent. if otherwise; besides which they pay 2 per 1000, duty for consulship, and some other small royal rights and claims.

**ADMINISTRATION**, a term used by anatomists for the art of dissecting with propriety.

**ADMINISTRATOR**, in Scots law, a person legally empowered to act for another whom the law presumes incapable of acting for himself. Thus tutors or curators are sometimes styled *administrators in law* to pupils, minors, or fatuous persons. But more generally the term is used to imply that power which is conferred by the law upon a father over the persons and estates of his children during their minority. See *Law*, title, *Minors, and their tutors and curators*.

**ADMINISTRATOR**, is sometimes used for the president of a province; for a person appointed to receive, manage, and distribute the revenues of an hospital or religious house; for a prince who enjoys the revenues of a secularized bishoprick; and for the regent of a kingdom, during a minority of the prince, or a vacancy of the throne.

**ADMINISTRATRIX**, a woman who acts as administrator.

**ADMIRABILIS**, in botany, a synonyme of the mirabilis. See *MIRABILIS*.

**ADMIRABILIS sal**, the same with Glauber's salt. See *GLAUBER'S SALT*.

**ADMIRAL**, in maritime affairs, a great officer who commands the naval forces of a kingdom or state.

*High ADMIRAL*, in the law of Scotland, a judge invested with supreme jurisdiction in all maritime causes within Scotland. See *LAW*, title, *Supreme judges, and courts of Scotland*.

**ADMIRAL** also denotes the commander in chief of a single fleet or squadron; or, in general, any flag-officer whatever. In the British navy, besides the admiral who commands in chief, there are the vice-admiral, who commands the second squadron; and the rear-admiral, who commands the third. The admiral carries his flag at the main-top-mast-head; the vice-admiral at the fore-top-mast-head; and the rear-admiral at the mizen-top-mast-head. See *FLAG*.

*Vice-ADMIRAL* likewise denotes an officer invested with the jurisdiction of an admiral, within a certain district. There are a number of such in *G. Britain*.

**ADMIRAL**,

- ADMIRAL** is also an appellation given to the most considerable ship of a fleet of merchant-men, or of the vessels employed in the cod-fishery of Newfoundland. This last has the privilege of chusing what place he pleases on the shore to dry his fish; gives proper orders, and appoints the fishing places to those who come after him; and as long as the fishing-season continues, he carries a flag on his main-mast.
- ADMIRAL**, in zoology, the English name of a species of the voluta, a shell fish belonging to the order of vermes testacea. See *VOLUTA*.
- High Court of ADMIRALTY*, in Scotland, the court in which the high-admiral is judge. See *ADMIRAL*.
- ADMIRATION**, in general, denotes surprize, wonder, or astonishment at any extraordinary event. Sometimes also it signifies the expression of wonder.
- ADMISSION**, among ecclesiastical writers, is the act of a bishop's allowing a clerk to be properly qualified for serving a cure.
- ADMITTENDO clerico**, in the English law, a writ granted to a person who has recovered his right of presentation against the bishop, &c. in the common pleas, by which the bishop, or metropolitan is ordained to admit his clerk.
- ADMITTENDO in socium**, in the English law, a writ for the afficiation of certain persons to justices of assize formerly appointed.
- ADMONITION**, in ecclesiastical discipline, is a formal warning of an offender of his irregularities, and advising him to reform.
- ADMONITIO fistium**, among the Romans, a military punishment, not unlike our whipping, only it was performed with vine-branches.
- ADMORTIZATION**, in the feudal customs, the reduction of the property of lands or tenements to mortmain. See *MORTMAIN*.
- ADNATA**, in anatomy, one of the coats of the eye, which is also called *conjunctiva* and *albuginea*. See *ANATOMY*, Part VI.
- ADNATA**, is also used for any hair, wool, or the like, which grows upon animals or vegetables.
- ADNOUN**, a term used by some grammarians for an adjective.
- AD osto**, implied the highest degree of perfection, among ancient philosophers.
- ADOLESCENCE**, in the flower of youth, or time of growth in the human species, commencing at infancy, and terminating in manhood.
- ADOLPH Fredrick's Schacht**, a silver-mine in Sweden, which, from 1742 to 1747, produced a great deal of silver.
- ADOM**, in geography, a populous village in the province of Stuhl-Weissenberg, belonging to Hungary. It lies in a fruitful country, towards the river Danube, 19. 20. long. 47. 30. lat.
- ADONAL**, one of the names of the Supreme Being in the scriptures. The proper meaning of the word is *my lord*, in the plural number, as *Adoni* is *my lord* in the singular.
- ADONIA**, in mythology, festivals in honour of Venus, and in memory of Adonis, with whom she is said to have been in love.
- ADONIAS**, in botany, an obsolete name of the anemone. See *ANEMONE*.
- ADONIDES**, in botany, a name given to botanists who described or made catalogues of plants cultivated in any particular place.
- ADONION**, in botany, an obsolete name of a species of southernwood.
- ADONIS**, in zoology. See *EXOCOETUS*.
- ADONIS**, in botany, a genus of the polyandria polygynia class. The English names are, adonis-flower, pheasant's eye, red maithes, or red morocco. The calix of this genus is pentaphyllous, the petals are five, and the seeds are naked. There are five species of the adonis, viz. the estivalis, autumnalis, vernalis, appennina, and capensis; none of which are natives of Britain, excepting the autumnalis. See Plate III. fig. 1. which represents the adonis appennina.
- ADONIS potio**, in antiquity, an ancient beverage made of wine, mixed with flower of roasted adon. It was the same with cyceon.
- ADOPTIANI**, in church history, a sect of ancient heretics, followers of Felix of Urgel, and Elipand of Toledo, who, towards the end of the eighth century, advanced the notion, that Jesus Christ, in his human nature, is the Son of God, not by nature, but by adoption.
- ADOPTION**, a solemn act whereby any one takes another man's son into his family, and makes him his heir, investing him with all the rights and privileges of a son.
- ADOPTIVE**, in general, signifies any thing adopted. Thus we say, *adoptive children*, &c.
- ADOPTIVE arms**, in heraldry, or, *arms of adoption*, those which a person enjoys by the gift or concession of another, and to which he was not otherwise intitled.
- ADOPTIVI**. See *ADOPTIANI*.
- ADORATION**, is the homage and submission due to the Supreme Being.
- ADOSSE**, in heraldry, signifies two figures or bearings, being placed back to back. Thus the arms of the duchy of Bar are two bars *adosse*, or back to back.
- ADOUR**, the name of a river of France, which rises in the mountains of Bigorre, and running N. by Tarbes through Gascony, afterwards turns E. and, passing by Dax, falls into the bay of Biscay, below Bayonne.
- ADOXA**, or *TUBEROSE MOSCHATIL*, in botany, a genus of the octandria tetragynia class. There is only one species of the adoxa, which is a native of Britain and other parts of Europe.
- ADPERCEPTION**, a term used by Leibnitz for the act whereby the mind becomes conscious of its perceptions.
- AD pondus omnium**, among physicians, an abbreviation in their prescriptions, signifying that the last mentioned ingredient is to weigh as much as all the rest together.
- AD quod damnum**, in the English law, a writ directed to the sheriff, commanding him to enquire into the damage which may befall from granting certain privileges to a place, as a fair, market, or the like.

ADRA, in geography, a sea-port town of Spain, in the kingdom of Granada, 37 miles S. E. of Granada, and 12 S. W. of Almeria, 1. 10. W. long. 36. 0. lat.

ADRACANTH. See TRACACANTH.

ADRACHNE, in botany, an obsolete name of a species of arbutus. See ARBUTUS.

ADRAMMELECH, in antiquity, or mythology, a deity worshipped by the inhabitants of Sepharvaim, a people planted in the Holy Land by the kings of Assyria, after Salmanazar had taken Samaria, and put a final period to the kingdom of Israel. The worshippers of Adrammelech burnt their children in the fire to the honour of that idol. The name is Persian, and signifies *the magnificent king*.

ADRIUNE, in botany, an obsolete name of the cyclamen. See CYCLAMEN.

ADROBE, the name of two rivers in that part of Asiatic Tartary which is subject to Moscow: They both fall into the Wolga beneath Cazan.

ADSCRIPTS, a term used by some mathematicians for the natural tangents. See TANGENT.

ADSIDELLA, in antiquity, the table at which the flames sat during the sacrifices.

ADSTAT, a small town belonging to Denmark in the island of Iceland, not far from Holar.

ADSTRICTION, among physicians, a term used to denote the rigidity of any part.

ADVANCE, in the mercantile style, denotes money paid before goods are delivered, work done, or business performed.

ADVANCED ditch, in fortification, is that which surrounds the glacis or esplanade of a place.

ADVANCED guard, or *vanguard*, in the art of war, the first line or division of an army, ranged, or marching in order of battle; or, it is that part which is next the enemy, and marches first towards them.

ADVANCED guard, is more particularly used for a small party of horse stationed before the main-guard.

ADVANCER, among sportsmen, one of the starts, or branches of a buck's attire; between the back antler and the palm.

ADUAR, in the Arabian and Moorish customs, a kind of ambulatory village, consisting of tents, which these people remove from one place to another, as suits their convenience.

ADVENT, in the calendar, properly signifies the approach of the feast of the Nativity. It includes four Sundays, which begin on St Andrew's day, or on the Sunday before or after it. During advent, and to the end of the octaves of Epiphany, the solemnizing of marriage is forbid, without a special licence.

ADVENTITIOUS, an epithet applied to any thing that is accidental or fortuitous.

AD VENTREM *inspicendum*, in law, a writ by which a woman is to be searched whether she be with child by a former husband, on her with-holding of lands from the next, failing issue of her own body.

ADVENTURE, in a general sense, some extraordinary or accidental event. It also denotes a hazardous or difficult undertaking.

*Bill of ADVENTURE*, among merchants, a writing sign-

ed by a merchant, testifying the goods mentioned in it to be shipped on board a certain vessel belonging to another person, who is to run all hazards; the merchant only obliging himself to account to him for the produce.

ADVENTURER, in a general sense, denotes one who hazards something.

ADVERB, in grammar, a word joined to verbs, expressing the manner, time, &c. of an action: thus, in the phrase, *he was warmly attached to the interest of his master*, the word *warmly* is an adverb. See GRAMMAR.

ADVERSARIA, among the ancients, a book of accounts, not unlike our journals, or day-books. It is more particularly used for a kind of common-place-book. See COMMON-PLACE-BOOK.

ADVERSARY, a person who is an enemy to, or opposes another.

ADVERSATIVE, in grammar, a word expressing some difference between what goes before and what follows it. Thus, in the phrase, *he is an honest man, but a great enviousist*, the word *but* is an adversative conjunction.

ADVERSATOR, in antiquity, a servant who attended the rich in returning from supper, to give them notice of any obstacles in the way, at which they might be apt to stumble.

ADVERTISEMENT, in a general sense, denotes any information given to persons interested in an affair; and is more particularly used for a brief account of an affair inserted in the public papers, for the information of all concerned.

ADULT, an appellation given to any thing that is arrived at maturity: Thus we say, an adult person, an adult plant, &c. Among civilians, it denotes a youth between fourteen and twenty-five years of age.

ADULTERATION, the act of debasing, by an improper mixture, something that was pure and genuine.

ADULTERY, an unlawful commerce between one married person and another, or between a married and unmarried person. See SCOTS LAW, titles, *Marriage, and Crimes*.

ADVOCATE, among the Romans, a person who undertook the defence of causes. The term is still kept up in all countries where the civil law obtains.

*King's ADVOCATE*, is the principal crown-lawyer in Scotland. His business is to act as a public prosecutor, and to plead in all causes that concern the crown; but particularly in such as are of a criminal nature. The office of King's advocate is not very ancient: It seems to have been established about the beginning of the 16th century. Originally he had no power to prosecute crimes without the concurrence of a private party; but in the year 1597, he was empowered to prosecute crimes at his own instance.

*Faculty of ADVOCATES*, in Scotland, a respectable body of lawyers, who plead in all causes before the Courts of Session, Justiciary, and Exchequer. They are also intitled to plead in the house of peers, and other supreme courts in England.

In the year 1660, the faculty founded a library upon

upon a very extensive plan, suggested by that learned and eminent lawyer Sir George M'Kenzie of Rosehaugh, advocate to King Charles II. and King James VII. who enriched it with many valuable books. It has been daily increasing since that time, and now contains not only the best collection of law-books in Europe, but a very large and select collection of books on all subjects. Besides, this library contains a great number of original manuscripts, and a vast variety of Jewish, Grecian, Roman, Scots, and English coins and medals.

A candidate for the office of an advocate undergoes three several trials: The first is in Latin, upon the civil law and Greek and Roman antiquities; the second, in English, upon the municipal law of Scotland; and in the third, he is obliged to defend a Latin thesis, which is impugned by three members of the faculty. Immediately before putting on the gown, the candidate makes a short Latin speech to the lords, and then takes the oaths to the government and *de fidei*.

The faculty at present consists of above 200 members. As an advocate or lawyer is esteemed the gentlest profession in Scotland, many gentlemen of fortune take the degree of advocate, without having any intention of practising at the bar. This circumstance greatly increases their number, gives dignity to the profession, and enriches their library and public fund. It is from this respectable body, that all vacancies on the bench are generally supplied.

*Fiscal* ADVOCATE, *fisci advocatus*, in Roman antiquity, an officer of state under the Roman Emperors, who pleaded in all causes wherein the *fiscus*, or private treasury, was concerned.

*Consistorial* ADVOCATES, officers of the consistory at Rome, who plead in all oppositions to the disposal of benefices in that court; they are ten in number.

ADVOCATE of a city, in the German polity, a magistrate appointed in the Emperor's name to administer justice.

*Bill of* ADVOCATION, in Scots law, a writing drawn up in the form of a petition, whereby a party, in an action before an inferior court, applies to the supreme court, or court of Session, for calling the action from the inferior court before itself. See LAW, title, *Jurisdiction*, and *judges in general*.

*Letters of* ADVOCATION, in Scots law, the decree or warrant of the court of Session upon cognizance of the facts set forth in the bill, drawn up in the form of a summons, and passing under the signet, discharging the inferior judge and all others from further procedure in the cause, and advocating it to itself. See *Bill of* ADVOCATION.

ADVOCATIONE *decimarum*, a writ which lies for claiming a fourth part for tithes, or upwards, belonging to any church.

ADVOUSON, or ADVOUZEN. See ADVOWZON. ADVOU, in law, signifies the patron of a church, or he who has a right to present to a benefice.

*Paramount* ADVOWEE, is used for the king, as being the highest patron.

ADVOWING. See AVOWING.

ADVOWTRY, a term used in some old law-books for adultery.

ADVOWZON, in law, is the right of patronage, or presenting to a vacant benefice.

ADUST, among physicians, a term applied to the blood, &c. when too hot and fiery.

ADUSTION, among physicians, the same with inflammation.

ADYTUM, in pagan antiquity, the most retired and sacred place of their temples, into which none but the priests were allowed to enter.

ADZEL, a small town of Livonia, situated on the south-side of the river Aa, about ten German leagues south-west of Dorpt.

ÆACEA, in Grecian antiquity, solemn festivals and games celebrated at Ægina, in honour of Æacus; who, on account of his justice upon earth, was thought to have been appointed one of the judges in hell.

ÆCHMALOTARCHA, in Jewish antiquity, the title given to the principal leader or governor of the Hebrew captives residing in Chaldea, Assyria, and the neighbouring countries.

ÆDES, in Roman antiquity, besides its more ordinary signification of a house, likewise signified an inferior kind of temple, consecrated to some deity.

ÆDICULA, a term used to denote the inner part of the temple, where the altar and statue of the deity stood.

ÆDILATE, the office of ædile, sometimes called *ædilitiy*. See the next article.

ÆDILE, in Roman antiquity, a magistrate whose business it was to superintend buildings of all kinds, but more especially public ones, as temples, aqueducts, high-ways, bridges, &c.

ÆDITUUS, in Roman antiquity, an officer belonging to the temples, who had the charge of the offerings, treasure, and sacred utensils. The female deities had a woman-officer of this kind called *æditua*.

ÆGAGROPILA, a ball composed of a substance resembling hair, generated in the stomach of the chamois-goat. This ball is of the same nature with those found in cows, hogs, &c.

ÆGILETHRON, in botany, an obsolete name of the mercurialis. See MERCURIALIS.

ÆGIAS, among physicians, a white speck on the pupil of the eye, which occasions dimness of sight.

ÆGILOPS, among physicians, a species of abscess. See SURGERY, title, *Of abscesses*, or *tumors*.

ÆGILOPS, in botany, a genus of the polygamia monœcia class. There are five species of this plant, which is a kind of grass, *viz.* the ovata, caudata, squarrosa, triuncialis, and incurvata, only the last of which is a native of Britain, and grows by the sea-shore. The English name is *sea-bard-grass*.

ÆGINETIA, in botany, a synonyme of a species of orobanche. See OROBANCHE.

ÆGIPAN, in heathen mythology, a denomination given to the god Pan, because he was represented with the horns, legs, feet, &c. of a goat.

ÆGIS, in heathen mythology, is particularly used for the shield or cuirass of Jupiter and Pallas.

ÆGIUCHUS, in heathen mythology, a surname of Jupiter,

piter, given him on account of his having been suckled by a goat.  
**ÆGLEFINUS**, or **HADDOCK**, in ichthyology, a species of the gadus. See **GADUS**.  
**ÆGOCEPHALUS**, in ornithology, an obsolete name of a species of tringa. See **TRINGA**.  
**ÆGOCERAS**, in botany, an obsolete name of a species of ononis. See **ONONIS**.  
**ÆGOCERATOS**, in botany, a synonyme of the hugonia. See **HUGONIA**.  
**ÆGOLETHRON**, in botany, an obsolete name of the rhododendron hirsutum. See **RHODODENDRON**.  
**ÆGONICHUS**, in botany, an obsolete name of the lithospermum. See **LITHOSPERMUM**.  
**ÆGOPHTHALMUS**, a name given to any of the semipellucid gems with circular spots in them, resembling the eye of a goat.  
**ÆGOPOGON**, in botany, an obsolete name of the tragapodon. See **TRAGAPODON**.  
**ÆGOPIDIUM**, a genus of the pentandria digynia class. There is but one species of this plant, which is a native of Britain and other parts of Europe. The English name is *herb-gerard*, *gout-weed*, or *ash-weed*.  
**ÆGYPTIACUM**, in pharmacy, the name of several detergent ointments.  
**ÆGYPTILLA**, the name of a stone variegated with different colours, and said to be capable of giving water the colour and taste of wine.  
**ÆINAUTÆ**, in antiquity, a denomination given to the senators of Miletus, because they held their deliberations on board a ship, and never returned to land till matters had been agreed on.  
**ÆLURUS**, in Egyptian mythology, the deity or god of cats; represented sometimes like a cat, and sometimes like a man with a cat's head.  
**ÆNEATORES**, in Roman antiquity, a general name for the musicians of an army.  
**ÆNIGMA**, denotes any dark saying, wherein some well-known thing is concealed under obscure language.  
**ÆNIGMATOGRAPHY**, or **ÆNIGMATOLOGY**, the art of resolving, or making enigmas.  
**ÆOLIC**, in a general sense, denotes something belonging to Æolis.  
**ÆOLIC dialect**, among grammarians, one of the five dialects of the Greek tongue, agreeing in most things with the Doric dialect. See **DORIC**.  
**ÆOLIC verse**, in prosody, a verse, consisting of an iambus, or spondee; then of two anapæsts, separated by a long syllable; and lastly, of another syllable. Such as,  
*O stelliferi conditor orbis.*  
**ÆOLIPILE**, a hollow metalline ball with a slender neck, or pipe; which after being filled with water, and a great degree of heat applied to it, the water issues out with great velocity in the form of an elastic vapour. See **PNEUMATICS**.  
**ÆOLIS**, in ancient geography, a country lying upon the western coast of Asia Minor.  
**ÆOLUS**, the god of the winds.  
**ÆON**, signifies the age or duration of any thing.

**ÆON**, among the Platonists, was used to denote any virtue, attribute, or perfection.  
**ÆON**, in mythology, the first woman, according to the Platonian writers.  
**ÆON**, among anatomists, an obsolete name for the spinal marrow.  
**ÆONIAN**, in botany, an obsolete name of the sedum majus. See **SEDUM**.  
**ÆRA**, in chronology, a series of years commencing from a certain fixed point of time, called an *epocha*; thus we say, the Christian æra, that is, the number of years elapsed since the birth of Christ. See **ASTRONOMY**, *Of the division of time*.  
**ÆRA of Nabonassar**. See **NABONASSAR**.  
**ÆRA of the Hegira**. See **HEGIRA**.  
**ÆRARIIUM**, in Roman antiquity, the treasury or place where the public money was deposited.  
**ÆRARIIUM privatum**, was the emperor's privy purse, or place where the moneys arising from his private patrimony were deposited.  
**ÆRARIUS**, in a general sense, denotes any person employed in coining or managing the public monies.  
**ÆRARIUS** was more particularly used by the Romans for a degraded citizen, whose name had been struck off the list of his country.  
 The *ærarii* were so called on account of their being liable to all the taxes and other burdens of the state, without enjoying any of its privileges. Hence, *inter ærarios referri*, was a more severe punishment than *tribu moveri*.  
**ÆRIAL**, in a general sense, denotes something partaking of the nature of air; thus, aerial substance, aerial particles, &c.  
**ÆRIANS**, in church-history, a branch of Arians, who, to the doctrines of that sect, added some peculiar dogmas of their own; as, that there is no difference between bishops and priests; a doctrine maintained by many modern divines, particularly of the presbyterian and reformed churches.  
**ÆERICA**, in ichthyology, a synonyme of the clupea hengerus, or herring. See **CLUPEA**.  
**Flos ÆRIS**, among alchemists, small scales procured from copper melted by a strong heat; it is sometimes used for ærugo or verdegris.  
**ÆROGRAPHY** signifies a description of the air, especially of its dimensions, and other most obvious properties; in which sense it differs but little from *ærology*, which is a scientific account of the nature and its obvious properties of air. See **PNEUMATICS**.  
**ÆROMANCY**, a species of divination performed by means of air, wind, &c. It is also used for the art of foretelling the various changes of the air and weather, by means of barometers, hygrometers, &c.  
**ÆROMÉTRY**, the art of measuring the motion, gravity, elasticity, rarefaction, condensation, &c. of air. See **PNEUMATICS**.  
**ÆROPHOBIA**, among physicians, signifies the dread of air.  
**ÆROPHYLACEA**, a term used by naturalists for caverns or reservoirs of air, supposed to exist in the bowels of the earth.

**ÆRRA**, a small town of Portugal, in the province of Estramadura, situated upon the river Zatus.

**ÆRESCHOT**, a town of the Dutch Netherlands, situated in Brabant, about fifteen miles eastward of Mechlin.

**ÆRUGINOUS**, in ornithology, the trivial name of a species of falco. See **FALCO**.

**ÆRUGINOUS**, an epithet given to such things are resemble or partake of the nature of the rust of copper.

**ÆRUGO**, properly signifies the rust of copper, or verdgris; but is applied indifferently to rust of any kind.

**ÆRUGO salis**, a kind of reddish slimy matter, separated from Egyptian *natrum*; probably a mixture of bitumen and a red earth.

**ÆRUSCATORES**, in antiquity, a kind of strolling beggars, not unlike gypsies, who drew money from the credulous by fortune-telling, &c. It was also a denomination given to gripping exactors, or collectors of the revenue.

**ÆRY**, or **AIRY**, among sportsmen. See **AIRY**.

**ÆS**, properly signifies copper, or money coined of that metal. See **COPPER**.

**Æs flavum**, yellow copper, among the Romans, an appellation given to the coarser kinds of brass. See **BRASS**.

**Æs calarium**, the name of a certain regulus of antimony, employed in preparing the fine blue colour called *smalt*.

**Æs usum**, a preparation of copper, by exposing plates of it in a reverberatory furnace, till they crumble into a powder, which is called *æt usum*. It is used for colouring glass, eating off dead flesh, or cleansing foul ulcers.

**ÆSALON**, in ornithology, an obsolete name of a species of falco. See **FALCO**.

**ÆSCH**, in ichthyology, an obsolete name of a species of salmo. See **SALMO**.

**ÆSCHYNOMENE**, in botany, a genus of the diadelphia decandria class. There are seven species of this genus, none of which are natives of Britain. The calix of the *æschynomene* is bilabiated, and the pod jointed. It is also a synonyme of several species of the mimosa, or sensitive plant. See **MIMOSA**.

**ÆSCULANUS**, or **ÆRES**, in mythology, a deity who presided over the coinage of copper-money.

**ÆSCULAPIUS's serpent**, or **COLUBER ÆSCULAPII**. See **COLUBER**.

**ÆSCULUS**, in botany, a genus of the heptandria monogynia class. There are only two species of it, *viz.* the castanum, and the pavia, both natives of India. The calix of the *æsculus* is monophyllous with five teeth; the corolla has five petals unequally coloured, and inserted into the calix.

**ÆSTIMATIO capitis**, a term met with in old law-books for a fine anciently ordained to be paid for offences committed against persons of quality, according to their several degrees.

**ÆSTIVAL**, in a general sense, denotes something connected with, or belonging to summer. Hence, *æstival sign*, *æstival solstice*, &c.

**ÆSTUARIA**, in geography, denotes an arm of the sea, which runs a good way within land. Such is the Bristol channel, and many of the friths of Scotland.

**ÆSTUARIES**, in ancient baths, were secret passages from the hypocaustum into the chambers. See **BATH**, and **HYPOCAUSTUM**.

**ÆSTUARY**, among physicians, a vapour-bath, or any other instrument for conveying heat to the body.

**ÆTH**, or **ATH**, a strong little town in the Austrian Netherlands, and province of Hainault, situated on the river Dender, about twenty miles S. W. of Brussels.

**ÆTHALE**, a term used by the ancients for the cadmia fornacum. See **CADMITA**.

**ÆTHALIES**, a name given by the Greeks to the sedum. See **SEDUM**.

**ÆTHER**, the name of an imaginary fluid, supposed by several authors, both ancient and modern, to be the cause of gravity, heat, light, muscular motion, sensation, and, in a word, of every phenomenon in nature. Anaxagoras maintained that æther was of a similar nature with fire; Perrault represents it as 7200 times more rare than air; and Hook makes it more dense than gold itself. Whoever has an inclination to know the various hypotheses concerning æther, may consult Shebber, Perrault, Hook's posthumous works, *Ac. Erud.* Lipf. 1716, Bernouilli's *Cogitat. de gravitate ætheris*, &c. &c.

Before the method of philosophising by induction was known, the hypotheses of philosophers were wild, fanciful, ridiculous. They had recourse to æther, occult qualities, and other imaginary causes, in order to explain the various phenomena of nature: But since the days of the great Lord Verulam, who may be styled the parent of genuine philosophy, a contrary course has happily been followed. He convinced the world, that all knowledge must be derived from experiment and observation; and that every attempt to investigate causes by any other means must be unsuccessful. Since his time, the best philosophers have followed the tract which he pointed out. Boyle, Locke, Newton, Hales, and a few others, in little more than one century, have improved and extended science far beyond what the accumulated force of all the philosophers since the creation had been able to effectuate: A striking proof both of the comprehensive genius of Bacon, and of the solidity of his plan of investigation.

It must indeed be acknowledged, that there is a propensity in the human mind, which, unless it be properly restrained, has a direct tendency both to corrupt science, and to retard our progress in it. Not contented with the examination of objects which readily fall within the sphere of our observation, we feel a strong desire to account for things which, from their very nature, must, and ever will, elude our researches. Even Sir Isaac Newton himself was not proof against this temptation. It was not enough that he had discovered the nature of light and colours, the application of gravity to the motions of the heavenly bodies, &c. he must go further, and attempt to assign the cause of gravity itself. But, how does he proceed in this matter? Not in the

the way of experiment, which had led him to his former discoveries, but in the way of conjecture, which will never lead any man to truth. He had recourse to a subtle elastic æther, not much different from that of the ancients, and by it accounted for every thing he did not know, such as the cause of gravitation, muscular motion, sensation, &c.

Notwithstanding the reputation of Sir Isaac, philosophers have generally looked upon this attempt as the foible of a great man, or, at least, as the most useful part of his works; and accordingly peruse it rather as a dream or a romance, than as having any connection with science. But we are sorry to find, that some late attempts have been made to revive this doctrine of æther, particularly in a dissertation *De ortu animalium caloris*, published in May last.

As the revival of an old doctrine becomes in some measure a new one, we shall plead no other apology for inserting a specimen of the method of reasoning employed in this dissertation.

The author makes frequent use of a species of argument termed *dilemma* by logicians. For example, in the first part of the work, after endeavouring to prove that animal heat cannot be owing to fermentation, the motion of the fluids, and other causes that have usually been assigned, he draws this conclusion:—"If none of these causes are sufficient to produce the effect; therefore, by dilemma," says he, "it must be sought for in the nature and action of the nerves."—This is a new species of dilemma:—If the author had proved, that the cause of heat in animals could not possibly exist *anywhere*, but either in fermentation, the motion of the fluids, &c. or in the nerves, after having disproved its existence in all the rest, his conclusion in favour of the nerves would have been just; but, as he has not so much as attempted this, the conclusion is not only false, but ridiculous.

However, upon the authority of this dilemma, the author first gives what he calls a Compend of a *new* doctrine concerning the nerves, and then proceeds to inquire in what manner the nerves produce animal heat: He tells us, "That *thought* (*cogitatio*) and sensation depend upon impulses either on the extremities of the nerves, or the sensorium commune, and the consequent motions produced by these impulses: That these motions are so quick, as to be almost instantaneous: That as all motion is mechanical; therefore *thought*, sensation, and muscular motion, must likewise be mechanical: That such quick motions cannot be produced without the intervention of some extremely elastic power; and, as Sir Isaac Newton has shown, that the impulses which occasion the different sensations must be owing to an elastic power; therefore the muscular motions of animals must be occasioned by the oscillations of some elastic power." But," says he, "as this elastic power cannot exist in the solid nervous fibres, nor in any inelastic fluid; therefore, by *dilemma*, it must exist in an elastic fluid; and hence also, by the former *dilemma*, this elastic fluid must be seated, either in the nerves, or in their medullary substance."

Here again the author calls Sir Isaac into his assistance.—"What confirms this opinion," says he, "is the Newtonian æther, which pervades all nature, and which, with a few variations in its modification, Sir Isaac has shown to be the cause of cohesion, elasticity, gravity, electricity, magnetism, &c. in the following manner: 1. As the rays of light, when reflected, do not touch the solid parts of bodies, but are reflected a little before they reach them, it is plain that the æther not only fills the pores of bodies, but likewise floats upon their surfaces; and hence it becomes the cause of attraction and repulsion.—2. All metals, and inelastic fluids, are non-electrics; on the other hand, all solid bodies, metals excepted, are electrics, *i. e.* proper for accumulating æther. But æther, thus accumulated in such a variety of bodies, may produce various motions in the parts of these bodies, without inducing any change in the bodies themselves. Hence æther, with some variations in its modification, is sufficient to account for all the phenomena of electricity. 3. As iron, by accumulating æther around it, exhibits all the wonders of magnetism; so this magnetical æther is more analogous to the nervous æther of animals than any other kind of it. For, as the magnetical æther passes along iron without changing any part of the iron; so the nervous æther, in like manner, passes along the medullary substance of the nerves, and excites motion in any part that is continuous with them, without inducing any change in the nerves.—4. The irritability and life of plants, which very much resemble those in animals, cannot be explained by any inelastic cause, and must therefore be attributed to an ætherial one. Lastly, As the common æther is differently modified in each of the substances above taken notice of, and also produces various motions or effects peculiar to each, it likewise varies and has some peculiar qualities when residing in animal bodies; so that the nervous or animal æther is not exactly the same, but differs in some respects from those species of æther which give rise to cohesion, gravity, magnetism, electricity," &c.

Having thus explained the nature and qualities of æther, our author starts a very important question, *viz.* "Whence is æther derived? and whether does it leave any body after having once got possession of it?" In answer to this, he observes, "That certain bodies have the power of collecting the electrical matter from every circumjacent body, and of accumulating it in their pores and on their surfaces, but do not suffer it again to transmigrate into any other body. There are other substances of an opposite nature, which do not accumulate the electric matter, but instantly allow it to pass into others, unless prohibited by an electric. Hence," says he, "nothing more is necessary for substances of the former kind, but to be in such circumstances as allow them to accumulate the electric matter. In the same manner," proceeds our author, "the nervous æther, which is diffused through every part of nature, flows

flows copiously into the medullary part of the nerves, when no obstacle stands in its way: but, when once it has got there, it keeps firm possession, and never afterwards leaves it. Now," says he, "a quantity of æther probably constitutes one of the staminal parts of animal bodies, and increases in proportion to their age and growth: For nothing is more ridiculous than to suppose that what is commonly called the nervous fluid can be daily wasted by labour and exercise, and daily repaired by a new secretion from the brain. To refute this vulgar notion, nothing more is necessary than to say, That it is one of Boerhaave's theories, and must be false, as all Boerhaave's other theories have been proved to be ill-founded! But æther is of a more fixed and determinate nature; whenever it gets possession of any substance, it never forsakes it, unless the texture and constitution of the body itself be changed. Hence," continues our author, "the æther of an acid body remains as long as the body continues to be acid; the same observation holds with regard to the æther of an alkaline body: But, if these two be blended together into a neutral salt, the æther must likewise be changed into a neutral; and therefore, in the formation of the medullary or staminal part of animals, the æther which before belonged to, or had the properties of some other substance, is instantaneously changed into animal æther, and remains so till the dissolution of that animal." Our author next observes, "That bodies require to be in a certain state or condition in order to the formation of an æther that is proper for them. This condition of bodies is called an excited state: Thus, as sulphur, when fluid, does not receive the electric matter, but, when solid, instantly receives it; in the same manner, the nerves, though properly formed, do not admit an æther adapted to their nature, unless they be in an excited state. Hence," says he, "the æther of a dead, and that of a living person, are very different, although the texture and figure of the nerves be the same. The state necessary for constituting the æther of a living animal, seems to depend on heat and moisture; because these things are absolutely necessary in the constitution of life: And hence," concludes our author, "the excited state of the nerves depends on heat and moisture. There are also certain circumstances," says he, "which contribute to render the state of the nerves more or less apt for accumulating æther: A spasmodic fever, for example, renders the nerves of the whole body less pervious to the motion of the æther; and hence, in cases of this nature, health, and all the vital functions, must be injured."

"These," our author observes, "are the outlines of a new doctrine concerning the nature and functions of the nerves;" and, upon this foundation, proceeds to give his new theory of animal heat.

"From the foregoing reasoning," says he, "the heat, as well as all the functions of animals, seem to be occasioned by the oscillations of the nervous æther betwixt the extremities of the sentient nerves

and the brain, or, more properly, betwixt the brain and muscles. But electrical æther, as above observed, varies a little from common æther; all inflexible fluids, as was likewise formerly remarked, are non-electrics; and all solid bodies, metals excepted, are electrics: These circumstances," says our author, "seem to be owing to the oscillations of the electric matter in bodies. In the same manner," says he, "the nature of animals may be such, and the nerves may be so constituted, as to form an æther adapted to their nature, and to excite those oscillations which occasion animal heat. The wonderful effects of heat and cold upon the nerves," continues our author, "confirms this theory: Every action, and even life itself, requires a certain degree of heat; for, as the heat of the external air is so variable, it was absolutely necessary that animal bodies should be endowed with the faculty of producing a degree of heat suited to their nature, independent of external circumstances: Hence we see the reason why the degree of heat so seldom varies in the same species of animals. However, although the nervous æther is always ready for exciting heat by its oscillations; yet, in order to bring about this effect successfully, external stimuli are necessary, otherwise the æther would be in danger of stagnating, which would occasion sleep, a palsy, and, last of all, death. The most permanent of these stimuli is the pulsation of the arteries; which is the reason why heat is so connected with the circulation of the blood, and why many authors have mistaken it for the true cause of animal heat."

Our author now concludes with observing, "That by his theory, the varieties of heat in different parts of the body, the heat and flushing of the face from shame, and all the other phenomena of heat in animal bodies, admit of a better explanation, than by any other theory hitherto invented." Having thus given a pretty full account of an attempt to explain the most abstruse operations of nature, as nearly as possible in the very words of the author, we cannot deny ourselves the liberty of making a few observations.

To give a formal refutation of this author's reasoning, is no part of our plan. It is, perhaps, wrong to say that he has reasoned; for the whole hypothetical part of his essay is a mere farrago of vague assertions, non-entities, illogical conclusions, and extravagant fancies. His æther seems to be an exceedingly tractable sort of substance: Whenever the qualities of one body differ from those of another, a different modification of æther at once solves the phenomenon. The æther of iron must not, to be sure, be exactly the same with the nervous æther, otherwise it would be in danger of producing sensation in place of magnetism. It would likewise have been very improper to give the vegetable æther exactly the same qualities with those of animal æther; for, in such a case, men would run great risk of striking root in the soil, and trees and hedges might eradicate and run about the fields. Nothing can be more ludicrous than to see

a writer treating a mere *ens rationis* as familiarly as if it were an object of our senses: The notion of compounding the æther of an *acid* and that of an *alkali*, in order to make a *neutral* of it, is completely ridiculous. But if men take the liberty of substituting *names* in place of *facts* and *experiments*, it is an easy matter to account for any thing.

By this method of philosphising, obscurity is for ever banished from the works of nature. It is impossible to gravel an ætherial philosopher. Ask him what questions you please, his answer is ready:—"As we cannot find the cause *any where* else; ergo, by dilemma, it must be owing to æther!" For example, ask one of those fages, What is the cause of gravity? he will answer, 'Tis æther! Ask him the cause of *thought*, he will gravely reply, "The solution of this question was once universally allowed to exceed the limits of human genius: But now, by the grand *discoveries* we have lately made, it is as plain as that three and two make five:—Thought is a mere *mechanical* thing, an evident effect of certain motions in the brain produced by the *oscillations* of a subtle elastic fluid called *æther*!" This is indeed astonishing!

Such jargon, however, affords an excellent lesson to the true philosopher. It shows to what folly and extravagance mankind are led, whenever they deviate from experiment and observation in their inquiries into nature. No sooner do we leave these only faithful guides to science, than we instantly land in a labyrinth of nonsense and obscurity, the natural punishment of folly and presumption.

When endeavouring to account for that propensity in the human mind which prompts us to attempt the solution of things evidently beyond our reach, we recollected a passage in Swift's works, which explains it in the most satisfactory manner.

"Let us next examine (says the Dean) the great introducers of new schemes in philosophy, and search till we can find from what faculty of the soul the disposition arises in mortal man, of taking it into his head to advance new systems, with such an eager zeal, in things agreed on all hands *impossible to be known*; from what feeds this disposition springs, and to what quality of human nature these grand innovators have been indebted for their number of disciples; because it is plain, that several of the chief among them, both *ancient* and *modern*, were usually mistaken by their adversaries, and indeed by all except their own followers, to have been persons crazed, or out of their wits; having generally proceeded, in the common course of their words and actions, by a method very different from the vulgar dictates of *unrefined* reason; agreeing, for the most part, in their several models, with their present undoubted successors in the *Academy of modern Beulah*. Of this kind were *Epicurus*, *Diogenes*, *Apollonius*, *Lucretius*, *Paracelsus*, *Des Cartes*, and others; who, if they were now in the world, tied fast, and separated from their followers, would, in this *undistinguishing* age,

"incur manifest danger of *phlebotomy*, and *whips*, and *chains*, and *dark chambers*, and *straw*. For what man, in the natural state or course of thinking, did ever conceive it in his power to reduce the notions of all mankind exactly to the same length, and breadth, and height of his own? Yet this is the first *humble* and *civil* design of all innovators in the empire of reason.——Now, I would gladly be informed, how it is possible to account for such imaginations as these in particular men, without recourse to my *phenomenon* of vapours, (*i. e.* æther), ascending from the lower faculties to overshadow the brain, and there distilling into conceptions, for which the narrowness of our mother-tongue has not yet assigned any other name besides that of *madness* or *phrenzy*. Let us therefore now conjecture how it comes to pass that none of these great projectors do ever fail providing themselves and their notions with a number of *implicit disciples*; and I think the reason is easy to be assigned.—For there is a peculiar string in the harmony of human understanding, which, in several individuals, is exactly of the same tuning. This if you can dextrously screw up to its right key, and then *strike gently* upon it, whenever you have the good fortune to light among those of the *same pitch*, they will, by a secret necessary sympathy, strike exactly at the same time. And in this one circumstance lies all the *skill* or *luck* of the matter: For if you chance to jar the string, among those who are either above or below your own height, instead of subscribing to your doctrine, they will *tie you fast*, call you *mad*, and *feed you with bread and water*. It is therefore a point of the nicest conduct, to distinguish and adapt this noble talent with respect to the difference of *persons* and of *times*.—For, to speak a bold truth, it is a fatal miscarriage so ill to order affairs as to pass for a *fool* in one company, when in another you might be treated as a *philosopher*: Which I desire *some certain gentlemen of my acquaintance* to lay up in their hearts as a very *seasonable inuendo*."

We would not have dwelt so long upon this article, had it not been to guard, as far as our influence extends, the minds of those who may be unacquainted with the genuine principles of philosophy, from being led into a wrong track of investigation.

ÆTHER, in chymistry, a name given to any volatile spirit. The spirit which generally goes by that name is procured by distilling spirit of wine with oil of vitriol, and then precipitating with an alkali. See CHEMISTRY.

ÆTHERIAL, an epithet for any thing partaking of the nature of æther.

ÆTHIOPIS, in botany, a synonyme of a species of *salvia*. See SALVIA.

ÆTHIOPS mineral, a preparation of mercury made by rubbing equal quantities of quicksilver and flour of sulphur in a mortar, till the mercury wholly disappears, and a fine black powder remains.

ÆTHIOPS albus, a preparation of mercury made by rubbing

- rubbing quicksilver with a double quantity of crabeyes or candied sugar, till it is extinguished.
- ÆTHIOPS** of *Dr Plumber*, a medicine prepared by levigating sulphur auratum antimonii with an equal quantity of calomel.
- ÆTHUSA**, in botany, a genus of the pentandria digynia class. The volucrum is dimidiated, triphyllous, and pendulous. There is but one species, *viz.* the æthusa synapium, or fools-parsley, a native of Britain.
- ÆTIANS**, in church-history, a branch of Arians who maintained, that the Son and Holy Ghost are in all things dissimilar to the Father.
- ÆTIOLOGY**, that branch of physic which assigns the causes of diseases.
- ÆTITE**, or **ÆΤΙΤΕΣ**, a name given to pebbles or stones of any kind which have a loose nucleus rattling in them, called, in English, *Eagle-stones*.
- ÆTNA**, a famous burning mountain or volcano of Sicily. It is one of the highest mountains of the whole island, and situated on the eastern coast not far from Catania. It is remarked of this mountain, that its eruptions ceased immediately when those of Vesuvius began. See **VESUVIUS**.
- ÆTNA fult**, a name used by some authors for saline substances, found near the opening of mount Ætna and other volcanos.
- ÆTOLARCHA**, in Grecian antiquity, the principal magistrate or governor of the Ætolians.
- AFFA**, a weight used on the gold-coast of Guinea, and equal to an ounce.
- AFFECTIO bovina**, a disorder incident to cattle, occasioned by a small worm which eats its way all over the body.
- AFFECTION**, in a general sense, denotes an attribute inseparable from its subject, or an essential property of it. Thus, quantity, figure, weight, &c. are affections of all bodies.
- AFFECTIONS of the mind**. See **PASSIONS**, and **MORALS**.
- AFFEERERS**, or **AFFEERORS**, in law, persons appointed in court-leets, courts-baron, &c. to settle, upon oath, the fines to be imposed upon those who have been guilty of faults arbitrarily punishable.
- AFFERI**, in law. See **AVERIA**.
- AFFETUOSO**, or *con AFFETTO*, in the Italian music, intimates, that the part to which it is added ought to be played in a tender moving way, and consequently rather slow than fast.
- AFFIANCE**, in law, denotes the mutual plighting of troth between a man and a woman to marry each other.
- AFFICHE**, a term used by the French for bills or advertisements hung or pasted up in public places to make any thing known.
- AFFIDATIO dominorum**, in old law-books, denotes an oath of allegiance taken by the lords in parliament.
- AFFIDATUS**, or **AFFIDIATUS**, in old law-books, signifies a tenant by fealty, or one who put himself under the protection of his lord, vowing fealty to him.
- AFFIDAVIT**, signifies an oath in writing, sworn before some person who is authorized to take the same.
- AFFILIATION**, a term used by some for adoption. See **ADOPTION**.
- AFFINAGE**, a term sometimes met with in old law-books, for the refining of metals.
- AFFINITY**, in Scots law, the connection formed by marriage betwixt one of the married persons and the blood-relations of the other. See **LAW**, title, **MARRIAGE**.
- AFFINITY**, is also used to denote conformity or agreement: Thus we say, the affinity of languages, the affinity of words, the affinity of sounds, &c.
- AFFINITY of bodies**. See **CHEMISTRY**, chapter, *Of elective attractions*.
- AFFIRMATION**, in logic, the asserting the truth of any proposition.
- AFFIRMATION**, is also used for the ratifying or confirming the sentence or decree of some inferior court: thus we say, the house of lords affirmed the decree of the lord-chancellor, or the decree of the lords of session.
- AFFIX**, among grammarians, denotes much the same with prefix. See **PREFIX**.
- AFFLATUS**, among heathen mythologists and poets, denotes the inspiration of some divinity.
- AFFORAGE**, in the French customs, a duty paid to the lord of a district, for permission to sell wine or other liquors within his seigniory. It is also used for the rate or price of provisions fixed by the provost of Paris, or by the sheriffs.
- AFFORCEMENT**, among old law-writers, denotes a fortress or place of strength.
- AFFORCIAMENTUM curie**, a term used in old charterly for the summoning a court in an extraordinary manner.
- AFFORESTING**, in old law-books, is the turning lands into a forest; as the converting a forest to other uses is called *disafforesting*, or *deafforesting*.
- AFFRAY**, or **AFFRAYMENT**, in law, formerly signified the crime of affrighting other persons, by appearing in unusual armour, brandishing a weapon, &c. but at present, affray denotes a skirmish or fight between two or more.
- AFFREIGHTMENT**, a term used in some law-books for the freight of a ship.
- AFFRI**, or **AFRA**, a term met with in old law-books for horses, bullocks, or any beast used in ploughing.
- AFFRONTÉE**, in heraldry, an appellation given to animals facing one another on an escutcheon, a kind of bearing, which is otherwise called *confrontie*, and stands opposed to *adessée*.
- AFFUIAGE**, in ancient customs, denotes the right or privilege of cutting wood in a forest for fuel.
- AFFILIATION**. See **AFFILIATION**.
- AFOBA**, in botany, an obsolete name of the phaeolus or kidney-bean. See **PHASEOLUS**.
- AFRA avis**, an obsolete name of the melcagris, or turkey. See **MELCAGRIS**.
- AFRA**, or **AFRUM**, in botany, a synonyme of a species of guaiacum. See **GUAIACUM**.
- AFRICA**, one of the four principal divisions of the earth;

earth; divided from Europe on the N. by the Mediterranean sea; from America on the W. by the Atlantic ocean; from the countries towards the south-pole, by the Great South-sea; from the island of Madagascar in the E. by the Mozambique channel; and from Asia also on the E. by the Red-sea. It is also joined to Asia by a narrow neck of land betwixt the Mediterranean and Red-sea, called the *isthmus of Suez*: Hence Africa is a peninsula somewhat resembling a pyramid, whose base from Tangier to the isthmus of Suez is about 2000 miles; its perpendicular, from the vertex at the cape of Good Hope to Buria, 3600 miles; and from cape Verd, to cape Guard a Fui, it is 3500. The situation of this quarter on the globe is betwixt 35. o. S. and 36. o. N. lat. and betwixt 17. 35. W. and 53. 21. E. long. Hence it lies, for the most part, within the tropics; by which means, in many places, the heat is almost insupportable. Along the coasts, it is in general reckoned abundantly fruitful, and its produce excellent. The Romans very justly considered Africa as the *patria ferarum*, for there is no other place breeds the number or the variety. In this quarter there are several deserts, some of them of vast extent, covered with sand, by which whole caravans have been sometimes smothered. The principal rivers are the Nile and the Niger, the first of which disembogues itself into the Mediterranean, after traversing Abyssinia, Nubia, and Egypt; and the last into the Atlantic ocean, by a western course from Upper Ethiopia. Geographers are not yet agreed about the sources of either of these rivers; according to some, their sources are not far distant from each other. There are some mountains in Africa remarkably high, particularly in Abyssinia and Barbary, in which last is the famous mount Atlas, which separates Barbary from Biledulgerid. The prevailing religions here, are Mahometanism and Paganism: Christianity only takes place among the Abyssinians and European settlements. The government in Africa is in general despotic, and the inhabitants black. In the division, geographers have gone variously to work; we shall confine ourselves to the more general, *viz.* EGYPT, BARBARY, GUINEY, CONGO, CAFFRARIA, ABYSSINIA, NUBIA, and NIGRITIA, with the islands that surround it; for which, see these articles.

**AFRICA**, is also a considerable sea-port town of Barbary, about seventy miles S. of Tunis.

**AFRICA**, *Afrique*, is likewise a small town of France, situated in the province of Gascony, and generality of Montauban.

**AFRICAN company**, a society of merchants, established by King Charles II. for trading to Africa; which trade is now laid open to all his majesty's subjects, paying 10 per cent. for maintaining the forts.

**AFSAGERS**, persons appointed by the burgo-masters of Amsterdam, to preside over the public sales made in that city.

**AFT**, in the sea-language, the same with abaft. See **ABAFT**.

**AFTER-BIRTH**, in midwifery. See **MIDWIFERY**, and **SECUNDINES**.

**AFTER-MATH**, in husbandry, signifies the grass which springs or grows up after mowing.

**AFTER-PAINS**, in midwifery, pains in the groin, &c. after child-birth. See **MIDWIFERY**, title, *After-pains*.

**AFTER-SWARMS**, in the management of bees, are those which leave the hive some time after the first has swarmed. See **APIS**.

**AFTO**, in botany. See **ERYSIMUM**.

**AGA**, in the Turkish language, signifies a great lord or commander. Hence the Aga of the janissaries is the commander in chief of that corps; as the general of the horse is denominated *spabiclar aga*. See **JANISSARIES**, and **SPAHI**.

**AGADES**, or **AGDES**, a people or kingdom of Africa, lying on the northern bank of the river Niger, betwixt the kingdoms of CANO on the E. and Tombut on the W. with that of Zaara on the N.

**AGADES**, or **ANDEGAST**, the capital city of the said kingdom.

**AGADES**, is also the Moorish name for the town of Santa-Cruz, in the kingdom of Sus.

**AGAG**, or **ARGAGA**, a kingdom of Africa, dependent on the kingdom of Monomotapa.

**AGAI**, in commerce. See **AGIO**.

**AGAI**, is also the name of a people of Ethiopia, inhabiting near the source of the Nile, and professing a kind of Christianity.

**AGALLOCHA**, in botany, the trivial name of the *excoecaria*. See **EXCOECARIA**.

**AGALMATA**, in antiquity, a term originally used for any kind of ornaments in a temple, but afterwards for the statues only.

**AGANIPIDES**, in ancient poetry, a designation given to the muses, from a fountain of mount Helicon called *Aganippe*.

**AGAPÆ**, or **AGAPES**, in church-history, certain love-fests kept by the ancient Christians, as a token of brotherly charity and mutual benevolence.

However innocent the original intention of these festivals might have been, abuses in time got footing in them, and gave great occasion to scandal; so that it became necessary to forbid the kifs of charity between different sexes, as well as to have any beds or couches in the place where they assembled.

**AGAPETÆ**, in church-history, a kind of nuns among the primitive Christians, who attended on and served the clergy.

At first there was nothing scandalous in those societies, though they gave great offence afterwards, and were wholly abolished by the council of Lateran, in 1130.

**AGARENI**, a name used by some writers for the Arabs, as being descended from Agar, or Hagar, Abraham's hand-maid.

**AGARICO-fungus**, in botany, a synonyme of the *agaricus alneus*, or alder-agaric.

**AGARICO-pylorus**, a synonyme of the *boletus vericolor*. See **BOLETUS**.

**AGARICUS**, in botany, a genus of the cryptogamia fungi. Of this genus there are 28 species, 24 of which

are natives of Britain. Several species of the agaric grow upon the trunks of the larch, the oak, and other trees. It is of a spongy substance, resembling the mushroom, and irregular in its figure and size. This plant has of late been tried for stopping hæmorrhages after amputations: but the success has not been so remarkable as to bring it into general use.

*Mineral* AGARIC, a marly earth resembling the vegetable of that name in colour and texture. It is found in the fissures of rocks, and on the roofs of caverns; and is sometimes used as an astringent in fluxes, hæmorrhages, &c.

AGASYLLIS, a name used by the Greeks for ammoniac. See AMMONIAC.

AGAT, is a stone resembling the onyx in colour, but, in place of zones, is adorned with lines or spots of various colours, which run into fo many figures, as to resemble trees, flowers, fruits, herbs, &c. Of the agat there are several species, distinguished from each other chiefly by their colour; as, the white-veined agat, the lead-coloured agat, the flesh-coloured agat, &c.

AGAT, is also the name of an instrument used by gold-wire-drawers, so called from the agat in the middle of it, which forms its principal part.

AGATA, or *St Agata di Gott*, a city and bishop's see of Naples, and province of Principato, situated almost in the middle between Capua and Beneventum.

AGATONSI, a small island of the Archipelago, situated between that of Lesbos and the continent.

AGATTON, a town of Africa, on the coast of Guiney, situated near the mouth of the river Formosa, about eighty miles south of Benin.

AGATY, in botany, a synonyme of the æschynomene. See ÆSCHYNOMENE.

AGAVE, in botany, a genus of the hexandria monogynia class. Under this genus Linnæus ranks 4 species of the Aloes, viz. the america, vivipara, virginica, and fetida. See ALOE.

AGAZES, a name given to the inhabitants of Paraguay in S. America.

AGDE, a small but well inhabited city of France, in the province of Languedoc, near the mouth of the river Eraut, about thirty miles S. W. of Montpellier. It is the see of a bishop.

AGE, a certain portion or part of duration applied to the existence of particular objects: thus we say, the age of the world, the age of Rome, &c. that is, the time or number of years elapsed since the creation of the world, or the building of Rome. See ASTRONOMY, *Of the division of time.*

The ancient poets also divided the duration of the world into four ages or periods; the first of which they called the *golden age*, the second the *silver age*, the third the *brass age*, and the fourth the *iron age*.

AGE, in law, signifies a certain period of life, when persons of both sexes are enabled to do certain acts: thus, a man at twelve years of age ought to take the oath of allegiance to the king in a leet; at fourteen he may marry, chuse his guardian, and claim his lands held in soccage.

Twenty-one is called full age, a man or woman being then capable of acting for themselves, of managing their affairs, making contracts, disposing of their estates, and the like.

AGE-PRIER, *actum precari*, in law, is when an action being brought against a person under age, for lands descended to him, he, by motion or petition, shews the matter to the court, praying the action may be staid till his full age; which the court generally agrees to.

AGE of the moon, in astronomy, the time elapsed since her last conjunction with the sun. See ASTRONOMY.

AGEDA, in geography, a small town and river of Portugal, situated in the province of Beiran, between the cities of Oporto and Coimbra.

AGEMA, in Macedonian antiquity, was a body of soldiery, not unlike the Roman legion. See LEGION.

AGEMOGLANS, or AGIAMOGLANS, or AZAMOGLANS, in the Turkish customs, Christian children raised every third year, by way of tribute, from the Christians tolerated in the Turkish empire.

AGEN, an ancient city of France, in the province of Guienne, situated on the river Garonne, about sixty miles S. E. of Bourdeaux. It is a bishop's see, and the capital of the Agenois.

AGENDA, among philosophers and divines, signifies the duties which a man lies under an obligation to perform: thus, we meet with the agenda of a Christian, or the duties he ought to perform, in opposition to the credenda, or things he is to believe.

AGENDA, among merchants, a term sometimes used for a memorandum book, in which is set down all the business to be transacted during the day, either at home or abroad.

AGENHINE, the same with hogenhine. See HOGENHINE.

AGENOIS. See AGEN.

AGENORIA, in mythology, the goddess of courage and industry, as Vacuna was of indolence.

AGENT, in a general sense, denotes any active power or cause. Agents are either natural or moral. Natural agents are such inanimate bodies as have a power to act upon other bodies in a certain and determinate manner, as gravity, fire, &c. Moral agents, on the contrary, are rational creatures, capable of regulating their actions by a certain rule.

AGENT, is also used to denote a person intrusted with the management of an affair, whether belonging to a society, company, or private person.

AGENTS of bank and exchange, in the commercial polity of France, are much the same with our exchange-brokers.

AGENT and patient, in law, is said of a person who is the doer of a thing, and also the party to whom it is done.

AGENTS in rebus, in antiquity, signifies officers employed under the emperors of Constantinople, and differing only in name from the frumentarii, whom they succeeded. See FRUMENTARIUM.

AGER, in Roman antiquity, a certain portion of land allowed to each citizen. See AGRARIAN LAW.

- AGER**, is also used by middle-age writers, for an acre of land. See **ACRE**.
- AGER mineralium**, among chemists, signifies the element of water, as water is supposed to be the origin of minerals.
- AGER nature**, a name sometimes applied to the uterus, as it nourishes the semen in the same manner as the earth nourishes seeds.
- AGER**, in geography, a small town of Catalonia in Spain, situated near the source of the river Noguera.
- AGERATUM**, or **MAUDLIN**, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; the pappus has five ariæ or auns; the calix is oblong; and the stylus a little longer than the flower. There are three species of the agratum, *viz.* the conyzoides, the ciliare, and the altissimum, all natives of America.
- AGERATUS lapis**, a stone used by the ancients in dying and dressing leather.
- AGERIUM**. See **AGISTMENT**.
- AGGA**, or **AGONNA**, a British settlement on the gold-coast of Guiney. It is situated under the meridian of London, in 6 degrees of N. lat.
- ÆGER**, in the ancient military art, a bank or rampart, composed of various materials, as earth, boughs of trees, &c.
- The æger of the ancients was of the same nature with what the moderns call *lines*.
- AGGERHUYS**, a city of Norway, capital of the province of the same name. It is subject to Denmark, and situated in 28. 35. E. long. and 59. 30. N. lat.
- AGGIA-SARAI**, a town situated on the shore of the Caspian sea, between Turkestan and the country of Bulgar.
- AGGLUTINANTS**, in pharmacy, medicines of a glutinous or viscid nature, given with a view to strengthen the solids.
- AGGLUTINANTS**, among surgeons. See **VULNERARIES**.
- AGGLUTINATION**, in a general sense, denotes the joining two or more things together, by means of a proper glue or cement.
- AGGLUTINATION**, among physicians, the adherence of new substance, or the giving a glutinous quality to the animal fluids.
- AGGLUTINATION**, is also a term used by astronomers to denote the meeting of two or more stars in the same part of the zodiac, or the seeming coalition of several stars.
- AGGRAVATION**, a term used to denote whatever heightens a crime, or renders it more black.
- AGGREGATE**, in a general sense, denotes the sum of several things added together, or the collection of them into one whole. Thus, a house is an aggregate of stones, wood, mortar, &c. It differs from a mixed or compound, inasmuch as the union in these last is more intimate than between the parts of an aggregate. See **CHEMISTRY**, *Of mixts*.
- AGGRESSOR**, among lawyers, denotes the person who began a quarrel, or made the first assault.
- AGHER**, **ACHER**, or **AUGHER**, a town of Ireland, which sends two members to parliament. It is situated in the southern part of Ulster, not far from Clougher.
- AGHRIM**, a town of Ireland, in the county of Wicklow, and province of Leinster, situated about thirteen miles south-west of Wicklow.
- AGIADES**, in the Turkish armies, a kind of pioneers employed in fortifying camps, and the like offices.
- AGIASMA**. See **HAGIASMA**.
- AGIGENSALON**, a town of Turkey, upon the road from Constantinople to Ispahan, about a day's journey from the city of Tocoa.
- AGILD**, or **AGILDE**, in old law-books, denotes a person of so little account, that whoever killed him was liable to no fine or other punishment.
- AGILITY**, an aptitude of the several parts of the body to motion; or it may be defined, the art or talent of making the best use of our strength.
- AGILLARIUS**, in old law-books. See **HAYWARD**.
- AGINCOURT**, a village of the French Netherlands; famous on account of the victory obtained by Henry V. of England over the French, in 1415.
- AGIO**, in commerce, a term chiefly used in Holland and at Venice, where it denotes the difference between the value of bank-stock and the current coin.
- AGIO of assurance**, the same with what we call *policy of assurance*. See **POLICY of assurance**.
- AGIST**. See the next article.
- AGISTMENT**, **AGISTAGE**, or **AGISTATION**, in law, the taking in other people's cattle to graze at so much *per week*. It is also used in a metaphorical sense, for any tax, burden, or charge; thus, the tax levied for repairing the banks of Romney marsh was called *agistamentum*.
- AGISTOR**, or **AGISTATOR**, an officer belonging to foresters, who has the care of cattle taken in to be grazed, and levies the moneys due on that account.
- AGISTALIA animalium in foresta**, in old law-books, signifies the drift of cattle or beasts in a forest.
- AGITATION**, the act of shaking a body, or tossing it backwards and forwards.
- AGITATOR**, in antiquity, a term sometimes used for a charioteer, especially those who drove in the circus at the curule games.
- AGITATORS**, in the English history, certain officers set up by the army, in 1647, to take care of its interests.
- Cromwell joined the agitators, only with a view to serve his own ends; which being once accomplished, he found means to get them abolished.
- AGLA**, or **AQUILA**, a town of Africa in the kingdom of Fez, situated not far from the river Guarga.
- AGLAOPHOTIS**, in botany, an obsolete name of the pæonia. See **PÆONIA**.
- AGLECTS**, **AGLETS**, or **AGLEEDS**, in botany. See **ANTHERÆÆ**.
- AGLIA**, in geography, a fortress of Piedmont, with the title of marquissate, situated in the Canavois.
- AGMOT**, or **AGMET**, the name of a town, district, and river of Africa, in the empire of Morocco.
- AGMEN**, in the Roman art of war, denoted an army,

- or rather a part of it, in march : Thus we read of the *primum agmen*, or van-guard ; *medium agmen*, or main body ; and the *postremum agmen*, or rear-guard.
- AGMONDESHAM**, in geography. See **AMERSHAM**.
- AGNABAT**, a town of Transylvania, subject to the house of Austria, situated about ten miles north-east of Hermanstadt.
- AGNANO**, a lake of the kingdom of Naples, in the province of Lavoro.
- AGNANTHUS**, in botany, a synonyme of the cornutia. See **CORNUTIA**.
- AGNATE**, in Scots law, any male relation by the father's side. See **LAW**, title, *Minors, and their tutors and curators*.
- AGNEL**, an ancient French coin, otherwise called *mounton d'or*. See **MOUTON D'OR**.
- AGNELET**, an ancient French coin, worth about twenty sols.
- AGNO**, a river of Naples, which, taking its rise in the mountainous parts of Terra di Lavoro, washes the town of Acerra, and, passing between Capua and Aversa, falls into the Mediterranean, about seven miles N. of Puzzoli.
- AGNOETÆ**, in church-history, a sect of heretics, so called on account of their maintaining, that Christ, with respect to his human nature, was ignorant of many things, and particularly of the day of judgment, an opinion which they built upon the text, Mark xiii. 32.
- AGNOMEN**, in Roman antiquity, a kind of fourth or honorary name, given to a person on account of some extraordinary action, virtue, or other accomplishment. Thus, the agnomen *Africanus* was bestowed upon Publius Cornelius Scipio, on account of his great achievements in Africa.
- AGNON**, a small river of Bourgogne in France, otherwise called *Ignon*.
- AGNONE**, a city of the kingdom of Naples, in the province of the Hither Abruzzo, called by some *Ancone*.
- AGNOS**, in ichthyology, an obsolete name of the uranoscopus. See **URANOSCOPIUS**.
- AGNUS**, or **LAMB**, in zoology, the young of the ovine or sheep. See **OVIS**.
- Agnus castus**, in botany, the trivial name of a species of the vitex. See **VITEX**.
- Agnus Dei**, in the church of Rome, a cake of wax stamped with the figure of a lamb supporting a cross. These being consecrated by the pope with great solemnity, and distributed among the people, are supposed to have great virtues ; as, to preserve those who carry them worthily, and with faith, from all manner of accidents ; to expel evil spirits, &c. It is also a popular name for that part of the mass, where the priest strikes his breast thrice, and says the prayer beginning with the words *Agnus Dei*.
- AGNUS Scythicus**, in botany, the name of a fictitious plant said to grow in Tartary, resembling a lamb.
- AGOBEL**, a small town of Africa, in the empire of Morocco, and province of Hea.
- AGOGA**, among ancient naturalists, denoted a drain for carrying off water from a mine.
- AGOGE**, among ancient musicians, a species of modulation, wherein the notes proceeded by contiguous degrees.
- AGON**, in the public games of the ancients, a term used indifferently for any contest or dispute, whether respecting bodily exercises, or accomplishments of the mind. Thus poets, musicians, &c. had their agonies, as well as the athleteæ. It was also used for one of the ministers employed in the heathen sacrifices, whose business it was to strike the victim.
- AGON**, in Roman antiquity, a place near the Tiber, where the curule games were celebrated, otherwise called *circus Flammineus*.
- AGON**, among physicians. See **AGONY**.
- AGONALIS**, in Roman antiquity. See **SALII**.
- AGONALIA**, in Roman antiquity, festivals celebrated in honour of Janus, or of the god Agonius, whom the Romans invoked before undertaking any affair of importance.
- AGONENSES**. See **SALII**.
- AGONISMA**, in antiquity, denotes the prize given to the victor in any combat or dispute.
- AGONISTARCHA**, in antiquity, the officer who directed the preparatory exercises of the athleteæ ; tho' some make him the same with the agonotheta. See **AGONOTHETA**.
- AGONISTICA**, a term used to denote the science of whatever belonged to the agonies, or public exercises of the ancients.
- AGONISTICI**, in church-history, a name given by Donatus to such of his disciples as he sent to fairs, markets, and other public places, to propagate his doctrine.
- AGONISTICON**, a term used by physicians for cold water, as being supposed to combat the febrile heat.
- AGONIUM**, in Roman antiquity, was used for the day on which the *rex sacrorum* sacrificed a victim, as well as for the place where the games were celebrated, otherwise called *Agon*.
- AGONOTHETA**, or **AGONOTHETES**, in Grecian antiquity, was the president or superintendent of the sacred games ; who not only defrayed the expences attending them, but inspected the manners and discipline of the athleteæ, and adjudged the prizes to the victors.
- AGONUS**, in ichthyology, a synonyme of the clupea alosa. See **CLUPEA**.
- AGONY**, any extreme pain. It is also used for the pangs of death.
- AGONYCLITÆ**, or **AGONYCLITES**, in church-history, a sect of christians, in the seventh century, who prayed always standing, as thinking it unlawful to kneel.
- AGORÆUS**, in heathen antiquity, an appellation given to such deities as had statues in the market-places ; particularly Mercury, whose statue was to be seen in almost every public place.
- AGORANOMUS**, in Grecian antiquity, a magistrate of Athens, who had the regulation of weights and measures, of the prices of provisions, &c.

AGOUGES, a river of France, which, after watering part of Auvergne, falls into the Sible.

AGRA, a city of the Hither India, and capital of a kingdom of the same name. It is situated on the river Jenma, and is a large, populous, and beautiful city, where the Mogul frequently resides.

AGRAM, a city and bishop's see of Hungary, situated near the frontiers of Carniola.

AGRARIAN *laws*, among the Romans, those relating to the division and distribution of lands; of which there were a great number; but that called the *Agrarian law*, by way of eminence, was published by Spurius Cassius, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres which each citizen might enjoy.

AGRARIUM. See AGISTMENT.

AGREDA, a town of Spain, in old Castile, near the frontiers of Arragon, and about three leagues south-west of Taracon.

AGREDA, is also a town of South America, situated at the foot of the mountains in the kingdom of Popaian.

AGREEMENT, in law, signifies the consent of several persons to any thing done or to be done.

AGRESSES, or OGRESSES, in heraldry, a term sometimes used for pellets. See PELLETS.

AGRESTÆ, among physicians, denotes unripe grapes, said to be of a cooling nature.

AGRI, or ACRI, a river of the kingdom of Naples, which arising in the Apennine mountains, not far from Marfico Nuovo, falls into the gulph of Tarento.

AGRIA, a town and river of Upper Hungary. The town is a bishop's see, and situated about thirty-five miles N. E. of Buda.

## A G R I C U L T U R E .

AGRICULTURE is the art of assisting the earth, by means of culture, manure, &c. to bring forth plants in greater quantity, and likewise of a larger size and better quality, than it would produce without these assistances.

AGRICULTURE is an art of such consequence to mankind, that their very existence, especially in a state of society, depends upon it. A compendious view, therefore, of every material discovery that hath hitherto

been made in this art, must be useful both to the farmer and philosopher.

To accomplish this end with the greater perspicuity, the subject shall be divided into two parts. Under the first, Vegetation, and the Structure of Plants, shall be considered. The second will contain the various Operations upon the Soil, in order to prepare it for the reception and nourishment of plants.

For the ease of the reader, each of these parts shall be subdivided into a number of sections.

### P A R T I .

#### *Of Vegetation, and the Structure of Plants.*

THE vegetation and œconomy of plants is one of those subjects in which our knowledge is extremely circumscribed. Many hypotheses have been invented; as many have been, or may easily be, refuted. Hypotheses in matters that evidently exceed our powers do much hurt: But they are likewise of some use. They incite to further inquiries; and these inquiries are carried on with greater spirit, because they are intended for the purpose of confuting. It is true this spirit is not the most friendly to impartial observation; but it makes us more indefatigable in our researches.

Retailing theories is no part of our plan. A total inattention to the structure and œconomy of plants is the chief reason of the small progress that has been made in the principles of vegetation, and of the instability and fluctuation of our theories concerning it.

To recall the attention of philosophers and cultivators, to the only source from which any solid theory can ever be formed on this subject, we shall give a short descrip-

tion of the structure of plants, beginning with the seed, and tracing its progress and evolution to a state of maturity.

#### SECT. I. *Of Seeds.*

THE seeds of plants are of various figures and sizes. Most of them are divided into two lobes; though some, as those of the cress-kind, have six; and others, as the grains of corn, are not divided, but intire.

But, as the essential properties of all seeds are the same, when considered with regard to the principles of vegetation, our particular descriptions shall be limited to one seed, *viz.* the great garden-bean. Neither is the choice of this seed altogether arbitrary; for, after it begins to vegetate, its parts are more conspicuous than many others, and consequently better calculated for investigation.

This seed is covered with two coats or membranes.

The

Fig. 5. Radical

Fig. 6. Plumel

Fig. 7.

Fig. 8.

Fig. 10. Section of Fig. 9. Magnified

Fig. 9. WORMWOOD ROOT cut transversely

The outer coat is extremely thin, and full of pores ; but may be easily separated from the inner one, (which is much thicker), after the bean has been boiled, or lain a few days in the soil. At the thick end of the bean, there is a small hole visible to the naked eye, immediately over the radicle or future root, that it may have a free passage into the soil. Plate IV. fig. 1. A. When these coats are taken off, the body of the seed appears, which is divided into two smooth portions or lobes. The smoothness of the lobes is owing to a thin film or cuticle with which they are covered.

At the basis of the bean is placed the radicle or future root, Plate IV. fig. 3. A. The trunk of the radicle, just as it enters into the body of the seed, divides into two capital branches, one of which is inserted into each lobe, and sends off smaller ones in all directions through the whole substance of the lobes, Plate IV. fig. 7. A. A. These ramifications become so extremely minute towards the edges of the lobes, that they require the finest glasses to render them visible. To these ramifications Grew and Malpighius have given the name of *feminal root*; because, by means of it, the radicle and plume, before they are expanded, derive their principal nourishment.

The plume, bud, or germ, Plate IV. fig. 3, is inclosed in two small corresponding cavities in each lobe. Its colour and consistence is much the same with those of the radicle, of which it is only a continuation; but having a quite contrary direction: For the radicle descends into the earth, and divides into a great number of smaller branches or filaments; but the plume ascends into the open air, and unfolds itself into all the beautiful variety of stem, branches, leaves, flowers, fruit, &c. The plume in corn shoots from the smaller end of the grain, and, among maltsters, goes by the name of *acrospire*.

The next thing to be taken notice of is the substance, or parenchymatous part of the lobes. This is not a mere concremented juice, but is curiously organized, and consists of a vast number of small bladders resembling those in the pith of trees, Plate IV. fig. 4.

Besides the coats, cuticle, and parenchymatous parts, there is a substance perfectly distinct from these, distributed in different proportions through the radicle, plume, and lobes. This inner substance appears very plainly in a transverse section of the radicle or plume. Towards the extremity of the radicle, it is one entire trunk; but higher up, it divides into three branches; the middle one runs directly up to the plume, and the other two pass into the lobes on each side, and spread out into a great variety of small branches through the whole body of the lobes, Plate IV. fig. 7. This substance is very properly termed the *feminal root*: for when the seed is sown, the moisture is first absorbed by the outer coats, which are every where furnished with sap and air-vessels; from these it is conveyed to the cuticle; from the cuticle it proceeds to the pulpy part of the lobes; when it has got thus far, it is taken up by the mouths of the small branches of the feminal root, and passes from one branch into another, till it is all collected into the main trunk, which communicates both with the plume and radicle, the two principal involved organs of the future plant. After this the sap, or vegetable food, runs in two oppo-

site directions; part of it ascends into the plume, and promotes the growth and expansion of that organ; and part of it descends into the radicle, for nourishing and evolving the root and its various filaments. Thus the plume and radicle continue their progress in opposite directions, till the plant arrives at maturity.

It is here worth remarking, that every plant is really possessed of two roots, both of which are contained in the seed. The plume and radicle, when the seed is first deposited in the earth, derive their nourishment from the feminal root: but, afterwards, when the radicle begins to shoot out its filaments, and to absorb some moisture, not, however, in a sufficient quantity to supply the exigencies of the plume, the two lobes, or main body of the seed, rise along with the plume, assume the appearance of two leaves, resembling the lobes of the seed in size and shape, but having no resemblance to those of the plume, for which reason they have got the name of *dissimilar leaves*.

These dissimilar leaves defend the young plume from the injuries of the weather, and at the same time, by absorbing dew, air, &c. assist the tender radicle in nourishing the plume, with which they have still a connection by means of the feminal root above described. But, when the radicle or second root has descended deep enough into the earth, and has acquired a sufficient number of filaments or branches for absorbing as much aliment as is proper for the growth of the plume; then the feminal, or dissimilar leaves, their utility being entirely superseded, begin to decay and fall off.

PLATE IV. Fig. 1. A, The foramen, or hole in the bean through which the radicle shoots into the soil.

Fig. 2. A transverse section of the bean; the dots being the branches of the feminal root.

Fig. 3. A, The radicle.

B, The plume or bud.

Fig. 4. A, A longitudinal section of one of the lobes of the bean a little magnified, to show the small bladders of which the pulpy or parenchymatous part is composed.

Fig. 5. 6. A, A transverse section of the radicle.

B, A transverse section of the plume, showing the organs or vessels of the feminal root.

Fig. 7. A, A view of the feminal root branched out upon the lobes.

Fig. 8. The appearance of the radicle, plume, and feminal root, when a little further advanced in growth.

Having thus briefly described the seed, and traced its evolution into three principal organic parts, *viz.* the plume, radicle, and feminal leaves, we shall next take an anatomical view of the root, trunk, leaves, &c.

SECT. II. *Of the Root.*

IN examining the root of plants, the first thing that presents itself is the skin, which is of various colours in different plants. Every root, after it has arrived at a certain age, has a double skin. The first is coeval with the other parts, and exists in the feed: but afterwards there is a ring sent off from the bark, and forms a second skin; *e. g.* in the root of the dandelion, towards the end of May, the original or outer skin appears shriveled, and is easily separated from the new one, which is fresher, and adheres more firmly to the bark. Perennial plants are supplied in this manner with a new skin every year; the outer one always falls off in the autumn or winter, and a new one is formed from the bark in the succeeding spring. The skin has numerous cells or vessels, and is a continuation of the parenchymatous part of the radicle. However, it does not consist solely of parenchyma; for the microscope shews that there are many tubular lignous vessels interperfed through it.

When the skin is removed, the true cortical substance or bark appears, which is also a continuation of the parenchymatous part of the radicle, but greatly augmented. The bark is of very different sizes. In most trees, it is exceeding thin in proportion to the wood and pith. On the other hand, in carrots, it is almost one half of the femiliameter of the root; and, in dandelion, it is nearly twice as thick as the woody part.

1. The BARK is composed of two substances; the parenchyma, or pulp, which is the principal part; and a few woody fibres. The parenchyma is exceedingly porous, and has a great resemblance to a sponge; for it shrivels considerably when dried, and dilates to its former dimensions when infused in water. These pores or vessels are not pervious so as to communicate with each other, but consist of distinct little cells or bladders, scarcely visible without the assistance of the microscope. In all roots, these cells are constantly filled with a thin watery liquor. They are generally of a spherical figure; though in some roots, as the bugloss and dandelion, they are oblong. In many roots, as the horse-raddish, peony, asparagus, potatoe, &c. the parenchyma is of one uniform structure. But in others it is more diversified, and puts on the shape of rays running from the centre towards the circumference of the bark. These rays sometimes run quite through the bark, as in lovage; and sometimes advance towards the middle of it, as in melilot and most of the leguminous and umbelliferous plants. These rays generally stand at an equal distance from each other in the same plant; but the distance varies greatly in different plants. Neither are they of equal sizes: In carrot they are exceedingly small, and scarcely discernible; in melilot and chervil, they are thicker. They are likewise more numerous in some plants than in others. Sometimes they are of the same thickness from one edge of the bark to the other; and some grow wider as they approach towards the skin. The vessels with which these rays are amply furnished, are supposed to be air-vessels, because they are always found to be dry, and not so transparent as the vessels which evidently contain the sap.

In all roots, there are lignous vessels dispersed in different proportions through the parenchyma of the bark. These lignous vessels run longitudinally through the bark in the form of small threads, which are tubular, as is evident from the rising of the sap in them when a root is cut transversely. These lignous sap-vessels do not run in direct lines through the bark, but, at small distances, incline towards one another in such a manner, that they appear to the naked eye to be inoculated; but the microscope discovers them to be only contiguous, and braced together by the parenchyma. These braces or connections are very various both in size and number in different roots; but in all plants they are most numerous towards the inner edge of the bark. Neither are these vessels single tubes, but, like the nerves in animals, are bundles of twenty or thirty small contiguous cylindrical tubes, which uniformly run from the extremity of the root, without sending off any branches, or suffering any change in their size or shape.

In some roots, as parsnip, especially in the ring next the inner extremity of the bark, these vessels contain a kind of lymph, which is sweeter than the sap contained in the bladders of the parenchyma. From this circumstance they have got the name of *lymph-ducts*.

These lymph-ducts sometimes yield a mucilaginous lymph, as in the comfrey; and sometimes a white milky glutinous lymph, as in the angelica, sonchus, burdock, scorzonera, dandelion, &c. The lymph-ducts are supposed to be the vessels from which the gums and balsams are secreted. The lymph of fennil, when exposed to the air, turns into a clear transparent balsam; and that of the scorzonera, dandelion, &c. condenses into a gum.

The situation of the vessels is various. In some plants; they stand in a ring or circle at the inner edge of the bark, as in asparagus; in others, they appear in lines, or rays, as in borage; in the parsnip, and several other plants, they are most conspicuous toward the outer edge of the bark; and in the dandelion, they are disposed in the form of concentric circles.

2. The WOOD of roots is that part which appears after the bark is taken off, and is firmer and less porous than the bark or pith. It consists of two distinct substances, *viz.* the pulpy, or parenchymatous, and the lignous. The wood is connected to the bark by large portions of the bark inserted into it. These insertions are mostly in the form of rays, tending to the centre of the pith, which are easily discernible by the eye in a transverse section of most roots. These insertions, like the bark, consist of many vessels, mostly of a round or oval figure.

The lignous vessels are generally disposed in collateral rows running longitudinally through the root. Some of these contain air, and others sap. The air-vessels are so called, because they contain no liquor. These air-vessels are distinguished by being whiter than the others.

3. The PITH is the central part of the root. Some roots have no pith, as the stramonium, nicotiana, &c. others have little or none at the extremities of the roots, but have a considerable quantity of it near the top. The pith, like every other part of a plant, is derived from

*Fig. 2.*  
*Transverse section of the ASH BRANCH. Magnified*

*Fig. 1.* K  
ASH BRANCH  
cut transversely

*Fig. 3.*  
a LEMON cut down

*Fig. 4.*  
LEMON cut transversely

from the feed: But in some it is more immediately derived from the bark. For the insertions of the bark running in betwixt the rays of the wood, meet in the centre, and constitute the pith. It is owing to this circumstance, that among roots which have no pith in their lower parts, they are amply provided with it towards the top, as in columbine, lovage, &c.

The bladders of the pith are of very different sizes, and generally of a circular figure. Their position is more uniform than in the bark. Their sides are not mere films, but a composition of small fibres or threads; which gives the pith, when viewed with a microscope, the appearance of a piece of fine gauze, or net-work.

We shall conclude the description of roots, with observing, that their whole substance is nothing but a congeries of tubes and fibres, adapted by nature for the absorption of nourishment, and of course the extension and augmentation of their parts.

PLATE IV. Fig. 9. A transverse section of the root of wormwood, as it appears to the naked eye.

Fig. 10. A section of fig. 9. magnified.

A A, The skin, with its vessels.

B B B B, The bark. The round holes, C C C, &c. are the lymph-ducts of the bark. All the other holes are little cells and sap-vessels.

D D D, Parenchymatous insertions from the bark, with the cells, &c.

E E E E, The rays of the wood, in which the holes are the air-vessels.

N. B. This root has no pith.

### SECT. III. Of the Trunk, Stalk, or Stem.

IN describing the trunks of plants, it is necessary to premise, that whatever is said with regard to them, applies equally to the branches,

The trunk, like the root, consists of three parts, *viz.* the bark, wood, and pith. These parts, though substantially the same in the trunk as in the root, are in many cases very different in their texture and appearance.

1. The skin of the bark is composed of very minute bladders, interspersed with longitudinal woody fibres, as in the nettle, thistle, and most herbs. The outside of the skin is visibly porous in some plants, particularly the cane.

The principal body of the bark is composed of pulp or parenchyma, and innumerable vessels much larger than those of the skin. The texture of the pulpy part, tho' the same substance with the parenchyma in roots, yet seldom appears in the form of rays running towards the pith; and when these rays do appear, they do not extend above half way to the circumference. The vessels of the bark are very differently situated, and destined for various purposes in different plants. For example, in the bark of the Pine, the inmost are lymph-ducts, and exceedingly small; the inmost are gum or resiniferous ves-

sels, destined for the secretion of turpentine; and are so large, as to be distinctly visible to the naked eye.

2. The Wood lies betwixt the bark and pith, and consists of two parts, *viz.* a parenchymatous, and lignous. In all trees, the parenchymatous part of the wood, though much diversified as to size and consistence, is uniformly disposed in diametrical rays, or insertions running betwixt similar rays of the lignous part.

The true wood is nothing but a congeries of old dried lymph-ducts. Between the bark and the wood a new ring of these ducts is formed every year, which gradually loses its softness as the cold season approaches, and, towards the middle of winter, is condensed into a solid ring of wood. These annual rings, which are distinctly visible in most trees when cut through, serve as natural marks to distinguish their age. Plate V. fig. 1, 2. The rings of one year are sometimes larger, sometimes less, than those of another, probably owing to the favourable or unfavourable of the season.

3. The PITH, though of a different texture, is exactly of the same substance with the parenchyma of the bark, and the insertions of the wood. The quantity of pith is various in different plants. Instead of being increased every year like the wood, it is annually diminished, its vessels drying up, and assuming the appearance and structure of wood; in so much that in old trees there is scarce such a thing as pith to be discerned.

A ring of sap-vessels are usually placed at the outer edge of the pith, next the wood. In the pine, fig, and walnut, they are very large. The parenchyma of the pith, is composed of small cells or bladders, of the same kind with those of the bark, only of a larger size. The general figure of these bladders is circular; though in some plants, as the thistle, and borage, they are angular. Though the pith is originally one connected chain of bladders; yet as the plant grows old, they shrivel, and open in different directions. In the walnut, after a certain age, it appears in the form of a regular transverse hollow division. In some plants, it is altogether wanting; in others, as the sorchus, nettle, &c. there is only a transverse partition of it at every joint. Many other varieties might be mentioned; but these must be left to the observation of the reader.

#### SECT. IV. Of the Leaves.

THE leaves of plants consist of the same substance with that of the trunk. They are full of nerves, or woody portions, running in all directions, and branching out into innumerable small threads, interwoven with the Parenchyma like fine lace or gauze.

The skin of the leaf, like that of an animal, is full of pores, which both serve for perspiration, and for the absorption of dews, air, &c. These pores, or orifices, differ both in shape and magnitude in different plants, which is the cause of that variety of texture or grain peculiar to every plant.

The pulpy or parenchymatous part, consists of very minute fibres, wound up into small cells or bladders. These cells are of various sizes in the same leaf.

All leaves, of whatever figure, have a marginal fibre, by which all the rest are bounded. The particular shape of this fibre determines the figure of the leaf.

The vessels of leaves have the appearance of insulating; but, when examined by the microscope, they are found only to be interwoven, or laid along each other.

What is called air-vessels, or those which carry no sap, are visible even to the naked eye in some leaves. When a leaf is slowly broke, they appear like small woolly fibres, connected to both ends of the broken piece.

PLATE VI. Fig. 1. The appearance of the air-vessels to the eye, in a vine leaf drawn gently asunder.

Fig. 2. A small piece cut off that leaf.

Fig. 3. The same piece magnified, in which the vessels have the appearance of a screw.

Fig. 4. The appearance of these vessels as they exist in the leaf before they are stretched out.

#### SECT. V. Of the Flower.

IT is needless here to mention any thing of the texture, or of the vessels, &c. of flowers, as they are pretty similar to those of the leaf. It would also be foreign to our present purpose, to take any notice of the characters and distinctions of flowers. These belong to the science of BOTANY, to which the reader is referred.

There is one curious fact, however, which must not be omitted, *viz.* That every flower is perfectly formed in all its parts many months before it appears outwardly; that is, the flowers which appear this year, are not, pro-

perly speaking, the flowers of this year, but of the last. For example, mezereon generally flowers in January; but these flowers were completely formed in the month of August preceeding. Of this fact any one may satisfy himself by separating the coats of a tulip root about the beginning of September; and he will find that the two innermost form a kind of cell, in the centre of which stands the young flower, which is not to make its appearance till the following April or May.

PLATE VI. Fig. 5. Exhibits a view of the tulip-root when dissected in September, with the young flower towards the bottom.

#### SECT. VI. Of the Fruit.

IN describing the structure of fruits, a few examples shall be taken from such as are most generally known.

1. A PEAR, besides the skin, which is a production of the skin of the bark, consists of a double parenchyma or pulp, sap, and air-vessels, calcary, and acetary.

The outer parenchyma is the same substance continued from the bark, only its bladders are larger and more succulent.

It is every where interperfed with small globules or grains, and the bladders respect these grains as a kind of centres, every grain being the centre of a number of bladders. The sap and air-vessels in this pulp are extremely small.

Next the core is the inner pulp or parenchyma, which consists of bladders of the same kind with the outer, only larger and more oblong, corresponding to those of the pulp, from which it seems to be derived. This inner pulp is much sourer than the other, and has none of the small grains interperfed through it; and hence it has got the name of *acetary*.

Between the acetary and outer pulp, the globules or grains begin to grow larger, and gradually unite into a hard stony body, especially towards the corculum, or stool of the fruit; and from this circumstance it has been called the *calcary*.

These grains are not derived from any of the organical parts of the tree, but seem rather to be a kind of concretions precipitated from the sap, similar to the precipitations from wine, urine, and other liquors.

The core is a roundish cavity in the centre of the pear, lined with a hard woody membrane, in which the seed is inclosed. At the bottom of the core there is a small duct or canal, which runs up to the top of the pear; this canal allows the air to get into the core, for the purpose of drying and ripening the seeds.

C C, The large vessels that surround the pith.

D D, Two of the large bags laid open, shewing the seeds, and their connection with the lamellæ or membranes which form the large bags.

2. In a LEMON, the parenchyma appears in three different forms. The parenchyma of the rind is of a coarse texture, being composed of thick fibres, woven into large bladders. Those nearest the surface contain the essential oil of the fruit, which bursts into a flame when the skin is squeezed over a candle. From this outmost parenchyma nine or ten infertions or lamellæ are produced, which run between as many portions of the pulp, and unite into one body in the centre of the fruit, which corresponds to the pith in trunks or roots. At the bottom and top of the lemon, this pith evidently joins with the rind, without the intervention of any lamellæ. This circumstance shows, that the pith and bark are actually connected in the trunk and roots of plants, though it is difficult to demonstrate the connection, on account of the closeness of their texture, and the minuteness of their fibres. Many vessels are dispersed through the whole of this parenchyma; but the largest ones stand on the inner edge of the rind, and the outer edge of the pith, just at the two extremities of each lamella.

The second kind of parenchyma is placed between the rind and the pith, is divided into distinct bodies by the lamellæ; and each of these bodies forms a large bag.

These bags contain a third parenchyma, which is a cluster of smaller bags, distinct and unconnected with each other, having a small stalk by which they are fixed to the large bag. Within each of these small bags are many hundreds of bladders, composed of extremely minute fibres. These bladders contain the acid juice of the lemon.

From this short sketch of the structure and composition of vegetables, both the farmer and philosopher may draw very useful and important conclusions. Some of them will perhaps be taken notice of in the course of this treatise.

### SECT. VII. Of the nature and motion of the Sap.

THE vessels in the roots of plants absorb moisture from the earth, and convey it to the trunk, branches, leaves, &c. This juice, when it first enters into the root, is crude; but as it ascends into the other parts of the plant, it undergoes several changes, by means of the different configurations of the vessels peculiar to each part. Thus the leaves, flowers, fruit, and seed, have all something peculiar in the structure and arrangement of their vessels, which produces considerable changes in the nature of the sap. It is not known how these changes are produced: but how the stomachs of animals make chyle from animal and vegetable substances, or how urine, saliva, bile, &c. is secreted from the common mass of blood, is as little known. The sap likewise moves in a lateral or horizontal direction.

Philosophers are greatly divided about what they call the circulation of the sap. Some contend, that it returns to the root betwixt the bark and wood. But Hales, who has made many accurate experiments on the subject, has shown, that it does not circulate, but ascends and descends in the same vessels; that it ascends in hot weather, and descends in cold, like the spirits in a thermometer.

Vegetables begin to absorb sap about the beginning of Spring, and soon after shoot out their buds, leaves, and flowers.

When plants are in a state of vegetation, especially in hot weather, there is a great deal of superfluous sap absorbed; but the superfluous parts are carried off by transpiration. Every part of a plant transpires; but the greatest quantity passes by the leaves.

Some have assigned the transpiration of plants, as the cause of the motion of the sap. It is undoubtedly one cause of this motion; because, if the transpiration be stopped, at a time when all the vessels are full, the motion of the sap must stop of course. But then there is a previous and principal cause, viz. that power in the ves-

fels, whatever it is, that first puts the sap in motion, before any transpiration has commenced.

Heat, moisture, and air, are the three chief circumstances that promote the ascent of the sap. Hence nothing is more favourable to vegetation than warm weather accompanied with rain: on the other hand, cold dry weather is its greatest enemy. In a wet, cold season, every thing rots; and in hot dry weather every thing is parched. But the circumstances most favourable to vegetation are cloudy, hot weather, inclinable to thunder, succeeded by plentiful rains.

### SECT. VIII. *Of the Food of Plants.*

It is thought to be an important question in agriculture, whether the several kinds of plants require the same, or different nourishment.

Upon a superficial view of this question, it would appear very improbable, that the same matter could nourish such a variety of plants, differing so essentially in smell, taste, figure, &c. Much, however, may depend upon the internal structure and arrangement of the vessels. One thing is certain, that if the vessels in any plant be uncommonly small, parts will be rejected by that plant which would be absorbed by one whose vessels are larger. Nay, changes may be made in the crude homogeneous nourishment, by a small difference in the figure or action of the vessels.

It is given out as a fact, by writers on this subject, that one plant will starve another, by robbing it of its nourishment. This does not seem to affect either side of the question; for it may starve its neighbour, either by extending its roots, and requiring a greater quantity of nourishment than the other; or it may absorb the peculiar food which is necessary for the growth of the other plant. In either case, the plant is deprived of a proper quantity of nourishment.

It is likewise proposed as a difficulty, Why a poisonous plant and its antidote will grow in the same soil, and very near each other. This argument is of the same nature with the former. It may be owing either to these plants imbibing different juices from the earth, or to peculiarities in the structure and action of their vessels. These, and many other ambiguous facts, have been advanced on both sides of this question, which we shall not spend time in enumerating.

The argument drawn from grafted plants, seems more direct and decisive. A stalk of a lemon, grafted on a branch of an orange-tree, grew, ripened its fruit, and preserved the figure and all the other qualities belonging to a lemon. This plainly indicates, that the organization of the lemon had given a different modification to the juices of the orange, through the intervention of which it received its nourishment.

It is also certain, that the different parts of the same

plant have frequently various smells, tastes, &c. although the nourishment derived from the root must be the same. This is an evidence, that the different structure of parts in the same plants is capable of producing very sensible changes in the nature and quality of the sap.

Repeated experiments show, that many plants of very opposite qualities, and even trees, have been nourished and brought to maturity by the purest water alone.

It is observed, on the other hand, that different plants require different soils. This is certainly true: But what then? Does not this difference in soil rather depend upon the greater or lesser quantity, than any peculiar quality in the food? Thyme grows best in a dry soil; but it will grow equally well in earth carried from a marsh to the top of a mountain.

The roots of plants are fitted to absorb every fluid that comes within their reach. They have been found by experiment to imbibe fluids that actually poison them. From this circumstance it may be fairly concluded, that they have not, like animals, the sagacity of chusing the food that is most proper for nourishing them, and rejecting that which is either noxious or less nourishing.

Mr Dickson, author of an excellent treatise on agriculture, published in 1765, has endeavoured to fix the particular ingredients that enter into the composition of the food of vegetables. He contends, that neither earth, water, air, oil, nor salt, can be called the food of plants; but he thinks that it consists of a combination of all these substances. His arguments in support of this theory are chiefly drawn from the chemical analysis, which shows, that all these substances may be extorted from vegetables by the force of fire; and from a consideration that a due admixture of these substances (or such things as contain them) is favourable, and even necessary, to vegetation.

His last argument is good: But whoever attempts to discover the properties of plants, or the ingredients of their food, from a chemical analysis, will probably never do much service to the science of agriculture. Fire and a retort is capable of torturing either animals or vegetables into forms and qualities which never existed either in these bodies, or in their food.

We shall conclude this section with observing, that the farmer, in nourishing his plants, should be directed entirely by experience. If he knows, that putrid animal and vegetable substances, that lime, foot, marle, &c. when applied with judgment, assist the growth of his plants, and augment his crop, it is of little consequence whether he be acquainted with their chemical analysis, or the particular mode of their operation. We do not mean that he should continue obstinately in the old beaten track, as it is called; but rather that he should try whether he can by any means improve upon the old method, and that his practice should be directed according to the success of these trials.

## P A R T II.

*Of the various Operations upon the Soil, in order to prepare it for the Reception and Nourishment of Plants.*

## S E C T. I. O F M A N U R E S.

**E**VERY substance which promotes the growth of plants is denominated a *manure*.

As to the operation of manures, some maintain, that they give to the earth an additional quantity of the vegetable food; others, that they are of no other use than to divide the soil, and therefore that tillage may be substituted in their place. This last opinion was embraced by Mr Tull, and is the fundamental principle in his horse-hoeing husbandry. A minute division of the soil will do a great deal; but the experience of all ages shows that it will do much more by the addition of manure.

In Scotland, it is the universal practice to dung lands, that are in constant tillage, at least once in five years; and it consists with observation, that the ground is considerably enriched the first year, but that the crops gradually decline till the virtues of the dung are entirely exhausted.

Some manures lose their virtue by being long exposed to the air. If dung be kept after it is sufficiently rotted, the most valuable part of it will evaporate. Others, as lime and marles, are of an opposite nature: the longer they are exposed to the air, their utility to the land is improved. From this circumstance it is probable, that marles and lime attract something from the air which renders them more favourable to vegetation.

There is a great variety of substances which, when laid upon land, act as manures. But the most usual manures in this country are dung, lime, marles, ashes, soot, sea-weed, shells, &c.

*Of Dung.*

**D**UNG is properly the excrement of animals; but what commonly goes by that name, is a mixture of excrements, putrefied vegetable and animal substances. If dunghills be kept after they are sufficiently rotted, the oily and more volatile parts, which are the best ingredients, fly off. They should likewise be placed in a dry situation, and raised high at the sides, to prevent these parts from being carried off by water; for much water prevents the uniform putrefaction of dunghills of this mixed kind.

To promote a proper putrefaction, the dung should not be laid in small heaps, but spread thick upon the dunghill; for by this means the fermentation commences sooner, the natural sap is preserved, and the dung is prevented from being burnt, or *fire-fanged*, as it is termed by farmers. Dung, when burnt in this manner, is dry, white, and useless as a manure. It is agreed, that dung-

hills ought to be covered, to prevent the exhalation of vegetable food. But the difficulty is, how to execute it. Some propose a thin layer of earth for this purpose; others, that a pit should be dug, built with flags at the side, and covered with a roof. The former would answer very well, were it not for the additions that are constantly making to dunghills; and the latter is so expensive, that few people will chuse to make trial of it. When dung comes from the stable or byre, it is mixed with straw; which absorbs the moisture, and prevents it from exhaling till the straw itself putrefies. When in this situation, if it be laid thick upon the top of the dunghill, there being but a small surface exposed to the air, the juices will be tolerably well preserved.

As dung thus loses its best qualities by being exposed to the sun and weather, it ought to be plowed in as soon as possible, after being laid upon land. If sufficiently putrefied, it should be plowed in with a shallow furrow, as its juices are washed down by the rain: It should likewise be spread very equally; for when large pieces lie scattered up and down, they become a nidus to insects and vermin.

*Of Lime.*

**L**IME being of an alkaline nature, attracts acids; Hence it is supposed to communicate to the soil a power of attracting the vegetable food from the air. Lime is a heavy substance, and penetrates deep into the soil; it sometimes even sinks below the reach of the plow. By fermenting with acids, it breaks down and divides the soil into small particles, and makes it soft, mellow, and evidently in a state of fermentation. It likewise dissolves oils, and all animal and vegetable substances, and converts them into vegetable food. This quality renders it peculiarly useful in destroying root-weeds.

These being the general properties of lime, it is supposed to have a twofold operation upon land. When a large quantity is used, especially after being long exposed to the air, it promotes vegetation by giving a kind of stimulus to the soil, and making it exert itself. This operation of lime is not merely hypothetical; for experience shews, that land thoroughly limed may be reduced to a poorer condition by cropping, than if it had not been limed at all. It is even possible to reduce limed land to a *caput mortuum*; and the more frequently and the better the land is plowed, it is the sooner reduced to this state.

Lime also enriches land, by augmenting the vegetable aliment. When intended for this purpose, only a small quantity should be employed; as a small quantity of lime is sufficient to impregnate a large quantity of earth;

and

and to communicate to it as high a degree of an absorbing quality as it is capable of receiving.

These different operations of lime is confirmed by experience, and agreeable to the practice in those parts of Scotland where lime is most used. When employed for the purpose of improving barren lands, it is laid on in large quantities, to give a stimulus to the soil, and make it exert all its vigour; and when applied to land already improved, it is used in small quantities, and repeated once every third or fourth year, to prevent too great an exertion, and impoverishing the land, by exhaulting too much of the vegetable food.

The lands in Scotland capable of the greatest improvement by lime, are the out-field and muir lands. The out-field land is generally kept three years in tillage, and carries three crops of oats; it is then allowed to rest six years, and after that is brought again into tillage. This method of cultivating out-field land is found, by calculation, to be sufficiently able to bear the expence, and allow a reasonable profit to the farmer, besides the improvement the lands derive from the lime.

In England, lime is sometimes used as a top-dressing for wheat. The method is this: They sow their wheat without laying on any manure; and in the beginning of February, for every acre of land, they take 20 bushels of unslaked lime, and 4 bushels of sand, or brick-rubbish. Towards the end of the month, the lime is slaked and mixed with the sand: In the last week of the month, this is scattered by way of top-dressing over the green wheat; and as rain generally succeeds, it is soon washed down to the roots of the plant, and gives them a vigour and strength of growth that is astonishing to people who have never seen this method practised. But, if the weather inclines to be dry, the quantity of sand must be doubled, to prevent the plants from being burnt by the corrosive quality of the lime.

### *Of Marles.*

THE general characters by which marle is best distinguished, are these: It attracts and ferments with acids, and does not bake in the fire like potter's earth, which distinguishes it sufficiently from clay; upon being exposed for some time to the air and weather, it dissolves like quick-lime, and falls into a fine powder; when dry, it is friable and unctuous like lead-ore; when wet, it is soft and slippery to the touch; whereas virgin-earth is rough and gritty.

There are a great variety of marles; but they are generally reduced to three kinds: The clay, the stone, and the shell marle.

The clay and stone marles are nearly of the same nature; but the shell-marle differs from both.

### *Of Clay and Stone Marles.*

THOUGH plants will not grow in these marles, when pure; yet, when mixed with soil, they become an excellent manure.

Stone and clay marles are possessed of much the same qualities with lime, and consequently act nearly in the

same manner upon the soil. They communicate to the soil a power of attracting the vegetable food from the air, dissolve the vegetable food, and prepare it for entering the roots of plants. They likewise attract oils so strongly, that they are frequently used for extracting greasy spots out of cloth; they are therefore supposed to attract oil from the air and earth, which is the chief ingredient in the nourishment of plants.

Both the clay and stone marles are long of dissolving. Large pieces of the stone-marle are sometimes found undissolved many years after it has been laid on the land. This renders it necessary to lay on a large quantity of them, lest their effects should not at first appear.

As marle may be used with safety in greater quantity than lime, it must communicate to the soil a stronger power of attracting the vegetable food, and consequently it ought always to be preferred. Marle is likewise preferable to lime in this respect, that it is longer of dissolving; and therefore the land will continue to carry better crops for several years longer after it has been marled. However, if the soil be soft and spongy, the marle, like lime, will sink below the reach of the plough, and prevent those advantages which might naturally be expected from it.

Though marle is preferable to lime as a manure; yet it must be considered, that their operation upon the earth is the same; consequently, when marled land has been exhaulted with crops, it cannot receive much benefit from an immediate application of marle a second time; for the same reason, it can receive as little advantage from lime: Dung therefore, as it contains a great proportion of the vegetable food, which lime and marles diminish, is the most proper manure for marled or limed lands exhaulted with crops.

What was said with regard to the application of lime, in smaller or larger quantities, to barren lands and lands in good order, may be said with equal propriety with regard to stone and clay marles.

### *Of Shell-marle.*

THIS marle is of a different nature from the stone and clay marles. It does not dissolve with water, but absorbs and swells with it like a sponge: It attracts acids more forcibly. But the principal difference betwixt the shell-marle and the other marles consists in this, that the shell-marle contains a great quantity of oil.

This marle is therefore supposed to promote vegetation, by increasing the food of plants, by communicating to the soil a power of attracting this food from the air, by dividing the soil into small particles, and by preparing the vegetable food for being absorbed by their roots.

As shell-marle does not exhaust land like lime and the other marles, it may be repeated as often as the husbandman pleases. Its effects are likewise more sudden.

### *Of Ashes.*

THE ashes of vegetables contain a large quantity of alkaline salt: Hence they attract acids more strongly than any other substances.

The operation of ashes upon the soil must therefore be of the same nature with that of lime, only it is more violent and sudden, and consequently it is sooner over. This is confirmed by experience. After land has been manured with ashes, the first crop is commonly very luxuriant; but a second crop almost entirely exhausts the land. Hence ashes should be laid out in small quantities, and should not be applied to land exhausted by lime or marle; neither should they be repeated, or followed by these manures.

Burnt turf is generally recommended as a manure. Turfs are chiefly composed of vegetables; their ashes, therefore, must be of the same nature with those of wood or any other vegetable substance. It is found by experience, that the burning of turfs turns out to advantage in proportion to the number of roots they contain; and therefore land, with a tough sward of grass, is most proper to be improved in this manner.

In burning turf, the heaps must be covered in such a manner as to prevent the flame from breaking out; otherwise the most useful part of the ashes will fly off.

To prevent burnt land from being exhausted, one or two crops only should be taken, and then the land ought to be laid out in grass. Its fertility will be greatly increased, if a little dung be added after the first crop.

### *Of Soot.*

SOOT contains oil, salt, and earth. It promotes vegetation in the same manner as dung or shell-marle. Soot is generally applied in the Spring as a top-dressing to winter corn or grass. The effects of soot used in this way are so sudden, that they evidently appear after the first rain. But its virtues are commonly exhausted by a single crop. However, when the effects of soot are over, the soil is not exhausted, as by ashes or lime; it may therefore be repeated as often as the farmer thinks proper; or it may be followed with advantage by ashes, lime, or marle.

### *Of Sea-weed.*

ALL plants that grow upon rocks, within reach of the sea, are good manures. These are frequently loosened and driven a-shore by the tide. They are of a soft pulpy nature, and soon putrefy.

Sea-weeds promote vegetation in the same manner as dung or soot; but their effects are not so lasting as dung. However, they are preferable to dung in this respect, that they do not produce so many weeds.

They may be applied to land in any situation, and are peculiarly proper for land that is exhausted by lime or ashes. When their effects cease, the land is not injured, and any kind of manure may be used after them.

The oftener sea-weeds are applied, the land becomes the richer. This is confirmed by experience. The lands near the shores, where the weeds have been long used as manures, are among the richest in Scotland, and have been kept almost constantly in tillage.

## *Of Shells.*

BEDS of shells are to be met with in many places, but particularly near the sea-shore.

These shells ferment with acids, and, like other animal-substances, contain oil, salt, and earth. Their operation is supposed to be of the same kind with that of shell-marle: But, as they take a long time to dissolve, their effects must be slower and weaker: They ought therefore to be applied in large quantities, otherwise their operation will be hardly perceptible.

Shells exhaust the land, but not near so much as lime or ashes; it is therefore improper to use them immediately after these manures.

When shells are found below the surface of the ground, as they generally are, they should be exposed to the air for some time before they are ploughed in: This not only assists their fermentation, but promotes their putrefaction.

### *Of Vegetables in an entire State, or sown for Manure.*

IT is a practice in many places, particularly in England, to sow turnip, pease, buck-wheat, &c. and to plough them down for manuring the land.

This practice is thought by some people to be attended with no advantage; because the plants, when ploughed down, can convey no more food to the soil than they take from it. But it ought to be considered, that some of the plants employed in this manner push their roots below the reach of the plough, and suck up the food to the surface; the seed that is sown likewise contains a great proportion of vegetable food; besides what the plants, when growing, may derive from the air, &c. From these circumstances it may be inferred, that they actually return more nourishment to the soil than they extract from it. The covering of the surface is also an advantage: Every farmer knows, that when the soil has been covered for a considerable time by a strong crop of pease, or any other corn laid down, the soil, though naturally hard and stiff, becomes soft, mellow, and free.

### *Of Water.*

RAIN-WATER contains a considerable quantity of vegetable food. When it falls upon land that has a descent, by running off, it must carry along with it some of the finest particles of the soil and the vegetable food contained in them. If this water, then, is let in upon a field, and allowed to settle, the land will receive from it not only the vegetable food contained in the water itself, but likewise what is contained in the particles of earth carried off from the higher grounds.

This method of manuring can only be used in fields which lie on the sides of rivers, or such as can be easily drained. In practising it, the water must not be allowed to run off violently, otherwise it does more hurt than good. Land in grass is most proper for this kind of

manuring. The firmness of the surface prevents any of the soil from being carried off when the water is draining, and the grass entangles the mud, &c. and hinders them from going along with the water.

This operation should be performed in the spring. In that season grass-lands suffer least from being overflowed.

### SECT. III. OF SOILS WITH RESPECT TO MANURES.

SOILS are very different in their natures, and composed of very different ingredients. Some soils contain more, and others less, of the food necessary for the nourishment of plants. It is necessary to inquire into these differences, in order to discover what manures are most proper for each kind.

The soils most common in Scotland are the black loamy, the clay, the sandy, and the mossy. Of these there are many varieties, according to the different proportions of that particular kind of earth from which they are denominated. Some soils are even so blended, that it is difficult to determine what kind of earth most prevails in them.

#### *Of the black Loamy Soil.*

PURE loam seems to be nothing else but the earth of pressed vegetables, accumulated by the successive decay of natural or artificial crops. In cultivated lands, dung and other manure greatly increase the quantity of the loam.

The principal qualities of loam are these: When allowed to rest, it acquires a degree of cohesion, but never becomes so hard and tough as clay: When turned up and exposed to the air, it becomes free and open, and easily crumbles down: When dry, it readily admits water, and swells and retains it like shell-marle; however, it only retains a proper quantity, and allows the rest to run off. It also contains oil, ferments with acids, and is of an absorbent nature.

There is no soil altogether pure; but that soil which has loam in its composition possesses in some degree all the qualities of loam; and these qualities are unquestionably the most proper for nourishing plants.

Its oils and salts afford food to the plants; the absorbent quality of which it is possessed, also attracts vegetable food from the air; its friableness, and fermenting with acids, give an easy passage to the roots to acquire this food.

Experience, the only sure guide in subjects of this kind, shows that a loamy soil is most fruitful. Some soils, when well limed or dunged, may bear as great crops as the loamy soil; but then they require a supply much sooner. The loamy soil has likewise another advantage over every other: It does not suffer so much from drought or rain, as clay and sandy soils.

All land called *in-field land* has a certain quantity of loam in its composition, probably owing to the dung

which is laid from time to time upon it. This is the only distinction betwixt out-field and in-field land.

The soil which contains a great proportion of loam, requires very little manure. It may be kept constantly in good heart by proper tillage and good management.

The common loamy soil requires manure, and no kind of manure is improper for it; dung, however, is unquestionably the best. Lime, unless managed with care, is in danger of hurting a loamy soil by exhauiting it.

#### *Of the Clay-Soil.*

THE richest kind of clay-soil is that which consists of clay and loam. To discover the nature of this soil, it is necessary to know the qualities of clay.

Clay is a very solid body, and its parts adhere firmly together: It does not easily admit water, but is capable of containing a great quantity, swells but little, and does not easily part with it. When dry, clay is very hard, and becomes the harder the more suddenly it is dried. In the process of drying, it contracts unequally, and breaks out into rents or fissures where the cohesion is weakest. It ferments with acids, but has no oil in its composition.

From a slight view of these qualities it appears, that a clay-soil is not so well adapted for the nourishment of plants as the loamy: it is more subject to receive injuries from drought or rain. In a rainy season, as it is averse to part with the water after it once admits it, the roots of plants will be much weakened or destroyed by being long soaked in the water. On the other hand, in a very dry season, it becomes so hard, that the roots cannot penetrate deep enough to search for food.

These observations are fully confirmed by experience. For it is well known to the husbandman, that the produce of clay-soils are extremely uncertain, as they are liable to be destroyed by dry or wet seasons. These soils labour under another disadvantage; as they repel water, especially when it falls in small quantities, they reap no benefit from dews or slight showers.

The clay-soil is said to contain vegetable food, but does not allow it to be easily dissolved: and hence lime, marles, or ashes, are the most proper manures for it, as they divide it into small particles. These manures likewise communicate to it a greater power of absorption; and therefore they will enable it both to receive and transmit water more readily, and of course make it less subject to be injured by the weather. Clay-soils, when mixed with loam, are very rich; but, when mixed with sand or till, they are very poor. Poor clay-soils require such manures as contain the greatest quantity of vegetable food; therefore dung, shell-marle, sea-weed, &c. are the best manures for them.

#### *Of the Sandy Soil.*

THERE are two kinds of sand that enter into the composition of soils; the one consists of small particles of flint, the other of broken shells.

The

The sandy-soil which is composed of stony particles, easily receives and transmits water; and consequently is not capable of containing a sufficient quantity for promoting the growth of plants: Its particles do not adhere, and is therefore unable to support plants that have few roots and grow high. Besides, it is susceptible of greater heat from the sun than any other soil, which is apt to parch the plants. As this soil contains no oil, it must be very defective in vegetable food; and, as it has no absorbent quality, it will receive but a small supply from the air.

From the qualities of this soil, the manures most proper for it are easily discovered. Clay will make it firmer, and enable it to retain the water; but clay contains little vegetable food. Dung will supply it with the food of plants; but will not render it firm, or make it retain water. Moss will help it to retain water, and supply it with vegetable food; but will not make it firmer. A mixture of clay and dung, or of clay and moss, seems therefore to be the most proper manure for this soil.

The qualities of a sandy soil composed of broken shells, are nearly the same with those of the former kind. The only differences are, that it ferments with acids, contains oil, and is capable of being dissolved. Hence this soil must have a larger quantity of vegetable food, and must also receive a greater supply from the air. A mixture of dung and clay, or of moss and clay, is likewise the most proper manure for this soil: But if any substance could be found that could reduce the particles of the shells to a state of putrefaction, it would be preferable to any thing hitherto known for improving a soil of this kind.

#### *Of the Mossy Soil.*

Moss principally consists either of live or at least uncorrupted vegetables. It must therefore have salt and oil in its composition. It does not easily putrefy, and prevents other bodies from putrefying. It swells with water like a sponge, and does not easily part with it.

To render the mossy soil fit for nourishing plants, the vegetables in it must be reduced to a state of putrefaction. This will not only supply it with vegetable food, but likewise render it firmer, and make it more easily part with water. Hence those manures which ferment most violently with acids, as the clay and stone marles, seem to be the most proper for this soil. These marles will not only raise a violent fermentation, but fill up the pores, and make the soil more solid. When the moss is deep, or has not a solid bottom, lime is improper, because it will soon penetrate beyond the reach of the plough; but, if it has a solid bottom, lime will answer very well.

It is improper to sow upon this soil till the fermentation raised by the manure is completely finished; for the violence of the fermentation sometimes throws the seeds, and even the roots, out of the ground.

Frequent ploughings make the mossy soil run much into weeds; and from this circumstance, the practice of ploughing it but seldom is found to answer better.

## SECT. IV. OF THE IMPEDIMENTS TO VEGETATION.

### 1. WEEDS, as an Impediment to Vegetation.

EVERY vegetable that grows in a field, different from the particular plant that is intended to be cultivated, may be called a weed.

Weeds injure the plants we desire to cultivate, by robbing them of part of their nourishment, and by preventing the spreading of their roots. Some weeds, as quickening grass, extend and interweave their roots in such a manner that it is difficult to pulverise the soil by tillage. It is therefore of great importance to the farmer to know how weeds may be destroyed. Weeds are generally divided into three classes, viz. those that are propagated by the seed; those that are propagated by the roots; and shrubs.

#### *Of destroying Weeds that are propagated by Seed.*

WEEDS are very different in their natures. Some, if prevented from vegetating, die in a few years by lying moist in the earth; others will lie many years in this situation, without losing the power of vegetating.

The first kind may be destroyed, by turning the land infested with them into grass for five or six years; and both kinds may be rooted out by allowing them to vegetate, and then tearing up the young plants before they begin to flower.

In order to promote the vegetation of the weeds that are intended to be destroyed, the land ought to be well ploughed; if a little dung, or other manure, be applied, the crop of weeds will be increased, and their destruction will be rendered more general.

Several weeds, as the thistle, dandelion, rag-weed, &c. are furnished with a kind of down, by which they float in the air, and are carried to great distances by the wind. Farmers should be as careful to root out all weeds of this kind from the roots of hedges, banks of fences, &c. as from their arable land; for although they may have the appearance of being inoffensive in that situation, they are transported from thence in great quantities by the wind into the adjacent fields.

There is another great source of weeds, but too little attended to by farmers. It is a general practice, to throw the seeds that are separated from the corn in winnowing upon the dung-hill; and by this means they are carried out with the dung, and again sown upon the land.

#### *Of destroying Weeds that are propagated by the Root.*

THERE are many different kinds of weeds propagated by the roots. Some of them infest land that is in tillage, and others land that is in grass.

Those that infest land in tillage may be destroyed by turning it into grass for some years. This is the most effectual

effectual means of rooting out quicken-grafs, and other root-weeds of the same nature. If the soil be hard and stiff, it is the sooner cleared of weeds by being laid out in grafs; But a soft spongy soil requires to be in grafs six or seven years before the weeds are destroyed.

Those weeds that infest lands in grafs, are easiest destroyed by turning the land into tillage. Neither is it necessary to continue it long in this situation; for the weeds commonly disappear after the first ploughing.

But as, in some cases, it may be inconvenient to turn a field infested with weeds from tillage into grafs, or from grafs into tillage, it is necessary to consider whether the same may not be accomplished, without altering the situation of the land.

When land is in tillage, the weeds may be destroyed by frequently stirring and turning it over in dry weather; for when the weeds are displaced, the drought prevents them from taking root again.

Land cannot be made too fine, nor the surface too smooth, when it is intended to be freed of seed-weeds; because by that the greatest number are brought to vegetate: But, when intended to be freed of root-weeds, the rougher the surface, the weeds are the more easily destroyed; because the drought has the easier access to their roots.

If grafs-lands be infested with weeds, and it is inconvenient to turn them into tillage, the only way of destroying the weeds, is to cut them frequently, or pull them up by the roots.

Some lands, after being in grafs a few years, are liable to be over-run with fog: In this case, rolling, by making the surface firmer, will be of great use in destroying the fog. This weed, as well as others, may be destroyed by depriving it of air. This may be done by covering the surface with a crop of pease, potatoes, or other plants that lie thick on the surface. A deep trenching will, in some cases, answer the same intention.

### *Of destroying Shrubs, as Furze, Broom, Bramble, &c.*

#### 1. FURZE.

THE common method of destroying furze (or whins) is by grubbing them out with a hoe. But it is impossible to root them out so compleatly as to prevent their springing again, especially if the land be continued in grafs. The most effectual method, therefore, is to bring the land into tillage immediately after the whins have been grubbed up. As long as it continues in tillage, no whins will appear; but if turned into grafs, they grow as numerous as ever.

To prevent this return of whins, the young plants that appear after the land is turned into grafs, should be pulled up by the roots. Unless they are very thick, this is neither troublesome nor expensive: When the ground is moist, it may be performed by young boys. If any of them rise afterwards, which is commonly the case, the same operation must be repeated every season till the land is compleatly cleared of them.

There is another scheme of management which in a

few years will effectually destroy whins. It is certain that the seeds of whins will not vegetate unless they are allowed to lie in the earth undisturbed for a considerable time. As long as land is left in tillage, although there be many whin-seeds in it, yet they never vegetate. Whin-plants do not even appear till two years after the land has been allowed to rest, or has been turned into grafs. Now, if a scheme of management be followed, by which the land is turned from tillage into grafs, and from grafs into tillage, the whins by degrees will be wholly eradicated.

It was observed above, that before lands infested with whins can be improved, the whins must be grubbed up. This operation is both tedious and expensive. The following method of rooting them out by the plough is more expeditious, less expensive, and has been tried with success.

This work must be performed by a strong Scotch plough, with a well redd beam. As it requires great force to tear up the roots, six horses should be yoked in pairs. Two drivers are likewise necessary, to prevent the horses from stepping aside. As the whins in rising are apt to entangle or choke the beam, another man is also necessary to push them off with a pitch-fork. A plough yoked and attended in this manner, will plow down whins near three feet high, with roots above four feet long, and an inch in diameter. This operation should be performed in the winter, when the land is well soaked with rain.

After the land has been ploughed in this manner, it should be allowed to lie till summer, when the whins torn up by the plough may be burned, the land harrowed, and the roots gathered. Afterwards the land may be dressed according to the judgment of the farmer; only the second ploughing should be across, that any roots which have been left may be torn up.

But when the whins are so strong that it is impossible to plough them down, they may be burned; and if the land be allowed to lie a few years after, it may be ploughed without much difficulty.

#### 2. BROOM.

BROOM is not so bushy, and does not cover the surface so much as whins; and therefore land infested with it is more easily cleared. Though the methods recommended for destroying whins will most effectually destroy broom, a more simple and less expensive one will sufficiently answer the purpose.

If broom, especially when it is old, be cut so low as to take away all the leaves, it will never spring again. A kind of scythe has lately been invented, by which broom may be cut in this manner with great expedition. If this method be observed, it is unnecessary to bring land from grafs into tillage in order to clear it of broom.

#### 3. BRAMBLE.

THIS plant is of a very different nature from whin or broom. The root sinks deep into the earth, and spreads very wide. Though cut in the winter, it rises and comes to such perfection as to carry fruit in the summer,

It is therefore a difficult matter to clear land of bramble, especially when it is stony; for the bramble pushes and interweaves its roots among the stones, which renders it necessary to dig out the stones before it can be sufficiently rooted up by ploughing or tearing. However, digging out the stones, and ploughing the land in such a manner as is most proper for cutting and tearing up the roots of bramble, may be the more safely recommended, as they at the same time serve many other useful purposes.

## 2. Of WATER, as an Impediment to Vegetation.

SOME plants require a greater, and some a lesser proportion of water in their food. The plants usually cultivated in our fields are of the latter kind, and are easily injured by an over-proportion of water. Hence, water may be considered as an impediment to vegetation; and it becomes necessary to consider the most proper methods of conveying it off the land.

### Of draining Land.

SOME lands are wet from their situation, being exposed to overflowsings from higher grounds, and having no proper descent to allow the water to run off.

The bottom of some land is of such a nature as to force out, in springs, the water that runs below the surface. Springs sometimes break out, because the channels, in which they run, reach the surface; and sometimes because they are interrupted in their course, which makes them force their way above ground.

The wetness of land is sometimes occasioned by violent and frequent rains; and sometimes all these causes may concur in rendering land wet.

Land that is wet from its situation may be drained in this manner: Although the wet land be so low, as to render it difficult to carry off the water; yet the water may be intercepted by a drain, before it reaches the low ground.

Land, wet by springs, lies generally in a sloping direction, which makes it the more easy to drain. When the water runs near the surface, before it breaks out, it may be intercepted by a drain drawn across the declivity, a little above the place where it first makes its appearance. But, if the channel lies deep, the drain should be drawn directly across where it springs up.

But, when the wetness of the land is owing to the climate, or a rainy season, the water cannot be interrupted by drains; however, obstructions may be removed, so as to allow the water to run off as quickly as possible. To drain land in this situation, it is necessary to lay it up in ridges properly placed, and to cut small drains across these ridges, communicating with each other, and with the furrows. By this method all the furrows betwixt the ridges become drains; the water, as it falls upon the ridges, immediately makes its way to the furrows; and, if it meets with an interruption in any of them, it is conveyed by the drains across the

ridges into some other furrow, along which it is carried off the field.

There are two kinds of drains, *viz.* open drains, and hollow drains. Hollow drains differ from open ones, in being filled with loose stones, covered with turf, brushwood, or straw, and a layer of earth thick enough to allow a plough to go easily through above. These hollow drains are attended with two advantages; no land is lost by them, and they are no impediment in ploughing.

Open drains, however, are in most cases preferable to hollow ones: They alone are capable of intercepting overflowsings from higher grounds, and for carrying off water that falls in rain. The water in these cases being always on the surface, will run freely over hollow drains, especially when situated on a declivity. But hollow drains may be used with advantage in land wet by springs; because nothing more is required than to continue the channels of the water below ground, and not allow it to break out, till it arrives at a place where it can do no harm.

It will not be improper here to mention, that some soils retain water much longer than others, and consequently are more liable to be damaged by water. Soils that have a large proportion of clay, or of mofs, are of this kind. As these soils naturally retain water like a sponge, casting drains, and laying the land up in ridges, will not convey it away. To drain such lands, their nature, and power of retaining water, must be changed by culture.

The clay-soil can only be drained by frequent stirring, and the application of such manures as raise a fermentation. These operations open the pores of the soil, and thereby afford a free passage to the water.

The mossy soil, on the other hand, is too open and porous, but is possessed of an absorbing quality, by which it retains the water. To drain this soil, it is necessary to condense it, and, if possible, to destroy its quality of retaining water. Frequent stirrings, and such manures as raise a fermentation, and tend to putrefy the mofs, are said to render it firm and solid; and thereby both prevent it from receiving so large a quantity of water, and destroy the quality of retaining it.

### Of draining Marshes.

THE soil of marshes, being composed of dissolved vegetables, dust blown in by the winds, and earth washed down from the high grounds with which they are generally surrounded, is light and spongy, but very rich and valuable when drained.

In draining a marsh, all the stagnating water should be first carried off by a large open drain, with a sufficient fall, and as deep as the bottom of the marsh. When the stagnating water is conveyed away, the earth by degrees will subside, and become solid; and some land will thus be gained on each side: The bottom likewise soon becomes firm enough to allow the drain to be gradually carried forward through the middle of the marsh. If the springs, which supply the water, rise near the middle of the marsh, this principal drain, with a few branches on each side, where the springs are largest or most

most numerous, will be sufficient. But, if the springs be irregularly dispersed through the whole marsh, as is frequently the case, side-drains parallel to the principal one will be necessary to intercept the water that comes from the higher grounds and supplies the springs. Cross drains, communicating with the parallel and principal drains, are likewise necessary; and should all be kept open till the soil hath fully subsided, and become firm; then the side-drains and cross-drains may be converted into hollow-drains, in the manner above described. But the principal drain, especially if the marsh be extensive, should always remain open.

## SECT. V. OF TILLAGE.

TILLAGE is the operation of breaking the soil into small particles, by stirring and turning it over, laying it up in ridges, &c. In this part of agriculture, it is necessary to be acquainted with the different soils proper for nourishing plants; the instruments best adapted for stirring and turning them over; and the construction and manner of using these instruments.

Soils, with respect to tillage, may be divided into stiff and light, wet and dry, deep and shallow. This division is the more proper on this account, that the method of performing the operation of tillage has always a reference to one or more of these qualities of soil, and to no other.

The instruments employed in tillage are various; as the plough, the harrow, the roller, &c. which are again greatly diversified by differences arising from their construction and particular uses.

### 1. Of the Scots Plough.

IN Scotland, this plough is still the most common and the most generally understood. If properly made, it is the best plough for answering all purposes, when only one is used; though others are, perhaps, more proper for some particular purposes.

The parts of which this plough is composed are, the head, the beam, the sheath, the wrest, the mold-board, the two handles, the two rungs, the sock, and the coulter; the two last are made of iron, and all the rest of wood.

The HEAD, Plate VIII. fig. 1. is designed for opening the ground below. The length of the head from A to B is about twenty inches, and the breadth from A to D about five inches; C is the point upon which the sock is driven, and the length from B to C is about six inches; *a* is the mortoise into which the larger handle is fixed; and *b* is the mortoise into which the sheath is fixed.

The head is that part of the plough which goes in the ground; therefore the shorter and narrower it is, the friction will be the less, and the plough more easily drawn; but the longer the head is, the plough goes more steadily, and is not so easily put out of its direction by any obstructions that occur. Twenty inches is considered as a mean length; and five inches as the most convenient breadth.

The SHEATH, fig. 2. E, is driven into the mortoise,

fig. 1. *b*, and thus fixed to the head A B. It is not perpendicular to the head, but placed obliquely, so as to make the angle formed by the lines A B and E B about 60 degrees. The sheath is about 13 inches long, besides what is driven into the mortoise *b*; about three inches broad, and one inch thick.

The sheath is fixed to the mold-board, as in fig. 11. E, in the same manner as the wrest is fixed to the head in fig. 7.

The MOLD-BOARD is designed to turn over the earth of the furrow made by the plough; and it is obvious, that, according to the position of the sheath, the mold-board will turn over the earth of the furrow more or less suddenly. Besides, when it forms a less angle with the head than 60 degrees, the plough is in great danger of being choked, as the farmers term it.

The LARGER HANDLE, fig. 3. F A, is fixed to the head, by driving it into the mortoise *a*, fig. 1. It is placed in the same plane with the head; and its length from A F is about five feet four inches, and its diameter at the place where it is fixed to the beam is about two inches and a half, and tapers a little to the top F. About ten inches from A, there is a curve in the handle, which, when F is raised to its proper height, makes the lower part of it nearly parallel to the sheath E B. This curve is designed to strengthen the handle. The proper position of the handle is, when the top F is about three feet two inches higher than the bottom of the head A B.

The longer the handles, the plough is the more easily managed, because the levers are more distant from the centre of motion. The higher the top of the handles, the plough is more easily raised out of the ground, provided they be no higher than the lower part of a man's breast.

The BEAM, fig. 4. is fixed to the larger handle and the sheath, all of which are placed in the same plane with the head. The length of it, from H to I, is about six feet; its diameter is about four inches. When the plough is in the ground, the beam should be just high enough not to be incommoded by any thing on the surface.

The position of the beam depends on the number of cattle in the plough. When two horses are yoked, the beam should be placed in such a manner as to make the perpendicular distance betwixt the bolt-hole of the beam and the plane of the head about 21 inches; when four horses are yoked, two a-breast, this distance should only be about 18 inches.

The SOCK, fig. 5. B P, is fixed to the end of the head, and is about two feet long. In fitting the sock to the head, the point ought to be turned a little to the land or left side; because otherwise, it is apt to come out of the land altogether. When turned to the left, it likewise takes off more land; when turned upwards, the plough goes shallow; and when downwards, it goes deeper.

The COULTER, fig. 6. is fixed to the beam, and is about two feet ten inches long, two inches and a half broad, sharp at the point and before, and thick on the back, like a knife. It is fixed and directed by wedges, so as to make the point of it equal to, or rather a little before

before the point of the sock, and upon a line with the left side of the head. This oblique position enables it to throw roots, &c. out of the land, which requires less force than cutting or pushing them forward.

The WREST, fig. 7. B D, is fixed to the head, and is about 26 inches long, two broad, and one thick. It is fixed to the head at B, in such a manner as to make the angle contained between the lines A B and B D about 25 degrees. The wrest is seldom or never placed in the same plane with the head, but gradually raised from the place where it is fixed to it; that is, from B to K, as in fig. 8. The position of the wrest determines the nature of the furrow. When the wrest is wide and low set, the furrow is wide; and when it is narrow and high set, the furrow is narrow.

Fig. 9. represents the two HANDLES, fixed together by the two rungs. The larger handle has been already described; the lesser one is a few inches shorter, and does not require to be quite so strong. The distance of the handles at the little rung depends on the position of the wrest. Their distance at M and P is about two feet six inches. The lesser handle is fixed to the mold-board at M, fig. 10. and to the wrest K B, at L.

Fig. 11. represents the plough complete, by joining together figures 6. and 10. in the sheath E B. The wrest B K is supposed to make an angle with the head A B, as in fig. 7. and the handles joined together, as in fig. 9.

After having given such a particular description of all the parts and proportions of the Scots plough, it will easily appear how it separates, raises, and turns over the earth of the furrow. If it had no coulter, the earth would open above the middle of the sock, and in a line before the sheath; but as the coulter opens the earth in a line with the left side of the head, if the soil has any cohesion, the earth of the furrow will be wholly raised from the left side, and as the sock moves forward, will be thrown on the right side of the sheath, and by the casting out of the mold-board, or the raising of the wrest, will be turned over.

This plough, though the best general one, is not altogether perfect. As the sock is high in the middle, and round on the sides, and as the point of it is in a line with the middle of the head, a great force is necessary to raise the earth of the furrow. Besides, as the sheath is nearly in a line with the point of the sock, and to the right of the left side of the head, the earth of the furrow, as it is raised, must strike against the sheath, and a part of it, instead of being turned wholly to the right, will fall to the left side. These defects make the plough heavy to draw; and, besides, this position of the sheath renders the Scots plough improper for hoeing, as the earth that falls to the left buries the young plants in the rows.

To remedy the defects arising from the sock, it should be made straight on the land-side, so as to be in a line with the land or left side of the head; and straight also below, so as to be in a line with the under side of the head, sloping on the furrow or left side; and likewise on the upper side from the point, so as to make it, at the root, about seven inches broad, and three inches thick; at the same time sloping all the way from the land to

the furrow, so as to form the furrow-side into a sharp edge. It is obvious, that this sock will meet with less resistance than the common one, will raise the earth of the furrow wholly from the left side, and turn it as it is raised.

To remedy the defect arising from the sheath, it should be brought a little nearer the larger handle, and another sheath should be fixed a little before it, to the left or land-side of the head and beam; to this sheath the mold-board should be fixed. If this be done, the earth of the furrow, as it is raised, will be resisted by the mold-board only, and wholly turned to the right.

The BRIDLE, or MUZZLE, is another article belonging to the plough. It is fixed to the end of the beam, and the cattle are yoked by it. The muzzle commonly used is a curved piece of iron, fixed to the beam by a bolt through it. In fig. 12. A B C is the muzzle, A C the bolt by which it is fixed to the beam; D is the swingle-tree, or cross-tree, to which the traces are fixed; and B is a hook, or cleek, as it is commonly called, which joins the muzzle and swingle-tree.

Some use another kind of muzzle, fig. 13. A B C D. It is fixed to the beam by two bolts, and has notches by which the cleek of the swingle-tree may be fixed either to the right or the left of the beam. There are also different holes for the hind-bolt to pass through, by which the draught may be fixed either above or below the beam. A D is the fore-bolt upon which the muzzle turns; on B C are four notches, betwixt any two of which the cleek of the swingle-tree may be fixed. When the cleek is fixed at B, the plough is turned towards the firm land, and takes off a broader furrow; and when fixed at C, it is turned towards the ploughed land, and takes off a narrower furrow. E and F are the holes on each side through which the hindmost bolt passes. When the bolt is put through the highest two, these holes being thereby brought to the middle of the beam, the fore-part of the muzzle is raised above the beam, and the plough is made to go deeper; and when put through the lowest two, the fore-part of the muzzle is sunk below the beam, and the plough is made to go shallower. This muzzle may be so constructed as to have the same play with the common one. Fig. 16. A is the end of the beam; B a plate of iron sunk into it, and, with a similar one in the other side, is rivetted into it by bolts; C is the muzzle fixed to these plates of iron by the bolt D, which bolt may be put through any of the holes E E. From the construction of this muzzle it is plain, that it has the same play with the common one, and that by it the land of the plough may be altered at pleasure.

#### *Of the Plough with the curved Mold-board.*

THE mold-board of the Scots plough is not quite straight, but is cast out above, and more and more so as it approaches the lesser handle.

Ploughs with a curved mold-board commonly have no wrest, the mold-board serving for both. The under-part of it, which serves in place of the wrest, becomes parallel to the plane of the head as it approaches the handle; and sometimes, after it has passed the handle,

is made to turn inwards; and the fore-part of it, which is straight below, is more and more curved the further up it comes, resembling the bow of a ship.

If one mold-board be preferable to another, it must be either because it throws the earth of the furrow more properly, or makes the plough more easily drawn. Now, the use of the mold-board is to raise the earth, turn it over, and, if it be taken off narrow, to shift it a little to the right hand. The common mold-board, when right made, performs all these operations gradually. But the curved mold-board, as it is cast out above in the fore-part, prevents the furrow from rising, and turns it over suddenly. In land that easily breaks in pieces, the common mold-board has the advantage, because it raises the earth of the furrow higher than the other, and leaves it more loose and open. But the curved mold-board is preferable in land that is not easily broke, for, by turning over the earth suddenly, it is apter to tear it asunder.

The plough is more easily drawn by the common mold-board, as it has less friction than the curved one.

### *Of the Plough with the feathered Sock.*

THE difference between the feathered and the common sock will be best understood by comparing their figures. Fig. 14. is the common sock, and fig. 15. the feathered one.

From the construction of the feathered sock, it is obvious, that it must meet with greater resistance than the common sock. However, when the plough takes off the earth of the furrow broader than that part of the sock which goes upon the head, it is more easily drawn than the plough with the common sock; for the earth which the common sock leaves to be opened by the wress, is more easily opened by the feather of the other sock. In sea, the feathered sock makes the plough go more easily, because the roots of the grass, which go beyond the reach of the plough, are more easily cut by the feather than they can be torn asunder by the common sock. The feathered sock is also of great use in cutting and destroying root-weeds. The common sock, however, answers much better in strong land.

It is proper here to add, that in fitting the feathered sock to the head, the point of it should be turned a little from the land, or a little to the right hand.

### *Of the Wheeled Plough.*

THE Scots wheeled plough is formed by adding wheels to the old Scots plough, and giving it a curved mold-board, or feathered sock, according to the inclination of the farmer. The advantage or disadvantage of the wheels is therefore the only thing to be considered in this place.

The following are the principal advantages of wheels to a plough of this kind. Wheels regulate the plough; they make it go to a certain depth, take off the earth of the furrow of a determinate breadth, and make the plough very easy to manage. Wheels likewise make it

easy for the ploughman to keep the ridges straight, which is difficult to do without them.

The disadvantages attending a wheeled plough are nearly equal to its advantages. It has too much machinery, which is an inconvenience in any instrument. It is improper for ploughing ridges across. It is also very inconvenient for ploughing narrow ridges; for it must be frequently altered in ploughing out a ridge. The wheel that goes in the furrow being higher than the other, when both wheels are going upon the surface, the beam must be changed from its ordinary position, and placed in such a manner as to keep the plough even, and to make it go a little deeper than ordinary. When a furrow is made for the wheel to go in, the beam must be altered again to its ordinary position; and when the ridge is near finished, so that both wheels are going in furrows, the position of the beam must be changed, to keep the plough even, and to prevent it from going too deep.

### *Of the Four-coultured Plough.*

In England, this plough is said to be used with success. But after repeated trials by those who attempted to use it in Scotland, they have been obliged to give it up.

So many coulters in the ground at once must meet with many obstacles, which will give different directions to the plough, according to the different parts of the coulters to which the resistance is applied. Besides, it is difficult to place the planes of the coulters exactly parallel to each other; and if this be not done, they will be continually acting upon the plough in different directions. When this plough is employed for breaking up grass-grounds, which is the chief design of it, the oblique position of the coulters is apt to raise the turf in such a manner as to intangle it betwixt them, and thereby entirely stop the plough.

This plough should always be made with wheels for regulating its direction; the planes of the coulters should be exactly parallel to each other: The first coulters must be set almost perpendicular, and should not go above two inches deep; the second should slope a little, and go somewhat deeper than the first, and so on to the last.

Soft meadow-land, free from stones, is best adapted to the nature of this plough.

### *Of the Iron Plough.*

This plough is formed upon the model of the old Scots plough; only the several parts of it are shorter, and the head and sock are of one piece like the English ploughshare.

This plough is lighter, and consequently more easily drawn than any other plough used in Scotland; and, as it is shorter, the friction is also diminished. Neither is the earth so apt to stick to it, and clog it while going. But these are only seeming advantages; for the lightness and shortness of it render it extremely subject to change its direction upon meeting with the least obstruction. Soft land,

land, with few stones, therefore, is the only land in which it can be employed with advantage.

The iron plough is subject to another inconvenience. When any thing goes wrong, it cannot be rectified on the field, but must be carried to the smithy, which is often at a considerable distance.

### *Of yoking Cattle in Ploughs.*

It is not easy to determine whether horses or oxen, or both together, are most proper for drawing ploughs; because, in this country, such a determination depends on circumstances almost as various as the number and situation of farms in it. If, indeed, real labour alone was sufficient to determine this point, oxen would be preferred; because they will stand to the draught, and overcome a resistance which horses would yield to. We shall therefore confine this head to the manner of yoking cattle, without regard to the kind of cattle employed.

The chief question on this subject is, Whether cattle should be yoked in pairs, or in a line before one another?

The most common way of yoking cattle is in pairs. Though this, upon the whole, be the best method, yet it is subject to some disadvantages. In ploughing the furrows betwixt the ridges, the cattle go upon the ploughed land, and tread it down with their feet, which is peculiarly hurtful to wet land: When there is but as much of the ridge unploughed as the cattle have hardly room to go upon, they frequently give the plough a wrong direction by going into the opposite furrow; or, which is still worse, they are apt to juggle the furrow-cattle upon the ploughed land.

To remove these inconveniencies, yoking the cattle in a line has been recommended. But this method has been attended with greater inconveniencies than those it is intended to remedy. When yoked in this manner, they go all in the furrow, which makes it necessary to give the plough more land than ordinary, either by means of the sock or muzzle; and consequently makes the draught too heavy. Besides, when cattle are yoked in a line, it gives some of them an opportunity of throwing the chief burden upon the others. There is still another inconvenience attends this method. When the cattle are all in a line, the whole force is applied to the direction of the traces of the hindmost horse; and consequently it cannot have such an effect on the plough as when a part of it is in a more horizontal direction.

Each of these methods, however, may be used with advantage in certain circumstances; yoking in pairs, as it is certainly the strongest draught, should be preferred in ploughing stiff land. On the other hand, yoking in a line answers best in wet land, which is liable to be much hurt by the treading of the cattle.

### *Of Ploughing.*

Ploughing is the action of the plough in stirring and turning over the soil. By opening the soil and enlarging the surface, it gives it an opportunity of extract-

ing the vegetable food from the air; and consequently increases the food of plants. Ploughing likewise dissolves and reduces to a state of putrefaction the dung, oils, and vegetable substances that happen to be mixed with the soil, and prepares them for entering the roots of plants. When properly managed, ploughing destroys weeds, and drains the land when too wet. Hence, ploughing is one of the most important operations in agriculture, and therefore merits the greatest attention.

When ploughing is designed to enrich the land, or increase the food of plants, the surface cannot be made too uneven; because the more of it is by this means exposed to the influence of the air.

But when the intention of ploughing is to destroy sced-weeds, the surface cannot be made too smooth, nor the mold too much broken; because, by this management, their vegetation is promoted, and consequently they may be more completely destroyed by ploughing them in.

Again, if you plough with a view to remove wetness, the land must be laid up in high ridges; for the greater the number of furrows, and the higher the ridges, the water is more expeditiously carried off.

Thus the manner of ploughing must always depend on the object in view. It frequently happens indeed, that two or more of these objects require our attention in ploughing the same piece of land. But the methods above mentioned are perfectly consistent with each, and may be combined so as to answer any intention that may occur.

In ploughing, there are some general rules to be observed, whatever be the object in view. Thus, land should never be ploughed when it is wet, because the intention of it will be frustrated, whatever may be the nature of the soil. A stiff soil, when ploughed wet, dries suddenly, and becomes hard. If a light soil be ploughed wet, the water hinders it from being reduced to small enough particles. Besides these disadvantages, the labour becomes very severe on the cattle, and the land is much hurt by their treading.

With regard to ploughing lee, or opening up grass-grounds, the common practice in Scotland is to plough it as shallow and narrow as possible, and to set the turf upon its edge. After this single furrow, the land is sown, and if it be good, a profitable crop may be expected; and the turf will be completely rotten before next season.

On the contrary, in breaking up of barren land, it should be ploughed deep, and the turf turned on its back.

### *Of Ridges.*

It was formerly observed, that ploughing in ridges removes wetness, enlarges the surface, and consequently affords more space for the plants to extract nourishment from the soil.

When the soil is wet, the ridges ought to be narrow, and steep; because, by this means, the number of drains is increased, and the water finds its way more easily into the furrows. They should likewise be raised high in the

middle or crown; for the higher they are raised, the more is the surface enlarged. However, if the soil be shallow, the ridges should not be raised high, as they deprive the furrows of soil.

But, in low flat-lying ground, the ridges should be made flat, in order to raise the furrows; for, in some cases, the higher the furrows are raised, it is the more easy to find a fall for carrying off the water. Flat ridges are also capable of being sown with greater exactness.

It is impracticable to give any general rule for laying out ridges. In some situations, narrow ridges are preferable to broad ones; in others, flat ridges are better than steep ones, &c. In laying out of ridges, therefore, every person must be determined in this point by the nature and situation of the soil, and the advantages or disadvantages of the different kinds of ridges.

But, whatever be the nature or situation of the soil, the ridges should always be made straight. In ploughing crooked ridges, the cattle must often go in a different direction from the plough, and are obliged to take short turnings, which hurt the land by the treading of the cattle. Besides, when the ridges are crooked, the fall for the water is diminished. In all soils too, the ridges should be made of the same breadth throughout, and equal to one another. When they are unequal, it is difficult to sow them with exactness, or to alter them when necessary; and the plough must often turn in the middle of the ridge, which hurts the land by the trampling of the cattle.

### Of the Position of the Ridges.

It is a matter of some consequence to know how ridges should be placed, so as best to answer the situation of the land.

In lands that have a slope, the ridges are commonly placed in a straight line from the top to the bottom of the declivity. When the declivity is gentle, this position is very proper, as it drains the land of water. But when the declivity is great, this position allows the soil to be washed away by the rain; and the quantity of soil carried off will always be in proportion to the violence with which the current runs: Hence, in a soil situated in this manner, the ridges should be placed across the declivity, to prevent the soil from being carried down by the water. Making the ridges very narrow will, in a good measure, answer the same purpose; however, it is not so proper as placing them across the declivity.

When land is very dry, cross ridges are also of great use; for they retain the water, and prevent the soil from being washed away.

### Of ploughing in Ridges.

THERE are three different ways of ploughing in ridges, viz. gathering, casting, and cleaving.

By *gathering*, the crown and furrows of the ridge are kept in the same position in which they were before: the plough begins in the crown, and plows out the ridge, turning the earth towards the crown, where it first en-

tered. Every ridge is ploughed by itself; or the halves of two contiguous ridges may be ploughed together. By this method, as the earth on each side is turned upon the crown, and thrown up out of the furrows, the ridge must be raised higher.

By *casting*, the crowns and furrows are likewise kept in their former position: The ridges are ploughed in pairs: The plough may enter in the furrow betwixt the ridges, and plough out the ridges, turning the earth towards the furrow where it entered; or, the plough may enter in the furrow on the right side of the two ridges, then turn to the one on the left, and plough out the ridges, turning the earth to these furrows, and from the furrow that is betwixt them. By this method of ploughing, the ridges are kept of the same height in the crown, and one of the furrows made a little higher, and the other a little lower than before.

*Cleaving* is the reverse of gathering. The plough enters in the furrow on the right-side of the ridge, turns to the furrow on the left-side, and ploughs out the ridge, turning the earth from the crown towards the furrows. Every ridge is ploughed by itself, or the halves of two contiguous ridges may be ploughed together. If the ridge be raised in the crown, this method of ploughing makes it flatter, by throwing some of it into the furrows.

There is another method of ploughing used in some places, called *ribbing*. This method is performed by making furrows about two feet distant from each other. One half of the surface is untouched by the plough; and the other half, which the plough turns up in making the furrows, is thrown on the top of what remains flat. The land may be ploughed in this manner either without regard to ridges, or the plough may be made to enter and turn, as in gathering, casting, or cleaving. This kind of ploughing is seldom practised, but in the beginning of winter, and upon land to be sown with barley, after two additional clean ploughings. Although some modern improvers have condemned ribbing, it certainly has its uses: It keeps the land dry; the rain that falls is confined to the furrows, from whence it is easily carried off; it promotes the rotting of the stubble, and exposes a greater part of the soil to the influence of the air.

### Of Harrows.

THE harrow is an instrument employed for smoothing the surface after the land is ploughed. One horse is sufficient to draw the harrow commonly used in Scotland. Sometimes two of them go a-breast, and sometimes three. When the surface is very rough, two are reckoned sufficient for the attention of one person: But when three can be used, they make better work, and are nearly equal to two pair.

There are several kinds of harrows used in Scotland. The common one is so well known that it needs no description.

When the land is rough, the harrows are apt to start, and get a-top of each other. To prevent this, some fix pieces of crooked timber to the out-side bulls that are contiguous to one another, which, by stretching a little over,

over, keep the harrows in their proper place. Others couple the harrows in such a manner as to allow them to go before and fall back of each other, and at the same time turn upon a hinge.

When stiff land is ploughed wet, it rises in large pieces, which, when dry, become so hard, that the common harrows make no impression on them. To reduce this kind of land, a large harrow, called a *break*, has been contrived. The break-harrow is sometimes made of the same figure with the common harrow, and sometimes in a triangular form. Both kinds are made heavier or lighter according to the nature of the soil for which they are intended. Some of them are so heavy as to require six or eight cattle to draw them. But the heaviest kind are very improper for land infested with large flint stones; because their weight hinders them from starting over the stones; and therefore they are often in danger of being torn asunder by the cattle.

There is another harrow, which, though little used, will be found to be very useful in many cases. It is of the same form with the common harrow, but much broader. The bulls are at a greater distance, and consequently the teeth thinner placed; the teeth are longer than those of the common harrow, but very little thicker; and those in the fore-part slope forward. It is made of such a weight as to be easily drawn by a couple of horses. This harrow goes deeper, opens land better, covers the seed deeper, and is more proper for tearing up roots than the common harrow.

The French harrow is of a triangular form, with a joint near the angle, to which the draught is fixed. It has two handles, by which it is either made to go deep or shallow, as occasion requires. Its principal use is to level steep ridges, which it does most effectually. It is drawn across the ridges: When, at the crown of the ridge, by pressing on the handles, the harrow sinks down, and carries earth along with it to the furrows; and, when at the furrows, by lifting up the handles, the harrow is brought out of the ground, and leaves the earth behind. This operation, however, is extremely improper, unless the land be in a very dry situation, and not liable to be damaged by water.

### Of Harrowing.

HARROWING smooths the surface, destroys weeds, and covers the seed after it is sown.

When the intention of harrowing is to destroy root-weeds, the harrows should be drawn across the ridges. However, if such weeds are not fully torn up, the harrowing, by filling up the hollows, and defending the roots from the drought, rather promotes their growth. For this reason, harrowing is improper for destroying root-weeds, excepting after a spring-fallow, when the land is soon after to be ploughed for seed.

But the smoother the surface is made, and the more the mold is broke, the vegetation of the seed-weeds is the more effectually promoted, and of course they are the more liable to be destroyed by harrowing. If the season be favourable, the land may be harrowed several times, and as many crops of weeds destroyed.

A light spongy soil can hardly get too much harrowing; for the more it is harrowed, it becomes the firmer. But if the soil be stiff, the less harrowing it gets, the better, provided the purposes proposed can be answered.

The common method of harrowing after the seed is sown, is first along the ridges, then across, and then along again. When the ridges are flat, they may be harrowed either along or across; and the work may be begun or ended either way. But when the ridges are steep, it is improper to begin by harrowing across, because too much of the seed will be drawn into the furrows.

### Of the Roller.

THE roller is intended for smoothing the surface, and making the land firmer. Rollers are sometimes made of stone, sometimes of wood, and sometimes of iron: but the only essential difference of rollers lies in their weight. As rollers, in different circumstances, require to be lighter and heavier, they are generally constructed so that their weight can either be augmented or diminished.

The common roller, in turning, is very severe upon the cattle, for it does not move on its axis, but is dragged along the surface. To remove this inconvenience, a roller has lately been constructed with a division in the middle, as if two rollers were joined together. In turning, both parts of this roller move round their axis, the one forward, and the other back.

### Of Rolling.

ROLLING is practised with advantage, both on land lying in grass, and in tillage. It presses down mole-hills, smooths the surface, and makes pasture-grass fole, and grow thicker.

Rolling upon land in tillage, not only smooths the surface, but breaks clods that the harrow cannot reduce. In a light soil, the roller should be applied immediately after the seed is sown; it is peculiarly useful to this kind of soil, by condensing and making it firmer.

### Of Sowing.

It is remarked by farmers, that the corn which is earliest sown is in general soonest ripe. However, as this operation depends on the nature of the weather, and a number of other circumstances, no precise time can be fixed for performing it.

The practice of sowing wheat, oats, barley, &c. at different times of the year, seems not to depend so much on the different natures of these grains, as on the inconveniences which would attend the sowing them all at the same time. It may however be observed, that wheat, the only grain in this country which is sown before winter, should be sown as early as possible, that its roots and leaves may be put forth before the frost comes on.

The most common method of sowing is by the hand. This method requires great skill and address in the sower: For, at the same time that he gives his arm a circular motion, to cast the seed with strength, he must open his

hand

hand gradually, that it may not fall in a heap, but be properly scattered and spread. It is remarkable, that good sowers, by the force of habit, take their handful out of the sheet so very exactly, that they will sow any quantity of seed on an acre, according as it is designed to be thinner or thicker. But this dexterity in a few sowers, is itself an objection to the method of sowing by the hand; because long practice and observation are necessary to make a good sower: This remark is too well justified by experience; for good sowers are extremely rare, and, in some places of the country, hardly to be got. Besides, in sowing by the hand, especially when the land is uneven, the seed rebounds on the clods, falls into the cavities, and often the greatest part of it is collected in the furrows.

Different plants require to be sown at different depths. The same seeds, however, may be laid deeper in light than in strong soils. Wheat requires to be placed two inches and a half or three inches below the surface: And it may be laid down as a general maxim in sowing, that small seeds should always be placed nearer the surface than such as are larger. Besides the unequal distribution of the seed when sown by the hand, too large a quantity of it may be used; for, as it is placed at different depths, that which is too deep never comes up, and that which lies on the surface, which may be observed on the best harrowed land, is eat up by the birds. When seed is sown thin, and placed at equal distances by a drill, a lesser quantity of it, by leaving room to spread and branch out, will produce even a better crop than a larger quantity sown irregularly by the hand. The fact has been confirmed by repeated experiments both in our own country and in France.

## SECT. VI. OF THE CULTURE OF PARTICULAR PLANTS.

### *Of the Culture of Wheat.*

THOUGH wheat be the most valuable grain that is cultivated in Scotland, there are many places where it cannot be sown with advantage; for it requires not only a rich soil, but a warm climate.

The English writers mention about 13 or 14 different kinds of wheat; but in Scotland we seldom use more than two, *viz.* the white and the red wheat. The last is reckoned the most hardy plant, and succeeds in some soils and climates where the white kind fails. Bearded wheat is used in some places. This is likewise a hardy plant, and is not so apt to lodge, or to be shaken out by the wind, as the other kinds. It succeeds very well in wet land, and the grain produces a great quantity of flour.

The white wheat most commonly used in Scotland, is not a particular species, but a mixture of all the species cultivated in England. This mixture is probably occasioned by want of care in providing ourselves with foreign seed. It is found by experience, that, in this

country at least, wheat degenerates; for which reason a fresh supply is every year brought from the English granaries, which generally consists of a mixture of all the kinds. Now it is at least very probable, that these different kinds of wheat require different soils; and therefore the farmer should endeavour to provide himself annually with a quantity of unmixed wheat, of such kinds as are found to succeed best in Scotland.

Wheat is commonly sown either upon land that has been summer-fallowed, or after a crop of pease. In the latter case, the seed cannot be sown till October; but in the former, it is generally sown in August. However, in Scotland, we sow wheat from the beginning of August till the middle of November. Some have tried sowing wheat in the spring; but the plants were neither so vigorous, nor the grain so large, as those that were sown in autumn. The sowing of oats in autumn has likewise been tried; but, though the crop was bulky, the quantity of grain was not in proportion. Upon the whole, the month of October seems to be the most proper time for sowing wheat; when it is either earlier or later, it is subject to a number of dangers.

The quantity usually sown upon a Scots acre, is from three to five firloths, Linlithgow measure, which is the measure always meant in this treatise. The proper quantity, however, must always depend upon the situation of the land; in proportion as it is clean and rich, a smaller quantity of seed is requisite; and in proportion as it is poor and full of weeds, a larger quantity becomes necessary.

A wet bed is most proper for wheat-feed. In the month of August, or even the beginning of September, it is dangerous to sow; if there be not as much moisture in the land as to make the seed vegetate, especially if the seed has been steeped in brine, and dried with lime. But though the danger be great in sowing when the land is very dry, yet the best situation of land for receiving seed is when it contains no more moisture than is sufficient to make the seed vegetate.

When wheat-land is light, or well reduced by fallowing, the seed should be ploughed in, or the land allowed to lie some time after it is ploughed before the wheat be sown. By this the land acquires a degree of firmness before the harrows go upon it, and the feet of the cattle are prevented from pressing the seed too deep into it.

Wheat-land should be ploughed so as to raise the ridges higher in the crown than is necessary on other occasions, in order to prevent it from being damaged by water: If the ridges are made narrower than ordinary, the same end will be served, because the water finds its way more easily to the furrows. Hence the old practice in Scotland, of cleaving for pease, and gathering for wheat, was well founded.

When the wheat is sown, and the land harrowed, the field should be carefully water-furrowed; and if there be ridges at the ends for the ploughs to turn upon in ploughing, a water-furrow should likewise be drawn betwixt them and the ridges, and the communication betwixt these and the furrows opened up.

*Of the Culture of Rye.*

RYE is a winter-grain, and thrives very well on land that is improper for wheat. As there is hardly a good market for this grain in Scotland, it is but little cultivated. In some places, the land is prepared for it by a fallow, and good crops are reaped in this way. It may be sown in October, November, or early in the spring. It may be sown after pease or barley; but it is improper to sow it after wheat or oats, as this would encourage the growth of root-weeds, and greatly exhaust the land.

Rye is sometimes sown as a grass-feed. If it be sown with this view in September, upon a well-prepared fallow, it will afford good feeding for sheep in March and April; and after it is cut down, the land may be ploughed, and sown with barley. This practice, however, will not answer in wet land.

*Of the Culture of Barley.*

THERE are four kinds of barley used in Scotland, the common barley, the Lincolnshire barley, the Highland barley, more commonly called *rough bear*, and the *Thanes*.

These different kinds are sown at different seasons. The Lincolnshire barley may be sown any time during the winter, or in the spring; the common barley and *Thanes* may be sown in April, the beginning of May, or even later; and the *rough bear* may be sown in May, or the beginning of June: but the precise time of sowing must be determined by the weather and the situation of the land. When the season is favourable, the land free from weeds, and not too wet, Lincolnshire barley may be sown in February, and the other kinds sooner than the periods above mentioned.

When barley is sown in winter, or early in the spring, the land ought to be ploughed some time before; but when sown late in the spring, or in the beginning of summer, it ought to be sown immediately after it is ploughed. In winter, or early in the spring, land is in no danger of becoming too dry; but in summer, land is very liable to become too dry for the purposes of vegetation. The farmer should therefore endeavour to have all his seed sown before the season be too far advanced.

The quantity of barley sown on an acre is from two to four firlots. When the land is clean and rich, two firlots are sufficient; but when it is infested with weeds, a larger quantity is necessary.

Barley has tender roots, and is not able to push them far in quest of food; it is therefore necessary to bring land defined for barley into good tilth, and to enrich it either by manures or frequent ploughings. Barley is often sown upon land that has been fallowed, or after a crop of pease. In some places it is sown after a crop of oats; and sometimes it is repeated for two or three years successively upon the same land.

When barley is to be sown upon fallow, in stiff land not much infested with annual weeds, it should be dressed in November in the same manner as for wheat; so that Lincolnshire barley may be sown, if the winter be favour-

able, or spring barley upon the winter-furrow, if the season proves unfavourable. But when barley is to be sown after wheat, pease, or oats, the land should be ploughed as soon after harvest as possible, and laid up in such a manner as to be best exposed to the air and frost, and to secure it against damage from rain. To answer these purposes, barley-land is sometimes ribbed at this season: But ribbing turns only a small quantity of the soil; and therefore it is better to gather it into narrow ridges of four or six furrows each, and to make proper drains for carrying off the water. As the first ploughing for barley-land is designed to cover the stubble, increase the vegetable food, and keep the land dry, it need not be very deep, but ought to be as broad as possible, provided it be clean ploughed.

If it be proposed to dung barley-land, the dung may be laid on during the winter-frost, and ploughed in as soon as the land is in proper condition. When the dunging is delayed till immediately before the last ploughing, or seed-furrow, the land, especially if it be of a stiff nature, is in danger of being battered so as to rise in large clods when ploughed.

In steering, the ploughing should be as deep as the plough can go, and the soil allows: For by deep ploughing at this season, part of the earth that has been exposed to the air through the winter, and part of it turned up by the ordinary ploughing, are mixed together for the nourishment of the crop. In steering, the furrows should not be so broad as in the former ploughing; on the contrary, the narrower they are the better. Cross-ploughing is very proper at this season, if the land be so dry as to allow it.

After steering, the land should be well harrowed. It makes the weeds spring, retains the sap, and, if the land be tolerably dry, takes out the roots of the quickening-grass. But, if the land be in no danger of losing the sap, the harrowing may be delayed for some time after it is ploughed; for by this method a greater number of weeds are destroyed.

Though, in general, frequent ploughings are beneficial, yet ploughing when the land is wet is destructive. When the spring is wet, the barley-land in many places is not in a proper condition to be sown. In this case, the steering-furrow must be omitted, and the land should get the seed-furrow as soon as it is in a proper condition.

When barley is to be sown a second time upon the same land, without any other crop intervening, two ploughings are sufficient.

As our summers in Scotland are sometimes very wet, barley-land should be water-furrowed, and dressed up in the same manner as wheat-land.

*Of the Culture of Oats.*

THE oat is a very hardy plant, and its roots are strong, which enables it to procure food where many other plants would starve; and hence the practice of giving less culture to oats than to any other grain.

There are three kinds of oats used in Scotland, the white, the black, and the grey. The white is the most common,

common, and used in all the low countries; the black is the hardiest, and is used in the cold hilly countries; and the grey is often sown with success upon light gravel or sand. The white is again divided into two kinds, called *cold seed* and *hot seed*. There is scarcely any difference in appearance betwixt these; but the hot seed ripens eight or ten days before the cold. Experience must determine which of them ought to be chosen for seed.

Though the oat be a hardy plant, and does not easily degenerate, yet the changing of seed is universally allowed to be a good practice. This change should always be made from a warm soil to a cold, and from a cold to a warm.

Oats are often sown upon grass-ground newly broken up, or, which is the same thing, upon lee once ploughed. They are likewise often sown after barley, sometimes after wheat, sometimes upon fallow, and sometimes they are repeated for several years successively upon the same land.

In ploughing lea for oats, when the land is soft and mellow, the plough should go as shallow as possible; and the carth of the furrows should be set upon its edges, to allow the harrows to have the greater impression in tearing it. But when the land is stiff, or the turf very tough, it is necessary to plough deeper, and to turn the turf fully over, so that the harrows may raise a kind of mold upon its back to fill up the hollows, and to nourish the seeds. When oats are to be sown upon lee, the land ought to be ploughed early in winter, that it may receive the greater benefit from the air and frost.

It is usual to lime lea-ground intended for oats. This is a very good custom; for lime promotes the corruption of the grass-roots, by which the land is sooner reduced. It is likewise common to spread the lime upon the sward some time before the land is ploughed: This is also very proper; for the lime is intangled in the sward, and is not so apt to penetrate too deep.

Oats are generally sown after barley; and the land is ploughed as soon as the wheat-seed is made, and the barley-land has got the first furrow. The stiff land, and land in danger of being damaged by wetness, should be first ploughed, to give the one the benefit of the winter-frost, and to put the other out of danger. It is likewise an advantage to light and dry land to be ploughed early in the season, as it makes the stubble rot sooner, and exposes the soil longer to the air.

It was formerly observed, that oats are sometimes sown upon fallow. In the hilly countries, they often follow the land that has been in lea for some years; and they find that this practice does better than giving it only one ploughing in the winter before the seed is sown. In the low countries, this practice of fallowing for oats is found to succeed very well. The fallow for oats should be managed through the summer in the same manner as if for barley or wheat. Before winter, it ought to get the last furrow, and be laid up in proper ridges, to preserve it dry during the winter.

Oats may be sown in any of the winter-months, or in the month of March. Some people have sown oats so early as the beginning of November, and have had good crops. But, if the land be properly laid up in

winter, it is better to delay the sowing till March.

The quantity of oats generally sown upon an acre, is from four to five firlots; and should always get a dry bed.

### *Of the Culture of Pease.*

The pea is a grain very different from any of those already mentioned. A crop of it is not so valuable, though it is much used in some places for bread.

The straw of pease is reckoned better for feeding horses than the straw of any other grain. A crop of pease does not require such a quantity of nourishment as a crop of any of the other grains mentioned above. When the crop is good, the straw covers the ground, and destroys all the small weeds by depriving them of a free communication with the air. Pease likewise minutely divide the particles of the soil; besides, they push their roots much deeper than any of the white grains, and extract part of their nourishment from below the reach of the plough.

There are two kinds of pease cultivated in Scotland, the white and the grey. The white is most common, and consists generally of a mixture of several kinds. All of these kinds seem to be species of the pea cultivated in our gardens. The grey pea seems to be a species of the vetch or tare. This is the hardiest plant of the two, and thrives on soils where the white pea does not succeed.

The straw of the grey pease, and the pease themselves, are better for horses than those of the white. The farmer should therefore cultivate this pea where the other does not thrive, although the value of the grain be inferior.

The white pea, like the oats, is divided into hot seed and cold seed. The sowing of the hot seed may be delayed three weeks after the cold seed is sown, and yet the pease will come as soon to maturity.

The time of sowing is from the first of February to the end of April. The early sown pease have the best chance to produce a crop of corn, and the late sown to produce a crop of straw. However, when the land is clean and in good heart, the pease may be sown early; because, on such land, a good crop both of corn and straw may be expected. But if the land be foul or wet, the sowing of pease should be delayed as long as possible; because on such land the crop is more precarious, and the failing of a crop of pease gives such encouragement to weeds, as to endanger the following crops likewise. In such a case, to prevent the bad consequences that may follow, the crop should be ploughed in; for when a bad crop of pease is allowed to stand, it does more harm to the land than all the value of the crop.

The quantity of pease sown upon an acre, is from 4 to 5 firlots. If the intention of sowing pease be to obtain straw, and enrich the land, they should be thick sown; because in that case they have a better chance to destroy the weeds, and to cover the surface. But when the principal design is to have a crop of corn, they should be thinner sown; for, when thin sown, they have more air, and fill better.

Pease are commonly sown after oats or barley, and sometimes

sometimes after wheat. Seldom more than one ploughing is given to pease, and they are usually sown immediately after it. The reason of this practice is, that the feed may be better covered; for the sooner that any grain is sown after ploughing, it is always the deeper covered. If rain falls soon after pease are sown, it makes them swell and come above ground, and then they are in danger of splitting, and of being destroyed by vermin.

Sometimes pease are sown and ploughed in. This answers very well in light land, particularly after a crop of barley, the culture of which opens the soil.

Land designed for pease is generally cloven. This is a good practice when the ridges are steep, as all of them were formerly. As wheat or barley are commonly sown after pease, the land must be ploughed before winter. Gathering is the most proper way of ploughing before winter, and this follows best after cleaving. But if the ridges be not high, casting is the best method of ploughing for pease; or, if the ridges be flat and narrow, the land may be ploughed in the ordinary way, reversing the former ploughing, and turning the furrows into the crowns. Though pease are generally the lowest-priced grain, yet sometimes they rise to a great price, when the prices of other grains are moderate. This makes the sowing of feed an article of great importance. By sowing in drills, one firlot will serve for an acre as completely as four in the broad cast-way: But the advantages of drilling fall to be considered afterwards.

### *Of the Culture of Beans.*

WHAT has been said with regard to the culture of pease, may be applied to beans. However, it is necessary to observe, that the bean pushes its roots further down than the pea; and therefore requires a deeper soil. The lands in Scotland, where beans are most commonly sown, and where they succeed best, are deep and wet clays.

In some lands, the crops of beans are very great, and almost as valuable as any grain. There is no crop succeeds better in the drill-husbandry than a crop of beans.

### *Of the Culture of Rye-grass.*

RYE-GRASS is the most common of all the artificial grasses cultivated in Scotland, and not the least valuable. It is a fibrous-rooted plant, and binds the soil; this circumstance has led many to think, that it greatly impoverishes land. However, the culture of this grass is attended with several peculiar advantages. It destroys weeds, particularly the quickening-grass, and grows upon soils which will not answer for any of the other artificial grasses. A shallow, wet, spongy soil, or one which has a mixture of mofs in it, is unfit for clover of every kind; but experience shows, that rye-grass, when unmixed with clover, will succeed upon any of these soils.

Rye-grass is usually sown along with a crop of barley or oats. When sown along with barley, the field should be rolled, or well harrowed, to preserve the sap at the dry season of the barley-feed. This precaution is not

so necessary, when the rye-grass is sown along with oats; because the land on which oats are sown is generally firmer, the sowing season is earlier, and consequently not so liable to be too dry.

This grass seldom hurts the crop of corn. On the contrary, when the soil is loose and open, it makes it firm, and prevents the corn from lodging.

Though the common method is to sow rye-grass with corn, yet, when the land is poor, it is better to sow it by itself, and still better to summer-fallow, and sow it in autumn. But, as the land by fallowing is made open and loose, and as the ploughing and sowing are near the rainy season, cattle ought not to be allowed to pasture upon it during the winter, except in the time of hard frost. Even when sown in the spring, the farmer should not allow much pasturing on it, especially in wet weather. But, if sown by itself, cattle may safely pasture upon it in the winter, as the roots, having nothing to obstruct their progress, penetrate deeper, and spread wider, than when any other grain grows along with it. This practice, however, can only be followed with safety in very clean land; otherwise weeds are apt to rise along with it, and prevent the surface from being covered; which, of course will keep the soil open.

Rye-grass is sometimes sown for hay, and sometimes for pasture. When for hay, from two to four firlots are commonly sown upon an acre.

Rye-grass rises very early in the spring, and, if the soil be dry and warm, affords good pasture all the winter. It is very hardy, stands the frost, and, if continued in pasture, does not wear out in many years. The best way of managing it is, to eat it down in the spring and beginning of summer, and then to let it rest till autumn. When allowed to get up in summer, it runs to seed, and becomes disagreeable to the cattle. Besides, by this method of managing rye-grass, a good crop may be expected in autumn.

When properly managed, rye-grass makes very good hay; and there is such a demand for the seed, that the farmer is often tempted to let it stand till the seed is perfected, and then to thresh it. When this is done, the hay can never be good; because the sap is exhausted, the stalk becomes dry and withered, and affords little nourishment to cattle. The hay ought therefore to be always cut before the seed ripens. This practice not only makes the best hay, but is likewise of great advantage to the land; for, when plants are allowed to perfect their seeds, the land is much more exhausted, than when they are cut before that period.

### *Of the Culture of Clover.*

THOUGH clover be used for the same purposes as rye-grass, it is, however, a plant of a very different nature. It has a large tap-root, which penetrates the soil perpendicularly downward, and opens the earth and makes it free: The roots of clover cannot penetrate the soil, unless it be free and open. Hence, a dry, open, deep soil, free from quicken-grass, is the most proper for this plant.

There are several kinds of clover cultivated in Scotland,

land, distinguished by the colour of their flowers, viz. the red, the white, and the yellow. The red is the largest plant, has the strongest stalk, and broadest leaves. The yellow sometimes grows tall, but the stalk is small. The white is the smallest plant, and is sometimes called *pop-clover*, from the resemblance its flowers bears to those of the pop.

Both the seasons and methods of sowing clover are various. Most of the English writers recommend the autumn. It has frequently been tried, at this season, in Scotland without success. When sown in spring, it answers much better in this country.

The common way of sowing clover, both in Scotland and England, is along with wheat, oats, or barley, in the spring. This method is sometimes attended with disadvantages. The clover sometimes hurts the corn, and the corn the clover. However, these disadvantages are probably more than over-balanced by the corn's protecting the clover from drought when very young, which it is much exposed to, especially when sown in the spring.

As the lodging of corn destroys all plants that are below; to prevent this, the corn sown along with clover ought to be sown thin, and the land made very clean of weeds.

Sometimes, in a wet season, the clover gets a-top of the corn, and destroys the crop. This seldom happens when it is sown with barley or wheat; because it is much later in the season when sown with barley than when sown with oats, and therefore is not so far advanced at harvest; and the wheat is advanced so far before the clover-feed is sown, that the clover can never get the better of it. To prevent the clover, then, from hurting the corn, it may be sown early in the season with wheat, or late in the season with barley. The Thanet barley, from the strength of its roots and stalk, is not so apt to lodge as the common barley; and, of course, it is the most proper kind to be sown along with clover. But, as all kinds of barley are more apt to lodge than oats, and as the season for sowing oats is more proper for sowing clover than the season of sowing barley, the farmer, when it is equally convenient for him, should prefer the sowing of clover with oats.

When clover is sown with barley or oats, after these grains are sown, and the land harrowed, the clover-feed is thin sown, and then the land is again harrowed or rolled. When the clover is sown with a crop of wheat, the clover is sown in the spring, and afterwards the wheat is rolled. It is common to sow clover-feed without any preparation given to the land; but it is better to harrow it before sowing. The harrowing does no harm to the wheat, and it makes the roller cover the feed more effectually. Clover-feed may be sown in the same manner amongst oats or early-sown barley. Some time after the corn has come up, the land may be harrowed, and the clover sown. If the weather be dry, the different parts of the operation should succeed one another as quickly as possible. The harrows should be immediately followed by the fower, and the fower by the roller, to prevent the drought from penetrating too deep.

The English writers differ widely as to the quantity of clover-feed proper to be sown on an acre. However,

the farmers in Scotland, who sow clover with oats or barley, find, that from 10 to 16 lb. of red, or from 12 to 18 lb. of white clover on the acre, produces a very good crop.

Clover, like rye-grass, is sometimes sown for hay, sometimes for pasture, and sometimes for both. The red clover is the most proper for hay, the white for pasture; and, when both are intended, a mixture of the two answers best. When red clover is sown without being mixed with any other kind, the farmer ought to bring his land into tillage again in two or three years: For, after the second year, a crop of this kind of clover is of little value.

When white clover is sown by itself, the farmer must not expect a crop of hay; for it seldom rises to such a height as to produce a good crop: But, to balance this, the field may be kept long in pasture, as this clover continues till worn out by the natural grass of the soil.

When a mixture of the two are sown, some crops of hay may be taken, and then the land may be allowed to lie some years longer for pasture. The red clover affords the crops of hay; and the white remains till the natural grass rises. In this case, there is commonly sown upon the acre, from 8 to 12 lb. of red clover, and from 6 to 8 of white. But these proportions may be varied according to the judgment of the farmer.

In Scotland, seldom more than one crop of hay in the season succeeds. The second crop is commonly so late, that it is very difficult to get the hay properly made. It may therefore be pastured on, or cut green for cattle. When clover is cut green for cattle, it is a proper way to feed them upon a field that needs dung. This method is preferable to feeding them in stalls; it saves the expence of carrying out the dung, and procures to the land the benefit of the urine, which is a very rich manure.

Before concluding this article, it must be observed, that red clover, while green, is dangerous to black cattle and sheep, when first given them, especially if wet with dew or rain. They ought therefore to be allowed it only sparingly at first, and brought to it by degrees. After being accustomed to it for a few days, the danger is over, and they may be allowed to use as much of it as they please.

### *Of the Culture of Clover mixed with Rye-grass.*

RED clover makes the best green forage for cattle. An acre of it will maintain more cattle than three or four acres of common grass: But then it is not so proper for hay. Clover-hay is very troublesome in making, and is not reckoned so good for feeding as some other kinds of hay. It likewise hurts the land, by encouraging the growth of quickening-grass. To remedy these disadvantages, it is common to sow rye-grass along with it. Clover, when mixed with rye-grass, is easier made into hay; the hay itself is much better; and the rye-grass, by covering the surface, prevents the growth of the quickening-grass. The quantity sown upon the acre in this way is from 8 to 12 lb. of clover, and from 1 to 3 firlots of rye-grass.

*Of the Culture of St-Foin.*

THE writers on agriculture reckon this grass preferable to clover in many respects: They say, that it produces a larger crop; that it does not hurt cattle when eaten green; that it makes better hay; and that it continues four times longer in the ground; and that it will grow on land that will bear no other crop. These are great advantages: But, as we have so little of that kind of grass in Scotland, it cannot be expected that any directions can be given concerning the manner of cultivating it, founded upon experience. We must therefore confine ourselves to such facts as are mentioned by authors of the best credit.

St-foin has a very long tap-root, which is able to pierce very hard earth. The roots grow very large, and the larger they are, they penetrate to the greater depth; and hence it may be concluded, that this grass, when it thrives well, receives a great part of its nourishment from below the *staple* of the soil: of course, a deep dry soil is best for the culture of St-foin. When plants draw their nourishment from that part of the soil that is near the surface, it is not of much consequence whether their number be great or small. But the case is very different when the plants receive their food, not only near, but also deep below the surface. Besides, plants that shoot their roots deep are often supplied with moisture, when those near the surface are parched with drought.

To render the plants of St-foin vigorous, it is necessary that they be sown thin. The best method of doing this is by a drill; because, when sown in this manner, not only the weeds, but also the supernumerary plants, can easily be removed. It is several years before St-foin comes to its full strength; and the number of plants sufficient to stock a field, while in this imperfect state, will make but a poor crop for the first year or two. It is therefore necessary that it be sown in such a manner as to make it easy to take up plants in such numbers, and in such order, as always to leave in the field the proper number in their proper places. This can only be done with propriety, by sowing the plants in rows by a drill. Supposing a field to be drilled in rows at ten inches distance, the partitions may be hand-hoed, and the rows dressed in such a manner as to leave a proper number of plants. In this situation the field may remain two years; then one fourth of the rows may be taken out in pairs, in such a manner as to make the beds of fifty inches, with six rows in each, and intervals of thirty inches, which may be ploughed. Next year, another fourth of the rows may be taken out in the same manner, so as to leave double rows with partitions of ten inches, and intervals of thirty: All of which may be hoed at once or alternately, as it may be found most convenient.

The great quantity of this grass which the writers on this subject assure us may be raised upon an acre, and the excellency and great value of the hay made of it, should induce farmers to make a complete trial of it, and even to use the spade in place of the hoe, or hoe-plough, if necessary.

The plants taken up from a field of St-foin may be set

in another field; and if the transplanting of this grass succeeds as well as the transplanting of lucern has done with Mr Lunin de Chateauvieux, the trouble and expence will be sufficiently recompensed by the largeness of the crops. In transplanting, it is necessary to cut off great part of the long tap-root: this will prevent it from striking very deep into the soil, and make it push out large roots in a sloping direction from the cut end of the tap-root. St-foin managed in this manner, will thrive even on shallow land that has a wet bottom, provided it be not overstocked with plants.

Whoever inclines to try the culture of this grass in Scotland, should take great pains in preparing the land, and making it as free from weeds as possible.

*Of the Culture of Lucern.*

THE writers on agriculture, ancient as well as modern, bestow the highest encomiums upon this grass, as affording excellent hay, and producing very large crops. Lucern remains at least ten or twelve years in the ground, and produces about eight tons of hay upon the Scots acre. There is but little of it cultivated in Scotland. However, it has been tried in several parts of this country; and it is found, that, when the seed is good, it comes up very well, and stands the winter-frost. But the chief thing that prevented this grass from being more used in this country, is the difficulty of keeping the soil open, and free from weeds. In a few years the surface becomes so hard, and the turf so strong, that it destroys the lucern before the plants have arrived at their greatest perfection: so that we cannot hope to cultivate lucern with success, unless we fall upon some method of destroying the natural grass, and prevent the surface from becoming hard and impenetrable. This cannot be done effectually by any other means than horse-hoeing. This method was first proposed by Mr Tull, and afterwards practised successfully by M. de Chateauvieux near Geneva. It may be of use therefore to give a view of that gentleman's method of cultivating lucern.

He does not mention any thing particular as to the manner of preparing the land; but only observes in general, that no pains should be spared in preparing it. He tried the sowing of lucern both in rows upon the beds where it was intended to stand, and likewise the sowing it in a nursery, and afterwards transplanting it into the beds prepared for it. He prefers transplanting; because, when transplanted, part of the tap-root is cut off, and the plant shoots out a number of lateral branches from the cut part of the root, which makes it spread its roots nearer the surface, and consequently renders it more easily cultivated: besides, this circumstance adapts it to a shallow soil, in which, if left in its natural state, it would not grow.

The transplanting of lucern is attended with many advantages. The land may be prepared in the summer for receiving the plants from the nursery in autumn; by which means the field must be in a much better situation than if the seed had been sown upon it in the spring. By transplanting, the rows can be made more regular, and the intended distances more exactly observed; and consequently

quently the hoeing can be performed more perfectly, and with less expence. M. Chateauxieux likewise tried the lucern in single beds three feet wide, with single rows; in beds three feet nine inches wide, with double rows; and in beds four feet three inches wide, with triple rows. The plants in the single rows were six inches asunder, and those in the double and triple rows were about eight or nine inches. In a course of three years he found, that a single row produced more than a triple row of the same length. The plants of lucern, when cultivated by transplantation, should be at least six inches asunder, to allow them room for extending their crowns.

He further observes, that the beds or ridges ought to be raised in the middle; that a small trench, two or three inches deep, should be drawn in the middle; and that the plants ought to be set in this trench, covered with earth up to the neck. He says, that if the lucern be sown in spring, and in a warm soil, it will be ready for transplanting in September; that, if the weather be too hot and dry, the transplanting should be delayed till October; and that, if the weather be unfavourable during both these months, this operation must be delayed till spring. He further directs, that the plants should be carefully taken out of the nursery, so as not to damage the roots; that the roots be left only about six or seven inches long; that the green tops be cut off within about two inches of the crown; that they be put into water as soon as taken up, there to remain till they are planted; and that they should be planted with a planting-flick, in the same manner as cabbages.

He does not give particular directions as to the times of horse-hoeing; but only says in general, that the intervals should be stirred once in the month during the whole time that the lucern is in a growing state. He likewise observes, that great care ought to be taken not to suffer any weeds to grow among the plants, at least for the first two or three years; and for this purpose, that the rows, as well as the edges of the intervals where the plough cannot go, should be weeded by the hand.

### *Of the Culture of Potatoes.*

THE potatoe is one of the most useful roots that are cultivated in this country, and is raised in a very different manner from any of the other roots. It has a number of eyes in it, each of which produce a separate plant. The largest potatoes are the best for feed; because, when cut according to the eyes, and properly sown, the plants are not in danger of crowding each other. The plant sends out roots in every direction to a considerable distance, and upon these the potatoes are formed.

There are several kinds both of the white and red potatoes. They succeed best in a light dry soil; and though there be but a small mixture of loam in it, if tolerably rich and properly cultivated, it seldom fails to produce a good crop. But a good crop is not to be expected from a stiff wet soil, unless it be laid up in ridges so as to make it dry, and a considerable quantity of dung laid on to render it open.

When the crop of potatoes is the chief point in view,

the land should have a ploughing before winter, especially if the soil be not very free and open. If dung be necessary, the proper time for laying it on is before this ploughing. When the potatoes are to be planted, which may be done any time in March or beginning of April, the land must again be ploughed in narrow furrows, and the potatoes dropped into every second furrow. But if the land be open and very loose, they may be dropped into every furrow; and as the plough opens the furrow for the second row, it buries the first row at a proper depth. The furrow should not be very deep; and two horses are sufficient. It is better in this case to make the horses go a-breast than in a line; because, as one of them only goes in the furrow, the potatoes are not so liable to be hurt or displaced. This method of planting them by the plough is greatly preferable to the *dibble* or planting-flick.

When a small quantity is intended to be cultivated, they may be planted with the spade. A small cross-trench or furrow should be opened with the spade at the end of the ridge. Into this furrow drop the potatoes at proper distances; and, in making the next furrow, the roots laid in the first will be covered in the same manner as is done by the plough.

According to the distance of the rows made by the plough, the distance of the plants in the rows should be regulated: One plant in a square foot is sufficient to allow them to be properly hoed. When planted in every second furrow ploughed narrow, the rows will be about 12 or 14 inches asunder. The plants may be placed at the same distance in the rows.

It is unnecessary to harrow the land after the potatoes are planted: This operation may be delayed till the weeds appear, which gives the farmer an opportunity of destroying them without any additional labour. Tho' potatoes be planted early in the spring, or even before winter, they do not come up till May. Before that time the weeds are far advanced; and, if they be not destroyed by the harrows, the land must be hoed. Indeed, the goodness of the crop depends so much upon preventing the weeds from coming to any height, that it is necessary to hoe potatoes frequently. If the rows be wide, a kind of breast-hoe may be used to throw the earth a little on each side, by which it will be raised about the plants.

When two or three plants are in one piece, as often happens in light land, they should be cleaned with the hand at the root, and only one stalk left to each plant. This not only gives air to the roots, but also prevents much of the nourishment from going into the stalks.

When the hulk that contains the feed, or the *apple*, as it is commonly called, is completely formed, the stalks may be cut down and given to cows. Milk-cows have been tried with this food; they eat it very freely, and it gives no bad flavour to the milk.

The time of taking up potatoes is commonly regulated by the market. But, if nothing be in view but the largeness of the crop, they ought to stand till October, or as long as they can be conveniently taken up before the frost sets in. The most expeditious method of taking them up is by the plough: Eight or nine persons to attend

attend the plough are sufficient. After the field is once ploughed, it ought to be harrowed, by which some of the potatoes will be raised; and, when these are gathered, it should be ploughed a second time.

### Of the Culture of Turnips.

TURNIPS have been long cultivated in England, and, in some places, are esteemed one of the most valuable crops that can be raised. The trials made in Scotland have been very successful, which gives great encouragement to proceed.

The goodness of the crop depends more on the openness of the soil than its richness. Land newly broke up is particularly proper for turnips. Though this kind of land be naturally poor, yet, with the assistance of a little dung, it seldom fails to produce an excellent crop. The land intended for turnips should be ploughed and laid up in ridges before winter, that it may have the benefit of the frost. This winter-ploughing, however, is unnecessary when the land is dry and light: The spring is early enough for this kind of land. It may get a second ploughing in the end of May, and a third in the middle or end of June, when the seed is to be sown. Though three ploughings are here mentioned, no particular number is intended; for the land ought to be ploughed over and over, till it be thoroughly pulverised. If dung be used, it should be well rotted, and laid on before the last ploughing.

Turnip-feed is usually sown by the hand; and about half a pound is sufficient for an acre. It should be mixed with sand, that it may be scattered the more equally. But sowing by a drill is better than sowing by the hand, as, in this way, the plants can be more easily hoed, and thinned. Turnips should be hoed as soon as the plants can be easily distinguished; for they grow quickly, and, if they meet with any obstruction from weeds, they are apt to become sickly; and, when this happens, they can never be recovered so as to produce a good crop.

Turnips may be cultivated with great success by the new husbandry. They have been tried in single, double, and triple rows, and, in alleys, from four to six feet wide, according to the situation of the land. The poorer the land is, or the more difficult to be reduced, the alleys ought to be the wider. After the ridges are formed, the turnip should be drilled upon the crowns; and, as soon as they come up, and are past all danger from the fly, they should be horse-hoed.

The turnip is proper food, either for sheep or black cattle. When the land is dry and needs manure, the sheep may be folded on it: But the fold must be removed every day; for it is improper to allow them to eat more at once than they can consume in that time. When the land is wet, or very rich, the turnip may be pulled, and the sheep fed with them on another field that needs manure. But, when designed for black cattle, they must be pulled up and given them, either in stalls or in another field, as the farmer shall find most convenient.

### Of the Culture of Carrot.

THE carrot is but rarely cultivated in our fields: Indeed, the present market does not encourage the cultivation of this plant. But they have lately been found to be excellent food for horses; they eat them greedily, and are well fed by them. Carrots are not difficult to raise; a very small field is sufficient, and the trial may easily be made by any farmer, at a very small expence.

The best crops of carrots, in our gardens, are produced by trenching. When the soil is hard below, though it be well dunged, it does not produce a good crop. Whenever the roots reach the hard soil, they become forked, *i. e.* the roots divide, which prevents them from growing large. Trenching makes the earth deep, and, by throwing what was on the surface into the bottom of the trench, lays good soil below for the roots to extend themselves into. Something like this must be done in our fields before we can expect a good crop.

M. de Chateauxvieux tried to raise a crop of carrots by the horse-hoeing husbandry, and was very successful. He sowed them in beds six feet broad, on the 4th of May. He stirred the alleys with the spade on the 15th and 27th of July, and a third time on the 6th of September. They were dug up on the 8th of November, measured from 18 to 25 inches in length, and from two to four in diameter, and weighed from 25 to 33 ounces.

Land that has a hard bottom of clay or till is improper; and it is vain to expect that such land can be prepared for carrots by the plough, without great trouble and expence. But, when land has a soft bottom, a good crop of carrots may be raised at a small expence by horse-hoeing.

As the seed, in this country, must be sown in March, the land should get a ploughing before winter, and be laid out in beds or ridges of the breadth proposed when the carrots are to be sown; the furrows betwixt these ridges should be made as deep as possible, because it is upon these furrows that the rows of carrots are to be sown. A second ploughing in winter should reverse the first, and turn the furrows into crowns; and, before the carrots are sown, one bout of the plough may raise the crown of the ridge still higher. Upon these crowns the seed must be sown out of the hand, into a small trench, drawn as straight as possible, and covered with a rake.

When the weeds first appear, the remaining part of the ridges may be ploughed out, turning the earth to the rows, and taking care not to go so near as to cover the plants. Before the seed is sown, which is some time in March, instead of ploughing the whole ridge, the plough should only go once about on the crown, to prevent the bad effects of too much moisture.

As soon as the plants can be easily distinguished, they should be hand-hoed, and thinned where they stand too thick; and after this the alleys must be regularly hoed, as directed in the culture of turnips.

It is natural to expect, that carrots raised in this way should be freer from worms, and much better every way,

way, than those raised in our gardens, except such as are sown upon newly trenched ground.

## SECT. VI. PRINCIPLES AND ADVANTAGES OF THE NEW HUSBANDRY.

THE general principles of the new husbandry may be reduced to two, *viz.* the promoting the growth of plants by hoeing, and the sowing of seed; both of which are equally profitable to the farmer.

But, before illustrating these principles and advantages, it will be necessary to describe the instruments that are commonly used in cultivating land by this new method.

Plate IX. fig. 1. is a marking plough. The principal use of this plough is to straighten and regulate the ridges. The first line is traced by the eye, by means of three poles, placed in a straight line. The plough draws the first furrow in the direction of this line; and, at the same time, with the tooth A, fixed in the block of wood near the end of the cross-poll or slider B B, marks the breadth of the ridge at the distance intended. The ploughman next traces the second line or rutt made by the tooth, and draws a small furrow along it; and continues in this manner till the whole field is laid out in straight and equidistant ridges.

—Fig. 2. is a plough for breaking up lee, or turning up the bottom of land when greatly exhausted. By its construction, the width and depth of the furrows can be regulated to a greater certainty than by any other hitherto known in this country. Its appearance is heavy; but two horses are sufficient to plough with it in ordinary free land; and only four are necessary in the stiffest clay-foils. This plough is likewise easily held and tempered. A, is the sword fixed in the sizers B, which runs thro' a mortise at the end of the beam E, and regulates the depth of the furrow, by raising or depressing the beam; it is fixed by putting the pin D, through the beam and sword, and is moveable at E.

—Fig. 3. is a jointed break harrow with 24 teeth shaped like coulters, and standing at about an angle of 80 degrees. By this instrument the land is finely pulverised, and prepared for receiving the seed from the drill. It requires four horses in stiff, and two in open land. This harrow is likewise used for levelling the ridges; this is done by pressing it down by the handles where the ridge is high, and raising it up when low.

—Fig. 4. is an angular weeding harrow, which may follow the break when necessary. The seven hindmost teeth should stand at a more acute angle than the rest, in order to collect the weeds, which the holder can drop at pleasure, by raising the hinder part, which is fixed to the body of the harrow by two joints.

—Fig. 5. is a pair of harrows with shafts. This harrow is used for covering the seed in the drills, the horse going in the furrow.

—Fig. 6. is a drill-plough, constructed in such a manner as to sow at once two rows of beans, pease, or wheat.

This machine is easily wrought by two horses. A, is the harrow for containing the seed; B, circular boxes for receiving the seed from the harrow; C C, two square boxes which receive the seed from small holes in the circular boxes, as they turn round; and last of all, the seed is dropped into the drills through holes in the square boxes, behind the coulters D. The cylinder E follows, which, together with the wheel F, regulates the depth of the coulters, and covers the feed; the harrow G comes behind all, and covers the feed more completely. H H, two sliders, which, when drawn out, prevent the feed from falling into the boxes; and, I, is a ketch which holds the rungs, and prevents the boxes from turning, and losing seed at the ends of the ridges.

—Fig. 7. is a single hoe-plough of a very simple construction, by which the earth, in the intervals, is stirred and laid up, on both sides, to the roots of the plants, and, at the same time, the weeds are destroyed. A A the mold-boards, which may be raised or depressed at pleasure, according as the farmer wants to throw the earth higher or lower upon the roots.

### Advantages of Horse-hoeing.

THE advantages of tillage before sowing have already been pointed out. In this place we must confine ourselves to the utility of tillage after sowing. This kind of tillage is most generally known by the name of *horse-hoeing*.

Land sowed with wheat, however well it may be cultivated in autumn, sinks in the winter; the particles get nearer together, and the weeds rise; so that in spring, the land is nearly in the same situation as if it never had been ploughed. This, however, is the season when it should branch and grow with most vigour; and consequently stands most in need of ploughing or hoeing, to destroy the weeds, to supply the roots with fresh earth, and, by dividing anew the particles of the soil, to allow the roots to extend and collect nourishment.

It is well known, that, in gardens, plants grow with double vigour after being hoed or transplanted. If plants growing in arable land could be managed with ease and safety in this manner, it is natural to expect, that their growth would be promoted accordingly. Experience shows, that this is not only practicable, but attended with many advantages.

In the operation of hoeing wheat, though some of the roots be moved or broke, the plants receive no injury; for this very circumstance makes them send forth a greater number of roots than formerly, which enlarge their pasture, and consequently augment their growth.

Sickly wheat has often recovered its vigour after a good hoeing, especially when performed in weather not very hot or dry.

Wheat, and such grain as is sown before winter, requires hoeing more than oats, barley, or other grain sown in the spring; for, if the land has been well ploughed before the sowing of spring-corn, it neither has time to harden nor to produce many weeds, not having been exposed to the winter's snow and rain.

*Fig. 1.*

*Fig. 2.*

*Fig. 3.*

*Fig. 4.*

*Fig. 5.*

*Fig. 6.*

*Fig. 7.*

*Of Sowing.*

As, in the practice of the new husbandry, plants grow with greater vigour than by the old method, the land should be sowed thinner. It is this principle of the new husbandry that has been chiefly objected to; for, upon observing the land occupied by a small number of plants, people are apt to look upon all the vacant space as lost. But this prejudice will soon be removed, when it is considered, that, in the best land cultivated in the common method, and sown very thick, each seed produces but one or two ears; that, in the same land sown thinner, every seed produces two or three ears; and that a single seed sometimes produces eighteen or twenty ears.

In the common method, as there are many more plants than can find sufficient nourishment, and as it is impossible to assist them by hoeing, numbers die before they attain maturity, the greatest part remain sickly and drooping; and thus part of the seed is lost. On the contrary, in the new method, all the plants have as much food as they require; and as they are, from time to time, assisted by hoeing, they become so vigorous as to equal in their production the numerous, but sickly plants cultivated in the common method.

*Of Hoeing.*

THE new husbandry is absolutely impracticable in lands that are not easily ploughed. Attempting to cultivate land according to this husbandry, without attending to this circumstance, that it is practicable in no land, excepting such as have already been brought into good tilth by the old method, has gone far to make it contemptible in many places.

When a field is in good tilth, it should be sown so thin as to leave sufficient room for the plants to extend their roots. After being well ploughed and harrowed, it must be divided into rows, at the distance of 30 inches from one another. On the sides of each of these rows, two rows of wheat must be sowed six inches distant from each other. By this means there will be an interval of two feet wide betwixt the rows, and every plant will have room enough to extend its roots, and to supply it with food. The intervals will likewise be sufficient for allowing the earth to be hoed or tilled without injuring the plants in the rows.

The first hoeing, which should be given before the winter, is intended to drain away the wet, and to dispose the earth to be mellowed by the frosts. These two ends will be answered by drawing two small furrows at a little distance from the rows, and throwing the earth taken from the furrows into the middle of the intervals. This first hoeing should be given when the wheat is in leaf.

The second hoeing, which is intended to make the plants branch, should be given after the hard frosts are over. To do this with advantage, after stirring the earth a little, near the rows, the earth which was thrown in the middle of the intervals should be turned back into the furrows. This earth, having been mellowed by the

winter, supplies the plants with excellent food, and makes the roots extend.

The third hoeing, which is intended to invigorate the stalk, should be given when the ears of the corn begin to shew themselves. This hoeing may, however, be very slight.

But the last hoeing is of the greatest importance, as it enlarges the grain, and makes the ears fill at their extremities. This hoeing should be given when the wheat is in bloom; a furrow must be drawn in the middle of the interval, and the earth thrown to the right and left on the foot of the plants. This supports the plants, prevents them from being laid, and prepares the ground for the next sowing, as the seed is then to be put in the middle of the ground that formed the intervals.

By this successive tillage, or hoeing, good crops will be obtained, provided the weather is not very unfavourable.

But as strong, vigorous plants are longer before they arrive at maturity, corn raised in the new way is later in ripening than any other, and must therefore be sown earlier.

In order to prepare the intervals for sowing again, some well-rotted dung may be laid in the deep furrows made in the middle of the intervals; and this dung must be covered with the earth that was before thrown towards the rows of wheat. But, if the land does not require mending, the deep furrow is filled without any dung. This operation should be performed immediately after harvest, that there may be time to give the land a slight stirring before the rows are sowed; which should occupy the middle of the space which formed the intervals during the last crop. The intervals of the second year take up the space occupied by the stubble of the first.

Supposing dung to be necessary, which is denied by many, a very small quantity is sufficient; a single layer, put in the bottom of each furrow, will be enough.

*Summary of the Operations necessary in executing the New Husbandry with the Plough.*

1. It is indispensibly necessary that the farmer be provided with a drill and hoe-plough.
2. The new husbandry may be begun either with the winter or spring corn.
3. The land must be prepared by four good ploughings, given at different times, from the beginning of April to the middle of September.
4. These ploughings must be done in dry weather, to prevent the earth from kneading.
5. The land must be harrowed in the same manner as if it were sowed in the common way.
6. The rows of wheat should be sowed very straight.
7. When the field is not very large, a line must be strained across it, by which a rill may be traced with a hoe for the horse that draws the drill to go in; and, when the rows are sown, fifty inches must be left betwixt each rill. But, when the field is large, stakes at five feet distance from each other, must be placed at the two ends. The workman must then trace a small furrow,

with a plough that has no mold-board, for the horse to go in that draws the drill, directing himself with his eye by the flukes.

8. The sowing should be finished about the end of September, or beginning of October.

9. The furrows must be traced the long way of the land, that as little ground as possible may be lost in head-lands.

10. The rows, if it can be done, should run down the slope of the land, that the water may get the easier off.

11. The seed-wheat must be plunged into a tub of lime-water, and stirred, that the light corn may come to the surface and be skimmed off.

12. The seed must next be spread on a floor, and frequently stirred, till it is dry enough to run through the valves of the happer of the drill.

13. To prevent smut, the seed may be put into a lye of ashes and lime.

14. After the happers of the drill are filled, the horse must go slowly along the furrow that was traced. That a proper quantity of seed may be sown, the aperture of the happer must be suited to the size of the grain.

15. As the drill is seldom well managed at first, the field should be examined after the corn has come up, and the deficiencies supplied.

16. Stiff lands that retain the wet, must be stirred or hoed in October. This should be done by opening a furrow in the middle of the intervals, and afterwards filling it up by a furrow drawn on each side, which will raise the earth in the middle of the intervals, and leave two small furrows next the rows, for draining off the water, which is very hurtful to wheat in winter.

17. The next stirring must be given about the end of March, with a light plough. In this stirring, the furrows made to drain the rows must be filled up by earth from the middle of the intervals.

18. Some time in May, the rows must be evened, which, though troublesome at first, soon becomes easy, as the weeds are soon kept under by tillage.

19. In June, just before the wheat is in bloom, another stirring must be given with the plough. A deep furrow must be made in the middle of the intervals, and the earth thrown upon the sides of the rows.

20. When the wheat is ripe, particular care must be taken in reaping it, to trample as little as possible on the ploughed land.

21. Soon after the wheat is carried off the field, the intervals must be turned up with the plough, to prepare them for the seed. The great furrow in the middle must not only be filled, but the earth raised as much as possible in the middle of the intervals.

22. In September, the land must be again sowed with a drill, as above directed.

23. In October, the stubble must be turned in for forming the new intervals; and the same management must be observed as directed in the first year.

We pretend not to determine whether the old or new husbandry be preferable in every country.

With regard to this point, the climate, the situation of particular land, skill and dexterity in managing the machinery, the comparative expence in raising crops, and many other circumstances, must be accurately attended to before a determination can be given. One observation, however, may be made in favour of the new husbandry:—Though the particular modes of cultivating land by it are perhaps too limited to be universally adopted; yet it has been of great use in raising suspicions concerning the old method, and in turning the views of philosophers and farmers towards improving in general. Many real improvements in agriculture have been the consequences of these suspicions; and as this spirit of inquiry remains in full vigour, particularly in our own country, a solid foundation is laid for expecting still further improvements in this useful art.

## A G R

AGRIFOLIUM, in botany. See AQUIFOLIUM.

AGRIMONY, in botany, a genus of the dodecandria digynia class. There are three species of this genus, viz. the eupatoria, repens, and agrimonoides; of which the eupatoria only is a native of Britain. The calix of the eupatoria is quinque-dentate; it has five petals, and two seeds in the bottom of the calix. It is said to be good in obstructions of the liver, &c.

AGRIMONOIDES, in botany, the trivial name of a species of the agrimonia.

AGRIMONY. See AGRIMONIA.

Hemp AGRIMONY. See EUPATORIUM.

Water-hemp AGRIMONY. See BIDENS.

AGRIOCINARA, in botany. See CINARA.

AGRIPPA, in midwifery, a term applied to children brought forth with their feet foremost. See MIDWIFERY.

## A G R

AGRIUM, in nat. hist. See NATRUM.

AGROM, the name of a disease incident to the inhabitants of the East-Indies, by which their tongues chape and cleave in different places.

AGROPOLI, a small town in the kingdom of Naples, and province of the Hither Principato.

AGROSTEMMA, or COCKLE, in botany, a genus of the decandria pentagynia class. The calix is monophyllous; the petals are five, and unguled; and the capsule one-valved. There are four species of the agrostemma, viz. the githago, a native of Britain; the coslirofa, a native of Sicily; the coronaria, a native of Italy; and the flos Jovis, a native of Switzerland.

AGROSTIS, bent-grass, in botany, a genus of the triandria digynia class. The calix has two valves, terminated by a beard or awn. There are fifteen species of the agrostis, eight of which are natives of Britain.

AGROS-

- AGROSTOGRAPHIA**, signifies the history or description of grasses.
- AGRYPNIA**, a term with physicians for an inaptitude, or for wanting to sleep.
- AGUALVA**, in geography, the name of a river of Portugal, and of a town in the island of Terceira.
- AGUAPECACA**, in ornithology, a barbarous name of a species of the tetrao. See **TETRAO**.
- AGUARA-QUIYA**, in botany, a barbarous name of the solanum. See **SOLANUM**.
- AGUARA-PONDA**, in botany, a barbarous name of a species of the viola. See **VIOLA**.
- AGUARICO**, a river of S. America, which, arising in the mountains of Cordelera, falls into the river of the Amazons.
- AGUBER**, a river of Africa, in the kingdom of Fez, which loses itself in the Beber. See **BEBER**.
- AGUE**, a general name for all kinds of periodical fevers. See **MEDICINE**, title, *Of agues or intermittents*.
- AGUE-tres**, in botany. See **SASSAFRAS**.
- AGUPERSE**, a town of France, situated in the Lyonnais, about fifteen miles north of Clermont.
- AGUER**, the name of Santa-croix, before it fell into the hands of the Portuguese.
- AGUGLIA**, a name used by some travellers for the obelisks of Egypt. See **OBELISK**.
- AGUIGAN**, one of the Marian islands. See **MARIAN islands**.
- AGUILAR**, a town of Spain, in the province of Navarre, about twenty-four miles west of Estella.
- AGUILAR Del Campo**, a town of Old Castile, with the title of marquise, about fifteen leagues north of the city of Burgos.
- AGUL**, in botany, a synonyme of the hedyfaryum. See **HEDYSARUM**.
- AGURAH**, in Jewish antiquity, the name of a silver coin, otherwise called *gerah*, and *kesbita*.
- AGURANDE**, a fortified town of France, in the country of Berry, about four leagues south of Chartres.
- AGUSADURA**, **AGUSAGE**, in our old customs, a certain fee paid by vassals to their lord, for the sharpening of their plough-tackle.
- AGUTI**, in zoology, the trivial name of a species of the mouse, belonging to the mammalia glires of Linnæus. See **MUS**.
- AGUTI-GUEPA**, in botany. See **SAGITTARIUM**.
- AGUTI-TREVA**, in botany, a barbarous name of a species of the citrus. See **CITRUS**.
- AGUTIGVEPO-OBI**, in botany, a synonyme of the thalia. See **THALIA**.
- AGUZ**, a river of Africa, in the empire of Morocco, and province of Duquela.
- AGWANA**, a kingdom of Africa, upon the golden coast, lying northwards of Aquemboe.
- AGYEI**, in antiquity, a kind of obelisks, sacred to Apollo, erected in the vestibles of houses, by way of security.
- AGYNIANI**, in church-history, a sect of heretics who condemned all carnal commerce with women.
- AGYRTÆ**, in Grecian antiquity, a kind of strolling vagabonds, not unlike our modern gypsies.
- AHETULLA**, the trivial name of a species of the coluber, belonging to the order of amphibia serpentes. See **COLUBER**.
- AHALOTH**. See **XYLO-ALOES**.
- AHANIGER**, in zoology. See **ACUS**.
- AHAUSEN**, in geography, the same with Ahuys. See **AHUYS**.
- AHICCYATLI**, in zoology, the Indian name of a serpent resembling the rattle-snake, only it wants the rattles. See **COLUBER**.
- AHMELLA**, in botany. See **BIDENS**.
- AHOUI**, in botany, a synonyme, and also the trivial name of a species of the cerbera. See **CERBERA**.
- AHRENSBOECK**, a fortress of Holstein, on the road from Lubec to Kiel.
- AHUAS**, a considerable town and district of Persia, in the province of Khurestan or Chusistan.
- AHUN**, a town of France, in the higher Marche, situated upon the river Creufe.
- AHUS**, a town of Germany, in the bishoprick of Munster, capital of a considerable district.
- AHUYS**, a sea-port town of Sweden, in the province of Gothland, situated in 32. 14. E. long. and 56. 0. N. lat.
- AIA**, the name of a small river of Italy, which falls into the Tiber, near the village Magliano.
- AIAIA**, in ornithology, a species of the platelea, a bird of the order of grallæ. See **PLATALEA**.
- AJAJOUNI**, the name given by the Turks to a town of Lesser Asia, otherwise called *Hagia*.
- AJAN**, or **AYAN**, the name of a large maritime country of Africa, lying southwards of the mouth of the Red-sea, the natives of which are white.
- AJANTIA**, in antiquity, an annual festival celebrated in the island of Salamis in honour of Ajax.
- AJASALOUÉ**, the modern name by which the Turks call Ephesus. See **EPHESUS**.
- AJAX**, in Grecian antiquity, a kind of dance representing the madness of Ajax after his defeat by Ulysses.
- AJAZZO**, the name of two towns, the one in the island of Corfica; and the other in Lesser Asia, about fifty miles west of Aleppo.
- AICHMALOTARCHA**. See the article **ÆCHMALOTARCHA**.
- AICHSTAT**, a city of Germany in the circle of Franconia, about fourteen miles N. W. of Ingolstat.
- AID**, in a general sense, denotes any kind of assistance given by one person to another.
- AID**, or **AYDE**, in law, denotes a petition made in court to call in help from another person who has interest in land, or any other thing contested.
- AID-de-camp**, in military affairs, an officer employed to receive and carry the orders of a general.
- AID-major**, the French term for an adjutant. See the article **ADJUTANT**.
- AID**, *auxilium*, in ancient customs, a subsidy paid by vassals to their lord on certain occasions.
- Such were the aid of relief, paid upon the death of the Lord Mesne to his heir; the *aid chevau*, or capital

- pical aid, due to the chief lord on several occasions, as, to make his eldest for a knight, to make up a portion for marrying his daughter, &c.
- Royal Aid**, an appellation sometimes given to the land-tax.
- AIDS**, in the French customs, certain duties paid on all goods exported or imported into that kingdom.
- Court of Aids**, in France, a sovereign court established in several cities, which has cognizance of all causes relating to the taxes, gabels, and aids.
- AIDS**, in the menage, are the same with what some writers call *cherishings*, and used to avoid the necessity of corrections.
- The inner heel, inner leg, inner rein, &c. are called *inner aids*; as the outer heel, outer leg, outer rein, &c. are called *outer aids*.
- AIDS of officers of wood**. See **ASSIZER**.
- AIDNELLI**, or **AIDIN-ILI**, the modern or Turkish name of Natolia, or Lesser Asia. See **NATOLIA**.
- AIELO**, or **AIELLO**, a small town of the kingdom of Naples, in the Farther Abruzzo, with the title of *Duchy*.
- AIGHENDALE**, the name of a liquid measure used in Lancashire, containing seven quarts.
- AIGITHALUS**, in ornithology, an obsolete name of the parus or titmouse. See **PARUS**.
- AIGLE**, in geography, the name of a town of France, in the Higher Normandy; also of a promontory in Provence, lying southward of the city of Ciotad; and of a town and district of Switzerland, in the canton of Bern.
- AIGRE**, a river of France, otherwise called *Egre*. See the article **EGRE**.
- AIGLETTE**, in heraldry. See **EAGLET**.
- AIGRETTA**, in ornithology, an obsolete name of the ardea alba. See **ARDEA**.
- AIGRE-marine**. See **AQUA marina**.
- AIGUILLON**, or **EGUILLON**, a small town of France, in the province of Guienne, situated at the conflux of the rivers Garonne and Lot.
- AIGUISCE**, **AIGUISSE**, or **EGUISCE**, in heraldry, denotes a cross with its four ends sharpened, but so as to terminate in obtuse angles.
- It differs from the cross fitchee, in as much as the latter tapers by degrees to a point, and the former only at the ends.
- AILE**, or **AIEL**, in law, a writ which lies where a person's grandfather, or great-grandfather, being seized of lands, &c. in fee simple the day that he died, and a stranger abates or enters the same day, and dispossesses the heir of his inheritance.
- AILESBUURY**, the county town of Buckinghamshire, situated near the Thames, about forty-four miles W. of London. It sends two members to parliament, and gives the title of *earl* to the noble family of Bruce. W. long. 16. 55. N. lat. 51. 40.
- AIMARGUES**, a small town of France, in the province of Languedoc, and diocese of Nîmes.
- AIN**, a river of France, which, after watering part of Franche Comte and Bresse, falls into the Rhone, about four leagues above Lyons.
- AIPIMIXIRA**, in ichthyology, the American name of a fish called *puđano*.
- AIR**, a thin transparent fluid which encompasses the globe of the earth to a considerable height. For the weight, pressure, elasticity, &c. of air, see **PNEUMATICS**.
- AIR**, in medicine, one of the six non-naturals, and as essential to the life of animals as food, or any of the ordinary evacuations.
- AIR**, in mythology, was adored by the heathens under the names of Jupiter and Juno; the former representing the superior and finer part of the atmosphere, and the latter the inferior and grosser part. The augurs also drew presages from the clouds, thunder, lightning, &c.
- AIR**, in painting, &c. denotes the manner and very life of action; or it is that which expresses the disposition of the agent.
- It is sometimes also used in a somewhat synonymous sense with gesture or attitude.
- AIR**, in music, denotes the melody proper for songs, odes, and the like; being usually quick and lively.
- Sometimes it is used for the songs themselves, called by the Romans *aera*, from which the modern term *air* is derived.
- AIRS**, in the menage, are the artificial motions of taught horses, as the demivolt, curvet, capriole, &c. See **DEMIVOLT**, &c.
- AIR-bladder**, a vesicle in the bodies of most fishes, by which, being filled with air, they are enabled to sink or raise themselves in the water, by compressing or expanding the air contained in this bag, and thereby rendering their bodies at pleasure specifically heavier or lighter than water.
- AIR-gun**, a machine for exploding balls by means of condensed air. See **PNEUMATICS**.
- AIR pump**, a machine by which the air contained in a proper vessel may be exhausted, or drawn out. See **PNEUMATICS**.
- AIR-shafts**, among miners, are holes made to meet the adits, and supply them with fresh air. These, when the adits are long, or exceeding thirty or forty fathom, become highly necessary, as well to give vent to the damps and noxious vapours, as to let in fresh air.
- AIR-threads**. See **GOSAMER**.
- AIR-vessels**, are spiral ducts in the leaves, &c. of plants, supposed to be analogous to the lungs of animals, in supplying the different parts of a plant with air.
- AIRA**, in botany, a genus of the triandria digynia class. There are 14 species of the aira, nine of which are natives of Britain. The English name is *hair-grass*.
- AIREBA**, in ichthyology, a synonyme of the raja pastinaca. See **PASTINACA**.
- AIRANI**, in church-history, a branch of Arians, who, beside the common dogma of that sect, denied the consubstantiality of the Holy Ghost with the Father and Son.
- AIRE**, in geography, a sea-port town in Scotland, situated in 4. 40. W. long. and 55. 30. N. lat. at the

- the mouth of a river of the same name, which discharges itself into the frith of Clyde. Aire is the chief town of the county, and very ancient. About a mile north from the town, there is a lazar-house, commonly called *the King's chapel*, which King Robert de Bruce set apart for the maintenance of lepers.
- AIRE**, is also the name of two towns of France, the one situated in the province of Gascony, about sixty-five miles S. of Bourdeaux; and the other in Artois, about thirty-five miles S. E. of Calais.
- AIRESHIRE**, a county of Scotland, the capital of which is the town of Aire. It lies eastward of the frith of Clyde.
- AIRING**, a term peculiarly used for the exercising horses in the open air.
- AIRON**, a river of France in the Nivernois.
- AIRONO**, a town of Italy, in the duchy of Milan.
- AIROU**, a river of France in the province of Normandy.
- AIRY**, or **AERY**, among sportsmen, a term expressing the nest of a hawk or eagle.
- AIRY triplicity**, among astrologers, denotes the three signs, gemini, libra, and aquarius.
- AISE**, in geography. See **AISNE**.
- AISIAMENTA**, in law, the same with easement. See **EASEMENT**.
- AISNE**, or **AISE**, a river of France which rises on the frontiers of Lorraine, near Clermont, and falls into the Ouse, a little below Soissons.
- AITOCZU**, a considerable river of Lesser Asia, which, arising in the mountain Taurus, falls into the fourth part of the Euxine sea.
- AJUGA**, in botany, a genus of the didynamia gymnospermia class. There are four species of the ajuga, of which the reptans or bugle, and the pyramidalis or mountain bugle, are natives of Britain.
- AJURU-catinga**, in ornithology, the Indian name of a species of the pittaacus or parrot. See **PSITTACUS**.
- AJURU-curau**, in ornithology, the Indian name of two species of Brazilian parrots, beautifully variegated with blue, green, red, yellow, and black.
- AJURU-para**, another parrot resembling the ajuru-catinga, but smaller.
- AJUTAGE**, or **ADJUTAGE**, a kind of tube fitted to the mouth of the vessel through which the water of a fountain is to be played. To the different form and structure of ajutages, is owing the great variety of fountains. See **FOUNTAIN**.
- AIX**, in geography, the name of several places, *viz.* of a large city of France, the capital of Provence; of a small town of Savoy, about eight miles N. of Chambery; of an island on the coast of Gascony, between that of Oleron and the main-land; and of a village of Champagne, situated in the generality of Chalons.
- AIX-LA-CHAPELLE**, otherwise called *Aach*, *Ach*, and *Ahen*, an imperial city of Germany, in the duchy of Juliers. It is large and populous; being much resorted to by foreigners, as well as by the Germans, on account of its hot baths.
- AIZOON**, in botany, a genus of the icofandria pentandria class. The cup is divided into five parts; the flowers consists of one leaf; the capsule or seed-vessel
- has five cells; and the flower-cup rests on the top of the fruit. There are three species of the aizoon, *viz.* the canariense, the hispanicum, and the paniculatum, which last is a native of Africa. This plant resembles the sedum or house-leek.
- AKISSAR**, or **AK-HISSAR**, a town of Lesser Asia, situated upon the river Hermus.
- AKOND**, in the Persian affairs, the chief judge in all cases of contracts and other civil affairs. He is at the head of the lawyers, and has his deputies in all courts of the kingdom.
- AKROCZIM**, a town of Poland, with a castle of considerable strength, situated in the Palatinate of Masovia.
- AKSTADT**, in geography. See the article **AICHSTAT**.
- AL**, an Arabic particle prefixed to words, and signifying much the same with the English particle *the*: Thus they say, alkermes, alkoran, &c. *i. e.* the kermes, the koran, &c.
- AL**, or **ALD**, a Saxon term frequently prefixed to the names of places, denoting their antiquity, as Aldborough, Aldgate, &c.
- ALA**, a Latin term properly signifying a wing; from a resemblance to which several other things are called by the same name: Thus,
- ALA**, in botany, is used in different senses; sometimes it denotes the hollow between the stalk of a plant and the leaves; sometimes it is applied to the two side-petals of the papilionaceous flowers; others use it for the slender membranaceous expansions found in the stems of plants, thence denominated *alated stalks*.
- ALA**, in botany, an obsolete name of the helenium. See **HELENIUM**.
- ALÆ**, in anatomy, a term applied to the lobes of the liver, the cartilages of the nostril, &c.
- ALÆ**, in the Roman art of war, were the two wings or extreme parts of the army drawn up in order of battle.
- ALABA**, in geography, the name of a kingdom of Africa, dependent on the empire of Abyssinia, or Ethiopia, the capital of which is called by the same name.
- ALABASTER**, in natural history, a genus of fossils resembling marble, which are bright, brittle, and do not give fire with steel; they ferment with acids, and readily calcine with heat. There are three species of alabaster; 1. The snow-white shining alabaster, or lydium of the ancients, is found in Taurus in pieces large enough to make dishes, or the like. It cuts very freely, and is capable of a fine polish. 2. The yellowish alabaster, or phengites of Pliny, is found in Greece, and is of a soft loose open texture, pretty heavy, and nearly of the colour of honey. This species has likewise been found in Germany, France, and in Derbyshire in England. 3. Variegated, yellow, and reddish alabaster. This species is the common alabaster of the ancients, and is so soft that it may be cut with a knife: It is remarkably bright, and almost transparent; admits of a fine polish, and consists of large angular sparry concretions. It is not proof against water; it ferments violently with aqua-fortis, and

- burns to a pale yellow. The colour of this species is a clear pale yellow resembling amber, and variegated with undulated veins; some of which are pale red, others whitish, and others of a pale brown. It was formerly brought from Egypt, but is now to be met with in several parts of England. The alabasters are frequently used by statuaries for small statues, vases, and columns. After being calcined and mixed with water, they may be cast in any mould like plaster of Paris.
- ALABASTER**, in antiquity, a term not only used for a box of precious ointment; but also for a liquid measure, containing ten ounces of wine, or nine of oil.
- ALABASTRA**, in botany, a name used by the ancients for the calix or cup of flowers.
- ALABASTRUM dendroide**, a kind of laminated alabaster, beautifully variegated with the figures of shrubs, trees, &c.
- ALADINISTS**, a sect among the Mahometans, answering to free-thinkers among us.
- ALADULIA**, in geography, the most easterly division of Lesser Asia, comprehending the ancient Cappadocia, and Armenia Minor.
- ALAGON**, a small town of Spain, in the kingdom of Arragon, situated near the conflux of the river Xalon with the Ebro.
- ALAIS**, a considerable town of France, in the province of Languedoc, situated on the river Gardon, at the foot of the Cevennes.
- ALAISEE**, in heraldry, the same with humetty. See **HUMETTY**.
- ALALCOMENIUS**, in Grecian antiquity, the Boeotian name of the month called, by the Athenians, *Μεμακτηριον*. See **ΜΕΜΑΚΤΗΡΙΟΝ**.
- ALAMIRE**, or **A-LA-MI-RE**, among musicians, a note of the modern scale of music. See **SCALE**.
- ALAMODALITY**, in a general sense, is the accommodating a person's behaviour, dress, and actions to the prevailing taste of the country or times in which he lives.
- ALAMODE**, in commerce, a thin glossy black silk, chiefly used for womens hoods, and mens mourning scarfs.
- ALAN**, a small river of England in the county of Cornwall, which falls into the Bristol channel.
- ALAN**, is also a small town of France, with a very fine castle, situated in the eastern division of Gascony.
- ALANA gelba**, a name by which some writers call the yellowish tripoli. See **TRIPOLI**.
- ALAND**, or **ALANDT**, an island of the Baltic sea, situated between 18. and 20. degrees of long. and between 59. and 61. degrees of lat.
- ALANQUER**, or **ALENCUER**, a town of Portugal, in the province of Estremadura, and about seven leagues from Lisbon.
- ALANORARIUS**, in our old customs, was a keeper of spaniels, setting-dogs, &c. for the use of sportsmen. The word is derived from *alan*, a gothic term for a grey-hound.
- ALANTEJO**, in geography. See the article **ALENTEJO**.
- ALAPOULI**, in botany, an obsolete name of a species of the *averrhoa*. See **AVERRHOA**.
- ALAUCECA**, a stone brought from the E. Indies in small glossy fragments, said to stop hæmorrhages by external application.
- ALARAF**, among Mahometans, denotes the partition-wall which separates heaven from hell.
- ALARBES**, or **ALARABES**, a name given to those Arabians who live in tents, and distinguish themselves by their dress from the others who live in towns.
- ALARES**, in Roman antiquity, an epithet given to the cavalry, on account of their being placed in the two wings of the army.
- ALARES musculi**. See **PTERYGOIDEUS**.
- ALARM**, in the military art, denotes either the apprehension of being suddenly attacked, or the notice thereof, signified by firing a cannon, firelock, or the like. False alarms are frequently made use of to harrafs the enemy, by keeping them constantly under arms. Sometimes also this method is taken to try the vigilance of the picket-guard, and what might be expected from them in case of real danger.
- ALARM-bell**, that rung upon any sudden emergency, as a fire, mutiny, or the like.
- ALARM-post**, or **ALARM-place**, the ground for drawing up each regiment in case of an alarm. This is otherwise called the *rendezvous*.
- ALARM**, in fencing, is the same with what is otherwise called an *appel*, or challenge. See **CHALLENGE**.
- ALATAMAHA**, a large river of N. America, which, rising in the Apalachian mountains, runs south-east through the province of Georgia, and falls into the Atlantic ocean, below the town of Frederica.
- ALATED animals**, such as are furnished with wings.
- ALATED leaves**, in botany, such as are composed of several pinnated ones. See **PINNATED**.
- ALATERNOIDES**, in botany, a synonyme of a species of the *myrica*. See **MYRICA**.
- ALATERNUS**, in botany, the trivial name of a species of the *rhamnus*. See **RHAMNUS**.
- ALATRI**, or **ALATRO**, a town of Italy in the Campagna di Roma, situated near the frontiers of Naples.
- ALAVA**, or **ALABRO**, in geography, a territory of Spain, being the south-east division of the province of Biscay.
- ALAUUDA**, or **LARK**, in ornithology, a genus of birds of the order of passeres; the characters of which are these: The beak is cylindrical, subulated, strait; and the two mandibles or chaps are of equal size. The tongue is bifid, and the hinder claw is straight, and longer than the toe. There are nine species of the *alauuda*. 1. *Alauuda-arvensis*, or common sky-lark, which rises in the air almost perpendicularly, and begins to sing early in the spring, and generally leaves off about midsummer. See Plate III. fig. 2. 2. *Alauuda-pratenfis*, or tit-lark, has the two outward feathers of the wing edged with white, and frequents the meadows. 3. The *arborea*, or wood-lark, is a native of Europe, and is distinguished by an annular white fillet about the head. 4. The *campeltris*, has one half of its chief feathers of the wings brown, except

- except two in the middle which are white, and the throat and breast are yellowish. 5. The *trivialis*, whose chief feathers on the tail are brown, only half of the outermost is white, and the second is white at the end, in the shape of a wedge; there is likewise a double whitish line on the wings. It is a native of Sweden, and perches on the tops of trees. 6. The *crifata*; the chief tail-feathers are black, but the two outermost are edged with white, and the head is crested. It is a native of Europe. 7. The *spinolera*, the chief tail-feathers are black, only the outermost two are obliquely half white. It is a native of Italy. 8. The *alpestris*; the chief wing-feathers are half white, the throat yellow, and it has a black streak under the eyes and on the breast. It is a native of N. America. 9. The *magna*, is yellow on the belly, with a crooked black streak on the breast, and the three side-feathers of the tail white. It is a native of Africa and America.
- ALAUDA marina**, (flint, or water-ouzel, in ornithology, an obsolete name of a species of the, *sturnus*. See **STURNUS**.)
- ALAUDA**, in ichthyology, an obsolete name of a species of the blennius. See **BLENNIVS**.
- ALAUTA**, in ichthyology. See **ALOSA**.
- ALAUTA**, a considerable river of Turkey in Europe, which, after watering the north-east part of Transylvania, and part of Wallachia, falls into the Danube almost opposite to Nicopolis.
- ALB**, or **ALBE**, in the Romish church, a vestment of white linen hanging down to their feet, and answering to the surplice of our clergy. In the ancient church, it was usual, with those newly baptized, to wear an alb, or white vestment; and hence the Sunday after easter was called *dominica in albis*, on account of the albs worn by those baptized on easter-day.
- ALB** is also the name of a Turkish coin, otherwise called *asper*. See **ASPER**.
- ALBA firma**, or **ALBUM**, in our old customs, denoted rent paid in silver, and not in corn, which was called *black-mail*.
- ALBA terra**, one of the numerous names for the philosopher's stone.
- ALBAHURIM**, *figura sexdecim laterum*, a figure of great importance according to astrological physicians, who built their prognostics on it.
- ALBANENSES**, in church-history, the same with **Albigenses**. See **ALBIGENSES**.
- ALBANI**, in Roman antiquity, a college of the *salii*, or priests of Mars, so called from mount Albanus the place of their residence. See **SALII**.
- ALBANIA**, a province of Turkey in Europe, situated on the east-side of the gulph of Venice.
- ALBANO**, a town of Italy, in the Campagna di Roma, about twelve miles south-east of Rome, 13. o. E. long. 41. 35. N. lat.
- ALBANS**, or **ST ALBANS**, a town of Hertfordshire, situated about 20 miles north-west of London. It returns two members to parliament, and gives the title of *duke* to the noble family of Beauclerc, 51. 40. N. lat.
- ALBANUM**, a term used by some chemicists for salt of urine.
- ALBANY**, a town of N. America, in the province of New-York, situated on Hudson's river, in 74. o. W. long. and 43. o. N. lat.
- ALBARA**, among physicians, a malignant itch, nearly allied to the leprosy.
- ALBARAZIN**, a town of Spain, in the kingdom of Arragon, situated upon the river Guadalavir, about one hundred and ten miles east of Madrid.
- ALBARDEOLA**, in ornithology. See **PLATALEA**.
- ALBARIUM opus**, in Roman antiquity, a kind of plaster made of mere lime, used for covering the ceilings of houses.
- ALBATI equi**, an appellation given to such horses, in the games of the ancient circus, as wore white furniture, in contradistinction from the *veneti*, *prasinii*, and *ruffeti*. See **VENETI**, **PRASINI**, &c.
- ALBAZIN**, a town of Greater Tartary, with a strong castle: It is situated upon the river Amur, or Yamour, in 54. o. of N. lat. and belongs to the Muscovites.
- ALBE**, a small piece of money, current in Germany, worth only a French sol and seven deniers.
- ALBELLUS**, in ornithology, the trivial name of a species of the mergus. See **MERGUS**.
- ALBEMARLE**, a town of France, in the province of Normandy, from whence the noble family of Keppel takes the title of earl, in 2. o. E. long. 49. 45. N. lat.
- ALBEMARLE** is also the name of the most northerly district of N. Carolina. See **CAROLINA**.
- ALBENGA**, a sea-port town of Italy situated on the Mediterranean, about fifteen miles north-east of Oneglia.
- ALBERTUS**, a gold coin, worth about fourteen French livres: it was coined during the administration of Albertus archduke of Austria.
- ALBESIA**, in antiquity, a kind of shields otherwise called *decumana*. See **DECUMANA**.
- ALBICILLA**, in ornithology, the trivial name of a species of the falco. See **FALCO**.
- ALBIGENSES**, in church-history, a sect of Christians which appeared in the 12th and 13th centuries. They are ranked among the grossest heretics, the Manicheans, by Roman Catholics; from which charge Protestants generally acquit them, though with some limitation. See **MANICHEANS**.
- At the time of the Reformation, those of the **Albigenses** who remained embraced Calvinism.
- ALBIGENSES** is also a name sometimes, though improperly, used for a sect more usually known by that of *Waldenses*. See **WALDENSES**.
- ALBIGEOIS**, a small district of France in the higher Languedoc, containing the dioceses of Albi and Castres.
- ALBII**, in church-history, the same with **Albigenses**. See **ALBIGENSES**.
- ALBINOS**, the name by which the Portuguese call the white Moors, who are looked upon by the negroes as monsters. They are the issue of a white man and black woman, and at a distance might be taken for Europeans; but, when you come near them, their

- white colour appears like that of persons affected with a leprosy.
- ALBION**, the ancient name of Britain. See **BRITAIN**.
- NEW ALBION**, a name given by Sir Francis Drake to California. See **CALIFORNIA**.
- ALBLASSERWAERT**, a district of South Holland, lying eastward of Dort, between the rivers Meuse and Leck.
- ALBOGALERUS**, in Roman antiquity, a white cap worn by the *flamen dialis*, on the top of which was an ornament of olive branches.
- ALBONA**, **ALBONO**, or **ALBOGNA**, a river of Italy in the duchy of Milan, which waters the Novarese and district of Laumello.
- ALBORAK**, amongst the Mahometan writers, the beast on which Mahomet rode, in his journeys to heaven.
- ALBORAN**, a small island of Africa, lying on the coast of the kingdom of Fez.
- ALBOURG**, or **ALBURG**, a sea-port town of N. Jutland, in the kingdom of Denmark.
- ALBRET**, or **ALBRIT**, a small town of France, in the province of Gascony, about thirty-five miles S. of Bourdeaux.
- ALBUCA**, in botany, a genus of the hexandria monogynia class. There are only two species of this plant, viz. the major, with lanceolated leaves; and minor, with subulated leaves; both natives of the Cape of Good Hope.
- ALBUCUS**, in botany, an obsolete name of a species of asphodelus.
- ALBUGINEA tunica**, in anatomy, the third or innermost coat or covering of the testes; it is likewise the name given to one of the coats of the eye. See **ANATOMY**, Part VI.
- ALBUGINEUS**, in anatomy, a term sometimes applied to the aqueous humour of the eye.
- ALBUGO**, in medicine, a distemper occasioned by a white opaque spot growing on the *cornea* of the eye, and obstructing vision.
- ALBULA**, in ichthyology, the trivial name of a species of the salmo. See **SALMO**.
- ALBULA indica**, in ichthyology, an obsolete name of the salmo bimaculatus. See **SALMO**.
- ALBUM**, in antiquity, a kind of table, or register, wherein the names of certain magistrates, public transactions, &c. were entered. Of these there were various sorts; as the *album senatorum*, *album judicum*, *album pretoris*, &c.
- ALBUM**. See **ALBUMEN**, **CERUSS**.
- ALBUM gracum**, among physicians, the white dung of dogs, formerly prescribed for inflammations of the throat, &c. but now justly despised.
- ALBUM nigrum**, a term for mice-dung.
- ALBUM oculi**, the white of the eye. See **ALBUGINEA**, **ADNATA**.
- ALBUMEN**, among physicians, the white of an egg. See **EGG**.
- ALBUQUERQUE**, a city of Spain, in the kingdom of Leon and province of Estremadura, situated on the frontiers of Portugal, 7. 6. W. long. 30. 0. N. lat.
- ALBURN**, the English name of a compound colour, being a mixture of white and red, or reddish brown.
- ALBURNUM**, that part of the wood which is next the bark of trees.
- ALBURNUS**, in ichthyology, the trivial name of a species of the cyprinus. See **CYPRINUS**.
- ALBURNUS lacustris**, an obsolete name of the cyprinus ballerus. See **CYPRINUS**.
- ALBUS pisces**, an obsolete name of the cyprinus grislagine. See **CYPRINUS**.
- ALBY**, or **ALBI**, a city of France in the province of Languedoc, situated in 0. 40. E. long. and 43. 50. N. lat.
- ALCA**, in ornithology, a genus of the order of anseres. The beak of this genus is without teeth, short, convex, compressed, and frequently furrowed transversely; the inferior mandible is gibbous near the base; the feet have generally three toes. The species of the alca are six. 1. The tordo, or razor-bill, with four furrows on the bill, and a white line on each side running from the bill to the eyes. Great numbers of them hatch together in the caverns of rocks, and lay but one egg at a time. 2. The impennis, or northern penguin, with a compressed bill furrowed on each side, and an oval spot on each side of the eyes. 3. The arctica, or puffin, with a compressed bill and four furrows; the orbit of the eyes and temples are white. 4. The lomvia, or sea-hen, with a smooth oblong bill, and the upper mandible yellow on the edges. 5. The grylle, or Greenland dove, with a smooth subulated bill, and a large white spot on the belly and wings; the feet are red. 6. The alle, or black and white diver, with a smooth conical bill, a white streak on the belly and wings, and black feet. All the species of this genus frequent the northern shores of Europe.
- ALCACER de Sal**, or **ALCAREZ**, a town of Portugal in the province of Estremadura, about forty-five miles south-east of Lisbon; 9. 0. W. long. 38. 30. N. lat.
- ALCAICS**, in ancient poetry, a denomination given to several kinds of verse, from the inventor Alcaeus.
- ALCAID**, **ALCAÏDE**, or **ALCALDE**, in the polity of the Moors, Spaniards, and Portuguese, a magistrate, or officer of justice, answering nearly to the French provost, and the British justice of peace.—The alcaid among the Moors is vested with supreme jurisdiction, both in civil and criminal cases.
- ALCALA de Guadiara**, a town of Spain in the province of Andalusia, about six miles S. of Seville.
- ALCALA de Henares**, a town of Spain, in the province of New Castile, about sixteen miles E. of Madrid.
- ALCALA de Real**, a city of Spain, in the province of Andalusia, about fifteen miles north-west of the city of Granada.
- ALCALY**. See **ALKALI**.
- ALCANITZ**, a small town of Spain, in the kingdom of Arragon, situated on the river Guadaloupe.
- ALCANNA**, in commerce, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a considerable trade. It is much used by the Turkish women, to give a golden colour to their

*Fig. 1. ALCA or  
Razor bill*

*Fig. 2. ALCEDO or  
Kings Fisher*

their nails and hair. In dying, it gives a yellow colour, when steeped with common water; and a red one, when infused in vinegar. There is also an oil extracted from the berries of alcanna, and used in medicine as a calmer.

**ALCANNA.** See **ICHTHYOCOLLA.**

**ALCANTARA**, a city of Spain, in the province of Estremadura, on the frontiers of Portugal; 7. o. W. long. 39. 10. N. lat.

**Knights of Alcantara**, a military order of Spain, which took its name from the above-mentioned city.

The knights of Alcantara make a very considerable figure in the history of the expeditions against the Moors.

**ALCARAZ**, a town of Spain, in the province of New-Castile, situated on the river Guadarema; 3. o. W. long. 38. 3. N. lat.

**ALCÁZAR de Sal**, a small town of Portugal, in the province of Estremadura, near the confines of that of Alentejo.

**ALCE**, or **ALCES**, in zoology, the trivial name of a species of the cervus, belonging to the order of mammalia pecora. See **CERVUS.**

**ALCEA**, or **VERVAIN-MALLOW**, in botany, a genus of the monodelphia polyandria class. There are only two species of this genus, *viz.* the rosea and sicifolia. This genus differs little from the common mallow, either in figure or medical virtues, excepting that the leaves of the alcea are more deeply divided.

**ALCEA vesicaria**, in botany, an obsolete name of a species of the ketmia. See **KETMIA.**

**ALCEDO**, or the **KINGS-FISHER**, in ornithology, a genus of the order of picæ. The alcedo has a long, trait, thick, triangular bill; with a fleshy, plain, short, flat tongue. There are seven species of the alcedo, *viz.* 1. The ispada, or common kings-fisher, with a short tail, blue above, and yellowish below. It haunts the shores of Europe and Asia. 2. The erithaca, with a short tail, a blue back, a yellow bill, a purple head and rump, and the throat and opposite part of the neck white. It is a native of Bengal. 3. The alcyon, with a short black tail, white belly, and ferruginous breast. It is a native of America. 4. The todus, with a short green tail, a blood-coloured throat, and a white belly. It is a native of America; and is the green sparrow, or green humming-bird of Edwards. 5. The smyrnensis, with a short green tail, ferruginous wings, and green back. It is a native of Africa and Asia. 6. The rudis, with a brown short tail variegated with white. It is a native of Persia and Egypt. 7. The dea, with two very long feathers in the tail, a blackish blue body, and greenish wings. It is a native of Surinam. All the species of this genus dive in the water, and catch fish with their long beaks.

**ALCHEMILLA**, or **LADIES-MANTLE**, a genus of the tetrandria monogynia class. The leaves of this genus are serrated. The cup is divided into eight segments; the flowers are apetalous, and collected in bunches upon the tops of the stalk; the seed-capsules general-

ly contain two conic seeds in each. There are only three species of the alchemilla, *viz.* the vulgaris of the shops, which is esteemed a powerful vulnerary; the minor, or least ladies-mantle; and the alpina, or cinque-foil ladies-mantle; all of which are natives of Britain.

**ALCHEMIST**, a practitioner in alchemy. See **ALCHEMY.**

**ALCHEMY**, that branch of chemistry which had for its principal objects the transmutation of metals into gold; the panacea, or universal remedy; an alkali, or universal menstruum; an universal ferment; and many other things equally ridiculous. See **CHEMISTRY, Introduction.**

**ALCHEMY** is also sometimes used as a synonymous term for chemistry in general.

**ALCHIMILLA.** See **ALCHEMILLA.**

**ALCHIMY**, **ALCHYMY**, and **ALCHYMIST.** See **ALCHEMY**, and **ALCHEMIST.**

**ALCHITRAM**, or **ALCHITRAN**, a term among alchemists for the oil of juniper, &c.

**ALCIBIUM**, or **ALCIBIADUM**, in botany, an obsolete term of a species of echium. See **ECHIUM.**

**ALCMAER**, a town of N. Holland, remarkable for the fine pastures in its neighbourhood, and the great quantities of butter and cheese made there.

**ALCMANIAN**, in ancient lyric poetry, a kind of verse consisting of two dactyles and two trochees; as,

*Virginibus puerisque canto.*

**ALCOA arbor**, the name of a tree in St Helena, said to emulate ebony.

**ALCOBACO**, a small town of Portugal, in the province of Estremadura: It is defended by a pretty strong castle; but what makes it most remarkable, is the abbey of St Bennet, which is the burying-place of most of the kings of Portugal.

**ALCOHOL**, or **ALKOOL**, in chemistry, spirit of wine highly rectified. It is also used for any highly rectified spirit.—Alcohol is extremely light and inflammable: It is a strong antiseptic, and therefore employed to preserve animal substances. For the other qualities of alcohol, see **CHEMISTRY.**

**ALCOHOL** is also used for any fine impalpable powder.

**ALCOHOLIZATION**, among chemists, the process of rectifying any spirit. It is also used for pulverization.

**ALCOLA**, a term among chemists for the tartar of urine.

**ALCORAN**, or **ALKORAN**, the name of a book held equally sacred among the Mahometans, as the Bible is among Christians.

The word *alkoran* properly signifies *reading*; a title given it by way of eminence, just as we call the Old and New Testaments *Scriptures*. See **MAHOMETANISM.**

**ALCORAN**, in a figurative sense, is an appellation given to any books full of impostures or impiety.

**ALCORAN**, among the Persians, is also used for a narrow kind of steeple, with two or three galleries, where

the priests, called Moravites, say prayers with a loud voice.

**ALCORANISTS**, among the Mahometans, an appellation given to those who adhere closely to the alcoran as the ultimate rule of faith: Such are the Persians, in contradistinction from the Turks, Arabs, &c. who admit a multitude of traditions besides the alcoran.

**ALCOST**, an obsolete name of a species of tansey.

**ALCOVE**, among builders, a recess, or part of a chamber separated by an eltrade, or partition of columns, and other corresponding ornaments, in which is placed a bed of state, and sometimes seats to entertain company.

These alcoves are frequent in Spain, and the bed raised two or three ascents, with a rail at the foot.

**ALCOYTIN**, a small town of Portugal, in the province of Algarva, defended by one of the strongest castles in that kingdom.

**ALCYON**, the trivial name of a species of alcedo. See **ALCEDO**.

**ALCYONIUM**, in obsolete name of a submarine plant. It is also used for a kind of coral, or alstroites, frequently found fossil in England.

**ALDABARAM**, in anatomy. See **SESAMOIDEA**.

**ALDARU**, in botany, an obsolete name of a species of pistachia. See **PISTACHIA**.

**ALDBOROUGH**, a sea-port town of Suffolk, which sends two members to parliament; 1. 40. E. long. 52. 20. N. lat.

**ALDBOROUGH**, is also a market-town of Yorkshire, about fifteen miles north-west of the city of York.

**ALDEA**, a town of Portugal, in the province of Eiltramadura, about ten miles S. of Lisbon.

**ALDEBAC**, the Arabian term for bird-lime.

**ALDEBARAN**, in astronomy, a star of the first magnitude, called, in English, the bull's eye, as making the eye of the constellation Taurus.

**ALDEGO**, a river of Italy, in the territories of Venice, which loses itself in the Adige.

**ALDENAER**, a small town of Germany in the electorate of Cologne, situated on the river Aar.

**ALDENBURG**. See **ALTENBURG**.

**ALDER-tree**, in botany. See **BETULA**.

**ALDERMAN**, in the British policy, a magistrate subordinate to the lord-mayor of a city or town-corporate.

The number of these magistrates is not limited, but is more or less according to the magnitude of the place. In London they are twenty-six; each having one of the wards of the city committed to his care. This office is for life; so that when one of them dies, or resigns, a ward-mote is called, who return two persons, one of whom the lord-mayor and aldermen chuse to supply the vacancy. By the charter of the city of London, all the aldermen who have been lord-mayors, together with the three eldest ones not arrived at that dignity, are justices of the peace.

**ALDERMAN**, among our Saxon ancestors, was a degree of nobility answering to earl or count at present.

**ALDERMAN** was also used, in the time of King Edgar, for a judge or justice; in which sense Alwin is called *aldermannus totius Angliæ*.

**ALDERNEY**, or **AUVERGNI**, an island on the coast of Normandy, subject to the crown of Great Britain.

**ALDII**, an appellation given to those servants who attended their masters to the wars.

**ALDROVANDA**, in botany, a genus of the pentandria pentagynia class; or which there is but one species. The calix is divided into five parts; the petals are five; and the capsule has five valves, with ten seeds. It is a native of Italy and the Indies.

**ALE**, a fermented liquor, obtained from an infusion of malt; and differing only from beer in having a less proportion of hops. See **BREWING**.

Ale is thought to be the same kind of liquor with the cerevisia, zythum, and curmi of the ancients.

**Medicated ALES**, those wherein medicinal herbs have been infused, or put to ferment: Such are the cerevisia cephalica, cerevisia epileptica, &c.

**ALE-berry**, the popular name for ale that is boiled with bread and mace, sweetened, strained, and drunk hot.

**ALE-connor**, an officer in London who inspects the measures of public houses. They are four in number, and chosen by the common-hall of the city.

**ALE-floer**, a tax paid yearly to the lord-mayor, by all who sell ale within the city.

**Ale-measure**. See **MEASURE**.

**ALEA**, in Roman antiquity, denotes in general all manner of games of chance; but, in a more restricted sense, was used for a particular game played with dice and tables, not unlike our backgammon. See **BACKGAMMON**.

**ALEATORIUM**, a place in the ancient gymnasia, where they played at the aleæ.

**ALEC**, in ichthyology, an obsolete name a species of sparus. See **SPARUS**.

**ALECOST**. See **ALCAST**.

**ALECTORIA**, a stone said to be formed in the gall-bladders of old cocks, to which the ancients ascribed many fabulous virtues.

**ALECTORICARDITES**, the name of a stone resembling a pullet's head.

**ALECTORIUS lapis**. See **ALECTORIA**.

**ALECTOROMANTIA**, in Grecian antiquity, a species of divination performed by means of a cock, in the following manner: A circle being described on the ground, and divided into twenty-four equal portions, in each of these spaces was written one of the letters of the alphabet, and on each of the letters was laid a grain of wheat; after which a cock being turned loose in the circle, particular notice was taken of the grains picked up by the cock, because the letters under them, being formed into a word, made the answer desired.

**ALEAGAR**, or **ALEGER**, the name of a kind of vinegar made of ale instead of wine.

**ALEGRETTE**, a town of Portugal, in the province of Alentejo, situated on the river Cayz; 7. 50. W. long. 39. 0. N. lat.

**ALEIPHA**, among ancient physicians, the name of animal or vegetable oils, when used as unguents.

**ALEMBIC**, in chemistry. See **CHEMISTRY**.

**ALEMBROTH**, an obsolete name of a kind of fixed alkaline salt.

**ALENGNER**,

**ALENGNER**, a town of Portugal, in the province of Estremadura, about twenty-seven miles N. E. of Lisbon.

**ALENON salt**, an obsolete name of the oil of almonds.

**ALENTEJO**, a province of Portugal, lying southward of Tagus.

**ALENON**, a strong city of Normandy, situated under the same meridian with London, in 48. 32. N. lat.

It is the capital of the dutchy of the same name.

**ALEORE**, among ancient physicians, denoted the intervals of ease that alternately succeed acute pains.

**ALEPPO**, a large city of Asiatic Turkey, situated in E. long. 37. 4. and N. lat. 36. 30.

It is an inland town, lying almost in the middle between the river Euphrates and the Levant sea. The Christians, who are allowed the free exercise of their religion, have their houses and churches in the suburbs.

The beglerbeg of Aleppo commands the whole extent of country, between the Levant-sea and the Euphrates.

**ALERION**, or **ALLERION**, in heraldry. See **ALLERION**.

**ALESSANO**, a town of the kingdom of Naples, situated about twelve miles west of the city Otranto.

**ALESSIO**, a town of European Turkey, in the province of Albania, situated near the mouth of the river Drimo.

**ALET**, or **ALETH**, a city of France, situated in the Upper Languedoc, at the foot of the Pyrennees, about thirty-two miles south-west of Narbonne, 2. o. E. long. 43. 10. N. lat.

**ALETRIS**, in botany, a genus of the hexandria monogynia class. The corolla is tunnel-shaped, the stamina are inserted into the base of the petals; and the capsule consists of three cells. There are only three species of the aletris, *viz.* the farinosa, a native of America; the capensis, a native of the Cape of Good Hope; and the fragrans, a native of Africa. The two first are perennial plants, and the last is a fruit-bearing shrub. These are all ranked among the aloes of different authors. See **ALOE**.

**ALEUROMANCY**, a species of divination performed by means of meal or flour.

**ALEXANDERS**, in botany. See **SMYRNIUM**.

**ALEXANDRETTA**, in geography, the same with Scanderoon. See the article **SCANDEROON**.

**ALEXANDRIA**, a sea-port town of Egypt, situated in 31. 15. E. long. and 30. 40. N. lat. about fourteen miles westward of the most westerly branch of the river Nile.

**ALEXANDRIA** is also the name of a city of Italy, situated on the river Tanaro, about forty miles N. W. of Genoa, 8. 52. E. long. 44. 45. N. lat.

**ALEXANDRIAN**, or **ALEXANDRIN**, in poetry, a kind of verse, consisting of twelve, or of twelve and thirteen syllables alternately; so called from a poem on the life of Alexander, written in this kind of verse by some French poet.

Alexandrines are peculiar to modern poetry, and seem well adapted to epic poems. They are sometimes used by most nations of Europe, but chiefly by the French, whose tragedies are generally composed of Alexandrines.

**ALEXANDRINUM**, the name of a plaster described by Celsus.

**ALEXICACUS**. See **ALEXETERIAL**.

**ALEXICACUS** was also a name under which the fishermen used to invoke Neptune, to preserve their nets from being torn to pieces by the sword-fish.

**ALEXIPHARMICS**, among physicians, properly signify medicines which correct or expel poison.

**ALEXITERIAL**. See the last article.

**ALFAQUES**, among the Moors, the name generally used for their clergy, or those who teach the Mahometan religion, in opposition to the Morabites, who answer to monks among Christians.

**ALFELD**, a town of Germany, in the bishoprick of Hildesheim, and circle of Lower Saxony, situated about ten miles S. of Hildesheim, in 9. 50. E. long. and 52. o. N. lat.

**ALFET**, in our old customs, denotes a caldron full of boiling water, wherein an accused person, by way of trial or purgation, plunged his arm up to the elbow.

**ALGA**, in botany, the trivial name of the lichen, fungus, and several other plants of the cryptogamia class.

**ALGAROT**, in chemistry, an Arabic term for an emetic powder, prepared from regulus of antimony, dissolved in acids, and separated by repeated lotions in warm water.

**ALGARVA**, the most southerly province of the kingdom of Portugal.

## A L G E B R A.

**ALGEBRA** is a general method of computation by certain signs and symbols, which have been contrived for this purpose, and found convenient. It is called an **UNIVERSAL ARITHMETIC**, and proceeds by operations and rules similar to those in common arithmetic, founded upon the same principles. But as a number of symbols are admitted into this science, being

necessary for giving it that extent and generality which is its greatest excellence, the import of those symbols must be clearly stated.

In geometry, lines are represented by a line, triangles by a triangle, and other figures by a figure of the same kind: But, in algebra, quantities are represented by the same letters of the alphabet; and various signs have been

been imagined for representing their affections, relations, and dependencies.

The relation of equality is expressed by the sign  $=$ ; thus, to express that the quantity represented by  $a$  is equal to that which is represented by  $b$ , we write  $a = b$ . But if we would express that  $a$  is greater than  $b$ , we write  $a > b$ ; and if we would express algebraically that  $a$  is less than  $b$ , we write  $a < b$ .

QUANTITY is what is made up of parts, or is capable of being greater or less. It is increased by *addition*, and diminished by *subtraction*; which are therefore the two primary operations that relate to quantity. Hence it is, that any quantity may be supposed to enter into algebraic computations two different ways, which have contrary effects; either as an *increment*, or as a *decrement*; that is, as a quantity to be added, or as a quantity to be subtracted. The sign  $+$  (*plus*) is the mark of *addition*, and the sign  $-$  (*minus*) of *subtraction*. Thus the quantity being represented by  $a$ ,  $+a$  imports that  $a$  is to be added, or represents an increment; but,  $-a$  imports that  $a$  is to be subtracted, and represents a decrement. When several such quantities are joined, the signs serve to shew which are to be added and which are to be subtracted. Thus  $+a + b$  denotes the quantity that arises when  $a$  and  $b$  are both considered as increments, and therefore expresses the sum of  $a$  and  $b$ . But  $+a - b$  denotes the quantity that arises, when from the quantity  $a$  the quantity  $b$  is subtracted; and expresses the excess of  $a$  above  $b$ . When  $a$  is greater than  $b$ , then  $a - b$  is itself an increment; when  $a = b$ , then  $a - b = 0$ ; and when  $a$  is less than  $b$ , then  $a - b$  is itself a decrement.

As addition and subtraction are opposite, or an increment is opposite to a decrement, there is an analogous opposition between the affections of quantities that are considered in the mathematical sciences; as, between excess and defect; between the value of effects or money due to a man, and money due by him. When two quantities, equal in respect of magnitude, but of those opposite kinds, are joined together, and conceived to take place in the same subject, they destroy each other's effect, and their amount is *nothing*. Thus, 100 *l.* due to a man and 100 *l.* due by him balance each other, and in estimating his stock may be both neglected. When two unequal quantities of those opposite qualities are joined in the same subject, the greater prevails by their difference. And, when a greater quantity is taken from a lesser of the same kind, the remainder becomes of the opposite kind.

A quantity that is to be added is likewise called a *positive* quantity; and a quantity to be subtracted is said to be *negative*: They are equally real, but opposite to each other, so as to take away each other's effect, in any operation, when they are equal as to quantity. Thus,  $3 - 3 = 0$ , and  $a - a = 0$ . But though  $+a$  and  $-a$  are equal as to quantity, we do not suppose in algebra that  $+a = -a$ ; because, to infer equality in this science, they must not only be equal as to quantity, but of the same quality, that in every operation the one may have the same effect as the other. A decrement may be equal to an increment, but it has in all operations a contrary effect; a motion downwards may be equal to a mo-

tion upwards; and the depression of a star below the horizon may be equal to the elevation of a star above it: But those positions are opposite, and the distance of the stars is greater than if one of them was at the horizon, so as to have no elevation above it, or depression below it. It is on account of this contrariety, that a negative quantity is said to be less than nothing, because it is opposite to the positive, and diminishes it when joined to it; whereas the addition of 0 has no effect. But a negative is to be considered no less as a real quantity than the positive. Quantities that have no sign prefixed to them are understood to be positive.

The number prefixed to a letter is called the *numeral coefficient*, and shews how often the quantity represented by the letter is to be taken. Thus  $2a$  imports that the quantity represented by  $a$  is to be taken twice;  $3a$  that it is to be taken thrice; and so on. When no number is prefixed, *unit* is understood to be the coefficient. Thus  $1$  is the coefficient of  $a$  or of  $b$ .

Quantities are said to be *like* or *similar*, that are represented by the same letter or letters equally repeated. Thus  $+3a$  and  $-5a$  are like; but  $a$  and  $b$ , or  $a$  and  $aa$  are unlike.

A quantity is said to consist of as many terms as there are parts joined by the signs  $+$  or  $-$ ; thus  $a + b$  consists of two terms, and is called a *binomial*;  $a + b + c$  consists of three terms, and is called a *trinomial*. These are called *compound* quantities: A *simple* quantity consists of one term only, as  $+a$ , or  $+a + b$ , or  $+a + b + c$ .

## CHAP. I. OF ADDITION.

CASE I. To add quantities that are like, and have like signs.

RULE. Add together the coefficients, to their sum prefix the common sign, and subjoin the common letter or letters.

EXAMPLE. To  $+5a$  to  $-6b$  to  $a + b$   
 Add  $+4a$  add  $-2b$  add  $3a + 5b$   
 Sum  $+9a$  Sum  $-8b$  Sum  $4a + 6b$

CASE II. To add quantities that are like, but have unlike signs.

RULE. Subtract the lesser coefficient from the greater, prefix the sign of the greater to the remainder, and subjoin the common letter or letters.

EXAMP. To  $-4a$  |  $+5b - 6c$   
 Add  $+7a$  |  $-3b + 8c$   
 Sum  $+3a$  |  $2b + 2c$

This rule is easily deduced from the nature of positive and negative quantities.

If there are more than two quantities to be added together, first add the positive together into one sum, and then the negative (by Case I.); then add these two sums together (by Case II.)

CASE III. To add quantities that are unlike.

RULE. Set them all down one after another, with their signs and coefficients prefixed.

EXAMPLE. 
$$\begin{array}{r} \text{To } + 3a \\ \text{Add } + 3b \\ \hline \text{Sum } 2a + 3b \end{array} \quad \left| \begin{array}{r} + 3a \\ - 4x \\ \hline 3a - 4x \end{array} \right.$$

CHAP. II. OF SUBTRACTION.

GENERAL RULE. "Change the signs of the quantity to be subtracted into their contrary signs, and then add it so changed to the quantity from which it was to be subtracted, (by the rules of the last chapter): the sum arising by this addition is the remainder." For, to subtract any quantity, either positive or negative, is the same as to add the opposite kind.

EXAMP. 
$$\begin{array}{r} \text{From } + 5a \\ \text{Subtract } + 3a \\ \hline \text{Remaind. } 5a - 3a, \text{ or } 2a \end{array} \quad \left| \begin{array}{r} 8a - 7b \\ 3a + 4b \\ \hline 5a - 11b \end{array} \right.$$

It is evident, that to subtract or take away a decrement is the same as adding an equal increment. If we take away  $-b$  from  $a-b$ , there remains  $a$ ; and if we add  $+b$  to  $a-b$ , the sum is likewise  $a$ . In general, the subtraction of a negative quantity is equivalent to adding its positive value.

CHAP. III. Of MULTIPLICATION.

IN MULTIPLICATION, the general rule for the signs is, That when the signs of the factors are like, (i. e. both +; or both -), the sign of the product is +; but when the signs of the factors are unlike, the sign of the product is -.

CASE I. When any positive quantity,  $+a$ , is multiplied by any positive number,  $+n$ , the meaning is, That  $+a$  is to be taken as many times as there are units in  $n$ ; and the product is evidently  $na$ .

CASE II. When  $-a$  is multiplied by  $n$ , then  $-a$  is to be taken as often as there are units in  $n$ , and the product must be  $-na$ .

CASE III. Multiplication by a positive number implies a repeated addition: But multiplication by a negative implies a repeated subtraction. And when  $+a$  is to be multiplied by  $-n$ , the meaning is, That  $+a$  is to be subtracted as often as there are units in  $n$ : Therefore the product is negative, being  $-na$ .

CASE IV. When  $-a$  is to be multiplied by  $-n$ , then  $-a$  is to be subtracted as often as there are units in  $n$ ; but (by chap. II.) to subtract  $-a$  is equivalent to adding  $+a$ , consequently the product is  $+na$ .

The II<sup>d</sup> and IV<sup>th</sup> Cases may be illustrated in the following manner.

By the definitions,  $+a - a = 0$ ; therefore if we multiply  $+a - a$  by  $n$ , the product must vanish, or be 0, because the factor  $a - a$  is 0. The first term of the product is  $+na$  (by Case I.) Therefore the second term of the product must be  $-na$ , which destroys  $+na$ ; so that the whole product must be  $+na - na = 0$ . Therefore  $-a$  multiplied by  $+n$  gives  $-na$ .

In like manner, if we multiply  $+a - a$  by  $-n$ , the first term of the product being  $-na$ , the latter term of the product must be  $+na$ ; because the two together must destroy each other, or their amount be 0, since one of the factors (viz.  $a - a$ ) is 0. Therefore  $-a$  multiplied by  $-n$ , must give  $+na$ .

In this general doctrine, the multiplier is always considered as a number. A quantity of any kind may be multiplied by a number.

If the quantities to be multiplied are simple quantities, "find the sign of the product by the last rule; after it place the product of the coefficients, and then set down all the letters after one another as in one word."

EXAMP. 
$$\begin{array}{r} \text{Mult. } +a \\ \text{By } +b \\ \hline \text{Prod. } +ab \end{array} \quad \left| \begin{array}{r} -2a \\ +4b \\ \hline -8ab \end{array} \right. \quad \left| \begin{array}{r} 6x \\ -5a \\ \hline -30ax \end{array} \right.$$

$$\begin{array}{r} \text{Mult. } -8x \\ \text{By } -4a \\ \hline \text{Prod. } +32ax \end{array} \quad \left| \begin{array}{r} +3ab \\ -5ac \\ \hline -15aac \end{array} \right.$$

To multiply compound quantities, you must "multiply every part of the multiplicand by all the parts of the multiplier, taken one after another, and then collect all the products into one sum: That sum shall be the product required."

EXAMP. 
$$\begin{array}{r} \text{Mult. } a + b \\ \text{By } a + b \\ \hline \text{Prod. } \left\{ \begin{array}{l} a^2 + ab \\ + ab + b^2 \end{array} \right\} \left\{ \begin{array}{l} 2a - 3b \\ 4a + 5b \end{array} \right\} \left\{ \begin{array}{l} 8aa - 12ab \\ + 10ab - 15bb \end{array} \right\} \\ \hline \text{Sum } aa + 2ab + bb \quad 8aa - 2ab - 15bb \\ \text{Mult. } a + a + b + b + b \\ \text{By } a - b \\ \hline \text{Prod. } \left\{ \begin{array}{l} aaa + aab + abb \\ - aab - abb - bbb \end{array} \right\} \\ \hline \text{Sum } aaa \dots o \dots o \dots - bbb \end{array}$$

Products that arise from the multiplication of two, three, or more quantities, as  $abc$ , are said to be of two, three, or more dimensions; and those quantities are called factors or roots.

If all the factors are equal, then these products are called powers; as  $aaa$ , or  $aaa$ , are powers of  $a$ . Powers are expressed sometimes by placing above the

root, to the right hand, a figure expressing the number of factors that produce them. Thus,

$$\begin{array}{l} a \\ aa \\ aaa \\ aaaaa \end{array} \left. \begin{array}{l} \text{is called the} \\ 1^{\text{st}} \\ 2^{\text{d}} \\ 3^{\text{d}} \\ 4^{\text{th}} \\ 5^{\text{th}} \end{array} \right\} \begin{array}{l} \text{Power of the} \\ \text{root } a, \text{ and} \\ \text{is shortly} \\ \text{expressed} \\ \text{thus,} \end{array} \left\{ \begin{array}{l} a^1 \\ a^2 \\ a^3 \\ a^4 \\ a^5 \end{array} \right.$$

These figures which express the number of factors that produce powers, are called their *indices* or *exponents*; thus 2 is the index of  $a^2$ . And powers of the same root are multiplied by adding their exponents. Thus  $a^2 \times a^3 = a^5$ .  $a^4 \times a^3 = a^7$ .  $a^3 \times a = a^4$ .

Sometimes it is useful not actually to multiply compound quantities, but to set them down with the sign of multiplication ( $\times$ ) between them, drawing a line over each of the compound factors. Thus  $\overline{a + b} \times \overline{a - b}$  expresses the product of  $a + b$ , multiplied by  $a - b$ .

#### CHAP. IV. Of DIVISION.

THE same rule for the signs is to be observed in division as in multiplication; that is, "If the signs of the dividend and divisor are like, the sign of the quotient must be +; if they are unlike, the sign of the quotient must be -." This will be easily deduced from the rule in multiplication, if you consider, that the quotient must be such a quantity as, multiplied by the divisor, shall give the dividend.

The general rule in division is, "to place the dividend above a small line, and the divisor under it, expunging any letters that may be found in all the quantities of the dividend and divisor, and dividing the coefficients of all the terms by any common measure." Thus, when you divide  $10ab + 15ac$  by  $2ad$ , expunging  $a$  out of all the terms, and dividing all the coefficients by 5, the quotient is  $\frac{2b + 3c}{4d}$ ; and

$$2b) ab + bb \left( \frac{a+b}{2} \right.$$

"Powers of the same root are divided by subtracting their exponents, as they are multiplied by adding them." Thus, if you divide  $a^5$  by  $a^2$ , the quotient is  $a^{5-2}$  or  $a^3$ . And  $b^6$  divided by  $b^4$  gives  $b^{6-4}$  or  $b^2$ ; and  $a^2 b^3$  divided by  $a^2 b^3$  gives  $a^0 b^0$  for the quotient.

"If the quantity to be divided is compound, then you must range its parts according to the dimensions of some one of its letters, as in the following example." In the dividend  $a^2 + 2ab + b^2$ , they are ranged according to the dimensions of  $a$ , the quantity  $a^2$ , where  $a$  is of two dimensions, being placed first,  $2ab$ , where it is of one dimension, next, and  $b^2$ , where  $a$  is not at all, being placed last. "The divisor must be ranged according to the dimensions of the same letters; then you are to divide the first term of the dividend by the first term of the divisor, and to set down the quotient, which, in this example, is  $a$ ; then multiply this quotient by the whole divisor, and subtract the product from the dividend, and the remainder shall give a new dividend, which, in this example, is  $a + b^2$ ."

$$\begin{array}{r} (a+b) \overline{) a^2 + 2ab + b^2} \\ \underline{a^2 + a^2 b} \phantom{+ b^2} \\ \phantom{a^2} ab + b^2 \\ \phantom{a^2} \underline{ab + ab} \\ \phantom{a^2} \phantom{ab} b^2 \\ \phantom{a^2} \phantom{ab} \underline{b^2} \\ \phantom{a^2} \phantom{ab} \phantom{b^2} 0 \quad 0 \end{array}$$

"Divide the first term of this new dividend by the first term of the divisor, and set down the quotient, (which in this example is  $b$ ), with its proper sign. Then multiply the whole divisor by this part of the quotient, and subtract the product from the new dividend; and if there is no remainder, the division is finished." If there is a remainder, you are to proceed after the same manner, till no remainder is left; or till it appear that there will be always some remainder.

Some examples will illustrate this operation.

EXAMP. I.  $(a+b) \overline{) a^2 - b^2} (a - b$

$$\begin{array}{r} \underline{a^2 + ab} \\ -ab - b^2 \\ \underline{-ab - b^2} \\ 0 \quad 0 \end{array}$$

EXAMP. II.  $(a-b) \overline{) a^3 - 3aab + 3abb - bbb} (aa - 2ab + bb$

$$\begin{array}{r} \underline{a^3 - ab^2} \\ -2aab + 3abb - bbb \\ \underline{-2aab + 2abb} \\ \phantom{-2aab + 2abb} abb - bbb \\ \phantom{-2aab + 2abb} \underline{abb - bbb} \\ \phantom{-2aab + 2abb} \phantom{abb - bbb} 0 \quad 0 \end{array}$$

It often happens, that the operation may be continued without end, and then you have an *infinite series* for the quotient; and by comparing the first three or four terms you may find what law the terms observe: by which means, without any more division, you may continue the quotient as far as you please. Thus, in dividing 1 by  $1 - a$ , you find the quotient to be  $1 + a + a^2 + a^3 + a^4 + a^5 + \&c.$  which series can be continued as far as you please, by adding the powers of  $a$ .

The operation is thus:

$$1 - a) 1 (1 + a + a^2 + a^3 + a^4 + a^5, \&c.$$

$$\begin{array}{r} \underline{1 - a} \\ +a \\ +a - a^2 \\ \underline{+a - a^2} \\ +a^2 \\ +a^2 - a^3 \\ \underline{+a^2 - a^3} \\ +a^3 \\ +a^3 - a^4 \\ \underline{+a^3 - a^4} \\ +a^4 \\ +a^4 - a^5 \\ \underline{+a^4 - a^5} \\ +a^5, \&c. \end{array}$$

Note, The sign + placed between any two quantities,

ties, expresses the quotient of the former divided by the latter. Thus,  $a + b \div a - x$  is the quotient of  $a + b$ , divided by  $a - x$ .

CHAP. V. Of FRACTIONS.

In the last chapter it was said, that the quotient of any quantity  $a$ , divided by  $b$ , is expressed by placing  $a$  above a small line, and  $b$  under it, thus,  $\frac{a}{b}$ . These quotients are also called *fractions*; and the dividend, or quantity placed above the line, is called the *numerator* of the fraction, and the divisor, or quantity placed under the line, is called the *denominator*.

“If the numerator of a fraction be equal to the denominator, then the fraction is equal to unity. Thus,  $\frac{a}{a}$  and  $\frac{b}{b}$  are equal to unit. If the numerator is greater than the denominator, then the fraction is greater than unit.” In both these cases, the fraction is called *improper*. But “if the numerator is less than the denominator, then the fraction is less than unit,”

and is called *proper*. Thus,  $\frac{5}{3}$  is an improper fraction; but  $\frac{3}{4}$  and  $\frac{2}{3}$  are proper fractions. A mixt quantity is that whereof one part is an *integer*, and the other a *fraction*. As  $3 \frac{4}{5}$  and  $5 \frac{2}{3}$  and  $a + \frac{a^2}{b}$ .

PROBLEM I.

To reduce a MIXT quantity to an IMPROPER FRACTION.

RULE. Multiply the part that is an integer by the denominator of the fractional part; and to the product add the numerator; under their sum place the former denominator.

Thus  $2 \frac{1}{3}$  reduced to an improper fraction gives  $\frac{7}{3}$ ;  $a + \frac{a^2}{b} = \frac{ab + a^2}{b}$ ; and  $a - x + \frac{a^2 - ax}{x} = \frac{a^2 - x^2}{x}$ .

PROBLEM II.

To reduce in IMPROPER fraction to a MIXT QUANTITY.

RULE. Divide the numerator of the fraction by the denominator, and the quotient shall give the integral part; the remainder set over the denominator shall be the fractional part.

Thus  $\frac{12}{5} = 2 \frac{2}{5}$ ;  $\frac{ab + a^2}{b} = a + \frac{a^2}{b}$ .

PROBLEM III.

To reduce fractions of different denominations to fractions of equal value that shall have the same denominator.

RULE. Multiply each numerator, separately taken; into all the denominators but its own, and the products shall give the new numerators. Then multiply all the denominators into one another, and the product shall give the common denominator. Thus,

The fractions  $\frac{a}{b}$ ,  $\frac{b}{c}$ ,  $\frac{c}{d}$ , are respectively equal to these fractions  $\frac{acd}{bcd}$ ,  $\frac{bbd}{bcd}$ ,  $\frac{ccb}{bcd}$ , which have the same denominator  $bcd$ . And the fractions  $\frac{3}{7}$ ,  $\frac{1}{4}$ ,  $\frac{4}{7}$ , are respectively equal to these  $\frac{36}{100}$ ,  $\frac{25}{100}$ ,  $\frac{56}{100}$ .

PROBLEM IV.

To ADD and SUBTRACT fractions.

RULE. Reduce them to a common denominator, and add or subtract the numerators; the sum or difference set over the common denominator, is the sum or remainder required.

$$\frac{a}{b} + \frac{c}{d} + \frac{d}{e} = \frac{ade + bce + d^2b}{bde}; \frac{a}{b} - \frac{c}{d} = \frac{ad - bc}{bd}; \frac{2}{3} + \frac{3}{4} = \frac{8 + 9}{12} = \frac{17}{12} = 1 \frac{5}{12}; \frac{3}{4} - \frac{2}{3} = \frac{9 - 8}{12} = \frac{1}{12}; \frac{4}{5} - \frac{3}{4} = \frac{16 - 15}{20} = \frac{1}{20}; \frac{x}{3} - \frac{2x}{6} = \frac{x}{6}$$

PROBLEM V.

To MULTIPLY fractions.

RULE. Multiply their numerators one into another to obtain the numerator of the product; and their denominators multiplied into one another shall give the denominator of the product. Thus,

$$\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}; \frac{2}{3} \times \frac{4}{5} = \frac{8}{15}$$

If a mixt quantity is to be multiplied, first reduce it to the form of a fraction (by Prob. I.) And, if an integer is to be multiplied by a fraction, you may reduce it to the form of a fraction by placing unit under it.

EXAMP.  $5 \frac{2}{3} \times \frac{3}{4} = \frac{17}{3} \times \frac{3}{4} = \frac{51}{12}$

PROBLEM VI.

To DIVIDE Fractions.

RULE. Multiply the numerator of the dividend by the denominator of the divisor, their product shall give the numerator of the quotient. Then multiply the denominator of the dividend by the numerator of the divisor, and their product shall give the denominator.

Thus,  $\frac{4}{5} \div \frac{2}{3} = \frac{10}{12}; \frac{3}{7} \div \frac{5}{8} = \frac{24}{35}; \frac{c}{d} \div \frac{a}{b} = \frac{cb}{da}$ .

## PROBLEM VII.

To find the greatest common measure of two numbers; that is, the greatest number that can divide them both without a remainder.

RULE. First divide the greater number by the lesser, and if there is no remainder, the lesser number is the greatest common divisor required. If there is a remainder, divide your last divisor by it; and thus proceed continually, dividing the last divisor by its remainder, till there is no remainder left, and then the last divisor is the greatest common measure required.

Thus, the greatest common measure of 45 and 63 is 9; and the greatest common measure of 256 and 48 is 16.

$$\begin{array}{r}
 45 \overline{) 63} \quad (1 \qquad \qquad \qquad 48 \overline{) 256} \quad (5 \\
 \underline{45} \qquad \qquad \qquad \underline{240} \\
 18 \quad 45 \quad (2 \qquad \qquad \qquad 16 \quad 48 \quad (3 \\
 \underline{36} \qquad \qquad \qquad \underline{48} \\
 9 \quad 18 \quad (2 \qquad \qquad \qquad 0 \\
 \underline{18} \\
 0
 \end{array}$$

Much after the same manner the greatest common measure of algebraic quantities is discovered; only the remainders that arise in the operation are to be divided by their simple divisors, and the quantities are always to be ranged according to the dimensions of the same letter.

Thus to find the greatest common measure of  $a^3 - b^3$  and  $a^2 - 2ab + b^2$ ;

$$\begin{array}{r}
 a^3 - b^3 \overline{) a^3 - 2ab + b^2} \quad (1 \\
 \underline{a^3 - b^3} \\
 -2ab + 2b^2 \text{ Remainder,} \\
 \text{which divided by } -2b \text{ is reduced to} \\
 a - b \overline{) a^2 - b^2} \quad (a + b \\
 \underline{a^2 - b^2} \\
 0 \quad 0 \quad 0
 \end{array}$$

Therefore  $a - b$  is the greatest common measure required.

The ground of this operation is, That any quantity that measures the divisor and the remainder (if there is any) must also measure the dividend; because the dividend is equal to the sum of the divisor multiplied into the quotient, and of the remainder added together. Thus, in the last example,  $a - b$  measures the divisor  $a^2 - b^2$ , and the remainder  $-2ab + 2b^2$ ; it must therefore likewise measure their sum  $a^2 - 2ab + b^2$ . You must observe in this operation to make that the dividend which has the highest powers of the letter, according to which the quantities are ranged.

## PROBLEM VIII.

To reduce any fraction to its lowest terms.

RULE. Find the greatest common measure of the numerator and denominator; divide them by that com-

mon measure, and place the quotients in their room, and you shall have a fraction equivalent to the given fraction expressed in the least terms.

$$\text{Thus, } \frac{25bc}{25bc} \cdot \frac{75abc}{125bcx} = \frac{3a}{5x}; \quad \frac{156aa + 156ab}{572aa - 572ab} = \frac{3a + 3b}{11a - 11b}.$$

When unit is the greatest common measure of the numbers and quantities, then the fraction is already in its lowest terms. Thus  $\frac{3a}{5d}$  cannot be reduced lower.

And, numbers whose greatest common measure is unit, are said to be *prime* to one another.

If a vulgar fraction is to be reduced to a decimal (that is, a fraction whose denomination is 10, or any of its powers), "annex as many cyphers as you please to the numerator, and then divide it by the denominator, the quotient shall give a decimal equal to the vulgar fraction proposed." Thus,

$$\frac{2}{3} = .66666, \text{ \&c.} \qquad \qquad \frac{3}{5} = .6; \\
 \frac{2}{7} = .2857142, \text{ \&c.}$$

These fractions are added and subtracted like whole numbers; only care must be taken to set similar places above one another, as units above units, and tenths above tenths, &c. They are multiplied and divided as integer numbers; only there must be as many decimal places in the product as in both the multiplicand and multiplier; and in the quotient as many as there are in the dividend more than in the divisor. And in division the quotient may be continued to any degree of exactness you please, by adding cyphers to the dividend. The ground of these operations is easily understood from the general rules for adding, multiplying, and dividing fractions.

## CHAP. VI. Of the INVOLUTION of QUANTITIES.

THE products arising from the continual multiplication of the same quantity were called (in Chap. III.) the powers of that quantity. Thus,  $a, a^2, a^3, \text{ \&c.}$  are the powers of  $a$ ; and  $a^2b, a^2b^2, a^3b^3, \text{ \&c.}$  are the powers of  $ab$ . In the same chapter, the rule for the multiplication of powers of the same quantity is, "To add the exponents, and make their sum the exponent of the product." Thus  $a^4 \times a^3 = a^7$ ; and  $a^3b^3 \times a^6b^2 = a^9b^5$ . In Chap. IV. you have the rule for dividing powers of the same quantity, which is "To subtract the exponents, and make the difference the exponent of the quotient."

$$\text{Thus, } \frac{a^6}{a^2} = a^{6-4} = a^2; \text{ and } \frac{a^5b^3}{a^4b} = a^{5-4}b^{3-1} = ab^2.$$

If you divide a lesser power by a greater, the exponent of the quotient must, by this rule, be negative.

Thus,

Thus,  $\frac{a^4}{a^6} = a^{-6} = a^{-2}$ . But,  $\frac{a^4}{a^6} = \frac{1}{a^2}$ ; and hence  $\frac{1}{a^2}$  is expressed also by  $a^{-2}$  with a negative exponent.

It is also obvious, that  $\frac{a}{a} = a^{-1} = a^0$ ; but  $\frac{a}{a} = 1$ , and therefore  $a^0 = 1$ . After the same manner  $\frac{1}{a} = \frac{a^0}{a} = a^{-1}$ ;  $\frac{1}{a^2} = \frac{a^0}{a^2} = a^{-2}$ ;  $\frac{1}{a^3} = \frac{a^0}{a^3} = a^{-3}$ ; so that the quantities  $a, 1, \frac{1}{a}, \frac{1}{a^2}, \frac{1}{a^3}, \dots$  may be expressed thus,  $a^1, a^0, a^{-1}, a^{-2}, a^{-3}, a^{-4}, \dots$ . Those are called the *negative powers* of  $a$  which have negative exponents; but they are at the same time *positive powers* of  $\frac{1}{a}$  or  $a^{-1}$ .

*Negative powers (as well as positive) are multiplied by adding, and divided by subtracting their exponents.*

Thus the product of  $a^{-2}$  (or  $\frac{1}{a^2}$ ) multiplied by  $a^{-3}$  (or  $\frac{1}{a^3}$ ) is  $a^{-2-3} = a^{-5}$  (or  $\frac{1}{a^5}$ ); also  $a^{-6} \times a^4 = a^{-6+4} = a^{-2}$  (or  $\frac{1}{a^2}$ ); and  $a^{-3} \times a^3 = a^0 = 1$ . And, in general, any positive power of  $a$  multiplied by a negative power of  $a$  of an equal exponent gives UNIT for the product; for the positive and negative destroy each other, and the product gives  $a^0$ , which is equal to unit.

Likewise  $\frac{a^{-5}}{a^{-2}} = a^{-5+2} = a^{-3} = \frac{1}{a^3}$ ; and  $\frac{a^{-2}}{a^{-5}} = a^{-2+5} = a^3$ . But also,  $\frac{a^{-2}}{a^{-5}} = \frac{a^{-2}}{a^{-2} \times a^{-3}} = \frac{1}{a^{-3}}$ ; therefore  $\frac{1}{a^{-3}} = a^3$ : And, in general, "A my quantity placed in the denominator of a fraction may be transposed to the numerator, if the sign of its power be changed." Thus  $\frac{1}{a^3} = a^{-3}$ , and  $\frac{1}{a^{-3}} = a^3$ .

The quantity  $a^m$  expresses any power of  $a$  in general, the exponent ( $m$ ) being undetermined; and  $a^{-m}$  expresses  $\frac{1}{a^m}$ , or a negative power of  $a$  of an equal exponent:

and  $a^m \times a^{-m} = a^{m-m} = a^0 = 1$  is their product.  $a^m$  expresses any other power of  $a$ ;  $a^m \times a^n = a^{m+n}$  is the product of the powers  $a^m$  and  $a^n$ , and  $a^{m-n}$  is their quotient.

To raise any simple quantity to its second, third, or fourth power, is to add its exponent twice, thrice, or four times to itself; therefore the second power of any quantity is had by doubling its exponent, and the third by trebling its exponent; and, in general, the power expressed by  $m$  of any quantity is had by multiplying the exponent by  $m$ , as is obvious from the multiplication of powers. Thus the second power or square of  $a$  is

$a^2 \times a^2 = a^4$ ; its third power or cube is  $a^3 \times a^2 = a^5$ ; and the  $m^{\text{th}}$  power of  $a$  is  $a^m \times a^m = a^{2m}$ . Also, the square of  $a^4$  is  $a^4 \times a^4 = a^8$ ; the cube of  $a^4$  is  $a^4 \times a^4 \times a^4 = a^{12}$ ; and the  $m^{\text{th}}$  power of  $a^4$  is  $a^{4m}$ . The square of  $a b c$  is  $a^2 b^2 c^2$ , the cube is  $a^3 b^3 c^3$ , the  $m^{\text{th}}$  power  $a^m b^m c^m$ .

The raising of quantities to any power is called *involution*, and any simple quantity is involved by multiplying the exponent by that of the power required, as in the preceding examples.

The coefficient must also be raised to the same power by a continual multiplication of itself by itself, as often as unit is contained in the exponent of the power required. Thus the cube of  $3 a b$  is  $3 \times 3 \times 3 \times a^3 b^3 = 27 a^3 b^3$ .

As to the signs, When the quantity to be involved is positive, it is obvious that all its powers must be positive. And, when the quantity to be involved is negative, yet all its powers, whose exponents are even numbers, must be positive: for any number of multiplications of a negative, if the number be even, gives a positive; since  $- \times - = +$ , therefore  $- \times - \times - \times - = + \times + = +$ ; and  $- \times - \times - \times - \times - \times - = + \times + \times + = +$ .

The power then only can be negative when its exponent is an odd number, though the quantity to be involved be negative. The powers of  $-a$  are  $-a, +a^2, -a^3, +a^4, -a^5, \dots$ . Those whose exponents are 2, 4, 6,  $\dots$  are positive; but those whose exponents are 1, 3, 5,  $\dots$  are negative.

The involution of compound quantities is a more difficult operation. The powers of any binomial  $a + b$  are found by a continual multiplication of it by itself, as follows:

$$\begin{array}{r}
 a + b = \text{Root.} \\
 \times a + b \\
 \hline
 a^2 + ab \\
 + ab + b^2 \\
 \hline
 a^2 + 2ab + b^2 = \text{the square or 2d power.} \\
 \times a + b \\
 \hline
 a^3 + 2a^2b + ab^2 \\
 + a^2b + 2ab^2 + b^3 \\
 \hline
 a^3 + 3a^2b + 3ab^2 + b^3 = \text{cube or 3d power, \&c.}
 \end{array}$$

If the powers of  $a - b$  are required, they will be found the same as the preceding, only the terms in which the exponent of  $b$  is an odd number, will be found negative; "because an odd number of multiplications of a negative produces a negative." Thus, the cube of  $a - b$  will be found to be  $a^3 - 3a^2b + 3ab^2 - b^3$ : Where the 2d and 4th terms are negative, the exponent of  $b$  being an odd number in these terms. In general, "The terms of any power of  $a - b$  are positive and negative by turns."

It is to be observed, That "in the first term of any power of  $a \pm b$ , the quantity  $a$  has the exponent of the power required; that in the following terms, the exponents of  $a$  decrease gradually by the same differ-

ence (*viz.* unit), and that in the last terms it is never found. The powers of  $b$  are in the contrary order; it is not found in the first term, but its exponent in the second term is unit, in the third term its exponent is 2; and thus its exponent increases, till in the last term it becomes equal to the exponent of the power required."

As the exponents of  $a$  thus decrease, and at the same time those of  $b$  increase, "the sum of their exponents is always the same, and is equal to the exponent of the power required." Thus, in the 6th power of  $a + b$ , *viz.*  $a^6 + 6a^5b + 15a^4b^2 + 20a^3b^3 + 15a^2b^4 + 6ab^5 + b^6$ , the exponents of  $a$  decrease in this order, 6, 5, 4, 3, 2, 1, 0; and those of  $b$  increase in the contrary order, 0, 1, 2, 3, 4, 5, 6. And the sum of their exponents in any term is always 6.

To find the coefficient of any term, the coefficient of the preceding term being known, you are to "divide the coefficient of the preceding term by the exponent of  $b$  in the given term, and to multiply the quotient by the exponent of  $a$  in the same term, increased by unit." Thus to find the coefficients of the terms of the 6th power of  $a + b$ , you find the terms are

$$a^6, a^5b, a^4b^2, a^3b^3, a^2b^4, ab^5, b^6;$$

and you know the coefficient of the first term is unit; therefore, according to the rule, the coefficient of the second term will be  $\frac{1}{1} \times 5 \times 1 = 6$ ; that of the third

term will be  $\frac{6}{2} \times 4 \times 1 = 3 \times 5 = 15$ ; that of the

fourth term will be  $\frac{15}{3} \times 3 \times 1 = 5 \times 4 = 20$ ; and those of the following will be 15, 6, 1, agreeable to the preceding table.

In general, if  $a + b$  is to be raised to any power  $m$ , the terms, without their coefficients will be  $a^m, a^{m-1}b, a^{m-2}b^2, a^{m-3}b^3, a^{m-4}b^4, \dots, m-5b^5$ , &c. continued till the exponent of  $b$  becomes equal to  $m$ .

The coefficients of the respective terms, according to the last rule, will be

$$1, m, m \times \frac{m-1}{2}, m \times \frac{m-1}{2} \times \frac{m-2}{3}, m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4}, m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5},$$

&c. continued until you have one coefficient more than there are units in  $m$ .

It follows therefore by these last rules, that  $(a + b)^m = a^m + m a^{m-1}b + m \times \frac{m-1}{2} a^{m-2}b^2 + m \times \frac{m-1}{2} \times \frac{m-2}{3} a^{m-3}b^3 + m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} a^{m-4}b^4 +$  &c. which is the general theorem for raising a quantity consisting of two terms to any power  $m$ .

If a quantity consisting of three or more terms is to be involved, "you may distinguish it into two parts, considering it as a binomial, and raise it to any power by the preceding rules; and then, by the same rules, you may substitute, instead of the powers of these compound parts, their values." Thus,

$$a + b + c = \overline{a + b} + c = \overline{a + b}^2 + 2c \times \overline{a + b} + c^2 = a^2 + 2ab + b^2 + 2ac + 2bc + c^2.$$

In these examples,  $a + b + c$  is considered as composed of the compound part  $a + b$  and the simple part  $c$ ; and then the powers of  $a + b$  are formed by the preceding rules, and substituted for  $\overline{a + b}^3$  and  $\overline{a + b}^2$ .

## CHAP. VII. Of EVOLUTION.

THE reverse of involution, or the resolving of powers into their roots, is called *evolution*. The roots of single quantities are easily extracted "by dividing their exponents by the number that denominates the root required." Thus, the square root of  $a^8$  is  $a^{\frac{8}{2}} = a^4$ ; and the square root of  $a^4 b^8 c^2$  is  $a^2 b^4 c$ . The cube root of  $a^6 b^3$  is  $a^{\frac{6}{3}} b^{\frac{3}{3}} = a^2 b$ ; and the cube root of  $x^6 y^6 z^{12}$  is  $x^2 y^2 z^4$ . The ground of this rule is obvious from the rule for involution. The powers of any root are found by multiplying its exponent by the index that denominates the power; and therefore, when any power is given, the root must be found by dividing the exponent of the given power by the number that denominates the kind of root that is required.

It appears, from what was said of involution, that "any power that has a positive sign may have either a positive or negative root, if the root is denominated by any even number." Thus the square-root of  $+a^2$  may be  $+a$  or  $-a$ , because  $+a \times +a$  or  $-a \times -a$  gives  $+a^2$  for the product.

But if a power have a negative sign, "no root of it denominated by an even number can be assigned," since there is no quantity that multiplied into itself an even number of times can give a negative product. Thus the square root of  $-a^2$  cannot be assigned, and is what we call an *impossible* or *imaginary* quantity.

But if the root to be extracted is denominated by an odd number, then shall "the sign of the root be the same as the sign of the given number whose root is required." Thus the cube root of  $-a^3$  is  $-a$ , and the cube root of  $-a^6 b^3$  is  $-a^2 b$ .

If the number that denominates the root required is a divisor of the exponent of the given power, then shall the root be only a *lower power of the same quantity*. As the cube root of  $a^{12}$  is  $a^4$ , the number 3 that denominates the cube root being a divisor of 12.

But if the number that denominates what sort of root is required is not a divisor of the exponent of the given power, "then the root required shall have a fraction for its exponent." Thus the square root of  $a^3$  is  $a^{\frac{3}{2}}$ ; the cube root of  $a^5$  is  $a^{\frac{5}{3}}$ , and the square root of  $a$  itself is  $a^{\frac{1}{2}}$ .

These powers that have fractional exponents are called *imperfect powers* or *surds*; and are otherwise expressed by placing the given power within the radical sign  $\sqrt{\quad}$ , and placing above the radical sign the number that denominates what kind of root is required. Thus  $\sqrt[2]{a^3}$ ,

$\sqrt[3]{a^5}$ ; and  $\sqrt[2]{a}$  are expressed by  $\sqrt[2]{a^3}$ ,  $\sqrt[3]{a^5}$ , and  $\sqrt[2]{a}$ . In numbers the square root of 2 is expressed by  $\sqrt{2}$ , and the cube root of 4 by  $\sqrt[3]{4}$ .

The

The square root of any compound quantity, as  $a^2 + 2ab + b^2$  is discovered after this manner. "First, take care to dispose the terms according to the dimensions of the alphabet, as in division; then find the square root of the first term  $a$ , which gives  $a$  for the first member of the root. Then subtract its square from the proposed quantity, and divide the first term of the remainder ( $2ab + b^2$ ) by the double of that member, *viz.*  $2a$ , and the quotient  $b$  is the second member of the root. Add this second member to the double of the first, and multiply their sum ( $2a + b$ ) by the second member  $b$ , and subtract the product ( $2ab + b^2$ ) from the foresaid remainder ( $2ab + b^2$ ) and if nothing remains, then the square root is obtained;" and in this example it is found to be  $a + b$ .

The manner of the operation is thus,

$$\begin{array}{r} a^2 + 2ab + b^2 \quad (a + b) \\ \underline{a^2} \\ 2a + b \quad 2ab + b^2 \\ \underline{\times b \quad 2ab + b^2} \\ \phantom{2a + b} 0 \quad 0 \end{array}$$

"But if there had been a remainder, you must have divided it by the double of the sum of the two parts already found, and the quotient would have given the third member of the root."

Thus, if the quantity proposed had been  $a^2 + 2ab + 2ac + b^2 + 2bc + c^2$ , after proceeding as above, you would have found the remainder  $2ac + 2bc + c^2$ , which divided by  $2a + 2b$  gives  $c$  to be annexed to  $a + b$  as the 3d member of the root. Then adding  $c$  to  $2a + 2b$ , and multiplying their sum  $2a + 2b + c$  by  $c$ , subtract the product  $2ac + 2bc + c^2$  from the foresaid remainder; and since nothing now remains, you conclude that  $a + b + c$  is the square root required.

The square-root of any number is found out after the same manner. If it is a number under 100, its nearest square root is found by the following table; by which also its cube root is found if it be under 1000, and is biquadrate if it be under 10000.

The root	1	2	3	4	5	6	7	8	9
Square	1	4	9	16	25	36	49	64	81
Cube	1	8	27	64	125	216	343	512	729
Biquad.	1	16	81	256	625	1296	2401	4096	6561

But if it is a number above 100, then its square root will consist of two or more figures, which must be found by different operations by the following

R U L E.

"To find the square root of any number, place a point above the number that is in the place of units, puts the place of tens, and place again a point over that of hundreds, and go on towards the left hand placing a point over every 2d figure; and by these points the number will be distinguished into as many parts as there are figures in the root. Then find the square root of the first part, and it will give the first figure of

the root; subtract its square from that part, and annex the second part of the given number to the remainder. Then divide this new number (neglecting its last figure) by the double of the first figure of the root, annex the quotient to that double, and multiply the number thence arising by the said quotient, and if the product is less than your dividend, or equal to it, that quotient shall be the second figure of the root. But if the product is greater than the dividend, you must take a less number for the second figure of the root than that quotient." Much after the same manner may the other figures of the quotient be found, if there are more points than two placed over the given number.

To find the square root of 99856, first point it thus, 99856; then find the square root of 9 to be 3, which therefore is the first figure of the root; subtract 9, the square of 3, from 9, and to the remainder annex the second part 98, and divide (neglecting the last figure 8) by the double of 3, or 6, and place the quotient after 6, and then multiply 61 by 1, and subtract the product 61 from 98. Then to the remainder (37) annex the last part of the proposed number (56), and dividing 3756 (neglecting the last figure 6) by the double of 31, that is by 62, place the quotient after, and multiplying 626 by the quotient 6, you will find the product to be 3756, which subtracted from the dividend, and leaving no remainder, the exact root must be 316.

EXAMP.

$$\begin{array}{r} 99856 \quad (316) \\ \underline{9} \\ 61 \quad 98 \\ \underline{\times 1 \quad 61} \\ 626 \quad 3756 \\ \underline{\times 6 \quad 3756} \\ 0 \end{array}$$

In general, to extract any root out of any given quantity, "First range that quantity according to the dimensions of its letters, and extract the said root out of the first term, and that shall be the first member of the root required. Then raise this root to a dimension lower by unit than the number that denominates the root required, and multiply the power that arises by that number itself; divide the second term of the given quantity by the product, and the quotient shall give the second member of the root required."

Thus to extract the root of the 5th power out of  $a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5$ , I find, that the root of the 5th power out of  $a^5$  gives  $a$ , which I raise to the 4th power, and multiplying by 5, the product is  $5a^4$ ; then dividing the second term of the given quantity  $5a^4b$  by  $5a^4$ , I find  $b$  to be the second member; and raising  $a + b$  to the 5th power, and subtracting it, there being no remainder, I conclude that  $a + b$  is the root required. If the root has three members, the third is found after the same manner from the first two considered as one member, as the second member was found from the first; which may be easily understood from what was said of extracting the square root.

In extracting roots it will often happen that the exact root cannot be found in finite terms; thus the square root of  $a^2 + x^2$  is found to be

$$a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7} + \dots, \text{ \& c.}$$

The operation is thus;

$$a^2 + x^2 \left( a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \dots, \text{ \& c.} \right)$$

$a^2$

$$2a + \frac{x^2}{2a} \quad \times + x^2$$

$$\times \frac{x^2}{2a} = x^2 + \frac{x^4}{4a^2}$$

$$2a + \frac{x^2}{a} - \frac{x^4}{8a^3} \quad \times - \frac{x^4}{8a^3} = -\frac{x^4}{4a^2}$$

$$\times - \frac{x^6}{8a^5} = -\frac{x^6}{4a^2} - \frac{x^6}{8a^5} + \frac{x^8}{64a^8}$$

$$+ \frac{x^6}{8a^5} - \frac{x^8}{64a^8} \text{ \& c.}$$

"The general theorem which we gave for the involution of binomials will serve also for their evolution;" because to extract any root of a given quantity is the same thing as to raise that quantity to a power whose exponent is a fraction that has its denominator equal to the number that expresses what kind of root is to be extracted. Thus, to extract the square root of  $a + b$  is to raise  $a + b$  to a power whose exponent is  $\frac{1}{2}$ .

The roots of numbers are to be extracted as those of algebraic quantities. "Place a point over the units, and then place points over every third, fourth, or fifth figure towards the left hand, according as it is the root of the cube, of the 4th or 5th power that is required; and, if there be any decimals annexed to the number, point them after the same manner, proceeding from the place of units towards the right hand. By this means the number will be divided into so many periods as there are figures in the root required. Then inquire which is the greatest cube, biquadrate, or 5th power in the first period, and the root of that power will give the first figure of the root required. Subtract the greatest cube, biquadrate, or 5th power, from the first period, and to the remainder annex the first figure of your second period, which shall give your dividend.

"Raise the first figure already found to a power less by unit than the power whose root is sought, that is, to the 2d, 3d, or 4th power, according as it is the cube root, the root of the 4th, or the root of the 5th power that is required, and multiply that power by the index of the cube, 4th, or 5th power, and divide the dividend by this product, so shall the quotient be the second figure of the root required.

"Raise the part already found of the root, to the power whose root is required, and if that power be

"found less than the two first periods of the given number, the second figure of the root is right. But, if it be found greater, you must diminish the second figure of the root till that power be found equal to or less than those periods of the given number. Subtract it, and to the remainder annex the next period; and proceed till you have gone through the whole given number, finding the third figure by means of the two first, as you found the second by the first; and afterwards finding the fourth figure (if there be a fourth period) after the same manner from the three first."

Thus to find the cube root of 13824, point it 13824; find the greatest cube in 13, viz. 8, whose cube root 2 is the first figure of the root required. Subtract 8 from 13, and to the remainder 5 annex 8, the first figure of the second period; divide 58 by triple the square of 2, viz. 12, and the quotient is 4, which is the second figure of the root required, since the cube of 24 gives 13824, the number proposed. After the same manner the cube root of 13312053 is found to be 237.

$$\begin{array}{r} 13824 \quad (24 \\ \text{Subtr. } 8 = 2 \times 2 \times 2 \\ \hline 3 \times 4 = 12 \quad 58 \quad (4 \\ \text{Subtr. } 24 \times 24 \times 24 = 13824 \\ \hline \text{Rem. } \dots 0 \dots \end{array}$$

In extracting of roots, after you have gone through the number proposed, if there is a remainder, you may continue the operation by adding periods of cyphers to that remainder, and find the true root in decimals to any degree of exactness.

## CHAP. VIII. Of PROPORTION.

WHEN quantities of the same kind are compared, it may be considered, either how much the one is greater than the other, and what is their *difference*; or, it may be considered how many times the one is contained in the other; or, more generally, what is their *quotient*. The first relation of quantities is expressed by their *arithmetical ratio*; the second by their *geometrical ratio*. That term whose ratio is inquired into is called the *antecedent*, and that with which it is compared is called the *consequent*.

When of four quantities the difference betwixt the first and second is equal to the difference betwixt the third and fourth, those quantities are called *arithmetical proportionals*; as the numbers 3, 7, 12, 16. And the quantities  $a, a+b, c, c+b$ . But quantities form a *series* in arithmetical proportion, when they "increase or decrease by the same constant difference." As these,  $a, a+b, a+2b, a+3b, a+4b, \text{ \& c. } x, x-b, x-2b, \text{ \& c.}$  or the numbers 1, 2, 3, 4, 5, \& c. and 10, 7, 4, 1, -2, -5, -8, \& c.

In four quantities *arithmetically proportional*, "the sum of the extremes is equal to the sum of the mean terms."

“ terms.” Thus,  $a, a+b, e, e+b$ , are arithmetical proportionals, and the sum of the extremes  $(a+e+b)$  is equal to the sum of the mean terms  $(a+b+e)$ . Hence, to find the fourth quantity arithmetically proportional to any three given quantities; “ Add the second and third, and from their sum subtract the first term, the remainder shall give the fourth arithmetical proportional required.”

In a series of arithmetical proportionals, “ the sum of the first and last terms is equal to the sum of any two terms equally distant from the extremes.” If the first terms are  $a, a+b, a+2b, \&c.$  and the last term  $x$ , the last term but one will be  $x-b$ , the last but two  $x-2b$ , the last but three  $x-3b, \&c.$  So that the first half of the terms, having those that are equally distant from the last term set under them, will stand thus;

$$\begin{array}{r} a, a+b, a+2b, a+3b, a+4b, \&c. \\ x, x-b, x-2b, x-3b, x-4b, \\ \hline a+x, a+x, a+x, a+x, a+x, \&c. \end{array}$$

And it is plain, that if each term be added to the term above it, the sum will be  $a+x$ , equal to the sum of the first term  $a$  and the last term  $x$ . From which it is plain, that “ the sum of all the terms of an arithmetical progression is equal to the sum of the first and last taken half as often as there are terms;” that is, the sum of an arithmetical progression is equal to the sum of the first and last terms multiplied by half the number of terms. Thus, in the preceding series, if  $n$  be the number of terms, the sum of all the terms will be  $a+x \times \frac{n}{2}$ .

The common difference of the terms being  $b$ , and  $b$  not being found in the first term, it is plain that “ its coefficient in any term will be equal to the number of terms that precede that term ” Therefore in the last term  $x$  you must have  $n-1 \times b$ , so that  $x$  must be equal to  $a+n-1 \times b$ . And the sum of all the terms being  $a+x \times \frac{n}{2}$ , it will also be equal to  $\frac{2an+n^2b-nb}{2}$ , or to  $a+\frac{nb-b}{2} \times n$ . Thus for example, the series  $1+2+3+4+5, \&c.$  continued to a hundred, must be equal to  $\frac{2 \times 100 + 10000 - 100}{2} = 5050$ .

If a series have (0) nothing for its first term, then “ its sum shall be equal to half the product of the last term multiplied by the number of terms.” For then  $a$  being = 0, the sum of the terms, which is in general  $a+x \times \frac{n}{2}$ , will in this case be  $\frac{nx}{2}$ . From which it is evident, that “ the sum of any number of arithmetical proportionals beginning from nothing, is equal to half the sum of as many terms equal to the greatest term.”

Thus, 
$$\begin{array}{r} 0+1+2+3+4+5+6+7+8+9= \\ = 9+0+9+0+9+0+9+0+9= \frac{10 \times 9}{2} = 45. \end{array}$$

“ If of four quantities the quotient of the first and second be equal to the quotient of the third and fourth, Vol. I No. 4.

“ then those quantities are said to be in geometrical proportion.” Such are the numbers 2, 6, 4, 12; and the quantities  $a, ar, b, br$ ; which are expressed after this manner;

$$\begin{array}{l} 2 : 6 :: 4 : 12. \\ a : ar :: b : br. \end{array}$$

And you read them by saying, As 2 is to 6, so is 4 to 12; or, as  $a$  is to  $ar$ , so is  $b$  to  $br$ .

In four quantities geometrically proportional, “ the product of the extremes is equal to the product of the middle terms.” Thus,  $axbr=arxb$ . And, if it is required to find a fourth proportional to any three given quantities, “ multiply the second by the third, and divide their product by the first, the quotient shall give the fourth proportional required.” Thus, to find a fourth proportional to  $a, ar$ , and  $b$ , multiply  $ar$  by  $b$ , and divide the product  $arb$  by the first term  $a$ , the quotient  $br$  is the fourth proportional required.

In calculations it sometimes requires a little care to place the terms in due order; for which you may observe the following

**RULE.** First set down the quantity that is of the same kind with the quantity sought; then consider, from the nature of the question, whether that which is given is greater or less than that which is sought; if it is greater, then place the greatest of the other two quantities on the left hand; but if it is less, place the least of the other two quantities on the left hand, and the other on the right.

Then shall the terms be in due order; and you are to proceed according to the rule, multiplying the second by the third, and dividing their product by the first.

**EXAMP.** “ If 30 men do any piece of work in 12 days, how many men shall do it in 18 days?”

Because it is a number of men that is sought, first set down 30, the number of men that is given: you will easily see that the number that is given is greater than the number that is sought; therefore place 18 on the left hand, and 12 on the right; and find a 4th proportional to 18, 30, 12, viz.  $\frac{30 \times 12}{18} = 20$ .

When a series of quantities increase by one common multiplier, or decrease by one common divisor, they are said to be in *geometrical proportion continued*.

As,  $a, ar, ar^2, ar^3, ar^4, ar^5, \&c.$  or,  
 $a, \frac{a}{r}, \frac{a}{r^2}, \frac{a}{r^3}, \frac{a}{r^4}, \frac{a}{r^5}, \&c.$

The common multiplier or divisor is called their *common ratio*.

In such a series, “ the product of the first and last is always equal to the product of the second and last but one, or to the product of any two terms equally remote from the extremes.” In the series,  $a, ar, ar^2, ar^3, \&c.$  if  $y$  be the last term, then shall the four last terms of the series be  $y, \frac{y}{r}, \frac{y}{r^2}, \frac{y}{r^3}$ ; now it is

plain, that  $ax_j = ar \times \frac{y}{r} = ar^2 \times \frac{y}{r^2} = ar^3 \times \frac{y}{r^3}, \&c.$

"The sum of a series of geometrical proportionals wanting the first term, is equal to the sum of all but the last term multiplied by the common ratio."

$$\text{For } ar + ar^2 + ar^3, \text{ \&c. } + \frac{y}{r^3} + \frac{y}{r^2} + \frac{y}{r} + y =$$

$$= r \times a + ar + ar^2, \text{ \&c. } + \frac{y}{r^4} + \frac{y}{r^3} + \frac{y}{r^2} + \frac{y}{r}.$$

Therefore if  $s$  be the sum of the series,  $s - a$  will be equal to  $\frac{y}{r} \times r$ ; that is,  $s - a = sr - yr$ , or  $sr - s = yr - a$ , and  $s = \frac{yr - a}{r - 1}$ .

Since the exponent of  $r$  is always increasing from the second term, if the number of terms be  $n$ , in the last term its exponent will be  $n - 1$ . Therefore  $y = ar^{n-1}$ ; and  $yr = ar^{n-1} \times r = ar^n$ ; and  $s = \left( \frac{yr - a}{r - 1} \right) = \frac{ar^n - a}{r - 1}$ . So that having the first term of the series, the number of the terms, and the common ratio, you may easily find the sum of all the terms.

If it is a decreasing series whose sum is to be found, as of  $y + \frac{y}{r} + \frac{y}{r^2} + \frac{y}{r^3}$ , &c.  $+ ar^3 + ar^2 + ar + a$ , and the number of the terms be supposed infinite, then shall  $a$ , the last term, be equal to nothing. For, because  $n$ , and consequently  $r^{n-1}$  is infinite,  $a = \frac{r}{r^{n-1}} = 0$ .

The sum of such a series  $= \frac{yr}{r-1}$ ; which is a finite sum, though the number of terms be infinite. Thus,

$$1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \text{ \&c. } = \frac{1 \times 2}{2 - 1} = 2.$$

$$\text{and } 1 + \frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81} + \text{ \&c. } = \frac{1 \times 3}{3 - 1} = \frac{3}{2}$$

## CHAP. IX. Of EQUATIONS that involve only one unknown Quantity.

An equation is "a proposition asserting the equality of two quantities." It is expressed most commonly by setting down the quantities, and placing the sign (=) between them.

An equation gives the value of a quantity, when that quantity is alone on one side of the equation: and that value is known, if all those that are on the other side are known. Thus if I find that  $x = \frac{4 \times 6}{3} = 8$ , I have a known value of  $x$ . There are the last conclusions we are to seek in questions to be resolved; and if there be only one unknown quantity in a given equation, and only one dimension of it, such a value may always be found by the following rules.

**RULE I.** Any quantity may be transposed from one side of the equation to the other, if you change its sign.

For to take away a quantity from one side, and to place it with a contrary sign on the other side, is to subtract it from both sides; and it is certain, that "when from e-

qual quantities you subtract the same quantity, the remainders must be equal."

By this rule, when the known and unknown quantities are mixed in an equation, you may separate them by bringing all the unknown to one side, and the known to the other side of the equation; as in the following examples.

$$\text{Suppose } 5x + 50 = 4x + 56$$

$$\text{by Transposit. } 5x - 4x = 56 - 50, \text{ or, } x = 6$$

$$\text{And if } 2x + a = x + b$$

$$2x - x = b - a, \text{ or, } x = b - a.$$

**RULE II.** Any quantity by which the unknown quantity is multiplied may be taken away, if you divide all the other quantities on both sides of the equation by it.

For that is to divide both sides of the equation by the same quantity, and when you divide equal quantities by the same quantity, the quotients must be equal. Thus,

$$\text{If } ax = b$$

$$\text{then } x = \frac{b}{a};$$

$$\text{and if } 3x + 12 = 27$$

$$\text{by Rule 1st. } 3x = 27 - 12 = 15$$

$$\text{and by Rule 2d. } x = \frac{15}{3} = 5$$

**RULE III.** If the unknown quantity is divided by any quantity, that quantity may be taken away if you multiply all the other members of the equation by it. Thus,

$$\text{If } \frac{x}{b} = b + 5$$

$$\text{then shall } x = bb + 5b$$

By this rule, an equation whereof any part is a fraction may be reduced to an equation that shall be expressed by integers. If there are more fractions than one in the given equation, you may, by reducing them to a common denominator, and then multiplying all the other terms by that denominator, abridge the calculation thus;

$$\text{If } \frac{x}{5} + \frac{x}{3} = x - 7$$

$$\text{then } \frac{3x + 5x}{15} = x - 7$$

$$\text{and by this Rule } 3x + 5x = 15x - 105$$

$$\text{and by R. 1. and 2. } x = \frac{105}{2} = 52\frac{1}{2}$$

**RULE IV.** If that member of the equation that involves the unknown quantity be a *surd* root, then the equation is to be reduced to another that shall be free from any *surd*, by bringing that member first to stand alone upon one side of the equation, and then taking away the radical sign from it, and raising the other side of the equation to the power denominated by the *surd*.

$$\text{Thus if } \sqrt{4x + 16} = 12$$

$$4x + 16 = 144$$

$$\text{and } 4x = 144 - 16 = 128$$

$$\text{and } x = \frac{128}{4} = 32.$$

**RULE V.** If that side of the equation that contains the unknown quantity be a compleat square, cube, or other power; then extract the square root, cube root, or the root of that power, from both sides of the equation; and thus the equation shall be reduced to one of a lower degree.

$$\begin{aligned} &\text{If } x^2 + 6x + 9 = 20 \\ &\text{then } x + 3 = \sqrt{20} \\ &\text{and } x = \sqrt{20} - 3. \end{aligned}$$

**RULE VI.** A proportion may be converted into an equation asserting the product of the extreme terms equal to the product of the mean terms; or any one of the extremes equal to the product of the means divided by the other extreme.

$$\begin{aligned} &\text{If } 12 : x :: \frac{x}{2} : 4 : 1 \\ &\text{then } 12 \cdot x = 2x \dots 3x = 12 \dots \text{and } x = 4. \\ &\text{Or if } 20 : x :: x : 7 : 3 \\ &\text{then } 60 = 3x = 7x \dots 10x = 60 \dots \text{and } x = 6. \end{aligned}$$

**RULE VII.** If any quantity be found on both sides of the equation with the same sign prefixed, it may be taken away from both: Also, if all the quantities in the equation are multiplied or divided by the same quantity, it may be struck out of them all. Thus,

$$\text{If } 3x + b = a + b \dots 3x = a \dots \text{and } x = \frac{a}{3}$$

**RULE VIII.** Instead of any quantity in an equation, you may substitute another equal to it.

$$\begin{aligned} &\text{Thus if } 3x + y = 24 \\ &\text{and } y = 9 \\ &\text{then } 3x + 9 = 24 \dots x = \frac{24 - 9}{3} = 5. \end{aligned}$$

The further improvements of this rule shall be taught in the following chapter.

**CHAP. X. Of the SOLUTION of QUESTIONS that produce SIMPLE EQUATIONS.**

**SIMPLE** equations are those "wherein the unknown quantity is only of one dimension." In the solution of which, we are to observe the following directions.

**DIRECT. I.** "After forming a distinct idea of the question proposed, the unknown quantities are to be expressed by letters, and the particulars to be translated from the common language into the algebraic manner of expressing them, that is, into such equations as shall express the relations or properties that are given of such quantities."

Thus, if the sum of two quantities must be 60, that condition is expressed thus,  $x + y = 60$ .  
If their difference must be 24, that condition gives  $x - y = 24$ .

If their product must be 1640, then  $xy = 1640$ .  
If their quotient must be 6, then  $\frac{x}{y} = 6$ .

If their proportion is as 3 to 2, then  $x : y :: 3 : 2$  or  $2x = 3y$ ; because the product of the extremes is equal to the product of the mean terms.

**DIRECT. II.** "After an equation is formed, if you have one unknown quantity only, then, by the rules of the preceding chapter, bring it to stand alone on one side, so as to have only known quantities on the other side:" thus you shall discover its value.

**EXAMP.** "A person being asked what was his age, answered that  $\frac{1}{2}$  of his age multiplied by  $\frac{1}{3}$  of his age gives a product equal to his age. *Quæ*. What was his age?"

It appears from the question, that if you call his age  $x$ , then shall  $\dots \frac{3x}{4} \times \frac{x}{12} = x$   
that is  $\dots \frac{3x^2}{48} = x$   
and by Rule 3.  $\dots 3x^2 = 48x$   
and by R. 7.  $\dots 3x = 48$   
whence by R. 2.  $\dots x = 16$ .

**DIRECT. III.** "If there are two unknown quantities, then there must be two equations arising from the conditions of the question: Suppose the quantities  $x$  and  $y$ ; find a value of  $x$  or  $y$  from each of the equations, and then, by putting these two values equal to each other, there will arise a new equation involving one unknown quantity; which must be reduced by the rules of the former chapter."

**EXAMP. I.** "Let the sum of two quantities be  $s$ , and their difference  $d$ . Let  $s$  and  $d$  be given, and let it be required to find the quantities themselves." Suppose them to be  $x$  and  $y$ , then, by the supposition,

$$\begin{aligned} &x + y = s \\ &x - y = d \\ &\text{whence } \begin{cases} 2x = s + d \\ 2y = s - d \end{cases} \\ &\text{and } \begin{cases} x = \frac{s + d}{2} \\ y = \frac{s - d}{2} \end{cases} \end{aligned}$$

**EXAMP. II.** "A privateer running at the rate of 10 miles an hour, discovers a ship 18 miles off making way at the rate of 8 miles an hour: It is demanded how many miles the ship can run before she be overtaken?"

Let the number of miles the ship can run before she be overtaken be called  $x$ , and the number of miles the privateer must run before she come up with the ship be  $y$ . then shall (by supp.)  $y = x + 18 \dots$  and  $x : y :: 8 : 10$   
whence

whence  $10x=8y \dots x=\frac{4y}{5}$  . . and  $x=y-18$ . whence

$$y-18=\frac{4y}{5} \text{ and } y=90 \dots x=y-18=72.$$

To find the time, say, If 8 miles give 1 hour, 72 miles will give 9 hours . . thus, 8:1::72:9.

EXAMP. III. "Suppose the distance between London and Edinburgh to be 360 miles; and that a courier sets out from Edinburgh, running at the rate of 10 miles an hour; another sets out at the same time from London, and runs 8 miles an hour: It is required to know where they will meet?"

Suppose the courier that sets out from Edinburgh runs  $x$  miles, and the other  $y$  miles, before they meet, then shall,

$$\text{by suppos. } \begin{cases} x+y=360 \\ x:y::5:4 \end{cases}$$

$$x=\frac{5y}{4}$$

$$x=360-y$$

$$\frac{5y}{4}=360-y$$

$$\frac{5y}{4}+y=360$$

$$9y=1440$$

$$y=\frac{1440}{9}=160$$

$$x=360-y=200$$

EXAMP. IV. "Two merchants were copartners; the sum of their stock was 300 l. One of their stocks continued in company 11 months, but the other drew out his stock in 9 months; when they made up their accounts they divided the gain equally. Q<sup>u</sup>. What was each man's stock?" Suppose the stock of the first to be  $x$ , and the stock of the other to be  $y$ ; then,

$$\text{by suppos. } \begin{cases} x+y=300 \\ 11x=9y \end{cases}$$

$$x=\frac{9y}{11}=300-y$$

$$11y+9y=3300$$

$$20y=3300$$

$$y=\frac{11y}{20}=165 \dots x=300-y=135.$$

DIRECT. IV. "When in one of the given equations the unknown quantity is of one dimension, and in the other of a higher dimension; you must find a value of the unknown quantity from that equation where it is of one dimension, and then raise that value to the power of the unknown quantity in the other equation; and by comparing it, so involved, with the value you deduce from that other equation, you shall obtain an equation that will have only one unknown quantity, and its powers."

That is, when you have two equations of different dimensions, if you cannot reduce the higher to the same dimension with the lower, you must raise the lower to the same dimension with the higher.

EXAMP. V. "The sum of two quantities, and the difference of their squares, being given, to find the quantities." Suppose them to be  $x$  and  $y$ , their sum  $s$ , and the difference of their squares  $d$ . Then,

$$\begin{cases} x+y=s \\ x^2-y^2=d \end{cases} \quad \begin{cases} *d+y^2=s^2-2xy+y^2 \\ d=s^2-2xy \\ 2xy=s^2-d \\ y=\frac{s^2-d}{2s} \\ x^2=s^2-2xy+y^2 \\ x^2=d+y^2, \text{ whence } * \text{ and } x=\frac{s^2+d}{2s} \end{cases}$$

DIRECT. V. "If there are three unknown quantities, there must be three equations in order to determine them, by comparing which, you may, in all cases, find two equations involving only two unknown quantities; and then, by *Direct.* 3d, from these two you may deduce an equation involving only one unknown quantity; which may be resolved by the rules of the last chapter."

From three equations involving any three unknown quantities,  $x$ ,  $y$ , and  $z$ , to deduce two equations, involving only two unknown quantities, the following rule will always serve.

RULE. "Find three values of  $x$  from the three given equations; then, by comparing the first and second value, you will find an equation involving only  $y$  and  $z$ ; again, by comparing the first and third, you will find another equation involving only  $y$  and  $z$ ; and, lastly, those equations are to be resolved by *Dir.* 3.

## EXAMP. VI.

$$\begin{aligned} &\text{Suppose} \\ &\begin{cases} x+y+z=12 \\ x+2y+3z=20 \end{cases} \text{ then, } \begin{cases} \left\{ \begin{matrix} 12-y-z \\ 20-2y-3z \end{matrix} \right\} \text{ 1st} \\ \left\{ \begin{matrix} 18-\frac{3y}{2}-3z \end{matrix} \right\} \text{ 2d} \\ \left\{ \begin{matrix} 12-y-z=20-2y-3z \\ 12-y-z=18-\frac{3y}{2}-3z \end{matrix} \right\} \text{ 3d} \end{cases} \text{ Value.} \end{aligned}$$

These two last equations involve only  $y$  and  $z$ , and are to be resolved by *Direct.* 3d, as follows,

$$\begin{cases} 2y-y+3z-z=20-12=8 \\ y+2z=8 \end{cases}$$

$$36-3y-6z=24-2y-2z$$

$$12=y+4z$$

$$\text{whence } y = \begin{cases} 8-2z \dots \text{1st value} \\ 12-4z \dots \text{2d value} \end{cases}$$

$$8-2z=12-4z$$

$$2z=12-8=4$$

and

$$z=2$$

$$y=(8-2z)=4$$

$$x=(12-y-z)=6.$$

This method is general, and will extend to all equations that involve 3 unknown quantities: but there are often

often easier and shorter methods to deduce an equation involving one unknown quantity only; which will be best learned by practice.

EXAMP. VII.  $\begin{cases} x+y=a \\ x+z=b \\ y+z=c \end{cases}$   
 Supp.

$$\begin{array}{r} x=a-y \\ a-y+z=b \\ y+z=c \\ \hline a+0+2z=b+c \end{array}$$

$$\begin{array}{l} 2z=b+c-a \\ \left\{ \begin{array}{l} z=\frac{b+c-a}{2} \\ y(=c-z)=\frac{c+a-b}{2} \\ x(=a-y)=\frac{a+b-c}{2} \end{array} \right. \end{array}$$

It is obvious from the 3d and 5th directions, in what manner you are to work if there are four, or more, unknown quantities, and four, or more, equations given. By comparing the given equations, you may always at length discover an equation involving only one unknown quantity; which, if it is a simple equation, may always be resolved by the rules of the last chapter. We may conclude then, that "When there are as many simple equations given as quantities required, these quantities may be discovered by the application of the preceding rules."

If indeed there are more quantities required than equations given, then the question is not limited to determinate quantities; but is capable of an infinite number of solutions. And, if there are more equations given than there are quantities required, it may be impossible to find the quantities that will answer the conditions of the question; because some of these conditions may be inconsistent with others.

CHAP. XI. *Containing some general THEOREMS for the exterminating unknown QUANTITIES in given EQUATIONS.*

IN the following *Theorems*, we call those coefficients of the *same order* that are prefixed to the same unknown quantities in the different equations. Thus in *Theor.* 2d,  $a, d, g$ , are of the same order, being the coefficients of  $x$ : also  $b, e, b$ , are of the same order, being the coefficients of  $y$ : and those are of the same order that affect no unknown quantity.

But those are called *opposite* coefficients that are taken each from a different equation, and from a different order of coefficients: As,  $a, e$ , and  $d, b$ , in the first theorem; and  $a, e, k$ , in the second; also,  $a, b, f$ ; and  $d, b, k, &c.$

THEOREM I.

Suppose that two equations are given, involving two unknown quantities, as,

$$\begin{cases} ax+by=c \\ dx+ey=f \end{cases}$$

then shall  $y = \frac{af-dc}{ae-db}$ ;

where the numerator is the difference of the products of the opposite coefficients in the orders in which  $y$  is not found, and the denominator is the difference of the products of the opposite coefficients taken from the orders that involve the two unknown quantities.

For, from the first equation, it is plain, that

$$ax=c-by \dots \text{and } x = \frac{c-by}{a}$$

from the 2d,  $dx=f-ey \dots \text{and } x = \frac{f-ey}{d}$

therefore  $\frac{c-by}{a} = \frac{f-ey}{d}$ , and  $cd-dby=af-acy$

whence  $acy-dby=af-cd$ ,

and  $y = \frac{af-cd}{ae-db}$ ,

after the same manner,  $x = \frac{cd-bf}{ae-db}$ .

EXAMP. Supp.  $\begin{cases} 5x+7y=100 \\ 3x+8y=80 \end{cases}$

then  $y = \frac{5 \times 80 - 3 \times 100}{5 \times 8 - 3 \times 7} = \frac{100}{19} = 5 \frac{5}{19}$

and  $x = \frac{240}{19} = 12 \frac{12}{19}$ .

THEOREM II.

SUPPOSE now that there are three unknown quantities and three equations, then call the unknown quantities  $x, y$ , and  $z$ .

Thus,

$$\begin{cases} ax+by+cz=m \\ dx+ey+fz=n \\ gx+hy+kz=p \end{cases}$$

Then shall  $z = \frac{aep-ahn+dbm-dhp+gbn-gem}{ask-ahf+ahc-dbk+ghf-gec}$ ;

where the numerator consists of all the different products that can be made of three opposite coefficients taken from the orders in which  $z$  is not found, and the denominator consists of all the products that can be made of the three opposite coefficients taken from the orders that involve the three unknown quantities.

CHAP. XII. *Of Quadratic EQUATIONS.*

IN the solution of any question, where you have got an equation that involves one unknown quantity, but involves

volves at the same time the square of that quantity, and the product of it multiplied by some known quantity, then you have what is called a *Quadratic equation*; which may be resolved by the following

## R U L E.

1. "Transport all the terms that involve the unknown quantity to one side, and the known terms to the other side of the equation.
2. "If the square of the unknown quantity is multiplied by any coefficient, you are to divide all the terms by that coefficient, that the coefficient of the square of the unknown quantity may be unit.
3. "Add to both sides the square of half the coefficient prefixed to the unknown quantity itself, and the side of the equation that involves the unknown quantity will then be a complete square.
4. "Extract the square root from both sides of the equation; which you will find, on one side, always to be the unknown quantity, with half the foresaid coefficient subjoined to it; so that, by transposing this half, you may obtain the value of the unknown quantity expressed in known terms." Thus,

$$\begin{array}{l}
 \text{Suppose } y^2 + ay = b \\
 \text{Add the square of } \frac{a}{2} \text{ to } \left. \begin{array}{l} y^2 + ay + \frac{a^2}{4} = b + \frac{a^2}{4} \\ \text{both sides} \end{array} \right\} \\
 \text{Extract the root, } y + \frac{a}{2} = \pm \sqrt{b + \frac{a^2}{4}} \\
 \text{Transpose } \frac{a}{2}, y = \pm \sqrt{b + \frac{a^2}{4}} - \frac{a}{2}
 \end{array}$$

The square root of any quantity, as  $+aa$ , may be  $+a$ , or  $-a$ ; and hence, "All quadratic equations admit of two solutions." In the last example, after finding

$$\begin{array}{l}
 \text{that } y^2 + ay + \frac{a^2}{4} = b + \frac{a^2}{4}, \text{ it may be inferred that } y + \frac{a}{2} \\
 = +\sqrt{b + \frac{a^2}{4}} \text{ or to } -\sqrt{b + \frac{a^2}{4}}; \text{ since } -\sqrt{b + \frac{a^2}{4}} \times \\
 \sqrt{b + \frac{a^2}{4}} \text{ gives } b + \frac{a^2}{4}, \text{ as well as } +\sqrt{b + \frac{a^2}{4}} \times \sqrt{b + \frac{a^2}{4}}. \\
 \text{There are therefore two values of } y; \text{ the one gives } y = \\
 +\sqrt{b + \frac{a^2}{4}} - \frac{a}{2}, \text{ the other, } y = -\sqrt{b + \frac{a^2}{4}} - \frac{a}{2}.
 \end{array}$$

Since the squares of all quantities are positive, it is plain that "the square root of a negative quantity is imaginary, and cannot be assigned." Therefore there are some quadratic equations that cannot have any solution. For example, suppose

$$\begin{array}{l}
 y^2 - ay + 3a^2 = 0 \\
 \text{then } y^2 - ay = -3a^2 \\
 \text{add } \frac{a^2}{4} \text{ to both, } y^2 - ay + \frac{a^2}{4} = -3a^2 + \frac{a^2}{4} \\
 = \frac{11a^2}{4} \\
 \text{extract the root, } y - \frac{a}{2} = \pm \sqrt{\frac{11a^2}{4}} \\
 \text{and } y = \frac{a}{2} \pm \sqrt{\frac{11a^2}{4}}.
 \end{array}$$

whence the two values of  $y$  must be imaginary or impossible, because the root of  $-\frac{11a^2}{4}$  cannot possibly be assigned.

Suppose that the quadratic equation proposed to be resolved is  $y^2 - xy = b$

$$\begin{array}{l}
 \text{then } y^2 - xy + \frac{a^2}{4} = b + \frac{a^2}{4} \\
 y - \frac{a}{2} = \pm \sqrt{b + \frac{a^2}{4}} \\
 \text{and } y = \frac{a}{2} \pm \sqrt{b + \frac{a^2}{4}}. \text{ If the square root of } \\
 b + \frac{a^2}{4} \text{ cannot be extracted exactly, you must, in order} \\
 \text{to determine the value of } y, \text{ nearly approximate to the} \\
 \text{value of } \sqrt{b + \frac{a^2}{4}}, \text{ by the rules in chap. 7. The following} \\
 \text{examples will illustrate the rule for quadratic equations.}
 \end{array}$$

EXAMP. I. "To find that number which if you multiply by the product shall be equal to the square of the same number having 12 added to it."

$$\begin{array}{l}
 \text{Call the number } y, \text{ then} \\
 y^2 + 12 = 8y \\
 \text{transp. } y^2 - 8y = -12 \\
 \text{add the Sq. of } 4, y^2 - 8y + 16 = -12 + 16 = 4 \\
 \text{extract the R. } y - 4 = \pm 2 \\
 \text{transp. } y = 4 \pm 2 = 6 \text{ or } 2.
 \end{array}$$

EXAMP. II. "To find a number such, that if you subtract it from 10, and multiply the remainder by the number itself, the product shall give 21."

$$\begin{array}{l}
 \text{Call it } y. \text{ Then} \\
 10 - y \times y = 21 \\
 \text{that is, } 10y - yy = 21 \\
 \text{transp. } y^2 - 10y = -21 \\
 \text{add the sq. of } 5, y^2 - 10y + 25 = -21 + 25 = 4 \\
 \text{extract, } y - 5 = \pm \sqrt{4} = \pm 2 \\
 \text{and } y = 5 \pm 2 = 7 \text{ or } 3.
 \end{array}$$

EXAMP. III. "A company dining together in an inn, find their bill amounts to 175 shillings; two of them were not allowed to pay, and the rest found that their shares amounted to 10 s. a man more than if all had paid. Q<sup>u</sup>. How many were in company?"

Suppose their number  $x$ ; then if all had paid, each man's share would have been  $\frac{175}{x}$ : but now the share

of each person is  $\frac{175}{x-2}$ , seeing  $x-2$  is the number of those that pay. It is therefore, by the question,

$$\begin{array}{l}
 \frac{175}{x-2} - \frac{175}{x} = 10. \\
 \text{and } 175x - 175x + 350 = 10x^2 - 20x \\
 \text{that is, } 10x^2 - 20x = 350 \\
 \text{and } x^2 - 2x = 35 \\
 \text{add } 1 \dots x^2 - 2x + 1 = 35 + 1 = 36 \\
 \text{extr. } \sqrt{x-1} = \pm 6 \\
 x = 1 \pm 6 = 7, \text{ Or, } -5.
 \end{array}$$

It is obvious, that the positive value  $\gamma$  gives the solution of the question; the negative value  $-\gamma$  being, in the present case, useless.

Any equation of this form  $y^2 + ay = b$ , where the greatest index of the unknown quantity  $y$  is double to the index of  $y$  in the other term, may be reduced to a quadratic  $z^2 + az = b$ , by putting  $ym = z$ , and consequently  $y^2 = z^2$ . And this quadratic resolved as above gives

$$z = -\frac{a}{2} \pm \sqrt{b + \frac{a^2}{4}}$$

And seeing  $ym = z = -\frac{a}{2} \pm \sqrt{b + \frac{a^2}{4}}$ ,  $y =$

$$= \sqrt{\frac{-\frac{a}{2} \pm \sqrt{b + \frac{a^2}{4}}}{m}}$$

EXAMP. "The product of two quantities is  $a$ , and the sum of their squares  $b$ . Quid. The quantities?"

Supp.  $\begin{cases} xy = a \dots \text{or } x = \frac{a}{y} \text{ and } x^2 = \frac{a^2}{y^2} \\ x^2 + y^2 = b \dots x^2 = b - y^2 \end{cases}$

whence  $b - y^2 = \frac{a^2}{y^2}$   
mult. by  $y^2 \dots by^2 - y^4 = a^2$   
transp.  $y^4 - by^2 = -a^2$

Put now  $y^2 = z \dots$  and conseq.  $\dots y^4 = z^2$ , and it is

$$\text{add } \frac{b^2}{4} \dots z^2 - bz + \frac{b^2}{4} = \frac{b^2}{4} - a^2$$

$$\text{ext. } \sqrt{\dots} z - \frac{b}{2} = \pm \sqrt{\frac{b^2}{4} - a^2}$$

and  $z = \frac{b}{2} \pm \sqrt{\frac{b^2}{4} - a^2}$  and, seeing  $y = \sqrt{z}$ ,

$$y = \pm \sqrt{\frac{\frac{b}{2} \pm \sqrt{\frac{b^2}{4} - a^2}}{1}}$$

CHAP. XIII. Of SURDS.

If a lesser quantity measures a greater so as to leave no remainder, as  $2a$  measures  $10a$ , being found in it five times, it is said to be an *aliquot* part of it, and the greater is said to be a *multiple* of the lesser. The lesser quantity in this case is the *greatest common measure* of the two quantities: for as it measures the greatest, so it also measures itself, and no quantity can measure it that is greater than itself.

When a third quantity measures any two proposed quantities, as  $2a$  measures  $6a$  and  $10a$ , it is said to be a *common measure* of these quantities; and if no greater quantity measure them both, it is called their *greatest common measure*.

Those quantities are said to be *commensurable* which have any common measure; but if there can be no quantity found that measures them both, they are said to be *incommensurable*; and if any one quantity be called *rational*, all others that have any common measure with it, are also called rational: But those that have no common measure with it, are called *irrational* quantities.

If any two quantities  $a$  and  $b$  have any common measure  $x$ , this quantity  $x$  shall also measure their sum or difference  $a \pm b$ . Let  $x$  be found in  $a$  as many times as unit is found in  $m$ , so that  $a = mx$ , and in  $b$  as many times as unit is found in  $n$ , so that  $b = nx$ ; then shall  $a \pm b = mx \pm nx = (m \pm n)x$ ; so that  $x$  shall be found in  $a \pm b$ , as often as unit is found in  $m \pm n$ : now since  $m$  and  $n$  are integer numbers,  $m \pm n$  must be an integer number or unit, and therefore  $x$  must measure  $a \pm b$ .

It is also evident, that if  $x$  measure any number as  $a$ , it must measure any multiple of that number. If it be found in  $a$  as many times as unit is found in  $m$  so that  $a = mx$ , then it will be found in any multiple of  $a$ , as  $na$ , as many times as unit is found in  $mn$ ; for  $na = mnx$ .

If two quantities  $a$  and  $b$  are proposed, and  $b$  measure  $a$  by the units that are in  $m$  (that is, be found in  $a$  as many times as unit is found in  $m$ ) and there be a remainder  $c$ , and if  $x$  be supposed to be a common measure of  $a$  and  $b$ , it shall be also a measure of  $c$ . For by the supposition  $a = mb + c$ , since it contains  $b$  as many times as there are units in  $m$ , and there is  $c$  besides of remainder. Therefore  $a - mb = c$ . Now  $x$  is supposed to measure  $a$  and  $b$ , and therefore it measures  $mb$ , and consequently  $a - mb$ , which is equal to  $c$ .

If  $c$  measure  $b$  by the units in  $n$ , and there be a remainder  $d$ , so that  $b = nc + d$ , and  $b - nc = d$ , then shall  $x$  also measure  $d$ ; because it is supposed to measure  $b$ , and it has been proved that it measures  $c$ , and consequently  $nc$ , and  $b - nc$  which is equal to  $d$ . Whence, as, after subtracting  $b$  as often as possible from  $a$ , the remainder  $c$  is measured by  $x$ ; and, after subtracting  $c$  as often as possible from  $b$ , the remainder  $d$  is also measured by  $x$ ; so, for the same reason, if you subtract  $d$  as often as possible from  $c$ , the remainder (if there be any) must still be measured by  $x$ : and if you proceed, still subtracting every remainder from the preceding remainder, till you find some remainder, which, subtracted from the preceding, leaves no further remainder, but exactly measures it, this last remainder will still be measured by  $x$ , any common measure of  $a$  and  $b$ .

The last of these remainders, *viz.* that which exactly measures the preceding remainder, must be a common measure of  $a$  and  $b$ : suppose that  $d$  was this last remainder, and that it measured  $c$  by the units in  $r$ , then shall  $c = rd$ , and we shall have these equations,

$$\begin{aligned} a &= mb + c \\ b &= nc + d \\ c &= rd. \end{aligned}$$

Now it is plain that since  $d$  measures  $c$ , it must also measure  $nc$ , and therefore must measure  $nc + d$ , or  $b$ . And since it measures  $b$  and  $c$ , it must measure  $mb + c$ , or  $a$ : so that it must be a common measure of  $a$  and  $b$ . But further, it must be their *greatest* common measure; for every common measure of  $a$  and  $b$  must measure  $d$ , by the last article; and the greatest number that measures  $d$ , is itself, which therefore is the greatest common measure of  $a$  and  $b$ .

But if, by continually subtracting every remainder from the preceding remainder, you can never find one that measures that which precedes it exactly, no quantity can

be found that will measure both  $a$  and  $b$ ; and therefore they will be *incommensurable* to each other.

For if there was any common measure of these quantities, as  $x$ , it would necessarily measure all the remainders  $c$ ,  $d$ , &c. For it would measure  $a=mb$ , or  $c$ , and consequently  $b=nc$ , or  $d$ , and so on; now these remainders decrease in such a manner, that they will necessarily become at length less than  $x$ , or any assignable quantity. For  $c$  must be less than  $\frac{2}{3}a$ ; because  $c$  is less than  $b$ , and therefore less than  $mb$ , and consequently less than  $\frac{1}{3}c + \frac{2}{3}mb$ , or  $\frac{1}{3}a$ . In like manner  $d$  must be less than  $\frac{1}{3}b$ ; for  $d$  is less than  $c$ , and consequently less than  $\frac{1}{3}d + \frac{2}{3}nc$ , or  $\frac{1}{3}b$ . The third remainder, in the same manner, must be less than  $\frac{1}{3}c$ , which is itself less than  $\frac{1}{3}a$ : Thus these remainders decrease, so that every one is less than the half of that which preceded it next but one. Now if from any quantity you take away more than its half, and from the remainder more than its half, and proceed in this manner, you will come at a remainder less than any assignable quantity. It appears therefore, that if the remainders  $c$ ,  $d$ , &c. never end, they will become less than any assignable quantity, as  $x$ , which therefore cannot possibly measure them, and therefore cannot be a common measure of  $a$  and  $b$ .

In the same way the greatest common measure of two numbers is discovered. Unit is a common measure of all integer numbers, and two numbers are said to be *prime* to each other when they have no greater common measure than unit; such as 9 and 25. Such always are the least numbers that can be assumed in any given proportion; for if these had any common measure, then the quotients that would arise by dividing them by that common measure would be in the same proportion, and, being less than the numbers themselves, these numbers would not be the least in the same proportion; against the supposition.

The least numbers in any proportion always measure any other numbers that are in the same proportion. Suppose  $a$  and  $b$  to be the least of all integer numbers in the same proportion, and that  $c$  and  $d$  are other numbers in that proportion, then will  $a$  measure  $c$ , and  $b$  measure  $d$ .

For if  $a$  and  $b$  are not aliquot parts of  $c$  and  $d$ , then they must contain the same number of the same kind of parts of  $c$  and  $d$ ; and therefore dividing  $a$  into parts of  $c$ , and  $b$  into an equal number of like parts of  $d$ , and calling one of the first  $m$ , and one of the latter  $n$ ; then as  $m$  is to  $n$ , so will the sum of all the  $m$ 's be to the sum of all the  $n$ 's; that is,  $m : n :: a : b$ , therefore  $a$  and  $b$  will not be the least in the same proportion; against the supposition. Therefore  $a$  and  $b$  must be aliquot parts of  $c$  and  $d$ . Hence we see that numbers which are prime to each other are the least in the same proportion; for if there were others in the same proportion less than them, these would measure them by the same number, which therefore would be their common measure against the supposition, for we supposed them to be prime to each other.

If two numbers  $a$  and  $b$  are prime to one another, and a third number  $c$  measures one of them  $a$ , it will be prime to the other  $b$ . For if  $c$  and  $b$  were not prime to

each other, they would have a common measure, which, because it would measure  $c$ , would also measure  $a$ , which is measured by  $c$ , therefore  $a$  and  $b$  would have a common measure, against the supposition.

If two numbers  $a$  and  $b$  are prime to  $c$ , then shall their product  $ab$  be also prime to  $c$ : For if you suppose them to have any common measure as  $d$ , and suppose that  $d$  measures  $ab$  by the units in  $e$ , so that  $de=ab$ , then shall  $d : a :: b : e$ . But since  $d$  measures  $c$ , and  $c$  is supposed to be prime to  $a$ , it follows that  $d$  and  $a$  are prime to each other; and therefore  $d$  must measure  $b$ ; and yet, since  $d$  is supposed to measure  $c$  which is prime to  $b$ , it follows that  $d$  is also prime to  $b$ ; that is,  $d$  is prime to a number which it measures, which is absurd.

It follows from the last article, that if  $a$  and  $c$  are prime to each other, then  $a^2$  will be prime to  $c$ : For by supposing that  $a$  is equal to  $b$ , then  $ab$  will be equal to  $a^2$ ; and consequently  $a^2$  will be prime to  $c$ . In the same manner  $c^2$  will be prime to  $a$ .

If two numbers  $a$  and  $b$  are both prime to other two  $c$ ,  $d$ , then shall the product  $ab$  be prime to the product  $cd$ ; for  $ab$  will be prime to  $c$  and also to  $d$ , and therefore, by the same article,  $cd$  will be prime to  $ab$ .

From this it follows, that if  $a$  and  $c$  are prime to each other, then shall  $a^2$  be prime to  $c^2$ , by supposing, in the last, that  $a=b$ , and  $c=d$ . It is also evident that  $a^2$  will be prime to  $c^3$ , and in general any power of  $a$  to any power of  $c$  whatsoever.

Any two numbers,  $a$  and  $b$ , being given, to find the least numbers that are in the same proportion with them, divide them by their greatest common measure  $x$ , and the quotients  $c$  and  $d$  shall be the least numbers in the same proportion with  $a$  and  $b$ .

For if there could be any other numbers in that proportion less than  $c$  and  $d$ , suppose them to be  $e$  and  $f$ , and these being in the same proportion as  $a$  and  $b$  would measure them: And the number by which they would measure them, would be greater than  $x$ , because  $e$  and  $f$  are supposed less than  $c$  and  $d$ , so that  $x$  would not be the greatest common measure of  $a$  and  $b$ ; against the supposition.

Let it be required to find the least number that any two given numbers,  $a$  and  $b$ , can measure. First, "If they are prime to each other, then their product  $ab$  is the least number which they can both measure."

For if they could measure a less number than  $ab$  as  $c$ , suppose that  $c$  is equal to  $ma$ , and to  $nb$ ; and since  $c$  is less than  $ab$ , therefore  $ma$  will be less than  $ab$ , and  $m$  less than  $b$ ; and  $nb$  being less than  $ab$ , it follows that  $n$  must be less than  $a$ ; but since  $ma=nb$ , and consequently  $a : b :: n : m$ , and  $a$  and  $b$  are prime to each other, it would follow that  $a$  would measure  $n$ , and  $b$  measure  $m$ , that is, a greater number would measure a less, which is absurd.

But if the numbers  $a$  and  $b$  are not prime to each other, and their greatest common measure is  $x$ , which measures  $a$  by the units in  $m$ , and measures  $b$  by the units in  $n$ , so that  $a=mx$ , and  $b=nx$ , then shall  $an$  (which is equal to  $bm$ , because  $a : b :: mx : nx :: m : n$ , and therefore  $an=bm$ ) be the least number that  $a$  and  $b$  can both measure. For if they could measure any number  $c$  less than

than  $na$ , so that  $c=la=kb$ , then  $a : b :: m : n :: k : l$ ; and because  $x$  is supposed to be the greatest common measure of  $a$  and  $b$ ; it follows that  $m$  and  $n$  are the least of all numbers in the same proportion; and therefore  $m$  measures  $k$ , and  $n$  measures  $l$ . But as  $c$  is supposed to be less than  $na$ , that is,  $la$  less than  $na$ , therefore  $l$  is less than  $n$ , so that a greater would measure a lesser, which is absurd. Therefore  $a$  and  $b$  cannot measure any number less than  $an$ ; which they both measure, because  $na=mb$ .

It follows from this reasoning, that if  $a$  and  $b$  measure any quantity  $c$ , the least quantity  $na$ , which is measured by  $a$  and  $b$ , will also measure  $c$ . For if you suppose, as before, that  $c=la$ , you will find, that  $n$  must measure  $l$ , and  $na$  must measure  $la$  or  $c$ .

Let  $a$  express any integer number, and  $\frac{m}{n}$  any fraction reduced to its lowest terms, so that  $m$  and  $n$  may be prime to each other, and consequently  $an+m$  also prime to  $n$ , it will follow that  $an+m^2$  will be prime to  $n^2$ , and consequently  $\frac{an+m^2}{n^2}$  will be a fraction in its least terms, and can never be equal to an integer number. There-

fore the square of the mixt number  $a+\frac{m}{n}$  is still a mixt number, and never an integer. In the same manner, the cube, biquadrate, or any power of a mixt number, is still a mixt number, and never an integer. It follows from this, that the square root of an integer must be an integer or an incommensurable. Suppose that the integer proposed is  $B$ , and that the square root of it is less than  $a+1$ , but greater than  $a$ , then it must be an incommensurable; for if it is a commensurable, let it be  $a+\frac{m}{n}$  where  $\frac{m}{n}$  represents any fraction reduced to its

least terms; it would follow, that  $a+\frac{m}{n}$  squared would give an integer number  $B$ , the contrary of which we have demonstrated.

It follows from the last article, that the square roots of all numbers but of 1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, 144, &c. (which are the squares of the integers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, &c.) are incommensurables: in the same manner, the cube roots of all numbers but of the cubes of 1, 2, 3, 4, 5, 6, 7, 8, 9, &c. are incommensurables; and quantities that are to one another in the proportion of such numbers must also have their square roots or cube roots incommensurable.

The roots of such numbers being incommensurable are expressed therefore by placing the proper radical sign over them; thus,  $\sqrt[2]{2}$ ,  $\sqrt[3]{3}$ ,  $\sqrt[4]{5}$ ,  $\sqrt[5]{6}$ ,  $\sqrt[6]{7}$ ,  $\sqrt[7]{8}$ ,  $\sqrt[8]{9}$ , &c. express numbers incommensurable with unit. These numbers, though they are incommensurable themselves with unit, are commensurable in power with it, because their powers are integers, that is, multiples of unit. They may also be commensurable sometimes with one another, as the  $\sqrt[3]{8}$ , and the  $\sqrt[4]{2}$ , because they are to one another as 2 to 1: And when they have

a common measure, as  $\sqrt[2]{2}$  is the common measure of both, then their ratio is reduced to an expression in the least terms, as that of commensurable quantities, by dividing them by their greatest common measure. This common measure is found as in commensurable quantities, only the root of the common measure is to be made

their common divisor. Thus,  $\frac{\sqrt[4]{12}}{\sqrt[2]{3}} = \sqrt[2]{4} = 2$ , and

$$\frac{\sqrt[4]{18a}}{\sqrt[2]{2}} = 3\sqrt[2]{a}.$$

A rational quantity may be reduced to the form of any given surd, by raising the quantity to the power that is denominated by the name of the surd, and then setting the radical sign over it thus,  $a = \sqrt[2]{a^2} = \sqrt[3]{a^3} = \sqrt[4]{a^4} = \sqrt[5]{a^5} = \sqrt[n]{a^n}$ , and  $4 = \sqrt[3]{16} = \sqrt[4]{64} = \sqrt[5]{256} = \sqrt[n]{1024} = \sqrt[n]{4^n}$ .

As surds may be considered as powers with fractional exponents, "they are reduced to others of the same value that shall have the same radical sign, by reducing these fractional exponents to fractions having the same value and a common denominator." Thus,  $\sqrt[n]{a} = a^{\frac{1}{n}}$

$\sqrt[m]{a} = a^{\frac{1}{m}}$ , and  $\frac{1}{n} = \frac{m}{mn}$ ,  $\frac{1}{m} = \frac{n}{nm}$ , and therefore  $\sqrt[n]{a}$  and  $\sqrt[m]{a}$ , reduced to the same radical sign, become  $\sqrt[nm]{a^m}$  and  $\sqrt[nm]{a^n}$ . If you are to reduce  $\sqrt[3]{3}$  and  $\sqrt[2]{2}$  to the same denominator, consider,  $\sqrt[3]{3}$  as equal to  $3^{\frac{1}{3}}$ , the  $\sqrt[2]{2}$  as equal to  $2^{\frac{1}{2}}$ , whose indices reduced to a common denominator, you have  $3^{\frac{2}{6}} = 3^{\frac{2}{6}}$  and  $2^{\frac{3}{6}} = 2^{\frac{3}{6}}$ , and consequently  $\sqrt[3]{3} = \sqrt[6]{3^2} = \sqrt[6]{27}$ , and  $\sqrt[2]{2} = \sqrt[6]{2^3} = \sqrt[6]{8}$ ; so that the proposed surds  $\sqrt[3]{3}$  and  $\sqrt[2]{2}$  are reduced to other equal surds  $\sqrt[6]{27}$  and  $\sqrt[6]{8}$ , having a common radical sign.

Surds of the same rational quantity are multiplied by adding their exponents, and divided by subtracting them;

$$\text{thus } \sqrt[2]{a} \times \sqrt[3]{a} = a^{\frac{1}{2}} \times a^{\frac{1}{3}} = a^{\frac{3+2}{6}} = a^{\frac{5}{6}} = \sqrt[6]{a^5}; \text{ and}$$

$$\frac{\sqrt[3]{a}}{\sqrt[5]{a}} = \frac{a^{\frac{1}{3}}}{a^{\frac{1}{5}}} = a^{\frac{1}{3} - \frac{1}{5}} = a^{\frac{5-3}{15}} = a^{\frac{2}{15}} = \sqrt[15]{a^2};$$

$$\sqrt[m]{a} \times \sqrt[n]{a} = a^{\frac{m+n}{mn}}; \quad \frac{\sqrt[m]{a}}{\sqrt[n]{a}} = a^{\frac{n-m}{mn}}; \quad \sqrt[2]{2} \times \sqrt[3]{2} = \sqrt[6]{2^5} = \sqrt[6]{32}; \quad \frac{\sqrt[2]{2}}{\sqrt[3]{2}} = \sqrt[6]{2}.$$

If the surds are of different rational quantities, as  $\sqrt[n]{a^2}$  and  $\sqrt[m]{b^3}$ , and have the same sign, "multiply these rational quantities into one another, or divide them

“ them by one another, and set the common radical sign  
 “ over their product or quotient.” Thus,  $\sqrt[n]{a^2} \times \sqrt[n]{b^3} =$   
 $\sqrt[n]{a^2 b^3}$ ;  $\sqrt[2]{2} \times \sqrt[2]{5} = \sqrt[2]{10}$ ;  $\frac{\sqrt[m]{a^2}}{\sqrt[m]{b^3}} = \sqrt[m]{\frac{a^2}{b^3}} = \sqrt[m]{\frac{a^2}{b^3}}$ ;

If the furds have not the same radical sign, “ reduce  
 “ them to such as shall have the same radical sign, and

“ proceed as before,”  $\sqrt[m]{a} \times \sqrt[n]{b} = \sqrt[mn]{a^n b^m}$ ;  $\frac{\sqrt[m]{a}}{\sqrt[n]{x}} =$

$$\sqrt[mn]{\frac{a^n}{x^m}}$$

$$\sqrt[2]{2} \times \sqrt[3]{4} = 2^{\frac{1}{2}} \times 4^{\frac{1}{3}} = 2^{\frac{1}{2}} \times 2^{\frac{2}{3}} = 2^{\frac{3}{6} + \frac{4}{6}} = 2^{\frac{7}{6}} = \sqrt[6]{2^7} = \sqrt[6]{128}$$

If the furds have any rational coefficients, their product or quotient must be prefixed; thus,  
 $2\sqrt[2]{3} \times 5\sqrt[2]{6} = 10\sqrt[2]{18}$ .

The powers of furds are found as the powers of other quantities, “ by multiplying their exponents by the index of the power required;” thus the square of  $\sqrt[3]{2}$  is  $2^{\frac{2}{3}} \times 2 = 2^{\frac{4}{3}} = \sqrt[3]{16}$ ; the cube of  $\sqrt[5]{3} = 3^{\frac{3}{5}} \times 3 = 3^{\frac{6}{5}} = \sqrt[5]{125}$ . Or you need only, in involving furds, “ raise the quantity under the radical sign to the power required, continuing the same radical sign; unless the index of that power is equal to the name of the furd, or a multiple of it, and in that case the power of the furd becomes “ rational.” Evolution is performed “ by dividing the fraction which is the exponent of the furd by the name of the root required.” Thus the square root of  $\sqrt[4]{a^4}$  is  $\sqrt[4]{a^2}$  or  $\sqrt[2]{a^2}$ .

The furd  $\sqrt[m]{a^m x} = a\sqrt{x}$ ; and in like manner, if a power of any quantity of the same name with the furd divides the quantity under the radical sign without a remainder, as here  $a^m$  divides  $a^m x$ , and 25 the square of 5 divides 75 the quantity under the sign in  $\sqrt[2]{75}$  without a remainder, then place the root of that power rationally before the sign, and the quotient under the sign, and thus the furd will be reduced to a more simple expression.

Thus,  $\sqrt[2]{75} = 5\sqrt[2]{3}$ ;  $\sqrt[2]{48} = \sqrt[2]{3 \times 16} = 4\sqrt[2]{3}$ ;  $\sqrt[3]{81} = \sqrt[3]{27 \times 3} = 3\sqrt[3]{3}$ .

When furds by the last article are reduced to their least expressions, if they have the same irrational part, they are added or subtracted, “ by adding or subtracting their rational coefficients, and prefixing the sum or “ difference to the common irrational part.” Thus,  
 $\sqrt[2]{75} + \sqrt[2]{48} = 5\sqrt[2]{3} + 4\sqrt[2]{3} = 9\sqrt[2]{3}$ ;  $\sqrt[3]{81} + \sqrt[3]{24} = 3\sqrt[3]{3} + 2\sqrt[3]{3} = 5\sqrt[3]{3}$ .

Compound furds are such as consist of two or more joined together. The simple furds are commensurable in power, and by being multiplied into themselves give at length rational quantities; yet compound furds multiplied into themselves commonly give still irrational pro-

ducts. But when any compound furd is proposed, there is another compound furd which multiplied into it gives a rational product. Thus,  $\sqrt{a} + \sqrt{b}$  multiplied by  $\sqrt{a} - \sqrt{b}$  gives  $a - b$ , and “ the investigation of that furd “ which multiplied into the proposed furd will give a “ rational product,” is made easy by the following theorems.

THEOREM I.

Generally, if you multiply  $a^m - b^m$  by  $a^{n-m} + a^{n-2m} b^m + a^{n-3m} b^2 m + a^{n-4m} b^3 m$ , &c. continued till the terms be in number equal to  $\frac{n}{m}$ , the product shall be  $a^n - b^n$ ; for  
 $a^{n-m} + a^{n-2m} b^m + a^{n-3m} b^2 m + a^{n-4m} b^3 m$ , &c. . .  $b^{n-m} \times a^{n-m} b^m$

$$a^n + a^{n-1} m + a^{n-2} m^2 b^2 m + a^{n-3} m^3 b^3 m, \text{ \&c.}$$

$$- a^{n-1} m - a^{n-2} m^2 b^2 m - a^{n-3} m^3 b^3 m, \text{ \&c.} - b^n$$

THEOREM II.

$a^{n-1} m - a^{n-2} m^2 b^2 m + a^{n-3} m^3 b^3 m - a^{n-4} m^4 b^4 m$ , &c. multiplied by  $a^{n-1} + b^m$  gives  $a^n - b^n$ , which is demonstrated as the other. Here the sign of  $b^m$  is positive, when  $\frac{n}{m}$  is an odd number.

When any binomial furd is proposed, “ suppose the index of each number equal to  $m$ , and let  $n$  be the least integer number that is measured by  $m$ , then shall  $a^{n-m} \pm a^{n-2m} b^m + a^{n-3m} b^2 m$ , &c. give a compound furd, which multiplied into the proposed furd  $a^{n-m} \pm b^m$  will give a rational product.” Thus to find the furd

which multiplied by  $\sqrt{a} - \sqrt{b}$ , will give a rational quantity. Here  $m = \frac{1}{2}$ , and the least number which is measured by  $\frac{1}{2}$  is unit; let  $n = 1$ , then shall  $a^{n-m} + a^{n-2m} b^m + a^{n-3m} b^2 m$ , &c. =  $a^{1-\frac{1}{2}} + a^{1-2 \times \frac{1}{2}} b^{\frac{1}{2}} = a^{\frac{1}{2}} + a^{\frac{1}{2}} b^{\frac{1}{2}} = \sqrt{a} + \sqrt{ab} + \sqrt{b^{\frac{1}{2}}}$ , which multiplied by  $\sqrt{a} - \sqrt{b}$  gives  $a - b$ .

To find the furd which multiplied by  $\sqrt[4]{a^3} + \sqrt[4]{b^3} = a^{\frac{3}{4}} + b^{\frac{3}{4}}$ , gives a rational product. Here  $m = \frac{1}{4}$  and  $n = 3$ , and  $a^{n-m} - a^{n-1} m b^m + a^{n-3m} b^2 m$ , &c. =  $a^{3-\frac{1}{4}} - a^{3-\frac{2}{4}} b^{\frac{1}{4}} - a^{3-\frac{3}{4}} b^{\frac{3}{4}} = a^{\frac{11}{4}} - a^{\frac{5}{4}} b^{\frac{1}{4}} - a^{\frac{9}{4}} b^{\frac{3}{4}} = \sqrt[4]{a^{11}} - \sqrt[4]{a^5 b} - \sqrt[4]{a^9 b^3}$ .

THEOREM III.

Let  $a^m \pm b^l$  be multiplied by  $a^{n-m} \pm a^{n-2m} b^l + a^{n-3m} b^{2l} - a^{n-4m} b^{3l}$ , and the product shall give  $a^n \pm b^m$ : “ therefore  $n$  must be taken the least integer that shall give  $\frac{nl}{m}$  also an integer.

Dem.  $a^{n-m} \pm a^{n-2m} b^2 + a^{n-4m} b^4 + \dots$   
 $\times a^{m \pm b^2} \dots \&c. a^0 b^m$   
 $\frac{a^{n-m} \pm a^{n-2m} b^2 + a^{n-4m} b^4 + \dots}{\pm a^{n-m} b^2 + a^{n-2m} b^4 + \dots}$   
 $\frac{\pm a^{n-m} b^2 + a^{n-2m} b^4 + \dots}{a^n}$

arising will be that of the proposed quantity divided by the binomial furd, expressed in its least terms. Thus,

$$\frac{3}{\sqrt{5}-\sqrt{2}} = \frac{3\sqrt{5+3}\sqrt{2}}{3} = \sqrt{5+\sqrt{2}}$$

$$\frac{\sqrt{6}}{\sqrt{7}-\sqrt{3}} = \frac{\sqrt{42+\sqrt{18}}}{4}$$

When the square root of a furd is required, it may be found nearly by extracting the root of a rational quantity that approximates to its value. Thus to find the square root of  $3+2\sqrt{2}$ , we first calculate  $\sqrt{2}=1,41421$ ; and therefore  $3+2\sqrt{2}=5,82842$ . whose root is found

to be nearly 2,41421: So that  $\sqrt{3+2\sqrt{2}}$  is nearly 2,41421. But sometimes we may be able to express the roots of furds exactly by other furds; as in this example the square root of  $3+2\sqrt{2}$  is  $1+\sqrt{2}$ , for  $1+\sqrt{2} \times 1+\sqrt{2} = 1+2\sqrt{2}+2=3+2\sqrt{2}$ .

In order to know when and how this may be found, let us suppose that  $x+y$  is a binomial furd, whose square will be  $x^2+y^2+2xy$ : If  $x$  and  $y$  are quadratic furds, then  $x^2+y^2$  will be rational, and  $2xy$  irrational; so that  $2xy$  shall always be less than  $x^2+y^2$ , because the difference is  $x^2+y^2-2xy=x-y$  which is always positive. Suppose that a proposed furd consisting of a rational part A, and an irrational part B, coincides with this, then  $x^2+y^2=A$  and  $xy=\frac{1}{2}B$ : Therefore by what was said of equations, Chap. 12th,

$$y^2 = A - x^2 = \frac{B^2}{4x^2}, \text{ and therefore,}$$

$$Ax^2 - x^4 = \frac{B^2}{4} \text{ and } x^4 - Ax^2 + \frac{B^2}{4} = 0;$$

from whence we have  $x^2 = \frac{A + \sqrt{A^2 - B^2}}{2}$  and  $y^2 =$

$\frac{A - \sqrt{A^2 - B^2}}{2}$ . Therefore when a quantity partly rational, partly irrational, is proposed to have its root extracted, call the rational part A, the irrational B, and the square of the greatest member of the root shall be  $\frac{A + \sqrt{A^2 - B^2}}{2}$ , and the square of the lesser part shall be  $\frac{A - \sqrt{A^2 - B^2}}{2}$ . And as often as the square root of

$A^2 - B^2$  can be extracted, the square root of the proposed binomial furd may be expressed itself as a binomial furd. For example, if  $3+2\sqrt{2}$  is proposed, then  $A=3$ ,  $B=2\sqrt{2}$  and  $A^2 - B^2 = 9 - 8 = 1$ .

Therefore  $x^2 = \frac{A + \sqrt{A^2 - B^2}}{2} = 2$ , and  $y^2 = \frac{A - \sqrt{A^2 - B^2}}{2} = 1$ . Therefore  $x+y = 1+\sqrt{2}$ .

To find the square root of  $-1+\sqrt{-8}$ , suppose  $A = -1$ ,  $B = \sqrt{-8}$ , so that  $A^2 - B^2 = 9$  and  $\frac{A + \sqrt{A^2 - B^2}}{2} = \frac{-1+3}{2} = 1$ , and  $\frac{A - \sqrt{A^2 - B^2}}{2} = \frac{-1-3}{2} = -2$ , therefore the root required is  $1+\sqrt{-2}$ .

But

The sign of  $b^m$  is positive only when  $m$  is an odd number, and the binomial proposed is  $a^m \pm b^l$ .

If any binomial furd is proposed whose two numbers have different indices, let these be  $m$  and  $l$ , and take  $n$  equal to the least integer number that is measured by  $m$  and by  $\frac{m}{l}$ ; and  $a^{n-m} \pm a^{n-2m} b^2 + a^{n-4m} b^4 + \dots + a^{n-2m} b^2 + a^{n-2m} b^4 + \dots$  &c. shall give a compound furd, which multiplied by the proposed  $a^m \pm b^l$  shall give a rational product. Thus  $\sqrt[3]{a} - \sqrt[3]{b}$  being given, suppose  $m=\frac{1}{3}$ ,  $l=\frac{1}{3}$ , and  $\frac{m}{l}=\frac{1}{3}$ , therefore you have  $n=3$ , and  $a^{n-m} + 2a^{n-2m} b^2 + a^{n-4m} b^4 + \dots + a^{n-2m} b^2 + a^{n-2m} b^4 + \dots$  &c.  $= a^{3-\frac{1}{3}} + a^{3-1} b^{\frac{2}{3}} + a^3 - 2a^{\frac{2}{3}} b^2 + a^2 b^{\frac{2}{3}} + a^2 b^{\frac{2}{3}} = a^{\frac{8}{3}} + a^2 b^{\frac{2}{3}} + a^{\frac{8}{3}} + 2ab + a^{\frac{2}{3}} b^{\frac{2}{3}} + b^{\frac{2}{3}} = \sqrt{a^2} + a^2 \times \sqrt{b} + \sqrt{a^2} \times \sqrt{b^2} + ab + \sqrt{a} \times \sqrt{b^2} + \sqrt{b^2} = a^2 \sqrt{a} + a^2 \sqrt{b} + a \sqrt{a} \sqrt{b^2} + ab + b \sqrt{a} \sqrt{b} + b \sqrt{b^2}$ , which multiplied by the  $\sqrt[3]{a} - \sqrt[3]{b}$  gives  $a^3 - b^3 = a^3 - b^3$ .

By these theorems any binomial furd whatsoever being given, you may find a furd which multiplied by it shall give a rational product.

Suppose that a binomial furd was to be divided by another, as  $\sqrt{20+12}$  by  $\sqrt{5-3}$ , the quotient may be expressed by  $\frac{\sqrt{20+\sqrt{12}}}{\sqrt{5-\sqrt{3}}}$ . But it may be expressed in a more simple form by multiplying both numerator and denominator by that furd which, multiplied into the denominator, gives a rational product: Thus  $\frac{\sqrt{20+\sqrt{12}}}{\sqrt{5-\sqrt{3}}} = \frac{\sqrt{20+\sqrt{12}}}{\sqrt{5-\sqrt{3}}} \times \frac{\sqrt{5+\sqrt{3}}}{\sqrt{5+\sqrt{3}}} = \frac{\sqrt{100+2\sqrt{60}+6}}{5-3} = \frac{16+2\sqrt{60}}{2} = 8+2\sqrt{15}$ .

In general, when any quantity is divided by a binomial furd, as  $a^m \pm b^l$ , where  $m$  and  $l$  represent any fractions whatsoever, take  $n$  the least integer number that is measured by  $m$  and  $\frac{m}{l}$ , multiply both numerator and denominator by  $a^{n-m} + a^{n-2m} b^2 + a^{n-4m} b^4 + \dots$  &c. and the denominator of the product will become rational, and equal to  $a^n - b^{\frac{n}{l}}$ ; then divide all the members of the numerator by this rational quantity, and the quoti-

But though  $x$  and  $y$  are not quadratic surds or roots of integers, if they are the roots of like surds, as if they are equal to  $\sqrt{m}\sqrt{z}$  and  $\sqrt{n}\sqrt{z}$ , where  $m$  and  $n$  are integers, then  $A = m+r\sqrt{z}$  and  $\frac{1}{2}B = \sqrt{mnz}$ ;  $A^2 - B^2 = m - n$   $\times z$  and  $x^2 = \frac{A + \sqrt{A^2 - B^2}}{2} = \frac{m+n\sqrt{z} + m - n}{2} \times z = ma/z$ ,  $y^2 = \frac{A - \sqrt{A^2 - B^2}}{2} = \frac{m+n\sqrt{z} + m - n}{2} \times z = ma/z$ , and  $x+y = \sqrt{m}\sqrt{z} + \sqrt{n}\sqrt{z}$ . The part A here easily distinguishes itself from B by its being greater.

If  $x$  and  $y$  are equal to  $\sqrt{m}\sqrt{z}$  and  $\sqrt{n}\sqrt{z}$ , then  $x^2 + 2xy + y^2 = m/z + n/z + 2\sqrt{mn}\sqrt{z}$ . So that if  $z$  or  $t$  be not multiples one of the other, or of some number that measures them both by a square number, then will A itself be a binomial.

Let  $x+y+z$  express any trinomial surd, its square  $x^2 + y^2 + z^2 + 2xy + 2xz + 2yz$  may be supposed equal to  $A+B$  as before. But rather multiply any two radicals as  $2xy$  by  $2xz$ , and divide by the third  $2yz$  which gives the quotient  $2x^2$  rational, and double the square of the surd  $x$  required. The same rule serves when there are four quantities  $x^2 + y^2 + z^2 + t^2 + 2xy + 2xz + 2yz + 2yt + 2zt$ , multiply  $2xy$  by  $2xz$ , and the product  $4x^2yz$  divided by  $2yz$  gives  $2x^2$  a rational quotient, half the square of  $2x$ . In like manner  $2xy \times 2yz = 4y^2xz$ , which divided by  $2xz$  another member gives  $2y^2$ , a rational quote, the half of the square of  $2y$ . In the same manner  $z$  and  $t$  may be found; and their sum  $x+y+z+t$ , the square root of the septinomial  $x^2 + y^2 + z^2 + t^2 + 2xy + 2xz + 2yz + 2yt + 2zt$ , discovered.

For example, to find the square root of  $10 + \sqrt{24} + \sqrt{40} + \sqrt{60}$ ; I try  $\frac{\sqrt{24} \times \sqrt{40}}{\sqrt{60}}$  which I find to be  $\sqrt{16} = 4$ , the half of the square root of the double of which, viz.  $\frac{1}{2} \times \sqrt{3} = \sqrt{2}$ , is one member of the square root required; next  $\frac{\sqrt{24} \times \sqrt{60}}{\sqrt{40}} = 6$ , the half of the square root of the double of which is  $\sqrt{3}$  another member of the root required; lastly,  $\frac{\sqrt{40} \times \sqrt{60}}{\sqrt{24}} = 10$ , which gives  $\sqrt{5}$  for the third member of the root required: from which we conclude, that the square root of  $10 + \sqrt{24} + \sqrt{40} + \sqrt{60}$ , is  $\sqrt{2} + \sqrt{3} + \sqrt{5}$ ; and trying, you find it succeeds, since multiplied by itself it gives the proposed quadrinomial.

For extracting the higher roots of a binomial, whose two members being squared are commensurable numbers, there is the following

**RULE.** " Let the quantity be  $A \pm B$ , whereof A is the greater part, and  $c$  the exponent of the root required. Seek the least number  $n$  whose power  $n^c$  is divisible by  $AA - BB$ , the quotient being Q.

" Compute  $\sqrt[n]{A+B} \times \sqrt[n]{Q}$  in the nearest integer number, which suppose to be  $r$ . Divide  $A/\sqrt[n]{Q}$  by its greatest rational divisor, and let the quotient be  $t$ ,

" and let  $\frac{r + \frac{n}{r}}$  in the nearest integer number, be

"  $t$ , so shall the root required be  $\frac{r + \sqrt{r^2 - \frac{n}{r}}}{\sqrt[n]{Q}}$ , if

" the  $c$  root of  $A \pm B$  can be extracted.

**EXAMP. I.** Thus to find the cube root of  $\sqrt[3]{968 + 25}$ , we have  $A^3 - B^3 = 343$ , whose divisors are 7, 7, 7, whence  $n=7$ , and  $Q=1$ . Further,  $A + B \times \sqrt[3]{Q}$ , that is,  $\sqrt[3]{968 + 25}$  is a little more than 56, whose nearest cube root is 4. Wherefore  $r=4$ . Again, dividing  $\sqrt[3]{968}$  by its greatest rational divisor, we have  $A/\sqrt[3]{Q} = 22\sqrt[3]{2}$ , and the radical part  $\sqrt[3]{2} = t$ ; and  $\frac{r + \frac{n}{r}}{2\sqrt[3]{2}}$ , or  $\frac{5}{2\sqrt[3]{2}}$ , in the nearest integers, is  $2 = t$ . And lastly,  $t^3 = 2\sqrt[3]{2}$ ,  $\sqrt[3]{1^3 - n} = 1$ , and  $\sqrt[3]{Q} = \sqrt[3]{1} = 1$ . Whence  $2\sqrt[3]{2} + 1$  is the root, whose cube, upon trial, I find to be  $\sqrt[3]{968 + 25}$ .

**EXAMP. II.** To find the cube root of  $68 - \sqrt[3]{4374}$ , we have  $A^3 - B^3 = 250$ , whose divisors are 5, 5, 5, 2.

Thence  $n=5 \times 2 = 10$ , and  $Q=4$ , and  $\sqrt[3]{A+B} \times \sqrt[3]{Q}$ , or  $\sqrt[3]{68 + \sqrt[3]{4374} \times 2}$  is nearly  $7 = r$ ; again  $A/\sqrt[3]{Q}$ , or  $68 \times \sqrt[3]{4} = 136 \times \sqrt[3]{4}$ , that is,  $t=1$ , and  $\frac{r + \frac{n}{r}}{2}$ , or  $\frac{7 + \frac{10}{7}}{2}$ , is nearly  $= 4 = t$ . Therefore  $t^3 = 4$ ,  $\sqrt[3]{1^3 - n} = \sqrt[3]{-6}$ , and  $\sqrt[3]{Q} = \sqrt[3]{4} = \sqrt[3]{2}$ , whence the root to be tried is  $\frac{4 - \sqrt[3]{6}}{\sqrt[3]{2}}$ .

**CHAP. XIV. Of the GENESIS and RESOLUTION of EQUATIONS in general; and the number of Roots an Equation of any Degree may have.**

AFTER the same manner, as the higher powers are produced by the multiplication of the lower powers of the same root, equations of superior orders are generated by the multiplication of equations of inferior orders involving the same unknown quantity. And " an equation of any dimension may be considered as produced " by the multiplication of as many simple equations as " it has dimensions, or of any other equations what- " soever, if the sum of their dimensions is equal to the " dimension of that equation." Thus, any cubic equation may be conceived as generated by the multiplication of three simple equations, or of one quadratic and one simple equation. A biquadratic is generated by the multiplication of four simple equations, or of two quadratic equations, or, lastly, of one cubic and one simple equation.

If the equations which you suppose multiplied by one another are the same, then the equation generated will be nothing else but some power of those equations, and the operation is merely *evolution*; of which we have treated already: and, when any such equation is given, the simple equation by whose multiplication it is produced is found by *evolution*, or the extraction of a root.

But when the equations that are supposed to be multiplied

multiplied by each other are *different*, then other equations than powers are generated; which to resolve into the simple equations whence they are generated is a different operation from involution, and is what is called, *the resolution of equations.*

But as evolution is performed by observing and tracing back the steps of involution; so to discover the rules for the resolution of equations, we must carefully observe their *generation.*

Suppose the unknown quantity to be  $x$ , and its values in any simple equations to be  $a, b, c, d$ , &c. then those simple equations, by bringing all the terms to one side, become  $x-a=0$ ,  $x-b=0$ ,  $x-c=0$ , &c. And, the product of any two of these, as  $x-a \times x-b=0$  will give a quadratic equation, or an equation of two dimensions. The product of any three of them, as  $x-a \times x-b \times x-c=0$ , will give a cubic equation, or one of three dimensions. The product of any four of them will give a *biquadratic* equation, or one of four dimensions, as  $x-a \times x-b \times x-c \times x-d=0$ . And, in general, "in the equation produced, the highest dimension of the unknown quantity will be equal to the number of simple equations that are multiplied by each other."

When any equation, equivalent to this biquadratic  $x-a \times x-b \times x-c \times x-d=0$ , is proposed to be resolved, the whole difficulty consists in finding the simple equations  $x-a=0$ ,  $x-b=0$ ,  $x-c=0$ ,  $x-d=0$ , by whose multiplication it is produced; for each of these simple equations gives one of the values of  $x$ , and one solution of the proposed equation. For, if any of the values of  $x$ , deduced from those simple equations, be substituted in the proposed equation in place of  $x$ , then all the terms of that equation will vanish, and the whole be found equal to nothing. Because, when it is supposed that  $x=a$ , or  $x=b$ , or  $x=c$ , or  $x=d$ , then the product  $x-a \times x-b \times x-c \times x-d$  does vanish, because one of the factors is equal to nothing. There are therefore four suppositions that give  $x-a \times x-b \times x-c \times x-d=0$  according to the proposed equation; that is, there are four roots of the proposed equation. And after the same manner, "any other equation admits of as many solutions as there are simple equations multiplied by one another that produce it, or, as many as there are units in the highest dimension of the unknown quantity in the proposed equation."

But as there are no other quantities whatsoever besides these four ( $a, b, c, d$ ) that substituted in the product  $x-a \times x-b \times x-c \times x-d$ , in the place of  $x$ , will make the product vanish; therefore the equation  $x-a \times x-b \times x-c \times x-d=0$ , cannot possibly have more than these four roots, and cannot admit of more solutions than four. If you substitute in that product a quantity neither equal to  $a$ , nor  $b$ , nor  $c$ , nor  $d$ , which suppose  $e$ , then since neither  $e-a$ ,  $e-b$ ,  $e-c$ , nor  $e-d$  is equal to nothing; their product  $e-a \times e-b \times e-c \times e-d$  cannot be equal to nothing, but must be some real product: and therefore there is no supposition beside one of the forefaid four that gives a just

value of  $x$  according to the proposed equation. So that it can have no more than these four roots. And after the same manner it appears, that "no equation can have more roots than it contains dimensions of the unknown quantity."

To make all this still plainer by an example, in numbers; suppose the equation to be resolved, to be  $x^4 - 10x^3 + 35x^2 - 50x + 24 = 0$ , and that you discover that this equation is the same with the product of  $x-1 \times x-2 \times x-3 \times x-4$ , then you certainly infer that the four values of  $x$  are 1, 2, 3, 4; seeing any of these numbers placed for  $x$  makes that product, and consequently  $x^4 - 10x^3 + 35x^2 - 50x + 24$ , equal to nothing, according to the proposed equation. And it is certain that there can be no other values of  $x$  besides these four: since when you substitute any other number for  $x$  in those factors  $x-1$ ,  $x-2$ ,  $x-3$ ,  $x-4$ , none of the factors vanish; and therefore their product cannot be equal to nothing, according to the equation.

It may be useful sometimes to consider equations as generated from others of an inferior sort besides simple ones. Thus a cubic equation may be conceived as generated from the quadratic  $x^2 - px + q = 0$ , and the simple equation  $x-a=0$ , multiplied by each other; whose product

$$\left. \begin{aligned} x^3 - px^2 + qx - aq \\ - ax^2 + apx \end{aligned} \right\} = 0 \text{ may express any cubic equation whose roots are the quantity } (a) \text{ the value of } x \text{ in the simple equation, and the two roots of the quadratic equation, viz. } \frac{p + \sqrt{p^2 - 4q}}{2} \text{ and } \frac{p - \sqrt{p^2 - 4q}}{2};$$

as appears from Chap. 12. And, according as these roots are *real* or *impossible*, two of the roots of the cubic equation are *real* or *impossible*.

In the doctrine of involution, we shewed, that "the square of any quantity, positive or negative, is always positive;" and therefore "the square root of a negative is impossible or imaginary." For example, the  $\sqrt{a^2}$  is either  $+a$ , or  $-a$ ; but  $\sqrt{-a^2}$  can neither be  $+a$  nor  $-a$ , but must be *imaginary*. Hence is understood, that "a quadratic equation may have no impossible expression in its coefficients; and yet, when it is resolved into the simple equations that produce it, they may involve impossible expressions." Thus, the quadratic equation  $x^2 + a^2 = 0$  has no impossible coefficient; but the simple equations from which it is produced, viz.  $x + \sqrt{-a^2} = 0$ , and  $x - \sqrt{-a^2} = 0$ , both involve an imaginary quantity; as the square  $-a^2$  is a real quantity, but its square root is imaginary. After the same manner, a biquadratic equation, when resolved, may give four simple equations, each of which may give an impossible value for the root: and the same may be said of any equation that can be produced from quadratic equations only, that is, whose dimensions are of the even numbers.

But, "a cubic equation (which cannot be generated from quadratic equations only, but requires one simple equation besides to produce it) if none of its coefficients are impossible, will have, at least, one real root," the same with the root of the simple equation

whence it is produced. The square of an impossible quantity may be real, as the square of  $\sqrt{-a^2}$  is  $-a^2$ ; but "the cube of an impossible quantity is still impossible," as it still involves the square root of a negative:

as,  $\sqrt{-a^2} \times \sqrt{-a^2} \times \sqrt{-a^2} = \sqrt{-a^6} = a^3\sqrt{-1}$ , is plainly imaginary. From which it appears, that though two simple equations involving impossible expressions, multiplied by one another, may give a product where no impossible expression may appear; yet "if three such simple equations be multiplied by each other, the impossible expression will not disappear in their product."

And hence it is plain, that though a quadratic equation whose coefficients are all real may have its two roots impossible, yet "a cubic equation whose coefficients are real cannot have all its three roots impossible."

In general, it appears, that the impossible expressions cannot disappear in the equation produced, but when their number is *even*; that there are never in any equations, whose coefficients are real quantities, single impossible roots, or an odd number of impossible roots, but "that the roots become impossible in pairs, and that "an equation of an odd number of dimensions has always one real root."

"The roots of equations are either *positive* or *negative*, according as the roots of the simple equations whence they are produced are positive or negative."

If you suppose  $x=a$ ,  $x=b$ ,  $x=c$ ,  $x=d$ , &c. then shall  $x+a=0$ ,  $x+b=0$ ,  $x+c=0$ ,  $x+d=0$ ; and the equation  $x+a \times x+b \times x+c \times x+d=0$  will have its roots,  $-a$ ,  $-b$ ,  $-c$ ,  $-d$ , &c. negative.

But to know when the roots of equations are positive, and when negative, and how many there are of each kind, shall be explained in the next chapter.

## CHAP. XV. Of the SIGNS and COEFFICIENTS of Equations.

WHEN any number of simple equations are multiplied by each other, it is obvious that the highest dimension of the unknown quantity in their product is equal to the number of those simple equations; and the term involving the highest dimension is called the *first* term of the equation generated by this multiplication. The term involving the next dimension of the unknown quantity, less than the greatest by unit, is called the *second* term of the equation; the term involving the next dimension of the unknown quantity, which is less than the greatest by two, the *third* term of the equation, &c.; and that term which involves no dimension of the unknown quantity, but is some known quantity, is called the *last* term of the equation.

"The number of terms is always greater than the "highest dimension of the unknown quantity by unit." And when any term is wanting, an asterisk is marked in its place. The signs and coefficients of equations will be understood by considering the following table, where the simple equations  $x=a$ ,  $x=b$ , &c. are multiplied by one another, and produce successively the higher equations.

$$\begin{array}{l} x-a=0 \\ \times x-b=0 \\ =x^2-ax \\ \quad -bx+ab \end{array} \left. \vphantom{\begin{array}{l} x-a=0 \\ \times x-b=0 \\ =x^2-ax \\ \quad -bx+ab \end{array}} \right\} =0, \text{ a quadratic.}$$

$$\begin{array}{l} \times x-c=0 \\ =x^3-a \\ \quad -b \\ \quad -c \end{array} \left. \vphantom{\begin{array}{l} \times x-c=0 \\ =x^3-a \\ \quad -b \\ \quad -c \end{array}} \right\} \begin{array}{l} +ab \\ +ac \\ +bc \end{array} \left. \vphantom{\begin{array}{l} +ab \\ +ac \\ +bc \end{array}} \right\} \times x-abc=0, \text{ a cubic.}$$

$$\begin{array}{l} \times x-d=0 \\ =x^4-a \\ \quad -b \\ \quad -c \\ \quad -d \end{array} \left. \vphantom{\begin{array}{l} \times x-d=0 \\ =x^4-a \\ \quad -b \\ \quad -c \\ \quad -d \end{array}} \right\} \begin{array}{l} +ab \\ +ac \\ +ad \\ +bc \\ +bd \\ +cd \end{array} \left. \vphantom{\begin{array}{l} +ab \\ +ac \\ +ad \\ +bc \\ +bd \\ +cd \end{array}} \right\} \begin{array}{l} -abc \\ -abd \\ -acd \\ -bcd \end{array} \left. \vphantom{\begin{array}{l} -abc \\ -abd \\ -acd \\ -bcd \end{array}} \right\} \times x+abcd=0, \text{ a biqua-} \\ \text{dratic.}$$

$$\begin{array}{l} \times x-e=0 \\ =x^5-a \\ \quad -b \\ \quad -c \\ \quad -d \\ \quad -e \end{array} \left. \vphantom{\begin{array}{l} \times x-e=0 \\ =x^5-a \\ \quad -b \\ \quad -c \\ \quad -d \\ \quad -e \end{array}} \right\} \begin{array}{l} +ab \\ +ac \\ +ad \\ +bc \\ +bd \\ +cd \\ +de \end{array} \left. \vphantom{\begin{array}{l} +ab \\ +ac \\ +ad \\ +bc \\ +bd \\ +cd \\ +de \end{array}} \right\} \begin{array}{l} -bc \\ -abd \\ -abe \\ -acd \\ -ade \\ -bce \\ -bde \\ -cde \end{array} \left. \vphantom{\begin{array}{l} -bc \\ -abd \\ -abe \\ -acd \\ -ade \\ -bce \\ -bde \\ -cde \end{array}} \right\} \times x-abcde=0, \\ \text{(a sursolid.)} \\ \text{\&c.}$$

From the inspection of these equations it is plain, that the coefficient of the first term is *unit*.

The coefficient of the second term is the *sum of all the roots* ( $a, b, c, d, e$ ), *having their signs changed*.

The coefficient of the third term is the *sum of all the products that can be made by multiplying any two of the roots* ( $a, b, c, d, e$ ), *by one another*.

The coefficient of the fourth term is the *sum of all the products that can be made by multiplying into one another any three of the roots*, with their signs changed. And after the same manner all the other coefficients are formed.

The last term is always the *product of all the roots having their signs changed*, multiplied by one another.

Although in the table such simple equations only are multiplied by one another as have positive roots, it is easy to see, that "the coefficients will be formed according to the same rule when any of the simple equations have negative roots." And, in general, if  $x^3-px^2+qx-r=0$  represent any cubic equation, then shall  $p$  be the sum of the roots;  $q$  the sum of the products made by multiplying any two of them;  $r$  the product of all the three: and, if  $-p, +q, -r, +s, -t, +u$ , &c. be the coefficients of the 2d, 3d, 4th, 5th, 6th, 7th, &c. terms of any equation, then shall  $p$  be the sum of all the roots,  $q$  the sum of the products of any two,  $r$  the sum of the products of any three,  $s$  the sum of the products of any four,  $t$  the sum of the products of any five,  $u$  the sum of the products of any six, &c.

When

When therefore any equation is proposed to be resolved, it is easy to find the sum of the roots, (for it is equal to the coefficient of the second term having its sign changed); or to find the sum of the products that can be made by multiplying any determinate number of them.

But it is also easy "to find the sum of the squares, or of any powers, of the roots.

The sum of the squares is always  $p^2 - 2q$ . For calling the sum of the squares  $B$ , since the sum of the roots is  $p$ ; and "the square of the sum of any quantities is always equal to the sum of their squares added to double the products that can be made by multiplying any two of them," therefore  $p^2 = B + 2q$ , and consequently  $B = p^2 - 2q$ . For example,  $a + b + d = a^2 + b^2 + d^2 + 2ab + 2ac + 2bc$ ; that is,  $p^2 = B + 2q$ . And  $a + b + c + d = a^2 + b^2 + c^2 + d^2 + 2ad + 2ab + ac + ad + bc + bd + cd$ , that is, again,  $p^2 = B + 2q$ , or  $B = p^2 - 2q$ . And so for any other number of quantities. In general therefore, "the sum of the squares of the roots may always be found by subtracting  $2q$  from  $p^2$ ;" the quantities  $p$  and  $q$  being always known, since they are the coefficients in the proposed equation.

"The sum of the cubes of the roots of any equation is equal to  $p^3 - 3pq + 3r$ , or to  $Bp - pq + 3r$ ." For  $B - q \times p$  gives always the excess of the sum of the cubes of any quantities above the triple sum of the products that can be made by multiplying any three of them.

Thus,  $a^3 + b^3 + c^3 - ab - ac - bc \times a + b + c (= B - q \times p) = a^3 + b^3 + c^3 - 3abc$ . Therefore if the sum of the cubes is called  $C$ , then shall  $B - q \times p = C - 3r$ , and  $C = Bp - qp + 3r$  (because  $B = p^2 - 2q) = p^3 - 3pq + 3r$ .

After the same manner, if  $D$  be the sum of the 4th powers of the roots, you will find that  $D = pC - qB + pr - 4r$ , and if  $E$  be the sum of the 5th powers, then shall  $E = pD - qC + rB - pr + 5r$ . And after the same manner the sum of any powers of the roots may be found; the progression of these expressions of the sum of the powers being obvious.

As for the signs of the terms of the equation produced, it appears, from inspection, that the signs of all the terms in any equation in the table are alternately + and -: these equations are generated by multiplying continually  $x - a, x - b, x - c, x - d, \&c.$  by one another. The first term is always some pure power of  $x$ , and is positive; the second is a power of  $x$  multiplied by the quantities  $-a, -b, -c, \&c.$  And since these are all negative, that term must therefore be negative. The third term has the products of any two of these quantities ( $-a, -b, -c, \&c.$ ) for its coefficient; which products are all positive, because  $- \times -$  gives +. For the like reason, the next coefficient, consisting of all the products made by multiplying any three of these quantities must be negative, and the next positive. So that the coefficients, in this case, will be positive and negative by turns. But, "in this case the roots are all positive;" since  $x = a, x = b, x = c, x = d, x = e, \&c.$  are the assumed simple equations. It is plain then, that "when all the roots are positive, the signs are alternately + and -."

But if the roots are all negative, then  $x + a \times x + b \times$

$x + c \times x + d, \&c. = 0$ . will express the equation to be produced; all whose terms will plainly be positive; so that, "when all the roots of an equation are negative, it is plain there will be no changes in the signs of the terms of that equation."

In general, "there are as many positive roots in any equation as there are changes in the signs of the terms from + to -, or from - to +; and the remaining roots are negative." The rule is general, if the impossible roots be allowed to be either positive or negative; and may be extended to all kinds of equations.

In quadratic equations, the two roots are either both positive, as in this

$$(x - a \times x - b = 0) \quad x^2 - ax + ab = 0,$$

where there are two changes of the signs: Or they are both negative, as in this

$$(x + a \times x + b = 0) \quad x^2 + a \quad \left. \begin{matrix} +b \\ +c \end{matrix} \right\} x + ab = 0,$$

where there is not any change of the signs: Or there is one positive and one negative, as in

$$(x - a \times x + b = 0) \quad x^2 - a \quad \left. \begin{matrix} +b \\ +c \end{matrix} \right\} x - ab = 0,$$

where there is necessarily one change of the signs; because the first term is positive, and the last negative, and there can be but one change whether the 2d term be + or -.

Therefore the rule given in the last paragraph extends to all quadratic equations.

In cubic equations, the roots may be,

1°. All positive, as in this;  $x - a \times x - b \times x - c = 0$ , in which the signs are alternately + and -, as appears from the table; and there are three changes of the signs.

2°. The roots may be all negative, as in the equation  $x + a \times x + b \times x + c = 0$ , where there can be no change of the signs. Or,

3°. There may be two positive roots and one negative, as in the equation  $x - a \times x - b \times x + c = 0$ ; which gives

$$x^3 - a \quad \left. \begin{matrix} +ab \\ -b \\ +c \end{matrix} \right\} x^2 - ac \quad \left. \begin{matrix} +ab \\ -bc \end{matrix} \right\} x + abc = 0.$$

Here there must be two changes of the signs; because if  $a + b$  is greater than  $c$ , the second term must be negative, its coefficient being  $-a - b + c$ .

And if  $a + b$  is less than  $c$ , then the third term must be negative, its coefficient  $+ab - ac - bc = c(ab - c \times a + b) *$  being in that case negative. And there cannot possibly be three changes of the signs, the first and last terms having the same sign.

4°. There may be one positive root and two negative, as in the equation  $x + a \times x + b \times x - c = 0$ , which gives

$$x^3 + a \quad \left. \begin{matrix} +ab \\ +b \\ -c \end{matrix} \right\} x^2 - ac \quad \left. \begin{matrix} +ab \\ -bc \end{matrix} \right\} x - abc = 0.$$

where

\* Because the rectangle  $a \times b$  is less than the square  $a + b \times a + b$ , and therefore much less than  $a + b \times c$ .

where there must be always one change of the signs, since the first term is positive and the last negative. And there can be but one change of the signs, since if the 2d term is negative, or  $a+b$  less than  $c$ , the third must be negative also, so that there will be but one change of the signs. Or, if the second term is affirmative, whatever the third term is, there will be but one change of the signs. It appears therefore, in general, that in cubic equations, there are as many affirmative roots as there are changes of the signs of the terms of the equation.

There are several confectaries of what has been already demonstrated, that are of use in discovering the roots of equations. But before we proceed to that, it will be convenient to explain some transformations of equations, by which they may often be rendered more simple, and the investigation of their roots more easy.

### CHAP. XVI. Of the Transformation of Equations; and exterminating their intermediate Terms.

WE now proceed to explain the transformation of equations that are most useful: and, first, "The affirmative roots of an equation are changed into negative roots of the same value, and the negative roots into affirmative, by only changing the signs of the terms alternately, beginning with the second." Thus, the roots of the equation  $x^4 - x^3 - 19x^2 + 49x - 30 = 0$  are  $+1, +2, +3, -5$ ; whereas the roots of the same equation having only the signs of the second and fourth terms changed, viz.  $x^4 + x^3 - 19x^2 + 49x - 30 = 0$  are  $-1, -2, -3, +5$ .

To understand the reason of this rule, let us assume an equation, as  $x - aXx - bXXx - cXXX - dXXx - e$ , &c.  $= 0$ , whose roots are  $+a, +b, +c, +d, +e$ , &c. and another, having its roots of the same value, but affected with contrary signs, as  $x + aXx + bXXx + cXXX + dXXx + e$ , &c.  $= 0$ . It is plain, that the terms taken alternately, beginning from the first, are the same in both equations, and have the same sign, "being products of an even number of the roots;" the product of any two roots having the same sign as their product when both their signs are changed; as  $+aX - b = -aX + b$ .

But the second terms, and all taken alternately from them, because their coefficients involve always the products of an odd number of the roots, will have contrary signs in the two equations. For example, the product of four, viz.  $abcd$ , having the same sign in both, and one equation in the fifth term having  $abcdX + e$ , and the other  $abcdX - e$ , it follows, that their product  $abcde$  must have contrary signs in the two equations: these two equations therefore that have the same roots, but with contrary signs, have nothing different but the signs of the alternate terms, beginning with the second. From which it follows, "that if any equation is given, and you change the signs of the alternate terms, beginning with the second, the new equation will have roots of the same value, but with contrary signs."

It is often very useful "to transform an equation into

"another that shall have its roots greater or less than the roots of the proposed equation by some given difference."

Let the equation proposed be the cubic  $x^3 - px^2 + qx - r = 0$ . And let it be required to transform it into another equation whose roots shall be less than the roots of this equation by some given difference ( $e$ ), that is, suppose  $y = x - e$ , and consequently  $x = y + e$ ; then, instead of  $x$  and its powers, substitute  $y + e$  and its powers, and there will arise this new equation.

$$\left. \begin{aligned} (A) y^3 + 3ey^2 + 3e^2y + e^3 \\ - py^2 - 2pey - pe^2 \\ + qy + qe \\ - r \end{aligned} \right\} = 0,$$

whose roots are less than the roots of the preceding equation by the difference ( $e$ ).

If it had been required to find an equation whose roots should be greater than those of the proposed equation by the quantity ( $e$ ), then we must have supposed  $y = x + e$ , and consequently  $x = y - e$ , and then the other equation would have had this form.

$$\left. \begin{aligned} (B) y^3 - 3ey^2 + 3e^2y - e^3 \\ - py^2 + 2pey - pe^2 \\ + qy - qe \\ - r \end{aligned} \right\} = 0.$$

If the proposed equation be in this form  $x^3 + px^2 + qx + r = 0$ , then, by supposing  $x = y$ , there will arise an equation agreeing in all respects with the equation (A), but that the second and fourth terms will have contrary signs.

And by supposing  $x = y$ , there will arise an equation agreeing with (B) in all respects, but that the second and fourth terms will have contrary signs to what they have in (B).

The first of these suppositions gives this equation,

$$\left. \begin{aligned} (C) y^3 - 3ey^2 + 3e^2y - e^3 \\ + py^2 + 2pey + pe^2 \\ + qy - qe \\ + r \end{aligned} \right\} = 0.$$

The second supposition gives the equation,

$$\left. \begin{aligned} (D) y^3 + 3ey^2 + 3e^2y + e^3 \\ + py^2 + 2pey + pe^2 \\ + qy + qe \\ + r \end{aligned} \right\} = 0.$$

The first use of this transformation of equations is to shew "how the second (or other intermediate) term may be taken away out of an equation."

It is plain, that in the equation (A) whose second term is  $3e - p \times y^2$ , if you suppose  $e = \frac{1}{3}p$ , and consequently  $3e - p = 0$ , then the second term will vanish.

In the equation (C) whose second term is  $-3e + p \times y^2$ , supposing  $e = \frac{1}{3}p$ , the second term also vanishes.

Now the equation (A) was deduced from  $x^3 - px^2 + qx - r = 0$ , by supposing  $y = x - e$ : and the equation (C) was deduced from  $x^3 + px^2 + qx + r = 0$ ; by supposing  $y = x + e$ . From which this rule may easily be deduced for exterminating the second term out of any cubic equation.

RULE.

**RULE.** Add to the unknown quantity of the given equation the third part of the coefficient of the second term with its proper sign, viz.  $\pm \frac{1}{3}p$ , and suppose this aggregate equal to a new unknown quantity ( $y$ ). From this value of  $y$  find a value of  $x$  by transposition, and substitute this value of  $x$  and its powers in the given equation, and there will arise a new equation that shall want the second term.

**EXAMP.** Let it be required to exterminate the second term out of this equation,  $x^3 - 9x^2 + 26x - 34 = 0$ , suppose  $x - 3 = y$ , or  $y + 3 = x$ ; and substituting according to the rule, you will find

$$\left. \begin{array}{r} y^3 + 9y^2 + 27y + 27 \\ - 9y^2 - 54y - 81 \\ + 26y + 78 \\ \hline - 34 \end{array} \right\} = 0$$

$$y^3 + 3y - 10 = 0.$$

In which there is no term where  $y$  is of two dimensions, and an asterisk is placed in the room of the 2d term, to shew it is wanting.

Let the equation proposed be of any number of dimensions represented by ( $n$ ); and let the coefficient of the second term with its sign prefixed be  $-p$ , then supposing  $x - \frac{p}{n} = y$ , and consequently  $x = y + \frac{p}{n}$ , and substituting this value for  $x$  in the given equation, there will arise a new equation that shall want the second term.

It is plain from what was demonstrated in chap. 15. that the sum of the roots of the proposed equation is  $+p$ ; and since we suppose  $y = x - \frac{p}{n}$ , it follows, that, in the new equation, each value of  $y$  will be less than the respective value of  $x$  by  $\frac{p}{n}$ ; and, since the number of the roots is  $n$ , it follows, that the sum of the values of  $y$  will be less than  $+p$ , the sum of the values of  $x$ , by  $n \times \frac{p}{n}$ , the difference of any two roots, that is, by  $+p$ : therefore the sum of the values of  $y$  will be  $+p - p = 0$ .

But the coefficient of the second term of the equation of  $y$  is the sum of the values of  $y$ , viz.  $+p - p$ , and therefore that coefficient is equal to nothing; and consequently, in the equation of  $y$ , the second term vanishes. It follows then, that the second term may be exterminated out of any given equation by the following

**RULE.** Divide the coefficient of the second term of the proposed equation by the number of dimensions of the equation; and assuming a new unknown quantity  $y$ , add to it the quotient having its sign changed. Then suppose this aggregate equal to  $x$  the unknown quantity in the proposed equation; and for  $x$  and its powers, substitute the aggregate and its powers, so shall the new equation that arises want its second term.

If the proposed equation is a quadratic, as  $x^2 - px + q$

$= 0$ , then, according to the rule, suppose  $y + \frac{1}{3}p = x$ , and substituting this value for  $x$ , you will find,

$$\left. \begin{array}{r} y^2 + py + \frac{1}{3}p^2 \\ - py - \frac{1}{3}p^2 \\ \hline + q \end{array} \right\} = 0,$$

$$y^2 + q = 0.$$

And from this example the use of exterminating the 2d term appears: for commonly the solution of the equation that wants the 2d term is more easy. And, if you can find the value of  $y$  from this new equation, it is easy to find the value of  $x$ , by means of the equation  $y + \frac{1}{3}p = x$ . For example,

Since  $y^2 + q - \frac{1}{3}p^2 = 0$ , it follows, that  $y^2 = \frac{1}{3}p^2 - q$ , and  $y = \pm \sqrt{\frac{1}{3}p^2 - q}$ , so that  $x = y + \frac{1}{3}p = \frac{1}{3}p \pm \sqrt{\frac{1}{3}p^2 - q}$ ;

which agrees with what we demonstrated, chap. 12.

If the proposed equation is a biquadratic, as  $x^4 - px^3 + qx^2 - rx + t = 0$ , then, by supposing  $x - \frac{1}{4}p = y$  or  $x = y + \frac{1}{4}p$ , an equation shall arise having no second term. And if the proposed equation is of 5 dimensions, then you must suppose  $x = y + \frac{1}{5}p$ . And so on.

When the second term in any equation is wanting, it follows, that "the equation has both affirmative and negative roots," and that "the sum of the affirmative roots is equal to the sum of the negative roots:" by which means the coefficient of the 2d term, which is the sum of all the roots of both sorts, vanishes, and makes the second term vanish.

In general, "The coefficient of the 2d term is the difference between the sum of the affirmative roots and the sum of the negative roots:" and the operations we have given serve only to diminish all the roots when the sum of the affirmative is greatest, or increase the roots when the sum of the negative is greatest, so as to balance them, and reduce them to an equality.

It is obvious, that in a quadratic equation that wants the second term, there must be one root affirmative and one negative; and these must be equal to one another.

In a cubic equation that wants the second term, there must be either two affirmative roots equal, taken together to a third root that must be negative; or, two negative equal to a third that must be positive.

"Let an equation  $x^3 - px^2 + qx - r = 0$  be proposed, and let it be now required to exterminate the third term."

By supposing  $y = x - e$ , the coefficient of the 3d term in the equation of  $y$  is found (see equation A) to be  $3e^2 - 2pe + q$ . Suppose that coefficient equal to nothing, and by resolving the quadratic equation  $3e^2 - 2pe + q = 0$ , you will find the value of  $e$ , which substituted for it in the equation  $y = x - e$ , will shew how to transform the proposed equation into one that shall want the third term.

The quadratic  $3e^2 - 2pe + q = 0$ , gives  $e = \frac{p \pm \sqrt{p^2 - 3q}}{3}$ .

So that the proposed cubic will be transformed into an equation wanting the third term by supposing  $y = x - \frac{p - \sqrt{p^2 - 3q}}{3}$ , or  $y = x - \frac{p + \sqrt{p^2 - 3q}}{3}$ .

If the proposed equation is of  $n$  dimensions, the value of  $e$ , by which the 3d term may be taken away, is had by resolving the quadratic equation  $e^2 + \frac{2p}{n} \times e + \frac{2q}{n \times n - 1} = 0$ , supposing  $-p$  and  $+q$  to be the coefficients of the 2d and 3d terms of the proposed equation.

The 4th term of any equation may be taken away by solving a cubic equation, which is the coefficient of the 4th term in the equation, when transformed, as in the former part of this chapter. The fifth term may be taken away by solving a biquadratic; and after the same manner the other terms can be exterminated if there are any.

There are other transformations of equations that, on some occasions, are useful.

An equation, as  $x^3 - px^2 + qx - r = 0$ , "may be transformed into another that shall have its roots equal to the roots of this equation multiplied by a given quantity," as  $f$ , by supposing  $y = fx$ , and consequently  $x = \frac{y}{f}$ , and substituting this value for  $x$  in the proposed

equation, there will arise  $\frac{y^3}{f^3} - \frac{py^2}{f^2} + \frac{qy}{f} - r = 0$ , and multiplying all by  $f^3$ .  $y^3 - fpy^2 + f^2qy - f^3r = 0$ , where the coefficient of the 2d term of the proposed equation multiplied into  $f$ , makes the coefficient of the 2d term of the transformed equation; and the following coefficients are produced by the following coefficients of the proposed equation, (as  $q$ ,  $r$ , &c.) multiplied into the powers of  $f$  ( $f^2$ ,  $f^3$ , &c.).

Therefore "to transform any equation into another whose roots shall be equal to the roots of the proposed equation multiplied by a given quantity ( $f$ )," you need only multiply the terms of the proposed equation, beginning at the 2d term, by  $f$ ,  $f^2$ ,  $f^3$ ,  $f^4$ , &c. and putting  $y$  instead of  $x$ , there will arise an equation having its roots equal to the roots of the proposed equation multiplied by ( $f$ ) as required.

The transformation mentioned above is of use when the highest term of the equation has a coefficient different from unity; for, by it, the equation may be transformed into one that shall have the coefficient of the highest term unit.

If the equation proposed is  $ax^3 - px^2 + qx - r = 0$ , then transform the equation into one whose roots are equal to the roots of the proposed equation multiplied by ( $a$ ).

That is, suppose  $y = ax$  or  $x = \frac{y}{a}$  and there will arise

$$\frac{ay^3}{a^3} - \frac{py^2}{a^2} + \frac{qy}{a} - r = 0; \text{ so that}$$

$$y^3 - py^2 + qay - ra^2 = 0.$$

From which we easily draw this

**RULE.** Change the unknown quantity  $x$  into another  $y$ , prefix no coefficient to the highest term, pass the 2d, multiply the following terms, beginning with the 3d, by  $a$ ,  $a^2$ ,  $a^3$ ,  $a^4$ , &c. the powers of the coefficient of the highest term of the proposed equation, respectively.

Thus the equation  $3x^3 - 13x^2 + 14x + 16 = 0$ , is trans-

formed into the equation  $y^3 - 13y^2 + 14 \times 3 \times x + 16 \times 9 = 0$  or  $y^3 - 13y^2 + 42x + 144 = 0$ .

Then finding the roots of this equation, it will easily be discovered what are the roots of the proposed equation, since  $3x = y$ , or  $x = \frac{y}{3}$ . And therefore, since one of the values of  $y$  is  $-2$ , it follows, that one of the values of  $x$  is  $-\frac{2}{3}$ .

By the last rule, "an equation is easily cleared of 'fractions.'" Suppose the equation proposed is  $x^3 -$

$\frac{p}{m}x^2 + \frac{q}{n}x - \frac{r}{e} = 0$ . Multiply all the terms by the product of the denominators, you find

$$mne \times x^3 - ncp \times x^2 + meq \times x - mnre = 0.$$

Then (as above) transforming the equation into one that shall have unit for the coefficient of the highest term, you find

$$y^3 - np \times y^2 + m^2e^2nq \times y - m^3n^3e^3r = 0.$$

Or, neglecting the denominator of the last term  $\frac{r}{e}$

you need only multiply all the equation by  $mn$ , which will give

$$mn \times x^3 - np \times x^2 + mq \times x - \frac{mnr}{e} = 0. \text{ And}$$

then  $y^3 - np \times y^2 + m^2nq \times y - \frac{m^3n^3r}{e} = 0$ .

Now after the values of  $y$  are found, it will be easy to discover the values of  $x$ ; since, in the first case,  $x = \frac{y}{mne}$ ; in the second,  $x = \frac{y}{mn}$ .

For example, the equation

$$x^3 - \frac{4}{3}x - \frac{146}{9} = 0, \text{ is first reduced}$$

to this form  $3x^3 - 4x - 146 = 0$ , and then transformed into  $y^3 - 12y - 146 = 0$ .

Sometimes, by these transformations, "furds are taken away." As for example,

The equation  $x^3 - p\sqrt{a} \times x^2 + qx - r\sqrt{a} = 0$ , by putting  $y = \sqrt{a} \times x$ , or  $x = \frac{y}{\sqrt{a}}$ , is transformed into this equation,

$$\frac{y^3}{a\sqrt{a}} - p\sqrt{a} \times \frac{y^2}{a} + q \times \frac{y}{\sqrt{a}} - r\sqrt{a} = 0. \text{ Which, by multi-}$$

plying all the terms by  $a\sqrt{a}$ , becomes  $y^3 - pay^2 + qay - ra^2 = 0$ , an equation free of furds. But in order to make this succeed, the furd ( $\sqrt{a}$ ) must enter the alternate terms, beginning with the second.

"An equation, as  $x^3 - px^2 + qx - r = 0$ , may be transformed into one whose roots shall be the quantities re-

"ciprocals of  $x$ ;" by supposing  $y = \frac{1}{x}$ , and  $y = \frac{z}{r}$ , or

(by one supposition),  $x = \frac{r}{z}$ , becomes  $z^3 - qz^2 + prz -$

$r^2 = 0$ .

In the equation of  $y$ , it is manifest, that the order of the coefficients is inverted; so that, if the second term had been wanting in the proposed equation, the last but one should have been wanting in the equations of  $y$  and  $z$ . If the 3d had been wanting in the equation proposed, the last but two had been wanting in the equations of  $y$  and  $z$ .

Another use of this transformation is, that the great-  
eB

est root in the one is transformed into the least root in the other. For since  $x = \frac{1}{y}$ , and  $y = \frac{1}{x}$ , it is plain, that when the value of  $x$  is greatest, the value of  $y$  is least, and conversely.

How an equation is transformed so as to have all its roots affirmative, shall be explained in the following chapter.

CHAP. XVII. Of finding the Roots of Equations when two or more of the Roots are equal to each other.

§1. BEFORE we proceed to explain how to resolve equations of all sorts, we shall first demonstrate how an equation that has two or more roots equal, is depressed to a lower dimension; and its resolution made, consequently, more easy. And shall endeavour to explain the grounds of this and many other rules we shall give in the remaining part of this treatise, in a more simple and concise manner than has hitherto been done.

In order to this, we must look back to the last chapter, where we find, that if any equation, as  $x^3 - px^2 + qx - r = 0$ , is proposed, and you are to transform it into another that shall have its roots less than the values of  $x$  by any given difference, as  $e$ , you are to assume  $y = x - e$ , and substituting for  $x$  its value  $y + e$ , you find the transformed equation,

$$\left. \begin{array}{l} y^3 + 3ey^2 + 3e^2y + e^3 \\ - py^2 - 2pey - pe^2 \\ + qy + qe \\ - r \end{array} \right\} = 0.$$

Where we are to observe,

1°. That the last term ( $e^3 - pe^2 + qe - r$ ) is the very equation that was proposed, having  $e$  in place of  $x$ .

2°. The coefficient of the last term but one is  $3e^2 - 2pe + q$ , which is the quantity that arises by multiplying every term of the last coefficient  $e^3 - pe^2 + qe - r$  by the index of  $e$  in each term, and dividing the product  $3e^3 - 2pe^2 + qe$  by the quantity  $e$  that is common to all the terms.

3°. The coefficient of the last term but two is  $3e - p$ , which is the quantity that arises by multiplying every term of the coefficient last found ( $3e^2 - 2pe + q$ ) by the index of  $e$  in each term, and dividing the whole by  $2e$ .

§2. These same observations extend to equations of all dimensions. If it is the biquadratic  $x^4 - px^3 + qx^2 - rx + s = 0$  that is proposed, then by supposing  $y = x - e$ , it will be transformed into this other,

$$\left. \begin{array}{l} y^4 + 4ey^3 + 6e^2y^2 + 4e^3y + e^4 \\ - py^3 - 3pey^2 - 3pe^2y - pe^3 \\ + qy^2 + 2qey + qe^2 \\ - ry + re \\ + s \end{array} \right\} = 0$$

Where again it is obvious, That the last term is the equation that was proposed, having  $e$  in place of  $x$ : That the last term but one has for its coefficient the quantity

that arises by multiplying the terms of the last quantity by the indices of  $e$  in each term, and dividing the product by  $e$ : That the coefficient of the last term but two, (*viz.*  $6e^2 - 3pe + q$ ) is deduced in the same manner from the term immediately following, that is, by multiplying every term of  $4e^3 - 3pe^2 + 2qe - r$  by the index of  $e$  in that term, and dividing the whole by  $e$  multiplied into the index of  $y$  in the term sought, that is, by  $e \times 2$ : And the next term is  $4e - p = \frac{6e^2 \times 2 - 3pe \times 1}{3e}$ .

The demonstration of this may easily be made general by the theorem for finding the powers of a binomial, since the transformed equation consists of the powers of the binomial  $y + e$  that are marked by the indices of  $e$  in the last term, multiplied each by their coefficients  $1, -p, +q, -r, +s$ , &c. respectively.

§3. From the last two articles we can easily find the terms of the transformed equation without any involution. The last term is had by substituting  $e$  instead of  $x$  in the proposed equation; the next term, by multiplying every part of that last term by the index of  $e$  in each part, and dividing the whole by  $e$ ; and the following terms in the manner being in the foregoing article; the respective divisors being the quantity  $e$  multiplied by the index of  $y$  in each term.

The demonstration for finding when two or more roots are equal will be easy, if we add to this, that "when the unknown quantity enters all the terms of any equation, then one of its values is equal to nothing." As in the equation  $x^3 - px^2 + qx = 0$ , where  $x = 0 = 0$  being one of the simple equations that produce  $x^3 - px^2 + qx = 0$ , it follows that one of the values of  $x$  is 0. In like manner, two of the values of  $x$  are equal to nothing in this equation  $x^3 - px^2 = 0$ ; and three of them vanish in the equation  $x^4 - px^3 = 0$ .

It is also obvious (*conversely*) that "if  $x$  does not enter all the terms of the equation, *i. e.* if the last term "be not wanting, then none of the values of  $x$  can be equal to nothing," for if every term be not multiplied by  $x$ , then  $x = 0$  cannot be a divisor of the whole equation, and consequently  $0$  cannot be one of the values of  $x$ . If  $x^2$  does not enter into all the terms of the equation, then two of the values of  $x$  cannot be equal to nothing. If  $x^3$  does not enter into all the terms of the equation, then three of the values of  $x$  cannot be equal to nothing, &c.

§4. Suppose now that two values of  $x$  are equal to one another, and to  $e$ ; then it is plain that two values of  $y$  in the transformed equation will be equal to nothing: since  $y = x - e$ . And consequently, by the last article, the two last terms of the transformed equation must vanish.

Suppose it is the cubic equation of § 1. that is proposed, *viz.*  $x^3 - px^2 + qx - r = 0$ ; and because we suppose  $x = e$ , therefore the last term of the transformed equation, *viz.*  $e^3 - pe^2 + qe - r$  will vanish. And since two values of  $y$  vanish, the last term but one, *viz.*  $3e^2y - 2pey + qy$  will vanish at the same time. So that  $3e^2 - 2pe + q = 0$ . But, by supposition,  $e = x$ ; therefore, when two values of  $x$ , in the equation,  $x^3 - px^2 + qx - r = 0$ , are equal, it follows, that  $3x^2 - 2px + q = 0$ . And thus,

thus, "the proposed cubic is depressed to a quadratic that has one of its roots equal to one of the roots of that cubic."

"If it is the biquadratic that is proposed, viz.  $x^4 - px^3 + qx^2 - rx + r = 0$ , and two of its roots be equal; then supposing  $x = y$ , two of the values of  $y$  must vanish, and the equation of § 2. will be reduced to this form.

$$\left. \begin{array}{l} y^4 + 4ey^3 + 6e^2y^2 \\ - 3\beta y^3 - 3\beta e y^2 \\ + qy^2 \end{array} \right\} *** = 0. \text{ So that}$$

$4e^3 - 3\beta e^2 + 2qe - r = 0$ ; or, because  $x = e$ ,  
 $4x^3 - 3\beta x^2 + 2qx - r = 0$ .

In general, when two values of  $x$  are equal to each other, and to  $e$ , the two last terms of the transformed equation vanish; and consequently, "if you multiply the terms of the proposed equation by the indices of  $x$  in each term, the quantity that will arise will be  $= 0$ , and will give an equation of a lower dimension than the proposed, that shall have one of its roots equal to one of the roots of the proposed equation."

That the last two terms of the equation vanish when the values of  $x$  are supposed equal to each other, and to  $e$ , will also appear by considering, that since two values of  $y$  then become equal to nothing, the product of the values of  $y$  must vanish, which is equal to the last term of the equation; and because two of the four values of  $y$  are equal to nothing, it follows also that one of any three that can be taken out of these four must be  $= 0$ ; and therefore, the products made by multiplying any three must vanish; and consequently the coefficient of the last term but one, which is equal to the sum of these products, must vanish.

§ 5. After the same manner, if there are three equal roots in the biquadratic  $x^4 - px^3 + qx^2 - rx + r = 0$ , and if  $e$  be equal to one of them, three values of  $y$  ( $= x - e$ ) will vanish, and consequently  $y^3$  will enter all the terms of the transformed equation; which will have this form,

$$\left. \begin{array}{l} y^4 + 4ey^3 \\ - \beta y^3 \end{array} \right\} *** = 0. \text{ So that here}$$

$6e^2 - 3\beta e + q = 0$ ; or, since  $x = e$ , therefore,

$6x^2 - 3\beta x + q = 0$ : and one of the roots of this quadratic will be equal to one of the roots of the proposed biquadratic.

In this case, two of the roots of the cubic equation  $4x^3 - 3\beta x^2 + 2qx - r = 0$  are roots of the proposed biquadratic, because the quantity  $6x^2 - 3\beta x + q$  is deduced from  $4x^3 - 3\beta x^2 + 2qx - r$ , by multiplying the terms by the indexes of  $x$  in each term.

In general, "whatever is the number of equal roots in the proposed equation, they will all remain but one in the equation that is deduced from it, by multiplying all the terms by the indexes of  $x$  in them; and they will all remain but two in the equation deduced in the same manner from that;" and so of the rest.

§ 6. What we observed of the coefficients of equations transformed by supposing  $y = x - e$ , leads to this easy demonstration of this rule; and will be applied in the next chapter to demonstrate the rules for finding the limits of equations.

It is obvious, however, that though we make use of equations whose signs change alternately, the same reasoning extends to all other equations.

It is a consequence also of what has been demonstrated, that "if two roots of any equation, as,

" $x^3 - px^2 + qx - r = 0$ , are equal, then

"multiplying the terms by any arithmetical series, as, " $a + 2b, a + 2b, a + 2b, a$ , the product will be  $= 0$ ."

For, since

$$ax^3 - apx^2 + aqx - ar = 0; \text{ and}$$

$$3x^2 - 2px + q \times bx = 0, \text{ it follows that}$$

$$ax^3 + 3bx^2 - apx^2 - 2bp^2 + aqx + bq - ar = 0.$$

Which is the product that arises by multiplying the terms of the proposed equation by the terms of the series,  $a + 2b, a + 2b, a + 2b, a$ ; which may represent any arithmetical progression.

## CHAP. XVIII. Of the LIMITS of Equations.

WE now proceed to shew how to discover the limits of the roots of equations, by which their solution is most facilitated,

Let any equation, as  $x^3 - px^2 + qx - r = 0$  be proposed; and transform it, as above, into the equation

$$\left. \begin{array}{l} y^3 + 3ey^2 + 3e^2y + e^3 \\ - \beta y^2 - 2\beta ey - \beta e^2 \\ + qy + qe \\ - r \end{array} \right\} = 0.$$

Where the values of  $y$  are less than the respective values of  $x$  by the difference  $e$ . If you suppose  $e$  to be taken such as to make all the coefficients of the equation of  $y$  positive, viz.  $e^3 - \beta e^2 + qe - r, 3e^2 - 2\beta e + q, 3e - \beta$ ; then there being no variation of the signs in the equation, all the values of  $y$  must be negative; and consequently, the quantity  $e$ , by which the values of  $x$  are diminished, must be greater than the greatest positive value of  $x$ ; and consequently must be the limit of the roots of the equation  $x^3 - px^2 + qx - r = 0$ .

It is sufficient therefore, in order to find the limit, to "inquire what quantity substituted for  $x$  in each of these "expressions  $x^3 - px^2 + qx - r, 3x^2 - 2\beta x + q, 3x - \beta$ , "will give them all positive;" for that quantity will be the limit required.

How these expressions are formed from one another, was explained in the beginning of the last chapter.

EXAMP. If the equation  $x^5 - 2x^4 - 10x^3 + 30x^2 + 63x + 120 = 0$  is proposed; and it is required to determine the limit that is greater than any of the roots; you are to inquire what integer number substituted for  $x$  in the proposed equation, and following equations deduced from it by § 3. chap. 17. will give, in each, a positive quantity,

$$5x^4 - 8x^3 - 30x^2 + 60x + 63$$

$$5x^3 - 6x^2 - 15x + 15$$

$$5x^2 - 4x - 5$$

$$5x - 2.$$

The least integer number which gives each of these positive, is 2; which therefore is the limit of the roots of

of the proposed equation; or a number that exceeds the greatest positive root.

If the limit of the *negative* roots is required, you may (by chap. 16.) change the negative into positive roots; and then proceed as before to find their limits. Thus, in the example, you will find, that  $-3$  is the limit of the negative roots. So that the five roots of the proposed equation are betwixt  $-3$  and  $+2$ .

Having found the limit that surpasses the greatest positive root, call it  $w$ . And if you assume  $y = m - x$ , and for  $x$  substitute  $m - y$ , the equation that will arise will have all its roots positive; because  $m$  is supposed to surpass all the values of  $x$ , and consequently  $m - x$  ( $\Rightarrow$ ) must always be affirmative. And, by this means, any equation may be changed into one that shall have all its roots affirmative.

Or, if  $-n$  represent the limit of the negative roots, then by assuming  $y = x + n$ , the proposed equation shall be transformed into one that shall have all its roots affirmative; for  $+n$  being greater than any negative value of  $x$ , it follows, that  $y = x + n$  must be always positive.

The greatest negative coefficient of any equation increased by unit, always exceeds the greatest root of the equation.

To demonstrate this, let the cubic  $x^3 - px^2 - qx - r = 0$  be proposed; where all the terms are negative except the first. Assuming  $y = x - e$ , it will be transformed into the following equation;

$$(A) \left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ - 3y^2 - 2py - pe^2 \\ - 3y - r \end{aligned} \right\} = 0.$$

<sup>1</sup>o. Let us suppose that the coefficients  $p, q, r$ , are equal to each other; and if you also suppose  $e = p + 1$ , then the last equation becomes

$$(B) \left. \begin{aligned} y^3 + 2py^2 + p^2y + 1 \\ + 3y^2 + 3py \\ + 3y \end{aligned} \right\} = 0;$$

where all the terms being positive, it follows that the values of  $y$  are all negative, and that consequently  $e$ , or  $p + 1$ , is greater than the greatest value of  $x$  in the proposed equation.

<sup>2</sup>o. If  $q$  and  $r$  be not  $= p$ , but less than it, and for  $e$  you still substitute  $p + 1$  (since the negative part  $(-3y - r)$

becomes less, the positive remaining undiminished), *a fortiori* all the coefficients of the equation ( $A$ ) become positive. And the same is obvious if  $q$  and  $r$  have positive signs, and not negative signs, as we supposed. It appears therefore, "that if, in any cubic equation,  $p$  be the greatest negative coefficient, then  $p + 1$  must surpass the greatest value of  $x$ ."

<sup>3</sup>o. By the same reasoning it appears, that if  $q$  be the greatest negative coefficient of the equation, and  $e = q + 1$ , then there will be no variation of the signs in the equation of  $y$ : for it appears from the last article, that if all the three ( $p, q, r$ ) were equal to one another, and  $e$  equal to any one of them increased by unit, as to  $q + 1$ , then all the terms of the equation ( $A$ ) would be

positive. Now if  $e$  be supposed still equal to  $q + 1$ , and  $p$  and  $r$  to be less than  $q$ , then, *a fortiori*, all these terms will be positive, the negative part, which involves  $p$  and  $r$  being diminished, while the positive part and the negative involving  $q$  remain as before.

<sup>4</sup>o. After the same manner it is demonstrated, that if  $r$  is the greatest negative coefficient in the equation, and  $e$  is supposed  $= r + 1$ , then all the terms of the equation ( $A$ ) of  $y$  will be positive; and consequently  $r + 1$  will be greater than any of the values of  $x$ .

What we have said of the cubic equation  $x^3 - px^2 + qx - r = 0$ , is easily applicable to others.

In general, we conclude, that "the greatest negative coefficient in any equation increased by unit, is always a limit that exceeds all the roots of that equation."

But it is to be observed at the same time, that the greatest negative coefficient increased by unit, is very seldom the *nearest* limit: that is best discovered by the rule in the beginning of this chapter.

Having shewn how to change any proposed equation into one that shall have all its roots affirmative; we shall only treat of such as have all their roots positive, in what remains relating to the limits of equations.

Any such equation may be represented by  $x - a \times x - b \times x - c \times x - d$ , &c.  $= 0$ , whose roots are  $a, b, c, d$ , &c.

And of all such equations two limits are easily discovered from what precedes, *viz.*  $o$ , which is less than the least, and  $e$ , found as directed in the beginning of this chapter, which surpasses the greatest root of the equation.

But, besides these, we shall now shew how to find other limits betwixt the roots themselves. And, for this purpose, will suppose  $a$  to be the least root,  $b$  the second root,  $c$  the third, and so on; it being arbitrary.

If you substitute  $o$  in place of the unknown quantity, putting  $x = 0$ , the quantity that will arise from that supposition is the last term of the equation, all the others that involve  $x$  vanishing.

If you substitute for  $x$  a quantity less than the least root  $a$ , the quantity resulting will have the same sign as the last term; that is, will be positive or negative according as the equation is of an even or odd number of dimensions. For all the factors  $x - a, x - b, x - c$ , &c. will be negative, and their product will be *positive* or *negative* according as their number is *even* or *odd*.

If you substitute for  $x$  a quantity greater than the least root  $a$ , but less than all the other roots, then the sign of the quantity resulting will be contrary to what it was before; because one factor ( $x - a$ ) becomes now positive, all the others remaining negative as before.

If you substitute for  $x$  a quantity greater than the two least roots, but less than all the rest, both the factors  $x - a, x - b$ , become positive, and the rest remain as they were. So that the whole product will have the same sign as the last term of the equation. Thus successively placing instead of  $x$  quantities that are limits betwixt the roots of the equation, the quantities that result will have alternately the signs  $+$  and  $-$ . And, *conversely*, "if you find quantities which, substituted in "place of  $x$  in the proposed equation, do give alternately positive and negative results, those quantities "are the limits of that equation."

It is useful to observe, that, in general, "when, by substituting any two numbers for  $x$  in any equation, the results have contrary signs, one or more of the roots of the equation must be betwixt those numbers." Thus, in the equation,  $x^3 - 2x^2 - 5 = 0$ , if you substitute 2 and 3 for  $x$ , the results are  $-5$ ,  $+4$ ; whence it follows, that the roots are betwixt 2 and 3: for when these results have different signs, one or other of the factors which produce the equations must have changed its sign; suppose it is  $x=e$ , then it is plain that  $e$  must be betwixt the numbers supposed equal to  $x$ .

Let the cubic equation  $x^3 - px^2 + qx - r = 0$  be proposed, and let it be transformed, by assuming  $y = x - e$ , into the equation

$$\left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ - 3y^2 - 2pey - pe^2 \\ + 3y^2 + 3qe \\ - r \end{aligned} \right\} = 0.$$

Let us suppose  $e$  equal successively to the three values of  $x$ , beginning with the least value; and because the last term  $e^3 - pe^2 + qe - r$  will vanish in all these suppositions, the equation will have this form,

$$\left. \begin{aligned} y^3 + 3ey^2 + 3e^2y \\ - 3y^2 - 2pe \\ + q \end{aligned} \right\} = 0;$$

where the last term  $3e^2 - 2pe + q$  is, from the nature of equations, produced of the remaining values of  $y$ , or of the excesses of two other values of  $x$  above what is supposed equal to  $e$ ; since always  $y = x - e$ . Now,

1<sup>o</sup>. If  $e$  be equal to the least value of  $x$ , then those two excesses being both positive, they will give a positive product, and consequently  $3e^2 - 2pe + q$  will be, in this case, positive.

2<sup>o</sup>. If  $e$  be equal to the second value of  $x$ , then of those two excesses, one being negative and one positive, their product  $3e^2 - 2pe + q$ , will be negative.

3<sup>o</sup>. If  $e$  be equal to the third and greatest value of  $x$ , then the two excesses being both negative, their product  $3e^2 - 2pe + q$  is positive. Whence,

If in the equation  $3e^2 - 2pe + q = 0$ , you substitute successively in the place of  $e$ , the three roots of the equation  $e^3 - pe^2 + qe - r = 0$ , the quantities resulting will successively have the signs  $+$ ,  $-$ ,  $+$ ; and consequently the three roots of the cubic equation are the limits of the roots of the equation  $3e^2 - 2pe + q = 0$ . That is, the least of the roots of the cubic is less than the least of the roots of the other; the second root of the cubic is a limit between the two roots of the other; and the greatest root of the cubic is the limit that exceeds both the roots of the other.

We have demonstrated, that the roots of the cubic equation  $e^3 - pe^2 + qe - r = 0$  are limits of the quadratic  $3e^2 - 2pe + q$ ; whence it follows (*conversely*) that the roots of the quadratic  $3e^2 - 2pe + q = 0$  are the limits between the first and second, and between the second and third roots of the cubic  $e^3 - pe^2 + qe - r = 0$ . So that if you find the limit that exceeds the greatest root of the cubic, by the beginning of this chapter you will have (with  $o$ ,

which is the limit less than any of the roots) four limits for the threeroots of the proposed cubic.

It was demonstrated in chap. 17. §3. how the quadratic  $3e^2 - 2pe + q$  is deduced from the proposed cubic  $e^3 - pe^2 + qe - r = 0$ , *viz.* by multiplying each term by the index of  $e$  in it, and then dividing the whole by  $e$ ; and what we have demonstrated of cubic equations is easily extended to all others; so that we conclude "that the last term but one of the transformed equation is the equation for determining the limits of the proposed equation." Or, that the equation arising by multiplying each term by the index of the unknown quantity in it, is the equation whose roots give the limits of the proposed equation; if you add to them the two mentioned in p. 109. col. 2. par. 4.

For the same reason, it is plain that the root of the simple equation  $3e - p = 0$ , (*i. e.*  $\frac{1}{3}p$ ) is the limit between the two roots of the quadratic  $3e^2 - 2pe + q = 0$ . And, as  $4e^3 - 3pe^2 + 2qe - r = 0$  gives three limits of the equation  $e^3 - pe^2 + qe - r = 0$ , so the quadratic  $6e^2 - 3pe + q = 0$  gives two limits that are betwixt the roots of the cubic  $e^3 - 3pe^2 + 2qe - r = 0$ ; and  $4e - p = 0$  gives one limit that is betwixt the two roots of the quadratic  $6e^2 - 3pe + q = 0$ . So that we have a complete series of these equations arising from a simple equation to the proposed, each of which determines the limits of the following equation.

If two roots in the proposed equation are equal, then "the limit that ought to be betwixt them must, in this case, become equal to one of the equal roots themselves." Which perfectly agrees with what was demonstrated in the last chapter, concerning the rule for finding the equal roots of equations.

And, the same equation that gives the limits, giving also one of the equal roots, when two or more are equal, it appears, that "if you substitute a limit in place of the unknown quantity in an equation," and, instead of a positive or negative result, it be found  $= 0$ , then you may conclude, that "not only the limit itself is a root of the equation, but that there are two roots in that equation equal to it and to one another."

It having been demonstrated, that the roots of the equation  $x^3 - px^2 + qx - r = 0$  are the limits of the roots of the equation  $3x^2 - 2px + q = 0$ , the three roots of the cubic equation, which suppose to be  $a, b, c$ , substituted for  $x$  in the quadratic  $3x^2 - 2px + q$ , must give the results positive and negative alternately. Suppose these three results to be  $+N, -M, +L$ ; that is,  $3a^2 - 2pa + q = N$ ,  $3b^2 - 2pb + q = -M$ ,  $3c^2 - 2pc + q = L$ ; and since  $a^3 - pa^2 + qa - r = 0$ , and  $3a^3 - 2pa^2 + qa = N \times a$ , subtracting the former multiplied into 3 from the latter, the remainder is  $pa^2 - 2qa + 3r = N \times a$ . In the same manner  $pb^2 - 2qb + 3r = -M \times b$ , and  $pc^2 - 2qc + 3r = +L \times c$ . Therefore  $px^2 - 2qx + 3r$  is such a quantity, that if, for  $x$ , you substitute in it successively  $a, b, c$ , the results will be  $+N \times a, -M \times b, +L \times c$ . Whence  $a, b, c$ , are limits of the equation  $px^2 - 2qx + 3r = 0$ , by p. 109. col. 2. par. 8. and, *conversely*, the roots of the equation  $px^2 - 2qx + 3r = 0$  are limits between the first and second, and between the second and third roots of the cubic  $x^3 - px^2 + qx - r = 0$ . Now the equation  $px^2 - 2qx + 3r = 0$  ar-

rises from the proposed cubic by multiplying the terms of this latter by the arithmetical progression 0, -1, -2, -3. And, in the same manner, it may be shewn that the roots of the equation  $px^3 - 2qx^2 + 3rx - 4r = 0$  are limits of the equation  $x^4 - px^3 + q^2 - rx + s = 0$ .

Or, multiply the terms of the equation

$$\begin{array}{l} x^3 - px^2 + qx - r = 0 \\ \text{by } a + 3b, a + 2b, a + b, a \\ \hline ax^3 - apx^2 + aqx - ar (=0) \\ + 3bx^3 - 2bp^2x^2 + bqx (=3x^3 - 2px^2 + qx \times bx.) \end{array}$$

Any arithmetical series where  $a$  is the least term, and  $b$  the common difference, and the products (if you substitute for  $x$ , successively,  $a, b, c$ , the three roots of the proposed cubic) shall be  $+N \times bx$ ,  $-M \times bx$ ,  $+L \times bx$ . For the first part of the product  $a \times x^3 - px^2 + qx - r = 0$ ; and  $a, b, c$ , being limits in the equation  $3x^3 - 2px^2 + q = 0$ , their substitution must give results  $N, M, L$ , alternately positive and negative.

In general, the roots of the equation  $x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + \dots$ , &c. = 0 are limits of the roots of the equation  $n \times x^{n-1} - (n-1) \times px^{n-2} + (n-2) \times qx^{n-3} - \dots - 3 \times rx^{n-4} + \dots$ , &c. = 0; or of any equation that is deduced from it by multiplying its terms by any arithmetical progression,  $a, 2b, 3c, 4d, 5e$ , &c. And, conversely, the roots of this new equation will be limits of the proposed equation

$$x^n - px^{n-1} + qx^{n-2} - \dots, \text{ \&c. } = 0.$$

“If any roots of the equation of the limits are impossible, then must there be some roots of the proposed equation impossible.” For as (in p. 110. col. 1. par. 2.) the quantity  $3e^2 - 2pr + q$  was demonstrated to be equal to the product of the excesses of two values of  $x$  above the third supposed equal to  $e$ ; if any impossible expression be found in those excesses, then there will of consequence be found impossible expressions in these two values of  $x$ .

And “from this observation rules may be deduced for discovering when there are impossible roots in equations.” Of which we shall treat afterwards.

Besides the method already explained, there are others by which limits may be determined which the root of an equation cannot exceed.

Since the squares of all real quantities are affirmative, it follows, that “the sum of the squares of the roots of any equation must be greater than the square of the greatest root.” And the square root of that sum will therefore be a limit that must exceed the greatest root of the equation.

If the equation proposed is  $x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + \dots$ , &c. = 0, then the sum of the squares of the roots (p. 103. col. 1. par. 1.) will be  $p^2 - 2q$ . So that  $\sqrt{p^2 - 2q}$  will exceed the greatest root of that equation.

Or if you find, by p. 103. col. 1. par. 4. the sum of the 4th powers of the roots of the equation, and extract the biquadratic root of that sum, it will also exceed the greatest root of the equation.

If you find a mean proportional between the sum of the squares of any two roots,  $a, b$ , and the sum of their

biquadrates ( $a^4 + b^4$ ), this mean proportional will be  $\sqrt[4]{a^6 + a^4b^2 + a^2b^4 + b^6}$ . And the sum of the cubes is  $a^3 + b^3$ . Now, since  $a^2 - 2ab + b^2$  is the square of  $a - b$ , it must be always positive; and if you multiply it by  $a^2b^2$ , the product  $a^2b^2 - 2a^2b^3 + a^2b^4$  will also be positive; and consequently  $a^2b^2 + a^2b^4$  will be always greater than  $2a^2b^3$ . Add  $a^4 + b^6$  and we have  $a^6 + a^4b^2 + a^2b^4 + b^6$  greater than  $a^6 + 2a^2b^3 + b^6$ ; and extracting the root  $\sqrt[4]{a^6 + a^4b^2 + a^2b^4 + b^6}$  greater than  $a^3 + b^3$ . And the same may be demonstrated of any number of roots whatever.

Now, if you add the sum of all the cubes taken affirmatively to their sum with their proper signs, they will give double the sum of the cubes of the affirmative roots. And if you subtract the second sum from the first, there will remain double the sum of the cubes of the negative roots. Whence it follows, that “half the sum of the mean proportional betwixt the sum of the squares and the sum of the biquadrates, and of the sum of the cubes of the roots with their proper signs, exceeds the sum of the cubes of the affirmative roots;” and “half their difference exceeds the sum of the cubes of the negative roots.” And, by extracting the cube root of that sum and difference, you will obtain limits that shall exceed the sums of the affirmative and of the negative roots. And since it is easy, from what has been already explained, to diminish the roots of an equation so that they all may become negative but one, it appears how, by this means, you may approximate very near to that root. But this does not serve when there are impossible roots.

Several other rules like these might be given for limiting the roots of equations. We shall give one not mentioned by other authors.

In a cubic  $x^3 - px^2 + qx - r = 0$ , find  $q^2 - 2pr$ , and call it  $e^2$ ; then shall the greatest root of the equation always be greater than  $\sqrt[4]{3}$ , or  $\sqrt[4]{\frac{e^4}{3}}$ . And,

In any equation  $x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + \dots$ , &c. = 0, find  $\frac{q^2 - 2pr + 2r^2}{n}$ , and extracting the root of the 4th power out of that quantity, it shall always be less than the greatest root of the equation.

### СНАР. XIX. Of the Resolution of Equations, all whose Roots are commensurate.

It was demonstrated in chap. 15. that the last term of any equation is the product of its roots: from which it follows, that the roots of an equation, when commensurable quantities, will be found among the divisors of the last term. And hence we have, for the resolution of equations, this

**RULE.** Bring all the terms to one side of the equation, find all the divisors of the last term, and substitute them successively for the unknown quantity in the equation. So shall that divisor which, substituted in this manner,

manner, gives the result = 0, be the root of the proposed equation.

For example, suppose this equation is to be resolved,

$$\left. \begin{aligned} x^3 - 3ax^2 + 2a^2x - 2a^2b \\ - bx^2 + 3abx \end{aligned} \right\} = 0.$$

where the last term is  $2a^2b$ , whose simple literal divisors are  $a, b, 2a, 2b$ , each of which may be taken either positively or negatively; but as here we find there are variations of signs in the equation, we need only take them positively. Suppose  $x=a$  the first of the divisors, and substituting  $a$  for  $x$ , the equation becomes

$$\left. \begin{aligned} a^3 - 3a^3 + 2a^3 - 2a^2b \\ - a^2b + 3a^2b \end{aligned} \right\} \text{or, } 3a^3 - 3a^3 + 3a^2b - 3a^2b = 0$$

So that, the whole vanishing, it follows, that  $a$  is one of the roots of the equation.

After the same manner, if you substitute  $b$  in place of  $x$ , the equation is

$$\left. \begin{aligned} b^3 - 3ab^2 + 2a^2b - 2a^2b \\ - b^3 + 3ab^2 \end{aligned} \right\} = 0,$$

which vanishing, shews  $b$  to be another root of the equation.

Again, if you substitute  $2a$  for  $x$ , you will find all the terms destroy one another so as to make the sum = 0. For it will then be

$$\left. \begin{aligned} 8a^3 - 12a^3 + 4a^3 - 2a^2b \\ - 4a^2b + 6a^2b \end{aligned} \right\} = 0.$$

Whence we find, that  $2a$  is the third root of the equation. Which, after the first two ( $+a, +b$ ) had been found, might have been collected from this, that the last term being the product of the three roots,  $+a, +b$ , being known, the third must necessarily be equal to the last term divided by the product  $ab$ , that is,  $\frac{2a^2b}{ab} = 2a$ .

Let the roots of the cubic equation

$$x^3 - 2x^2 - 33x + 90 = 0 \text{ be required.}$$

And first the divisors of 90 are found to be 1, 2, 3, 5, 6, 9, 10, 15, 18, 30, 45, 90. If you substitute 1 for  $x$ , you will find  $x^3 - 2x^2 - 33x + 90 = 56$ ; so that 1 is not a root of the equation. If you substitute 2 for  $x$ , the result will be 24; but, putting  $x=3$ , you have

$$x^3 - 2x^2 - 33x + 90 = 27 - 18 - 99 + 90 = 17 - 117 = 0.$$

So that three is one of the roots of the proposed equation. The other affirmative root is  $+5$ ; and after you find it, as it is manifest from the equation, that the other root is negative, you are not to try any more divisors taken positively, but to substitute them, negatively taken, for  $x$ : and thus you find, that  $-6$  is the third root. For putting  $x=-6$ , you have

$$x^3 - 2x^2 - 33x + 90 = 216 - 72 + 198 + 90 = 0.$$

This last root might have been found by dividing the last term 90, having its sign changed by 15, the product of the two roots already found.

When one of the roots of an equation is found, in order to find the rest with less trouble, divide the proposed equation by the simple equation which you are to de-

duce from the root already found, and the quotient shall give an equation of a degree lower than the proposed; whose roots will give the remaining roots required.

As for example, the root  $+3$ , first found, gave  $x-3=0$ , or  $x-3=0$ , whence dividing thus,

$$\begin{array}{r} x-3 \overline{) x^3 - 2x^2 - 33x + 90} \phantom{(x^2 + x - 30)} \\ \underline{x^3 - 3x^2} \phantom{+ 90} \\ \phantom{x^3} - 33x + 90 \phantom{(x^2 + x - 30)} \\ \phantom{x^3} \underline{-30x + 90} \\ \phantom{x^3} \phantom{-30x} 0 \phantom{+ 90} \\ \phantom{x^3} \phantom{-30x} \phantom{0} 0 \phantom{+ 90} \end{array}$$

The quotient shall give a quadratic equation  $x^2 + x - 30 = 0$ , which must be the product of the other two simple equations from which the cubic is generated, and whose roots therefore must be two of the roots of that cubic.

Now the roots of that quadratic equation are easily found, by chap. 12. to be  $+5$  and  $-6$ . For,

$$\begin{aligned} x^2 + x - 30 &= 0 \\ \text{add } \frac{1}{2} \dots x^2 + x + \frac{1}{4} - 30 + \frac{1}{4} &= \frac{x^2 + 1}{4} \\ \sqrt{\dots x + \frac{1}{2}} &= \sqrt{\frac{x^2 + 1}{4}} = \frac{x + 1}{2} \\ \text{and } \dots x &= \frac{x + 1}{2} - \frac{1}{2} = +5 \text{ or } -6. \end{aligned}$$

After the same manner, if the biquadratic  $x^4 - 2x^3 - 25x^2 + 26x + 120 = 0$  is to be resolved; by substituting the divisors of 120 for  $x$ , you will find, that  $+3$ , one of those divisors, is one of the roots; the substitution of 3 for  $x$  giving  $81 - 54 - 225 + 78 + 120 = 279 - 279 = 0$ . And therefore, dividing the proposed equation by  $x-3$ , you must inquire for the roots of the cubic  $x^3 + x^2 - 22x - 40 = 0$ , and finding that  $+5$ , one of the divisors of 40, is one of the roots, you divide that cubic by  $x-5$ , and the quotient gives the quadratic  $x^2 + 6x + 8 = 0$ , whose two roots are  $-2, -4$ . So that the four roots of the biquadratic are  $+3, +5, -2, -4$ .

This rule supposes that you can find all the divisors of the last term; which you may always do thus.

“ If it is a simple quantity, divide it by its least divisor that exceeds unit, and the quotient again by its least divisor, proceeding thus till you have a quotient that is not divisible by any number greater than unit. “ This quotient, with these divisors, are the first or simple divisors of the quantity. And the products of the multiplication of any 2, 3, 4, &c. of them are the compound divisors.”

As to find the divisors of 60; first I divide by 2, and the quotient 30 again by 2, then the next quotient 15 by 3, and the quotient of this division 5 is not farther divisible by any integer above units; so that the simple divisors are,

2, 2, 3, 5;

The products of two, 4, 6, 10, 15.

The products of three, 12, 20, 30.

The product of all four, . . . . . 60.

The divisors of 90 are found after the same manner;

Simple

Simple divisors, 2, 3, 3, 5.  
 The products of two, 6, 9, 10, 15.  
 The products of three, 18, 30, 45.  
 The product of all four, . . . . . 90.

The divisors of 21abb.  
 The simple divisors, 3, 7, a, b, b.  
 The products of two, 21, 3a, 3b, 7a, 7b, ab, bb.  
 The products of three, 21a, 21b, 3ab, 3bb, 7ab, 7bb, abb.  
 The products of four, 21ab, 21bb, 3abb, 7abb.  
 The products of the five, . . . . . 21abb.

But as the last term may have very many divisors, and the labour may be very great to substitute them all for the unknown quantity, we shall now shew how it may be abridged, by limiting to a small number the divisors you are to try. And, first, it is plain, from p. 109, col. 1. par. 4. that "any divisor that exceeds the greatest negative coefficient by unity is to be neglected." Thus, in resolving the equation  $x^4 - 2x^3 - 25x^2 + 26x + 120 = 0$ , as 25 is the greatest negative coefficient, we conclude, that the divisors of 120 that exceed 26 may be neglected.

But the labour may be still abridged, if we make use of the rule in the beginning of ch. 18.; that is, if we find the number which substituted in these following expressions,

$$\begin{aligned} x^4 - 2x^3 - 25x^2 + 26x + 120, \\ 2x^3 - 3x^2 - 25x + 13, \\ 6x^2 - 6x - 25, \\ 2x - 1, \end{aligned}$$

will give in them all a positive result: for that number will be greater than the greatest root, and all the divisors of 120 that exceed it may be neglected.

That this investigation may be easier, we ought to begin always with that expression where the negative roots seem to prevail most; as here in the quadratic expression  $6x^2 - 6x - 25$ ; where finding that 6 substituted for  $x$  gives that expression positive, and gives all the other expressions at the same time positive, I conclude, that 6 is greater than any of the roots, and that all the divisors of 120 that exceed 6 may be neglected.

If the equation  $x^3 + 11x^2 + 10x - 72 = 0$  is proposed, the rule of p. 109. col. 1. par. 4. does not help to abridge the operation; the last term itself being the greatest negative term. But, by chap. 18. we inquire what number substituted for  $x$  will give all these expressions positive.

$$\begin{aligned} x^3 + 11x^2 + 10x - 72 \\ 3x^2 + 22x + 10 \\ 3x + 11. \end{aligned}$$

Where the labour is very short, since we need only attend to the first expression; and we see immediately that 4 substituted for  $x$  gives a positive result, whence all the divisors of 72 that exceed 4 are to be rejected; and thus by a few trials, we find, that +2 is the positive root of the equation. Then dividing the equation by  $x - 2$ , and resolving the quadratic equation that is the quotient of the division, you find the other two roots to be  $-9$ , and  $-4$ .

But there is another method that reduces the divisors of the last term, that can be useful, still to more narrow limits.

Suppose the cubic equation  $x^3 - px^2 + qx - r = 0$  is proposed to be resolved. Transform it to an equation whose roots shall be less than the values of  $x$  by unity, assuming  $y = x - 1$ . And the last term of the transformed equation will be  $1 - p + q - r$ ; which is found by substituting unity, the difference of  $x$  and  $y$ , for  $x$ , in the proposed equation; as will easily appear from p. 106, col. 1. par. 4. where, when  $y = x - e$ , the last term of the transformed equation was  $e^3 - pe^2 + qe - r$ .

Transform again the equation  $x^3 - px^2 + qx - r = 0$ , by assuming  $y = x + 1$ , into an equation whose roots shall exceed the values of  $x$  by unity, and the last term of the transformed equation will be  $-1 - p - q - r$ , the same that arises by substituting  $-1$ , the difference between  $x$  and  $y$ , for  $x$ , in the proposed equation.

Now the values of  $x$  are some of the divisors of  $r$ , which is the term left when you suppose  $x = 0$ ; and the values of the  $y$ 's are some of the divisors of  $1 - p + q - r$ , and of  $-1 - p - q - r$ , respectively. And these values are in arithmetical progression increasing by the common difference unit; because  $x - 1$ ,  $x$ ,  $x + 1$ , are in that progression. And it is obvious the same reasoning may be extended to any equation of whatever degree. So that this gives a general method for the resolution of equations whose roots are commensurable.

**RULE.** Substitute, in place of the unknown quantity, successively the terms of the progression, 1, 0,  $-1$ , &c. and find all the divisors of the sums that result; then take out all the arithmetical progressions you can find among these divisors, whose common difference is unit; and the values of  $x$  will be among the divisors arising from the substitutions of  $x = 0$  that belong to these progressions. The values of  $x$  will be affirmative when the arithmetical progression increases, but negative when it decreases.

**EXAMP.** Let it be required to find one of the roots of the equation  $x^3 - x^2 - 10x + 6 = 0$ . The operation is thus;

Suppos.	Result.	Divisors, Arith. Prog. decr.
$x = 1$	$x^3 - x^2 - 10x + 6 =$	$-4 \mid 1, 2, 4 \mid 4$
$x = 0$		$+6 \mid 1, 2, 3, 6 \mid 3$ gives $x = -3$
$x = -1$		$+14 \mid 1, 2, 7, 14 \mid 2$

Where the suppositions of  $x = 1$ ,  $x = 0$ ,  $x = -1$ , give the quantity  $x^3 - x^2 - 10x + 6$  equal to  $-4$ ,  $6$ ,  $14$ ; among whose divisors we find only one arithmetical progression

4, 3, 2; the term of which, opposite to the supposition of  $x = 0$ , being 3, and the series decreasing, we try if  $-3$  substituted for  $x$  makes the equation vanish; which

succeeding one of its roots must be  $-3$ . Then dividing the equation by  $x+3$ , we find the roots of the (quadratic) quotient  $x^2-4x+2=0$  are  $2\pm\sqrt{2}$ .

If it is required to find the roots of the equation  $x^3-3x^2-46x-72=0$ , the operation will be thus;

Suppos.	Results	Divisors.	Progressions.
$x = 1$	$-120$	$1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 20, 24, 30, 40, 60, 120$	$8 \ 3 \ 4 \ 5$
$x = 0$	$72$	$1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72.$	$9 \ 2 \ 3 \ 4$
$x = -1$	$-30$	$1, 2, 3, 5, 6, 10, 15, 30.$	$10 \ 1 \ 2 \ 3$

Of these four arithmetical progressions having their common difference equal to unit, the first gives  $x=9$ , the others give  $x=2$ ,  $x=-3$ ,  $x=-4$ ; all which succeed except  $x=3$ : so that the three values of  $x$  are  $+9$ ,  $-2$ ,  $-4$ .

CHAP. XX. *Of the Resolution of Equations by finding the Equations of a lower Degree that are their Divisors.*

To find the roots of an equation is the same thing as to find the simple equations, by the multiplication of which into one another it is produced, or, to find the simple equations that divide it without a remainder.

If such simple equations cannot be found, yet if we can find the quadratic equations from which the proposed equation is produced, we may discover its roots afterwards by the resolution of these quadratic equations. Or, if neither these simple equations, nor these quadratic equations can be found, yet, by finding a cubic or biquadratic that is a divisor of the proposed equation, we may depress it lower, and make the solution more easy.

Now, in order to find the rules by which these divisors may be discovered; we shall suppose, that

$$\left. \begin{matrix} mx-n \\ mx^2-nx+r \\ mx^3-nx^2+rx-s \end{matrix} \right\} \text{are the } \begin{cases} \text{simple} \\ \text{quadratic} \\ \text{cubic} \end{cases}$$

divisors of the proposed equation; and if  $E$  represent the quotient arising by dividing the proposed equation by that divisor, then

$$\begin{matrix} E \times \underline{mx-n} \\ E \times \underline{mx^2-nx+r} \end{matrix}$$

Or,  $E \times \underline{mx^3-nx^2+rx-s}$ , will represent the proposed equation itself. Where it is plain, that "since  $m$  is the coefficient of the highest term of the divisors, it must be a divisor of the coefficient of the highest term of the proposed equation."

Next we are to observe, that, supposing the equation has a simple divisor  $mx-n$ , if we substitute in the equation  $E \times \underline{mx-n}$ , in place of  $x$ , any quantity, as  $a$ , then the quantity that will result from this substitution will necessarily have  $ma-n$  for one of its divisors: hence, in this substitution,  $mx-n$  becomes  $ma-n$ .

If we substitute successively for  $x$ , any arithmetical progression,  $a, a-e, a-2e$ , &c. the quantities that will result from these substitutions will have among their divisors

$ma-n$ ,  
 $ma-mc-n$ ,  
 $ma-2mc-n$ , which are also in arithmetical progression, having their common difference equal to  $me$ .

If, for example, we substitute for  $x$  the terms of this progression,  $1, 0, -1$ , the quantities that result have among their divisors the arithmetical progression  $m-n, -n, -m-n$ ; or, changing the signs,  $n-m, n, n+m$ . Where the difference of the terms is  $m$ , and the term belonging to the supposition of  $x=0$  is  $n$ .

It is manifest therefore, that when an equation has any simple divisor, if you substitute for  $x$  the progression  $1, 0, -1$ , there will be found amongst the divisors of the sums that result from these substitutions, one arithmetical progression at least, whose common difference will be unit or a divisor  $m$  of the coefficient of the highest term, and which will be the coefficient of  $x$  in the simple divisor required: and whose term, arising from the supposition of  $x=0$ , will be  $n$ , the other member of the simple divisor  $mx-n$ .

From which this rule is deduced for discovering such a simple divisor, when there is any.

**RULE.** Substitute for  $x$  in the proposed equation successively the numbers  $1, 0, -1$ . Find all the divisors of the sums that result from this substitution, and take out all the arithmetical progressions you can find amongst them, whose difference is unit, or some divisor of the coefficient of the highest term of the equation. Then suppose  $n$  equal to that term of any one progression that arises from the supposition of  $x=0$ , and  $m$  the foresaid divisor of the coefficient of the highest term of the equation, which  $m$  is also the difference of the terms of this progression; so shall you have  $mx-n$  for the divisor required.

You may find arithmetical progressions giving divisors that will not succeed; but if there is any divisor, it will be found thus by means of these arithmetical progressions.

If the equation proposed has the coefficient of its highest term  $=1$ , then it will be  $m=1$ , and the divisor will be  $x-n$ , and the rule will coincide with that given in the end of the last chapter, which we demonstrated after a different manner; for the divisor being  $x-n$ , the value of  $x$  will be  $+n$ , the term of the progression that is a divisor of the sum that arises from supposing  $x=0$ . Of this case we gave examples in the last chapter; and though it is easy to reduce an equation whose highest term has a coefficient different from unit, to one where that coefficient shall be unit, by p. 106. col. 1. par. 6.; yet, without that reduction, the equation may be resolved by this rule, as in the following

EXAMP.

EXAMP. Suppose  $8x^3 - 26x^2 + 11x + 10 = 0$ , and that it is required to find the values of  $x$ ; the operation is thus;

Suppos.	Results.	Divisors.	Progr.
$x = 1$	$8x^3 - 26x^2 + 11x + 10 = 0$	$+ 3$	$1, 3$
$x = 0$		$+ 10$	$1, 2, 5, 10$
$x = -1$		$- 35$	$1, 5, 7, 35$

The difference of the terms of the last arithmetical progression is 2, a divisor of 8, the coefficient of the highest term  $x^3$  of the equation, therefore supposing  $m=2$ ,  $n=5$ , we try the divisor  $2x-5$ ; which succeeding, it follows, that  $2x-5=0$ , or  $x=2\frac{1}{2}$ .

The quotient is the quadratic  $4x^2 - 3x - 2 = 0$ , whose roots are  $\frac{3+\sqrt{41}}{8}$ , and  $\frac{3-\sqrt{41}}{8}$ , so that the three roots of the proposed equation are  $2\frac{1}{2}$ ,  $\frac{3+\sqrt{41}}{8}$ ,  $\frac{3-\sqrt{41}}{8}$ . The other arithmetical progression gives  $x+2$  for a divisor; but it does not succeed.

If the proposed equation has no simple divisor, then we are to inquire if it has not some quadratic divisor (if itself is an equation of more than three dimensions.)

An equation having the divisor  $mx^2 - nx + r$  may be expressed, as in the first article of this chapter, by  $EXmx^2 - nx + r$ ; and if we substitute for  $x$  any known quantity  $a$ , the sum that will result will have  $ma^2 - na + r$  for one of its divisors; and, if we substitute successively for  $x$  the progression  $a, a-e, a-2e, a-3e$ , &c. the sums that arise from this substitution will have

$$\begin{aligned} & ma^2 - na + r \\ & m \times a - e^2 - n \times a - e + r \\ & m \times a - 2e^2 - n \times a - 2e + r \\ & m \times a - 3e^2 - n \times a - 3e + r, \\ & \&c. \end{aligned}$$

among their divisors respectively.

These terms are not now, as in the last case, in arithmetical progression; but if you subtract them from the squares of the terms  $a, a-e, a-2e, a-3e$ , &c. multiplied by  $m$  a divisor of the highest term of the proposed equation, that is from

$$\begin{aligned} & ma^2 \\ & m \times a - e^2 \\ & m \times a - 2e^2 \\ & m \times a - 3e^2, \&c. \end{aligned}$$

$$\begin{aligned} & na - r \\ & n \times a - e - r \\ & n \times a - 2e - r \end{aligned}$$

$n+2-3e-r$ , &c. shall be in arithmetical progression, having their common difference equal to  $ne$ .

If, for example, we suppose the assumed progression  $a, a-e, a-2e, a-3e$ , &c. to be  $2, 1, 0, -1$ , the divisors will be

$$\begin{array}{r} 4m - 2n + r \\ m - n + r \\ + r \\ \hline m + n + r, \text{ which subtracted from } 4m, \\ m, 0, m, \text{ leave } 2n - r \\ \hline n - r \\ - r \\ \hline -n - r, \text{ an arithmetical progression} \end{array}$$

whose difference is  $+n$ ; and whose term, arising from the substitution of 0 for  $x$ , is  $-r$ .

From which it follows, that by this operation, if the proposed equation has a quadratic divisor, you will find an arithmetical progression that will determine to you  $n$  and  $r$ , the coefficient  $m$  being supposed known; since it is unit, or a divisor of the coefficient of the highest term of the equation. Only you are to observe, that if the first term  $mx^2$  of the quadratic divisor is negative, then in order to obtain an arithmetical progression, you are not to subtract, but add the divisors  $-4m - 2n + r, -m - n + r, +r, -m + n + r$ , to the terms  $4m, m, 0, m$ .

The general rule therefore, deduced from what we had said, is,

“Substitute in the proposed equation for  $x$  the terms 2, 1, 0, -1, &c. successively. Find all the divisors of the sums that result, adding and subtracting them from the squares of these numbers 2, 1, 0, -1, &c. multiplied by a numerical divisor of the highest term of the proposed equation, and take out all the arithmetical progressions that can be found amongst these sums and differences. Let  $r$  be that term in any progression that arises from the substitution of  $x=0$ , and let  $+n$  be the difference arising from subtracting that term from the preceding term in the progression; lastly, let  $m$  be the fore said divisor of the highest term; then shall  $mx^2 - nx + r$  be the divisor that ought to be tried.” And one or other of the divisors found in this manner will succeed, if the proposed equation has a quadratic divisor.

### CHAP. XXI. Of the Method by which you may approximate to the Roots of NUMERICAL Equations by their Limits.

WHEN any equation is proposed to be resolved, first find the limits of the roots (by chap. 17.) as for example, if the roots of the equation  $x^2 - 16x + 55 = 0$  are required, you find the limits are 0, 8, and 17, by p. 110. col. 2. par. 2.; that is, the least root is between 0 and 8, and the greatest between 8 and 17.

In order to find the first of the roots, I consider, that if I substitute 0 for  $x$  in  $x^2 - 16x + 55$ , the result is positive, viz. +55, and consequently any number betwixt 0 and 8 that gives a positive result, must be less than the least root, and any number that gives a negative result must be greater. Since 0 and 8 are the limits, I try 4, that is, the mean betwixt them, and supposing  $x=4$ ,  $x^2 - 16x + 55 = 16 - 64 + 55 = 7$ , from which I conclude that the root is greater than 4. So that now we have the root limited between 4 and 8. Therefore

I next try 6, and substituting it for  $x$  we find  $x^3 - 16x + 55 = 36 - 96 + 55 = -5$ ; which result being negative, I conclude that 6 is greater than the root required, which therefore is limited now between 4 and 6. And substituting 5, the mean between them, in place of  $x$ , I find  $x^3 - 16x + 55 = 25 - 80 + 55 = 0$ ; and consequently 5 is the least root of the equation. After the same manner you will discover 11 to be the greatest root of that equation.

Thus by diminishing the greater, or increasing the lesser limit, you may discover the true root when it is a commensurable quantity. But, by proceeding after this manner, when you have two limits, the one greater than the root, the other lesser, that differ from one another but by unit, then you may conclude the root is *incommensurable*.

We may however, by continuing the operation in fractions, approximate to it. As if the equation proposed is  $x^3 - 6x + 7 = 0$ , if we suppose  $x = 2$ , the result is  $4 - 12 + 7 = -1$ , which being negative, and the supposition  $x = 2$  giving a positive result, it follows that the root is *between* 2 and 2. Next we suppose  $x = 1$ ; whence  $x^3 - 6x + 7 = 1 - 6 + 7 = 2$ , which being positive, we infer the root is *between* 1 and 2, and consequently incommensurable. In order to approximate to it, we suppose  $x = 1\frac{1}{2}$ , and find  $x^3 - 6x + 7 = 2\frac{1}{8} - 9 + 7 = \frac{1}{8}$ ; and this result being positive, we infer the root must be *between* 2 and  $1\frac{1}{2}$ . And therefore we try next  $1\frac{1}{3}$ , and find  $x^3 - 6x + 7 = \frac{4}{27} - 4 + 7 = 3\frac{1}{27} - 10\frac{2}{27} + 7 = \frac{1}{27}$ , which is negative; so that we conclude the root to be *between*  $1\frac{1}{2}$  and  $1\frac{1}{3}$ . And therefore we try next  $1\frac{1}{4}$ , which giving also a negative result, we conclude the root is *between*  $1\frac{1}{2}$  (or  $1\frac{3}{4}$ ) and  $1\frac{1}{3}$ . We try therefore  $1\frac{2}{3}$ , and the result being positive, we conclude that the root must be *between*  $1\frac{2}{3}$  and  $1\frac{1}{3}$ , and therefore is nearly  $1\frac{1}{2}$ .

Or you may approximate more easily by transforming the equation proposed into another whose roots shall be equal to 10, 100, or 1000 times the roots of the former, by p. 106. col. 1. par. 4. and taking the limits greater in the same proportion. This transformation is easy; for you are only to multiply the 2d term by 10, 100, or 1000, the 3d term by their squares, the 4th by their cubes, &c. The equation of the last example is thus transformed into  $x^3 - 600x + 70000 = 0$ , whose roots are 100 times the roots of the proposed equation, and whose limits are 100 and 200. Proceeding as before, we try 150, and find  $x^3 - 600x + 70000 = 22500 - 90000 + 70000 = 2500$ , so that 150 is less than the root. You next try 175, which giving a negative

result must be greater than the root: and thus proceeding, you find the root to be *between* 158 and 160: from which you infer, that the least root of the proposed equation  $x^3 - 6x + 7 = 0$  is *between* 1.58 and 1.59, being the hundredth part of the root of  $x^3 - 600x + 70000 = 0$ .

If the cubic equation  $x^3 - 15x^2 + 63x - 50 = 0$  is proposed to be resolved, the equation of the limits will be (by p. 110. col. 2. par. 2.)  $3x^3 - 30x + 63 = 0$ , or  $x^3 - 10x + 21 = 0$ , whose roots are 3, 7; and by substituting 0 for  $x$ , the value of  $x^3 - 15x^2 + 63x - 50$  is negative; and by substituting 3 for  $x$ , that quantity becomes positive.  $x = 1$  gives it negative, and  $x = 2$  gives it positive, so that the root is *between* 1 and 2, and therefore incommensurable. You may proceed as in the foregoing examples to approximate to the root. But there are other methods by which you may do that more easily and readily; which we proceed to explain.

When you have discovered the value of the root to be less than an unit (as, in this example, you know it is a little above 1), suppose the difference *between* its real value and the number that you have found nearly equal to it, to be represented by  $f$ : as in this example. Let  $x = 1 + f$ . Substitute this value for  $x$  in the equation, thus,

$$\begin{aligned} x^3 &= 1 + 3f + 3f^2 + f^3 \\ -15x^2 &= -15 - 30f - 15f^2 \\ +63x &= 63 + 63f \\ -50 &= -50 \\ \hline x^3 - 15x^2 + 63x - 50 &= -1 + 36f - 12f^2 + f^3 = 0. \end{aligned}$$

Now because  $f$  is supposed less than unit, its powers  $f^2, f^3$ , may be neglected in this approximation; so that assuming only the two first terms, we have  $-1 + 36f = 0$ , or  $f = \frac{1}{36} = .027$ ; so that  $x$  will be nearly 1.027.

You may have a nearer value of  $x$  by considering, that seeing  $-1 + 36f - 12f^2 + f^3 = 0$ , it follows that

$$f = \frac{1}{36 - 12f + f^2} = (\text{by substituting } \frac{1}{36} \text{ for } f) \\ \text{nearly} = \frac{1}{36 - 12 \times \frac{1}{36} + \frac{1}{36} \times \frac{1}{36}} = \frac{1 \times 36}{36 \times 36 - 12 \times 36 + 36} = .02803.$$

But the value of  $f$  may be corrected and determined more accurately, by supposing  $g$  to be the difference *between* its real value and that which we last found nearly equal to it. So that  $f = .02803 + g$ . Then by substituting this value for  $f$  in the equation  $f^3 - 12f^2 + 36f - 1 = 0$ , it will stand as follows,

$$\left. \begin{aligned} f^3 &= 0.0000220226 + 0.0023578 + 0.08409g^2 + g^3 \\ -12f^2 &= -.00942816 - 0.67272g - 12g^2 \\ +36f &= 1.00908 + 36g \\ -1 &= -1. \end{aligned} \right\} = 0$$

---

$$= -0.0003261374 + 35.329637g - 11.9195g^2 + g^3 = 0.$$

Of which the first two terms, neglecting the rest, give  $35.329637 \times g = 0.0003261374$ , and  $g = \frac{0.0003261374}{35.329637} = 0.00000923127$ . So that  $f = 0.02803923127$ ; and

$x = 1 + f = 1.02803923127$ ; which is very near the true root of the equation that was proposed.

If still a greater degree of exactness is required, suppose  $h$  equal to the difference *between* the true value of  $g$  and

and that we have already found, and proceeding as above you may correct the value of  $g$ .

It is not only one root of an equation that can be obtained by this method, but, by making use of the other limits, you may discover the other roots in the same manner. The equation of p. 116. col. 2. par. 1.  $x^3 - 15x^2 + 63x - 50 = 0$ , has for its limits 0, 3, 7, 50. We have already found the least root to be nearly 1.028039. If it is required to find the middle root, you proceed in the same manner to determine its nearest limits to be 6 and 7; for 6 substituted for  $x$  gives a positive, and 7 a negative result. Therefore you may suppose  $x = 6 + f$ , and by substituting this value for  $x$  in that equation, you find  $f^3 + 3f^2 - 9f + 4 = 0$ , so that  $f = \frac{4}{3}$  nearly. Or, since  $f = \frac{4}{9 - 3f - f^2}$ , it is (by substituting  $\frac{4}{3}$  for  $f$ )

$f = \frac{4}{9 - \frac{4}{3} - \frac{16}{9}} = \frac{12 \cdot 4}{27 - 12 - 16} = \frac{48}{-5}$ , whence  $x = 6 + \frac{12 \cdot 4}{-5}$  nearly. Which value may still be corrected as in the preceding articles. After the same manner you may approximate to the value of the highest root of the equation.

“In all these operations, you will approximate sooner to the value of the root, if you take the three last terms of the equation, and extract the root of the quadratic equation consisting of these three terms.”

Then, in p. 116. col. 2. par. 2. instead of the two last terms of the equation  $f^3 - 12f^2 + 36f - 1 = 0$ , if you take the three last, and extract the root of the quadratic  $12f^2 - 36f + 1 = 0$ , you will find  $f = .028031$ , which is much nearer the true value than what you discover by supposing  $36f - 1 = 0$ .

It is obvious that this method extends to all equations. “By assuming equations affected with general coefficients, you may, by this method, deduce general rules or theorems for approximating to the roots of proposed equations of whatever degree.”

CHAP. XXII. *Of the Rules for finding the Number of impossible Roots in an Equation.*

THE number of impossible roots in an equation may, for most part, be found by this

**RULE.** Write down a series of fractions whose denominators are the numbers in this progression, 1, 2, 3, 4, 5, &c. continued to the number which expresses the dimension of the equation. Divide every fraction in the series by that which precedes it, and place the quotients in order over the middle terms of the equation. And, if the square of any term multiplied into the fraction that stands over it gives a product greater than the rectangle of the two adjacent terms, write under the term the sign +, but if that product is not greater than the rectangle, write —; and the signs under the extreme terms being +, there will be as many imaginary roots as there are changes of the signs from + to —, and from — to +.

Thus, the given equation being  $x^3 + px^2 + 3p^2x - q = 0$ , I divide the second fraction of the series  $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}$ ,  
Vol. I. No. 5. 3

by the first, and the third by the second, and place the quotients  $\frac{1}{2}$  and  $\frac{1}{3}$ , over the middle terms in this manner,

$$\begin{array}{ccccccc} & & \frac{1}{2} & & \frac{1}{3} & & \\ & & + & - & + & - & \\ x^3 & + & px^2 & + & 3p^2x & - & q = 0 \end{array}$$

Then because the square of the second term multiplied into the fraction that stands over it, that is,  $\frac{1}{2} \times p^2 x^2$ , is less than  $3p^2 x^2$  the rectangle under the first and third terms, I place under the second term the sign —; but as  $\frac{1}{3} \times 9p^2 x^2 (= 3p^2 x^2)$  the square of the third term multiplied into its fraction is greater than nothing, and consequently much greater than  $-pqx^2$ , the negative product of the adjoining terms, I write under the third term the sign +. I write + likewise under  $x^3$  and  $-q$  the first and last terms; and finding in the signs, thus marked, two changes, one from + to —, and another from — to +, I conclude the equation has two impossible roots.

When two or more terms are wanting in the equation, under the first of such terms place the sign —, under the second +, under the third —, and so on alternately; only when the two terms to the right and left of the deficient terms have contrary signs, you are always to write the sign + under the last deficient term.

As in the equations

$$\begin{array}{cccccccc} x^5 + ax^4 & * & * & * & * & + a^5 = 0 \\ + & + & - & + & - & + \\ \text{and } x^5 + ax^4 & * & * & * & * & - a^5 = 0 \\ + & + & - & + & + & + \end{array}$$

the first of which has four impossible roots, and the other two.

Hence too we may discover if the imaginary roots lie hid among the affirmative, or among the negative roots. For the signs of the terms which stand over the signs below that change from + to —, and — to +, shew, by the number of their variations, how many of the impossible roots are to be reckoned affirmative; and that there are as many negative imaginary roots as there are repetitions of the same sign.

As in the equation

$$\begin{array}{ccccccc} x^5 - 4x^4 + 4x^3 - 2x^2 - 5x - 4 = 0 \\ + & + & - & + & + & + & + \end{array}$$

the signs (+ + —) of the terms  $-4x^4 + 4x^3 - 2x^2$  which stand over the signs + — + pointing out two affirmative roots, we infer that two impossible roots lie among the affirmative: and the three changes of the signs in the equation (+ — + — —) giving three affirmative roots and two negative, the five roots will be one real affirmative, two negative, and two imaginary affirmatives. If the equation had been

$$\begin{array}{ccccccc} x^5 - 4x^4 - 4x^3 - 2x^2 - 5x - 4 = 0 \\ + & + & - & - & + & + & + \end{array}$$

the terms  $-4x^4 - 4x^3$  that stand over the first variation + —, shew by the repetition of the sign —, that one imaginary root is to be reckoned negative, and the

terms  $-2x^2 - 5x$  that stand over the last variation  $-+$ , give, for the same reason, another negative impossible root; so that the signs of the equation  $(+ - - - -)$  giving one affirmative root, we con-

clude that of the four negative roots two are imaginary.

This always holds good, unless, which sometimes may happen, "there are more impossible roots in the equation than are discoverable by the rule."

## A L H

ALGENEB, a fixed star of the second magnitude on the right shoulder of Perseus. See PERSEUS.

ALGER, or ALGERI, a city on the north-west coast of the island of Sardinia, situated in E. long.  $8^{\circ} 40'$ , and N. lat.  $41^{\circ} 30'$ .

ALGIABARIL, among the Mahometans, the name of a sect of predelinarians. See PREDESTINATION.

ALGIERS, a kingdom of Africa, situated between  $30^{\circ}$  and  $37^{\circ}$  of N. lat. and between  $1^{\circ}$  W. and  $9^{\circ}$  E. long. It is bounded by the Mediterranean on the north, by the kingdom of Tunis on the east, by mount Atlas on the south, and by the river Mulvia, which separates it from the empire of Morocco, on the west; extending 600 miles, from east to west, along the Babary coast.

The Turks, who are masters of this kingdom, are but few in number in comparison of the Moors, or natives, who have no share in the government. The Arabs, who live in tents, are distinct from either. The dey of Algiers is an absolute, though an elective monarch. He is chosen by the Turkish soldiers only, and is frequently deposed, or even put to death by them.

ALGIERS is also the name of the capital of the above-mentioned kingdom, situated near the mouth of the river Safran, on the Mediterranean sea, opposite to the island of Majorca; its E. long. being  $3^{\circ} 27'$ , and its N. lat.  $36^{\circ} 49'$ .

ALGOIDES, in botany. See ZANNICHELLIA.

ALGOL, the name of a fixed star of the third magnitude in the constellation Perseus, otherwise called Medusa's head. See ASTRONOMY, *Of the fixed stars.*

ALGOSQUIN, one of the two principal languages spoken in N. America, viz. from the river of St Laurence to that of Mississippi; the other which is called Haron, being spoken in Mexico.

ALGOR, with physicians, an unusual coldness in any part of the body.

ALGORITHM, and arabic word expressive of numerical computation. See ARITHMETIC, Chap. I.

ALGOSAREL, in botany, an obsolete name of the daucus. See DAUCUS.

ALGUAZIL, in the Spanish policy, an officer whose business it is to see the decrees of a judge executed.

ALHAGI, in botany, the trivial name of a species of hedyсарum. See HYDEBARUM.

ALHAMA, a small town of Granada in Spain, surrounded with hills, and situated about twenty-five miles S. W. of Granada, W. long.  $4^{\circ}$ , N. lat.  $37^{\circ}$ .

ALHANDAL, among Arabian physicians, a name used for colocynth. See COLOCYNTH.

ALHEAL, in botany. See GALEOPSIS, STACHYS.

## A L I

ALHENNA, in botany, a synonyme of the Lawsonia. See LAWSONIA.

ALHIDADE, or ALIDADE, a term of Arabic origin, signifying the index or diopter of a mathematical instrument for taking heights and distances. See DIOPTRER.

ALJAMEIA, the name by which the Moriscoes of Spain called the Spanish language.

ALICANT, a large sea-port town of Spain, in the province of Valencia, with a very strong castle. It is situated in W. long.  $36'$ , and N. lat.  $38^{\circ} 37'$ .

ALICATA, a mountain of Sicily, near the valleys Mazara and Noto, upon which was situated (as is generally thought) the famous Dædalion, where the tyrant Phalaris kept his brazen bull.

ALICE, a cape of the Hither Calabria in the kingdom of Naples, called in Latin *Alicium promontorium*.

ALICES, an obsolete name of the spots that precede the eruption of the small-pox.

ALICULA, in Roman antiquity, a kind of chlamys worn by children, which some call *tunica manicata*.

ALICUR, a very small island in the Tuscan sea, about fifteen miles west from the Lipari, on the coast of Sicily.

ALIDADE. See ALHIDADE.

ALIDES, among the Mahometans, a designation given to the descendants of Ali; between whom and the Omniades, there was a warm dispute about the kaliphate. See KALIPHATE.

ALJEBUT; in botany, an obsolete name of a species of mimosa. See MIMOSA.

ALIBI, in Scots law; when a person pursued for the commission of a crime, libelled to have been committed at a certain place, and upon a certain day, proves in his defence, that he was elsewhere at the time libelled, he is said to have proved *alibi*. See LAW, tit. *Crimes*.

ALIEN, in Scots law, a person who owes allegiance to a foreign prince; and who, on that account, cannot hold any feudal right in Scotland without being naturalized. See LAW, title, *Constitution of heritable rights*.

ALIEN duty, an impost laid on all goods imported by aliens, over and above the customs paid for such goods imported by British, and on British bottoms.

ALIEN-priorities, a kind of inferior monasteries, formerly very numerous in England, and so called from their belonging to foreign abbays.

ALIENABLE, denotes something that may be alienated. See ALIENATION.

ALIENATION, in law, denotes the act of making over a man's property in land, tenements, &c. to another person.

**ALIENATION**, in mortmain, is making over lands, tenements, &c. to a body politic, or to a religious house, for which the king's licence must first be obtained, otherwise the lands, &c. alienated will be forfeited. See **MORTMAIN**.

**ALIFANUS**, in botany, a synonyme of the rhexia. See **RHAXIA**.

**ALIFORMIS**, in anatomy, the name of a pair of muscles. See **ANATOMY**, Part II.

**ALIFORMIS processus**, the name given by some to the prominences of the os cuneiforme. See **ANATOMY**, Part I.

**ALIMA**, a kind of sand found in gold mines, of which they make lead.

**ALIMENT**, whatever promotes the growth or nourishment of animal or vegetable bodies. See **FOOD**.

*Obligation of ALIMENT*, in Scots law, the natural obligation on parents to provide their children with the necessaries of life, &c. See **LAW**, titles, *Marriage*, and *Obligations and contracts in general*.

**ALIMENTARY**, an epithet for every thing that belongs to aliment or food.

**ALIMENTARY debt**, in Scots law, an obligation come under by one person to pay a certain sum annually for the maintenance of another, either gratuitously, in consideration of a sum of money sunk, or by way of wages. See **LAW**, title, *Arreignment and pointing*.

**ALIMENTARY children**, in Roman antiquity, an appellation given to those educated in houses not unlike our hospitals.

**ALIMENTARY law**, among the Romans, that whereby children were obliged to maintain their aged parents.

**ALIMENTATION**, a term used by some writers, particularly Lord Bacon, for what is commonly called nutrition. See **NUTRITION**.

**ALIMONY**, in law. See *Obligation of ALIMENT*.

**ALIMOS**, in botany, an obsolete name of the glycyrrhiza. See **GLYCYRRHIZA**.

**ALIOS-BATON**, in ichthyology, an obsolete name of a species of rana or frog. See **RANA**.

**ALIPILARIUS**, or **ALIPILUS**, in Roman antiquity, a servant belonging to the baths, whose business it was, by means of waxen plasters, and an instrument called *volvela*, to take off the hairs from the arm-pits, and even arms, legs, &c. this being deemed a point of cleanliness.

**ALIPTA**, in Grecian antiquity. See **JATRALIPTRA**.

**ALIPSTERIUM**, in the ancient gymnasia, the same with *elæothesium*. See **ELÆOTHESIUM**.

**ALIPOW montis coti**, a kind of white turbith, found in Languedoc, used as a purgative. See **TURBITH**.

**ALIQVANT parts**, those parts which one number cannot measure. See **ARITHMETIC**.

**ALIQVOT parts**, those parts which one number can measure. See **ARITHMETIC**.

**ALISE**, or **ALIZE**, a small town of France, in the district of Auxois.

**ALISE**, or **ELISE**, is a small island in the Irish sea, not far from the mull of Galloway.

**ALISMA**, in botany, a genus of the hexandria polygynia class. The characters of the alisma are these.

The calix consists of three pieces or leaves; the flower has three petals; and the seeds are numerous. There are seven species of this plant, *viz.* the plantago, or great water-plantain, which grows in all the marshy parts of this country; the ranunculoides, or lesser water-plantain; the natans, or creeping water-plantain; the damafonium, or star-headed water-plantain; all of which are natives of Britain: the flava, cordifolia, and subulata, are natives of America.

**ALITES**, in Roman antiquity, a designation given to such birds as afforded matter of auguries by their flight; in which sense they are contradictorily distinguished from those called *oscines*. See **OSCINES**.

**ALIZE**, in geography. See **ALISE**.

**ALKA**, in ornithology. See **ALCA**.

**ALKAHEST**, or **ALCAHEST**, in chemistry, an universal menstruum capable of resolving all bodies into their first principles. Van Helmont pretended he was possessed of such a menstruum; but, however credulous people might be imposed on in his days, the notion is now become as ridiculous as the philosophers stone, the perpetuum mobile, &c. It is likewise used by some authors for all fixed salts volatilized.

**ALKAHESTIC**, an epithet applied to all powerful menstruums.

**ALKALI**, in chemistry, a name for all substances which ferment with acids. See **CHEMISTRY**, *Of Alkalis, or alkaline substances*. Alkali originally signified only the salt of the kali.

**ALKALINE**, an epithet for every body which possesses any of the qualities of an alkali.

**ALKALIZATION**, in chemistry, the impregnating any liquor with alkaline bodies.

**ALKALY**. See **ALKALI**.

**ALKANET**, in botany, the English name of the anchusa. See **ANCHUSA**.

**ALKEKENGI**, in botany, a synonyme of several species of the atropa and physalis; it is also the trivial name of a species of the physalis. See **PHYSALIS**, and **ATROPA**.

**ALKERMES**, in pharmacy, a compound cordial medicine made in the form of a confection. The principal ingredient is the kermes. See **KERMES**.

**ALKIN**, a city of Arabia Felix, seven days journey, S. from Mecca.

**ALKOOL**. See **ALCOHOL**.

**ALKY of lead**, a sweet substance obtained by the chemists from lead.

**ALL-HALLOWS**, the same with All-faints. See the next article.

**ALL-SAINTS**, a festival observed by most denominations of Christians, in commemoration of all the saints in general. It is kept on the first of November.

**ALL-SAINTS bay**, or *baia de todos santos*, a spacious harbour near St Salvador in Brazil, in S. America, on the Atlantic Ocean, W. long. 40°, S. lat. 12°.

**ALL-SOULS**, a festival kept in commemoration of all the faithful deceased, on the second of November.

**ALLA**, or **ALLAH**, the name by which all the professors of Mahometanism call the Supreme Being.

The term alla is Arabic, derived from the verb *alah*,

to adore. It is the same with the Hebrew *eloah*, which signifies the *adorable Being*.

**ALLANTOIS**, or **ALLANTOIDES**, a gut-shaped vesicle investing the fœtus of cows, goats, sheep, &c. filled with a liquor conveyed to it from the urachus.

**ALLAY**. See **ALLOY**.

**ALLEGATA**, in Roman antiquity, a kind of subscription used by the emperors, importing the writings to be verified.

**ALLEGATION**, in matters of literature, is the quoting an author in regard to the subject in hand.

**ALLEGIANCE**, in law, denotes the obedience which every subject owes to his lawful sovereign.

*Oath of ALLEGIANCE*, in the British policy, that taken in acknowledgment of the king as a temporal prince; as the oath of supremacy acknowledges him for the supreme head of the church.

**ALLEGORICAL**, a term applied to whatever belongs to, or partakes of, the nature of an allegory. See **ALLEGORY**.

**ALLEGORIST**, one who deals in allegories: such were many of the Christian fathers.

**ALLEGORY**, in composition, consists in choosing a secondary subject, having all its properties and circumstances resembling those of the principal subject, and describing the former in such a manner as to represent the latter. The principal subject is thus kept out of view, and we are left to discover it by reflection. In other words, an allegory is, in every respect, similar to an hieroglyphical painting, excepting only that words are used instead of colours. Their effects are precisely the same: An hieroglyphic raises two images in the mind; one seen, that represents one that is not seen: An allegory does the same; the representative subject is described; and the resemblance leads us to apply the description to the subject represented.

There cannot be a finer or more correct allegory than the following, in which a vineyard is made to represent God's own people the Jews

“ Thou hast brought a vine out of Egypt; thou  
 “ hast cast out the heathen, and planted it. Thou  
 “ didst cause it to take deep root, and it filled the  
 “ land. The hills were covered with its shadow, and  
 “ the boughs thereof were like the goodly cedars.  
 “ Why hast thou then broken down her hedges, fo  
 “ that all that pass do pluck her? The boar out of  
 “ the wood doth waste it, and the wild beast doth de  
 “ vor it. Return, we beseech thee, O God of hosts:  
 “ look down from heaven, and behold, and visit this  
 “ vine and the vineyard thy right hand hath planted,  
 “ and the branch thou madest strong for thyself.”  
 Psal. lxxx.

Nothing gives greater pleasure than an allegory, when the representative subject bears a strong analogy, in all its circumstances, to that which is represented. But most writers are unlucky in their choice, the analogy being generally so faint and obscure, as rather to puzzle than to please. Allegories, as well as metaphors and similes, are unnatural in expressing any severe passion which totally occupies the mind. For this reason, the following speech of Macbeth is justly

condemned by the learned author of the *Elements of Criticism*:

Method! I heard a voice cry, Sleep no more!  
 Macbeth doth murder Sleep; the innocent sleep;  
 Sleep that knits up the ravell'd sleeve of Care,  
 The birth of each day's life, for Labour's bath,  
 Balm of hurt minds, great Nature's second course,  
 Chief nourisher in life's feast. A C ii. Sc. 3.

**ALLEGRO**, in music, an Italian word, denoting that the part is to be played in a sprightly, brisk, lively, and gay manner.

*Piu* **ALLEGRO**, signifies, that the part it is joined to should be sung or played quicker; as

*Poco piu* **ALLEGRO**, intimates, that the part to which it refers, ought to be played or sung only a little more briskly than allegro alone requires.

**ALLEGRET**. See **ALEGRETTE**.

**ALLELENGYON**, in antiquity, a tax paid by the rich for the poor, when absent in the army.

**ALLELOPHAGI**, a term used by some authors for a kind of flies which are said to feed upon each other.

**ALLELUJAH**, in botany, an obsolete name for the oxys. See **Oxys**.

**ALLELUJAH**, among ecclesiastical writers. See **HALLELUJAH**.

**ALLEMAND**, a sort of grave solemn music, with good measure, and a slow movement. It is also a kind of dance, very common in Germany and Switzerland.

**ALLEMANNIC**, in a general sense, denotes any thing belonging to the ancient Germans. Thus, we meet with *Allemannic history*, *Allemannic language*, *Allemannic law*, &c.

**ALLENDORF**, a little city in the Landgrate of Hesse-Cassel in Germany, situated upon the river Weser; E. long. 10°, N. lat. 51° 30'

**ALLER**, a river which runs through the Dutchy of Lunenburg, and falls into the Weser, a little below Verden.

**ALLER**, or **ALDER**, a term used in our old writers to denote the superlative degree. Thus, *aller-good* signifies the greatest good.

**ALLERION**, or **ALERION**, in heraldry, a sort of eagle without beak or feet, having nothing perfect but the wings. They differ from martlets by having their wings expanded, whereas those of the martlet are close; and denote imperialists vanquished and disarmed; for which reason they are more common in French than in German coats of arms.

**ALEU**, or **ALLODE**. See **ALLODIAL**, and **ALLODIUM**.

**ALLEVIARE**, in old records, signifies to levy or raise an accustomed fine or imposition.

**ALLEVIATION**, is the act of making a thing lighter, or more easy to be borne.

**ALLEVEURE**, a small brass Swedish coin, worth about  $\frac{2}{3}$  of an English money.

**ALLEY**, in gardening, a straight parallel walk, bounded on both sides with trees, shrubs, &c. and usually covered with gravel or turf.

**Covered ALLEY**, that over which the branches of trees meeting, form a shade.

**ALLEY of compartment**, that which divides the squares of a parterre. See **PARTERRE**.

**ALLEY**, among builders, denotes a narrow passage leading from one place to another

**ALLEY**, in perspective, that which, in order to have a greater appearance of length, is made wider at the entrance than at the termination

**ALLIANCE**, in the civil and canon law, the relation contracted between two persons or two families by marriage.

**ALLIANCE** is also used for a treaty entered into by sovereign princes and states, for their mutual safety and defence.

In this sense, alliances may be distinguished into such as are offensive, whereby the contracting parties oblige themselves jointly to attack some other power; and into defensive ones, whereby they bind themselves to stand by and defend each other, in case they are attacked by others.

**ALLIANCE**, in a figurative sense, is applied to any kind of union or connection: thus we say, there is an alliance between the church and state.

**ALLIGATI**, in Roman antiquity, the basest kind of slaves, who were usually kept fettered. See **SLAVE**.

**ALLIER**, a river of France, which, arising in Languedoc, waters part of Auvergne and Bourbonnois, and falls into the Loire, a little below Nevers.

## A L L I G A T I O N .

**ALLIGATION**, the name of a method of solving all questions that relate to the mixture of one ingredient with another. Though writers on arithmetic generally make alligation a branch of that science; yet, as it is plainly nothing more than an application of the common properties of numbers, in order to solve a few questions that occur in particular branches of business, we chuse rather to keep it distinct from the science of arithmetic.

Alligation is generally divided into *medial* or *alternate*.

### I. ALLIGATION MEDIAL.

Alligation medial, from the rates and quantities of the simples given, discovers the rate of the mixture.

**RULE.** As the total quantity of the simples,  
To their price or value;  
So any quantity of the mixture,  
To the rate.

**EXAMP.** A grocer mixeth 30 lb. of currants, at 4 d. per lb. with 10 lb. of other currants, at 6 d. per lb.: What is the value of 1 lb. of the mixture. *Ans.* 4½ d.

lb.	d.	d.
30,	at 4 amounts to	120
10,	at 6	60
40		180

If 40 : 180 :: 1 : 4½

**Note 1.** When the quantity of each simple is the same, the rate of the mixture is readily found by adding the rates of the simples, and dividing their sum by the number of simples, thus.

Suppose a grocer mixes several sorts of sugar, and of

each an equal quantity, *viz.* at 50 s. at 54 s. and at 60 s. per Cwt. the rate of the mixture will be 54 s. 8 d. per Cwt.; for,

$$50 + 54 + 60 = 164, \text{ and } 3)164(54 \text{ 8}$$

**Note 2.** If it be required to increase or diminish the quantity of the mixture, say, As the sum of the given quantities of the simples, to the several quantities given; so the quantity of the mixture proposed, to the quantities of the simples sought.

**Note 3.** If it be required to know how much of each simple is in an assigned portion of the mixture, say, As the quantity of the mixture, to the several quantities of the simples given; so the quantity of the assigned portion, to the quantities of the simples sought. Thus,

Suppose a grocer mixes 10 lb. of raisins, with 30 lb. of almonds, and 40 lb. of currants, and it be demanded, how many ounces of each sort are found in every pound, or in every sixteen ounces of the mixture, say,

80 :	10	::	16	:	2 raisins.
80 :	30	::	16	:	6 almonds.
80 :	40	::	16	:	8 currants.

Proof 16

**Note 4.** If the rates of two simples, with the total value and total quantity of the mixture be given, the quantity of each simple may be found as follows, *viz.* multiply the lesser rate into the total quantity, subtract the product from the total value, and the remainder will be equal to the product of the excess of the higher rate above the lower, multiplied into the quantity of the higher-priced simple; and consequently the said remainder, divided by the difference of the rates, will quote the said quantity. Thus,

Suppose a grocer has a mixture of 400 lb weight, that cost him 7 l. 10 s. consisting of raisins, at 4 d. per lb.

and almonds at 6 d. how many pounds of almonds were in the mixture?

	<i>lb.</i>	<i>Rates.</i>	
	400	6 d.	
<i>L. s.</i>	7	4	4 d.
10 = 1800	—	—	—
1600	1600 d.	2 d.	
2) 200 (100 lb. of almonds at 6 d. is,			<i>L. s.</i>
And 300 lb. of raisins, at 4 d. is,			2 10
Total 400			5 0
		Proof	7 10

## II. ALLIGATION ALTERNATE.

Alligation alternate, being the converse of alligation medial, from the rates of the simples, and rate of the mixture given, finds the quantities of the simples.

### R U L E S.

I. Place the rate of the mixture on the left side of a brace, as the root; and on the right side of the brace set the rates of the several simples, under one another, as the branches.

II. Link or alligate the branches, so as one greater, and another less than the root may be linked or yoked together.

III. Set the difference betwixt the root and the several branches, right against their respective yoke-fellows. These alternate differences are the quantities required.

*Note 1.* If any branch happen to have two or more yoke-fellows, the difference betwixt the root and these yoke-fellows must be placed right against the said branch, one after another, and added into one sum.

*Note 2.* In some questions, the branches may be alligated more ways than one; and a question will always admit of so many answers, as there are different ways of linking the branches.

Alligation alternate admits of three varieties, *viz.*

1. The question may be unlimited, with respect both to the quantity of the simples, and that of the mixture.
2. The question may be limited to a certain quantity of one or more of the simples.
3. The question may be limited to a certain quantity of the mixture.

#### Variety I.

When the question is unlimited, with respect both to the quantity of the simples, and that of the mixture, this is called *Alligation Simple*.

*EXAMP.* A grocer would mix sugars, at 5 d. 7 d. and 10 d. *per lb.* so as to sell the mixture or compound at 8 d. *per lb.*: What quantity of each must he take?

		<i>lb.</i>	
8	{	5	2
		7	2
		10	3, 1
			4

Here the rate of the mixture 8 is placed on the left

side of the brace, as the root; and on the right side of the same brace are set the rates of the several simples, *viz.* 5, 7, 10, under one another, as the branches; according to Rule I.

The branch 10 being greater than the root, is alligated or linked with 7 and 5, both these being less than the root; as directed in Rule II.

The difference between the root 8 and the branch 5, *viz.* 3, is set right against this branch's yoke-fellow 10. The difference between 8 and 7 is likewise set right against the yoke-fellow 10. And the difference betwixt 8 and 10, *viz.* 2, is set right against the two yoke-fellows 7 and 5; as prescribed by Rule III.

As the branch 10 has two differences on the right, *viz.* 3 and 1, they are added; and the answer to the question is, that 2 lb. at 5 d. 2 lb. at 7 d. and 4 lb. at 10 d. will make the mixture required.

The truth and reason of the rules will appear by considering, that whatever is lost upon any one branch is gained upon its yoke-fellow. Thus, in the above example, by selling 4 lb. of 10 d. sugar at 8 d. *per lb.* there is 8 d. lost; but the like sum is gained upon its two yoke-fellows; for by selling 2 lb. of 5 d. sugar at 8 d. *per lb.* there is 6 d. gained; and by selling 2 lb. of 7 d. sugar at 8 d. there is 2 d. gained; and 6 d. and 2 d. make 8 d.

Hence it follows, that the rate of the mixture must always be mean or middle with respect to the rates of the simples; that is, it must be less than the greatest, and greater than the least; otherwise a solution would be impossible. And the price of the total quantity mixed, computed at the rate of the mixture, will always be equal to the sum of the prices of the several quantities cast up at the respective rates of the simples.

#### Variety II.

When the question is limited to a certain quantity of one or more of the simples, this is called *Alligation Partial*.

If the quantity of one of the simples only be limited, alligate the branches, and take their differences, as if there had been no such limitation; and then work by the following proportion.

As the difference right against the rate of the simple whose quantity is given,  
To the other differences respectively;  
So the quantity given,  
To the several quantities sought.

*EXAMP.* A distiller would, with 40 gallons of brandy at 12 s. *per gallon*, mix rum at 7 s. *per gallon*, and gin at 4 s. *per gallon*: How much of the rum and gin must he take, to sell the mixture at 8 s. *per gallon*?

		<i>Gal.</i>	
8	{	12	1, 4
		7	4
		4	4
		5	40 of brandy,
		4	32 of rum.
		4	32 of gin.
			} <i>Ans.</i>

The operation gives for answer, 5 gallons of brandy,  
4 of

4 of rum, and 4 of gin. But the question limits the quantity of brandy to 40 gallons; therefore say,

$$\text{If } 5 : 4 :: 40 : 32$$

The quantity of gin, by the operation, being also 4, the proportion needs not be repeated.

Variety III.

When the question is limited to a certain quantity of the mixture, this is called *Alligation Total*.

After linking the branches, and taking the differences, work by the proportion following,

- As the sum of the differences,
- To each particular difference;
- So the given total of the mixture,
- To the respective quantities required.

EXAMP. A vintner hath wine at 3 s. per gallon, and

would mix it with water, so as to make a composition of 144 gallons, worth 2 s. 6 d. per gallon: How much wine, and how much water must he take?

<i>Gal.</i>		
30	36	120 of wine. } <i>Ans.</i>
0	6	
36		144 total.
120	× 36	= 4320
24	× 0	= 0

Proof 144)4320(30

$$\begin{aligned} \text{As } 36 : 30 &:: 144 : 120 \\ \text{As } 36 : 6 &:: 144 : 24 \end{aligned}$$

There being here only two simples, and the total of the mixture limited, the question admits but of one answer.

A L L

ALLIGATOR, in zoology, a synonyme of the lacerta crocodilus. See LACERTA.

ALLIGATOR-pear, in botany. See PYRUS.

ALLIONIA, in botany, a genus of the tetrandria monogynia class. The characters of which are: The common calix is oblong, simple, and three flowered; the proper calix is above the fruit, and obsolete; the corolla is irregular; and the receptacle without any covering. There are only two species of the allionia, viz. the violacea, and incarnata, both natives of America.

ALLIOTH, a star in the tail of the greater bear, much used for finding the latitude at sea.

ALLIUM garlick, in botany, a genus of the hexandria monogynia class. The characters are: The corolla is open, and divided into six parts; the spathe is multiflorous; the capsule is above the flower; and the flowers are in the form of an umbell. There are no less than 37 species of the allium, only five of which, viz. the ampeloprasum, or great round-headed garlick; the arenarium, or broad-leaved mountain-garlick; the vineale, or crow-garlick; the oleraceum, or wild garlick with an herbaceous striated flower; and the ursinum, or ramson, are natives of Britain. Allium is a powerful diuretic, and, along with honey, has good effects in asthma.

ALLOA, a port-town of Scotland, situated on the river Forth, remarkable for the coal-mines in its neighbourhood. W. long. 3° 45', N. lat. 56° 10'.

ALLOCATION denotes the admitting or allowing of an article of an account, especially in the exchequer. Hence,

*Allocatio facienda* is a writ directed to the lord treasurer, or barons of the exchequer, commanding them to allow an accountant such sums as he has lawfully expended in the execution of his office.

ALLOCATO *comitatus*, a new writ of exigent allowed, before any other county court held, on a former not being complied with. See EXIGENT.

A L L

ALLOCUTION, in Roman antiquity, denotes an harangue made by a general to his army, frequently mentioned on ancient medals.

ALLODIAL goods, in Scots law, are such as are enjoyed by the owner, independent of any other. Lands are likewise said to be allodial, when they are held without the necessity of acknowledging a superior. See LAW, title, *Constitution of heritable rights*.

ALLODIUM, or ALLEUD, denotes lands which are the absolute property of their owner, without being obliged to pay any service or acknowledgement whatever to a superior lord.

ALLOGIA, a term found in old writers on military affairs, for winter-quarters.

ALLOM. See ALUM.

ALLONGE, in fencing, denotes a thrust or pass at the adversary. See PASS.

ALLOPHYLLUS, in botany, a genus of the octandria monogynia class. The characters are: The calix is four leaved; the leaves are globular; the flower consists of four petals, less than the calix; and the stigma is forked. There is only one species, which is found in Zeylon.

ALLOTTING, or ALLOTMENT of goods, in commerce, is the dividing a ship's cargo into several parts, which are to be purchased by several persons, whose names being written upon as many slips of paper, are applied by an indifferent person to the several lots; by which means the goods are divided without partiality, each man having the parcel upon which his name is fixed.

ALLOWANCES, at the custom house, to goods rated by weight, are two, viz. draught and tare. See DRAUGHT and TARE.

ALLOY, or ALLAY, a proportion of a baser metal mixed with a finer one. Thus all gold coin has an alloy of silver and copper, as silver coin has of copper alone; the proportion in the former case, for standard gold, being two carrats of alloy in a pound troy of gold;

- gold; and, in the latter, eighteen penny-weight of alloy for a pound of silver.
- ALUM.** See **ALUM.**
- ALUMNIOR**, in some of our old statutes, a person whose trade it is to colour, or paint upon paper or parchment.
- ALLUSION**, in rhetoric, a figure by which something is applied to, or understood of another, on account of some similitude between them.
- ALLUVION**, in law, denotes the gradual increase of land along the sea-shore, or on banks of rivers. See **LAW**, title, *Division of rights*.
- ALLY**, in matters of polity, a sovereign prince or state that has entered into alliance with others. See **ALLIANCE**.
- ALMACANTARS.** See **ALMUCANTARS**.
- ALMACARRON**, a port-town of Spain, in the province of Murcia, at the mouth of the Guadalentin; W. long.  $1^{\circ} 15'$ , N. lat.  $37^{\circ} 40'$ .
- ALMADE**, a town of Spain, in the province of la Mancha, in the kingdom of Castile, situated upon the top of a mountain, where are the most ancient, as well as the richest silver mines in Europe.
- ALMADIE**, a kind of canoe, or small vessel, about four fathoms long, usually made of bark, and used by the negroes of Africa.
- ALMADIE** is also the name of a kind of long boats, fitted out at Calicut, which are eighty feet in length, and six or seven in breadth. They are exceeding swift, and are otherwise called *cathuri*.
- ALMAGEST**, in matters of literature, is particularly used for a collection or book composed by Ptolemy, containing various problems of the ancients both in geometry and astronomy.
- ALMAGEST** is also the title of other collections of this kind. Thus, Riccioli has published a book of astronomy which he calls the *New Almagest*; and Plucknet, a book which he calls *Almagestrum Botanicum*.
- ALMAGRA**, a fine deep red ochre. See **OCCHRE**.
- ALMAN-FURNACE**, the same with almond-furnace. See **ALMOND**.
- ALMANAC**, in matters of literature, a table containing the kalendar of days and months, the rising and setting of the sun, the age of the moon, &c.
- Regiomontanus is allowed to have been the first who reduced almanacs to their present form.
- Construction of ALMANACS.** The first thing to be done is, to compute the sun's and moon's place for each day of the year, or it may be taken from some ephemerides and entered in the almanac; next, find the dominical letter, and, by means thereof, distribute the kalendar into weeks; then, having computed the time of easter, by it fix the other moveable feasts; adding the immoveable ones, with the names of the martyrs, the rising and setting of each luminary, the length of day and night, the aspects of the planets, the phases of the moon, and the sun's entrance into the cardinal points of the ecliptic, *i. e.* the two equinoxes and solstices.
- ALMANDINE**, a name given by ancient naturalists to the carbuncle. See **CARBUNCLE**.
- ALMANZA**, a little town in the province of New Castile in Spain, remarkable for the defeat of the confederate army by the French, in 1707; W. long.  $1^{\circ} 19'$ , N. lat.  $39^{\circ}$ .
- ALMARIA**, a term found in some ancient records for the archives of a church, monastery, and the like.
- ALMARIC herefy**, one broached in France in 1209, the distinguishing tenet of which was, That no Christian could be saved unless he believed himself to be a member of Christ.
- ALMEDA**, a town in the province of Beira in Portugal; W. long.  $9^{\circ} 40'$ , N. lat.  $38^{\circ} 40'$ .
- ALMEDIA**, a frontier town in the province of Trálos Montes, in Portugal; W. long.  $7^{\circ} 10'$ , N. lat.  $40^{\circ} 40'$ .
- ALMEHRAB**, in the Mahometan customs, a nich in their mosques, pointing towards the kebla or temple of Mecca, to which they are obliged to bow in praying. See **KEBLA**.
- ALMELILETU**, a term used by Avicenna, for a preternatural heat which sometimes remains after a fever is gone.
- ALMENE**, in botany, an obsolete name of the lotus. See **LOTUS**.
- ALMENE**, in commerce, a weight of two pounds used to weigh saffron in several parts of the continent of the E. Indies.
- ALMENDINE, ALMENDINE, or ALBANDINE**, a species of ruby. See **RUBY**.
- ALMERIA**, a sea-port town of Spain in the kingdom of Granada, situated at the mouth of the river Almorla, or Boliduy.
- ALMERY.** See **AMBERY**.
- ALMIGGIM-wood**, is thought to be that of the Indian pine-tree, which being light and white, was greatly esteemed for making-musical instruments.
- ALMISSA**, a city of Dalmatia, subject to the Venetians, and called by the Slavonians Omisich.
- ALMIZADIR**, an obsolete term among chemists for verdigris, &c.
- ALMODIA**, a kind of very long and narrow boat, used in the E. Indies.
- ALMOGIZA**, a term used by Arabian writers for the limb of the astrolabe. See **ASTROLABE**.
- ALMOIN, or Frank-ALMOIN, in law.** See **Frank-ALMOIN**.
- ALMOND**, the fruit of the almond-tree. See **AMYGDALUS**.
- ALMOND-tree.** See **AMYGDALUS**.
- Egyptian ALMOND**, in botany. See **BRABEJUM**.
- ALMOND**, in commerce, a measure by which the Portuguese sell their oil; twenty-six almonds make a pipe.
- ALMONDS**, in anatomy. See **AMYGDALÆ**.
- ALMOND-furnace**, among refiners, that in which the slags of litharge, left in refining silver, are reduced to lead again, by the help of charcoal.
- ALMOND** is also the name of a species of rock-crystal, used by lapidaries in adorning candlesticks, &c. on account of their resemblance to the fruit of that name.
- ALMONDBURY**, a village in England, in the west riding of Yorkshire, six miles from Halifax.

**ALMONER**, an officer appointed to distribute alms to the poor.

**ALMONRY, AUMBRY, AMBRY.** See **AMBRY**.

**ALMS**, a general term for what is given out of charity to the poor.

In the early ages of Christianity, the alms of the charitable were divided into four parts; one of which was allotted to the bishop, another to the priests, and a third to the deacons and sub-deacons, which made their whole subsistence; the fourth part was employed in relieving the poor, and in repairing the churches.

**ALMS**, also denotes lands or other effects left to churches or religious houses, on condition of praying for the soul of the donor. Hence,

*Free ALMS* was that which is liable to no rent or service.

*Reasonable ALMS* was a certain portion of the estates of intestate persons, allotted to the poor.

**ALMS-box**, or **ALMS-chest**, in churches, and hospitals, &c. a strong box, with a hole or slit in the upper part, to receive the alms of the charitably disposed.

**ALMS-footh**, or **ALMS-footh**, a term anciently used for Peter's pence. See **PETER'S PENCE**.

**ALMS-house**, a kind of hospital for the maintenance of a certain number of poor, aged, or disabled persons.

**ALMSTAD**, a town of Sweden, in the province of Smaland, four miles E. of Christianstad.

**ALMOXARIFARGO**, an old duty paid upon the British woollen manufactures in old Spain: Also a duty of 2½ per cent. paid in Spanish America, upon the exportation of bulls hides in European vessels.

**ALMUCANTARS**, in astronomy, an Arabic word denoting circles of the sphere passing through the center of the sun, or a star, parallel to the horizon, being the same as parallels of altitude. See *Parallels of ALTITUDE*.

**ALMUCIUM**, denotes a kind of cover for the head, worn chiefly by monks and ecclesiastics: It was of a square form, and seems to have given rise to the bonnets of the same shape, still retained in universities and cathedrals.

**ALMUCIA**, is sometimes also used for the furs, or muffs, worn by the ancient canons on their left arms.

**ALMUG-TREE**, mentioned in Scripture, is supposed to be the fame with that which produces the gum arabic.

**ALMUNECAR**, a port-town of Granada, in Spain, situated upon the Mediterranean: W. long. 3° 45'. N. lat. 36° 40'.

**ALMUTAZAPHUS**, a magistrate of Arragon, whose office it was to inspect measures and weights, and search houses for stolen goods.

**ALMUTHEN**, in astrology, the planet which surpasses the rest with respect to dignities. See **DIGNITY**.

**ALNABATI**, in botany, an obsolete name of the siliqua. See **SILVIQUA**.

**ALNAGE**, or **AULNAGE**, in the English polity, the measuring of woollen manufactures with an ell, and the other functions of the alnager.

**ALNAGER**, in the English polity, a public sworn officer, whose business is to examine into the sfiize of all woollen cloth made throughout the kingdom, and to

fix seals upon them. Another branch of his office is to collect an alnage-duty to the king.

**ALNAM**, in botany, an obsolete name of the Pulegium. See **PULEGIUM**.

**ALNEY**, a small island formed by the branches of the Severn, near Gloucester, in England; called also the Eight.

**ALNUS**, in botany, a synonyme of a species of betula, or alder-tree. See **BETULA**.

**ALNUS**, in the ancient theatres, that part which was most distant from the stage.

**ALNWICK**, the county-town of Northumberland, in England, situated upon the alne.

**ALOA**, in Grecian antiquity, a festival kept in honour of Ceres by the husbandmen, and supposed to resemble our harvest-home.

**ALOE**, in botany, a genus of the hexandria monogynia class. The characters are: The corolla is erect, open at the top, and the nectarium at the bottom of it; the filaments of the stamina are inserted in the receptacle, the leaves are thick, succulent, and for the most part beset with bristles; the fruit is oblong and cylindrical, and divided into three cells, which contain flat femicircular seeds. There are eight species of the aloe, viz. the perfoliata, variegata, disticha, spiralis, viscosa, pumila, uvaria, and retusa, most of them natives of Africa. The retusa, or pearl aloe, is a very beautiful plant. It is smaller than most of the aloe kind. The leaves are short, very thick, sharp pointed, and turning down with a large thick end, appear there triangular. The colour of the leaves is a fine green, striped in an elegant manner with white, and frequently tipped with red at the point. The flower-stalk, which rises in the midst of the leaves, is round, smooth, of a purple colour, and generally about eight inches high. When the plant has been properly cultivated, the flowers are striped with green and white; and sometimes they are entirely white. This aloe is singular in not having the bitter resinous juice with which the leaves of most others abound; when a leaf of this species is cut, what runs from it is watery, colourless, and perfectly insipid. Linnæus says that this plant thrives best in a clay soil, and that it grows wild in the clay-grounds of Africa. See plate XI. fig. 1.

The inspissated juice of the aloe is a stimulating cathartic bitter, and is used in various forms, for cleansing the primæ viæ, attenuating and resolving viscid juices, for promoting the uterine and hæmorrhoidal fluxes, killing worms, &c.

**ALOE-WOOD.** See **XVLO-ALOES**.

**ALOEDARY**, an obsolete name of a purging medicine, whose chief ingredient is aloes.

**ALLOETICS**, the name of all medicines whose chief ingredient is aloes.

**ALOGIANS**, in church-history, a sect of ancient heretics, who denied that Jesus Christ was the Logos, and consequently rejected the gospel of St. John.

**ALOGOTROPHIA**, among physicians, the unequal growth or nourishment of any part of the body, as in the rickets.

- ALOIDES**, in botany, an obsolete name of the stratiotes. See **STRATIOTES**.
- ALOOF**, in sea-language, a word of command from the person who conns to the mar at the helm, to keep the ship near the wind, when sailing upon a quarter-wind.
- ALOPECIA**, in medicine, signifies a falling off of the hair, occasioned either by want of nourishment, or a bad fate of the humours. It is also used by Galen for a change in the colour of the hair.
- ALOPECIAS**, in zoology, an obsolete name of a species of the squalus or shark. See **SQUALUS**.
- ALOPECOPITHECUS**, in zoology, an obsolete name of a species of the didelphis. See **DIDELPHIS**.
- ALOPECURUS**, or **FOX-TAIL GRASS**, in botany, a genus of the triandria digynia class. The calix is bivalved, and the flower consists of one hollow valve, with a long awn inserted near the base on the back part. There are seven species of the alopecurus, viz. the pratensis, or meadow fox-tail grass; the bulbosus, or bulbous fox-tail grass; the geniculatus, or stote fox-tail grass; and the myosuroides, or field fox-tail grass; the above four grow wild in Britain: the agrestis, the montipeliensis, the panicus, and the hordeiformis, all natives of France, and the southern parts of Europe, except the last, which is a native of India.
- ALOSA**, the shad, or mother of herrings, a species of the clupea. See **CLUPEA**.
- ALOST**, a town in the Austrian Flanders, upon the river Dender, half-way between Brussels and Ghent.
- ALP**, in ornithology, an obsolete name of a species of the loxia. See **LOXIA**.
- ALPHA**, among grammarians, the name of the first letter of the greek alphabet, answering to our A.
- ALPHABET**, in matters of literature, the natural or accustom'd series of the several letters of a language. See **LANGUAGE**, and **CHARACTER**.
- ALPHABET**, is also used for a cypher, or table of the usual letters of the alphabet, with the corresponding secret characters, and other blank symbols intended to render the writing more difficult to be decyphered. See **DECYPHERING**.
- ALPHABETICAL**, something belonging to, or partaking of the nature of an alphabet. Thus we say, alphabetical order, method, &c.
- ALPHENIC**, a name sometimes used for white barley-sugar, or twisted sugar.
- ALPHESERA**, in botany, an obsolete name of a species of bryonia. See **BRYONIA**.
- ALPHESTES**, in ichthyology, an obsolete name of a species of labrus. See **LABRUS**.
- ALPHETA**, in astronomy, the same with lucida coronæ. See **LUCIDA CORONÆ**.
- ALPHITIDION**, a term for a fracture, wherein the bone is crushed to pieces.
- ALPHITOMANCY**, a species of divination, otherwise called aleuromancy. See **ALEUROMANCY**.
- ALPHONSIN**, in surgery, an instrument used in extracting bullets, in gun-shot-wounds. See **SURGERY**, *Of Gun-shot wounds*.
- ALPHONSINE TABLES**, astronomical tables, calculated by order of Alphonfus king of Castile, in the construction of which that prince is supposed to have contributed his own labour.
- ALPHOS**, among physicians, a disease of the skin, which is rough, and sprinkled with white spots.
- ALPINE**, something belonging to the Alps. See **ALPS**.
- ALPINIA**, in botany, a genus of the monandria monogynia class, of which there is but one species. The flower is tubulous, and divided into six segments; the capsule, which becomes a fruit, is divided into three cells, each containing one seed. It is a native of America.
- ALPS**, a chain of exceeding high mountains, separating Italy from France and Germany.
- ALQUIER**, a liquid measure, used in Portugal to measure oil, two of which make an almond. See **ALMOND**.
- ALRAMECH**, in astronomy, the name of a star of the first magnitude, otherwise called arcturus. See **ARCTURUS**, and **ASTRONOMY**.
- ALRUM**, in botany, an obsolete name of the tree from which the gum bdellium is procured. See **BDELLIUM**.
- ALSACE**, a province formerly belonging to Germany, but almost entirely ceded to France by the peace of Munster; is situated between the river Rhine on the east, and Lorrain on the west, Switzerland on the south, and the palatinate of the Rhine on the north.
- ALSADAF**, in materia medica, an obsolete name of the unguis odoratus. See **UNGUIS**.
- ALSAHARATICA**, in botany, an obsolete name of the parthenium. See **PARTHENIUM**.
- ALSEN**, an island in the lesser belt, at the entrance of the Baltic sea, between Sleswic and Funen. E. long. 10° 12', N. lat. 55° 12'.
- ALSCHARCUR**, in materia medica. See **SKINK**.
- ALSFIELD**, or **ASFIELD**, a town of Hesse Cassel, in Germany. E. long. 9° 5'. N. lat. 50° 40'.
- ALSIMBEL**, in botany, an obsolete name of a species of nardus. See **NARDUS**.
- ALSINA**, in botany, a synonyme of the theligonum. See **THELIGONUM**.
- ALSINASTRUM**, in botany, the trivial name and also a synonyme of the elatine. See **ELATINE**.
- ALSINE**, *Chickweed*, in botany, a genus of the pentandria trigynia class: The calix is divided into five parts; the flowers consist of five petals divided in the middle; and the capsule has three valves. There are three species of the alsine, viz. the media, or common chickweed, a native of Britain; the mucronata, a native of Switzerland; and the segetalis, a native of France.
- The alsine media has sometimes been recommended in heticcal cases.
- ALSIRAT**, in the Mahometan theology, denotes a bridge laid over the middle of hell, the passage or path whereof is sharper than the edge of a sword; over which every body must pass at the day of judgement, when the wicked will tumble headlong into hell, whereas the good will fly over it like the wind.
- ALSONE**, a small city of Languedoc in France, upon the river Fresquel, between Carcassone and St. Papoul.

**ALSWANGEN**, a town of Livonia, in the dutchy of Courland, situated upon the Baltic.

**ALT**, in music, a term applied to the high notes in the scale. See **MUSIC**.

**ALTAMURA**, a city in the kingdom of Naples, at the foot of the Apennines. E. long.  $17^{\circ}$ . N. lat.  $41^{\circ}$ .

• **ALTAR**, a place upon which sacrifices were anciently offered to some deity.

The heathens at first made their altars only of turf; afterwards they were made of stone, of marble, of wood, and even of horn, as that of Apollo in Delos. Altars differed in figure as well as in materials. Some were round, others square, and others oval. All of them were turned towards the east, and stood lower than the statues of the gods, and were generally adorned with sculpture, inscriptions, and the leaves and flowers of the particular tree consecrated to the deity. Thus, the altars of Jupiter were decked with oak, those of Apollo with laurel, those of Venus with myrtle, and those of Minerva with olive.

The height of altars also differed according to the different gods to whom they sacrificed. Those of the celestial gods were raised to a great height above the ground; those appointed for the terrestrial, were almost on a level with the surface of the earth. On the contrary, they dug a hole for the altars of the infernal gods.

Before temples were in use, altars were erected sometimes in groves, sometimes in the highways, and sometimes on the tops of mountains; and it was a custom to engrave upon them the name, ensign, or character of the deity to whom they were consecrated.

In the great temples of ancient Rome, there were ordinarily three altars: The first was placed in the sanctuary, at the foot of the statue of the divinity, upon which incense was burnt, and libations offered; the second was before the gate of the temple, and upon it they sacrificed the victims; and the third was a portable altar, upon which were placed the offering and the sacred vessels.

Besides these uses of altars, the ancients swore upon them, and swore by them, in making alliances, confirming treaties of peace, and other solemn occasions. Altars also served as places of refuge to all those who fled to them, whatever crime they had committed.

Among the Jews, altars in the patriarchal times were very rude. The altar which Jacob set up at Bethel was nothing but a stone, which served him instead of a bolster; that of Gideon, a stone before his house; and the first which God commanded Moses to erect was probably of earth, or unpolished stones, without any iron; for if any use was made of that metal, the altar was declared impure.

The principal altars of the Jews were those of *incense*, of *burnt-offering*, and the *altar*, or *table*, for the *shew-bread*.

The altar of incense was a small table of shittim-wood, covered with plates of gold, of one cubit in length, another in width, and two in height.

At the four corners, were four kinds of horns, and all round a little border or crown over it. This was the altar hidden by Jeremiah before the captivity; and upon it the officiating priest offered, every morning and evening, incense of a particular composition. See plate XI. fig. 2.

The altar of burnt-offerings was made of Shittim-wood, and carried upon the shoulders of the priests by slaves of the same wood, overlaid with brass. In the time of Moses, this altar was five cubits square, and three high; but in Solomon's temple it was much larger, being twenty cubits square, and ten in height. It was covered with brass; and at each corner was a horn or spire wrought out of the same wood with the altar, to which the sacrifices were tied. Within the hollow was a grate of brass, on which the fire was made; through it fell the ashes, and were received in a pan below. At the four corners of the grate were four rings, and four chains, which kept it up at the horns. This altar was placed in the open air, that the smoke of the burnt-offerings might not fully the inside of the tabernacle. See plate XI. fig. 3.

The altar, or table for the shew-bread, was likewise of shittim-wood, covered with plates of gold, having a little border round it, adorned with sculpture: It was two cubits long, one wide, and one and an half in height. Upon this table, which stood in the holy of holies, were put, every sabbath-day, twelve loaves, with salt and incense.

The Jewish altars, after the return from the captivity, and the building of the second temple, were in some respects different from those described above.

That of burnt-offerings was a large pile, built of unblew stones, thirty-two cubits square at the bottom, and twenty-four square at the top. The ascent was by a gentle rising, thirty-two cubits in length, and sixteen in breadth.

**ALTAR** is also used among Christians for the communion-table. See **COMMUNION-TABLE**.

**ALTAR** is sometimes also used to denote the offerings made at the altar, in contradistinction from the settled revenues of a church.

**ALTAR**, in astronomy. See **ARA**.

**ALTAR-THANE**, in old law books, an appellation given to the priest or parson of a parish, to whom the altarage belonged. See **ALTARAGE**.

**ALTARAGE**, in law, altars erected in virtue of donations, before the Reformation, within a parochial church, for the purpose of singeing of masks for deceased friends. See **SCOTS LAW**, title, *Ecclesiastical persons*.

**ALTARAGE** likewise signifies the profits arising to the priest on account of the altar.

**ALTARIST**, the same with altar-thane. See **ALTAR-THANE**.

**ALTEA**, a sea-port town of Spain, situated upon the Mediterranean, in the province of Valencia, about 45 miles south of the city Valencia, W. lon.  $15^{\circ}$ . N. lat.  $38^{\circ}$ .  $40^{\circ}$ .

**ALTEMBURG**, a town of Transilvania, subject to the house of Austria, situated in  $23^{\circ}$  E. long. and  $46^{\circ}$   $25'$  N. lat.

ALTEMBURG,

ALTEMBERG is also used by some for Altenburg. See ALTENBURG.

ALTENA, a port-town of-Holstein, in Germany, situated on the river Elbe. It belongs to the Danes, and is the place where all their East India goods are sold.

ALTENBURG, a town of Misnia, in the upper Saxony, about 25 miles S. of Leipzig, and subject to the duke of Saxe Altenburg. E. long.  $12^{\circ} 44'$ , N. lat.  $50^{\circ} 52'$ .

ALTEMBERG-OWAR, a fortified town of lower Hungary, situated on the river Danube, and subject to the house of Austria. E. long.  $17^{\circ} 20'$ , N. lat.  $48^{\circ} 15'$ .

ALTENSPACH, a city of Germany, in the circle of Swabia, situated between the lakes of Constance and Zeill.

ALTERANTS, or ALTERATIVE medicines, such as correct the bad qualities of the blood and other humours, without occasioning any sensible evacuation.

ALTERATE, in music and geometry. See SESQUI-ALTERATION, in a general sense, denotes some variation in the qualities or circumstances of a thing, without wholly changing its nature.

ALTERATION, in medicine, is particularly used to denote the action of alterant medicines. See ALTERNANTS.

ALTERCUM, in botany, an obsolete name of the Hyosciamus. See HYOSCIAMUS.

ALTERDOCHAON, a town of Portugal, in Estremadura, three leagues S. W. of Portalegre.

ALTERITY, a term used by some philosophers for what is more usually called diversity. See DIVERSITY.

ALTERN-BASE, in trigonometry, a term used in contradistinction to the true base. Thus in oblique triangles, the true base is either the sum of the sides, and then the difference of the sides is called the altern-base; or the true base is the difference of the sides, and then the sum of the sides is called the altern-base.

ALTERNATE, in a general sense, a term applied to such persons or things as succeed each other by turns. Thus, two who command each his day, are said to have an alternate command, or to command alternately.

ALTERNATE, in heraldry, is said in respect of the situation of the quarters.

Thus the first and fourth quarters, and the second and third, are usually of the same nature, and are called alternate quarters.

ALTERNATE, in botany, when the leaves or branches of plants arise higher on opposite sides alternately.

ALTERNATE angles. See GEOMETRY.

ALTERNATE ratio. See ALGEBRA, and ARITHMETIC.

ALTERNATION, properly signifies a succession by turns. See ALTERNATE.

ALTHÆA, in botany, a genus of the monadelphia polyandria class. The calix of the althæa is double, and the outer one is divided into nine segments; and the capsules are numerous, each containing but one seed.

There are three species of this genus, viz. the officinalis, a native of Britain, the root and leaves of which are supposed to be balsamic, pectoral and stomatic; the cannabina, a native of Hungary; and the hirsuta, a native of France, Italy, &c.

ALTINGAR, the name of a flux-powder, used in the fusion of metals. See FLUX, and CHEMISTRY.

ALTIN, a kingdom of Asia, in great Tartary, between the sources of the Irich and the Oby. It is bounded on the north by the Kirgises, on the east by the Amaduners, on the south by the kingdom of Eluth, and on the west by the Irich, which separates it from Barabinskoi.

ALTIN, is also the capital of the kingdom of that name, situated in the northern part of the kingdom, at the head of the river Kilam.

ALTIN, in commerce, a kind of money current in Muscovy, worth three copics.

ALTITH. See ASA-FETIDA.

ALTITUDE, accessible, and inaccessible. See PRACTICAL GEOMETRY.

ALTITUDE, of a figure, is the nearest distance of its vertex from its base, or the length of a perpendicular let fall from the vertex to the base.

ALTITUDE in optics, is the height of an object above a line, drawn parallel to the horizon from the eye of the observer.

ALTITUDE of the eye, in perspective, is its perpendicular height above the geometrical plane.

ALTITUDE of a star, &c. in astronomy, is an arch of a vertical circle, intercepted between the star and the horizon. See ASTRONOMY.

ALTITUDE of motion, according to Dr Wallis, is its measure estimated in the line of direction of the moving force.

ALTITUDE, in astrology. See EXALTATION.

ALTITUDE of fluids, is more usually expressed by the term depth. See DEPTH.

Determinative ALTITUDE, that from whence a heavy body falling, acquires a certain velocity by its natural acceleration.

ALTKIRK, a town of Alsace in Germany, situated on the river Ill, in N. lat.  $47^{\circ} 40'$ , and E. lon.  $7^{\circ} 15'$ .

ALTMORE, a town of Ireland, in the county of Tyrone, and province of Ulster, situated in N. lat.  $54^{\circ} 34'$ , and W. long.  $7^{\circ} 2'$ .

ALTMUL, a river of Germany, which arising in Franconia, runs S. E. by the city of Anspach; and continuing its course E. by Pappenheim and Aichstet, falls into the Danube at Kelheim, about 12 miles above Ratibon.

ALTO, and BASSO, in law, denotes the absolute submission of all differences high and low to some arbitrator.

ALTOM, a name given, in several parts of the Turkish dominions, to what the Europeans call a sequin. See SEQUIN.

ALTO-MONTE, a town of the hither Calabria, in the kingdom of Naples, at the foot of the Apennines, ten miles from Cassano.

ALTO-RELIEVO. See RELIEVO.

ALTO-

*Fig. 1.*  
ALOE floribus sessilibus bilabiatis  
or PEARL ALOE

*Fig. 2.*  
ALTAR of  
Burnt Offering

*Fig. 3.*  
ALTAR of Incense

*A. Bell Sculp't*

**ALTO-RIPIENO**, in music, the tenor of the great chorus which sings and plays only now and then in some particular places.

**ALTORF**, a town of Germany, in the circle of Swabia, situated in N. lat.  $47^{\circ} 26'$ , and E. long.  $9^{\circ} 35'$ .

**ALTORF**, is likewise the name of a town in the circle of Franconia, situated in N. lat.  $49^{\circ} 20'$ , and E. long.  $11^{\circ} 20'$ .

**ALTORF**, is also the capital of the canton of Uri, in Switzerland, situated on the lake Lucern, in N. lat.  $46^{\circ} 50'$ , and E. long.  $8^{\circ} 30'$ .

**ALTRINGHAM**, a town of Cheshire in England, upon the borders of Lancashire, seven miles from Manchester.

**ALTRIP**, a small town of Germany, in the diocese of Spire, situated upon the Rhine, a little above Mannheim.

**ALTUMAL**, a term sometimes used to denote the mercantile style or dialect.

**ALTUS**, in music. See **COUNTER-TENOR**.

**ALTZHEIM**, or **ALTZEY**, a town of Germany, situated in N. lat.  $49^{\circ} 45'$ , and E. long.  $7^{\circ} 52'$ ; about 42 miles N. W. of Heidelberg.

**ALVA de Tormes**, a town of Spain, in the province of Leon, situated on the river Tormes, in N. lat.  $41^{\circ}$ , and W. long.  $6^{\circ}$ , about 16 miles S. E. of Salamanca.

**ALVAH**, among the Mahometans, the name by which they call the wood wherewith Moses sweetened the waters of Marah.

**ALVAHAT**, a province of higher Egypt, situated under the tropics.

**ALVARID**, in the history of Spain, a kind of magistrate or judge, differing very little from the alcaid. See **ALCAID**.

**ALVARISTS**, in church history, a branch of Thomists, so called from Alvares their leader; who asserted sufficient grace, instead of the efficacious grace of the ancient Thomists. See **THOMISTS**.

**ALUCO**, in ornithology, the trivial name of a species of strix. See **STRIX**.

**ALUDE**, a kind of sheep's leather, one side of which has the wool on.

**ALUDELS**, in chemistry, earthen pots ranged one above another, for retaining the flowers which ascend in the process of sublimation. The lowest aludel is fitted to the pot which contains the matter to be sublimed, and at the top is a close head for collecting the flowers which ascend highest. See **CHEMISTRY**.

**ALVEARIUM**, in anatomy, the hollow of the outer ear. See **ANATOMY**, Part VI.

**ALVEARIUM**, in matters of literature, is used in a figurative sense for a collection or thesaurus.

**ALVEOLUS**, in natural history, the name of the waxen cells in bee-hives. See **APIS**.

**ALVEOLUS**, in anatomy, the sockets in the jaws where-in the teeth are fixed. See **ANATOMY**, Part I.

**ALVEOLUS**, in botany, the name of the cells in which the seeds of several plants are ranged.

**ALVEOLUS**, in natural history, a sea fossilie of a conic figure, composed of a number of cells, like bee-hives, joined into each other, with a pipe of communication.

VOL. I. No. 6.

**ALVEUS**, in anatomy, a name sometimes given to the tumid lacteal vessels proceeding from the receptaculum chyli.

**ALVEUS**, is also used in Roman antiquity, for a kind of boat, fashioned out of the trunk of a single tree: Such was that in which Romulus and Remus were exposed.

**ALVIDONA**, a town of Calabria, in the kingdom of Naples, upon the gulph of Rossano.

**ALVI fluxus**, among physicians. See **DIARRHOEA**. *Obstructio ALVI*, a Latin phrase for costiveness. See **COSTIVENESS**.

**ALVIDUCA**, among physicians, a term for laxative medicines.

**ALUM**, or **ALUMEN**, in natural history, a peculiar kind of salt, sometimes found pure, but often separated from several substances, as a soft reddish stone in Italy, several kinds of earth, and, in England, from a whitish or bluish stone, called Irish slate. Alum, in medicine, is a powerful astringent. In dying, it fixes the colours upon the stuff. See **CHEMISTRY**.

*Process of making ALUM.* At Whitby, in Yorkshire, alum is made thus: Having burnt a quantity of the ore with whins, or wood, till it becomes white, then they barrow it in a pit, where it is steeped in water for eight or ten hours. This liquor, or lixivium, is conveyed by troughs to the alum-house, into cisterns, and from them into the pans, where it is boiled about 24 hours. They add a certain quantity of the lee of kelp; the whole is drawn off into a settler; where having remained about an hour, that the sulphur and other dregs may have time to settle to the bottom, it is conveyed into coolers. This done, to every tun of the liquor they add about eight gallons of urine; and having stood four days and nights, till quite cool, the alum begins to crystallize on the sides of the vessel, from which being scraped off, it is washed with fair water, and then thrown in a bing, to let the water drain off. After this it is thrown into a pan, called the roching pan, and there melted; in which state it is conveyed by troughs into tuns, where it stands about 10 days, till perfectly condensed. Then slaving the tuns, the alum is taken out, chipped, and carried to the store-houses.

This is what we commonly call *roche* or *rock alum*, as being prepared from stones cut from the rocks of the quarry; and stands contradiistinguished from the common alum, or that prepared from earths.

*Artificial ALUM*, that prepared by art, in contradistinction from the native alum. It is also used for alum produced by causing burnt earthen vessels imbibe a large quantity of oil of vitriol; the effect of which is, that they are thereby reduced to a muckage, which, being exposed to the open air, affords crystals of pure alum. Tobacco-pipes, wetted with spirit of sulphur, likewise afford beautiful crystals of plumose alum.

*Burnt ALUM*, is that melted in a fire-shovel, or crucible, where it is allowed to bubble till it becomes a white hard substance.

The watery part of the alum being thus expelled,

the remainder is left possessed of all its acids, less clogged, and more in a condition to exert its effects. It proves a gentle escharotic, and is used in small quantities, mixed with other ingredients, in tooth-powders.

*Crude ALUM*, that which has undergone no other refinement than what it receives at the alum-works.

*Native ALUM*, or *Fossil ALUM*, that formed by nature, without the assistance of art.

There are still mines of native alum in the island of Chio, consisting of a kind of vaults, or apartments crusted over with alum, which may be looked upon as exfoliations from the rock.

*Plumose ALUM*, or *Plume ALUM*, a kind of natural alum, composed of a sort of threads, or fibres, resembling feathers; whence it has its name.

*Prepared ALUM*, or *Purified ALM*, that which is dissolved in hot rain-water, and afterwards made to crystallize, by evaporating the water.

*Roche-ALUM*, or *Rock-ALUM*. See the article, *Process of making ALUM, supra*.

*Roman ALUM*, a sort of rock-alum, of a reddish colour, made in the country near Rome.

*Saccharine ALUM*, is a composition of common alum with rose-water, and the whites of eggs, which being boiled to the consistence of a paste, is formed in the shape of a sugar-loaf; it is used as a cosmetic.

*Scissile ALUM*, the same with plumose alum.

*ALUMEN*, the Latin name of alum.

*ALUMEN catini*, a name sometimes used for the salt of the keli.

*ALUMEN scagliola*, a name sometimes used for *lapis specularis*.

*ALUMINOUS*, an epithet for things that partake of the nature of alum.

*ALUMTA*, in botany. See *LUTEOLA*.

*ALUS*, or *ALUM*, in botany, an obsolete name of the symphytum. See *SYMPHYTUM*.

*ALVUS*, in anatomy, a term used for the belly in general, but more frequently applied to the bowels.

*ALWAIJH*, a sect of Mahometans who believe all great crimes to be unpardonable.

*ALYPIAS*, the name of a kind of white turbith. See *TURBITH*.

*ALPUM*, in botany, a synonyme and likewise the trivial name of a species of globularia. See *GLOBULARIA*.

*ALYSSOIDES*, in botany, a synonyme of the alyssum. See *ALYSSUM*.

*ALYSSUM*, or *ALYSSON*, in botany, a genus of the tetradynamia filiculosa. The flowers of the alyssum consist of four leaves in the form of a cross: The capsule is short and smooth, and contains a number of roundish seeds. There are 14 species of the alyssum, none of which are natives of Britain.

*ALYTARCHA*, a priest of Antioch in Syria, who, in the games instituted in honour of the gods, presided over the officers who carried rods to clear away the crowd, and keep order.

In the Olympic games, the alytarches had the same

command, and obliged every person to preserve order and decency.

*ALZACHI*, in botany, an obsolete name of the anguria. See *ANGURIA*.

*ALZAGI*, or *ALZEGI*. See *ZEGI*.

*ALZARAC*, the Arabian name of a coarse kind of camphor.

*ALZIRA*, a town of Spain, in the province of Valentia, situated on the river Xucar, about 18 miles S of the city of Valencia, W. long. 20°, N. lat. 39° 10'.

*ALZIZ*, among Arabian physicians. See *ZIZ*.

*ALZUM*. See *BELLIIUM*.

*AMA*, among ecclesiastical writers, denotes a vessel in which wine or water were kept for the service of the eucharist.

*AMA*, is sometimes also used for a wine-measure, as a pipe, or the like.

*AMABYR*, or *AMVABYR*, a custom which formerly prevailed in Wales, and some other parts of the kingdom; being a certain fine, or sum of money, paid to the lord upon marrying a maid within his manor.

*AMACACHES*, a people of Brazil, in S. America, near the government of Rio Janeiro.

*AMACUSA*, an island of Japan, separated by a narrow strait from Saicoco, or Ximo.

*AMACUSA*, is also the capital of the province of that name.

*AMACAO*. See *MACOA*.

*AMADABAT*, a large populous trading city in the E. Indies, the capital of the province of Guzurat, or Cambay, and situated in 72° E. long. and 23° 40' N. lat.

*AMADAN*, or *HAMADAN*, in geography. See *HAMADAN*.

*AMADANAGER*, a town in the higher peninsula of India, situated in 74° 15' E. long. and 18° N. lat.

*AMADIA*, a city of Asiatic Turkey, in the province of Curdestan, situated on a high mountain, in 43° E. long. and 37° N. lat.

*AMAIN*, or *AMAYNE*, in the sea-language, a term importing to lower something at once. Thus, to strike amain, is to lower, or let fall, the top-sails; to wave amain, is to make a signal, by waving a drawn sword, or the like, as a demand that the enemy strike their top-sails.

*AMAK*, or *AMAKA*, an island of Denmark, lying in 13° 5' E. long. and 55° 29' N. lat. and separated by a very narrow channel from Copenhagen.

*AMALFA*, a city of Italy, in the kingdom of Naples, and province of the hither Principato. It is the see of an archbishop, and remarkable for giving birth to Flavius Blendus, inventor of the seaman's compass. E. long. 15° 20', N. lat. 48° 50'.

*AMALGAM*, mercury united with some metal. See *CHEMISTRY*.

*AMALGAMATION*, in chemistry, the operation of making an amalgam, or mixing mercury with any metal. See *CHEMISTRY*.

*AMALGAMATION*, is also used by some, in a less proper sense, for a solution of sulphur with mercury.

AMAN,

**AMAN**, a port of Africa, in the kingdom of Morocco, upon the Atlantic ocean, between cape Ger, and cape Cantin.

**AMAN**, is also the name of a kingdom, near the middle of the island of Sumatra, in the E. Indies.

**AMANCE**, a town of Lorrain, situated in 6° 10' E. long. and 48° 40' N. lat. about seven miles N. E. of Nancy.

**AMAND**, or **ST AMAND**, the name of two towns, one situated in the duchy of Bourbon, in the province of Lyonnais in France; and the other in French Flanders, about six miles N. of Valenciennes.

**AMANTEA**, a sea-port town and bishop's see of the kingdom of Naples, situated near the bay of Euphemia, in the province of Calabria, in 16° 20' E. long. and 39° 15' N. lat.

**AMAPALLA**, a sea-port town of Mexico, in the province of Guatimala, situated on the Pacific ocean, in 93° W. long. and 12° 30' N. lat.

**AMARACUS**, in botany, a synonyme of the origanum. See **ORIGANUM**.

**AMARANTA**, or **AMARANTE**, an order of knight-hood, instituted in 1653, by Christina Queen of Sweden, in memory of a masquerade, wherein she had assumed that name, which signifies *unfading*, or *immortal*. Her nobility likewise assumed different characters, *viz.* of gods, goddesses, shepherds, nymphs, &c. and so well pleased was the Queen with the diversion, that she instituted this order in memory of it, consisting of 16 lords, and as many ladies, with the motto, *Dolce nella memoria*.

**AMARANTH**, in botany. See **AMARANTHUS**.

**AMARANTHOIDES**, in botany, the trivial name of a species of illecebrum. See **ILLECEBRUM**.

**AMARANTHUS**, in botany, a genus of the monœcia pentandria class. The flowers have no petals; the calix is multifold; and the seeds are contained in membranaceous vessels, and very numerous. There are 22 species of amaranthus, none of them natives of Britain, except the blitum, or lesser blite; all the others are found in the Indies. The amaranthus is said to be astringent.

**AMARYLLIS**, in botany, a genus of the hexandria monogynia class. The ipatha of the amaryllis consists of one leaf, the flower, like other liliaceous plants, has six petals, and the stigma is trifid. There are 12 species of the amaryllis, all of them natives of the warm climates. Fig. 1. of plate XII. represents the orientalis, a native of the E. Indies.

**AMASIA**, the northern division of lesser Asia, lying on the S. shore of the Euxine sea.

**AMASIA**, is also the name of the capital city of the above province, situated in 36° E. long. and 42° N. lat. about 70 miles S. of the Euxine sea.

**AMASTRIS**, or **AMASTRO**, a city of Turkey in Asia, in the province of Bresangil, situated on the Black Sea.

**AMATIDES**, a name used by some for an incombustible stone. See **AMIANTHUS**.

**AMATITLAN**, a town of N. America, situated in the valley of Mixco, in the province of Guatimala.

**AMATORII musculi**, in anatomy, a term sometimes used for the obliquus superior and obliquus inferior muscles of the eye, as these muscles assist in opening or drawing the eye sideways. See **ANATOMY**, part VI.

**AMATRICE**, a city of the kingdom of Naples, in the farther Abruzzo, upon the confines of the pope's territories, and the marquisate of Ancona.

**AMAUROSIS**, in medicine, a distemper in the eye, occasioned by an insensibility of the retina. See **MEDICINE**.

**AMAUSA**, a term used by chemists for pastes counterfeiting gems.

**AMAXOBII**, the same with *hamaxobii*.

**AMAZON**, in a general sense, denotes a bold daring woman.

**AMAZONS**, were an ancient nation of women, inhabiting that part of lesser Asia now called *Amasia*. See **AMASIA**.

The Amazons are said to have killed all their male children, and to have cut off the right breasts of their females, to fit them for martial exercises. The existence, however, of such a nation is controverted by many judicious authors, and defended by others, particularly Mr Petit, who has published a dissertation on the subject, wherein are several curious inquiries concerning their arms, dress, &c.

We also read of Scythian Amazons, of German Amazons, of Lybian Amazons, and Amazons of America, living on the banks of the great river which bears their name, who are represented as governed by a queen, no man being permitted to live among them; only, at a certain season, those of the neighbouring nations are suffered to visit them for the sake of procreation. The Amazons of Lybia are famous for their wars with another female nation called Gorgons. See **GORGONS**.

On medals, the bust of the Amazons is ordinarily represented armed with a little battle-ax, called by the Romans *biceps*, or *securis*, which they carried on their shoulder with a small buckler, in form of a half moon, distinguished by the name of *pelta*, upon their left arm.

**AMAZONS**, in a figurative sense, an appellation given to bees, as being governed by a queen.

**AMAZON**, in geography, a great river in S. America, which rising in Peru, near the equator, runs eastward a course of more than 3000 miles; and, like other rivers between the tropics, annually overflows its banks, at which season it is about 150 miles broad where it falls into the ocean.

**AMAZONIAN**, denotes something belonging to the amazons.

**AMBACHT**, a term used in some parts of Germany and Flanders, for the magistracy of a city, or the district or territory belonging to it.

**AMBADAR**, a city of Africa, in the upper Ethiopia, situated upon the Nile, between the provinces of Darnbea and Sæva.

**AMBAGES**. See **CIRCUMLOCUTION**.

**AMBAMARJAM**, or **AMBARA**, the capital city of Abyssinia,

Abyssinia, or higher Ethiopia, situated on the side of a lake, out of which the river Nile issues; 35° E. long. and 13° S. lat.

AMBARVALIA, in antiquity, a ceremony among the Romans, when, in order to procure for the gods an happy harvest, they conducted the victims thrice round the corn-fields in procession, before sacrificing them. *Ambarvalia* were either of a private or public nature: the private were performed by the master of a family; and the public by the priests who officiated at the solemnity, called *fratres arvales*. The prayer preferred on this occasion, the formula of which we have in Cato, de Re Rust. cap. cxlii. was called *carmeu ambarvale*.

At these feasts they sacrificed to Ceres a sow, a sheep, and a bull, or heifer, whence they take the name of *juvetaurilia*.

The method of celebrating them, was to lead a victim round the fields, while the peasants accompanied it, and one of their number, crowned with oak, hymned forth the praises of Ceres, in verses composed on purpose.

This festival was celebrated twice a-year, at the end of January, according to some, or in April, according to others; and for the second time in the month of July.

AMBARVALIS, in botany, an obsolete name of the polygala. See POLYGALA.

AMBE, in surgery, an instrument for reducing dislocated bones.

AMBE, in anatomy, a term for the superficial jutting out of a bone.

AMBER, *succinum*, or *electrum*, in natural-history, a hard bituminous inflammable substance, brittle, somewhat transparent, generally of a yellowish colour, and when warm sends forth a fragrant bituminous odour. Amber is likewise endowed with an electrical virtue; when rubbed, it attracts straws or other light bodies. The taste of amber is acrid, bituminous, and somewhat astringent. It does not effervesce with acids, and is soluble in spirit of wine and essential oils. When subjected to a chemical analysis, it first yields a subacid water, afterwards a yellow fetid oil, and a volatile salt; what remains in the retort, is a black, light, friable matter, resembling the *bitumen Judaicum*.

Amber is chiefly found in Prussia, and in the Baltic sea, near the shore of Sudavia, where it is found swimming on the surface of the water, and is taken in nets. It is esteemed a powerful medicine in hysteric and hypochondriac cafes.—Naturalists are much divided about the origin of amber: Some maintaining it to be an animal substance, others a resinous juice oozing from poplars and firs near the shore, and running into the sea. But it has lately been found to be a true bitumen; the veins of which were discovered, by the Prussians, in the bowels of the earth, in the marsh near Kultrin.

AMBER, in geography, a river, which rising in the S. W. part of Bavaria, runs N. E. by Landsparg and Dachau, and falls into Isar, a little above Landshut.

AMBERG, a fortified town of Bavaria, situated on the river Ills, about 30 miles N. of Ratibon, in 12° E. long. and 49° 25' N. lat.

AMBERGREASE, or AMBERGRISE, in natural history, is a solid, opaque, ash-coloured, fat, inflammable substance, variegated like marble, remarkably light, rugged and uneven in its surface, and has a fragrant odour when heated. It does not effervesce with acids; melts freely over a fire, into a kind of yellow rosin, and is hardly soluble in spirit of wine. Ambergrise is greatly used by perfumers on account of its sweet smell. In medicine it is used for nervous complaints. It is found in great quantities in the Indian ocean, near the Molucca isles, as also near Africa, and sometimes near the northern parts of England, Scotland, and Norway. There has been many different hypotheses concerning the origin of ambergrease; but the most probable is that which supposes it to be a fossil bitumen, or naphtha, exuding out of the bowels of the earth, in a fluid form, and distilling into the sea, where it hardens, and floats on the surface.

AMBERING, a term used by some writers for giving the scent of amber to any thing.

AMBERT, a city of France, in the lower Auvergne, remarkable for its manufactures in paper and camblots.

AMBERTUWAY, in botany, a barbarous name of a tree, the leaves of which, when boiled in wine, are said to create an appetite, and is used by the people in Guinea with that intention.

AMBIAM, a kingdom of Ethiopia, situated between the Nile, and a river which rises out of the lake Zaffan.

AMBIDEXTER, a person who can use both hands with the same facility and for the same purposes that the generality of people do their right hands.

AMBIEGNE *oves*, in the heathen sacrifices, an appellation given to such ewes as, having brought forth twins, were sacrificed together with their two lambs, one on each side. We find them mentioned among other sacrifices to Juno.

AMBIENT, a term used for such bodies, especially fluids, as encompass others on all sides: thus, the air is frequently called an ambient fluid, because it is diffused round the earth.

AMBIERLE, a city of France, three leagues from Rouanne, and 15 from Lyons, on the borders of the Lionnois.

AMBIGENAL *hyperbolas*, a name given by Sir Isaac Newton to one of the triple hyperbolas of the second order, having one of its infinite legs falling within an angle formed by the asymptotes, and the other without.

AMBIGUITY, in rhetoric and grammar, a defect of language, whereby words are rendered ambiguous. See the next article.

AMBIGUOUS, a term applied to a word or expression which may be taken in different senses.

AMBILLON, a village of France, in Touraine, where there is a great quarry for mill-stones.

AMBIT, in geometry, is the same with what is otherwise

- wife called the perimeter of a figure. See PERIMETER.
- AMBITUS**, in Roman antiquity, the setting up for some magistracy or office, and formally going round the city to solicit the interest and votes of the people. On these occasions, it was not only usual to solicit the interest of their friends and others with whom they were personally acquainted, but the candidates, being attended by persons of an extensive acquaintance, who suggested to them the names of the citizens, and thence called *nomenclatores*, or *interpretes*, made their application to all they met. This method of suing for offices was deemed allowable, and therefore never prohibited by law; but to refrain all undue influence, whether by bribery, or exhibiting games, shews, and the like, many laws were enacted, and severe fines imposed.
- AMBLE**, in horsemanship, a peculiar pace by which a horse's two legs of the same side move at the same time.
- AMBLETEUSE**, a small sea-port-town of Picardy in France, situated about five miles north of Boulogne.
- AMBLYGON**, in geometry, denotes an obtuse angled triangle, or a triangle one of whose angles consists of more than ninety degrees.
- AMBLYOPI**. See *GUTTA SERENA*.
- AMBO**, or **AMBON**, in ecclesiastical antiquity, a kind of pulpit or reading-desk, where that part of the divine service called the gradual was performed.
- AMBOHETSMENES**, a province in the island of Madagascar, near the mountains of the same name.
- AMBONUM**. See *OCULUS BELI*.
- AMBOINA**. See *AMBOYNA*.
- AMBOISE**, a town of Orleans, in France, situated on the river Loire, about ten miles east of Tours, in 1° E. long, and 47° 25' N. lat.
- AMBOYNA**, an island of the E. Indies, lying between the Molucca isles and those of Banda, in 126° E. long, and 3° 40' S. lat.
- In this island, which is about seventy miles in circumference, the Dutch have a strong fort, garrisoned by seven or eight hundred men. What makes it the more remarkable, is the cruel usage and expulsion of the English factors by the Dutch, in the reign of K. James I.
- AMBOSINE**, a province of Africa, in the kingdom of Benin.
- AMBOTE**, a town of Poland, in Samogitia, upon the river Wardaria, two Polish miles from Siade, and nine from the Baltic sea.
- AMBOULE**, a large country in the island of Madagascar, to the north of Carcanossi.
- AMBOULE** is also the name of a considerable village in that country.
- AMBOURNAY**, a small town of France, upon the river Ain, on the road from Lyons to Geneva.
- AMBRÁ**, or **AMBRAGRISIA**. See *AMBERGREENE*.
- AMBRASI**, a river of Africa, which, after washing the kingdom of Congo, falls into the Ethiopian Ocean.
- AMBRES**, a city of France, in the Upper Languedoc, in the diocese of Castrès.
- AMBRESBERRY**, a market-town in Wiltshire, about six miles north of Salisbury, and situated in 1° 40' W. long, and 51° 20' N. lat.
- AMBROSE**, or *St Ambrose in the wood*, an order of religious, who use the Ambrosian office, and wear an image of that saint engraven on a little plate: in other respects they conform to the rule of the Augustins. See *AMBROSIAN OFFICE*, and *AUGUSTINS*.
- AMBROSIA**, in heathen antiquity, denotes the solid food of the gods, in contradistinction from the drink, which was called *nectar*. It had the appellation *ambrosia*, as being supposed to render those immortal who fed thereon.
- AMBROSIA**, is also a term for rough or crude wax, supposed to be the food of bees.
- AMBROSIA**, in Grecian antiquity, a name sometimes used for a festival of Bacchus, otherwise called *lenæa*. See *LENÆA*.
- AMBROSIA**, in botany, a genus of the monœcia pentandria class. The male floscules of the ambrosia have no petals; the fruit of the female is prickly, and shaped like a club, containing one oblong seed in each. There are four species of ambrosia, *viz.* the trifida, eliator, and the artemisifolia, all natives of America; and the maritima, a native of Greece.
- AMBROSIAN office**, in church-history, a particular formula of worship in the church of Milan, which takes its name from St Ambrose, who instituted that office in the fourth century. Each church originally had its particular office; and when the pope, in after-times, took upon him to impose the Roman office upon all the western churches, that of Milan sheltered itself under the name and authority of St Ambrose; from which time the Ambrosian ritual has prevailed.
- AMBROSIN**, a coin formerly struck by the dukes of Milan, representing St Ambrose on horseback, with a whip in his right hand.
- AMBRUN**, in geography, the same with Embrun. See *EMBRUN*.
- AMBRY**, a place in which are deposited all utensils necessary for house-keeping. In the ancient abbeys and priories, there was an office under this denomination, wherein were laid up all charities for the poor.
- AMBUBAJÆ**, in Roman antiquity, were immodest women, who came from Syria to Rome, where they lived by prostitution, and by playing on the flute.
- AMBUBEJA**, in botany, an obsolete name of the cichorium. See *CICHORIUM*.
- AMBUILA**, or **AMBOILA**, a country of Africa, in the kingdom of Congo, between the lake Aquelonde and St Salvador.
- AMBULATION**. See *WALKING*.
- AMBULATION**, in surgery, a term used for the spreading of a gangrene or mortification.
- AMBULATORY**, a term applied to such courts as were not fixed, but removed sometimes to one place, sometimes to another.
- AMBURBIUM**, in Roman antiquity, a procession made by the Romans round the city and pomerium, in which

they led a victim, and afterwards sacrificed it, in order to avert some calamity that threatened the city.

**AMBURY**, or **ANBURY**, among farriers, denotes a tumor, wart, or swelling, which is soft to the touch, and full of blood.

This disorder of horses is cured by tying a horse-hair very hard about its root, and, when it has fallen off, which commonly happens in about eight days, strewing some powder of verdigris upon the part, to prevent the return of the complaint. If the tumor be so low that nothing can be tied about it, they cut it out with a knife, or else burn it off with a sharp hot iron; and, in sinewy parts, where a hot iron is improper, they eat it away with oil of vitriol, or white sublimate.

**AMBUSCADE**, or **AMBUSH**, in the military art, properly denotes a place where soldiers may lie concealed, till they find an opportunity to surprize the enemy.

**AMBUSTION**, with physicians, the same with a burn.

**AMBY**, a town of the Austrian Netherlands, in the province of Limburg, situated opposite to Maestricht, on the east-side of the river Maese, in  $5^{\circ} 45'$  E. long. and  $50^{\circ} 56'$  N. lat.

**AMED**, or **AMIDA**, a city of Asia in Mesopotamia: the Arabians call it Diarbeker, and the Turks Kara-Amed.

**AMEDEWAT**. See **AMADABAT**.

**AMEDIANS**, in church-history, a congregation of religious in Italy, so called from their professing themselves *amantes Deum*, lovers of God; or rather, *amati Deo*, beloved of God.

**AMEIVA**, in zoology, the trivial name of a species of lacerta. See **LACERTA**.

**AMEL**, a term frequently used by Mr Boyle, in a synonymous sense with enamel. See **ENAMEL**.

**AMELAND**, an island of the United Provinces, in the German Ocean, near the coast of Friesland, from which it is separated by a straight called the Wadt.

**AMELBERG**, in geography, the same with Ommen-burg. See **OMMENBURG**.

**AMELIA**, a city of Italy, situated on a mountain about fifty miles N. E. of Rome, in  $13^{\circ} 20'$  E. long. and  $42^{\circ} 40'$  N. lat.

**AMELLUS**, in botany, a genus of the syngenesia polygamia-superflua class. The receptacle of the amellus is paleaceous; the calix is squarrous; and the rays of the corollula undivided. There are only two species of this genus, *viz.* the *lychnitis*, a native of the Cape; and the *umbellatus*, a native of Jamaica.

**AMEN**, in the scripture-language, a solemn formula or conclusion to all prayers, signifying, *So be it*.

**AMEND**, or **AMENDE**, in the French customs, a pecuniary punishment imposed by a judge for any crime, false profecution, or groundless appeal.

**AMENDE honorable**, an infamous kind of punishment inflicted in France upon traitors, parricides, or sacrilegious persons, in the following manner: The offender being delivered into the hands of the hangman, his shirt is stripped off, and a rope put about his neck, and a taper in his hand; then he is led into court, where he must beg pardon of God, the king, the

court, and his country. Sometimes the punishment ends here; but sometimes it is only a prelude to death, or banishment to the galleys.

**AMENDE honorable** is a term also used for making recantation in open court, or in presence of the person injured.

**AMENDOLARA**, a city of the kingdom of Naples, in the Hither Calabria.

**AMENDMENT**, in a general sense, denotes some alteration or change made in a thing for the better.

**AMENDMENT**, in law, the correction of an error committed in a process, which may be amended after judgment, unless the error lies in giving judgment, for in that case it is not amendable, but the party must bring a writ of error.

A bill may be amended on the file at any time before the plea is pleaded; but not afterwards, without motion and leave of the court.

**AMENDMENT of a bill**, in parliament, is some alteration made in the first draught of it.

**AMENIACEOUS**, in botany, an epithet applied to such plants as are furnished with an amentum. See **AMENTUM**.

**AMENTUM**, in botany, the name of a species of calix, consisting of valves, and hanging down in different directions from the caulis. Common oats afford a good example of the amentum.

**AMENTUM**, in Roman antiquity, a thong tied about the middle of a javelin or dart, and fastened to the forefinger, in order to recover the weapon as soon as it was discharged. The ancients made great use of the amentum, thinking it helped to enforce the blow. It also denotes a latchet that bound their sandals.

**AMERADE**, the same with emir. See **EMIR**.

**AMERCEMENT**, or **AMERCIAMENT**, in law, a pecuniary punishment imposed upon offenders at the mercy of the court.

**AMERGO**, or **MERGO**, a city of Africa, in the kingdom of Fez, three leagues from Beni-Tudi.

**AMERIA**, in geography. See **AMELIA**.

**AMERICA**, one of the four parts of the world, and by much the largest, extending near 9000 miles in length, and about 3000 in breadth. It is situated between  $35^{\circ}$  and  $145^{\circ}$  of W. long. and between  $58^{\circ}$  S. and  $80^{\circ}$  N. lat.; bounded by the lands and seas about the arctic pole on the north; by the Atlantic Ocean, which divides it from Europe and Africa on the west; by the vast Southern Ocean on the south; and by the vast Pacific Ocean, which divides it from Asia on the east. Although it is said to have taken its name from Americus Vespucius, a Florentine, it seems indisputable that it was first discovered by Christopher Columbus, a Genoese, *anno* 1491; unless some conjectures, much more ancient, be admitted, that it was first visited by a Carthaginian fleet, who afterwards settled in Mexico. It is certain, that its productions, whether animal or vegetable, differ greatly from those of any other country; and its original inhabitants, the Eskimaux only excepted, seem to have all the same original, for they agree in every particular, from Hudson's bay, to the Straits of Magellan, excepting only where difference

difference of circumstances may make some dissimilarity. They have all originally a red copper colour, and every part of their bodies without hair, except the head, where it is black, straight, and coarse. In the Spanish and Portuguese settlements, gold is found in great plenty. Its remarkable rivers are, St Lawrence and the Mississippi, in N. America; and the Amazons and Rio de la Plata in S. America. The Andes, which bound Chili on the east, are the highest mountains in the world.

**AMERICIMA**, in zoology, an obsolete name of a species of lacerta. See **LACERTA**.

**AMERSFORT**, a town of the Dutch Netherlands, in the province of Utrecht, situated on the river Ems, about fourteen miles north-east of Utrecht, in  $5^{\circ} 20'$  E. long. and  $52^{\circ} 25'$  N. lat.

**AMERSHAM**, a market-town of Buckinghamshire, about twenty-seven miles westward of London. It is situated in  $4^{\circ} W.$  long. and  $51^{\circ} 40'$  N. lat. and sends two members to parliament.

**AMETHYSTUS**, amethyst, a transparent gem of a purple colour, arising from a mixture of red and blue. However, their colour is various: Some have a mixture of yellow, and some resemble red wine and water; but the best kind is transparent and colourless, and resembling so much the diamond, that the difference can only be distinguished by the softness of the amethyst. This gem is found of various sizes, from the bulk of a small vetch, to an inch and an half in diameter. Its shape is sometimes roundish, sometimes oblong, and sometimes flated a little on one side; but its most common figure is that of a crystal, composed of four planes, and terminated by a flat short pyramid. The amethyst is found in India, Arabia, Armenia, Ethiopia, Cyprus, Germany, Bohemia, and Misnia; but as they are generally as soft as crystal, they are not much valued. It may be counterfeited many ways; but the Germans hardly think it worth the counterfeiting.

**AMETHYST**, in heraldry, a term for the purple colour in the coat of a nobleman, in use with those who blazon by precious stones, instead of metals and colours. This, in a gentleman's escutcheon, is called *Purple*, and in those of sovereign princes, *Mercury*.

**AMETHYSTEA**, in botany, a genus of the diandria monogynia class, of which there is but one species, viz. the carulea, a native of the mountains of Siberia. The corolla of this plant is quinquefide, the calix a little bell-shaped, and the capsule contains four gibbous seeds.

**AMETHYSTINE**, in a general sense, an appellation given to whatever partakes of the nature, or emulates the colour of the amethyst.

**AMEY**, a city of Savoy, situated in a plain, upon the lake Nicv.

**AMGAILA**, or **AMGAILAM**, an obsolete name of a species of acanthus. See **ACANTHUS**.

**AMHAR**, or **AMHARA**, a kingdom of Abyssinia in Africa, subject to the great Negus. It is bounded on the north by the kingdom of Bajender; on the east, by that of Angote; on the south, by the kingdom of

Walaca; and on the west, by the Nile, which separates it from the kingdom of Gojam. This country is remarkable for the mountains Gheshen and Ambacel, where the children and near relations of the kings of Abyssinia were formerly confined; upon which account it is regarded as the native country of the modern emperors.

**AMIA**, in ichthyology, the triviale name of a species of schomber. See **SCHOMBER**.

**AMIANTHUS**, or earth-lax, in natural history, a fibrous, flexile, elastic mineral substance, consisting of short, abrupt, and interwoven filaments. It is found in Germany, in the strata of iron ore, sometimes forming veins of an inch in diameter: There is another kind of amianthus, which is to be met with in the marble quarries of Wales. But this kind Linnæus affirms to be an asbestos. The amianthus does not give fire with steel, nor ferment with acids. It endures an intense heat without injury to its texture.

**AMICABLE**, in a general sense, denotes any thing done in a friendly manner, or to promote peace.

**AMICABLE benches**, in Roman antiquity, were, according to Pitusus, lower and less honourable seats allotted for the *judices pedanei*, or inferior judges, who, upon being admitted of the emperor's council, were dignified by him with the title *amici*.

**AMICITIA**, or *tenure in AMICITIA*, *tenere in amicitiam*, in the feudal customs, were lands granted freely to be enjoyed only so long as the donor pleased.

**AMICTUS**, in Roman antiquity, was any upper garment worn over the tunica.

**AMICTUS**, among ecclesiastical writers, the uppermost garment anciently worn by the clergy; the other five being the alba, sigillum, stola, manipulus, and planetæ.

The amictus was a linen garment, of a square figure, covering the head, neck, and shoulders, and buckled or clasped before the breast. It is still worn by the religious abroad.

**AMICULUM**, in Roman antiquity, a woman's upper garment, which differed from the pala. It was worn both by matrons and courtizans.

**AMICUS curia**, a law-term, to denote a by-stander who informs the court of a matter in law that is doubtful or mistaken.

**AMIENS**, the capital city of Picardy, in France, situated on the river Somme, in E. long.  $2^{\circ} 30'$ , and N. lat.  $49^{\circ} 50'$ . It is a beautiful town, and a bishop's see, under the archbishop of Rheims. Here too is an university of considerable note.

**AMIGDALUS**, in botany. See **AMYGDALUS**.

**AMIENTIES**, cotton cloths, which come from the E. Indies.

**AMILICTI**, in the ancient Chaldean theology, one of the triads of persons in the third order of the divine hierarchy. See **HIERARCHY**.

**AMINA**, a city of Ethiopia in Africa, nine miles from Albar.

**AMINEUM certum**, the name of a vinegar made of the wine of Amineæ, a town of Campania in Italy.

**AMIRANTE**, in the Spanish polity, a great officer of state, answering to our lord high-admiral.

**AMISIA**,

AMISIA, or AMISSA, in geography. See AMASIA.  
AMISS, or *drawing* AMISS, among sportsmen. See DRAWING.

AMISSA, or *lex amissa*. See LEX.

AMITTERE *legem terræ*, among lawyers, a phrase importing the loss of liberty of swearing in any court.

AMMA, in surgery. See HAMMA.

AMMA, among ecclesiastical writers, a term used to denote an abbess or spiritual mother.

AMMÆA, in geography. See AMED.

AMMAN, or AMMANT, in the German and Belgic policy, a judge who has the cognizance of civil causes.

AMMANT, is also used among the French for a public notary, or officer who draws up instruments and deeds.

AMMANNIA, in botany, a genus of the tetrandria monogynia class. The corolla consists of four petals inserted into the calix, which has eight teeth. The capsule has four cells. There are three species of ammanna, *viz.* the latifolia, and ramosior, both natives of America; and the baccifera, a native of China.

AMMERGAW, or AMMERLAND, a small territory in Westphalia, belonging to the King of Denmark.

AMMI, in botany, a genus of the pentandria digynia class. The involucrem is pinnated; and the flowers are all hermaphrodite, with radiated petals. There are two species of the ammi, *viz.* the majus and glaucifolium, both natives of Europe.

AMMINIÆ *uvæ*, a name sometimes given to a species of vine. See VITIS.

AMMITES, in natural history, the name of a congeries of stalagmite. See STALAGMITÆ.

AMMOCOETUS, in ichthyology. See AMMODYTES.

AMMOCHRYSOS, the name of a species of mica, a stone common in Germany. See MICA.

AMMODYTES, or SAND-EEL, in ichthyology, a genus of fishes belonging to the order of apodes. This fish resembles an eel, and seldom exceeds a foot in length. The head of the ammodytes is compressed, and narrower than the body; the upper jaw is larger than the under; the body is cylindrical, with scales hardly perceptible. There is but one species of the ammodytes, *viz.* the tobianus, a native of Europe. This fish gathers itself into a circle, and pierces the sand with its head in the centre.

AMMON, or HAMMON, in heathen antiquity. See HAMMON.

*Cornua* AMMONIS, in natural history. See SNAKE-STONES.

AMMONIAC, the name of a gum-resin extracted from an African plant. It is transported hither in the form of drops or granules, and sometimes in large masses composed of these granules adhering together. The best kind of it is that which is freed of dross, of a yellowish colour, and a bitterish taste. It is much used in obstructions of the viscera and infarctions of the lungs.

*Sal* AMMONIAC. See ARMONIAC.

AMMONITÆ. See SNAKE-STONES.

AMMUNITION, a general term for all warlike provisions, but more especially powder, ball, &c.

Ammunition, arms, utensils of war, gun-powder, imported without licence from his Majesty, are, by the laws of England, forfeited, and triple the value.

And again, such licence obtained, except for furnishing his Majesty's public stores, is to be void, and the offender to incur a preminure, and to be disabled to hold any office from the crown.

AMMUNITION *bread; shoes, &c.* such as are served out to the soldiers of an army or garrison.

AMNA, among ancient physicians. See AMNIS.

AMNESTY, in matters of policy, an act by which two parties at variance promise to pardon and bury in oblivion all that is past.

Amnesty is either general and unlimited, or particular and restrained, though most commonly universal, without condition or exceptions; such as that which passed in Germany at the peace of Osnaburg in the year 1648.

AMNESTY, in a more limited sense, denotes a pardon granted by a prince to his rebellious subjects, usually with some exceptions: such was that granted by Charles II. at his restoration.

AMNIMODAR, in astrology, denotes the planet which rectifies a nativity, or rather the method of doing it.

AMNIOS, in anatomy, a thin pellucid membrane which surrounds the fetus in the womb. See ANATOMY, Part VI.

AMNIS *alcalifatur*, a term for water impregnated with an alkali. See ALKALI.

AMOER, in geography, the same with Amour. See AMOUR.

AMOER is also an island situated east from Niulham, and north-west from the land of Yesso.

AMNITES. See AMMITES.

AMOEBÆUM, in ancient poetry, a kind of poem, representing a dispute between two persons who are made to answer each other alternately; such are the third and seventh of Virgil's eclogues.

AMOL, a city of Thabaristan in Asia upon the Gihun. See GIHUN.

AMOMUM, in botany, a genus of the monandria monogynia class. The corolla of the amomum is cut into four segments, one of which spreads open. There are four species of this genus, *viz.* the zinziber, zezumbet, cardamom, and grana paradisi, all natives of the Indies. See CARDAMOM, and GRANA PARADISI.

AMORBACH, a small city of Franconia, in Germany, belonging to the elector of Mentz.

AMORGO, an island of the Archipelago, about ninety miles north of Candia, lying in E. long. 26° 15', and N. lat. 37°.

AMORPHA, in botany, a genus of the diadelphia decandria class, of which there is but one species, *viz.* the fruticosa. The vexillum of the corolla is ovated and concave; it has no alæ or carina. It is a native of Carolina, and is sometimes called *barba Jovis Americana*.

AMORTIZATION, in law, the alienation of lands or tenements to a corporation or fraternity and their successors. See MORTMAIN.

AMOSSON,

AMOSSON, a river of France, in the province of Languedoc.

AMOVING, the act of expelling a person from his place or office.

AMOUR, a large river of Asia, which, arising in Siberia, runs eastward through Chinese Tartary, and falls into the bay of Corea in the Indian Ocean.

AMOY, an island on the south-west coast of China, situated in E. long. 118°, N. lat. 25°.

AMPANA, in botany, an obsolete name of the borassus. See BORASSUS.

AMPELIS, in botany. See VITIS.

AMPELITES, CANNEL-COAL, a hard, opaque, fossil, inflammable substance, of a black colour. It does not effervesce with acids; it is capable of a fine polish, and for that reason is turned into a number of toys, as snuff-boxes, and the like.

AMPER, or AMPOR, an Essex term for a phlegmon. See PHEGMON.

AMPEZO, a town in the Tyroleze, belonging formerly to the Venetians, but now to the house of Austria.

AMPERES, in antiquity, a kind of vessels wherein the rowers plied two oars at the same time, one with the right hand, and another with the left.

AMPHARTHROSIS, in anatomy, a term for such junctures of bones as have an evident motion, but different from the diarthrosis, &c. See DIARTHROSIS.

AMPHIBIA, in zoology, the name of Linnaeus's third class of animals, including all those which live partly in water, and partly on land. This class is subdivided into three orders, viz. 1. The amphibia reptiles; the amphibia serpentes; and the amphibia nantes. See NATURAL HISTORY.

AMPHIBIOUS, in botany, the name with aquatic. See AQUATIC.

AMPHIBLESTROIDES, in anatomy, a name by which some call the retina of the eye. See RETINA.

AMPHIBOLIA. See the next article.

AMPHIBOLOGY, in grammar and rhetoric, a term used to denote a phrase susceptible of two different interpretations. Amphibology arises from the order of the phrase, rather than from the ambiguous meaning of a word.

AMPHIBRACHYS, in ancient poetry, the name of a foot consisting of three syllables, whereof that in the middle is long, and the other two short; such is the word [ἀβιρέ].

AMPHICTYONS, in Grecian antiquity, an assembly composed of deputies from the different states of Greece, and resembling, in some measure, the diet of the German empire.

The amphictyons met regularly at Delphi twice a-year, viz. in spring and autumn, and decided all differences between any of the Grecian states, their determinations being held sacred and inviolable.

AMPHIDROMIA, in antiquity, constituted part of the lustration of infants. See LUSTRATION.

AMPHIDRYON, in ecclesiastical writers, denotes the veil or curtain which was drawn before the door of the bema in ancient churches.

AMPHIMACER, in ancient poetry, a foot consisting

of three syllables, whereof the first and last are long, and that in the middle short: such is the word [καῖτίτα].

AMPHIPNEUMA, with physicians, signifies great difficulty of breathing.

AMPHIPOLES, in antiquity, the principal magistrates of the city of Syracuse in Sicily, called Archons at Athens. See ARCHON.

AMPHIPOLIS, or STRYMON, a town of European Turkey, once the capital of Macedonia, situated in E. long. 40° 5', and N. lat. 41° 30'.

AMPHIPPIL, in Grecian antiquity, soldiers who, in war, used two horses without saddles, and were dexterous enough to leap from one to the other.

AMPHIPRORÆ, in the naval affairs of the ancients, vessels with a prow at each end. They were used chiefly in rapid rivers and narrow channels, where it was not easy to tack about.

AMPHIPROSTYLE, in the architecture of the ancients, a temple which had four columns in the front, and as many in the face behind.

AMPHISBÆNA, in zoology, a genus of serpents belonging to the order of amphibia serpentes, so called from the false notion of its having two heads, because it moves with either end foremost.

The head of the amphisbæna is small, smooth, and blunt; the nostrils are very small; the eyes are minute and blackish; and the mouth is furnished with a great number of small teeth. The body is cylindrical, about a foot long, and divided into about 200 annular convex segments like those of a worm; and it has about 40 longitudinal streaks, of which 12 on each side are in the form of small crosses like the Roman X; the anus is a transverse slit; and the last ring or segment of the belly has eight small papillæ, forming a transverse line before the anus; the tail, *i. e.* all the space below the anus, is short, consisting of thirty annular segments, without being marked with the cross-lines, and is thick and blunt at the point. The colour of the whole animal is black, variegated with white; but the black prevails most on the back, and the white on the belly. It has a great resemblance to a worm, living in the earth, and moving equally well with either end foremost. There are but two species, viz. 1. the fuliginosa, which answers exactly to the above description, and is found in Lybia, and in different parts of America. 2. The alba, which is totally white, is a native of both the Indies, and is generally found in ant-hillocks. The bite of the amphisbæna is reckoned to be mortal by many authors; but as it is not furnished with dogfangs, the usual instruments of conveying the poison of serpents, later writers esteem it not to be poisonous. They feed upon ants and earth-worms, but particularly the latter. See plate XI. fig. 2.

AMPHISCII, among geographers, a name applied to the people who inhabit the torrid zone. The Amphiscii, as the word imports, have their shadows one part of the year towards the north, and at the other towards the south, according to the sun's place in the ecliptic. They are also called Ascii. See ASCII.

**AMPHISMILA**, a dissecting-knife, with a double edge.  
**AMPHITANE**, among ancient naturalists, a stone said to attract gold, as the loadstone does iron.

**AMPHITAPA**, in antiquity, a garment frized or flagg-ed on both sides, which was laid under persons going to sleep.

**AMPHITHEATRE**, in antiquity, a spacious edifice, built either round or oval, with a number of rising seats, upon which the people used to behold the combats of gladiators, of wild beasts, and other sports.

Amphitheatres were at first only of wood; and it was not till the reign of Augustus, that Statilius Taurus built one, for the first time, of stone. The lowest part was of an oval figure, and called arena, because, for the conveniency of the combatants, it was usually strewn with sand; and round the arena were vaults filed *caveæ*, in which were confined the wild beasts appointed for the shows.

Above the *caveæ* was erected a large circular peristyle, or podium, adorned with columns. This was the place of the emperors, senators, and other persons of distinction.

The rows of benches were above the podium. Their figure was circular; and they were entered by avenues, at the end of which were gates, called vomitoria.

The most perfect remains we now have of amphitheatres, are that of Vespasian, called the coliseum, that at Verona in Italy, and that at Nîmes in Languedoc.

**AMPHITHEATRE**, in gardening, a temple erected on a rising ground, of a semicircular figure. These amphitheatres are formed of ever-greens, observing always to plant the shortest growing trees in the front, and the tallest behind. They are also made of slopes on the sides of hills, and covered with turf, being formerly esteemed great ornaments in gardens; but they are now generally excluded, as the natural slope of such hills is, to persons of true taste, far more beautiful than the stiff angular slopes of these amphitheatres.

**AMPHITHÛRA**, in the ancient churches, was the veil or curtain separating the chancel from the rest of the church.

**AMPHODONTA**, a term for animals who have teeth in both jaws.

**AMPHORA**, in antiquity, a liquid measure among the Greeks and Romans. The Roman amphora contained forty-eight sextaries, and was equal to about seven gallons one pint English wine-measure; and the Grecian or Attic amphora contained one third more. Amphora was also a dry measure, likewise in use among the Romans, and contained three bushels.

**AMPHORA**, among the Venetians, the largest measure used for liquids. It contains four bigorzas, the bigorza being four quarts, the quart four fachies, and each fachie four leras; but, by wholesale, the amphora is fourteen quarts, and the bigorza three quarts and a half.

**AMPHORA**, in astronomy, a name sometimes used for one of the twelve signs of the zodiac, more usually called aquarius. See **AQUARIUS**.

**AMPHOTIDES**, in antiquity, a kind of armour or

covering for the ears, worn by the ancient pugiles, to prevent their adversaries from laying hold of that part.

**AMPHTHILL**, a pretty town in the heart of Bedfordshire in England.

**AMPLIATION**, in a general sense, denotes the act of enlarging or extending the compass of a thing.

**AMPLIATION**, in Roman antiquity, was the deferring to pass sentence in certain causes. This the judge did, by pronouncing the word *amplius*; or by writing the letters N. L. for *non liquet*; thereby signifying, that as the cause was not clear, it would be necessary to bring further evidence.

**AMPLIFICATION**, in rhetoric. See **EXAGGERATION**.

**AMPLITUDE**, in astronomy, an arch of the horizon intercepted between the east or west point, and the centre of the sun, or a planet at its rising and setting, and so is either north and south, or ortive and occasive. See **ASTRONOMY**.

**Magnetical AMPLITUDE**, the different rising or setting of the sun from the east or west points of the compass. It is found by observing the sun, at his rising and setting, by an amplitude-compass.

**AMPLITUDE of the range of a projectile**, the horizontal line, subtending the path in which the projectile moved.

**AMPULLA**, in antiquity, a round big-balled vessel which the ancients used in their baths, to contain oil for anointing their bodies. It was also a cup made of glass, and sometimes of leather, for drinking out of at table.

**AMPULLACEÆ conchæ**, in natural history. See **DOLIA**.

**AMPURIAS**, a town of Spain, capital of the district of Ampouzdán in Catalonia, and situated in E. long. 2° 50', and N. lat. 42° 15'.

**AMPUTATION**, in surgery, the cutting off a limb, or any part, from the body of an animal. See **SURGERY**, title, *Of amputation*.

**AMRAS**, a strong castle in the Tyroleze, E. long. 12° 10', N. lat. 47°.

**AMSDORFIANS**, in church-history, a sect of Protestants in the XVIth century, who took their name from Amstorf their leader. They maintained, that good works were not only unprofitable, but were obstacles to salvation.

**AMSEGETES**, in Roman antiquity, those whose land bordered upon a public road.

**AMSTERDAM**, a large and beautiful city of Holland, situated on the river Amstel, and an arm of the sea, called Wye, a little eastward of the Zuyder-sea, in 4° 30' E. long. and 52° 20' N. lat.

It is computed to be half as big as London; and, in point of trade, equal to any town in the known world; there being people in it of almost every nation and religion of Europe, who apply themselves with the utmost diligence to heap up wealth, not with a view to enjoy it, but to have the pleasure of dying rich.

**AMSTERDAM**, is also the name of a town of the Curacoës, in America; likewise the name of three islands, one of which lies in the Indian ocean, between New Holland and Madagafcar; the second between Peru and

and the islands of Solomon; and the third in the Chinese sea, between Japan, and the island Formosa.

**AMULET**, a charm against witchcraft, or diseases, &c.

These amulets were made of stone, metal, simples, animals, and, in short, of every thing that imagination could suggest. Amulets sometimes consisted in strange unmeaning words, characters and sentences.—The ancients were extremely fond of amulets. Notwithstanding the progress of learning and refinement, there is not any country in Europe, even at this day, who do not believe in some charm or other.

**AMULET**, in cookery. See **OMELET**.

**AMULETICS**, among physicians, a name given to all medicines which are supposed to act as charms.

**AMURCA**, the name of an antiquated medicine, prepared by boiling the recement or dregs of oil of olives to the consistence of honey, and used as an astringent.

**AMURCA**, in anatomy. See *Capula atrabilaria*.

**AMUR**, a city of India, beyond the Ganges, near the lake Chiamai, on the borders of the kingdom of Kandiana.

**AMY**, in law, the next friend or relation to be entrusted for an infant. See **PROCHEN**.

*Alien AMY*, signifies a foreigner here, subject to some foreign prince, or power, in friendship with us.

**AMYGDALA**, the fruit of the almond-tree.

**AMYGDALA** is likewise used for a species of echinus marinus, a shell fish. See **ECHINUS**.

**AMYGDALE**, in anatomy. See **Tenillæ**.

**AMYGDALOIDES lapis**, in Nat. hist. a fossil substance, resembling the kernel of an almond.

**AMYGDALUS**, or **ALMOND-TREE**, in botany, a genus of the icofandria monogynia class. The calix is divided into five segments; and the corolla consists of five petals. The species are three, viz. the persica, or peach-tree; the communis, a native of Mauritania; and the nana, a native of Asia. Almonds are used in medicine as emollient, &c.

**AMYLON**, or **AMYLUM**, a term given to starch. See **STARCH**.

**AMYRBERIS**, in botany. See **BERBERIS**.

**AMYRIS**, in botany, a genus of the decandria monogynia class. The flower consists of four oblong petals. The stigma is quadrangular; the fruit is a berry of the drupa kind. There are four species of this genus, viz. The elemifera, maritima, toxicifera, and balsamifera, all natives of America.

**AMYTHAONIS emplastrum**, a plaster composed of gum ammoniac, wax, bdellium, &c. supposed by the ancients to be useful in convulsions.

**AMZEL**, in ornithology, the English name of a species of turdus. See **TURDUS**.

**AN HOUR AND WASTE**, in law, signifies a forfeiture of lands for a year and a day to the king, by persons committing petit treason and felony, and afterwards the land falls to the lord.

**ANA**, among physicians, denotes a quantity equal to that of the preceding ingredient. It is abbreviated thus,  $\bar{a}\bar{a}$ , or  $\bar{a}$ .

**ANA**, among occult philosophers, a term used to denote

the human mind, from whence some will have *anapsota*, a dæmon invoked by sick persons, to be derived.

**ANABAO**, one of the Molucca islands, S. W. from Timor.

**ANABAPTISTON**, the same with abaptiston. See **ABAPTISTON**.

**ANABAPTISTS**, a sect or denomination of Christians, who deduce their original from the apostolic age. This name was given them by their opponents, soon after the Reformation, by way of scorn, and imports *re-baptizing*; but this charge they disclaim, by denying that the sprinkling, or pouring of water, upon infants has any relation at all to the scripture-ordinance of baptism, either as to its *subjects* or *mode*.

Though they believe the salvation of elect infants; yet they deny their being the proper subjects of baptism: Because they can find neither precept nor example for such a practice in the N. Testament: Because Christ's commission to baptize appears to them to restrict this ordinance to such only as are taught, or made disciples, and believe the gospel, Mat. xxviii. 19. Mark xvi. 16.: Because the apostles, in executing Christ's commission, never baptized any but those who were first instructed in the Christian faith, and professed their belief of it, Acts ii. 41. viii. 12. xviii. 8.: And because the nature and design of the ordinance is such as can be of no advantage to infants, it being a sign and representation of spiritual blessings, intended to impress the mind of the person baptized with a comfortable sense of what is signified thereby, 1 Pet. iii. 21.; and as infants can neither discern the sign nor the thing signified, so they think they can reap no benefit from it, any more than from the Lord's supper, or any other ordinance of the gospel.

They repel the argument drawn from circumcision, by distinguishing betwixt the Old and New Testament dispensations, and betwixt the natural and spiritual seed of Abraham, Rom. ix. 8. Gal. iv. 22, 23, 28, 31. and maintain, that as circumcision belonged to the carnal birth, so baptism belongs only to the spiritual birth, or *those who are of faith*, Gal. iii. 7. Our Lord's words in Mark x. 13, 14. they consider as having no relation to infant-baptism, as he there neither enjoins nor exempts it; and they distinguish betwixt those who may be subjects of the kingdom of heaven in God's sight, and these whom he points out to us as proper visible subjects of gospel-ordinances. The argument from the apostles their baptizing whole houses, they answer, by shewing that these houses heard the word, believed, were comforted, and abounded in good works, Acts xvi. 32, 34, 40. and xviii. 8. 1 Cor. xvi. 15, 16. and so could not be infants.

The mode or manner of baptism they affirm to be *dipping* or *immersing* the whole body in water. This they say is the primary and proper meaning of the original word *Baptizō*, to dip, immerse, or plunge. In support of this sense of the word, they produce other places in the N. Testament where it is so rendered, as Mat. xxvi. 23. Luke xvi. 24. John xiii. 26. Rev. xix. 13. as also the circumstances of our Lord's baptism

tism in Jordan, Mat. iii. 16. Mark i. 9, 10. and of the eunuch's, Acts viii. 38, 39. and the reason of John's baptizing in Enon, John iii. 23. Hence they affirm, that no other mode can be called baptism, or so fitly represent communion with Christ in his death, burial, and resurrection, which is expressly the design of baptism, Rom. vi. 3, 4, 5.

Great troubles were occasioned in Germany by some who professed this tenet; but of all places where they prevailed, none suffered so much by them as the town of Munster. The Anabaptists, however, of Holland and Frizland disapproved of their seditious behaviour: and at present, though this sect still subsists, as well in Britain as abroad, yet they no longer pretend to be divinely inspired; they no longer oppose magistrates, nor preach up a community of goods. Those of them in England differ very little from the Protestant dissenters, except in rejecting infant-baptism; as appears from their confession of faith published 1689.

Within these four years, the Anabaptists have formed a congregation in Edinburgh, (which is the first appearance they ever made in Scotland); and seem to be a serious inoffensive people. They pray for the king and all inferior magistrates, and subject themselves (in civil matters) to every ordinance of man, for the Lord's sake. They consider the kingdom of Christ to be spiritual, and not of this world; and are strictly upon the congregational or independent plan, admitting of no jurisdiction or authority (in matters of religion) but that of the Great Lawgiver. Their church-officers are bishops (or elders) and deacons, and these they generally choose from among themselves. They make the reading of the scriptures a part of their public service, and eat the Lord's supper every sabbath-day. Their disciples, before they are admitted into communion, are first baptized in the Water of Leith, which they do at all seasons of the year; and, on these occasions, they are generally attended by a great number of spectators\*.

**ANABLEPS**, in ichthyology, the trivial name of a species of cobitis. See **COBITIS**.

**ANABOLÆUM**, or **ANABOLE**, in antiquity, a kind of great or upper coat, worn over the tunica. See **TUNICA**.

**ANABOLEUS**, in antiquity, an appellation given to grooms of the stable, or equestris, who assisted their masters in mounting their horses. As the ancients had no stirrups, or instruments that are now in use for mounting a horse, they either jumped upon his back, or were aided in mounting by anabolei.

**ANABROCHISMUS**, an obsolete term among physicians, for removing offensive hairs from the eye-lids.

\* *As we chuse to avoid every kind of misrepresentation, especially in matters of religious opinion; and as the most genuine and satisfactory account of the origin and principles of any sect is to be collected from themselves; we applied to the preachers of the Anabaptist congregation at Edinburgh, from whom we had the above account — The same conduct will be observed with regard to every other sect of any note.*

**ANABROSIS**, signifies a corrosion by acrid humours.

**ANACA**, in ornithology, an obsolete name of a species of psittacus. **PSITTACUS**.

**ANACALYPTERIA**, in antiquity, festivals among the Greeks on the day that the bride was permitted to lay aside her veil, and appear in public. The word is derived from a verb which signifies to *uncover*.

**ANACAMPSEROS**, in botany, a synonyme of the portulaca, and several other plants.

**ANACAMPTERIA**, in ecclesiastical antiquity, a kind of little edifices adjacent to the churches, designed for the entertainment of strangers and poor persons.

**ANACAMPTIC**, a name applied by the ancients to that part of optics which treats of reflection, being the same with what is now called catoptrics. See **CATOPTRICS**.

**ANACARDIUM**, or **CASHEW-NUT-TREE**, in botany, a genus of the decandria monogynia class, of which there is but one species, *viz.* the occidentale, a native of the Indies. The calix is divided into five parts; the flower consists of one quinquefide petal; the fruit is a kidney-shaped nut, inclosed in a fleshy receptacle. The kernel is of the same nature with an almond: The acrid juice contained between the kernels is recommended for tetters and other cutaneous diseases.

**ANACATHARSIS**, signifies a salivation, or discharge of noxious humours by spitting.

**ANACATHARTICS**, properly signify such medicines as promote the discharge of saliva.

**ANACEPHALÆOSIS**, in rhetoric, the same with recapitulation. See **RECAPITULATION**.

**ANACHIMOUSSE**, a country in the island of Madagascar, bordering on the south with Manaboule.

**ANACHORET**, in church-history, denotes a hermit, or solitary monk, who retires from the society of mankind into some desert, with a view to avoid the temptations of the world, and to be more at leisure for meditation and prayer.

Such were Paul, Anthony, and Hilarion, the first founders of monastic life, in Egypt and Palestine.

Anachorets, among the Greeks, consist principally of monks, who retire to caves or cells, with the leave of the abbot, and an allowance from the monastery; or who, weary of the fatigues of the monastery, purchase a spot of ground, to which they retreat, never appearing again in the monastery, unless on solemn occasions.

**ANACHRONISM**, in matters of literature, an error with respect to chronology, whereby an event is placed earlier than it really happened, in which sense it stands opposed to *Parachronism*.

**ANACLASTICS**, that part of optics which considers the refraction of light. See **REFRACTION**, and **OPTICS**.

**ANACLASTIC glasses**. See **GLASS**.

**ANACLETERIA**, in antiquity, a solemn festival celebrated by the ancients when their kings or princes came of age, and assumed the reins of government. It is so called, because proclamation being made of this event to the people, they went to salute their prince during the anacleteria, and to congratulate him upon his new dignity.

**ANACLINOPALE**, among the ancient athletes, a kind of wrestling, performed on the ground.

**ANACLINTERIA**, in antiquity, those parts of the trilinear couches on which a cushion was placed for supporting the head.

**ANACOLLEMA**, a composition of astringent powders, applied by the ancients to the head, to prevent deflections on the eyes.

**ANACREONTIC verse**, in ancient poetry, a kind of verse, so called from its being much used by the poet Anacreon. It consists of three feet and an half, usually spondees and iambuses, and sometimes anapests: Such is that of Horace,

*Lydia, dic per omnes.*

**ANACRISIS**, among civilians, an investigation of truth, interrogation of witnesses, and inquiry made into any fact, especially by torture.

**ANACUICS**, in geography, a people of Brazil in America.

**ANACYCLUS**, in botany, a genus of the syngenesia polygamia superflua class. The receptacle of the anacyclus is palaceous; the pappus emarginated; and the seeds have membranaceous edges. There are three species of this genus, viz. the creticus, orientalis, and valentinus, all natives of the east.

**ANADAVADEA**, in ornithology, a barbarous name of a species of alauda. See **ALAUDA**.

**ANADEMA**, in antiquity, denotes the fillet which the kings of Persia wore round their head. It denotes also a kind of ornament which women wore on their heads like a garland.

**ANADIPLOSIS**, in rhetoric and poetry, a repetition of the last word of a line, or clause of a sentence, in the beginning of the next: Thus,

*Pierides, vos hæc facietis maxima Gallo:*

*Gallo, cujus amor, &c.*

*Et matutinis accredula vocibus instat,*

*Vocibus instat, & assiduas jacit ore querelas.*

**ANADOLL**, the name by which the Turks call Natolia. See **NATOLIA**.

**ANADOLI hispani**, a name given by the Turks to the castle of the Dardanelles, on the Asiatic side.

**ANADOSIS**, among physicians, the distribution of the aliment over the body.

**ANADROMOUS**, among ichthyologists, a name given to such fishes as go to the sea from the fresh waters at stated seasons, and return back again, such as the salmon, &c. See **SALMON**.

**ANAEDEIA**, in Grecian antiquity, a stool whereon the accused person was placed to make his defence.

**ANÆSTHESIA**, signifies a privation of the senses.

**ANAGALLIS**, in botany, a genus of the pentandria monogynia class. The corolla of this plant consists of one rotated petal. There are four species of anagallis, viz. the arvensis, or male pimpernel, a native of Britain; the monelli, a native of Verona; the latifolia and the linifolia, both natives of Spain. The anagallis is supposed to be detensive and healing.

**ANAGARSKAYE**, a city of Muscovitish Tartary, in

the province of Dauria, near the source of the river Amour. See **AMOUR**.

**ANAGLYPHICE**, or **ANAGLYPTICE**, denotes the art of embossing. See **EMBOSSING**.

**ANAGNI**, a town of Italy in the Campagna di Roma, situated about 32 miles E. of Rome, in 13° 45' E. long. and 42° N. lat.

**ANAGNOSTA**, or **ANAGNOSTES**, in antiquity, a kind of literary servant, retained in the families of persons of distinction, whose chief business was to read to them during meals, or at any other time when they were at leisure.

**ANAGOGICAL**, signifies mysterious, transporting, and is used to express whatever elevates the mind.

**ANAGOGE**, or **ANAGOGE**, among ecclesiastical writers, the elevation of the mind to things celestial and eternal.

**ANAGRAM**, in matters of literature, a transposition of the letters of some name, whereby a new word is formed, either to the advantage or disadvantage of the person or thing to which the name belongs. Thus from Galenus, is formed Angelus; from James, Simea; and so of others.

**ANAGRAMMATIST**, a person who composes or deals much in anagrams.

**ANAGROS**, in commerce, a measure for grain used in some parts of Spain, particularly at Seville; 46 anagros make about 10½ quarters of London.

**ANAGYRIS**, in botany, a genus of the decandria monogynia class. This plant has a papilionaceous vexillum, the alæ of which are shorter than the carina. The capsule is a legumen. There is only one species of anagyris, viz. the fetida, a native of Spain, Sicily, and Italy. The leaves are said to be laxative, and the seeds emetic.

**ANALABE**, in the Greek church, a part of the dress of the eastern monks, answerable to the scapular of the west. See **SCAPULAR**.

**ANALECTA**, or **ANALECTES**, in antiquity, a servant whose employment it was to gather up the off-falls of tables.

**ANALECTA, analectis**, in a literary sense, is used to denote a collection of small pieces, as essays, remarks, &c.

**ANALEMMA**, in geometry, a projection of the sphere on the plane of the meridian, orthographically made by straight lines and ellipses, the eye being supposed at an infinite distance, and in the east or west points of the horizon.

**ANALEMMA**, denotes likewise an instrument of brass or wood, upon which this kind of projection is drawn, with an horizon and cursor fitted to it, wherein the solstitial colour, and all circles parallel to it, will be concentric circles; all circles oblique to the eye, will be ellipses; and all circles whose planes pass through the eye, will be right lines.

The use of this instrument is to shew the common astronomical problems, which it will do, though not very exactly, unless it be very large.

**ANALEPSIS**, the augmentation or nutrition of an emaciated body.

**ANALEPTICS**, restorative or nourishing medicines.

**ANALOGICAL**, in a general sense, denotes something belonging to, or partaking of the nature of analogy.—Hence,

**ANALOGICAL syllogism**, is one whose force chiefly depends on the analogy between the two premises.

**ANALOGISM**, among logicians, the arguing from the cause to the effect.

**ANALGISTA**, among civilians, denotes a tutor who is not obliged to give an account of his conduct.

**ANALOGY**, in matters of literature, a certain relation and agreement between two or more things, which in other respects are entirely different.

There is likewise an analogy between beings that have some conformity or resemblance to one another; for example, between animals and plants; but the analogy is still stronger between two different species of certain animals.

Analogy enters much into all our reasoning, and serves to explain and illustrate. A great part of our philosophy has no other foundation than analogy, the utility of which consists in superseding all necessity of examining minutely every particular body; for it suffices us to know that every thing is governed by general and immutable laws, in order to regulate our conduct with regard to all similar bodies, as we may reasonably believe that they are all endowed with the same properties: Thus, we never doubt that the fruit of the same tree has the same taste.

**ANALOGY**, among geometers, denotes a similitude of ratios. See **RATIO**.

**ANALOGY**, in medicine, the resemblance observable between different diseases, which indicates a similar treatment.

**ANALOGY**, among grammarians, is the correspondence which a word or phrase bears to the genius and received forms of any language.

**ANALOGY of doctrine**, among critics, is the explaining the passage of an author, in a manner consistent with the system which he is known to have generally followed.

**ANALOGY**, in rhetoric, a figure of speech, otherwise called comparison. See **COMPARISON**.

**ANALYSIS**, in a general sense, is the resolution of something compounded, into its constituent parts. Hence,

**ANALYSIS**, among logicians, is the resolving of knowledge into original principles, by tracing things backward to their causes.

**ANALYSIS**, among mathematicians, the art of discovering the truth or falsehood of a proposition, or its possibility or impossibility. This is done by supposing the proposition, such as it is, true; and examining what follows from thence, until we arrive at some evident truth, or some impossibility, of which the first proposition is a necessary consequence; and from thence establish the truth or impossibility of that proposition.

**ANALYSIS**, in chemistry, the reducing of an heterogeneous or mixt body, into its original principles or component parts. See **CHEMISTRY**.

**ANALYSIS**, is also used to signify the anatomical dissection of an animal. See **ANATOMY**.

**ANALYSIS**, among grammarians, is the explaining the etymology, construction, and other properties of words.

**ANALYSIS of powers**, is the operation of resolving them into their roots, otherwise called evolution. See **ALGEBRA**, and **ARITHMETIC**.

**ANALYSIS**, is also used for a brief, but methodical illustration of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a synopsis.

**ANALYSIS**, likewise denotes a table of the principal heads of a continued discourse, disposed in their natural order.

**ANALYST**, a person who makes use of the analytical method of resolving problems.

**ANALYTIC**, or **ANALYTICAL**, in a general sense, denotes something belonging to the analysis. See **ANALYSIS**. It is more particularly used for the mathematical and logical analysis, above explained.

**ANAMNESTICS**, among physicians, signs or symptoms from which the present state of the body is discovered.

**ANAMORPHOSIS**, in perspective, and painting, a monstrous projection, or representation of an image, on a plane or curve surface, which, beheld at a proper distance, shall appear regular, and in proportion. See **PERSPECTIVE**.

**ANANAS**, in botany, the trivial name of a species of bromelia. See **BROMELIA**.

**ANANCITIS**, in antiquity, a kind of figured stone, otherwise called *Synochitis*, celebrated for its magical virtue of raising the shadows of the infernal gods.

**ANANTHOCYCLUS**, in botany. See **COLUTEA**.

**ANAPÆST**, in ancient poetry, a foot consisting of two short syllables, and one long: Such is the word *scōpūlos*. It is just the reverse of the dactyl. See **DACTYL**.

**ANAPÆSTIC verses**, those consisting wholly or chiefly of anapæsts.

**ANAPES**, a town in Flanders, situated upon the river Marque, something more than a league's distance from Lille.

**ANAPHORA**, in rhetoric, the repetition of the same word or words in the beginning of a sentence, or verse: Thus Virgil,

*Pan etiam Arcadiæ mecum se judice certet,  
Pan etiam Arcadiæ dicat se judice victum.*

**ANAPHORA**, among physicians, the throwing off purulent matter by the mouth.

**ANAPHRODISIA**, signifies impotence, or want of power to procreate.

**ANAPLASIS**, signifies the replacing or setting a fractured bone.

**ANAPLEROSIS**, among physicians. See **PLETHORA**.

**ANAPLEROTICS**, medicines that promote the growth or granulation of the flesh, in wounds, ulcers, &c.

**ANAPODOPHYLLUM**, in botany. See **PODOPHYLLUM**.

**ANAPULA**, a province of Venezuela in South America.

*Fig. 2.*  
AMPHISBENA

*Fig. 3.*  
ANAS ARBOREA or Whitting Duck

*A. Bell's Sculp.*

PLATE II

ANATOMY OF THE WHISTLING DUCK

**ANAQUITO**, a country of Peru, in South America, in the government of Quito.

**ANARCHY**, in matters of polity, such a confusion in the state, that no supreme authority is lodged either in the prince or other rulers, and consequently the people live at large, without subordination, or any respect for the laws.

**ANARCHAS**, in ichthyology, a genus of fishes of the order of apodes. The head of the anarchas is a little obtuse; the teeth are thick set and roundish. The six fore ones, both above and below, are conical and diverging; the inferior and palate molares are round; the branchiostegæ membrane has six rays; the body is somewhat cylindrical; the tail-fin is distinct. There is one species of this genus; *viz.* the anarchas lupus, or sea-wolf. It grows generally to four or five feet in length. The lapis bufonites or lycodentes is the teeth of the anarchas petrified. It is a native of the northern coast of England.

**ANARRHINON**, in botany. See **ANTIRRHINUM**.

**ANARRHOPIA**, among physicians, a tendency of the humours to the head or superior parts.

**ANAS**, in ornithology, a genus of birds belonging to the order of anseres. The beak of this genus is a little obtuse, covered with an epidermis or skin, gibbous at the base, and broad at the apex; the tongue is obtuse and fleshy; the feet are webbed and fitted for swimming. Under this genus Linæus comprehends 38 species, *viz.* 1. The cygnus, or swan, with a femicylindrical black bill, yellow wax, and a white body. It is the wild swan of English authors, and a native of Europe and N. America. Linæus says, they frequently visit Sweden after a thaw; and they are caught with apples in which a hook is concealed. 2. The cygnoides, with a femicylindrical bill, gibbous wax, and tumid eye-brows: It is the swan-geese of Ray, from Guinea. There is likewise a variety of this species, of a less size, called the goose of Muscovy. 3. The tadorna, with a flat bill, a compressed forehead, a greenish black head, and the body is variegated with white. It is the hell-drake of Ray, and frequents the sea-coasts of Europe. 4. The spectabilis, has a compressed bill, gibbous at the base, a black feathery carina, and a hoary head. It is the grey-headed duck of Edwards, and is a native of Sweden and Canada. 5. The fusca, is of a blackish colour, has a white spot behind the eyes, and a white line on the wings. The male of this species is distinguished by a gibbosity at the base of the bill. It is the black duck of Ray, and a native of the European seas. 6. The nigra, is totally black, and has a gibbosity at the base of the bill; the tail resembles a wedge; the female is brownish. It is the lesser black duck of Ray, and a native of Britain and Lapland. 7. The anser, has a femicylindrical bill; the upper part of the body is ash-coloured, but paler below; and the neck is streaked. It is the wild-geese of Ray, and is a native of Europe and America. There is a variety of this species from America, which Edwards calls the laughing-geese; it has a white ring at the base of the bill, and its neck is streaked. The anseres migrate in large

troops. 8. The erythropus, is of a grey colour, and has a white forehead. It inhabits the north of Europe. 9. The canadensis, is brown, the neck and head are black, and the throat white. It is a native of Canada. 10. The cœrulefcens, is greyish above, and white underneath; the covert feathers of the wings and back are bluish. It is the blue-winged goose of Edwards, and a native of Canada. 11. The bernicla, is of a brown colour; with the head, neck, and breast black; and a white collar. It is the Brent-geese of Ray, and is a native of the northern parts of Europe. 12. The mollissima, or cutbert-duck of Ray, has a cylindrical bill, and the wax is divided behind and wrinkled. The feathers, which are very soft and valuable, fall off during incubation. The male is white above, but black below and behind; the female is greenish. It is a native of the north of Europe. 13. The moschata, or Muscovy duck of Ray, has a naked papilous face, and is a native of India. 14. The bahamensis, or Bahama duck, is grey, with a lead-coloured bill. It has a tawny spot on the sides, and a green yellowish spot on the wings. It is a native of Bahama. 15. The albeola, or little black and white duck, has a black back and wings; the head is bluish, and white on the hinder-part. It is a native of America. 16. The clypeata, or shoveller of Ray, has the end of its bill broad and rounded, and a crooked nail at the end of it. It is found near the European shores. 17. The strepera, or fat-billed duck of Aldrovandus, has the wings variegated with black, white, and red. It frequents the fresh waters of Europe. 18. The bucephala, or lesser duck of Catesby, has the back and wings black; and the head, both above and below, is interspersed with shining silky feathers. It frequents the fresh waters of N. America. 19. The clangula, or golden-eye of Ray, is variegated with black and white, and the head is interspersed with blackish green feathers; it has a white spot near the mouth. It dives much in quest of shell-fish; the eyes are of a shining gold colour. 20. The ruftica, is brownish, or ash-coloured, with a white spot on the ears and wings. It is a native of N. America. 21. The perpscillata, or great black duck, is white on the top of the head and of the neck, and has a black spot on the bill, immediately behind the nostrils. It is a native of Canada. 22. The glaucion, or greater wild-duck of Ray, has the iris of the eyes yellow, a grey head, and white collar. It frequents the northern shores of Europe. 23. The penelope, or widgeon of Ray, has a sharpish tail, black below; the head is brown, and the forehead white. It inhabits the marshy parts of Europe. 24. The acuta, or sea-peafant of Ray, has a long acuminated tail, black below, and a white line on each side of the back part of the head. It is a native of Europe. 25. The hyemalis, or long-tailed duck, has a tail shaped like a wedge, and long tail-feathers; the body is grey, and the temples white. It is a native of Europe and America. 26. The ferina, or red-headed widgeon of Ray, has ash-coloured wings, and a black rump. It frequents the maritime parts of Europe.

rope. 27. The querquedula, or first teal of Aldrovandus, has a green spot on the wings, and a white line above the eyes. It frequents the fresh waters of Europe. 28. The crecca, or common teal, has a green spot on the wings, and a white line both above and below the eyes. It frequents the fresh waters of Europe. This species is to be met with in Duddingston-loch, a fresh-water lake, within a mile of Edinburgh. 29. The histrionica, or dusky-spotted duck of Edwards, is of a brown colour, variegated with white and blue; has a double line on the ears and temples; the collar is white, and there is a white streak on the neck. It is a native of America. 30. The minuta, or little brown and white duck of Edwards, is of a greyish colour, with white ears, and the prime feathers of the wings blackish. It is a native of Canada. 31. The circa, or summer-teal of Ray, with the wings variegated with white spots, a white line above the eyes, and the beak and feet of an ash-colour. It frequents the lakes of Europe. 32. The autumnalis, or red-billed whistling duck of Edwards, is of a grey colour, with the prime feathers of the wings, the tail, and belly black; and the area of the wings yellow and white. It is a native of America. 33. The boschas, or common wild-duck of Ray; the intermediate tail-feathers of the drake are turned backward, and the bill is straight. It frequents the lakes of Europe. This duck feeds upon frogs and several sorts of insects.—The wild duck builds its nest among rushes or heath, near the water, and lays 12 or 14 eggs. At moulting-time, when they cannot fly, great numbers of them are taken with nets. Birds with flat bills, that find their food by groping, have three pair of nerves that extend to the end of their bills; these nerves are remarkably conspicuous in the head and bill of the wild-duck; and are larger than those of a goose, or any other bird yet known: This is the reason they grope for food more than any other bird whatever.—34. The adunca, or hook-billed domestic duck of Ray, has the same characters with the boschas, excepting that the bill is crooked. 35. The galericulata, or Chinese teal of Edwards, has a hanging crest; and on the hinder part of the back, on both sides, there is a crooked, flat, elevated feather; the crest is green and red; and the back is brown, and spotted with blue; the crest feathers on the back are red and blunt; one edge of the inmost wing-feather, when the wings are shut, is raised over the back, and is red, and like a spike before. It is a native of China. 36. The sponsa, or summer-duck of Catesby, has a depending green crest, variegated with blue and white; the back is likewise variegated with blue and white; the breast is grey, and spotted with white; and the throat is white. It is a native of N. America. 37. The arborea, or black-billed whistling-duck of Edwards, is of a reddish brown colour, with a sort of crest on the head; the belly is spotted with black and white. It is a native of America. Sloane informs us, that this duck perches on trees; that it is about 20 inches long, from the end of the bill to the point of the tail; that it makes a kind of whistling noise, from which cir-

cumflance it has received its name. See plate XII. fig. 3. 38. The fuligula, or tufted-duck of Ray, has a hanging crest, a black body, and the wings and belly spotted with white. It is a native of Europe. The male of this species disappears during the incubation of the female.

ANAS campestris, in ornithology. See TETRAO.

ANASCAPTA, among physicians. See ANA.

ANASARCA, in medicine, a species of dropsy, in which the skin is puffed up and swelled, and the impression of the fingers remain, for some time, in the part to which they are applied, but principally in the legs. See MEDICINE, title, Dropsy.

ANASSA, or ANASSIS, in botany, a synonyme of a species of bromelia. See BROMELIA.

ANASTALTICS, in pharmacy. See STYPTICS.

ANASTASIS, a term among ancient physicians, for a rising up to go to stool. It also signifies the passage of any humour, when expelled from one part, and obliged to remove to another.

ANASTATICA, or rose of Jericho, in botany, a genus of the tetradynamia siliculosa class. The flower consists of four roundish petals, disposed in the form of a cross; the seed is a short bilocular pod, containing in each cell a single roundish seed. There are two species of the anastatica, viz. the hierochuntica, a native of the sandy parts of Palestine, and the shores of the Red-sea; and the Syriaca, a native of Syria.

ANASTOCCHICOSIS, signifies a resolution of the solids and fluids.

ANASTOMASIS, or ANASTOMOSIS, in anatomy, the opening of the mouths of vessels, in order to discharge their contained fluids. It is likewise used for the communication of two vessels at their extremities; as the inoculation of a vein with a vein, of an artery with an artery, or of an artery with a vein.

ANASTOMATICS, medicines supposed to have the power of opening the mouths of the vessels, and promoting the circulation; such as deobstruent, cathartic, and sudorific medicines.

ANASTROPHE, in rhetoric, denotes the inversion of the natural order of words.

ANATHEMA, among ecclesiastical writers, imports whatever is set apart, separated, or divided; but is most usually meant to express the cutting off a person from the privileges of society, and communion with the faithful.

The anathema differs from excommunication in the circumstances of being attended with curses and execrations. It was practised in the primitive church against notorious offenders; and the form of that pronounced by Synecius against one Andronicus, is as follows: "Let no church of God be open to Andronicus, but let every sanctuary be shut against him. I admonish both private men and magistrates, neither to receive him under their roof, nor to their table; and priests more especially, that they neither converse with him living, nor attend his funeral when dead."

Several councils also have pronounced anathemas against such as they thought corrupted the purity of the

the faith; and their decisions have been conceived in the following form: *Si quis dixerit*, &c. *anathema sit*.

There are two kinds of anathemas, the one judiciary, and the other abjuratory. The former can only be denounced by a council, a pope, or a bishop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the heresy he abjures.

ANATHEMA, in heathen antiquity, was an offering or present made to some deity, and hung up in the temple. Whenever a person left off his employment, it was usual to dedicate the tools to the patron-deity of the trade. Persons too who had escaped from imminent danger, as shipwreck and the like, or had met with

any other remarkable instance of good fortune, seldom failed to testify their gratitude by some present of this kind.

ANATHEMA likewise denotes Christian offerings, otherwise called donations. See DONATIONS.

ANATHEMATIZING, the act of pronouncing an anathema against some person. See ANATHEMA.

ANATICULA, *little duck*, in the ancient Roman customs, a term of fondness used by lovers.

ANATIFERA *concha*, the trivial name of a species of the lepas, a testaceous animal. See LEPAS.

ANATOLIA, in geography, the same with Natolia. See NATOLIA.

ANATOMICAL, an epithet applied to any thing belonging to anatomy. See ANATOMY.

## A N A T O M Y.

ANATOMY is the art of dissecting the solid parts of animal bodies, with a view to discover their structure, connection, and uses.

ANATOMY is not only the basis of all medical knowledge, but is a very interesting object to the philosopher and natural historian.

In treating this useful subject, we shall divide it into the following parts: I. Of the BONES. II. Of the MUSCLES. III. Of the ARTERIES. IV. Of the VEINS. V. Of the NERVES. VI. Of such parts of the body as are not comprehended in any of the above, *e. g.* The BRAIN, THORAX, ABDOMEN, &c. &c.

### P A R T I.

#### O F T H E B O N E S.

##### SECT. I. *Of the BONES in general.*

BEFORE we examine the structure of the bones, the periosteum, a membrane with which they are covered, must be described.

The periosteum can be divided into layers of fibres. The exterior ones, composed of the fibres of the muscles connected to the bones, vary in their number, size, and direction, and consequently occasion a very great difference in the thickness and strength of the periosteum of different bones. The internal layer is every where nearly of a similar structure, and has its fibres in the same direction with those of the bone to which they are contiguous.

Except where muscles, cartilages, or ligaments, are inserted into the periosteum, its external surface is connected to the surrounding parts by thin cellular membranes, which can easily be stretched considerably, but

shorten themselves whenever the stretching force is removed.

When the periosteum is torn off from bones, we see a great number of white threads produced from that membrane into them; and after a successful injection of the arteries with a red liquor, numerous vessels are not only seen on the periosteum, but most of the fibres sent from the membrane to the bone shew themselves to be vessels entering it, with the injected liquor in them; and when they are broken, by tearing off the periosteum, the surface of the bone is almost covered with red points.

The great sensibility of the periosteum in the deep-seated species of paronychia, in exostoses, nodi, tophi, and gunmata, from a lues venerea, or whenever this membrane is in an inflamed state, is a sufficient proof that it is well provided with nerves; though they are perhaps too small to be traced.

The chief uses of the periosteum are: 1. To allow the muscles, when they contract or are stretched, to move

2<sup>d</sup> slide easily upon the bones. 2. To keep in due order, and to support the vessels in their passage to the bones. 3. By being firmly braced on the bones, to assist in setting limits to their increase, and to check their overgrowth. 4. To strengthen the conjunction of the bones with their epiphyses, ligaments, and cartilages, which are easily separated in young creatures, when this membrane is taken away. 5. To afford convenient origin and insertion to several muscles which are fixed to this membrane. And, lastly, to warn us when any injury is offered to the parts it covers.

The BONES are the most hard and solid parts of the body, and generally of a white colour; only in a living creature they are bluish, which is owing to the blood in the small vessels under their surface.

Bones are composed of a great many plates, each of which is made up of fibres or strings united by smaller fibrils; which being irregularly disposed and interwoven with the other larger fibres, make a reticular work.—This texture is plainly seen in the bones of foetuses, which have not their parts closely compacted, and in the bones of adults, which have been burnt, long exposed to the weather, or whose composition has been made loose by diseases.

The plates are said to be firmly joined to each other by a great number of clavicles, or small bony processes, which, rising from the inner plates, pierce through some, and are fixed into the more external ones.

Though the exterior part of bones is composed of firm compact plates, yet they are all more or less cavernous internally. In some, the solid sides are brought so near, that little cavity can be seen; and in others, the cavities are so large, that such bones are generally esteemed to be hollow or fistular. But the internal spongy texture is most evident in young animals.

This spongy, cavernous, internal part of bones, is generally called their *cancelli* or *lattice-work*.

The twisting and windings which these cancelli make, and the interstices which they leave, differ considerably in figure, number, and size; and therefore form little cells, which are as different, but communicate with each other.

The cancelli sustain the membranous bags of the marrow which are stretched upon them, and thereby hinder these membranous parts from being torn or removed out of their proper places, in the violent motions and different postures which the bones are employed in.

The depressions between the fibres of the external plates of bones appear like so many furrows on their surface, into each of which the periosteum enters.

Both on the ridges and furrows, numerous little pits or orifices of canals are to be seen, by which the vessels pass to and from the bones.

After a successful injection, the arteries can be traced in their course from the pits to the plates and fibres.

We may conclude, from arteries being accompanied with veins, so far as we can trace them in every other part of the body, that there are also veins in the bones.

The bones of a living animal are so insensible that they can be cut, rasped, or burnt, without putting the creature to pain, and the nerves distributed in their substance

cannot be strewn by dissection; from which it might be inferred, that they have no nerves distributed to them: But the general tenor of nature, which bestows nerves to all the other parts, should prevent our drawing such a conclusion.

The vascular texture of bones must make them subject to obstructions, ecchymoses, ulcers, gangrenes, and most other diseases which the softer parts are affected with; and therefore there may be a greater variety of *caries* than is commonly described.

On the internal surface of the solid parts of bones, there are orifices of canals, which pass outwards through the plates to open into other canals that are in a longitudinal direction, from which other transverse passages go out to terminate in other longitudinal canals; and this structure is continued through the whole substance of bones, both these kinds of canals becoming smaller gradually as they approach the outer surface.—These canals are to be seen to the best advantage in a bone burnt till it is white: When it is broken transversely, the orifices of the longitudinal canals are in view; and when we separate the plates, the transverse ones are to be observed.

Most bones have one or more large oblique canals formed through their sides for the passage of the medullary vessels.

The bones sustain and defend the other parts of the body.

Bones are lined within, as well as covered externally, with a membrane; which is therefore commonly called *periosteum internum*.

The internal periosteum is an extremely fine membrane; nay, frequently it has a loose reticular texture; and therefore it is compared by some to the arachnoide coat of the spinal marrow: so that we cannot expect to divide it into layers as we can divide the external periosteum. We can, however, observe its processes entering into the transverse pores of the bones, where probably they are continued to form the immediate canals for the marrow distributed through the substance of the bones; and along with them vessels are sent, as from the external periosteum, into the bone. These processes being of a very delicate texture, the adhesion of this membrane to the bone is so small, that it separates commonly more easily from the bone than from the marrow which it contains.

From the internal surface of the internal periosteum, a great number of thin membranes are produced; which, passing across the cavity, unite with others of the same kind, and form so many distinct bags, which communicate with each other; and these again are subdivided into communicating vesicular cells, in which the marrow is contained.

The MARROW is the oily part of the blood, separated by small arteries, and deposited in these cells. Its colour and consistence may therefore vary according to the state of the vessels, and their distribution on the membranes of the cells.

Besides the arteries already mentioned as being sent from the bones to the marrow, there is at least one artery for each bone; several bones have more, whose principal use is to convey and secrete this oily matter.

The blood, which remains after the secretion of the marrow, is returned by proper veins, which are collected from the membranes into one or two large trunks, to pass out at the same holes at which the arteries enter.

The vessels of the marrow, wrapt up in one common coat from the periosteum, pass through the bones by proper canals; the most considerable of which are about the middle of each bone, and are very oblique.

From the structure of the contents of the bones, we may judge how these parts, as well as others, may be subject to oedema, phlegmon, erysipelas, schirrus, &c. and may thence be led to a cure of each, before the common consequence, putrefaction, takes place, and frequently occasions the loss of the limb, if not of the patient.

The marrow is of very considerable use to the bones; for by entering their transverse canals, and passing from them into the longitudinal ones, it is communicated to all the plates, to soften and connect their fibres, whereby they are preserved from becoming too brittle.

When the marrow, after having served the uses mentioned, is reassumed into the mass of blood, it corrects the too great acrimony communicated to the saline particles of our fluids by their circulation and heat; in the same manner as lixivial salts are blunted by oil in making soap.

Since it is the nature of all oil to become thin and rancid when exposed long to heat, and bones have much oil in their firm hard substance, we may know why an ungrateful smell, and dark-coloured thin ichor, proceed more from corrupted bones than from other parts of the body; and we can understand the reason of the changes of colour which bones undergo, according to their different degrees of mortification.

Though bones so far agree in their structure and annexed parts, yet we may observe a considerable difference among them in their magnitude, figure, situation, substance, connection, uses, &c. Of these we shall only mention two, *viz.* that some bones are *broad* and *flat*, while others are *long* and *round*.

The *broad* bones have thin sides, by the plates being soon and equally sent off to form the lattice-work; which therefore is thicker, and nearly of an equal form all through. By this structure, they are well adapted to their uses, of affording a large enough surface for the muscles to rise from, and move upon, and of defending sufficiently the parts which they inclose.

The *round* bones have thick strong walls in the middle, and become very thin towards their ends, which is owing to very few plates separating at their middle; where, on that account, the cancelli are so fine and small that they are not taken notice of: But such bones are said to have a large reservoir of oil in this place. Towards their ends the lattice-work becomes very thick, and rather more complete than in the other sort of bones.—These round bones having strong forces naturally applied to them, and being otherwise exposed to violent injuries, have need of a cylindrical figure to resist external pressure, and of a considerable quantity of oil to preserve them from becoming too brittle. Besides which, they are advantageously provided with thick sides towards their middle, where the greatest forces are applied to injure

them; while their hollowness increases their diameter, and consequently their strength, to resist forces applied to break them transversely.

Many bones have protuberances, or processes, rising out from them. If a process stands out in a roundish ball, it is called *caput*, or *head*.—If the head is flattened, it obtains the appellation of *condyle*.—A rough unequal protuberance is called *tuberosity*.—When a process rises narrow, and then becomes large, the narrow or small part is named *cervix*, or *neck*.—Long ridges of bones are called *spines*.—Such processes as terminate in a sharp point, have the general name of *corone*, or *coronoid*, bestowed on them, though most of them receive particular names from the resemblance they have, or are imagined to have, to other substances, *e. g. mastoid, styloid, &c.*—Such processes as form brims of cavities, are called *supercilia*.

Processes serve for the advantageous origin and insertion of muscles, and render the articulations firm and stable.

In children these processes are real epiphyses, or distinct bones, which are afterwards united to the other parts; such are the styloid processes of the temporal bones, processes of the vertebrae, trochanters of the thigh, &c.

On the surfaces of a great many of the bones there are cavities, or depressions: If these are deep, with large brims, authors name them *cotyle*; if they are superficial, they obtain the designation of *glena*, or *glenoid*. These general classes are again divided into several species:—Of which *pits* are small roundish channels sunk perpendicularly into the bone;—*furrows* are long narrow canals, formed in the surface;—*notches* or *notches*, small breaches in the bone;—*sinuosities*, broad, but superficial depressions without brims;—*fissia*, large deep cavities, which are not equally surrounded by high brims;—*sinuses*, large cavities within the substance of the bones, with small apertures;—*foramina*, or holes, canals that pierce quite through the substance of the bones.—When this last sort of cavity is extended any long way within a bone, the middle part retains the name of *canal*, and its ends are called *boles*.

The cavities allow the heads of bones to play in them; they lodge and defend other parts; they afford safe passage to vessels, muscles, &c.

To the greater number of bones, whose ends are not joined to other bones by an immovable articulation, there are smaller ones annexed, which afterwards become scarce distinguishable from the substance of the bone itself. These are called *epiphyses*, or *appendices*. Some bones have one, others have two, three, or four of these appendices annexed by the means of cartilages, which are of a considerable thickness in children, but by age become thinner.

Several processes (*e. g. trochanters* of the thigh, *spine* of the *scapula*, &c.) have epiphyses; and processes frequently rise out from epiphyses; for example, at the lower end of the femur, ulna, tibia, &c.

The epiphyses are united chiefly to such bones as are destined for frequent and violent motion; and for this purpose they are wisely framed of a larger diameter than the

the bone they belong to; for by this means, the surface of contact between the two bones of any articulation being increased, their conjunction becomes firmer, and the muscles inserted into them act with greater force, by reason of their axes being further removed from the center of motion.

The softness of the ends of bones may be of some advantage in the womb, and at birth, after which the ossification begins at different points to form epiphyses, before the ossification can extend from the middle to the ends of the bones.

However solid and compact adult bones are, yet they were once cartilages, membranes, nay, a mere jelly. This needs no further proof, than repeated observations of embryos when dissected: And how much more tender must the bones be before that time, when neither knife nor eye is capable to discover the least rudiments of them? By degrees they become more solid, then assume the nature of gristles, and at last ossify; the cohesion of their plates and fibres always increasing in proportion to their increased solidities; as is evident from the time necessary to unravel the texture of bones of people of different ages, or of dense and of spongy bones, or of the different parts of the same bone, and from the more tedious exfoliations of the bones of adults than of children.

The ossification of bones depends principally on their vessels being so disposed, and of such diameters, as to separate a liquor, which may easily turn into a bony substance, when it is deprived of its thinner parts; as seems plain from the observation of the callous matter separated after fractures and ulcers, where part of the bone is taken out: For in these cases, the vessels extending themselves; and the liquors added to them, are gradually formed into granulated flesh; which fills up all the space where the bone is taken from, then hardens, till it becomes as firm as any other part of the bone. This happens frequently, even when the ends of the diseased bone are at a considerable distance from each other.

The induration of bones is also greatly assisted by their being exposed, more than any other parts, to the strong pressure of the great weights they support, to the violent contraction of the muscles fixed to them, and to the force of the parts they contain, which endeavour to make way for their own further growth. By all this pressing force, the solid fibres and vessels of bones are thrust closer; and such particles of the fluids conveyed in these vessels as are fit to be united to the fibres, are sooner and more firmly incorporated with them, while the remaining fluids are forcibly driven out by the veins, to be mixed with the mass of blood. In consequence of this, the vessels gradually diminish as the bones harden. From which again we can understand one reason, why the bones of young animals sooner re-unite after a fracture than those of old; and why cattle that are put too soon to hard labour, seldom are of such large size as others of the same brood, who are longer kept from labour.

From the effects of pressure only it is, that we can account for the bones of old people having their sides

much thinner, yet more dense and solid, while the cavities are much larger than in those of young people; and for the prints of muscles, vessels, &c. being so much more strongly marked on the surfaces of the former than of the latter, if they belong to people of near the same condition in life.—Presture must likewise be the cause, which, in people of equal ages, makes these prints stronger in the bones of those who had much labour and exercise, than they are in people who have led an indolent unactive life.

Having thus considered the bones when single, we shall next shew the different manner of their conjunctions. To express these, anatomists have contrived a great number of technical terms; about the meaning, propriety, and classing of which, there has been a variety of opinions. Some of these terms it is necessary to retain, since they serve to express the various circumstances of the articulations, and to understand the writers on this subject.

The ARTICULATIONS are most commonly divided into three classes, *viz.* symphysis, synarthrosis, and diarthrosis.

*Symphysis*, which properly signifies the concretion or growing together of parts, when used to express the articulations of bones, does not seem to comprehend, under the meaning generally given to it, any thing relating to the form or motion of the conjoined bones; but by it most authors only denote the bones to be connected by some other substance; and as there are different substances which serve this purpose, therefore they divide it into the three following species:

1. *Synchondrosis*, when a cartilage is the connecting substance: Thus the ribs are joined to the sternum; thus the bodies of the vertebrae are connected to each other; as are likewise the ossa pubis.

2. *Synneurosis*, or *syndesmosis*, when ligaments are the connecting bodies, as they are in all the moveable articulations.

3. *Syffarcosis*, when muscles are stretched from one bone to another, as they must be where there are moveable joints.

The second class of articulations, the *synarthrosis*, which is said to be the general term by which the immoveable conjunction of bones is expressed, is divided into three kinds.

1. The *future* is that articulation where two bones are mutually indented into each other, or as if they were sewed together. Thus the bones of the head are joined; thus epiphyses are joined to the bones, before their full connection and union with them.

2. *Gomphosis* is the fixing one bone into another, as a nail is fixed in a board: Thus the teeth are secured in their sockets.

3. *Schindylesis*, or ploughing, when a thin lamella of one bone is received into a long narrow furrow of another: Thus the processus azygos of the sphenoid, and the nasal process of the ethmoid bone, are received by the vomer.

The third class, or *diarthrosis*, is the articulation where the bones are so loosely connected as to allow large motion. This is subdivided into three kinds.

The

The first is *enarthrosis*, or the ball and socket, when a large head is received into a deep cavity; as the head of the os femoris is into the acetabulum coxædici.

The second is *arthrodia*, when a round head is received into a superficial cavity; as in the articulation of the arm-bone and scapula. These two species of diarthrosis allow motion to all sides.

The third is *ginglimus*, which properly signifies the hinge of a door or window; in it the parts of the bones mutually receive and are received, and allow of motion two ways: Workmen call it *charnal*.

\*The *ginglimus* is generally divided into three kinds, to which some give the names of *contiguous*, *distant*, and *compound*.

The first kind of *ginglimus* is, when a bone has several protuberances and cavities, which answer to as many cavities and processes of the other bone, with which it is articulated; as in the conjunction of the femur with the tibia.

The second species is, when a bone receives another at one end, and is received by the same bone at the other end; as in the radius and ulna.

The last sort is, when a bone receives another, and is received by a third; as in the oblique processes of the vertebrae.

If the moveable bones are not connected and kept firm by some strong substance, they would be luxated at every motion of the joints: and if their hard, rough, unequal surfaces were to play on each other, their motion would not only be difficult, but the loss of substance from attrition would be great. Therefore *ligaments* are made to obviate the first, and *cartilages* to prevent the other inconveniency. But because ligaments and cartilages turn rigid, inflexible, and rough, unless they are kept moist, a sufficient quantity of proper liquor is supplied for their lubrication, and to preserve them in a flexible state. Seeing then these parts are so necessary to the articulations, we shall next consider their structure, situation, and uses, so far as they are subservient to the bones, and their motions.

LIGAMENTS are white flexible bodies, thicker and firmer than membranes, and not so hard or firm as cartilages, without any remarkable cavity in their substance, difficultly stretched, and with little elasticity; serving to connect one part to another, or to prevent the parts to which they are fixed from being removed out of that situation which is useful and safe.

After maceration in water, the ligaments can easily be divided; and each ligamentous layer appears composed of fibres, the largest of which are disposed in a longitudinal direction.

The arteries of ligaments are very conspicuous after a tolerable injection, and the larger trunks of their veins are sometimes to be seen full of blood.

Such ligaments as form the sides of cavities, have numerous orifices of their arteries opening upon their internal surface, which keep it always moist: If we rub off that moisture, and then press the ligament, we can see the liquor oozing out from small pores; and we can

force thin liquors, injected by the arteries, into the cavities formed by ligaments.

The exhalent arteries must have corresponding absorbent veins, otherwise the cavities would soon be too full of liquor.

Ligaments then must be subject to the diseases common to other parts, where there is a circulation of fluids, allowance always being made for the size of vessels, nature of the fluids, and firmness of the texture of each part.

Some authors have alledged, that ligaments are insensible, and consequently that they have no nerves. But the violent racking pain felt on the least motion of a joint labouring under a rheumatism, the seat of which disease seems often to be in the ligaments, and the insufferable torture occasioned by incisions of ligaments, and by a collection of acrid matter in a joint, or by topi in the gout, would persuade us, that they are abundantly supplied with nerves.

The ligaments which connect the moveable bones commonly rise from the conjunction of the epiphyses of the one bone, and are inserted into the same place of the other; or where epiphyses are not, they come out from the cervix, and beyond the supercilia of the articulated bones; and after such a manner, in both cases, as to include the articulation in a purse or bag; with this difference, depending on their different motions, that where the motion is only to be in two directions, the ligaments are strongest on those sides towards which the bones are not moved; and when a great variety of motions is designed to be allowed, the ligaments are weaker than in the former sort of articulations, and are nearly of the same strength all round.

Part of the capsular ligaments is composed of the periosteum, continued from one bone to another, and their internal layer is continued on the parts of the bone or cartilage which the ligament includes.

Besides these common capsular ligaments of the joints, there are particular ones in several places, either for the firmer connection of the articulated bones, or for restraining and confining the motion to some one side; such are the cross and lateral ligaments of the knee, the round one of the thigh, &c.

From this account of the ligaments, we may conclude, that, *cæteris paribus*, in whatever articulation the ligaments are few, long, and weak, the motion is more free and quick; but luxations happen frequently: And, on the contrary, where the ligaments are numerous, short, and strong, the motion is more confined; but such a joint is less exposed to luxations.—Whence we may judge how necessary it is to attend to the different ligaments, and the changes which have been made on them by a luxation, when it is to be reduced.

Ligaments also supply the place of bones in several cases to advantage: Thus the parts in the pelvis are more safely supported below by ligaments, than they could have been by bone.—The ligaments placed in the great holes of the ossa innominata, and between the bones of the fore-arm and leg, afford convenient origin to muscles.—Immoveable bones are firmly connected by them;

of which the conjunction of the os sacrum and innominatum is an example.—They afford a socket for moveable bones to play in, as we see part of the astragalus does on the ligament stretched from the heel-bone to the scaphoid.

Numerous inconveniencies may arise from too long or short, strong or weak, lax or rigid ligaments.

**CARTILAGES** are solid, smooth, white elastic substances, between the hardness of bones and ligaments, and covered with a membrane, named *perichondrium*, which is of the same structure and use to them as the periosteum is to the bones.

Cartilages are composed of plates, which are formed of fibres, disposed much in the same way as those of bones are; as might be reasonably concluded from observing bones in a cartilaginous state before they ossify, and from seeing, on the other hand, so many cartilages become bony. This may be still further confirmed, by the exfoliation which cartilages are subject to, as well as bones.

The perichondrium of several cartilages, for example, those of the ribs and larynx, has arteries which can be equally well injected with those of the periosteum.

The granulated flesh which rises from the ends of metacarpal or metatarsal bones, when the cartilage exfoliates, after a finger or toe has been taken off at the first joint, is very sensible, from which the existence of nerves in cartilages may be inferred.

While cartilages are in a natural state, it is to be remarked, first, That they have no cavity in their middle for marrow. Secondly, That their outer surface is softest, which renders them more flexible. Thirdly, That they do not appear to change their texture near so much by acids as bones do. And, lastly, That as the specific gravity of cartilages is near a third less than that of bones, so the cohesion of their several plates is not so strong as in bones; whence cartilages laid bare in wounds or ulcers, are not only more liable to corrupt, but exfoliate much sooner than bones do.

Cartilages seem to be principally kept from ossifying, either by being subjected to alternate motions of flexion and extension, the effects of which are very different from any kind of simple pressure, or by being constantly moistened: Thus, the cartilages on the articulated ends of the great bones of the limbs, and the moveable ones placed between the moving bones in some articulations, which are obliged to suffer many and different flexions, and are plentifully moistened, scarce ever change into bone; while those of the ribs and larynx are often ossified.

The cartilages subservient to bones, are sometimes found on the ends of bones which are joined to no other; but are never wanting on the ends, and in the cavities of such bones as are designed for motion.

The uses of cartilages, so far as they regard bones, are, to allow, by their smoothness, such bones as are designed for motion, to slide easily without detraction, while, by their flexibility, they accommodate themselves to the several figures necessary in different motions, and, by their elasticity, they recover their natural position and shape as soon as the pressure is removed.

This springy force may also assist the motion of the joint to be more expeditious, and may render shocks in running, jumping, &c. less.—To these cartilages we chiefly owe the security of the moveable articulations: For without them the bony fibres would sprout out, and intimately coalesce with the adjoining bone; whence a true anchylosis must necessarily follow; which never fails to happen when the cartilages are eroded by acid matter, or ossified from want of motion or defect of liquor, as we see often happens after wounds of the joints, p<sup>ar</sup>throsis, scrophula, and spina ventosa, or from old age, and long immobility of joints. The moveable cartilages interposed in joints, serve to make the motions both freer and more safe than they would otherwise be.—Those placed on the ends of bones that are not articulated, as on the spine of the os illium, base of the scapula, &c. serve to prevent the bony fibres from growing out too far.—Cartilages sometimes serve as ligaments, either to fasten together bones that are immovably joined, such are the cartilages between the os sacrum and ossa illium, the ossa pubis, &c. or to connect bones that enjoy manifest motion, as those do which are placed between the bodies of the true vertebrae, &c.—Cartilages very often do the office of bones to greater advantage, than these last could, as in the cartilages of the ribs, those which supply brims to cavities, &c.

Too great thickness or thinness, length or shortness, hardness or suppleness of cartilages, may therefore cause great disorders in the body.

The liquor, which principally serves to moisten the ligaments and cartilages of the articulations, is supplied by glands, which are commonly situated in the joint, after such a manner as to be gently pressed, but not destroyed by its motion. By this means, when there is the greatest necessity for this liquor, that is, when the most frequent motions are performed, the greatest quantity of it must be separated. These glands are soft and pappy, but not friable: In some of the large joints they are of the conglomerate kind, or a great number of small glandules are wrapt up in one common membrane. Their excretory ducts are long, and hang loose, like so many fringes, within the articulation; which, by its motion and pressure, prevents obstructions in the body of the gland or its excretories, and promotes the return of this liquor, when fit to be taken up by the absorbent vessels, which must be in the joints, as well as in the other cavities of the body; and, at the same time, the pressure on the excretory ducts hinders a superfluous unnecessary secretion, while the s<sup>u</sup>briated disposition of these excretories does not allow any of the secreted liquor to be pushed back again by these canals towards the glands.

Very often these fountains of slimy liquor appear only as a net-work of vessels.—Frequently they are almost concealed by cellular membranes containing the fat;—and sometimes small simple mucous folliculi may be seen.

The different joints have these organs in different numbers and sizes; the conglomerate ones don't vary much, especially as to situation, in the similar joints of different bodies; but the others are more uncertain.

Upon pressing any of these glands with the finger, one can

can squeeze out of their excretories a mucilaginous liquor, which somewhat resembles the white of an egg, or serum of the blood; but it is manifestly salt to the taste. It does not coagulate by acids or by heat, as the serum does, but by the latter turns first thinner, and, when evaporated, leaves only a thin salt film.

The vessels which supply liquors for making the secretion of this mucus, and the veins which bring back the blood remaining after the secretion, are to be seen without any preparation; and, after a tolerable injection of the arteries, the glands are covered with them.

In a sound state, we are not conscious of any sensibility in those glands; but, in some cases, when they inflame and suppurate, the most racking pain is felt in them: a melancholy, though a sure proof that they have nerves.

These mucilaginous glands are commonly lodged in a cellular substance; which is also to be observed in other parts of the bag formed by the ligaments of the articulation; and contains a fatty matter, that must necessarily be attenuated, and forced through the including membranes into the cavity of the joint, by the pressure which it suffers from the moving bones.

After the liquor of the articulations becomes too thin and unserviceable, by being constantly pounded and rubbed between the moving bones, it is re-assumed into the mass of blood by the absorbent vessels.

## SECT. II. Of the SKELETON.

AMONG anatomists, *Skeleton* is universally understood to signify the bones of animals connected together, after the teguments, muscles, bowels, glands, nerves, and vessels are taken away.

A skeleton is said to be a natural one, when the bones are kept together by their own ligaments; and it is called *artificial*, when the bones are joined with wire, or any other substance which is not part of the creature to which they belonged.

The human skeleton is generally divided into the HEAD, the TRUNK, the SUPERIOR and the INFERIOR EXTREMITIES.

### OF THE HEAD.

By the *Head* is meant all that spheroidal part which is placed above the first bone of the neck. It therefore comprehends the cranium and bones of the face.

The cranium, helmet, or brain-case, consists of several pieces, which form a vaulted cavity, for lodging and defending the brain and cerebellum, with their membranes, vessels, and nerves.

The cavity of the cranium is proportioned to its contents. Hence such a variety of its size is observed in different subjects; and hence it is neither so broad nor so deep at its fore-part, in which the anterior lobes of the brain are lodged, as it is behind, where the large posterior lobes of the brain, and the whole cerebellum, are contained.

The external surface of the upper part of the cranium is very smooth, and equal, being only covered with the periosteum, (common to all the bones; but in the skull, distinguished by the name of *pericranium*), the thin frontal and occipital muscles, their tendinous aponeuroses, and with the common teguments of the body; while the external surface of its lower part has numerous risings, depressions, and holes, which afford convenient origin and insertion to the muscles that are connected to it, and allow safe passage for the vessels and nerves that run through and near it.

The internal surface of the upper part of the skull is commonly smooth, except where the vessels of the dura mater have made furrows in it, while the bones were soft.—Surgeons should be cautious when they trepan here, lest, in sawing or raising the bone where such furrows are, they wound these vessels.—In the upper part of the internal surface of several skulls, there are likewise pits of different magnitudes and figures, which seem to be formed by some parts of the brain being more luxuriant and prominent than others. Where these pits are, the skull is so much thinner than any where else, that it is often rendered diaphanous, the two tables being closely compacted without a diploe; the want of which is supplied by vessels going from the dura mater into a great many small holes observable in the pits.—The knowledge of these pits should teach surgeons to saw cautiously and slowly through the external table of the skull, when they are performing the operation of the trepan; since, in a patient whose cranium has these pits, the dura mater and brain may be injured, before the instrument has pierced near the ordinary thickness of a table of the skull.—The internal base of the skull is extremely unequal for lodging the several parts and appendices of the brain and cerebellum, and allowing passage and defence to the vessels and nerves that go into, or come out from these parts.

The bones of the cranium are composed of two tables, and intermediate cancelli, commonly called their *diploe*. The external table is thickest; the inner, from its thinness and consequent brittleness, has got the name of *vitrea*.

The diploe has much the same texture and uses in the skull, as the cancelli have in other bones.

The diploe of several old subjects is so obliterated, that scarce any vestige of it can be seen; neither is it observable in some of the hard craggy bones at the base of the skull. Hence an useful caution to surgeons who trust to the bleeding, want of resistance, and change of sound, as certain marks, in the operation of the trepan, for knowing when their instrument has sawed through the first table, and reached the diploe.

The cranium consists of eight bones, six of which are said to be proper, and the other two are reckoned common to it and to the face.—The six proper are, the os frontis, two ossa parietalia, two ossa temporum, and the os occipitium.—The common are, the os ethmoides, and sphenoides.

The os frontis forms the whole fore-part of the vault; the two ossa parietalia form the upper and middle part of it; the ossa temporum compose the lower part of the sides;

sides; the os occipitis makes the whole hinder-part, and some of the base; the os ethmoides is placed in the fore-part of the base; and the os sphenoides is in the middle of it.

These bones are joined to each other by five sutures; the names of which are, the coronal, lambdoid, sagittal, and two squamous.

The coronal suture is extended over the head, from within an inch or so of the external canthus of one eye, to the like distance from the other; which being near the place where the ancients wore their vittæ, coronæ, or garlands, this suture has hence got its name.—Though the indentations of this suture are conspicuous in its upper part, yet an inch or more of its end on each side has none of them; for it is squamous and smooth there.

The lambdoidal suture begins some way below, and farther back than the vertex or crown of the head, whence its two legs are stretched obliquely downwards, end to each side, in the form of the Greek letter  $\Lambda$ , and are generally said to extend themselves to the base of the skull.

This suture is sometimes very irregular, being made up of a great many small sutures, which surround so many little bones that are generally larger and more conspicuous on the external surface of the skull than internally. These bones are generally called *triquetra*, or *Wormiana*.

The sagittal suture is placed longitudinally, in the middle of the upper part of the skull, and commonly terminates at the middle of the coronal, and of the lambdoid sutures; between which it is said to be placed, as an arrow is between the string and bow.—However, this suture is frequently continued through the middle of the os frontis, down to the root of the nose; which often happens in women than men.

The squamous agglutinations, or false sutures, are one on each side, a little above the ear, of a semicircular figure, formed by the overlapping (like one scale upon another) of the upper part of the temporal bones, on the lower part of the parietal, where, in both bones, there are a great many small risings and furrows, which are indented into each other; though these inequalities do not appear till the bones are separated.

The bones of the skull are joined to those of the face by sphenoides and sutures.—The sphenoides is in the partition of the nose.—The sutures said to be common to the cranium and face are five, *viz.* the ethmoidal, sphenoidal, transverse, and two zygomatic.—Parts however of these sutures are at the junction of only the bones of the skull.

The ethmoidal and sphenoidal sutures surround the bones of these names; and in some places help to make up other sutures, particularly the squamous and transverse; and, in other parts, there is but one suture common to these two bones.

The transverse suture is extended quite across the face, from the external canthus of one orbit, to the same place of the other.

The zygomatic sutures are one on each side, being short, and flaring from above obliquely downwards and backwards, to join a process of the cheek-bone to one of

the temporal bones, which advances towards the face; so that the two processes thus united, form a sort of bridge or jugum, under which the temporal muscle passes; on which account the processes, and sutures joining them, have been called *zygomatic*.

The advantages of the sutures of the cranium are these: 1. That this capsule is more easily formed and extended into a spherical figure, than if it had been one continued bone. 2. That the bones which are at some distance from each other at birth might then yield, and allow to the head a change of shape, accommodated to the passage it is engaged in. Whence, in hard labour of child-bed, the bones of the cranium, instead of being only brought into contact, are sometimes made to mount one upon the other. 3. That the dura mater may be more firmly supported by its processes, which insinuate themselves into this conjunction of the bones; for doing this equally, and where the greatest necessity of adhesion is, the sutures are disposed at nearly equal distances, and the large reservoirs of blood, the sinuses, are under or near them. 4. That fractures might be prevented from reaching so far as they would in a continued bony substance. 5. That the connection at the sutures being capable of yielding, the bones might be allowed to separate; which has given great relief to patients from the violent symptoms which they had before this separation happened.

Having gone through the general structure of the cranium, we now proceed to examine each bone of which that brain-case consists.

The Os FRONTIS has its name from its being the only bone of that part of the face we call the forehead, though it reaches a good deal further. It has some resemblance in shape to the shell of the concha bivalvis, commonly called the *cockle*; for the greatest part of it is convex externally, and concave internally, with a serrated circular edge; while the smaller part has processes and depressions, which make it of an irregular figure.

The external surface of the os frontis is smooth at its upper convex part; but several processes and cavities are observable below; for, at each angle of each orbit, the bone juts out to form four processes, two internal, and as many external; which, from this situation, may well enough be named *angular*. Between the internal and external angular processes of each side, an arched ridge is extended, on which the eye-brows are placed.—Very little above the internal end of each of these superciliary ridges, a protuberance may be remarked, in most skulls, where there are large cavities, called *sinuses*, within the bone.—Betwixt the internal angular processes, a small process rises, which forms some share of the nose, and thence is named *nasal*.—Some observe a protuberant part on the edge of the bone, behind each external angular process, which they call *temporal* processes; but these are inconsiderable.—From the under part of the superciliary ridges, the frontal bone runs a great way backwards; which parts may justly enough be called *orbital* processes. These, contrary to the rest of this bone, are concave externally, for receiving the globes of the eyes, with their muscles, fat, &c.

In each of the orbital processes, behind the middle of the superciliary ridges, a considerable sinusity is observed, where

where the glandula innominata Galeni, or lachrymalis, is lodged.—Behind each internal angular process, a small pit may be remarked, where the cartilaginous pulley of the musculus obliquus major of the eye is fixed.—Betwixt the two orbital processes, there is a large discontination of the bone, into which the cribriform part of the os ethmoides is incased.—The frontal bone frequently has little caverns formed in it here where it is joined to the ethmoid bone.—Behind each external angular process, the surface of the frontal bone is considerably depressed where part of the temporal muscle is placed.

The *foramina*, or holes, observable on the external surface of the frontal bone, are three in each side.—One in each superciliary ridge, a little removed from its middle towards the nose; through which a twig of the ophthalmic branch of the fifth pair of nerves passes out of the orbit, with a small artery, from the internal carotid, to be distributed to the teguments and muscles of the forehead.—These vessels in some skulls make furrows in the os frontis, especially in the bones of children; and therefore we ought to beware of transverse incisions on either side of the os frontis, which might either open these vessels or hurt the nerves, while they are yet in part within the bone; for, when vessels are thus wounded, it is difficult to stop the hæmorrhage, because the adhesion of a part of the artery to the bone hinders its contraction, and consequently slyptic can have little effect; the sides of the furrow keep off compressing substances from the artery; and we would wish to shun cauteries or escharotics, because they make the bone carious; and nerves, when thus hurt, sometimes produce violent symptoms.—But we must remark, that often, instead of a hole, a notch only is to be seen: Nay, in some skulls, scarce a vestige even of this is left; in others, both hole and notch are observable, when the nerve and artery run separately. Frequently a hole is found on one side, and a notch on the other; at other times we see two holes; or there is a common hole without, and two distinct entries internally. Near the middle of the infide of each orbit, hard by, or in the transverse suture, there is a small hole for the passage of the nasal twig of the first branch of the fifth pair of nerves, and of a branch of the ophthalmic artery. This hole is sometimes entirely formed in the os frontis; in other skulls, the sides of it are composed of this last bone, and of the os planum. It is commonly known by the name of *orbitarium internum*, though *anterior* should be added, because of the next, which is commonly omitted.—This, which may be called *orbitarium internum posterius*, is such another as the former; only smaller, and about an inch deeper in the orbit: through it a small branch of the ocular artery passes to the nose.—Besides these six, there are a great number of small holes observable on the outer surface of this bone, particularly in the two protuberances above the eye-brows. Most of these penetrate no further than the sinuses, or than the diploe, if the sinuses are wanting. The place, size, and number of them, are however uncertain: They generally serve for the transmission of small arteries or nerves.

The internal surface of the os frontis is concave, except the orbital processes, which are convex, to sup-

port the anterior lobes of the brain. This surface is not so smooth as the external; for the larger branches of the arteries of the dura mater make some furrows in its sides and back-parts. The sinuosities from the luxuriant risings of the brain, mentioned when describing the general structure of the cranium, are often very observable on its upper part; and its lower and fore parts are marked with the contortions of the anterior lobes of the brain.—Through the middle of this internal surface, where always in children, and sometimes in old people, the bone is divided, either a ridge stands out, to which the upper edge of the falx is fastened, or a furrow runs, in which the upper side of the superior longitudinal sinus is lodged; on both those accounts chirurgical authors justly discharge the application of the trepan here.

Immediately at the root of this ridge or furrow there is a small hole, which sometimes pierces through the first table, and, in other skulls, opens into the superior sinus of the ethmoid bone within the nose. In it a little process of the falx is lodged, and a small artery, and sometimes a vein, runs; and the superior longitudinal sinus begins here.—This hole, however, is often not entirely proper to the os frontis; for in several skulls, the lower part of it is formed in the upper part of the base of the crista galli, which is a process of the ethmoid bone.

The os frontis is composed of two tables, and an intermediate diploe, as the other bones of the cranium are, and in a middle degree of thickness between the os occipitis and the parietal bones.

The diploe is also exhausted in that part above the eye-brows, where the two tables of the bone separate, by the external being protruded outwards, to form two large cavities, called *sinus frontales*.—These are divided by a middle perpendicular bony partition.—In some skulls, besides the large perpendicular septum, there are several bony pillars, or short partitions, found in each sinus; in others these are wanting.—For the most part, the septum is entire; at other times it is discontinued, and the two sinuses communicate.—Each sinus commonly opens by a roundish small hole, at the inner and lower part of the internal angular processes, into a sinus formed in the nose, at the upper and back part of the os unguis; near to which there are also some other small sinuses of this bone, the greater part of which open separately nearer the septum narium, and often they terminate in the same common canal with the large ones.

In a natural and found state, these cavities are of considerable advantage; for the organ of smelling being thus enlarged, the effluvia of odorous bodies more difficultly escape it; and their impressions being more numerous, are therefore stronger, and affect the organ more.—These and the other cavities which open into the nose, increase the sound of our voice, and render it more melodious, by serving as so many vaults to rebound the notes. Hence people labouring under a coryza, or stoppage of the nose from any other cause, when they are by the vulgar, though falsely, said to speak through their nose, have such a disagreeable harsh voice.—The liquor separated in the membrane of these sinuses, drills down upon the membrane of the nose to keep it moist.

From the description of these sinuses, it is evident,

how useless, nay, how pernicious it must be, to apply a trepan on this part of the skull; for this instrument, instead of piercing into the cavity of the cranium, would reach no further than the sinuses.

The upper circular part of the os frontis is joined to the ossa parietalia, from one temple to the other, by the coronal suture. From the termination of the coronal suture to the external angular processes, this bone is connected to the sphenoid by the sphenoidal suture. At the external canthi of the eyes, its angular processes are joined by the transverse suture to the ossa malarum, to which it adheres one third down the outside of the orbits; whence to the bottom of these cavities, and a little up on their internal sides, these orbital processes are connected to the sphenoidal bone by that same suture.—On the inside of each orbit, the orbital process is indented between the cribriform part of the ethmoid bone, and the os planum and unguis.—The transverse suture afterwards joins the frontal bone to the superior nasal processes of the ossa maxillaria superiora, and to the nasal bones. And, lastly, its nasal process is connected to the nasal lamella of the ethmoid bone.

The frontal bone serves to defend and support the anterior lobes of the brain. It forms a considerable part of the cavities that contain the globes of the eyes, helps to make up the septum narium, organ of smelling, &c. From the description of the several parts, the other uses of this bone are evident.

In a ripe child, the frontal bone is divided through the middle; the superciliary holes are not formed; often a small round piece of each orbital process, behind the superciliary ridge, is not ossified, and there is no sinus to be seen within its substance.

Each of the two *Ossa Parietalia*, or bones serving as walls to the encephalon, is an irregular square; its upper and fore sides being longer than the one behind or below. The inferior side is a concave arch; the middle part receiving the upper round part of the temporal bone.—The angle formed by this upper side and the fore one, is extended, as to have the appearance of a process.

The external surface of each os parietale is convex. Upon it, somewhat below the middle height of the bone, there is a transverse arched ridge, of a whiter colour generally than any other part of the bone; from which, in bones that have strong priets of muscles, we see a great many converging furrows, like so many radii drawn from a circumference towards a centre. From this ridge of each bone the temporal muscle rises; and, by the pressure of its fibres, occasions the furrows just now mentioned.—Below these, we observe, near the semicircular edges, a great many risings and depressions, which are joined to like inequalities on the inside of the temporal bone, to form the squamous suture. The temporal bone may therefore serve here as a buttress, to prevent the lower side of the parietal from starting outwards when its upper part is pressed or struck.

Near the upper sides of these bones, towards the hind part, is a small hole in each, through which a vein passes from the teguments of the head to the longitudinal sinus.—In several skulls, one of the ossa parietalia has not this

hole; in others, there are two in one bone; and in some not one in either. Most frequently this hole is through both tables; at other times the external table is only perforated.—The knowledge of the course of these vessels may be of use to surgeons, when they make any incision near this part of the head, lest, if the vessels are rashly cut near the hole, they shrink within the substance of the bone, and so cause an obstinate hæmorrhagy, which neither ligatures nor medicines can stop.

On the inner concave surface of the parietal bones, we see a great many deep furrows, disposed somewhat like the branches of trees: The furrows are largest and deepest at the lower edge of each os parietale, especially near its anterior angle, where sometimes a full canal is formed. They afterwards divide into small furrows, in their progress upwards.—In some skulls a large furrow begins at the hole near the upper edge, and divides into branches, which join with those which come upwards, shewing the communications of the upper and lower vessels of the dura mater.—In these furrows we frequently see passages into the diploe. On the inside of the upper edge of the ossa parietalia, there is a large sinusity, frequently larger in the bone of one side than of the other, where the upper part of the falx is fastened, and the superior longitudinal sinus is lodged.—Generally part of the lateral sinuses makes a depression near the angle, formed by the lower and posterior sides of these bones; and the pits made by the prominent parts of the brain are to be seen in no part of the skull more frequent, or more considerable, than in the internal surface of the parietal bones.

The ossa parietalia are amongst the thinnest bones of the cranium; but enjoy the general structure of two tables and diploe the completest, and are the most equal and smooth.

These bones are joined at their fore-side to the os frontis by the coronal suture; at their long inferior angles, to the sphenoid bone, by part of the suture of this name; at their lower edge, to the ossa temporum, by the squamous suture, and its posterior additamentum; behind, to the os occipitis, or ossa triquetra, by the lambdoid suture; and above, to one another, by the sagittal suture.

In a child born at the full time, none of the sides of this bone are completed; and there never is a hole in the ossified part of it near to the sagittal suture.

The large unossified ligamentous part of the cranium observable between the parietal bones, and the middle of the divided os frontis of new-born children, called by the vulgar the *open of the head*, was imagined by the ancients to serve for the evacuation of the superfluous moisture of the brain: and therefore they named it *bregma*, or the fountain; sometimes adding the epithet *pulsatilis*, or beating, on account of the pulsation of the brain felt through this flexible ligamento-cartilaginous substance. Hence very frequently the parietal bones are called *ossa bregmatica*.

All the bregma is generally ossified before seven years of age. Several authors say, they have observed it unossified in adults; and physicians, who order the application of medicines at the meeting of the coronal and sagittal

tal futures, seem yet to think that a derivation of noxious humours from the encephalon is more easily procured at this part than any other of the skull; and that medicines have a greater effect here, than elsewhere, in the internal disorders of the head.

*OSSA TEMPORUM*, so named, say authors, from the hair's first becoming grey on the temples, and thus discovering peoples ages, are each of them equal and smooth above, with a very thin femicircular edge; which, from the manner of its connection with the neighbouring bones, is distinguished by the name of *os squamosum*.—Behind this, the upper part of the temporal bone is thicker, and more unequal, and is sometimes described as a distinct part, under the name of *pars mammillaris*.—Towards the base of the skull, the temporal bone appears very irregular and unequal; and this part, instead of being broad, and placed perpendicularly, as the others are, is contracted into an oblong very hard substance, extended horizontally forwards and inwards, which in its progress becomes smaller, and is commonly called *os petrosum*.

Three external processes of each temporal bone are generally described.—The *first*, placed at the lower and hind-part of the bone, from its resemblance to a nipple, is called *mastoides*, or *mammillaris*. It is not solid, but within is composed of cancelli, or small cells, which have a communication with the large cavity of the ear, the drum; and therefore sounds, being multiplied in this vaulted labyrinth, are increased, before they are applied to the immediate organ of hearing. Into the mastoid process, the stenomastoides muscle is inserted; and to its back-part, where the surface is rough, the trachelomastoides, and part of the splenius are fixed.—About an inch farther forward, the *second* process begins to rise out from the bone; and having its origin continued obliquely downwards and forwards for some way, it becomes smaller, and is stretched forwards to join with the *os male*; they together forming the bony jugum, under which the temporal muscle passes. Hence this process has been named *zygomatic*. Its upper edge has the strong aponeurosis of the temporal muscle fixed into it; and its lower part gives rise to a share of the masseter.—The fore-part of the base of this process is an oblong tubercle, which in a recent subject is covered with a smooth polished cartilage, continued from that which lines the cavity immediately behind this tubercle.—From the under craggy part of the *os temporum*, the *third* process stands out obliquely forwards. The shape of it is generally said to resemble the ancient stylus scrip-torius; and therefore it is called the *styloid* process. Several muscles have their origin from this process, and borrow one half of their name from it; as *stylo-glossus*, *stylo-hyoideus*, *stylo-pharyngeus*: to it a ligament of the *os hyoides* is sometimes fixed; and another is extended from it to the inside of the angle of the lower jaw. This process is often, even in adults, not entirely ossified, but is ligamentous at its root, and sometimes is composed of two or three distinct pieces.—Round the root of it, especially at the fore-part, there is a remarkable rising of the *os petrosum*, which some have esteemed a process; and, from the appearance it makes with the styloid, have named it *vaginalis*.—Others again have, under

the name of *auditory* process, reckoned among the external processes that femicircular ridge, which, running between the root of the mastoid and zygomatic processes, forms the under part of the external meatus auditorius.

The sinuosities or depressions on the external surface of each *os temporum* are these:—A long fossa at the inner and back part of the root of the mammary process, where the posterior head of the digastric muscle has its origin.—Immediately before the root of the zygomatic process, a considerable hollow is left, for lodging the cratophite muscle.—Between the zygomatic, auditory, and vaginal processes, a large cavity is formed; through the middle of which, from top to bottom, a fissure is observable, into which part of the ligament that secures the articulation of the lower jaw with this bone is fixed. The fore-part of the cavity being lined with the same cartilage which covers the tubercle before it, receives the condyle of the jaw; and in the back-part a small share of the parotid gland, and a cellular fatty substance, are lodged.—At the inside of the root of the styloid apophyse, there is a thimble-like cavity, where the beginning of the internal jugular vein, or end of the lateral sinus, is lodged.—Round the external meatus auditorius, several sinuosities are formed for receiving the cartilages and ligaments of the ear, and for their firm adhesion.

The holes that commonly appear on the outside of each of these bones, and are proper to each of them, are five.—The *first*, situated between the zygomatic and mastoid processes, is the orifice of a large funnel-like canal, which leads to the organ of hearing; therefore is called *meatus auditorius externus*.—The *second* gives passage to the portia dura of the seventh pair of nerves; and, from its situation between the mastoid and styloid processes, is called *foramen stylo mastoideum*.—Some way before, and to the inside of the styloid process, is the *third* hole; the canal from which runs first upwards, then forwards, and receives into it the internal carotid artery, and the beginning of the intercostal nerve; where this canal is about to make the turn forwards, one, or sometimes two very small holes go off towards the cavity of the ear called *tympaanum*: through these Valsalva affirms the proper artery or arteries of that cavity are sent.—On the anterior edge of this bone, near the former, a *fourth* hole is observable, being the orifice of a canal which runs outwards and backwards, in a horizontal direction, till it terminates in the tympaanum. This, in the recent subject, is continued forward and inward, from the parts which were mentioned just now as its orifice in the skeleton, to the side of the nostrils: being partly cartilaginous, and partly ligamentous. The whole canal is named, *Iter a palato ad aurem*, or *Eustachian tube*.—On the external side of the bony part of this canal, and a-top of the chin in the cavity that receives the condyle of the lower jaw, is the course of the little nerve said commonly to be reflected from the lingual branch of the fifth pair, till it enters the tympaanum, to run across this cavity, and to have the name of *chorda tympani*.—The *fifth* hole is very uncertain, appearing sometimes behind the mastoid process; sometimes it is common to the temporal and occipital bones; and in several skulls there

is no such hole. The use of it, when found, is for the transmission of a vein from the external teguments to the lateral sinus: But, in some subjects, a branch of the occipital artery passes through this hole, to serve the back-part of the dura mater.

The internal surface of the ossa temporum is unequal; the upper circular edge of the squamous part having numerous small ridges and furrows for its conjunction with the parietal bones; and the rest of it is irregularly marked with the convolutions of the middle part of the brain, and with furrows made by the branches of the arteries of the dura mater.

From the under part of this internal surface, a larger transverse, hard, craggy protuberance runs horizontally inwards and forwards, with a sharp edge above, and two flat sides, one facing obliquely forwards and outwards, and the other as much backwards and inwards. To the ridge between these two sides, the large lateral process of the dura mater is fixed.

Sometimes a small bone, akin to the sesamoid, is found between the small end of this petrous process and the sphenoid bone.

Towards the back-part of the inside of the os temporum, a large deep fossa is conspicuous, where the lateral sinus lies; and frequently on the top of the petrous ridge, a furrow may be observed, where a small sinus is situated.

The internal proper foramina of each of these bones are, first, the internal meatus auditorius in the posterior plain side of the petrous process. This hole soon divides into two; one of which is the beginning of the aquæduct of Fallopius: the other ends in several very small canals, that allow a passage to the branches of the portio mollis of the seventh pair of nerves, into the vestibule and cochlea. Through it also an artery is sent, to be distributed to the organ of hearing.—The second hole, which is on the anterior plain side of the craggy process, gives passage to a reflected branch of the second branch of the fifth pair of nerves, which joins the portio dura of the auditory nerve, while it is in the aquæduct, small branches of blood-vessels accompanying the nerves, or passing through smaller holes near this one.—The passage of the cutaneous vein into the lateral sinus, or of a branch of the occipital artery, is seen about the middle of the large fossa for that sinus; and the orifice of the canal of the carotid artery is evident at the under part of the point of the petrous process.

The upper round part of the squamous bones is thin, but equal; while the low petrous part is thick and strong, but irregular and unequal, having the distinction of tables and diploe confounded, with several cavities, processes, and bones within its substance, which are parts of the organ of hearing. See the description of the bones, muscles, &c. of the ear, in part VI.

The temporal bones are joined above to the parietal bones by the squamous sutures, and their posterior additamenta: Before, to the sphenoid bone by the suture of that name; to the cheek-bones by the zygomatic sutures: Behind, to the occipital bone, by the lambdoid suture and its additamenta; and they are articulated with the

lower jaw in the manner which shall be described when this bone is examined.

Os OCCIPITIS, so called from its situation, is convex on the outside, and concave internally. Its figure is an irregular square, or rather rhomboid; of which the angle above is generally a little rounded; the two lateral angles are more finished, but obtuse; and the lower one is stretched forward in form of a wedge, and thence is called by some the *cuneiform process*.

The external surface is convex, except at the cuneiform apophyse, where it is flattened. At the base of this triangular process, on each side of the great hole, but more advanced forwards than the middle of it, the large oblong protuberances, named the *condyles*, appear, to serve for the articulation of this bone with the first vertebra of the neck. The smooth surface of each of these condyloid processes is longest from behind forwards, where, by their oblique situation, they come much nearer to each other than they are at their back-part. Their inner sides are lower than the external, by which they are prevented from sliding to either side out of the cavities of the first vertebra.—Round their root a small depression and spongy roughness is observable, where the ligaments for surrounding and securing their articulations adhere.—Though the motion of the head is performed on the condyles, yet the centre of gravity of that globe does not fall between them, but is a good way further forward; from which mechanism it is evident, that the muscles which pull the head back must be in a constant state of contraction: which is stronger than the natural contraction of the proper flexors, else the head would always fall forwards, as it does when a man is asleep, or labours under a palsy, as well as in infants, where the weight of the head far exceeds the proportional strength of these muscles.

All round the great foramen the edges are unequal, for the firmer adhesion of the strong circular ligament which goes thence to the first vertebra.—One end of each lateral or moderator ligament of the head, is fixed to a rough surface at the fore-part of each condyle, and the perpendicular one is connected to a rough part of the edge of the great hole between the two condyles.

On the inner surface of the os occipitis we see two ridges; one standing perpendicular, the other running horizontally across the first. The upper part of the perpendicular limb of the cross, to which the falx is fixed, is hollowed in the middle, or often on one side, for the reception of the superior longitudinal sinus, and the lower part of it has the small or third process of the dura mater fastened to it, and is sometimes hollowed by the occipital sinus. Each side of the horizontal limb is made hollow by the lateral sinuses inclosed in the transverse process of the dura mater; the fossa in the right side being generally a continuation of the one made by the longitudinal sinus in the perpendicular limb, and therefore is larger than the left one.—Round the middle of the cross there are four large depressions separated by its limbs; the two upper ones being formed by the back-part of the brain, and the two lower ones by the cerebellum.—Farther forward than the last mentioned depressions,

processions, is the lower part of the fossa for the lateral sinus on each side.—The inner surface of the cuneiform apophyse is made concave for the reception of the medulla oblongata, and of the basilar artery.—A furrow is made on each side, near the edges of this process, by a sinus of the dura mater, which empties itself into the lateral sinus.

The holes of this bone are commonly five proper, and two common to it and to the temporal bones.—The first of the proper holes, called *foramen magnum*, from its size, is immediately behind the wedge-like process, and allows a passage to the medulla oblongata, nervi accessorii, to the vertebral arteries, and sometimes to the vertebral veins.—At each side of this great hole, near its fore-part, and immediately above the condyles, we always find a hole, sometimes two, which soon unite again into one that opens externally; through these the ninth pair of nerves go out of the skull.—The fourth and fifth holes pierce from behind the condyle of each side, into the fossae of the lateral sinuses; they serve for the passage of the cervical veins to these sinuses. Often one of these holes is wanting, sometimes both, when the veins pass through the great foramen.—Besides these five, we frequently meet with other holes near the edges of this bone, for the transmission of veins; but their number and diameter are very uncertain. The two common foramina are the large irregular holes, one in each side, between the sides of the cuneiform process, and the edges of the petrous bones. In a recent subject, a strong membrane runs cross from one side to the other of each of these holes.

The occipital bone is among the thickest of the cranium, though unequally so; for it is stronger above, where it has no other defence than the common teguments, than it is below, where, being pressed by the lobes of the brain and cerebellum on one side, and by the action of the muscles on the other, it is so very thin, as to be diaphanous in many skulls.

The occipital bone is joined above to the ossa parietalia and triquetra when present, by the lambdoid suture;—laterally to the temporal bones, by the additamenta of the lambdoid suture;—below to the sphenoid bone, by the end of its cuneiform process, in the same way that epiphyses and their bones are joined.—The os occipitis is joined by a double articulation to the first vertebra of the neck, each condyle being received into a superior oblique process of that vertebra.

Os ETHMOIDES, or the sieve-like bone, has got its name from the great number of small holes with which that part of it first taken notice of is pierced. When this bone is entire, the figure of it is not easily described; but, by a detail of its several parts, some idea may be afforded of the whole; and therefore we shall distinguish it into the cribriform lamella with its process, the nasal lamella, cellular, and ossa spongiosa.

The thin horizontal lamella, is all (except its back-part) pierced obliquely by a great number of small holes, through which the filaments of the olfactory nerves pass.—From the middle of the internal side of this plate, a thick process rises upwards, and, being highest at the fore-part, gradually becomes lower, as it is extended

backwards. From some resemblance which this process was imagined to have to a cock's comb, it has been called *crista galli*. The falx is connected to its ridge, and to the perforated part of the cribriform plate.—When the crista is broke, its base is sometimes found to be hollow, with its cavity opening into the nose.

From the middle of the outer surface of the cribriform lamella, a thin solid plate is extended downwards and forwards, having the same common base with the crista galli. Generally it is not exactly perpendicular, but is inclined to one side or other, and therefore divides the cavity of the nose unequally. Its inclination to one side, and flexure in the middle, is sometimes so great, that it fills up a large share of one of the nostrils, and has been mistook for a polypus there.—It is thin at its rise, and rather still thinner in its middle; yet afterwards, towards its lower edge, it becomes thicker, that its conjunction with the bones and middle cartilage of the nose might be firmer.

At a little distance from each side of this external process, a cellular and spongy bony substance depends from the cribriform plate. The number and figure of the cells in this irregular process of each side, are very uncertain; only the cells open into each other, and into the cavity of the nose: The uppermost, which are below the aperture of the frontal sinuses, are formed like funnels.—The outer surface of those cells is smooth and plain, where this bone assists in composing the orbit; at which place, on each side, it has got the name of *os planum*; on the upper edge of which, a small notch or two may sometimes be observed, which go to the formation of the internal orbitar holes.

Below the cells of each side, a thin plate is extended inwards, and then bending down, it becomes thick, and of a spongy texture.—This spongy part is triangular, with a straight upper edge placed horizontally, an anterior one slanting from above, downwards and forwards, and with a pendulous convex one below.—The upper and lower edges terminate in a sharp point behind.—The side of this pendulous spongy part next to the septum narium is convex, and its external side is concave.—These two processes of the ethmoid bone have got the name of *ossa spongiosa*, or *turbinata superiora*, from their substance, figure, and situation.

All the prominencies, cavities and meanders of this ethmoid bone, are covered with a continuation of the membrane of the nostrils, in a recent subject.—Its horizontal cribriform plate is lodged between the orbitar processes of the frontal bone, to which it is joined by the ethmoid suture, except at the back-part, where it is connected with the cuneiform bone, by a suture common to both these bones.—Where the ossa plana are contiguous to the frontal bone within the orbit, their conjunction is reckoned part of the transverse suture.—Farther forward than the ossa plana, the cells are covered by the ossa unguis, which are not only contiguous to these cells, but cannot be separated from them, without breaking the bony substance.—Below the ossa unguis and plana, these cells and ossa spongiosa are overlapped by the maxillary bones.—The cellular part of each palate-bone is contiguous to each os planum and cellis backwards.—The

lower edge of the nasal perpendicular plate is received into the furrow of the vomer.—Its posterior edge is joined to the fore-part of the process azygos of the sphenoid bone.—Its upper edge joins the nasal process of the frontal and nasal bones, and its anterior one is connected to the middle cartilage of the nose.

From all which the uses of this bone are evident, *viz.* to sustain the anterior lobes of the brain; to give passage to the olfactory nerves, and attachment to the falx; to enlarge the organ of smelling, by allowing the membrane of the nose a great extent; to straiten the passage of the air through the nose, by leaving only a narrow winding canal, on the sensible membranous sides of which the substances conveyed along with the air must strike, to form part of the orbit of the eyes and septum narium; while all its parts are so light as not to be in hazard of separating by their weight; and they are so thin, as to form a large surface, without occupying much space.

OS SPHENOIDES, or wedge-like bone, so called because of its situation in the middle of the bones of the cranium and face, is of an irregular figure, and bears some faint resemblance to a bat with its wings extended.

When we view the external surface of the os sphenoides, two or three remarkable processes from each side of it may be observed; which are all of them again subdivided.—The first pair is the two large lateral processes or wings; the upper part of each of which is called the *temporal process*, because they join with the temporal bones in forming the temples, and the seat for some share of the crotaphite muscles. That part of the wings which juts out towards the inside, somewhat lower than the temporal apophyses, and is smooth and hollowed, where it makes up part of the orbit, is thence named *orbital process*. Behind the edge separating these two processes, there is often a small groove, made by a branch of the superior maxillary nerve, in its passage to the temporal muscle. The lowest and back-part of each wing, which runs out sharp to meet the ossa petrosa, has been styled the *spinous process*: from near the point of which a sharp pointed process is frequently produced downwards, which some call *styliform*, that affords origin to the ptery-staphylinus externus muscle. From this styliform process a very small groove is extended along the edge of the bone to the hollow at the root of the internal plate of the following processes, which forms part of the Eustachian tube.—The second pair of external processes of the cuneiform bone is the two which stand out almost perpendicular to the base of the skull. Each of them has two plates, and a middle fossa facing backwards, and are named *pterygoid* or *aliform* processes. The external plates are broadest, and the internal are longest. From each side of the external plates, the pterygoid muscles take their rise. At the root of each internal plate, a small hollow may be remarked, where the muscular ptery-staphylinus internus, or circumflexus palati, rises, and some share of the cartilaginous end of the Eustachian tube rests; and, at the lower end of the same plate, is a hook-like rising or process, round which the tendon of the last named muscle plays, as on a pulley.—To these another pair may be added, to wit, the little triangular thin process, which comes from each side

of the body of the sphenoid bone, where the pterygoid processes are rising from it, and are extended over the lower part of the aperture of the sinus, as far as to join the ethmoid bone, while their body hangs down into the nares.—Besides these pairs of processes, there is a sharp ridge which stands out from the middle of its base: Because it wants a fellow, it may be called *processus azygos*. The lower part of this process, where it is received into the vomer, is thick, and often not quite perpendicular, but inclining more to one side than the other. The fore-part of this process, where it joins the nasal plate of the os ethmoides, is thin and straight.

The depressions, sinuosities, and fossæ, on the external surface of this sphenoid bone, may be reckoned up to a great number, *viz.* two on the temporal apophyses where the crotaphite muscles lodge.—Two on the orbital processes, to make way for the globes of the eyes.—Two between the temporal and spinous processes, for receiving the temporal bones.—Two between the plates of the pterygoid processes, where the muscular pterygoidei interni and ptery-staphylini interni are placed.—Two between the pterygoid and orbital processes, for forming the holes common to this and to the cheek and maxillary bones.—Two on the lower ends of the aliform processes, which the palate-bones enter into.—Two at the roots of the temporal and pterygoid processes, where the largest share of the external pterygoid muscles have their rise.—Two at the sides of the process azygos, for forming part of the nose, &c.

What was described under the name of *temporal* and *spinous process* on the outside of the skull, are likewise seen on its inside, where they are concave, for receiving part of the brain; and commonly three apophyses on the internal surface of the sphenoid bone are only mentioned.—Two rising broad from the fore-part of its body, become smaller, as they are extended obliquely backwards.—The third standing on a long transverse base, near the back-part of the body of this bone, rises nearly erect, and of an equal breadth, terminating often in a little knob on each side. The three are called *clinoid*, from some resemblance which they were thought to have to the supporters of a bed.—From the roots of the anterior clinoid processes, the bone is extended on each side outwards and forwards, till it ends in a sharp point, which may have the name of the *transverse spinous* processes.—Between, but a little farther back than the two anterior clinoid processes, we see a protuberance considerably smaller than the posterior clinoid process, but of its shape.—Another process from between the transverse processes, often forces itself forwards into the os ethmoides.

Within the skull, there are two sinuosities in the internal part of each wing of the sphenoid bone, for receiving the middle part of the brain.—One between the transverse spinous processes, for lodging the part of the brain where the crura medullæ oblongatæ are.—Immediately before the third or middle clinoid process, a single pit generally may be remarked, from which a fossa goes out on each side to the holes through which the optic nerves pass. The pit is formed by the conjoined optic nerves; and in the fossæ these nerves are lodged, as

they

they run divided within the skull.—Between that third protuberance and the posterior clinoid process, the larger pit for the glandula pituitaria may be remarked. This cavity, because of its resemblance to a Turkish saddle, is always described under the name of *fella Turcica*, or *ephippium*.—On the sides of the posterior clinoid process a fossa may be remarked, that stretches upwards, then is continued forwards along the sides of the *fella Turcica*, near to the anterior clinoid processes, where a pit on each side is made. These fossæ point out the course of the two internal carotid arteries, after they have entered the skull.

The holes on each side of the *os sphenoides* are six proper, and three common.—The *first* is the round one immediately below the anterior clinoid processes, for the passage of the optic nerve, and of the branch of the internal carotid artery that is sent to the eye.—The *second* is the *foramen lacernum*, or large slit between the transverse spinous and orbitar processes: Through it the third, fourth, the first branch of the fifth, and the greater share of the sixth pair of nerves, and an artery from the internal carotid, go into the orbit. Sometimes a small branch of the external carotid enters near its end, to be distributed to the dura mater, and a vein, some call it the *venus dura*, or *Nuck's aqueductus*, returns through it to the cavernous sinus.—The *third* hole, situated a little below the one just now described, is called *rotundum*, from its shape. It allows passage to the second branch of the fifth pair of nerves, or superior maxillary nerve, into the bottom of the orbit.—The *fourth* is the *foramen ovale*, about half an inch behind the round hole. Through it the third branch of the fifth pair, or inferior maxillary nerve, goes out; and sometimes a vein from the dura mater passes out here.—Very near the point of the spinous process is the *fifth* hole of this bone: It is small and round, for a passage to the largest artery of the dura mater, which often is accompanied with a vein.—The *sixth* proper hole cannot be well seen, till the cuneiform bone is separated from all the other bones of the cranium; for one end of it is hid by a small protuberance of the internal plate of the pterygoid process, and by the point of the processus petrosus of the temporal bone. Its canal is extended above the inner plate of the pterygoid process; and where it opens into the cavity of the nose, it is concealed by the thin laminous part of the palate-bone. Through it a considerable branch of the second branch of the fifth pair of nerves is reflected.—Often in the middle of the *fella Turcica*, a small hole or two pierce as far as the cellular substance of the bone; and sometimes at the sides of this sella, one or more small holes penetrate into the sphenoidal sinuses.

The *first* of the common holes is that unequal fissure at the side of the *fella Turcica*, between the extreme point of the *os petrosum* and the spinous process of the cuneiform bone.—The *second* common hole is the large discontinuation of the external side of the orbit, left between the orbitar processes of the cuneiform bone, the *os maxillare, nasale, and palati*. In this large hole the fat for lubricating the globe of the eye and temporal muscle is lodged, and branches of the superior maxillary nerve, with small arteries from the carotid and veins, pass.

—The *third* hole is formed between the base of this bone and the root of the orbitar process of the palate-bone of each side. Through this a branch of the external carotid artery, and of the second branch of the fifth pair of nerves, are allowed a passage to the nostrils, and a returning vein accompanies them.

Under the *fella Turcica*, and some way farther forward, but within the substance of the sphenoid bone, are two sinuses, separated by a bony plate. Each of them is lined with a membrane, and opens into the upper and back part of each nostril by a round hole, which is at their upper fore-part. This hole is not formed only by the *os sphenoides*, which has an aperture near as large as any transverse section of the sinus, but also by the palate-bones which are applied to the fore-part of these sinuses, and close them up, that hole only excepted, which was already mentioned. Frequently the two sinuses are of unequal dimensions, and sometimes there is only one large cavity, with an opening into one nostril.

As this bone is extremely ragged and unequal, so its substance is of very different thickness, being in some places diaphanous; in others it is of a middle thickness, and its middle back-part surpasses the greatest share of the cranium in thickness.

The *os sphenoides* is joined, by its wings, to the parietal bones above, to the *os frontis* and *os alarum* before, to the temporal bones behind;—by the fore-part of its body and spinous processes, to the frontal and ethmoid bones;—by its back-part, behind the two sinuses, to the occipital, where it looks like a bone with the epiphyses taken off;—to the palate-bones, by the ends of the pterygoid processes, and still more by the fore-part of the internal plates of the pterygoid processes, and of the sinuses;—to the maxillary bones, by the fore-part of the external pterygoid plates;—to the vomer and nasal plate of the *os ethmoides*, by the processus *azygos*. All these conjunctions, except the last, which is a *schindylesis*, are said to be by the future proper to this bone; though it is at first sight evident, that several other figures, as the transverse, ethmoidal, &c. are confounded with it.

We see now how this bone is joined to all the bones of the cranium, and to most of the upper jaw; and therefore obtained the name of the *wedge-like bone*.

The *FACE* is the irregular pile of bones, composing the fore and under part of the head, which is divided into the upper and lower maxilla or jaws.

The *superior maxilla* is the common designation given to the upper immoveable share of the face. The shape of the superior jaw cannot easily be expressed; nor is it necessary, provided the shape and situation of all the bones which compose it are described. It is bounded above by the transverse suture, behind by the fore-part of the sphenoid bone, and below by the mouth.

The upper jaw consists of six bones on each side, of a thirteenth bone which has no fellow, placed in the middle, and of sixteen teeth. The thirteen bones are, two *ossa nasi*, two *ossa unguis*, two *ossa malarum*, two *ossa maxillaria*, two *ossa palati*, two *ossa spongiosa inferiora*, and the *vomer*.

The ossa nasi are placed at the upper part of the nose;—the ossa unguis are at the internal canthi of the orbits;—ossa malarum form the prominence of the cheeks;—ossa maxillaria form the side of the nose, with the whole lower and fore part of the upper jaw, and the greatest share of the roof of the mouth;—ossa palati are situated at the back-part of the palate, nostrils, and orbit;—ossa spongiosa are seen in the lower part of the nares;—and the vomer helps to separate these two cavities.

The bones of the upper jaw are joined to the bones of the skull by the schindylefis and sutures already described as common to the cranium and face, and they are connected to each other by gomphosis and fifteen sutures.

The gomphosis only is where the teeth are fixed in their sockets, and the schindylefis is only where the edges of the vomer are joined to other bones.

The first is the *anterior nasal*, which is straight, and placed longitudinally in the middle fore-part of the nose.

The second and third are the *lateral nasal*, which are at each side of the nose, and almost parallel to the first furrow.

Each of the two lacrymal is almost semicircular, and is placed round the lacrymal groove.

The sixth and seventh are the *internal orbital*: each of which is extended obliquely from the middle of the lower side of an orbit to the edge of its base.

The two external orbitals are continued, each from the end of the internal orbital, to the under and fore-part of the cheek.

The tenth is the *maxillary*, which reaches only from the lower part of the septum narium to between the two middle dentes incisives.

The *longitudinal palate* suture stretches from the middle of the foremost teeth through the middle of all the palate.

The *transverse palate* one runs across the palate, nearer the back than the fore-part of it.

Each of the two *palato-maxillary* is at the back-part of the side of each nostril.

The fifteenth is the *spinous*, which is in the middle of the lower part of the nostrils. This may perhaps be rather thought a double schindylefis.

These sutures of the face have not such conspicuous indentations as those of the skull have.

OSSA NASI, so named from their situation at the root of the nose, are each of an irregular oblong square figure, being broadest at their lower end, narrowest a little higher than their middle; and becoming somewhat larger at the top, where they are ragged and thickest, and have a curvature forwards, that their connection with the frontal bone might be stronger.—These bones are convex externally, and thereby better resist any violence from without; and they are concave internally, for enlarging the cavity of the nose.

The lower edge of these bones is unequal, and is stretched outwards and backwards, to join the cartilages of the nostrils.—Their anterior side is thick, especially above, and unequal, that their conjunction to each other might be stronger; and a small rising may be remarked

on their inner edge, where they are sustained by the septum narium.—Their posterior side, at its upper half, has externally a depression, where it is overlapped some way by the maxillary bones, while its lower half covers these bones: By which contrivance, they do not yield easily to pressure applied to their fore-part or sides.

A small hole is frequently to be observed on their external surface, into which two, three, or four holes, which appear internally, terminate for the transmission of small veins; sometimes the holes go no further than the cancelli of the bones.

The nasal bones are firm and solid, with very few cells or cancelli in them.

They are joined above to the frontal bone, by the middle of the transverse suture;—behind, to the maxillary bones, by the lateral nasal sutures;—below, to the cartilages of the nose;—before to one another, by the anterior nasal suture;—internally, to the septum narium.

These bones serve to cover and defend the root of the nose.

OSSA UNGUIS, or LACRYMALIA, are so named, because their figure and magnitude are something near to those of a nail of one's fingure, and because the tears pass upon them into the nose.

Their external surface is composed of two smooth concavities and a middle ridge.—The depression behind forms a small share of the orbit for the eye-ball to move on, and the one before is a deep perpendicular canal, or fossa, larger above than below, containing part of the lacrymal sac and duct. This is the part that ought to be pierced in the great operation for the fistula lacrymalis.—This fossa of the bone is cribriform, or has a great number of small holes through it, that the filaments from the membrane which lines it, insinuating themselves into these holes, might prevent a separation of the membrane, and secure the bone in its natural situation.—The ridge between these two cavities of the os unguis, is the proper boundary of the orbit at its internal canthus; and beyond which surgeons should not proceed backwards in performing operations here.—The internal or posterior surface of this bone consists of a furrow in the middle of two convexities.

The substance of the os unguis is as thin as paper, and very brittle; which is the reason that these bones are often wanting in skeletons, and need little force to pierce them in living subjects.

Each of these bones is joined, above, to the frontal bone, by part of the transverse suture;—behind, to the os planum of the ethmoid bone, by the same suture;—before, and below, to the maxillary bone, by the lacrymal suture;—internally, the ossa unguis cover some of the sinus ethmoidales.

These unguiform bones compose the anterior internal parts of the orbits, lodge a share of the lacrymal sac and duct, and cover the ethmoid cells.—Their situation and tender substance make a rash operator in danger of destroying a considerable share of the organ of smelling, when he is performing the operation of the fistula lacrymalis.

OSSA MALARUM are the prominent square bones which form the cheek on each side.—Before, their sur-  
face

face is convex and smooth; backward, it is unequal and concave, for lodging part of the crotaphyte muscles.

The four angles of each of these bones have been reckoned processes by some.—The one at the external canthus of the orbit, called the *superior orbital process*, is the longest and thickest.—The second terminates near the middle of the lower edge of the orbit in a sharp point, and is named the *inferior orbital process*.

—The third, placed near the lower part of the cheek, and thence called *maxillary*, is the shortest, and nearest to a right angle.—The fourth, which is called *zygomatic*, because it is extended backwards to the zygoma of the temporal bone, ends in a point, and has one side straight, and the other sloping.—Between the two orbital angles there is a concave arch, which makes about a third of the external circumference of the orbit, from which a fifth process is extended backwards within the orbit, to form near one third of that cavity; and hence it may be called the *internal orbital process*.—From the lower edge of each of the *os malarum*, which is between the maxillary and zygomatic processes, the *masseter* muscle takes its origin; and from the exterior part of the zygomatic process, the *musculus distortor oris* rises; in both which places the surface of the bone is rough.

On the external surface of each cheek bone, one or more small holes are commonly found, for the transmission of small nerves or blood-vessels from, and sometimes into the orbit.—On the internal surface are the holes for the passage of the nutritious vessels of these bones.—A notch on the outside of the internal orbital process of each of these bones assists to form the great slit common to this bone and to the sphenoid, maxillary, and palate-bones.

The substance of these bones is, in proportion to their bulk, thick, hard, and solid, with some cancelli.

Each of the *os malarum* is joined, by its superior and internal orbital processes, to the *os frontis*, and to the orbital process of the sphenoid bone, by the transverse future.—By the edge between the internal and inferior orbital processes, to the maxillary bone, by the internal orbital future.—By the side between the maxillary and inferior orbital process, again to the maxillary bone, by the external orbital future.—By the zygomatic process, to the *os temporum*, by the zygomatic future.

*Ossa Maxillaria Superiora*, are the largest bones, and constitute the far greater part of the upper jaw.

The processes of each *os maxillare* may be reckoned seven.—The first is the long nasal one at its upper and fore-part, which is broad below, and turns smaller, as it rises upwards, to make the side of the nose.—At the root of this, a transverse ridge may be observed within the nostrils, which supports the fore-part of the upper edge of the *os spongiosum inferius*.—The second is produced backwards and outwards, from the root of the nasal process, to form the lower side of the orbit; and therefore may be called *orbital*.—The edge of this orbital process, and the ridge of the nasal one, which is continued from it, make a considerable portion of the exter-

nal circumference of the orbit.—From the proper orbital process, a very rough triangular surface is extended downwards and outwards, to be connected to the cheek-bone; and therefore may be called the *malar process*, from the lowly protuberant part of which some share of the masseter muscle takes its rise.—Behind the orbital process, a large tuberosity or bulge of the bone appears, which is esteemed the fourth process.—On the internal part of this we often meet with a ridge, almost of the same height with that in the nasal process, which runs transversely, and is covered by a similar ridge of the palate-bone, on which the back-part of the upper edge of the *os spongiosum inferius* rests.—The convex back-part of this tuberosity is rough for the origin of part of the external pterygoid muscle, and more internally is scabrous, where the palate and sphenoid bones are joined to it.—That spongy protuberance at the lower circumference of this bone, where the sockets for the teeth are formed, is reckoned the fifth.—The sixth is the horizontal plate, which forms the greater part of the base of the nostrils, and roof of the mouth; its upper surface, which belongs to the nostrils, is very smooth, but the other below is arched and rough, for the stronger adhesion of the membrane of the mouth, which is stretched upon it, and in chewing, speaking, &c. might otherwise be liable to be separated.—The seventh rises like a spine from the inner edge of the last, and forms a small part of the partition of the nostrils.

The depressions in each maxillary bone are, 1. A sinusity behind the orbital process, made by the temporal muscle. 2. A pit immediately before the same process, where the origin of the *musculus elevator labiorum communis*, and *elevator labii superioris*, with a branch of the fifth pair of nerves, are lodged securely. 3. The hollow arch of the palate. 4. The femicircular great notch, or entry to the lower part of the nostrils, betwixt the root of the nasal process and spine of the palate-plate. 5. Sockets for the teeth: The number of these sockets is uncertain. 6. The lacrymal fossa in the nasal process, which assists the *os unguis* to form a passage for the lacrymal duct. Immediately on the outside of this, there is a small depression, from which the inferior or lesser oblique muscle of the eye has its origin. 7. The canal on the upper part of the great tuberosity within the orbit, which is almost a complete hole; in this a branch of the superior maxillary nerve passes.—Besides these, the superior surface of the great bulge is concave, to receive the under part of the eye.—Immediately above the transverse ridge in the nasal process, a small hollow is formed by the *os spongiosum*.

The holes of this bone are two proper and two common, which are always to be found, besides several others, whose magnitude, number, &c. are uncertain.—The first of the proper is the *external orbital*, immediately below the orbit, by which the *infra-orbital* branch of the second branch of the fifth pair of nerves, and a small artery, come out, after having passed in the canal, at the bottom of the orbit, described Numb. 7. of the depressions.—The second is the *foramen incisivum*, just behind the fore-teeth, which, at its under part, is one irregular hole common to both the maxillary bones when

they are joined; but, as it ascends, soon divides into two, three, or sometimes more holes; some of which open into each nostril. Through them small arteries and veins, and a twig of the second branch of the fifth pair of nerves pass, and make a communication between, or join the lining coats of the nose and mouth.

The first common hole is that which appears at the inner side of the back-part of the tuberosity and of the sockets of the teeth, and is formed by a fossa in this bone, and a corresponding one in the os palati: through it a nerve, which is a branch of the second branch of the fifth pair, runs to the palate.—The other common hole is the great slit in the outside of the orbit described already, as the second common hole of the sphenoid bone.

All the body of the maxillary bone is hollow, and leaves a large sinus akin to the frontal and sphenoid, which is commonly, but unjustly, called *antrum Highmorianum*.—At the bottom of this cavity, we may often observe some protuberances, in which the small points of the roots of the teeth are contained.—This cavern and the sockets of the teeth are often divided by the interposition only of a very thin bony plate, which is liable to be eroded by acrid matter collected in the antrum, or to be broke in drawing a tooth. The symptoms of a collection of a matter here naturally lead us to the practice of pulling out the teeth, and piercing through this plate into the antrum, to procure an evacuation of the collected matter.

The maxillary sinuses have the same uses as the frontal and sphenoid; and the situation of the sinuses is such, that the liquor drilling from them, from the cells of the ethmoid and palate-bones, and from the lacrymal ducts, may always moisten all the parts of the membrane of the nares in the different situations which the head is in.

The substance of the ossa maxillaria is compact and firm, except at the inferior processes, in which the teeth are lodged, where it is very spongy.

The maxillary bones are joined above by the upper ends of their nasal processes to the os frontis, by the transverse suture;—at the sides of these processes, to the ossa unguis, by the lacrymal sutures;—to the nasal bones, by the lateral nasal sutures;—by their orbital processes, to the cheek-bones, by the external orbital sutures;—by the internal sides of the internal orbital processes, to the ossa plana, by part of the ethmoidal suture;—by the back-part of the tuberosities, to the palate bones, by the suturæ palato-maxillares;—by the posterior edges of their palatine lamellæ, to the ossa palati, by the transverse palate-suture;—by their nasal spines, to the vomer, by the spinous suture;—by their sockets, to the teeth by gomphosis;—by the internal edge of the palatine-plate, to one another, by the longitudinal palate-suture; on the upper and fore-part of which a furrow is left for receiving the cartilage which forms the partition of the nostrils;—between the fore-part of the nostrils and mouth, to each other, by the mystachial suture;—sometimes they are connected to the ossa spongiosa inferiora, by a plain concretion or union of substance.

These bones form the greater part of the nose and of the roof of the mouth, and a considerable share of the orbit. They contain sixteen teeth, give rise to muscles, transmission to nerves, &c. as mentioned in the description of their several parts.

OSSA PALATI are commonly described as two small square bones, at the back-part of the palate or roof of the mouth, though they are of much greater extent, being continued up the back-part of the nostrils to the orbit. Each palate-bone may therefore be divided into four parts, the palate square bone, the pterygoid process, nasal lamella, and orbital process.

The square bone is unequally concave, for enlarging both the mouth and cavity of the nose. The upper part of its internal edge rises in a spine, after the same manner as the palate-plate of the maxillary bone does, to be joined with the vomer.—Its anterior edge is unequally ragged, for its firmer connection with the palate-process of the os maxillare.—The internal edge is thicker than the rest, and of an equal surface, for its conjunction with its fellow of the other side.—Behind, this bone is somewhat in form of a crescent, and thick, for the firm connection of the velum pendulum palati; the internal point being produced backwards, to afford origin to the palato-staphylinus, or azygos-muscle.—This square bone is well distinguished from the pterygoid process by a perpendicular fossa, which, applied to such another in the maxillary bone, forms a passage for the palatine branch of the fifth pair of nerves; and by another small hole behind this, through which a twig of the same nerve passes.

The pterygoid process is somewhat triangular, having a broad-base, and ending smaller above. The back-part of this process has three fossæ formed in it; the two lateral receive the ends of the two plates of the sphenoid bone, that are commonly compared to a bar's wing; the middle fossa makes up a part of what is commonly called the *fossa pterygoidea*; the fore-side of this palatine pterygoid process is an irregular concave, where it receives the back-part of the great tuberosity of the maxillary bone.—Frequently several small holes may be observed in this triangular process, particularly one near the middle of its base, which, a little above, communicates with the common and proper holes of this bone already taken notice of.

The nasal lamella of this bone is extremely thin and brittle, and rises upwards from the upper side of the external edge of the square bone, and from the narrow extremity of the pterygoid process; where it is so weak, and at the same time so firmly fixed to the maxillary bone, as to be very liable to be broken in separating the bones.—From the part where the plate rises, it runs up broad on the inside of the tuberosity of the maxillary bone, to form a considerable share of the sides of the maxillary sinus, and to close up the space between the sphenoid and the great bulge of the maxillary bone, where there would otherwise be a large slit opening into the nostrils. From the middle internal side of this thin plate, a cross ridge, placed on such another of the maxillary bone, is extended; on it the back-part of the os spongiosum

*spongiosum inferius* rests.—Along the outside of this plate, the perpendicular fossa made by the palate-nerve is observable.

At the upper part of this nasal plate, the palate-bone divides into two processes, which were already named *orbital*;—between which and the body of the sphenoid bone, that hole is formed, which was mentioned as the last of the holes common to the sphenoid bone.—Sometimes this hole is wholly formed in the os palati, by a crosß plate going from the one orbital process to the other. A nerve, artery, and vein belonging to the nostrils, pass here.—The anterior of the two orbital processes is the largest, and has its fore-part contiguous to the back-part of the maxillary sinus, and its upper surface appears in the bottom of the orbit, behind the back-part of the os maxillare planum.—It has cells behind, resembling those of the ethmoid bone, to which it is contiguous; it is placed on the aperture of the sinus sphenoidalis, so as to leave only a round hole at its upper fore-part.—The other part of the orbital process is extended along the internal side of the upper back-part of the maxillary tuberosity, to the base of the sphenoid bone, between the root of the processus azygos and the pterygoid process.

The palate-bones are joined to the maxillary, by the fore-edge of the palate square-bone, by the transverse palate-future:—By their thin nasal plates, and part of their orbital processes, to the same bones, by the palato-maxillares futures:—By their pterygoid processes, and back-part of the nasal plates, to the alæ vespertilionum, by the sphenoid future:—By the transverse ridges of the nasal plates, to the ossa spongiosa inferiora, by contact; hence frequently there is an intimate union of the substance of these bones in old skulls:—By the orbital processes, to the ossa plana and cellular ethmoidæ, by the ethmoid future:—To the body of the sphenoid bone, by the sphenoid future:—By the internal edge of the square-bones, to each other, by the longitudinal palate-future; and by their nasal spines, to the vomer, by the spinous future.

The palate-bones form part of the palate, nostrils, orbits, and fossæ pterygoideæ, and they cover part of the sinus maxillares, sphenoidales, and ethmoidici.

*OSSA TURBINATA*, or *spongiosa inferiora*, resemble the superior ossa spongiosa in shape and substance, but have their anterior and upper edges contiguous to the transverse ridges of the nasal processes of the maxillary and palate-bones.—From their upper straight edge, two small processes stand out: the posterior, which is the broadest, descends to cover some of the antrum Highmorianum; the anterior rises up to join the os unguis, and to make part of the lacrymal duct.

Below the spongy bones already mentioned, there are sometimes two others, one in each nostril, which seem to be a production of the sides of the maxillary sinus turned downwards. When this third sort of spongy bones is found, the middle one of the three in each nostril is the largest, and the lowest is the smallest.—Besides all these, there are often several other small bones floating out into the nostrils, that, from their shape,

might also deserve the name of *turbinata*, but are uncertain in their bulk, situation, and number.

They are joined to the ossa maxillaria, palati, and unguis, especially in old subjects.

Their use is, to straiten the nostrils, to afford a large surface for extending the organ of smelling, to cover part of the antra maxillaria, and to assist in forming the under part of the lacrymal ducts, the orifices of which into the nose are concealed by these bones.

*VOMER*, or bone resembling a ploughshare, is the thirteenth of the upper jaw, without a fellow, forming the lower and back-parts of the partition of the nose.

The figure of this bone is an irregular rhomboid.—Its sides are flat and smooth.—Its posterior edge appears in an oblique direction at the back-part of the nostrils.—The upper one is firmly united to the base of the sphenoid bone, and to the nasal plate of the ethmoid; and, when it can be got separated, is hollow, for receiving the processus azygos of the sphenoid.—The anterior edge has a long furrow in it, where the middle cartilage of the nose enters.—The lower edge is firmly united to the nasal spines of the maxillary and palate-bones.—These edges of this bone are much thicker than its middle, which is as thin as the finest paper.

Its situation is not always perpendicular, but often inclined and bended to one side, as well as the nasal plate of the ethmoid-bone.

The vomer is convex at its upper part, and then is straight as it is extended downwards and forwards, where it is composed of two plates; the edges of which have a great number of small processes, disposed somewhat like the teeth of a saw, but more irregularly, and several of them are reflected back. Between these plates, a deep fossa is left, which, so far as the top of the curvature, is wide, and has strong sides, for receiving the processus azygos of the sphenoid-bone. Beyond the arch forwards, the fossa is narrower and shallower gradually to the point of the bone, receiving for some way the nasal lamella ethmoidæ, which is so closely united to the vomer, by the little processes piercing into its substance, as to prevent any separation. The middle cartilage of the nose fills up what remains of the fossa at its fore-part.—The posterior edge of the vomer, which appears above the back-part of the palate-bones, is broader above; but as it descends forwards, becomes thinner, though it is still solid and firm.—The lower edge of this bone, which rests on the nasal spine of the palate and maxillary bones, has a little furrow on each side, of a small middle ridge, answering to the spines of the bones of different sides, and the interstice between them. This edge and the upper one meet in the pointed fore-end of this bone.

The body of the vomer has a smooth surface, and solid, but thin substance; and towards its sides, where it is thickest, some cancelli may be observed, when the bone is broken.

It is joined above to the sphenoid and ethmoid bones, and to the middle cartilage of the nose, by schindylesis;—below, to the maxillary and palate-bones, by the spinous future.

The vomer divides the nostrils, enlarges the organ of smelling, by allowing place for expanding the membrane of the nose on its sides, and sustains the palate-plates of the maxillary and palate-bones.

MAXILLA INFERIOR, the lower jaw, consists only of one moveable bone, and sixteen teeth incased into it.

This bone, which is somewhat of the figure of the Greek letter  $\nu$ , is situated at the lower part of the face, so as its convex middle part is forwards, and its legs are stretched back. It is commonly divided into the chin, sides, and processes.—The chin is the middle fore-part, the extent of which to each side is marked on the external surface by the holes observable there, and internally, by the beginning of an oblique ridge.—Beyond these, the sides appear, and are continued till the bone, by bending upwards, begins to form the processes.

On the fore-part of the chin, a transverse ridge appears in the middle, on each side of which the musculus quadratus, or depressores labii inferioris, and the levatores labii inferioris, depress the bone: And below these prints, a small rising may be observed, where the depressores commence.—On the back-part of the chin, sometimes three, always two, small protuberances appear in the middle. To the uppermost, when it is seen, the frænum of the tongue is connected. From the middle one, the musculus genioglossi rise; and from the lowest, the geniohyoidei have their origin.

At the lower and fore-part of the external surface of each side of the lower jaw, a small eminence may be observed, where the depressor labiorum communis rises. Near the upper edge of the side a ridge runs length-ways, to which the under part of the musculus buccinator is connected.—Internally, towards the upper edge of each side, another ridge appears, from which the mylohyoidei have their origin, and to which the internal membrane of the gums adheres.

In the upper edge of both chin and sides are a great many deep pits or sockets, for receiving the roots of the teeth. The number and magnitude of these sockets are various, because of the different number, as well of the teeth themselves, as of their roots, in different people. These sockets in this lower jaw, as well as in the upper one, are less deep as old age comes on; when freed from the teeth by any means, they are some time after filled up with an offscous net-work, which at last becomes entirely solid, and as smooth as any other part of the bone; so that in a great many old jaws one cannot observe a vestige of the sockets: But then the jaw becomes less, and much narrower.—Hence we may know why the chin and nose of edentulous people are much nearer than before the teeth were lost; while their lips either fall in towards the mouth, or stand prominent forwards.—When new teeth are protruded, new sockets are formed.—The lower edge of the chin and sides is smooth and equal, and is commonly called the *base* of the lower jaw.

—The ends of the base, where the jaw turns upwards, are called its angles; the external surface of each of which has several inequalities upon it, where the masseter muscle is inserted; as the internal surface also has, where the pterygoideus internus is inserted, and a liga-

ment, extended from the styloid process of the temporal bone, is fixed.

The processes are two on each side.—The anterior sharp thin coronoid ones have the crotaphyte muscles inserted into them.—The posterior processes, or condyles, terminate in an oblong smooth head, supported by a cervix. The heads, whose greatest length is transverse, and whose convexity is turned forwards, are tipped with a cartilage, as the articulated parts of all other moved bones are.—The fore-part of the root and neck of these condyloid processes are a little hollow and rough, where the external pterygoid muscles are inserted.

The holes of the lower jaw are two on each side; one at the root of the processes internally, where a large branch of the third branch of the fifth pair of nerves enters with an artery, and a vein returns. A small sharp process frequently juts out backwards from the edge at the fore-part of this hole, to which a ligament, extended from the temporal bone, is fixed, which saves the nerve and vessels from being too much pressed by the pterygoid muscles.—From the lower side of this hole, either a small superficial canal or a furrow descends, where a branch of the nerve is lodged, in its way to the mylohyoides muscle and sublingual gland.—The other hole is external, at the confines of the chin, where branches of the nerve and vessels come out.—The canal betwixt these two holes is formed in the middle of the substance of the bone, and is pierced by a great number of small holes by which the nerves and blood-vessels of the cancelli and teeth pass.

The lower jaw generally receives the roots of sixteen teeth into its sockets, by gomphosis; and its condyloid processes, covered with cartilage, are articulated with the temporal bones.

THE TEETH are the hard white bodies placed in the sockets of both jaws. Their number is generally sixteen above, and as many below; though some people have more, others have fewer.

The broad thick part of each tooth which appears without the socket, is the *bate*, or body.—The smaller processes sunk into the maxilla, are the roots or fangs, which become gradually smaller towards the end farthest from the bafe, or are nearly conical, by which the surface of their sides divides the pressure made on the bafes, to prevent the soft parts, which are at the small points of the sockets, to be hurt by such pressure.

Without the gums the teeth are covered with no membrane, and they are said to have no proper periosteum within the sockets; but that is supplied by the reflected membrane of the gums; which, after a good injection, may be evidently seen in a young subject, with the vessels from it penetrating into the substance of the teeth; and it may be discovered in any tooth recently pulled, by macerating it in water. The adhesion of this membrane to these roots is strengthened by the small furrows observable on them.

Each tooth is composed of its cortex, or enamel, and an internal bony substance. The cortex has no cavity or place for marrow, and is so solid and hard, that saws or files can with difficulty make impression on it. It is  
thickest

thickest upon the base, and gradually, as the roots turn smaller, becomes thinner.—The fibres of this enamel are all perpendicular to the internal substance, and are freight on the base, but at the sides are arched with a convex part towards the roots; which makes the teeth resist the compression of any hard body between the jaws, with less danger of breaking these fibres, than if they had been situated transversely. The spongy sockets in which the teeth are placed likewise serve better to prevent such an injury, than a more solid base would have done.

The bony part of the teeth has its fibres running straight, according to the length of the teeth. When it is exposed to the air, by the breaking or falling off of the hard cortex, it soon corrupts. And thence carious teeth are often all hollow within, when a very small hole appears only externally.

The teeth have canals formed in their middle, wherein their nerves and blood-vessels are lodged; which they certainly need, being constantly wasted by the attrition they are subjected to in mastication, and for their further growth, not only after they first appear, but even in adults; as is evident when a tooth is taken out: For then the opposite one becomes longer, and those on each side of the empty socket turn broader; so that when the jaws are brought together, it is scarce observable where the tooth is wanting.

The vessels are easily traced so long as they are in the large canal, but can scarce be observed in their distribution from that to the substance of the teeth of adults.—This plentiful supply of vessels must expose the teeth to the same disorders that attack other vascular parts.

Every root of each tooth has such a distinct canal, with vessels and nerves in it. These canals in the teeth with more than one root, come nearer each other, as they approach the base of the tooth: and at last are only separated by very thin plates, which being generally incomplete, allow a communication of all the canals; and frequently one common cavity only appears within the base, in which a pulpy substance, composed of nerves and vessels, is lodged.

The entry of the canals for these vessels is a small hole placed a little to a side of the extreme point of each root: sometimes, especially in old people, this hole is entirely closed up, and consequently the nerves and blood-vessels are destroyed.

The teeth are seen for a considerable time in form of mucus contained in a membrane; afterwards a thin cortical plate, and some few ossious layers appear within the membrane, with a large cavity filled with mucus in the middle; and gradually this exterior shell turns thicker, the cavity decreases, the quantity of mucus is lessened, and this induration proceeds till all the body is formed; from which the roots are afterwards produced.

In young subjects, different stamina, or rudiments of teeth, are to be observed. Those next the gums hinder ordinarily the deeper-seated ones from making their way out, while these prevent the former from sending out roots, or from entering deep into the bony sockets of the jaws; by which they come to be less fixed.

Children are seldom born with teeth; but at two

years of age they have twenty; and their number does not increase till they are about seven years old, when the teeth that first made their way through the gums are thrust out by others that have been formed deeper in the jaw, and some more of the teeth begin to discover themselves farther back in the mouth. About fourteen years of age, some more of the first crop are shed, and the number is increased.—This shedding of the teeth is of good use; for if the first had remained, they would have stood at a great distance one from another; because the teeth are too hard in their outer crust, to increase so fast as the jaws do. Whereas both the second layer, and the teeth that come out late, meeting, while they are soft, with a considerable resistance to their growth in length, from those situated upon them, necessarily come out broad, and fit to make that close guard to the mouth, which they now form.

The teeth are joined to the sockets by gomphosis, and the gums contribute to fix them there; as is evident by the teeth falling out when the gums are any way destroyed, or made too spongy; as in the scurvy or salivations: Whence some clais this articulation with the *symplocosis*.

The uses of the teeth are to masticate our aliment, and to assist us in the pronunciation of several letters.

Though the teeth so far agree in their structure, yet, because of some things wherein they differ, they are generally divided into three classes, *viz. incisores, canini, and molares*.

The incisores, are the four fore-teeth in each jaw, receiving their name from their office of cutting our aliment; for which they are excellently adapted, being each formed into a sharp-cutting edge at their base, by their fore-side turning inwards there, while they are sloped down and hollowed behind; so that they have the form of wedges; and therefore their power of acting must be considerably increased.

The incisores of the upper jaw, especially the two middle ones, are broader and longer generally than those of the under jaw.

Canini, from the resemblance to dogs tusks, are one on each side of the incisores in each jaw.—The two in the upper jaw are called *eye-teeth*, from the communication of nerves which is said to be betwixt them and the eyes.—The two in the lower jaw are named *angular*, or *wike-teeth*, because they support the angles of the mouth.

The canini are broader, longer, and stronger, than the incisores.—Their bases are formed into a sharp edge, as the incisores are; only that the edge rises into a point in the middle.—Each of them has generally but one long root, though sometimes they have two. The roots are crooked towards the end.—The canini of the upper jaw are larger, longer, and with more crooked roots, than those of the under jaw.

The dentes molares, or grinders, which have got their name because they grind our food, are generally five in each side of each jaw; in all twenty. Their bases are broader, more scabrous, and with a thinner cortical substance, than the other teeth. They have also more

T 1 roots,

roots, and as these roots generally divaricate from each other, the partitions of the sockets between them bear a large share of the great pressure they suffer, and hinder it to act on their points.

The numerous roots of the dentes molares prevent their loosening by the lateral pressure they suffer in grinding; and as the sockets in the upper jaw are more spongy, and the teeth are more liable, by their situation, to fall out, the grinders there have more numerous and more separated roots than in the lower jaw.

According to the division made of the skeleton, we should now proceed to the description of the trunk of the body. But must first consider a bone, which cannot well be said to belong to either the head or the trunk; nor is it immediately joined to any other, and therefore is very seldom preserved with skeletons.

The Os HYOIDES, which is situated horizontally between the root of the tongue and the larynx. It is properly enough named *hyoides*, from the resemblance it bears to the Greek letter *v*, and may, for a clearer demonstration of its structure, be distinguished into its body, cornua, and appendices.

The body is the middle broad part, convex before, and hollow behind.—The convex fore-part is divided into two, by a ridge, into the middle of which the mylo-hyoidei, and into the sides the stylo-hyoidei, muscles are inserted.—Above the ridge, the bone is horizontal, but pitted in the middle by the insertion of the two genio-hyoidei muscles, and a little hollowed more laterally by the basiglossi.—Below the ridge, it is convex, but a little flattened in the middle by the sterno-hyoidei, and pitted more externally by the coraco-hyoidei.—The concavity behind faces backwards and downwards to receive the thyroid cartilage, when the larynx and the os hyoides are pulled towards each other by the action of the sterno-hyoidei and hyothyroidei muscles; and to its upper edge, the ligamentous membranes of the epiglottis, tongue, and thyroid cartilage, are fixed.

The cornua of the os hyoides are stretched backwards from each side of its body, where often a small furrow points out the former separation.—These cornua are not always straight, nor of equal length; their two plain surfaces stand obliquely sloping from above, outwards and downwards.—Into the external, the cerato glossus is inserted above, and the thyro-hyoideus muscle below; and to the one behind, the ligamentous membrane of the tongue and larynx adheres. Each of the cornua becomes gradually smaller, as it is extended from the base; but ends in a round tubercle, from which a moveable cartilage stands out, which is connected to the upper process of the cartilago thyroidea.

Where the body of the os hyoides joins on each side with its cornua, a small styliform process, called *appendix*, rises upwards and backwards, into which the musculi stylo-hyoidei alteri, and part of the hyo-glossi muscles are fixed.

The substance of the os hyoides is cellular, but covered with a firm external plate, which is of sufficient strength to bear the actions of so many muscles as are inserted into it.

It is not articulated with any bone of the body, ex-

cept by means of the muscles and ligaments mentioned.

The use of the os hyoides, is to serve as a solid lever for the muscles to act with, in raising or depressing the tongue and larynx, or in enlarging and diminishing the capacity of the fauces.

## OF THE TRUNK.

THE TRUNK consists of the *spine, pelvis, and thorax.*

THE SPINE is the long pile of bones extended from the condyles of the occiput to the end of the rump. It somewhat resembles two unequal pyramids joined in a common base. It is not, however, straight; for its upper part being drawn backwards by strong muscles, it gradually advances forwards, to support the œsophagus, vessels of the head, &c. Then it turns backwards, to make place enough for the heart and lungs. It is next bended forwards, to support the viscera of the abdomen. It afterwards turns backwards, for the enlargement of the pelvis. And, lastly, it is reflected forwards, for sustaining the lowest great gut.

The spine is commonly divided into true and false vertebrae; the former constituting the long upper pyramid, which has its base below, while the false vertebrae make the shorter lower pyramid, whose base is above.

THE TRUE VERTEBRÆ are the twenty-four upper bones of the spine, on which the several motions of the trunk of our bodies are performed; from which use they have justly got their name.

Each of these vertebrae is composed of its body and processes.

The body is the thick spongy fore-part, which is convex before, concave backwards, horizontal and plain in most of them above and below.—Numerous small holes, especially on the fore and back-part of their surface, give passage to their vessels, and allow the ligaments to enter their substance.—The edges of the body of each vertebra are covered, especially at the fore-part, with a ring of bone firmer and more solid than the substance of the body any where else. These rings are of great use in preventing the spongy bodies from being broken in the motions of the trunk.

Between the bodies of two adjoining vertebrae, a substance between the nature of ligament and cartilage is interposed; which seems to consist of concentric curve fibres, when it is cut horizontally; but when it is divided perpendicularly, the fibres appear oblique and decussating each other.—The outer part of the intervertebral ligaments is the most solid and hard; and they gradually become softer till they are almost in the form of a glairy liquor in the centre; and therefore these substances were not improperly called *mucous ligaments* by the ancients. The external fibrous part of each is capable of being greatly extended, and of being compressed into a very small space, whilst the middle fluid part is incompressible, or nearly so; and the parts of this ligament between the circumference and centre approach in their properties to either, in proportion to their more solid

or more fluid texture. The middle point is therefore a fulcrum or pivot, on which the motion of a ball and socket may be made, with such a gradual yielding of the substance of the ligament, in whichever direction our spines are moved, as saves the body from violent shocks, and their dangerous consequences.—This ligamentocartilaginous substance is firmly fixed to the horizontal surfaces of the bodies of the vertebrae, to connect them, in which it is assisted by a strong membranous ligament, which lines all their concave surface, and by still a stronger ligament, that covers all their anterior convex surface.

From each side of the body of each vertebra, a bony bridge is produced backwards, and to a side; from the posterior end of which, one slanting process rises and another descends; the smooth, and what is generally the flattest side of each of these four processes, which are called the *oblique*, is covered with a smooth cartilage; and the two lower ones of each vertebra, are fitted to, and articulated with the two upper or ascending oblique processes of the vertebra below, having their articular ligaments fixed into the rough line round their edges.

From between the oblique processes of each side the vertebra is stretched out laterally into a process that is named *transverse*.

From the back-part of the roots of the two oblique, and of the transverse process of each side, a broad oblique bony plate is extended backwards, where these meet, the seventh process of the vertebra takes its rise, and stands out backwards: This being generally sharp pointed, and narrow edged, has therefore been called *spinal* process; from which this whole chain of bones has got its name.

Besides the common ligament which lines all the internal surface of the spinal processes, as well as of the bodies, there are particular ligaments that connect the bony bridges and processes of the contiguous vertebrae together.

The substance of the processes is considerably stronger and firmer, and has a thicker external plate than the bodies of the vertebrae have.

The seven processes form a concavity at their fore-part, which, joined to the one at the back-part of the bodies, makes a great hole, and the holes of all the vertebrae form a long large conduit, for containing the spinal marrow.—In the upper and lower edge of each lateral bridge, there is a notch. These are so adapted to each other in the contiguous vertebrae, as to form a round hole in each side between each two vertebrae, through which the nerves that proceed from the spinal marrow and its blood-vessels pass.

The articulations of these true vertebrae are plainly double; for their bodies are joined by the intervening cartilage above described, and their oblique processes being tipped with cartilages, are so connected by their ligaments, as to allow a small degree of motion to all sides.

The true vertebrae serve to give us an erect posture; to allow sufficient and secure motion to the head, neck, and trunk of the body, and to support and defend the bowels, and other soft parts.

Though the true vertebrae agree in the general structure which we have hitherto described; yet because of several specialities proper to a particular number, they are commonly divided into three classes, viz. *cervical*, *dorsal*, and *lumbar*.

The cervical are the seven uppermost vertebrae; which are distinguished from the rest by these marks.—Their bodies are smaller and more solid than any others, and flatted on the fore-part, to make way for the œsophagus; or rather this flat figure is owing to the pressure of that pipe, and to the action of the longi colli and anterior recti muscles.—They are also flat behind, where small processes rise, to which the internal ligaments are fixed.—The upper surface of the body of each vertebra is made hollow, by a slanting thin process which is raised on each side:—The lower surface is also excavated, but in a different manner; for here the posterior edge is raised a little, and the one before is produced a considerable way.—Hence we see how the cartilages between those bones are firmly connected, and their articulations are secure.

The cartilages between these vertebrae are thick, especially at their fore-part; which is one reason why the vertebrae advance forward as they descend, and have larger motion.

The oblique processes of these bones of the neck more justly deserve that name than those of any other vertebrae. They are situated slanting; the upper ones having their smooth and almost flat surfaces facing obliquely backwards and upwards, while the inferior oblique processes have their surfaces facing obliquely forwards and downwards.

The transverse processes of these vertebrae are framed in a different manner from those of any other bones of the spine: For besides the common transverse process rising from between the oblique processes of each side, there is a second one that comes out from the side of the body of each vertebra; and these two processes, after leaving a circular hole for the passage of the cervical artery and vein, unite, and are considerably hollowed at their upper part, with rising sides, to protect the nerves that pass in the hollow; and at last each side terminates in an obtuse point, for the insertion of muscles.

The spinal processes of these cervical bones stand nearly straight backwards, are shorter than those of any other vertebrae, and are forked or double at their ends; and hence allow a more convenient insertion to muscles.

So far most of the cervical vertebrae agree; but they have some particular differences, which oblige us to consider them separately.

The first, from its use of supporting the head, has the name of *atlas*; and is also called *epistrophe*, from the motion it performs on the second.

The atlas, contrary to all the other vertebrae of the spine, has no body; but, instead of it, there is a bony arch.—In the convex fore-part of which, a small rising appears, where the muscoli longi colli are inserted; and, on each side of this protuberance, a small cavity may be observed, where the recti interni minores take their rise.—The upper and lower parts of the arch are rough and unequal, where the ligaments that connect

connect this vertebra to the os occipitis, and to the second vertebra, are fixed.—The back-part of the arch is concave, smooth, and covered with a cartilage, in a recent subject, to receive the tooth-like process of the second vertebra.—In a first vertebra, from which the second has been separated, this hollow makes the passage for the spinal marrow to seem much larger than it really is: On each side of it a small rough sinuosity may be remarked, where the ligaments going to the sides of the tooth-like process of the following vertebra are fastened; and on each side, a small rough protuberance and depression is observable, where the transverse ligament, which secures the tooth-like process in the sinuosity, is fixed, and hinders that process from injuring the medulla spinalis in the flexions of the head.

The atlas has as little spinal process as body; but instead thereof, there is a large bony arch, that the muscles which pass over this vertebra at that place might not be hurt in extending the head.

The superior oblique processes of this atlas are large, oblong, hollow, and more horizontal than in any other vertebra.—They rise more in their external than internal brim; by which their articulations with the condyloid of the os occipitis are firmer.—Under the external edge of each of these oblique processes, is the fossa, or deep open channel, in which the vertebral arteries make the circular turn, as they are about to enter the great foramen of the occipital bone, and where the tenth pair of nerves goes out.—The inferior oblique processes extending from within outwards and downwards, are large, concave, and circular. So that this vertebra, contrary to the other fix, receives the bones with which it is articulated both above and below.

The transverse processes here are not much hollowed or forked, but are longer and larger than those of any other vertebra of the neck, for the origin and insertion of several muscles.

The hole for the spinal marrow is larger in this than in any other vertebra, not only on account of the marrow being largest here, but also to prevent its being hurt by the motions of this vertebra on the second one.—This large hole, and the long transverse processes, make this the broadest vertebra of the neck.

The condyles of the os occipitis move forwards and backwards in the superior oblique processes of this vertebra; but from the figure of the bones forming these joints, it appears, that very little motion can here be allowed to either side; and there must be still less circular motion.

The second vertebra colli is called *dentata*, from the tooth-like process on the upper part of its body.

The body of this vertebra is somewhat pyramidal, being large, and produced downwards, especially at its fore-side, to enter into a hollow of the vertebra below; while the upper part has a square process with a small point standing out from it. This it is that is imagined to resemble a tooth, and has given name to the vertebra.—The side of this process, on which the hollow of the anterior arch of the first vertebra plays, is convex, smooth, and covered with a cartilage; and it is of the same form behind, for the ligament, which is extended

transversely from one rough protuberance of the first vertebra to the other, and is cartilaginous in the middle, to move on it.

The superior oblique processes of this vertebra dentata are large, circular, very nearly in an horizontal position, and slightly convex, to be adapted to the inferior oblique processes of the first vertebra.

The transverse processes of the vertebra dentata are short, very little hollowed at their upper part, and not forked at their ends; and the canals through which the cervical arteries pass, are reflected outwards about the middle substance of each process; so that the course of these vessels may be directed towards the transverse processes of the first vertebra.

The spinal process of this vertebra tendata is thick, strong, and short, to give sufficient origin to the musculi recti majores, and obliqui inferiores, and to prevent the contusion of these and other muscles in pulling the head back.

The third vertebra of the neck is by some called *axis*; but this name is applied to it with much less reason than to the second.—This third, and the three below, have nothing particular in their structure; but all their parts come under the general description formerly given, each of them being larger as they descend.

The seventh vertebra of the neck is near to the form of those of the back, having the upper and lower surfaces of its body less hollow than the others:—The oblique processes are more perpendicular;—neither spinal nor transverse processes are forked.—This seventh and the sixth vertebra of the neck have the hole in each of their transverse processes, more frequently divided by a small cross bridge, that goes between the cervical vein and artery, than any of the other vertebrae.

The twelve dorsal may be distinguished from the other vertebrae of the spine by the following marks.

Their bodies are of a middle size, betwixt those of the neck and loins;—they are more convex before than either of the other two sorts; and are flattened laterally by the pressure of the ribs, which are inserted into small cavities formed in their sides. This flattening on their sides, which makes the figure of these vertebrae almost an half oval, is of good use; as it affords a firm articulation to the ribs, allows the trachea arteria to divide at a small angle, and the other large vessels to run secure from the action of the vital organs.—These bodies are more concave behind than any of the other two classes.—Their upper and lower surfaces are horizontal.

The cartilages interposed between the bodies of these vertebrae are thinner than in any other of the true vertebrae; and contribute to the concavity of the spine in the thorax, by being thinnest at their fore-part.

The oblique processes are placed almost perpendicular; the upper ones slanting but a little forwards, and the lower ones slanting as much backwards.—They have not as much convexity or concavity as is worth remarking.—Between the oblique processes of opposite sides, several sharp processes stand out from the upper and lower parts of the plates which join to form the spinal process; into these sharp processes strong ligaments are fixed, for connecting the vertebrae.

The transverse processes of the dorsal vertebrae are long, thicker at their ends than in the middle, and turned obliquely backwards.

The spinal processes are long, small pointed, and sloping downwards and backwards; from their upper and back-part a ridge rises, which is received by a small channel in the fore-part of the spinal process immediately above, which is here connected to it by a ligament.

The conduit of the spinal marrow is here more circular, but, corresponding to the size of that cord, is smaller than in any of the other vertebrae, and a larger share of the holes in the bony bridges, for the transmission of the nerves, is formed in the vertebra above, than in the one below.

The connection of the dorsal vertebrae to the ribs, the thinness of their cartilages, the erect situation of the oblique processes, the length, sloping, and connection of the spinal processes, all contribute to restrain these vertebrae from much motion, which might disturb the actions of the heart and lungs; and, in consequence of the little motion allowed here, the intervertebral cartilages sooner shrivel, by becoming more solid: And therefore, the first remarkable curvature of the spine observed, as people advance to old age, is in the least stretched vertebrae of the back; or old people first become round-shouldered.

The bodies of the four uppermost dorsal vertebrae deviate from the rule of the vertebrae, becoming larger as they descend; for the first of the four is the largest, and the other three below gradually become smaller, to allow the trachea and large vessels to divide at smaller angles.

The two uppermost vertebrae of the back, instead of being very prominent forwards, are flattened by the action of the musculi longi colli and recti majores.

The proportional size of the two little depressions in the body of each vertebra, for receiving the heads of the ribs, seems to vary in the following manner; the depression on the upper edge of each vertebra decreases as far down as the fourth, and after that increases.

The transverse processes are longer in each lower vertebra to the seventh or eighth, with their smooth surfaces, for the tubercles of the ribs, facing gradually more downwards; but afterwards, as they descend, they become shorter, and the smooth surfaces are directed more upwards.

The spinous processes of the vertebrae of the back become gradually longer and more slanting from the first, as far down as the eighth or ninth vertebra; from which they manifestly turn shorter and more erect.

The first vertebra, besides an oblong hollow in its lower edge, that assists in forming the cavity wherein the second rib is received, has the whole cavity for the head of the first rib formed in it.

The second has the name of *axillary*, without any thing particular in its structure.

The eleventh often has the whole cavity for the eleventh rib in its body, and wants the smooth surface on each transverse process.

The twelfth always receives the whole head of the last rib, and has no smooth surface on its transverse processes, which are very short.—The smooth surfaces of its inferior oblique processes face outwards as the lumbar do.

—And we may say in general, that the upper vertebrae of the back lose gradually their resemblance to those of the neck, and the lower ones come nearer to the figure of the lumbar.

The lowest order of the true vertebrae is the lumbar, which are five bones, that may be distinguished from any others by these marks: 1. Their bodies, though of a circular form at their fore-part, are somewhat oblong from one side to the other; which may be occasioned by the pressure of the large vessels, the aorta and cava, and of the viscera. The epiphyses on their edges are larger, and therefore the upper and lower surfaces of their bodies are more concave than in the vertebrae of the back. 2. The cartilages between these vertebrae are much the thickest of any, and render the spine convex within the abdomen, by their greatest thickness being at their fore-part. 3. The oblique processes are strong and deep; those in opposite sides being almost placed in parallel planes; the superior, which are concave, facing inwards, and the convex inferior ones facing outwards: and therefore each of these vertebrae receives the one above it, and is received by the one below; which is not so evident in the other two classes already described. 4. Their transverse processes are small, long, and almost erect, for allowing large motion to each bone, and sufficient insertion to muscles, and for supporting and defending the internal parts. 5. Betwixt the roots of the superior oblique and transverse processes, a small protuberance may be observed, where some of the muscles that raise the trunk of the body are inserted. 6. Their spinal processes are strong, straight, and horizontal, with broad flat sides, and a narrow edge above and below; this last being depressed on each side by muscles. And at the root of these edges, we see rough surfaces for fixing the ligaments. 7. The canal for the numerous cords, called *cauda equina*, into which the spinal marrow divides, is rather larger in these bones than what contains that marrow in the vertebrae of the back. 8. The holes for the passage of the nerves are more equally formed out of both the contiguous vertebrae than in the other classes; the upper one furnishes however the larger share of each hole.

The thick cartilages between these lumbar vertebrae, their deep oblique processes, and their erect spinal processes, are all fit for allowing large motion; though it is not so great as what is performed in the neck; which appears from comparing the arches which the head describes when moving on the neck, or the loins only.

The lumbar vertebrae, as they descend, have their oblique processes at a greater distance from each other, and facing more backwards and forwards.

Both transverse and spinal processes of the middlemost vertebrae of the loins are longest and thickest; in the vertebrae above and below they are less: so that these processes of the first and fifth are the least, to prevent their striking on the ribs or ossa ilium, or their bruising the muscles in the motions of the spine.

The epiphyses round the edges of the bodies of the lumbar vertebrae are most raised in the two lowest, which consequently make them appear hollower in the middle than the others are.

The body of the fifth vertebra is rather thinner than that of the fourth.—The spinal process of this fifth is smaller, and the oblique processes face more backwards and forwards than in any other lumbar vertebra.

The FALSE VERTEBRÆ compose the under pyramid of the spine. They are distinguished from the bones already described justly enough by this epithet of *false*; because, though each bone into which they can be divided in young people, resembles the true vertebra in figure, yet none of them contribute to the motion of the trunk of the body; they being intimately united to each other in adults, except at their lower part, where they are moveable; whence they are commonly divided into two bones, *os sacrum* and *coccygis*.

OS SACRUM, is so called from being offered in sacrifice by the ancients, is of an irregular triangular shape, broad above, narrow below, convex behind, for the advantageous origin of the muscles that move the spine and thigh backwards; and concave behind, for enlarging the cavity of the pelvis.—Four transverse lines of a colour different from the rest of the bone, which are seen on its fore-part, are the marks of division of the five different bones of which it consists in young persons.

The fore-part of the os sacrum is smooth and flat, to allow a larger space for the contained bowels, without any danger of hurting them.—The back-part of it is almost straight, without so large a cavity as the vertebrae have.—The bridges between the bodies and processes of this bone, are much thicker, and in proportion shorter, than in the former class of bones.—The strength of these cross-bridges is very remarkable in the three upper bones, and is well-proportioned to the incumbent weight of the trunk of the body, which these bridges sustain in a transverse, consequently an unfavourable, situation, when the body is erect.

There are only two oblique processes of the os sacrum; one standing out on each side from the upper part of the first bone.—Their plain erect surfaces face backwards, and are articulated with the inferior oblique processes of the last vertebra of the loins, to which each of these processes is connected by a strong ligament, which rises from a scabrous cavity round their roots, where mucilaginous glands are also lodged.—Instead of the other oblique processes of this bone, four rough tubercles are to be seen on each side of its surface behind, from which the *muculus sacer* has its origin.

The transverse processes here are not grown together into one large strong oblong process on each side; which, so far as it answers to the first three bones, is very thick, and divided into two irregular cavities, by a long perpendicular ridge.—The foremost of the two cavities has commonly a thin cartilaginous skin covering it in the recent subject, and is adapted to the unequal protuberance of the os ilium, and a strong ligament connects the circumference of these surfaces of the two bones.—The cavity behind is divided by a transverse ridge into two, where strong ligamentous strings that go from this bone to the os ilium, with a cellular substance containing mucus, are lodged.

The transverse processes of the two last bones of the

os sacrum are much smaller than the former.—At their back-part, near their edge, a knob and oblong flat surface give rise to two strong ligaments which are extended to the os ischium; and are therefore called *sacro-sciatici*.

The spinal processes of the three uppermost bones of the os sacrum appear short, sharp, and almost erect, while the two lower ones are open behind; and sometimes a little knob is to be seen on the fourth, though generally it is bifurcated, without the two legs meeting into a spine; in which condition also the first is often to be seen. The *muculus latissimus*, and *longissimus dorsi*, *sacro-lumbalis*, and *glutæus maximus*, have part of their origins from these spinal processes.

The canal between the bodies and processes of this bone, for the cauda equina, is triangular; and becomes smaller as it descends, as the cauda also does.—Below the third bone, this passage is no more a complete bony canal, but is open behind; and is only there defended by a strong ligamentous membrane stretched over it, which, with the muscles that cover it, and are very prominent on each side, is a sufficient defence for the bundle of nerves within.

At the root of each oblique process of this bone, the notch is conspicuous, by which, and such another in the last vertebra of the loins, a passage is left for the twenty-fourth spinal nerve; and, in viewing the os sacrum, either before or behind, four large holes appear in each side, in much the same height, as where the marks of the union of its several bones remain. Some of the largest nerves of the body pass through the anterior holes; and superficial grooves running outwards from them in different directions, shew the course of these nerves.—From the intervals of these grooves, the *pyriformis* muscle chiefly rises.—The holes in the back-part of the bone are covered by membranes which allow small nerves to pass through them.—The two uppermost of these holes, especially on the fore-side, are the largest; and as the bone descends, the holes turn smaller. Sometimes a notch is only formed at the lower part in each side of this bone; and in other subjects there is a hole common to it and the os coccygis, through which the twenty-ninth pair of spinal nerves passes; and frequently a bony bridge is formed on the back-part of each side by a process sent up from the back-part of the os coccygis, and joined to the little knobs which the last bone of the os sacrum has instead of a spinal process. Under this bridge or jugum, the twenty-ninth pair of spinal nerves runs in its course to the common holes just now described.

The substance of the os sacrum is very spongy, without any considerable solid external plates, and is lighter proportionally to its bulk than any other bone in the body; but is secured from injuries by the thick muscles that cover it behind, and by the strong ligamentous membranes that closely adhere to it.

This bone is articulated above to the last vertebra of the loins, in the manner that the lumbar vertebrae are joined; and therefore the same motions may be performed here.—The articulation of the lower part of the os sacrum to the os coccygis seems well enough adapted for  
allowing

allowing considerable motion to this last bone, was it not much confined by ligaments. Laterally, the os sacrum is joined to the ossa ilium by an immovable synchondrosis.

The uses of the os sacrum are, to serve as the common base and support of the trunk of the body, to guard the nerves proceeding from the end of the spinal marrow, to defend the back-part of the pelvis, and to afford sufficient origin to the muscles which move the trunk and thigh.

Os COCCYGIS, or *rump-bone*, is that triangular chain of bones depending from the os sacrum; each bone becoming smaller as they descend, till the last ends almost in a point. The os coccygis is convex behind, and concave before; from which crooked pyramidal figure, which was thought to resemble a cuckow's beak, it has got its name.

This bone consists of four pieces in people of middle age:—In children, very near the whole of it is cartilage: In old subjects, all the bones are united, and become frequently one continued bone with the os sacrum.

The highest of the four bones is the largest, with shoulders extended farther to each side than the end of the os sacrum;—the upper surface of this bone is a little hollow.——From the back of that bulbous part called its *shoulders*, a process often rises up on each side, to join with the bifurcated spine of the fourth and fifth bones of the os sacrum, to form the bony bridge mentioned in the description of the os sacrum.——Immediately below the shoulders of the os coccygis, a notch may be remarked in each side, where the thirtieth pair of the spinal nerves passes.——The lower end of this bone is formed into a small head, which very often is hollow in the middle.

The three lower bones gradually become smaller, and are spongy; but are strengthened by a strong ligament which covers and connects them.——Their ends, by which they are articulated, are formed in the same manner as those of the first bone are.

The lower end of the fourth bone terminates in a rough point, to which a cartilage is appended.

To the sides of these bones of the os coccygis, the coccygei muscles, and part of the levatores ani, and of the glutæi maximi, are fixed.

The os coccygis serves to sustain the intestinum rectum; and, in order to perform this office more effectually, it is made to turn with a curve forwards; by which also the bone itself, as well as the muscles and teguments, is preserved from any injury, when we sit with our body reclined back.

The *second* part of the trunk of the skeleton, the PELVIS, is the cylindrical cavity at the lower part of the abdomen, formed by the os sacrum, os coccygis, and ossa innominata; which last therefore fall now in course to be examined.

The OSSA INNOMINATA are two large broad bones, which form the fore-part and sides of the pelvis, and the lower part of the sides of the abdomen.—In children each of these bones is evidently divided into three; which are afterwards so intimately united, that scarce

the least mark of their former separation remains: notwithstanding, they are described as consisting each of three bones, to wit, the os ilium, ischium, and pubis.

OS ILIUM, or *haunch-bone*, is situated highest of the three, and reaches as far down as one third of the great cavity into which the head of the thigh-bone is received.

The external side of this bone is unequally convex, and is called its *dorsum*;—the internal concave surface is by some (but improperly) named *costa*.——The semicircular edge at the highest part of this bone, which is tipped with a cartilage in the recent subject, is named the *spine*, into which the external or descending oblique muscle of the abdomen is inserted; and from it the internal ascending oblique and the transverse muscles of the belly, with the glutæus maximus, quadratus lumborum, and latissimus dorsi, have their origin.——The ends of the spine are more prominent than the surface of the bone below them; therefore are reckoned processes.——From the anterior spinal process, the sartorius and facialis muscles have their rise, and the outer end of the doubled tendon of the external oblique muscle of the abdomen, commonly called *Fallopian's* or *Poupart's* ligament, is fixed to it.——The inside of the posterior spinal process, and of part of the spine forward from that, is made flat and rough where the sacro-lumbalis and longissimus dorsi rise; and to its outside ligaments, extended to the os sacrum and transverse processes of the fifth and fourth vertebræ of the loins, are fixed.——Below the anterior spinal process another protuberance stands out, which, by its situation, may be distinguished from the former, by adding the epithet of *inferior*, where the musculus rectus tibiæ has its origin.——Betwixt these two anterior processes the bone is hollowed where the beginning of the sartorius muscle is lodged.——Below the posterior spinal process, a second protuberance of the edge of this bone is in like manner observable, which is closely applied to the os sacrum.——Under this last process a considerable large niche is observable in the os ilium; between the sides of which and the strong ligament that is stretched over from the os sacrum to the sharp-pointed process of the os ischium of the recent subject, a large hole is formed, through which the musculus pyriformis, the great sciatic nerve, and the posterior crural vessels, pass, and are protected from compression.

The external broad side, or dorsum of the os ilium, is a little hollow towards the fore part; farther back it is as much raised; then is considerably concave; and, lastly, it is convex. These inequalities are occasioned by the actions of the muscles that are situated on this surface.——From behind the uppermost of the two anterior spinal processes, in such bones as are strongly marked by the muscles, a semicircular ridge is extended to the hollow passage of the sciatic nerve. Between the spine and this ridge, the glutæus medius takes its rise. Immediately from above the lowest of the anterior spinal processes, a second ridge is stretched to the niche. Between this and the former ridge, the glutæus minimus has its origin.——On the outside of the posterior spinal processes, the dorsum of the os ilium is flat and rough, where part of the musculus glutæus maximus and pyriformis rises.——The lowest part of this bone is the thickest, and is formed into a large

large cavity with high brims, to assist in composing the great acetabulum.

The internal surface of the os ilium is concave in its broadest fore part, where the internal iliac muscle has its origin, and some share of the intestinum ilium and colica is lodged.—From this large hollow, a small sinuosity is continued obliquely forwards, at the infide of the anterior inferior spinal process, where part of the psoas and iliacus muscles, with the crural vessels and nerves, pass.—The large concavity is bounded below by a sharp ridge, which runs from behind forwards, and, being continued with such another ridge of the os pubis, forms a line of partition between the abdomen and pelvis.—Into this ridge the broad tendon of the psoas parvus is inserted.

All the internal surface of the os ilium, behind this ridge, is very unequal: For the upper part is flat, but spongy, where the sacro-lumbalis and longissimus dorsi rise.—Lower down, there is a transverse ridge from which ligaments go out to the os sacrum.—Immediately below this ridge, the rough unequal cavities and prominences are placed, which are exactly adapted to those described on the side of the os sacrum.—In the same manner, the upper part of this rough surface is porous, for the firmer adhesion of the ligamentous cellular substance; while the lower part is more solid, and covered with a thin cartilaginous skin, for its immoveable articulation with the os sacrum.

Os ISCHIUM, or *hip-bone*, is of a middle bulk between the two other parts of the os innominatum, is situated lowest of the three, and is of a very irregular figure.—Its extent might be marked by an horizontal line drawn near through the middle of the acetabulum; for the upper bulbous part of this bone forms some less than the lower half of that great cavity, and the small leg of it rises to much the same height on the other side of the great hole common to this bone and the os pubis.

From the upper thick part of the os ischium, a sharp process, called by some *spinous*, stands out backwards, from which chiefly the musculus coccygeus and superior gemellus, and part of the levator ani, rise; and the anterior or internal sacrosciatic ligament is fixed to it.—Immediately below this process, a sinuosity is formed for the tendon of the musculus obturator internus.—In a recent subject, this part of the bone, which serves as a pulley on which the obturator muscle plays, is covered with a ligamentous cartilage, that, by two or three small ridges, points out the interitices of the fibres in the tendon of this muscle.—The outer surface of the bone at the root of this spinous process is made hollow by the pyriformis, or iliacus externus muscle.

Below the sinuosity for the obturator muscle, is the great knob or tuberosity, covered with cartilage or tendon.—The upper part of the tuberosity gives rise to the inferior gemellus muscle.—To a ridge at the infide of this, the external or posterior sacrosciatic ligament is so fixed, that between it, the internal ligament, and the sinuosity of the os ischium, a passage is left for the internal obturator muscle.—The upper thick smooth part of the tuber, called by some its *dorsum*, has two oblique impressions on it. The inner one gives origin to

the long head of the biceps flexor tibiae and femineus muscles, and the femimembranosus rises from the exterior one, which reaches higher and nearer the acetabulum than the other.—The lower, thinner, more scabrous part of the knob which bends forwards, is also marked with two flat surfaces, whereof the internal is what we lean upon in sitting, and the external gives rise to the largest head of the triceps adductor femoris.—Between the external margin of the tuberosity, and the great hole of the os innominatum, there is frequently an obtuse ridge extended down from the acetabulum, which gives origin to the quadratus femoris.—As the tuber advances forwards, it becomes smaller, and is rough, for the origin of the musculus transversalis and erector penis.—The small leg of it, which mounts upwards to join the os pubis, is rough and prominent at its edge, where the two lower heads of the triceps or quadriceps adductor femoris take their rise.

The upper and back part of the os ischium is broad and thick; but its lower and fore-part is narrower and thinner.

The os ilium and pubis of the same side are the only bones which are contiguous to the os ischium.

The Os PUBIS, or *share-bone*, is the least of the three parts of the os innominatum, and is placed at the upper fore-part of it.—The thick largest part of this bone is employed in forming the acetabulum; from which, becoming much smaller, it is stretched inwards to its fellow of the other side, where again it grows larger, and sends a small branch downwards to join the end of the small leg of the os ischium.—The upper fore-part of each os pubis is tuberos and rough where the musculus rectus and pyramidalis are inserted.—From this a ridge is extended along the upper edge of the bone, in a continued line with such another of the os ilium, which divides the abdomen and pelvis. The ligament of Fallopius is fixed to the internal end of this ridge, and the smooth hollow below it is made by the psoas and iliacus internus muscles passing with the anterior crural vessels and nerves behind the ligament.—Some way below the former ridge, another is extended from the tuberos part of the os pubis downwards, and outwards towards the acetabulum; between these two ridges the bone is hollow and smooth, for lodging the head of the pectineus muscle.—Immediately below, where the lower ridge is to take the turn downwards, a winding notch is made, which is comprehended in the great foramen of a skeleton, but is formed into a hole by a subtended ligament in the recent subject, for the passage of the posterior crural nerve, an artery, and a vein.—The internal end of the os pubis is rough and unequal, for the firmer adhesion of the thick ligamentous cartilage that connects it to its fellow of the other side:—The process which goes down from that to the os ischium is broad and rough before, where the gracilis and upper heads of the triceps, or rather quadriceps adductor femoris, have their origin.

Between the os ischium and pubis a very large irregular hole is left, which, from its resemblance to a door or shield, has been called *thyroides*. This hole is all, except the notch for the posterior crural nerve, filled up, in a recent subject, with a strong ligamentous membrane, that

that adheres very firmly to its circumference. From this membrane chiefly the two obturator muscles, external and internal, take their rise.—The great design of this hole, besides rendering the bone lighter, is to allow a strong enough origin to the obturator muscles, and sufficient space for lodging their bellies, that there may be no danger of disturbing the functions of the contained viscera of the pelvis by the actions of the internal, nor of the external being bruised by the thigh-bone, especially by its lesser trochanter, in the motions of the thigh inwards.—The bowels sometimes make their way through the niche for the vessels, at the upper part of this thyroid hole, which causes a hernia in this place.

In the external surface of the ossa innominata, near the outside of the great hole, a large deep cavity is formed by all the three bones conjunctly: For the os pubis constitutes about one fifth; the os ilium makes something less than two fifths, and the os ischium as much more than two fifths. The brims of this cavity are very high, and are still much more enlarged by the ligamentous cartilage, with which they are tipped in a recent subject. From this form of the cavity it has been called *acetabulum*; and, for a distinguishing character, the name of the bone that constitutes the largest share of it is added; therefore *acetabulum ossis ischii* is the name this cavity commonly bears.—Round the base of the supercilia the bone is rough and unequal, where the capsular ligament of the articulation is fixed.—The brims at the upper and back-part of the acetabulum are much larger and higher than any where else; which is very necessary to prevent the head of the femur from slipping out of its cavity at this place, where the whole weight of the body bears upon it, and consequently would otherwise be constantly in danger of thrusting it out.—As these brims are extended downwards and forwards, they become less; and at their internal lower part a breach is made in them; from the one side of which to the other, a ligament is placed in the recent subject; under which a large hole is left, which contains a fatty cellular substance and vessels.—Besides this difference in the height of the brims, the acetabulum is otherwise unequal: For the lower internal part of it is depressed below the cartilaginous surface of the upper-part, and is not covered with cartilage; into the upper-part of this particular depression, where it is deepest and of a semilunar form, the ligament of the thigh-bone, commonly called the *round one*, is inserted; while in its more superficial lower part the large mucilaginous gland of this joint is lodged. The largest share of this separate depression is formed in the os ischium.

The ossa innominata are joined at their back-part to each side of the os sacrum by a sort of suture, with a very thin intervening cartilage, which serves as so much glue to cement these bones together; and strong ligaments go from the circumference of this unequal surface to connect them more firmly. The ossa innominata are connected together at their fore-part by the ligamentous cartilage interposed between the two ossa pubis.—These bones can therefore have no motion in a natural state, except what is common to the trunk of the body, or to the os sacrum.

Each os innominatum affords a socket (the acetabulum) for the thigh-bones to move in, and the trunk of the body rolls here so much on the heads of the thigh-bones, as to allow the most conspicuous motions of the trunk, which are commonly thought to be performed by the bones of the spine.

The pelvis then has a large open above where it is continued with the abdomen, is strongly fenced by bones on the sides, back, and fore-part, and appears with a wide opening below, in the skeleton; but, in the recent subject, a considerable part of the opening is filled by the sacrospinous ligaments, pyriform, internal obturator, levatores ani, gemini, and coccygei muscles, which support and protect the contained parts better than bones could have done; so that space is only left at the lowest part of it, for the large excretories, the vesica urinaria, intestinum rectum, and in females, the uterus, to discharge themselves.

The THORAX, or *chest*, reaches from below the neck to the belly; and, by means of the bones that guard it, is formed into a large cavity: The figure of which is somewhat conoidal.

The bones which form the thorax are the twelve dorsal vertebrae behind, the ribs on the sides, and the sternum before.

The vertebrae have already been described as part of the spine.

The RIBS, or *costae*, (as if they were *custodes*, or guards, to those principal organs of the animal machine, the heart and lungs), are the long crooked bones placed at the side of the chest, in an oblique direction downwards in respect of the back-bone.—Their number is generally twelve on each side; though frequently eleven or thirteen have been found.

The ribs are all concave internally; where they are also made smooth by the action of the contained parts, which, on this account, are in no danger of being hurt by them; and they are convex externally, that they might resist that part of the pressure of the atmosphere, which is not balanced by the air within the lungs, during inspiration.—The ends of the ribs next the vertebrae are rounder than they are after these bones have advanced forwards, when they become flatter and broader, and have an upper and lower edge, each of which is made rough by the action of the intercostal muscles, inserted into them.—The upper edge of the ribs is more obtuse and rounder than the lower, which is depressed on its internal side by a long fossa, for lodging the intercostal vessels and nerves; on each side of which there is a ridge, to which the intercostal muscles are fixed. The fossa is not observable however at either end of the ribs: for, at the posterior or root, the vessels have not yet reached the ribs; and, at the fore-end, they are split away into branches, to serve the parts between the ribs.

At the posterior end of each rib, a little head is formed, which is divided by a middle ridge into two plain or hollow surfaces; the lowest of which is the broadest and deepest in most of them. The two plains are joined to the bodies of two different vertebrae, and the ridge forces itself into the intervening cartilage.—

A little way from this head, we find, on the external surface, a small cavity, where mucilaginous glands are lodged; and round the head, the bone appears spongy, where the capsular ligament of the articulation is fixed.

—Immediately beyond this a flattened tubercle rises, with a small cavity at, and roughness about its root, for the articulation of the rib with the transverse process of the lowest of the two vertebrae, with the bodies of which the head of the rib is joined.—Advancing further on this external surface, we observe in most of the ribs another smaller tubercle, into which ligaments which connect the ribs to each other, and to the transverse processes of the vertebrae, and portions of the longissimus dorsi, are inserted.—Beyond this the ribs are made flat by the sacro-lumbalis muscle, which is inserted into the part of this flat surface farthest from the spine, where each rib makes a considerable curve, called by some its *angle*.—Then the rib begins to turn broad, and continues so to its anterior end, which is hollow and spongy, for the reception of, and firm coalition with the cartilage that runs thence to be inserted into the sternum, or to be joined with some other cartilage.

To the fore-end of each rib a long broad and strong cartilage is fixed, and reaches thence to the sternum, or is joined to the cartilage of the next rib. This course, however, is not in a straight line with the rib; for generally the cartilages make a considerable curve, the concave part of which is upwards; therefore, at their insertion into the sternum, they make an obtuse angle above, and an acute one below.—These cartilages, as all others, are firmer and harder internally, than they are on their external surface.

The ribs then are articulated at each end, of which the fore one behind is doubly joined to the vertebrae; for the head is received into the cavities of two bodies of the vertebrae, and the larger tubercle is received into the depression in the transverse process of the lower vertebra.

Hitherto we have laid down the general structure and connection of the ribs, and shall next mark their differences.

In viewing the ribs from above downwards, their figure is still straighter; the uppermost being the most crooked of any.—Their obliquity, in respect of the spine, increases as they descend; so that though their distances from each other is very little different at their back-part, yet at their fore-ends the distances between the lower ones must increase.

The length of the ribs increases from the first and uppermost rib, as far down as the seventh; and from that to the twelfth, as gradually diminishes.—The superior of the two plain, or rather hollow surfaces, by which the ribs are articulated to the bodies of the vertebrae, gradually increases from the first to the fourth rib, and is diminished after that in each lower rib.—The distance of their angles from the heads always increases as they descend to the ninth, because of the greater breadth of the sacro-lumbalis muscle.

The ribs are commonly divided into *true* and *false*.

The *true* costae are the seven upper ones of each side, whose cartilages are all gradually longer as the ribs descend, and are joined to the breast-bone; so that being pressed

constantly between two bones, they are flattened at both ends, and are thicker, harder, and more liable to ossify, than the other cartilages that are not subject to so much pressure. These ribs include the heart and lungs; and therefore are the proper or true costodes of life.

The five inferior ribs of each side are the *false* or *bastard*, whose cartilages do not reach to the sternum; and therefore, wanting the resistance at their fore-part, they are there pointed; and, on this account, having less pressure, their substance is softer.—The cartilages of these false ribs are shorter as the ribs descend.—To all these five ribs the circular edge of the diaphragm is connected; and its fibres, instead of being stretched immediately transversely, and so running perpendicularly to the ribs, are pressed so as to be often, especially in expiration, parallel to the plane in which the ribs lie.

The first rib of each side is so situated, that the flat sides are above and below, while one edge is placed inwards, and the other outwards, or nearly so; therefore sufficient space is left above it for the subclavian vessels and muscle; and the broad concave surface is opposed to the lungs: But then, in consequence of this situation, the channel for the intercostal vessels is not to be found, and the edges are differently formed from all the other, except the second; the lower one being rounded, and the other sharp.—The head of this rib is not divided into two plain surfaces by a middle ridge, because it is only articulated with the first vertebra of the thorax.—Its cartilage is ossified in adults, and is united to the sternum at right angles.—Frequently this first rib has a ridge rising near the middle of its posterior edge, where one of the heads of the scalenus muscle rises.—Farther forward it is flattened, or sometimes depressed by the clavicle.

The fifth, sixth, and seventh, or rather the sixth, seventh, eighth, and sometimes the fifth, sixth, seventh, eighth, ninth ribs, have their cartilages at least contiguous; and frequently they are joined to each other by cross cartilages; and most commonly the cartilages of the eighth, ninth, tenth, are connected to the former, and to each other, by firm ligaments.

The eleventh, and sometimes the tenth rib, has no tubercle for its articulation with the transverse process of the vertebra, to which it is only loosely fixed by ligaments.—The fossa in its lower edge is not so deep as in the upper ribs, because the vessels run more towards the interstice between the ribs.—Its fore-end is smaller than its body, and its short small cartilage is but loosely connected to the cartilage of the rib above.

The twelfth rib is the shortest and straightest.—Its head is only articulated with the last vertebra of the thorax; therefore is not divided into two surfaces.—This rib is not joined to the transverse process of the vertebra, and therefore has no tubercle, being often pulled necessarily inwards by the diaphragm, which an articulation with the transverse process would not have allowed.—The fossa is not found at its under edge, because the vessels run below it.—The fore-part of this rib is smaller than its middle, and has only a very small-pointed cartilage fixed to it.—To its whole internal side the diaphragm is connected.

The

The STERNUM, or *breast-bone*, is the broad flat bone or pile of bones, at the fore-part of the thorax.—In adults of a middle age, it is composed of three bones, which easily separate after the cartilages connecting them are destroyed. Frequently the two lower bones are found intimately united; and very often in old people, the sternum is a continued bony substance from one end to the other; though we still observe two, sometimes three, transverse lines on its surface; which are marks of the former divisions.

When we consider the sternum as one bone, we find it broadest and thickest above, and becoming smaller as it descends. The internal surface of this bone is somewhat hollowed for enlarging the thorax; but the convexity on the external surface is not so conspicuous, because the sides are pressed outwards by the true ribs; the round heads of whose cartilages are received into seven smooth pits, formed in each side of the sternum, and are kept firm there by strong ligaments, which, on the external surface, have a particular radiated texture.—The pits at the upper part of the sternum are at the greatest distance one from another, and, as they descend, are nearer; so that the two lowest are contiguous.

The first of the three bones that compose the sternum, all agree, is somewhat of the figure of a heart, as it is commonly painted; only it does not terminate in a sharp point.—This is the uppermost thickest part of the sternum.

The upper middle part of this first bone, where it is thickest, is hollowed, to make place for the trachea arteria; though this cavity is principally formed by the bone being raised on each side of it, partly by the clavicles thrusting it inwards, and partly by the sterno-mastoides muscles pulling it upwards.—On the outside of each tubercle, there is an oblong cavity, that, in viewing it transversely from before backwards, appears a little convex: Into these glenæ the ends of the clavicles are received.—In the side of the under end of this first bone, the half of the pit for the second rib on each side is formed.—The upper part of the surface behind is covered with a strong ligament, which secures the clavicles.

The second or middle division of this bone, is much longer, narrower, and thinner than the first; but, excepting that it is a little narrower above than below, it is nearly equal all over in its dimensions of breadth or thickness.—In the sides of it are complete pits for the third, fourth, fifth, and sixth ribs, and an half of the pits for the second and seventh.

The third bone is much less than the other two, and has only one half of the pit for the seventh rib formed in it; wherefore it might be reckoned only an appendix of the sternum.—In young subjects it is always cartilaginous, and is better known by the name of *cartilago xiphoides*, or *ensiformis*, than any other; though the ancients often called the whole *sternum ensiforme*.—This third bone is seldom of the same figure, magnitude, or situation in any two subjects; for sometimes it is a plain triangular bone, with one of the angles below, and perpendicular to the middle of the upper side, by which it is connected to the second bone.—In other people, the

point is turned to one side, or obliquely forwards or backwards.—Frequently it is all nearly of an equal breadth, and in several subjects it is bifurcated; whence some writers give it the name of *furcella*, or *furcula inferior*; or else it is unossified in the middle.—In the greatest number of adults it is ossified, and tipped with a cartilage; in some, one half of it is cartilaginous; and in others, it is all in a cartilaginous state.—Generally several oblique ligaments, fixed at one end to the cartilages of the ribs, and by the other to the outer surface of the xiphoid-bone, connect it firmly to those cartilages.

The uses of the sternum are, to afford origin and insertion to several muscles; to sustain the mediastinum, to defend the vital organs, the heart and lungs, at the fore-part; and, lastly, by serving as a moveable fulcrum of the ribs, to assist considerably in respiration.

## OF THE SUPERIOR EXTREMITIES.

EACH superior extremity is divided into the *shoulder, arm, fore-arm, and hand*.

The SHOULDER consists of the *clavicle* and *scapula*. CLAVICULA, or *collar-bone*, is the long crooked bone, in figure like an Italic *s*, placed almost horizontally between the upper lateral part of the sternum, and what is commonly called the top of the shoulder, which, as a clavis or beam, it bears off from the trunk of the body.

The clavicle, as well as other long round bones, is larger at its two ends than in the middle. The end next to the sternum is triangular: The angle behind is considerably produced, to form a sharp ridge, to which the transverse ligament extended from one clavicle to the other is fixed.—The side opposite to this is somewhat rounded.—The middle of this protuberant end is irregularly hollowed, as the cavity in the sternum for receiving it is raised; but, in a recent subject, the irregular concavities of both are supplied by a moveable cartilage, which is not only much more closely connected every where, by ligaments, to the circumference of the articulation, than those of the lower jaw are; but it grows to the two bones at both its internal and external ends; its substance at the internal end being soft, but very strong, and resembling the intervertebral cartilages.

From this internal end the clavicle, for about two thirds of its length, is bended obliquely forwards and downwards. On the upper and fore-part of this curvature a small ridge is seen, with a plain rough surface before it; whence the musculus sterno-hyoideus and sterno-mastoides have in part their origin.—Near the lower angle, a small plain surface is often to be remarked; where the first rib and this bone are contiguous, and are connected by a firm ligament.—From this a rough plain surface is extended outwards, where the pectoral muscle has part of its origin.—Behind, the bone is made flat and rough by the insertion of the larger share of the subclavian muscle.—After the clavicle begins to be bended backwards, it is round, but soon after becomes broad and thin; which shape it retains to its external end.—Along the external concavity, a rough finosity runs, from which some part of the deltoid muscle takes its rise:—Opposite to this, on the convex edge, a scabrous

ridge gives insertion to a share of the *ocularis* muscle. The upper surface of the clavicle here is flat; but the lower is hollow, for lodging the beginning of the *musculus subclavius*; and towards its back-part a tubercle rises, to which, and a roughness near it, the strong short thick ligament connecting this bone to the coracoid process of the scapula is fixed.

The external end of this bone is horizontally oblong, smooth, sloping at the posterior side, and tipped in a recent subject with a cartilage, for its articulation with the acromion scapulae.

The medullary arteries, having their direction obliquely outwards, enter the clavicles by one or more small passages in the middle of their back-part.

The triangular unequal interior end of each clavicle, has the cartilage above described interposed betwixt it and the irregular cavity of the sternum.—The ligaments, which surround this articulation to secure it, are so short and strong, that little motion can be allowed any way; and the strong ligament that is stretched across the upper furcula of the sternum, from the posterior prominent angle of the one clavicle, to the same place of the other clavicle, serves to keep each of these bones more firmly in their place.—By the assistance, however, of the moveable intervening cartilage, the clavicle can, at this joint, be raised or depressed, and moved backwards and forwards so much, as that the external end, which is at a great distance from that axis, enjoys very conspicuous motions.

The uses of the clavicles are, to keep the scapulae, and consequently all the superior extremities, from falling in and forward upon the thorax.

**SCAPULA**, or *shoulder-blade*, is the triangular bone situated on the outside of the ribs, with its longest side, called its *base*, towards the spinal processes of the vertebrae, and with the angle at the upper part of this side about three inches, and the lower angle at a greater distance from these processes.—The back-part of the scapula has nothing but the thin ends of the *scrratus anticus major*, and *subscapularis* muscles, between it and the ribs: But as this bone advances forwards, its distance from the ribs increases.—The upper, or shortest side, called the *superior costa* of the scapula, is nearly horizontal, and parallel with the second rib.—The lower side, which is named the *inferior costa*, is extended obliquely from the third to the eighth rib.—The inferior angle of the scapula is very acute; and the upper one is near to a right angle.—The body of this bone is concave towards the ribs, and convex behind, where it has the name of *dorsum*.—Three processes are generally reckoned to proceed from the scapula.—The first is the large spine that rises from its convex surface behind, and divides it unequally.—The second process stands out from the fore-part of the upper side; and, from its imaginary resemblance to a crow's beak, is named *coracoides*.—The third process is the whole thick bulbous fore-part of the bone.

After thus naming the several constituent parts of the scapula, the particular description will be more easily understood.

The base, which is tipped with cartilage, is not all

straight: For, above the spine, it runs obliquely forwards to the superior angle; that here it might not be too protuberant backwards, and so bruise the muscles and teguments: Into the oblique space the *musculus patientiae* is inserted.—At the root of the spine, on the back-part of the base, a triangular plain surface is formed, by the pressure of the lower fibres of the *trapezius*.—Below this the edge of the scapula is scabrous and rough, for the insertion of the *scrratus major anticus*, and rhomboid muscles.

The back-part of the inferior angle is made smooth by the *latissimus dorsi* passing over it. This muscle also alters the direction of the inferior costa, some way forwards from this angle: and so far it is flattened behind by the origin of the *teres major*.—As the inferior costa advances forwards, it is of considerable thickness, is slightly hollowed and made smooth behind by the *teres minor*, while it has a fossa formed into it below by part of the *subscapularis*; and between the two a ridge, with a small depression, appears, where the *longus extensor cubiti* has its origin.

The superior costa is very thin; and near its fore-part there is a femimular notch, from one end of which to the other a ligament is stretched; and sometimes the bone is continued, to form one, or sometimes two holes, for the passage of the scapular blood-vessels and nerves.—Immediately behind this femimular cavity, the coracohyoind muscle has its rise.—From the notch, to the termination of the fossa for the *teres minor*, the scapula is narrower than any where else, and supports the third process. This part has the name of *cervix*.

The whole dorsum of the scapula is always said to be convex; but, by reason of the raised edges that surround it, it is divided into two cavities by the spine, which is stretched from behind forwards, much nearer to the superior than to the inferior costa.—The cavity above the spine is concave where the *supra-spinatus* muscle is lodged; while the surface of this bone below the spine, on which the *infra-spinatus* muscle is placed, is convex, except a fossa that runs at the side of the inferior costa.

The internal or anterior surface of this bone is hollow, except in the part above the spine, which is convex.—The *subscapularis* muscle is extended over this surface, where it forms several ridges and intermediate depressions, commonly mistaken for prints of the ribs; they point out the interstices of the bundles of fibres of which the *subscapularis* muscle is composed.

The spine rises small at the base of the scapula, and becomes higher and broader as it advances forwards.—On the sides it is unequally hollowed and crooked, by the actions of the adjacent muscles.—Its ridge is divided into two rough flat surfaces: Into the upper one, the *trapezius* muscle is inserted; and the lower one has part of the *deltoid* fixed to it.—The end of the spine, called *acromion*, or top of the shoulder, is broad and flat, and is sometimes only joined to the spine by a cartilage.—The anterior edge of the acromion is flat, smooth, and covered with a cartilage, for its articulation with the external end of the clavicle; and it is hollowed below, to allow a passage to the *infra* and *supra-spinati* muscles, and free motion to the *os humeri*.

The

The coracoid process is crooked, with its point inclining forwards; so that a hollow is left at the lower side of its root, for the passage of the infra-scapularis muscle.

—The end of this process is marked with three plain surfaces. Into the internal, the *ferratus minor anticus* is inserted: From the external, one head of the *biceps flexor cubiti* rises; and from the lower one, the *coraco-brachialis* has its origin.—At the upper part of the root of this process, immediately before the femilunar cavity, a smooth tubercle appears, where a ligament from the clavicle is fixed. From all the external side of this coracoid apophyse, a broad ligament goes out, which becomes narrower where it is fixed to the acromion.

From the cervix scapulae the third process is produced. The fore-part of this is formed into a glenoid cavity, which is of the shape of the longitudinal section of an egg, being broad below, and narrow above.—Between the brims of this hollow, and the fore-part of the root of the spine, a large sinuosity is left, for the transmission of the supra and infra-spinati muscles; and, on the upper part of these brims, we may remark a smooth surface, where the second head of the *biceps flexor cubiti* has its origin.—The root of the *supercilia* is rough all round, for the firmer adhesion of the capsular ligament of the articulation, and of the cartilage which is placed on these brims, where it is thick, but becomes very thin as it is continued towards the middle of the cavity, which it lines all over.

The medullary vessels enter the scapula near the base of the spine.

The scapula and clavicle are joined by plain surfaces, tipped with cartilage; by which neither bone is allowed any considerable motion, being tightly tied down by the common capsular ligament, and by a very strong one which proceeds from the coracoid process; but divides into two before it is fixed into the clavicle, with such a direction, as either can allow this bone to have a small rotation, in which its posterior edge turns more backwards, while the anterior one rises farther forwards; or it can yield to the fore-part of the scapula moving downwards, while the back-part of it is drawn upwards; in both which cases, the oblong smooth articulated surfaces of the clavicle and scapula are not in the same plane, but stand a little transversely, or across each other, and thereby preserve this joint from luxations, to which it would be subject, if either of the bones was to move on the other perpendicularly up and down, without any rotation.—The scapula is connected to the head, os hyoides, vertebrae, ribs, and arm-bone, by muscles, that have one end fastened to these bones, and the other to the scapula, which can move it upwards, downwards, backwards, or forwards; by the quick succession of these motions, its whole body is carried in a circle.

The use of the scapula is, to serve as a fulcrum to the arm; and, by altering its position on different occasions, to allow always the head of the os humeri a right situated socket to move in; and thereby to assist and to enlarge greatly the motions of the superior extremity, and to afford the muscles which rise from it more advantageous actions, by altering their directions to the bone which they are to move.

The ARM has only one bone, best known by the Latin name of *os humeri*; which is long, round, and nearly straight.

The upper end of this bone is formed into a large, round, smooth head, whose middle point is not in a straight line with the axis of the bone, but stands obliquely backwards from it.—The extent of the head is distinguished by a circular fossa surrounding its base, where the head is united to the bone, and the capsular ligament of the joint is fixed.—Below the fore-part of its base two tubercles stand out: The smallest one, which is situated most to the inside, has the tendon of the subscapularis muscle inserted into it.—The larger more external protuberance is divided, at its upper part, into three smooth plain surfaces; into the anterior of which, the *musculus supra-spinatus*; into the middle or largest, the *infra-spinatus*; into the one behind, the *teres minor*, is inserted.—Between these two tubercles, exactly in the fore part of the bone, a deep long fossa is formed, for lodging the tendinous head of the *biceps flexor cubiti*.—On each side of this fossa, as it descends into the *os humeri*, a rough ridge, gently flattened in the middle, runs from the roots of the tubercles.—The tendon of the pectoral muscle is fixed into the anterior of these ridges, and the *latissimus dorsi*, and *teres major*, are inserted into the internal one.—A little behind the lower end of this last, another rough ridge may be observed, where the *coraco-brachialis* is inserted.

—From the back-part of the root of the largest tubercle, a ridge also is continued, from which the *brevis extensor cubiti* rises.—This bone is flattened on the inside, about its middle, by the belly of the *biceps flexor cubiti*.—In the middle of this plain surface, the entry of the medullary artery is seen slanting obliquely downwards.—At the fore-side of this plane, the bone rises in a sort of ridge, which is rough, and often has a great many small holes in it, where the tendon of the strong deltoid muscle is inserted; on each side of which the bone is smooth and flat, where the *brachiiæus internus* rises. The exterior of these two flat surfaces is the largest; behind it a superficial spiral channel, formed by the muscular nerve and the vessels that accompany it, runs from behind forwards and downwards.—The body of the *os humeri* is flattened behind by the extensors of the fore-arm.—Near the lower end of this bone, a large sharp ridge is extended on its outside, from which the *musculus spinator radii longus*, and the longest head of the *extensor carpi radialis* rise.—Opposite to this, there is another small ridge, to which the aponeurotic tendon, that gives origin to the fibres of the internal and external *brachioiæi* muscles, is fixed; and from a little depression on the fore-side of it, the *pronator radii teres* rises.

The body of the *os humeri* becomes gradually broader towards the lower end, where it has several processes; at the roots of which there is a cavity before, and another behind. The anterior is divided, by a ridge, into two; the external, which is the least, receives the end of the radius; and the internal receives the coronoid process of the ulna in the flexion of the fore-arm, while the posterior deep triangular cavity lodges the olecranon in the extension of that member.—The sides of

the posterior cavity are stretched out into two processes, one on each side: These are called *condyles*; from each of which a strong ligament goes out to the bones of the fore-arm.—The external condyle, which has an oblique direction also forwards in respect of the internal, when the arm is in the most natural posture, is equally broad, and has an obtuse smooth head rising from it forwards.—From the rough part of the condyle, the inferior head of the *bicorns*, the *extensor digitorum communis*, *extensor carpi ulnaris*, *anconæus*, and some part of the *supinator radii brevis*, take their rise; and on the smooth head the upper end of the *radius* plays.—Immediately on the outside of this, there is a sinuosity made by the shorter head of the *bicorns* muscle, upon which the muscular nerve is placed.—The internal condyle is more pointed and protuberant than the external, to give origin to some part of the *flexor carpi radialis*, *pronator radii teres*, *palmaris longus*, *flexor digitorum sublimis*, and *flexor carpi ulnaris*.—Between the two condyles, is the *trochlea* or pulley, which consists of two lateral protuberances, and a middle cavity, that are smooth, and covered with cartilage.—When the fore-arm is extended, the tendon of the internal *brachii* muscle is lodged in the fore-part of the cavity of this pulley.—The external protuberance, which is less than the other, has a sharp edge behind; but forwards, this ridge is obtuse, and only separated from the little head, already described, by a small fossa, in which the joined edges of the *ulna* and *radius* move.—The internal protuberance of the pulley is largest and highest; and therefore, in the motions of the *ulna* upon it, that bone would be inclined outwards, was it not supported by the *radius* on that side.—Between this internal protuberance and condyle, a sinuosity may be remarked, where the *ulnar nerve* passes.

The round head at the upper end of this bone is articulated with the glenoid cavity of the *scapula*; which being superficial, and having long ligaments, allows the arm a free and extensive motion.

The motions which the arm enjoys by this articulation, are to every side; and by the succession of these different motions, a circle may be described. Besides which, the bone performs a small rotation round its own axis.

The *FORE-ARM* consists of two long bones, the *ulna* and *radius*; whose situation, in respect of each other, is oblique in the least straining or most natural posture; that is, the *ulna* is not directly behind, nor on the outside of the *radius*, but in a middle situation between these two, and the *radius* crosses it.—In the following description, by the term *posterior* is meant that part which is in the same direction with the back of the hand; by *anterior*, that answering to the palm; by *internal*, that on the same side with the thumb; by *external*, the side nearest the little finger.

*ULNA*, so named from its being used as a measure, is the longest of the two bones of the fore-arm, and situated on the outside of the *radius*.

At the upper end of the *ulna* are two processes.—The posterior is the largest, and formed like a hook, whose concave surface moves upon the pulley of the *os humeri*, and is called *olecranon*, or top of the cubit.—The convex back-part of it is rough and scabrous, where the long

*musculus*, *brevis*, and *brachii* *externus*, are inserted. The *olecranon* makes it unnecessary that the tendons of the *extensor* muscles should pass over the end of the *os humeri*; which would have been of ill consequence in the great flexions of this joint, or when any considerable external force is applied to this part.—The anterior process is not so large, nor does it reach so high as the one behind; but is sharper at its end, and therefore is named *coronoid*.—Between these two processes, a large femicircular or sigmoid concavity is left; the surface of which, on each side of a middle rising, is slanting, and exactly adapted to the pulley of the bone of the arm.—Across the middle of it, there is a small sinuosity for lodging mucilaginous glands; where, as well as in a small hollow on the internal side of it, the cartilage that lines the rest of its surface is wanting.—Round the brims of this concavity the bone is rough, where the capsular ligament of the joint is implanted.—Immediately below the *olecranon*, on the back-part of the *ulna*, a flat, triangular, spongy surface appears, on which we commonly lean.—At the internal side of this, there is a larger hollow surface, where the *musculus anconæus* is lodged; and the ridge at the inside of this gives rise to the *musculus supinator radii brevis*.—Between the top of the ridge and the *coronoid process*, is the feminated smooth cavity, lined with cartilage, in which, and a ligament extended from the one to the other end of this cavity, the round head of the *radius* plays.—Immediately below it, a rough hollow gives lodging to mucilaginous glands.—Below the root of the *coronoid process*, this bone is scabrous and unequal, where the *brachii* *internus* is inserted.—On the outside of that, we observe a smooth concavity, where the beginning of the *flexor digitorum profundus* sprouts out.

The body of the *ulna* is triangular.—The internal angle is very sharp where the ligament that connects the two bones is fixed;—the sides, which make this angle, are flat and rough, by the action and adhesion of the many muscles which are situated here.—At the distance of one third of the length of the *ulna* from the top, in its fore-part, the passage of the medullary vessels is to be remarked slanting upwards.—The external side of this bone is smooth, somewhat convex, and the angles at each edge of it are blunted by the pressure of the muscles equally disposed about them.

As this bone descends, it becomes gradually smaller; so that its lower end terminates in a little head, standing on a small neck.—Towards the fore but outer part of which last, an oblique ridge runs, that gives rise to the *pronator radii quadratus*.—The head is round, smooth, and covered with a cartilage on its internal side, to be received into the feminar cavity of the *radius*; while a styloid process rises from its outside, to which is fixed a strong ligament that is extended to the *os cuneiforme* and *pisiforme* of the wrist.—Between the back-part of that internal smooth side and this process, a sinuosity is left for the tendon of the *extensor carpi ulnaris*.—On the fore-part of the root of the process, such another depression may be remarked for the passage of the *ulnar artery* and nerve.—The end of the bone is smooth, and covered with a cartilage.—Between it and the bones of

the wrist, a double concave movable cartilage is interposed; which is a continuation of the cartilage that covers the lower end of the radius, and is connected loosely to the root of the styloid process, and to the rough cavity there, in which mucilaginous glands are lodged.

The ulna is articulated above with the lower end of the os humeri, where these bones have depressions and protuberances corresponding to each other, so as to allow an easy and secure extension of the fore-arm to almost a straight line with the arm, and flexion to a very acute angle; but, by the slanting position of the pulley, the lower part of the fore-arm is turned outwards in the extension, and inwards in the flexion; and a very small kind of rotation is likewise allowed in all positions, especially when the ligaments are most relaxed by the fore-arm being in a middle degree of flexion.—The ulna is also articulated with the radius and carpus, in a manner to be related afterwards.

**RADIUS**, so called from its imagined resemblance to a spoke of a wheel, is the bone placed at the inside of the fore-arm. Its upper end is formed into a circular little head, which is hollowed for an articulation with the tubercle at the side of the pulley of the os humeri; and the half of the round circumference of the head next to the ulna is smooth, and covered with a cartilage, in order to be received into the semilunated cavity of that bone.

—Below the head, the radius is much smaller; therefore this part is named its *cervix*, which is made round by the action of the supinator radii brevis.—At the external root of this neck, a tuberos process rises; in to the outer part of which the biceps flexor cubiti is inserted.—From this a ridge runs downwards and inwards, where the supinator radii brevis is inserted; and a little below, and behind this ridge, there is a rough scabrous surface, where the pronator radii teres is fixed.

The body of the radius is not straight, but convex on its internal and posterior surfaces; where it is also made round by the equal pressure of the circumjacent muscles, particularly of the extensors of the thumb; and the surfaces next to the ulna are flattened and rough, for the origin of the muscles of the hand; and both terminate in a common sharp spine, to which the strong ligament extended betwixt the two bones of the fore-arm is fixed. A little below the beginning of the plain surface, on its fore-part, where the flexor muscle of the last joint of the thumb takes its origin, the passage of the medullary vessels is seen slanting upwards.—The radius becomes broader and flatter towards the lower end, especially on its fore-part, where its pronator quadratus muscle is situated.

The lower end of the radius is larger than the superior; though not in such a disproportion as the upper end of the ulna is larger than its lower end.—Its back-part has a flat strong ridge in the middle, and fossæ on each side.—In a small groove immediately on the outside of the ridge, the tendon of the extensor tertii interodii pollicis plays.—In a large one beyond this, the tendons of the indicator and of the common extensor muscles of the fingers pass.—Contiguous to the ulna, there is a small depression made by the extensor minimi digiti,

—On the outside of the ridge there is a broad depression, which seems again subdivided, where the two tendons of the bicornis, or extensor carpi radialis, are lodged.—The internal side of this end of the radius is also hollowed by the extensors of the first and second joint of the thumb; immediately above which, a little rough surface shows where the supinator radii longus is inserted.—The ridges at the sides of the grooves, in which the tendons play, have an annular ligament fixed to them, by which the several sheaths for the tendons are formed.—The fore-part of this end of the radius is also depressed, where the flexors of the fingers and flexor carpi radialis pass.—The external side is formed into a semilunated smooth cavity, lined with a cartilage, for receiving the lower end of the ulna.—The lowest part of the radius is formed into an oblong cavity; in the middle of which is a small transverse rising, gently hollowed, for lodging mucilaginous glands; while the rising itself is insinuated into the conjunction of the two bones of the wrist that are received into the cavity.—The internal side of this articulation is fenced by a remarkable process of the radius, from which a ligament goes out to the wrist, as the styloid process of the ulna with its ligament guards it on the outside.

The ends of both the bones of the fore-arm being thicker than the middle, there is a considerable distance between the bodies of these bones; in the larger part of which a strong tendinous, but thin ligament, is extended, to give a large enough surface for the origin of the numerous fibres of the muscles situated here, that are so much sunk between the bones, as to be protected from injuries, which they would otherwise be exposed to.

As the head of the radius receives the tubercle of the os humeri, it is not only bended and extended along with the ulna, but may be moved round its axis in any position; and that this motion round its axis may be sufficiently large, the ligament of the articulation is extended farther down than ordinary on the neck of this bone, before it is connected to it; and it is very thin at its upper and lower part, but makes a firm ring in the middle.—This bone is also joined to the ulna by a double articulation; for above, a tubercle of the radius plays in a socket of the ulna; whilst below, the radius gives the socket, and the ulna the tubercle: But then the motion performed in these two is very different; for, at the upper end, the radius does no more than turn round its axis; while, at the lower end, it moves in a sort of cycloid upon the round part of the ulna; and as the hand is articulated and firmly connected here with the radius, they must move together.—When the palm is turned uppermost, the radius is said to perform the *supination*; when the back of the hand is above, it is said to be *prone*.

The **HAND** comprehends all from the joint of the wrist to the points of the fingers. Its back-part is convex, for greater firmness and strength; and it is concave before, for containing more surely and conveniently such bodies as we take hold of.

The hand is commonly divided into the *carpus*, *metacarpus*, and *fingers*.

The **CARPUS** is composed of eight small spongy bones, situated at the upper part of the hand, *viz.* the

*os scaphoides, lunare, cuneiforme, pisiforme, trapezium, trapezoides, magnum, unciniforme.*

The scaphoides is situated most internally of those that are articulated with the fore-arm.—The lunare is immediately on the outside of the former.—The cuneiforme is placed still more externally, but does not reach so high up as the other two.—The pisiforme stands forwards into the palm from the cuneiforme.—The trapezium is the first of the second row, and is situated betwixt the scaphoides and first joint of the thumb.—The trapezoides is immediately on the outside of the trapezium.—The os magnum is still more external.—The unciniforme is farther to the side of the little finger.

Os scaphoides is the largest of the eight except one. It is convex above, concave and oblong below; from which small resemblance of a boat it has got its name.—Its smooth convex surface is divided by a rough middle fossa, which runs obliquely across it.—The upper largest division is articulated with the radius.—Into the fossa the common ligament of the joint of the wrist is fixed; and the lower division is joined to the trapezium and trapezoides.—The concavity receives more than an half of the round head of the os magnum.—The external side of this hollow is formed into a femilunar plane, to be articulated with the following bone.—The internal, posterior, and anterior edges are rough, for fixing the ligaments that connect it to the surrounding bones.

Os lunare has a smooth convex upper surface, by which it is articulated with the radius.—The internal side, which gives the name to the bone, is in the form of a crescent, and is joined with the scaphoid;—the lower surface is hollow, for receiving part of the head of the os magnum.—On the outside of this cavity is another smooth, but narrow oblong sinusity, for receiving the upper end of the os unciniforme:—On the outside of which a small round convexity is found, for its connection with the os cuneiforme. Between the great convexity above, and the first deep inferior cavity, there is a rough fossa, in which the circular ligament of the joint of the wrist is fixed.

Os unciniforme is broader above, and towards the back of the hand, than it is below and forwards: which gives it the resemblance of a wedge.—The superior slightly convex surface is included in the joint of the wrist, being opposed to the lower end of the ulna.—Below this, the cuneiform bone has a rough fossa, wherein the ligament of the articulation of the wrist is fixed.—On the internal side of this bone, where it is contiguous to the os lunare, it is smooth and slightly concave.—Its lower surface, where it is contiguous to the os unciniforme, is oblong, somewhat spiral, and concave.—Near the middle of its anterior surface, a circular plane appears, where the os pisiforme is sustained.

Os pisiforme is almost spherical, except one circular plane, or slightly hollow surface, which is covered with cartilage for its motion on the cuneiform bone, from which its whole rough body is prominent forwards into the palm; having the tendon of the flexor carpi ulnaris, and a ligament from the styloid process of the ulna, fixed to its upper part; the transverse ligament of the wrist is connected to its internal side; ligaments extended to the

unciniform bone, and to the os metacarpi of the little finger, are attached to its lower part; the abductor minimi digiti has its origin from its fore-part; and, at the internal side of it, a small depression is formed, for the passage of the ulnar nerve.

Trapezium has four unequal sides and angles in its back-part, from which it has got its name.—Above, its surface is smooth; slightly hollowed, and semicircular, for its conjunction with the os scaphoides.—Its external side is an oblong concave square, for receiving the following bone.—The inferior surface is formed into a pulley; the two protuberant sides of which are external and internal. On this pulley the first bone of the thumb is moved.—At the external side of the external protuberance, a small oblong smooth surface is formed by the os metacarpi indicis.—The fore-part of the trapezium is prominent in the palm, and, near to the external side, has a sinusity in it, where the tendon of the flexor carpi radialis is lodged; on the ligamentous sheath of which the tendon of the flexor tertii internodii pollicis plays: And still more externally the bone is scabrous, where the transverse ligament of the wrist is connected, the abductor and flexor primi internodii pollicis have their origin, and ligaments go out to the first bone of the thumb.

Os trapezoides, so called from the irregular quadrangular figure of its back-part, is the smallest bone of the wrist, except the pisiforme.—The figure of it is an irregular cube.—It has a small hollow surface above, by which it joins the scaphoides; a long convex one intertingly, where it is contiguous to the trapezium; a small external one, for its conjunction with the os magnum; and an inferior convex surface, the edges of which are however so raised before and behind, that a sort of pulley is formed, where it sustains the os metacarpi indicis.

Os magnum, so called because it is the largest bone of the carpus, is oblong, having four quadrangular sides, with a round upper end, and a triangular plain one below.—The round head is divided by a small rising, opposite to the connection of the os scaphoides and lunare, which together form the cavity for receiving it.—On the inside, a short plain surface joins the os magnum to the trapezoides.—On the outside is a long narrow concave surface, where it is contiguous to the os unciniforme.—The lower end, which sustains the metacarpal bone of the middle finger, is triangular, slightly hollowed, and farther advanced on the internal side than on the external, having a considerable oblong depression made on the advanced inflexure by the metacarpal bone of the fore-finger; and generally there is a small mark of the os metacarpi digiti annularis on its external side.

Os unciniforme has got its name from a thin broad process that stands out from it forwards into the palm, and is hollow on its inside, for affording passage to the tendons of the flexors of the fingers. To this process also the transverse ligament is fixed, that binds down and defends these tendons; and the flexor and abductor muscles of the little finger have part of their origin from it.—The upper plain surface is small, convex, and joined with the os lunare:—The internal side is long, and slightly convex, adapted to the contiguous os magnum:—

The

The external surface is oblique, and irregularly convex, to be articulated with the cuneiform bone:—The lower end is divided into two concave surfaces; the external is joined with the metacarpal bone of the little finger, and the internal one is fitted to the metacarpal bone of the ring-finger.

The uses of the carpus are, to serve as a base to the hand, to protect its tendons, and to afford it a free large motion.

**METACARPUS** consists of four bones, which sustain the fingers.—Each bone is long and round, with its ends larger than its body.—The upper end, which some call the *base*, is flat and oblong, without any considerable head or cavity; but it is however somewhat hollowed, for the articulation with the carpus: It is made flat and smooth on the sides where these bones are contiguous to each other.—Their bodies are flattened on their back-part by the tendons of the extensors of the fingers.—

The anterior surface of these bodies is a little concave, especially in their middle; along which a sharp ridge stands out, which separates the musculi interossei placed on each side of these bones, which are there made flat and plain by these muscles.

Their lower ends are raised into large oblong smooth heads, whose greatest extent is forwards from the axis of the bone.—At the fore-part of each side of the root of each of these heads, one or two tubercles stand out, for fixing the ligaments that go from one metacarpal bone to another, to preserve them from being drawn asunder:—Round the heads a rough ring may be remarked, for the capsular ligaments of the first joints of the fingers to be fixed to; and both sides of these heads are flat, by pressing on each other.

The concavity on the fore-part of these metacarpal bones, and the placing their basis on the arched carpus, cause them to form a hollow in the palm of the hand, which is useful often to us.—The spaces between them lodge muscles, and their small motion makes them fit supporters for the fingers to play on.

Though the *os metacarpi* so far agree, yet they may be distinguished from each other by the following marks.

The *os metacarpi indicis* is generally the longest.—Its base, which is articulated with the *os trapezoides*, is hollow in the middle.—The small ridge on the internal side of this oblong cavity is smaller than the one opposite to it, and is made flat on the side by the trapezium.—The exterior ridge is also smooth, and flat on its outside, for its conjunction with the *os magnum*; immediately below which, a semicircular smooth flat surface shews the articulation of this to the second metacarpal bone.—The back-part of this base is flattened, where the long head of the extensor carpi radialis is inserted; and its fore-part is prominent, where the tendon of the flexor carpi radialis is fixed.—The external side of the body of this bone is more hollowed by the action of muscles, than the internal.—The tubercle at the internal root of its head is larger than the external.—Its base is so firmly fixed to the bone it is connected with, that it has no motion.

*Os metacarpi medii digiti* is generally the second in length.—Its base is a broad superficial cavity, slanting

outwards; the internal posterior angle of which is so prominent, as to have the appearance of a process.—The internal side of this base is made plain in the same way as the external side of the former bone, while its external side has two hollow circular surfaces, for joining the third metacarpal bone; and between these surfaces there is a rough fossa, for the adhesion of a ligament, and lodging mucilaginous glands.—The shorter head of the *bicornis* is inserted into the back-part of this base.—The two sides of this bone are almost equally flattened; only the ridge on the fore-part of the body inclines outwards.—The tubercles at the fore-part of the root of the head are equal.—The motion of this bone is very little more than the first metacarpal one has; and therefore these two firmly resist bodies pressed against them by the thumb, or fingers, or both.

*Os metacarpi digiti annularis* is shorter than the second metacarpal bone.—Its base is semicircular and convex, for its conjunction with the *os unciniforme*.—On its internal side are two smooth convexities, and a middle fossa, adapted to the second metacarpal bone.—The external side has a triangular smooth concave surface to join it with the fourth one. The anterior ridge of its body is situated more to the out than to the in-side.—The tubercles near the head are equal.—The motion of this third metacarpal bone is greater than the motion of the second.

*Os metacarpi minimi digiti* is the smallest and sharpest.—Its base is irregularly convex, and rises slanting outwards.—Its internal side is exactly adapted to the third metacarpal bone.—The external has no smooth surface, because it is not contiguous to any other bone; but it is prominent where the extensor carpi ulnaris is inserted.—As this metacarpal bone is furnished with a proper moving muscle, has the plainest articulation, is most loosely connected and least confined, it not only enjoys a much larger motion than any of the rest, but draws the third bone with it, when the palm of the hand is to be made hollow by its advancement forwards, and by the prominence of the thumb opposite to it.

The **THUMB** and four **FINGERS** are each composed of three long bones.

The thumb is situated obliquely in respect of the fingers, neither opposite directly to them, nor in the same plane with them.—All its bones are much thicker and stronger in proportion to their length, than the bones of the fingers are: Which was extremely necessary, since the thumb counteracts all the fingers.

The first bone of the thumb has its base adapted to the double pulley of the trapezium.—The edge at the fore-part of this base is produced farther than any other part; and round the back-part of the base a rough fossa may be seen, for the connection of the ligaments of this joint.—The body and head of this bone are of the same shape as the *os metacarpi*: only that the body is shorter, and the head flatter, with the tubercles at the fore-part of its root larger.

The articulation of the upper end of this bone is uncommon: For though it has protuberances and depressions adapted to the double pulley of the trapezium; yet it enjoys a circular motion, as the joints do where a

round head of one bone plays in the orbicular socket of another; only it is somewhat more confined and less expeditious, but stronger and more secure, than such joints generally are.

The second bone of the thumb has a large base formed into an oblong cavity, whose greatest length is from one side to the other.—Round it several tubercles may be remarked, for the insertion of ligaments.—Its body is convex, or a half-round behind; but flat before, for lodging the tendon of the long flexor of the thumb, which is tied down by ligamentous sheaths that are fixed on each side to the angle at the edge of this flat surface.

The articulation and motion of the upper end of this second bone is as singular as that of the former.—For its cavity being joined to the round head of the first bone, it would seem at first view to enjoy motion in all directions; yet, because of the strength of its lateral ligaments, oblong figure of the joint itself, and mobility of the first joint, it only allows flexion and extension; and these are generally much confined.

The third bone of the thumb is the smallest, with a large base, whose greatest extent is from one side to the other.—This base is formed into two cavities and a middle protuberance, to be adapted to the pulley of the former bone.—Its body is rounded behind; but is flatter than in the former bone, for sustaining the nail.—It is flat and rough before, by the insertion of the flexor tertii internodii.—This bone becomes gradually smaller, till near the lower end, where it is a little enlarged, and has an oval scabrous edge.

The motion of this third bone is confined to flexion and extension.

The orderly disposition of the bones of the fingers in three rows, has made them generally obtain the name of three *phalanges*.—All of them have half-round convex surfaces, covered with an aponeurosis, formed by the tendons of the extensors, lumbricales, and interossei, and placed directly backwards, for their greater strength; and their flat concave part is forwards, for taking hold more surely, and for lodging the tendons of the flexor muscles.—The ligaments for keeping down these tendons are fixed to the angles that arc between the convex and concave sides.

The bones of the first phalanx of the fingers answer to the description of the second bone of the thumb: only that the cavity in their base is not so oblong; nor is their motion on the metacarpal bones so much confined; for they can be moved laterally or circularly, but have no rotation, or a very small degree of it, round their axis.

The second bone of the fingers has its base formed into two lateral cavities, and a middle protuberance; while the lower end has two lateral protuberances, and a middle cavity; therefore it is joined at both ends in the same manner, which none of the bones of the thumb are.

The third bone differs nothing from the description of the third bone of the thumb, excepting in the general distinguishing marks; and therefore the second and third phalanx of the fingers enjoy only flexion and extension.

All the difference of the phalanges of the several fingers consists in their magnitude.—The bones of the

middle-finger being the longest and largest.—Those of the fore-finger come next to that in thickness, but not in length, for those of the ring-finger are a little longer. The little finger has the smallest bones. Which disposition is the best contrivance for holding the largest bodies; because the longest fingers are applied to the middle largest periphery of such substances as are of a spherical figure.

The uses of all the parts of our superior extremities are so evident in the common actions of life, that it is needless to enumerate them here; and therefore we shall proceed to the last part of the skeleton.

## OF THE INFERIOR EXTREMITIES.

THE INFERIOR EXTREMITIES depend from the acetabula of the ossa innominata; are commonly divided into three parts, *viz.* the *thigh, leg, and foot*.

The THIGH has only one bone; which is the longest of the body. The situation of it is not perpendicular for the lower end is inclined considerably inwards: So that the knees are almost contiguous, while there is a considerable distance between the thigh-bones above: Which is of good use to us, since sufficient space is thereby left for the external parts of generation, the two great cloacæ of urine and fœces, and for the large thick muscles that move the thigh inwards: And, at the same time, this situation of the thigh-bones renders our progression quicker, surer, straighter, and in less room.

The upper end of the thigh-bone is not continued in a straight line with the body of it, but is set off obliquely inwards and upwards, whereby the distance here between these two bones at their upper part is considerably increased.—This end is formed into a large smooth round head, which is the greater portion of a sphere-unequally divided.—Towards its lower internal part, a round rough spongy pit is observable, where the strong ligament, commonly called the *round one*, is fixed, to be extended from thence to the lower internal part of the receiving cavity, where it is considerably broader than near to the head of the thigh-bone.—The small part below the head, called the *cervix*, of the os femoris, has a great many large holes, into which the fibres of the strong ligament, continued from the capsular, enter, and are thereby surely united to it; and round the root of the neck, where it rises from the bone, a rough ridge is found, where the capsular ligament of the articulation itself is connected.—Below the back-part of this root, the large unequal protuberance, called *trochanter major*, stands out; the external convex part of which is distinguished into three different surfaces, whereof the one on the fore-part is scabrous and rough, for the insertion of the glutæus minimus; the superior one is smooth, and has the glutæus medius inserted into it; and the one behind is made flat and smooth by the tendon of the glutæus maximus passing over it.—The upper edge of this process is sharp and pointed at its back-part, where the glutæus medius is fixed; but forwards it is more obtuse, and has two superficial pits formed in it: Into the superior of these, the piriformis is implanted; and the obturator internus and gemini are fixed into the lower one.

one.—From the backmost prominent part of this great trochanter, a rough ridge runs backwards and downwards, into which the quadratus is inserted.—In the deep hollow, at the internal upper side of this ridge, the obturator externus is implanted.—More internally, a conoid process, called *trochanter minor*, rises, for the insertion of the musculus psoas and iliacus internus, and the pectineus is implanted into a rough hollow below its internal root.—The muscles inserted into these two processes being the principal instruments of the rotatory motion of the thigh, have occasioned the name of *trochanters* to the processes.

The body of the os femoris is convex on the fore-part, and made hollow behind, by the action of the muscles that move it and the leg, and for the conveniency of sitting, without bearing too much on these muscles.—

The fore-part of the thigh-bone is a little flattened above by the beginning of the cruræus muscle, as it is also below by the same muscle and the rectus.—Its external surface is likewise made flat below by the vastus externus, where it is separated from the former by an obtuse ridge.

—The vastus internus depresses a little the lower part of the internal surface.—The posterior concave surface has a ridge rising in its middle, commonly called *linea aspera*, into which the triceps is inserted, and the short head of the biceps flexor tibiae rises from it.—

At the upper part of it, the medullary vessels enter by a small hole that runs obliquely upwards.—A little above which, there is a rough fossa or two, where the tendon of the glutæus maximus is fixed.—The lower end of the linea aspera divides into two, which descend towards each side.—The two vasti muscles have part of their origin from these ridges; and the long tendon of the triceps is fixed to the internal, by means of part of the fascia aponeurotica of the thigh.—Near the beginning of the internal ridge, there is a discontinuation of the ridge, where the crural artery passes through the aponeurosis.—Between these two rough lines, the bone is made flat by the large blood-vessels and nerves which pass upon it; and near the end of each of these ridges, a small smooth protuberance may often be remarked, where the two heads of the external gastrocnemius muscle take their rise; and from the fore-part of the internal tubercle, a strong ligament is extended to the inside of the tibia.

The lower end of the os femoris is larger than any other part of it, and is formed into a great protuberance on each side, called its *condyles*; between which a considerable cavity is found, especially at the back-part, in which the crural vessels and nerves lie immersed in fat.

—The internal condyle is longer than the external.—Each of these processes seems to be divided in its plain smooth surface. The mark of division on the external is a notch, and on the internal a small protuberance. The fore-part of this division, on which the rotula moves, is formed like a pulley, the external side of which is highest.—Behind, there are two oblong large heads, whose greatest extent is backwards, for the motion of the tibia; and from the rough cavity between them, but near to the base of the internal condyle, the strong ligament, commonly called the cross one, has its rise.—A little

above which, a rough protuberance gives insertion to the tendon of the triceps.—The condyles, both on the outer and inner side of the knee, are made flat by the muscles passing along them.—On the back part of the internal, a slight depression is made by the tendons of the gracilis and sartorius; and on the external, such another is formed by the biceps flexor cruris; behind which, a deep fossa is to be observed, where the popliteus muscle has its origin.—From the tubercle immediately before this cavity, a strong round ligament goes out to the upper part of the fibula.—Round this lower end of the thigh-bone, large holes are found, into which the ligaments for the security of the joint are fixed, and blood-vessels pass to the internal substance of the bone.

The thigh-bone being articulated above with the acetabulum of the ossa innominata, which affords its round head a secure and extensive play, can be moved to every side; but is restrained in its motion outwards by the high brims of the cavity, and by the round ligament; for otherwise the head of the bone would have been frequently thrust out at the breach of the brims on the inside, which allows the thigh to move considerably inwards.

—The body of this bone enjoys little or no rotatory motion, though the head most commonly moves round its own axis; because the oblique progress of the neck and head from the bone is such, that the rotatory motion of the head can only bring the body of the bone forwards and backwards.—The os femoris is articulated below to the tibia and rotula in the manner afterwards to be described.

The necks of the small neck to the round head of the thigh-bone, and its upper end being covered with very thick muscles, make greater difficulty in distinguishing between a luxation and fracture here, than in any other part of the body.

The LEG is composed of three bones, *tibia*, *fibula*, and *rotula*.

TIBIA, so called from its resemblance to an old musical pipe or flute, is the long, thick, triangular bone, situated at the internal part of the leg, and continued in almost a straight line from the thigh-bone.

The upper end of the tibia is large, bulbous, and spongy, and is divided into two cavities by a rough irregular protuberance, which is hollow at its most prominent part, as well as before and behind. The anterior of the two ligaments that compose the great cross one, is inserted into the middle cavity, and the depression behind receives the posterior ligament.—The two broad cavities at the sides of this protuberance are not equal; for the internal is oblong and deep, to receive the internal condyle of the thigh-bone; while the external is more superficial and rounder, for the external condyle.—In each of these two cavities of a recent subject, a semilunar cartilage is placed, which is thick at its convex edge, and becomes gradually thinner towards the concave or interior edge.—The middle of each of these cartilages is broad, and the ends of them turn narrower and thinner, as they approach the middle protuberance of the tibia.—The thick convex edge of each cartilage is connected to the capsular and other ligaments of the articulation, but so near to their rise from the tibia, that the cartilages

cartilages are not allowed to change place far; while the narrow ends of the cartilages, becoming almost ligaments, are fixed at the insertion of the strong cross ligament into the tibia, and seem to have their substance united with it; therefore a circular hole is left between each cartilage and the ligament, in which the most prominent convex part of each condyle of the thigh-bone moves.—The circumference of these cavities is rough and unequal, for the firm connection of the ligaments of the joint.—Immediately below the edge, at its back-part, two rough flattened protuberances stand out: Into the internal, the tendon of the semimembranosus muscle is inserted; and a part of the cross ligament is fixed to the external.—On the outside of this last tubercle, a smooth slightly-hollowed surface is formed by the action of the popliteus muscle.

Below the fore-part of the upper end of the tibia, a considerable rough protuberance rises, to which the strong tendinous ligament of the rotula is fixed.—On the internal side of this, there is a broad, scabrous, slightly-hollowed surface, to which the internal long ligament of the joint, the aponeurosis of the vastus internus, and the tendons of the feminovosus, gracilis, and sartorius, are fixed.—Below the external edge of the upper end of the tibia, there is a circular flat surface, covered, in a recent subject, with cartilage, for the articulation of the fibula;—between which and the anterior knob, there is a rough hollow, from which the tibialis anticus, and extensor digitorum longus, take their origin.—From the smooth flat surface, a ridge runs obliquely downwards and inwards, to give rise to part of the solæus, tibialis posticus, and flexor digitorum longus, and insertion to the aponeurosis of the semimembranosus which covers the popliteus, and to some of the external fibres of this last named muscle.—At the inside of this ridge an oblique plain surface is left, where the greatest part of the musculus popliteus is inserted.—The remaining body of the tibia is triangular.—The anterior angle is very sharp, and is commonly called the *spine* or *spin*. This ridge is not straight; but turns first inwards, then outwards, and lastly inwards again.—The plain internal side is smooth and equal, being little subjected to the actions of muscles; but the external side is hollowed above by the tibialis anticus, and below by the extensor digitorum longus, and extensor pollicis longus.—The two angles behind these sides are rounded by the action of the muscles;—the posterior side comprehended between them is not so broad as those already mentioned, but is more oblique and flattened by the action of the tibialis posticus and flexor digitorum longus.—Some way above the middle of the bone, the internal angle terminates, and the bone is made round by the pressure of the musculus solæus.—Near to this, the passage of the medullary vessels is seen slanting obliquely downwards.

The lower end of the tibia is made hollow, but so as a small protuberance rises in the middle.—The internal side of this cavity, which is smooth, and, in a recent subject, is covered with cartilage, is produced into a considerable process, commonly named *malleolus internus*; the point of which is divided by a notch, and from it ligaments are sent out to the foot.—The external side

of this end of the tibia has a rough irregular femilinear cavity formed in it, for receiving the lower end of the fibula.—The posterior side has two lateral grooves, and a small middle protuberance. In the internal depression, the tendons of the musculus tibialis posticus, and flexor digitorum longus, are lodged; and in the external, the tendon of the flexor longus pollicis plays.—From the middle protuberance, ligamentous sheaths go out, for tying down these tendons.

FIBULA is the small long bone, placed on the outside of the leg, opposite to the external angle of the tibia; the shape of it is irregularly triangular.

The head of the fibula has a superficial circular cavity formed on its inside, which, in a recent subject, is covered with a cartilage, but so closely connected to the tibia by ligaments, as to allow only a small motion backwards and forwards.—This head is protuberant and rough on its outside, where a strong round ligament, and the musculus biceps, are inserted; and, below the back-part of its internal side, a tubercle may be remarked, that gives rise to the strong tendinous part of the solæus muscle.

The body of this bone is a little crooked inwards and backwards, which figure is owing to the actions of the muscles; but is still further increased by nurses, who often hold children carelessly by the legs.—The sharpest angle of the fibula is forwards, on each side of which the bone is considerably, but unequally, depressed by the bellies of the several muscles that rise from, or act upon it; and, in old people, these muscles make distinct sinuosities for themselves.—The external surface of the fibula is depressed obliquely from above downwards and backwards, by the two peronei.—Its internal surface is unequally divided into two narrow longitudinal planes, by an oblique ridge extended from the upper part of the anterior angle, to join with the lower end of the internal angle. To this ridge the ligament stretched between the two bones of the leg is connected.—The anterior of the two planes is very narrow above, where the extensor longus digitorum, and extensor longus pollicis, arise from it; but is broader below, where it has the print of the nonus Vesalii.—The posterior plane is broad and hollow, giving origin to the larger share of the tibialis posticus.—The internal angle of this bone has a tendinous membrane fixed to it, from which fibres of the flexor digitorum longus take their rise.—The posterior surface of the fibula is the plainest and smoothest, but is made flat above by the solæus, and is hollowed below by the flexor pollicis longus.—In the middle of this surface the canal for the medullary vessels may be seen slanting downwards.

The lower end of the fibula is extended into a spongy oblong head, on the inside of which is a convex, irregular, and frequently a scabrous surface, that is received by the external hollow of the tibia, and so firmly joined to it by a very thin intermediate cartilage and strong ligaments, that it scarce can move.—Below this, the fibula is stretched out into a coronoid process, that is smooth, covered with cartilage on its internal side, and is there contiguous to the outside of the first bone of the foot, the astragalus, to secure the articulation. This process, named *malleolus externus*, being situated farther back

back than the internal malleolus, and in an oblique direction, obliges us naturally to turn the fore-part of the foot outwards. At the lower internal part of this process, a spongy cavity for mucilaginous glands may be remarked; from its point, ligaments are extended to the astragalus, os calcis, and os naviculare, bones of the foot; and from its inside, short strong ones go out to the astragalus. On the back-part of it, a sinuosity is made by the tendons of the peronæi muscles.—When the ligament extended over these tendons from the one side of the depression to the other is broke, stretched too much, or made weak by a sprain, the tendons frequently start forwards to the outside of the fibula.

The conjunction of the upper end of the fibula with the tibia is, by plain surfaces, tipped with cartilage; and, at its lower end, the cartilage seems to glue the two bones together, not, however, so firmly in young people, but that the motion at the other end of such a long radius is very observable.

The principal use of this bone is to afford origin and insertion to muscles; the direction of which may be a little altered, on proper occasions, by its upper part shuffling backwards and forwards.—It likewise helps to make the articulation of the foot more secure and firm.

**ROTULA** is the small flat bone situated at the fore-part of the joint of the knee.—Its shape resembles the common figure of the heart with its point downwards.—The anterior convex surface of the rotula is pierced by a great number of holes, into which fibres of the strong ligament that is spread over it enter.—Behind, its surface is smooth, covered with cartilage, and divided by a middle convex ridge into two cavities, of which the external is largest, and both are exactly adapted to the pulley of the os femoris, on which they are placed in the most ordinary untraining postures of the leg; but when the leg is much bended, the rotula descends far down on the condyles; and when the leg is fully extended, the rotula rises higher, in its upper part, than the pulley of the thigh-bone.—The plain smooth surface is surrounded by a rough prominent edge, to which the capsular ligament adheres:—Below, the point of the bone is scabrous, where the strong tendinous ligament from the tubercle of the tibia is fixed.—The upper horizontal part of this bone is flatted and unequal, where the tendons of the extensors of the leg are inserted.

The substance of the rotula is cellular, with very thin external firm plates: But then these cells are so small, and such a quantity of bone is employed in their formation, that scarce any bone of its bulk is so strong. Besides, it is covered all over with a thick ligament, to connect its substance, and is moveable to one side or other; therefore is sufficiently strong to resist the ordinary actions of the large muscles that are inserted into it, or any common external force applied to it.

The parts which constitute the joint of the knee being now described, let us examine what are its motions, and how performed.—The two principal motions are flexion and extension.—In the former of these, the leg may be brought to a very acute angle with the thigh, by the condyles of the thigh-bones being round and made

smooth far backwards. In performing this, the rotula is pulled down by the tibia.—When the leg is to be extended, the rotula is drawn upwards, consequently the tibia forwards, by the extensor muscles; which, by means of the protuberant joint, and of this thick bone with its ligament, have in effect the chord, with which they act, fixed to the tibia at a considerable angle, therefore act with advantage; but are restrained from pulling the leg farther than to a straight line with the thigh, by the posterior part of the cross ligament, that the body might be supported by a firm perpendicular column: For at this time the thigh and leg are as little moveable in a rotatory way, or to either side, as if they were one continued bone.—But when the joint is a little bended, the rotula is not tightly braced, and the posterior ligament is relaxed; therefore this bone may be moved a little to either side, or with a small rotation in the superficial cavities of the tibia; which is done by the motion of the external cavity backwards and forwards, the internal serving as a sort of axis. Seeing then one part of the cross ligament is situated perpendicularly, and the posterior part is stretched obliquely from the internal condyle of the thigh outwards, that posterior part of the cross ligament prevents the leg's being turned at all inwards; but it could not hinder it from turning outwards almost round, was not that motion confined by the lateral ligaments of this joint, which can yield little.

The **FOOT** is divided into three parts, viz. *tarfus, metatarfus, and toes*: In the description of which, the broad of the foot shall be called *superior*; the sole, *inferior*; the side on which the great toe is, *internal*; that where the little toe is, *external*.

The **TARFUS** consists of seven spongy bones; to wit, the *astragalus, os calcis, naviculare, cuboides, cuneiforme externum, cuneiforme medium, and cuneiforme internum*.

The **ASTRAGALUS** is the uppermost of these bones.—The **OS CALCIS** is below the astragalus, and is considerably prominent backwards beyond the other bones, to form the heel.—The **OS NAVICULARE** is in the middle of the internal side of the tarsus.—The **OS CUBOIDES** is the most external of the row of four bones at its fore-part.—The **OS CUNEIFORME EXTERNUM** is placed at the inside of the cuboid.—The **CUNEIFORME MEDIUM** is between the external and internal cuneiform bones, and the internal cuneiform is put at the internal side of the foot.

In the description of these bones, let it be observed, That where-ever a ridge is mentioned, without a particular use assigned, a ligament is understood to be fixed to it: or where a spongy rough cavity, depression, or fossa, is remarked, without naming its use, a ligament is inserted, and mucilaginous glands are lodged.

The upper part of the astragalus is formed into a large smooth head, which is slightly hollowed in the middle; and therefore resembles a superficial pulley, by which it is fitted to the lower end of the tibia.—The internal side of this head is flat and smooth, to play on the internal malleolus.—The external side has also such a surface, but larger, for its articulation with the external malleolus.—Round the base of this head there is a rough fossa; and, immediately before the head, as follows

below its internal smooth surface, we find a considerable rough cavity.

The lower surface of the astragalus is divided by an irregular, deep, rough fossa; which, at its internal end, is narrow, but gradually widens, as it stretches obliquely outwards and forwards.—The smooth surface, covered with cartilage, behind this fossa, is large, oblong, extended in the same oblique situation with the fossa, and concave, for its conjunction with the os calcis.—The back-part of the edge of this cavity is produced into two sharp-pointed rough processes, between which is a depression, made by the tendon of the flexor pollicis longus.—The lower surface before the fossa is convex, and composed of three distinct smooth planes. The long one behind, and the exterior or shortest, are articulated with the heel-bone; while the internal, which is the most convex of the three, rests and moves upon a cartilaginous ligament, that is continued from the calcaneum to the os scaphoides.

The fore-part of this bone is formed into a convex oblong smooth head, which is received by the os naviculare.—Round the root of this head, especially on the upper surface, a rough fossa may be remarked.

The astragalus is articulated above to the tibia and fibula, which together form one cavity. Though, in this articulation, the bones have prominences and cavities so small, as might allow motions in all directions; yet the flexion and extension are the most considerable, the other motions being confined by the malleoli, and by the strong ligaments which go out from the points of these processes to the astragalus and os calcis. The astragalus is joined below to the os calcis; and before, to the os naviculare, in the manner to be explained when these bones are described.

Calcaneum is the largest bone of the seven.—Behind, it is formed into a large knob, commonly called the *heel*: The surface of which is rough behind, where the tendo Achillis is inserted into it; and above, it is hollow and spongy. Farther forwards, on the upper surface of the calcaneum, there is an irregular, oblong, smooth convexity, adapted to the concavity at the back-part of the astragalus: And beyond this a narrow fossa is seen, which divides it from two small concave smooth surfaces, that are joined to the fore-part of the astragalus.—Behind the posterior of these smooth surfaces, which is the largest, a small sinusity is made by the tendon of the flexor digitorum longus; at the fore-part of which a small rough protuberance appears, that gives rise to the musculus extensor digitorum brevis.

The external side of this bone is flat, with a superficial fossa running horizontally, in which the tendon of the musculus peroneus longus is lodged.—The internal side of the heel-bone is hollowed, for lodging the origin of the massa cornea Jac. Sylvii, and for the safe passage of tendons, nerves, and arteries.—Under the side of the internal smooth concavity, a particular groove is made by the tendon of the flexor pollicis longus; and from the thin protuberance on this internal side, the cartilaginous ligament that supports the astragalus, goes out to the os naviculare; on which ligament, and on the edge of this bone to which it is fixed, the groove is form-

ed for the tendon of the flexor digitorum profundus.

The lower surface of this bone is pressed flat at the back-part, by the weight of our bodies; and immediately before this plane, there are two tubercles, from the internal of which the musculus abductor pollicis, flexor digitorum sublimis, as also part of the aponeurosis plantaris, and of the abductor minimi digiti, have their origin; and the other part of the abductor minimi digiti and aponeurosis plantaris, rises from the external.—Before these protuberances this bone is concave, for lodging the flexor muscles; and at its fore-part we may observe a rough depression, from which, and a tubercle behind it, the ligament goes out that prevents this bone to be separated from the os cuboides.

The fore-part of the os calcis is formed into an oblong, pulley-like, smooth surface, which is circular at its upper external end, but is pointed below. This smooth surface is fitted to the os cuboides.

Though the surfaces by which the astragalus and os calcis are articulated, seem fit enough for motion; yet the very strong ligaments by which these bones are connected, prevent it, and render this principal part of our base, which rests on the ground, to wit, the os calcis, firm.

Os naviculare, is somewhat circular.—It is formed into an oblong concavity behind, for receiving the anterior head of the astragalus.—On the upper surface, there is a rough fossa.—Below, the os naviculare is very unequal and rough; but hollow for the safety of the muscles.—On its inside, a large knob rises out, from which the abductor pollicis takes in part its origin, the tendon of the tibialis posticus is inserted into it, and to it two remarkable ligaments are fixed; the first is the strong one, formerly mentioned, which supports the astragalus; the second is stretched from this bone obliquely cross the foot, to the metatarsal bones of the middle toe, and of the toe next to the little one.—On the outside of the os naviculare, there is a semicircular smooth surface, where it is joined to the os cuboides.—The fore-part of this bone is all covered with cartilage, and is divided into three smooth planes, fitted to the three ossa cuneiformia.

The os naviculare and astragalus are joined as a ball and socket, and the naviculare moves in all directions in turning the toes inwards, or in raising or depressing either side of the foot, though the motions are greatly restrained by the ligaments which connect this to the other bones of the tarsus.

Os cuboides is a very irregular cube.—Behind, it is formed into an oblong unequal concavity, adapted to the fore-part of the os calcis.—On its internal side, there is a small semicircular smooth cavity, to join the os naviculare.—Immediately before which, an oblong smooth plane is made by the os cuneiforme externum.—Below this, the bone is hollow and rough.—On the internal side of the lower surface, a round protuberance and fossa are found, where the musculus adductor pollicis has its origin. On the external side of this same surface, there is a round knob, covered with cartilage; immediately before which, a smooth fossa may be observed, in which the tendon of the peroneus primus runs obliquely cross

the foot; and on the knob, the thin flat cartilage proper to this muscle plays; in place of which, sometimes a bone is found:—More externally than the knob, a rough hollow is made, for the strong ligaments stretched betwixt this bone and the os calcis.—Before, the surface of the os cuboides is flat, smooth, and slightly divided into two planes, for sustaining the os metatarsi of the little toe, and of the toe next to it.

The form of the back-part of the os cuboides, and the ligaments connecting the joint there with the os calcis, both concur in allowing little motion in this part.

Os cuneiforme externum, is much of the shape of a wedge, being broad and flat above, with long fibres running obliquely downwards, and terminating in a sharp edge.—The upper surface of this bone is an oblong square.—The one behind is nearly a triangle, but not complete at the inferior angle, and is joined to the os naviculare.—The external side is an oblong square, divided as it were by a diagonal: The upper half of it is smooth, for its conjunction with the os cuboides: The other is a scabrous hollow; and in its superior anterior angle, a small smooth impression is made by the os metatarsi of the toe next to the little one.—The internal side of this bone is also quadrangular, with the fore-part of its edge made flat and smooth by the os metatarsi of the toe next to the great one; and the back-part is also flat and smooth, where the os cuneiforme medium is contiguous to it.—The fore-part of this bone is an oblong triangle, for sustaining the os metatarsi of the middle toe.

Os cuneiforme medium, or minimum, is still more exactly the shape of a wedge than the former.—Its upper part is square;—its internal side has a flat smooth surface above and behind, for its conjunction with the following bone; with a small rough fossa below; and a considerable share of it is rough and hollow.—The external side is smooth and a little hollowed, where it is contiguous to the last described bone.—Behind, this bone is triangular, where it is articulated with the os naviculare; and it is also triangular at its fore-part, where it is contiguous to the os metatarsi of the toe next to the great one.

Os cuneiforme maximum, or internum, differs from the two former in its situation, which is more oblique than theirs.—Besides, its broad thick part is placed below, and the small thin point is above and outwards; while its under broad surface is concave, for allowing a safe passage to the flexors of the great toe.—The surface of this os cuneiforme behind, where it is joined to the os naviculare, is hollow, smooth, and of a circular figure below, but pointed above.—The external side consists of two smooth and flat surfaces, whose direction is nearly at right angles with each other. With the posterior, that runs obliquely from below forwards and upwards, the os cuneiforme minimum is joined; and with the anterior, whose direction is longitudinal, the os metatarsi of the toe next to the great one is connected.—The fore-part of this bone is semilunar, but flat and smooth, for sustaining the os metatarsi of the great toe.—The internal side is scabrous, with two remarkable tubercles below, from which the musculus abductor pollicis rises, and the tibialis anticus is inserted into its upper part.

The three cuneiform bones are all so secured by ligaments, that very little motion is allowed in any of them.

These seven bones of the tarsus, when joined, are convex above, and leave a concavity below, for lodging safely the several muscles, tendons, vessels, and nerves that lie in the sole of the foot.—In the recent subject, their upper and lower surfaces are covered with strong ligaments, which adhere firmly to them; and all the bones are so tightly connected, by these and the other ligaments, which are fixed to the rough ridges and fossae formerly mentioned, that, notwithstanding the many surfaces covered with cartilage, some of which are of the form of the very moveable articulations, no more motion is here allowed, than only to prevent too great a shock of the fabric of the body in walking, leaping, &c. by falling on too solid a base.

METATARSUS is composed of five bones, which, in their general characters, agree with the metacarpal bones; but may be distinguished from them by the following marks: 1. They are longer, thicker, and stronger. 2. Their anterior round ends are not so broad, and are less in proportion to their bases. 3. Their bodies are sharper above and flatter on the sides, with their inferior ridge inclined more to the outside. 4. The tubercles at the lower parts of the round head are larger.

The first or internal metatarsal bone is easily distinguished from the rest by its thickness.—The one next to it is the longest, and with its sharp edge almost perpendicular.—The others are shorter and more oblique, as their situation is more external.

Os metatarsi pollicis is by far the thickest and strongest, as having much the greatest weight to sustain. Its base is oblong, irregularly concave, and of a semilunar figure, to be adapted to the os cuneiforme maximum.—The inferior edge of this base is a little prominent and rough, where the tendon of the peronæus primus muscle is inserted.—On its outside, an oblique circular depression is made by the second metatarsal bone.—Its round head has generally on its fore-part a middle ridge, and two oblong cavities, for the ossa sesamoidea; and on the external side, a depression is made by the following bone.

Os metatarsi of the second toe, is the longest of the five, with a triangular base supported by the os cuneiforme medium and the external side produced into a process; the end of which is an oblique smooth plane, joined to the os cuneiforme externum.—Near the internal edge of the base, this bone has two small depressions, made by the os cuneiforme maximum, between which is a rough cavity.—Farther forwards, we may observe a smooth protuberance, which is joined to the foregoing bone.—On the outside of the base are two oblong smooth surfaces, for its articulation with the following bone; the superior smooth surface being extended longitudinally, and the inferior perpendicularly; between which there is a rough fossa.

Os metatarsi of the middle toe, is the second in length.—Its base, supported by the os cuneiforme externum, is triangular, but slanting outwards, where it ends in a sharp-pointed little process; and the angle below is not completed.

The

The internal side of this base is adapted to the preceding bone; and the external side has also two smooth surfaces covered with cartilage, but of a different figure; for the upper one is concave, and, being round behind, turns smaller as it advances forwards; and the lower surface is little, smooth, convex, and very near the edge of the base.

Os metatarsi of the fourth toe, is near as long as the former, with a triangular flanting base, joined to the os cuboides, and made round at its external angle, having one hollow smooth surface on the outside, where it is pressed upon by the following bone, and two on the internal side, corresponding to the former bone; behind which is a long narrow surface impressed by the os cuneiforme externum.

Os metatarsi of the little toe, is the shortest, situated with its two flat sides above and below, and with the ridges laterally.—The base of it, part of which rests on the os cuboides, is very large, tuberos, and produced into a long-pointed process externally, where part of the abductor minimi digiti is fixed; and into its upper part the peroneus secundus is inserted.—Its inside has a flat conoidal surface, where it is contiguous to the preceding bone.

When we stand, the fore-ends of these metatarsal bones, and the os calcis, are our only supporters; and therefore it is necessary they should be strong, and should have a confined motion.

The bones of the Toes are much akin to those of the thumb and fingers; particularly the two of the great toe are precisely formed as the two last of the thumb; only their position, in respect of the other toes, is not oblique; and they are proportionally much stronger, because they are subjected to a greater force; for they sustain the force with which our bodies are pushed forwards by the foot behind at every step we make; and on them principally the weight of the body is supported, when we are raised on our tiptoes.

The three bones in each of the other four toes, compared to those of the fingers, differ from them in these particulars.—They are less, and smaller in proportion to their lengths:—Their bases are much larger than their anterior ends: Their bodies are more narrow above and below, and flatter on the sides.—The first phalanx

is proportionally much longer than the bones of the second and third, which are very short.

Of the four, the toe next to the great one has the largest bones in all dimensions, and more externally the toes are less.—The little toe, and frequently that next to it, have the second and third bones intimately united into one; which may be owing to their little motion, and the great pressure they are subjected to.

The toes are of good use to us in walking; for, when the sole is raised, they bring our body, with its centre of gravity, perpendicular to the advanced foot.

The only bones now remaining to complete the description of the skeleton, are the small ones, which are found at the joints of the fingers and toes, and in some other parts, called

OsSA SESAMOIDEA, which are of very different figures and sizes, though they are generally said to resemble the head of the sesamum.—They seem to be nothing else than the ligaments of the articulations, or the firm tendons of strong muscles, or both, become bony, by the compression which they suffer. Thus the sesamoid bones at the beginning of the gastrocnemii muscles, are evidently composed of the tendinous fibres only.—These, at the first joint of the great toe, are as plainly the same continued substance with the ligaments and the tendons of the adductor, flexor, brevis, and abductor.—That which is sometimes double at the second joint of that toe, is part of the capsular ligament; and if we enumerate the other sesamoid bones that are at any time found, we may observe all of them formed in this manner.—Their number, figure, situation, and magnitude, are so uncertain, that it were in vain to insist on the differences of each; and therefore we shall only in general remark,

1. That where-ever the tendons and ligaments are firmest, the actions of the muscles strongest, and the compression greatest, there such bones are most commonly found.

2. That, *ceteris paribus*, the older the subject is in which they are sought, their number is greater, and their size is larger.

3. The more labour any person is inured to, he has, *ceteris paribus*, the most numerous and largest ossa sesamoidea.

## EXPLANATION OF PLATE XIII.

FIGURE I. A MALE SKELETON.

A, Os frontis. B, Os parietale. C, Os temporum. D, Os occipitis. E, Ossa nasi. F, Os maxilæ. G, Os maxillare superius. H, Os maxillare inferius. I, The teeth, which are sixteen in each jaw. K, The seven vertebrae of the neck, with their intermediate cartilages. L, &c. The twelve dorsal vertebrae, with their intermediate cartilages. M, The five lumbar vertebrae, and, N, Their intermediate cartilages. O, Os

sacrum. P, Os coccygis. Q, Os ilium. R, Os pubis. S, Os ischium. T, The seven true ribs. U, The five false ribs. V, The sternum. X, The clavicle. Y, The scapula. Z, The os humeri. a, Ulna. b, Radius. c, The eight bones of the carpus. d, The five metacarpal bones. e, The phalanges of the fingers. f, The os femoris. g, The patella. h, The tibia. i, The fibula. k, The seven bones of the tarsus. l, The five metatarsal bones. m, The phalanges of the toes.

### O F T H E M U S C L E S.

#### SECT. I. *Of the MUSCLES in general.*

THE muscles are bundles of fibres of different figures and sizes, and for the most part consisting of two different portions; one whereof is thick, soft, and more or less red, forming what is called the body, fleshy substance, or belly of the muscle. The other is thin and small, of a close texture, and very white, forming the extremities, termed by anatomists *tendons* or *aponeuroses*. Both portions are covered by a particular membrane.

The fibres are, for the most part, ranked in fasciculi, in a lateral situation with respect to each other, and distinguished by membranous, cellular, or adipose septa, as by so many particular vaginae.

These fibres are connected to each other, and to the intermediate septa, by a great number of very small fine filaments, the capillary extremities of arteries, veins, and nerves running over them; and they are inclosed in a thin membranous, cellular covering, called the proper membrane of the muscle, being a continuation of the septa or vaginae already mentioned.

The disposition of the fibres is various: some are disposed like radii; others form planes more or less incurvated; and some form complete circumferences, the two extremities meeting and uniting together.

The difference of muscles is very considerable, and depends on many circumstances; the chief of which are, the size, figure, direction, situation, structure, connection, and use; and it is from these differences that the names of the greatest part of the muscles are taken.

From

From their size they are termed *great, middle, small, long, broad, thin*: From their figure, *triangular, scalenous, square*, &c. From their direction, *straight, oblique, transverse*. From their situation, *superior, inferior, external, &c.*

With respect to their structure, muscles are either simple or compound. Simple muscles are those whose fleshy fibres, or rather the fleshy portions of their moving fibres, are all uniformly disposed, and terminate in tendons lying either in a straight or oblique line.

Compound muscles are those whose fleshy fibres are disposed obliquely in several particular ranks, representing the same number of simple muscles, with their fibres, lying in opposite directions. In proportion to the number of these ranks or series, the muscle is said to be more or less compounded.

When the compound muscle is made up of two simple muscles only, these are so disposed as to represent a feather, and the compound muscle is from thence termed *penniform*.

Some are made up of two muscles more or less, in a lateral situation with respect to each other, and united at one extremity: others are made up of three or four muscles, situated in the same manner; and if they are united at that extremity which the ancients called the head of the muscle, they are called *bicipites, tricipites*, &c. according to the number of these heads; but if they are joined at the other extremity, they are termed *bicornes, tricornes*, &c.

The muscles are fixed by their extremities to different parts, and in different places of the human body. The greatest part of them are inserted in bones alone. Some are fixed partly to bones, and partly to cartilages; as those of the ear and nose: some partly to bones, and partly to the integuments; as several muscles of the face.

The names taken from the connections and insertions of muscles are generally of two kinds; one common, and referred to some considerable part of the body; as when we say, the muscles of the head, of the thorax, abdomen, &c.; the other proper, specifying more particularly the insertions of each muscle, as the *massoideus, sterno-mastoideus*, &c.

The general use of the muscles is to move all the parts of the body, whether hard, soft, or fluid. Most of the hard and soft parts are moved by these powers being fixed to them, and they move the rest without any such insertion.

The action of the muscles in general, consists chiefly in the contraction or shortening of their fleshy portion; by which the extremities of the muscle are brought nearer to each other, and consequently the parts are moved to which these extremities are fixed.

The principal phenomena of muscular action are these: The fleshy portion appears harder and more swelled in the time of action than of inaction, as may be readily perceived by touching it in both states: The hardness of this swelling increases in proportion as the motion is continued, as is likewise evident by the touch; and it likewise increases by merely adding to the weight or resistance of the part moved, though its situation does not continue to be changed.

## SECT. II. *The Muscles of the Abdomen.*

By the muscles of the abdomen, or lower belly, we mean those which form principally the sides or circumference of that cavity. They are commonly ten in number, five on each side; eight whereof are very large, the other two very small.

### OBLIQUUS EXTERNUS.

The *obliquus externus* is a broad thin muscle, fleshy on its upper and back-part, and tendinous on the anterior and greatest portion of the lower part. It reaches from half the lateral and inferior part of the thorax, to almost half the lateral and superior part of the pelvis; and from the back-part of the *regio lumbaris* to the *linea alba*.

It is fixed, by its upper part, to the ribs; by the lower, to the *os ilium*, *ligamentum Fallopii*, and *os pubis*; and, by the fore-part, to the *linea alba*. The posterior portion next the vertebrae of the loins has commonly no true muscular insertions.

### OBLIQUUS INTERNUS.

The internal oblique is a broad thin muscle like the former, having nearly the same extent and insertions; that is, in the lower ribs above; in the crista of the *os ilium* and *ligamentum Fallopii*, below; and in the *linea alba*, before: but it differs from it in this, that its lower part is more fleshy than the upper.

One portion of its lower extremity, which is entirely fleshy, is fixed, by very short tendinous fibres, in the middle space between the two labia of the *crista ossis ilium*, from the back-part of the tuberosity of that crista, near the symphysis of the *os sacrum*, almost all the way to the superior and anterior spine of the *os ilium*; so that its insertion reaches farther back than that of the external oblique.

The fleshy fibres thus fixed, run up first a little obliquely from behind forward, and then this obliquity increases proportionably as the fibres lie more anteriorly, and they cross those of the fleshy portion of the external oblique, being afterwards inserted exteriorly in the lower edges of the cartilages of all the false ribs, and those of the two lowest true ribs, reaching to the extremity of the *cartilago ensiformis*.

This muscle is likewise called *obliquus descendens*, for the same reason that the former is termed *ascendens, obliquus inferior*, and *obliquus minor*, because it does not reach so high, and is not quite so large as the external oblique.

### MUSCULI RECTI.

The *recti* are long narrow muscles, thicker than the obliqui. They lie near each other like two large bands, from the lower part of the thorax, to the *os pubis*, the *linea alba* coming between them. Their breadth diminishes, and their thickness increases gradually from above downward.

The

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

The superior extremity of each muscle is fixed to a part of the lower extremity of the sternum, to the three lowest true ribs, and to the first false rib, by the same number of digitations, of which that which is farthest from the sternum is the broadest.

The body of the muscle lies in the vagina, formed by the aponeurosis of the broad muscles of the abdomen. Exteriorly, it is divided into several portions, resembling distinct muscles placed endways, by transverse tendons, termed *eneruations*, which commonly are all above the umbilicus, very seldom below it, and they adhere very close to the vagina.

The lower extremity of this muscle is narrower than the upper, and ends in a thin tendon fixed in the internal labium of the upper edge of the os pubis, near the symphysis, and there it touches the tendon of the other rectus.

### MUSCULI PYRAMIDALES.

At the lower part of the recti, we meet commonly with two small muscles, which at first seem to be a portion or appendix of the former. They are named *pyramidales* from their figure; and by Fallopius, *succenturiati*.

At the lower extremity, they are broad and thick, being there fixed to the upper edge of the ossa pubis, immediately before the recti. They decrease gradually in breadth and thickness as they ascend, and end by a point in the linea alba, a little way below the umbilicus.

### TRANSVERSALES.

The transverse muscles are nearly of the same breadth with the obliques. Each of them is fixed to the ribs above; below, to the os ilium, and ligamentum Fallopii; before, to the linea alba; and behind, to the vertebrae.

The upper part of this muscle is fixed to the lower part of the inner surface of the cartilages of the two lowest true ribs, and of all the five false ribs, by fleshy digitations, the fibres of which run more or less transversely toward the linea alba, at some distance from which they become tendinous.

The middle part is fixed to the three first vertebrae of the loins, by a double aponeurosis, or two tendinous planes, one internal or anterior, the other external or posterior.

The inferior part of this muscle is fixed by an insertion wholly fleshy to the internal labium of the crista of the ilium, and to a great part of the ligamentum Fallopii. From thence many of its fibres run towards the linea alba, the rest to the os pubis, all of them becoming more or less tendinous before their insertion.

### USES OF THE ABDOMINAL MUSCLES.

The common uses are, to sustain the viscera of the abdomen, and to counterbalance the perpetual motions of ordinary respiration, and thereby gently and continually to act on the viscera; which action may be reckoned a

sort of trituration, of great importance to the animal economy. They compress the abdomen, in order to clear it of what ought to pass off by the natural outlets; to relieve the stomach, by vomiting, from whatever might be hurtful to it; and, lastly, to drive out, by a violent expiration, whatever may incommode the organs contained in the thorax.

The musculi recti serve to support the trunk of the body when inclined backward, and to bend or bring it forward again; to raise the body up when lying; and, lastly, to climb.

The pyramidales seem only to assist the action of the recti; though, when we consider the oblique direction of their fibres toward the linea alba, there may be some reason to think that they compress the bladder, especially when very full of urine.

The transversales seem to have no other use than that of bracing or girding the abdomen in different degrees.

### SECT. III. The MUSCLES which move the Bones of the Shoulder upon the Trunk.

#### TRAPEZIUS.

The trapezius is a large, broad, thin, fleshy plane, situated between the occiput and lower part of the back, and from thence extending to the shoulder, in the figure of a large irregular square. From this figure the ancient Greeks took its name, and, together with the trapezius of the other side, it forms a kind of lozenge.

Above, it is fixed in the superior transverse line of the os occipitis, by a thin series of fleshy fibres, reaching to the musculus occipitalis, and appearing to cover that muscle by a kind of aponeurosis. Behind, it is fixed to the five superior spinal apophyses of the neck, by means of the posterior cervical ligament, and immediately to the extremities of the two lowest spinal apophyses of the neck, and of all those of the back.

This muscle covers immediately the splenius or mastoideus superior, part of the complexus major, the angularis, rhomboides, and part of the latissimus dorsi.

#### RHOMBOIDES.

This muscle is a thin, broad, and obliquely square fleshy plane, situated between the basis of the scapula and the spina dorsi; and it is from its figure that it has been termed *rhomboides*.

It may be divided into two portions, one superior, the other inferior, which sometimes appear separate. The superior portion is fixed, by an insertion wholly fleshy, in the two or three lowest spinal apophyses of the neck, and partly in the posterior cervical ligament. The inferior portion is fixed, by a tendinous plane, in the three or four uppermost spinal apophyses of the back.

These two portions, of which the inferior is by much the broadest, being united, are inserted in the edge of the basis scapulae, from the small triangular space to the inferior angle, the superior portion covering a small part of the insertion of the angularis.

This whole muscle is covered by the trapezius, and covers immediately the *ferratus posticus superior*, being joined to each of these muscles by a filamentary or cellular substance.

#### ANGULARIS, VULGO LEVATOR SCAPULÆ PROPRIUS.

THIS is a long, and pretty thick muscle, about two fingers in breadth, lying above the superior angle of the scapula, along the posterior lateral part of the neck of that bone.

It is inserted above in the extremities of the transverse apophyses of the four first vertebræ of the neck, by four fleshy branches, ending in short tendons; sometimes the second, sometimes the third, or both, and sometimes the fourth of these branches, is wanting; these defects being made up by the largeness of the rest.

From thence these branches run down a little obliquely, and then uniting together, they are inserted in the superior angle of the scapula, and in the edge of its basis, from thence to the small triangular space, being there covered a little by the rhomboides.

This muscle is easily divided into two through its whole length. It is covered by the trapezius, and its insertions in the neck are sometimes mixed with those of the neighbouring muscles.

#### PECTORALIS MINOR.

THIS is a small fleshy muscle, something of a triangular shape, situated at the superior, lateral, and anterior part of the thorax.

By its basis it is inserted in the external labium of the upper edge of the second, third, fourth, and fifth true ribs; near their union with the cartilages, by the same number of digitations or separate fleshy portions, because of the intervals between the ribs; and for that reason it has been called *ferratus minor anticus*.

From thence these portions run up, more or less, obliquely toward the shoulder, and form a fleshy belly, which contracts as it passes before the two first ribs, and then becoming a short, flat, and broad tendon, is inserted in the upper part of the apophysis coracoides of the scapula, reaching all the way to the point of that process.

This muscle is covered by the *pectoralis major*, and adheres very closely to the external intercostal muscles.

#### SERRATUS MAJOR.

THIS is a broad, fleshy, and pretty thick muscle, lying on the lateral part of the thorax, between the ribs and scapula, by which it is covered. Its figure is that of an irregular square, its greatest breadth being in the back-part, where it terminates by digitations of unequal lengths, in a radiated disposition, their extremities describing an arch or curve; and from these digitations its name is taken.

It is inserted backward in the internal labium of all the basis of the scapula, from the superior to the inferior angle. From thence running forward wholly fleshy, it

increases gradually in breadth, and is inserted in all the true ribs, and often in one or two of the false ribs, by the same number of digitations.

#### SUBCLAVIUS.

THIS is a small oblong muscle, lying between the clavicle and first rib. It is fixed by one end in all the middle lower portion of the clavicle, at the distance of about an inch from each extremity; and by the other in the cartilage and a small part of the bone of the first rib. It seems likewise to adhere to the extremity of the clavicle next the sternum, by a kind of broad thin ligament.

USES of the MUSCLES which move the BONES of the SHOULDER on the TRUNK.

THE mechanism of the scapula, in relation to its motions and changes of situation, is very different from that of all the other bones of the body, except the os hyoides. All the other bones have solid fulcra or fixed points, on which they are either moved or fixed by the muscles; but the motions of the scapula, its changes of situation, and its continuance in any one given attitude, are brought about without the help of any solid fulcrum. The muscles alone sustain it and brace it down, in all its different motions and situations.

The scapula has this peculiarity likewise belonging to it, that it is the fulcrum and basis of all the motions of the os humeri, of some motions of the fore-arm, and even of all the most violent efforts made with these bones, without being itself either moved or fixed on any solid basis.

The use of the trapezius is to raise the shoulder, and to keep it from sinking.

The *ferratus major* raises the shoulder or top of the scapula, brings it forward, and hinders it from sinking. In all these, it is the principal actor; and it is impossible to conceive how labourers raise and support, by the shoulder alone, the heavy burdens with which they are loaded, without the assistance of this muscle.

According to the insertions and direction of the rhomboides, its general use must be, to draw backward and upward the sub-spinal portion of the basis scapulæ.

It is likewise a moderator to the trapezius and *ferratus major*, when they raise the shoulder, or carry the acromium upward; and it brings the scapula back to its natural situation, when the action of these muscles ceases.

The angularis, by its insertion in the superior angle of the scapula, moderates the descent of that angle, while the trapezius and *ferratus major* raise the acromium. Afterwards, when these two muscles cease to act, the angularis raises the superior angle, and by that means depresses the acromium.

The *pectoralis minor* assists the rhomboides and angularis, as moderators of the action of the trapezius and *ferratus major*, in turning the point of the acromium upward, the superior angle downward, and the inferior angle forward.

It is likewise an assistant to the rhomboides and angularis, in restoring the scapula to its natural situation, when

when the trapezius and ferratus major cease to act; by drawing downward the apophysis coracoides, in which it is inserted.

The subclavius can have no other ordinary use, but to bring down the clavícula, after it has been raised, together with the acromium, by the action of the trapezius and ferratus major.

#### SECT. IV. *The MUSCLES which move the Os Humeri on the Scapula.*

##### DELTOIDES.

THIS is a very thick muscle, covering the upper part of the arm, and forming what is termed the stump of the shoulder. It is broad above, and narrow below, in a triangular form; and its name is taken from the resemblance it bears to the Greek letter  $\Delta$  delta.

It is made up of eighteen or twenty small single muscles, in an opposite situation with respect to each other, and united by middle tendons; so that, taken all together, they form several penniform muscles. The outer surface appears almost wholly fleshy, but on the inner surface we see the several tendons.

Above, it is fixed in the whole inferior labium of the spina scapulae, in the convex or long edge of the acromium, and in the third part of the anterior edge of the clavicle next that apophysis. It surrounds the angle formed by the articulation of these two bones, by a particular slope and fold contrived for that purpose.

From thence it runs down above one third of the length of the os humeri, where it is inserted, by a thick tendon, in the large muscular rough impression below the bony ridge which goes from the great tuberosity of the head of the bone.

##### PECTORALIS MAJOR.

THIS is a large, thick, and fleshy muscle, covering the fore-part of the breast, from the sternum, where it is very broad, to the axilla, where it contracts in its passage to the arm.

The insertions in the sternum end by a great number of very short tendons which run toward the middle of the bone, meeting and decussating those from the same muscle on the other side. The lower insertions are most distinctly digitated, and they mix with those belonging to the rectus and obliquus externus of the abdomen, there being likewise several fasciculi of fibres common to the pectoralis with these muscles. This portion is also fixed to the ribs by internal fleshy strata covered by the external insertions, and forming, together with them, the thickness of the muscle.

From thence all the fleshy fibres contract in breadth, and approach each other, in their passage to the arm. The superior fibres run downward, joining those of the clavicular portion; those next them run less obliquely; the following more or less transversely; and the inferior run upward, in the same manner.

This muscle, together with the deltoides, sends off

an aponeurosis, which, joining that of the biceps, is spread over the muscles of the arm.

##### LATISSIMUS DORSI.

THIS is a broad, thin, and mostly fleshy muscle, lying between the axilla, where it is very narrow, and the back on which it expands itself by radiated fibres, both in length and breadth, from the middle of the back all the way to the lower part of the regio lumbaris; and from this situation it has its name.

Its insertions are partly tendinous, and partly fleshy. In the first place, it is sometimes, but not always, fixed in the inferior costa of the scapula near the angle, by a fasciculus of fleshy fibres. In the next place, it is fixed by an aponeurosis, in the spinal apophyses of the six or seven, and sometimes eight lowest vertebrae of the back, in those of all the vertebrae of the loins, in the superior spines and lateral parts of the os sacrum, and in the external labium of the posterior part of the os ilium.

##### TERES MAJOR.

THIS is a long, thick, flat muscle, situated a little obliquely between the inferior angle of the scapula, and the upper part of the arm.

It is fixed by its posterior fleshy extremity in all the large angular surface on the outside of the scapula, in the inferior costa of that bone, and near the angle. From thence it advances with longitudinal fibres toward the upper quarter of the os humeri, terminating in a broad flat tendon intermixed with some fleshy fibres, which at the upper edge are continued all the way to the insertion, lying in the same place with the tendon.

It is inserted, by its anterior extremity, at the lower part of the bony ridge of the small tuberosity, along the edge of the channel, almost opposite to, and sometimes a little lower than the insertion of the pectoralis major. It lines the cavity of the channel by a tendinous elongation, which joins that from the pectoralis, and seems to be continued with it.

##### TERES MINOR.

THIS is a very fleshy muscle, resembling the teres major, but narrower and shorter. It lies above the last named muscle, between the costa inferior of the scapula, and the head of the os humeri.

It is fixed by one end to all the middle part of the inferior costa of the scapula, and to the long particular surface immediately above that costa, reaching from the great angular surface near the neck of the bone. From thence it runs wholly fleshy, till it changes into a flat tendon, which is inserted in the posterior or inferior surface of the great tuberosity of the head of the bone, and likewise a little lower down.

##### INFRA-SPINATUS.

THIS is a triangular, fleshy, and pretty broad muscle, in some measure penniform, filling the whole infra-spinal cavity or fossa of the scapula.

It is fixed in the posterior half of the infra-spinal cavity or fossa, and to the corresponding part of the basis of the scapula.

From thence arise a great number of short fleshy fibres, which run more or less obliquely, and end in a middle tendinous plane, which terminates a little below the broadest part of the spine of the scapula, under the root of the acromium.

Then the fleshy fibres, leaving the bone, unite in one fleshy mass, which, passing under the acromium, over the articulation of the head of the os humeri, and adhering to the capsular ligament, terminates there in a flat broad tendon, which, adhering likewise to the capsula, is afterwards inserted in the greater middle surface of the great tuberosity of the head of the os humeri.

### SUPRA-SPINATUS.

THIS is a thick narrow muscle, in some measure penniform, filling all the supra-spinal cavity of the scapula.

It is fixed to all the posterior half of the supra-spinal fossa; and sometimes its insertion reaches near the neck of the bone. There the fibres leave the surface of the bone, and pass between the acromium and neck of the scapula, under the arch formed by the acromium and extremity of the clavicle, and under the ligament between the acromium and apophysis coracoides; being afterwards inserted in the superior surface of the great tuberosity of the head of the os humeri, very near the bony channel.

### CORACO-BRACHIALIS.

THIS is a long muscle lying on the inside of the upper half of the os humeri.

It is fixed above to the point of the coracoid apophysis, between the insertions of the biceps and pectoralis minor, by a tendon, which, as it descends, adheres for a good way to the tendons of these two muscles. Afterwards it becomes fleshy, and is inserted by a broad thin extremity, with a small mixture of tendinous fibres, in the middle part of the os humeri.

### SUBSCAPULARIS.

THIS muscle is of the same breadth and length with the scapula, of which it occupies all the inner or concave side; and from this situation it has its name. It is thick, and made up of several penniform portions nearly in the same manner with the deltoides.

It is fixed in the internal labium of the whole basis, and in almost the whole internal surface of the scapula; its fleshy portions lying in the intervals between the bony lines, when these are found. Near the neck, they leave the bone, and form a very broad tendon which is inserted in the surface of the small tuberosity of the head of the os humeri.

*USES of the MUSCLES which move the OS HUMERI on the SCAPULA.*

THE deltoides, from the disposition of its insertions in the scapula and clavicle, may raise the arm, or sepa-

rate it from the ribs, not only directly, but likewise obliquely in many different ways. The arm being lifted directly upward, the lateral, anterior, and posterior portions of this muscle may bring the arm, so raised, forward and backward.

The latissimus dorsi serves in general to bring down the arm when raised; it also serves to depress the shoulder, or to maintain it in that situation against any force that endeavours to raise it; as when we lean upon the elbow in sitting, or walk upon crutches.

The pectoralis major serves in general to bring the arm near the ribs, to press it strongly against them, and to carry it towards the fore-part of the thorax.

The teres major, by being inserted in the os humeri in a direction parallel to the latissimus dorsi, becomes a congener to the superior and posterior portion of that muscle; and accordingly moves the os humeri in the same manner with it. It turns the bone round its axis, when the fore-arm is carried behind the back.

It likewise pulls the arm directly backward, without moving it round its axis.

The coraco-brachialis brings the arm to the fore-side of the thorax, raising it at the same time; and, in this case, it may be reckoned a congener or assistant to the pectoralis major in great efforts; and may perform the same motion by itself, when no great force is necessary; as when the whole arm hangs down, and is moved backward and forward like a pendulum, the motion forward being performed by the coraco-brachialis, and the motion backward by the teres major, its antagonist.

This muscle may likewise move the scapula on the os humeri kept firmly depressed, as when sitting in a chair we take fast hold of the edge of it with the hand. In this case the coraco-brachialis may bring the acromium downward, and the inferior angle of the scapula, near the vertebrae. It serves likewise to bring the arm to its former situation, after it has been turned by the latissimus dorsi, in order to apply the hand to the back; and then it turns the os humeri upon its axis in a contrary direction to that given it by the other muscle.

The supra-spinatus joins with the deltoides in lifting up the arm; this muscle beginning that action, and the deltoides continuing it.

The infra-spinatus being inserted by its tendon in the middle surface of the great tuberosity of the os humeri, must perform different motions according to the different situations of that bone. If it acts while the arm hangs down, parallel to the trunk of the body, it may move the os humeri round its axis, from before outward; and consequently, if the fore-arm be at the same time bent, it will turn the hand from the body, &c.

When the arm hangs down in its natural situation, the subscapularis may turn it round its axis, from without forward, as it happens when in this situation we beat the breast with the fore-arm bent; and it likewise strongly assists the latissimus dorsi, when we turn the hand behind the back.

When the arm being raised, we move it backward, as in giving a back-stroke with the elbow or fist, the subscapularis hinders the head of the os humeri from being luxated forward.

The *teres minor* may turn the arm when depressed round its axis, from before outward; as it happens when the fore-arm, being bent and applied to the lower part of the breast, is removed from thence, without moving the elbow from the side.

SECT. V. *The MUSCLES which move the Bones of the Fore-arm on the Os Humeri.*

*BICEPS* *see* CORACO-RADIALIS.

THIS is a double muscle made up of two long fleshy bodies, more or less round, lying by the side of each other, on the middle anterior part, and a little toward the inside of the arm. These two bodies are separated above, each of them ending in a small tendon. As they run down they become contiguous, and afterwards closely united by one common broad tendon.

It is fixed by one of the superior tendons, in the apex of the coracoid apophysis of the scapula.

The other superior tendon is smaller and longer than the former, and the fleshy body belonging to it shorter and more compounded. This tendon is lodged in the bony channel of the os humeri, being surrounded by a membranous vagina continued from the capsular ligament, and ending at the fleshy body where it is entirely closed.

BRACHIÆUS.

THIS is an oblong, thick, and broad muscle, lying immediately on the anterior part of the lower half of the os humeri. The upper part of it is forked or sloped, and at the bending of the joint of the elbow the lower part contracts.

It is fixed to the surface of the os humeri by a great number of fleshy fibres, from the lower insertion of the *deltoides*, almost down to the two fossæ at the lower extremity of the bone, and from one edge of the fore-side of this lower extremity to the other: The fibres are for the most part longitudinal, those nearest the surface of the muscle being longest, the more internal growing gradually shorter.

ANCONÆUS MAJOR.

THIS is a long fleshy muscle lying on the backside of the os humeri.

It is fixed above by a short tendon to the inferior impression in the neck of the scapula, and to a small part of the inferior costa of that bone. From thence it passes between the extremities of the *subscapularis* and *teres minor*, and, having reached the backside of the lower extremity of the os humeri, it ends obliquely in a strong broad tendon, which, adhering closely in the capsular ligament, is afterwards fixed by a broad insertion in the rough tuberosity on the upper side of the olecranon.

ANCONÆUS EXTERNUS.

THIS is a long muscle lying on the outer part of the

backside of the os humeri, from its neck to the external condyle.

It is fixed above in the neck of the os humeri under the inferior surface of the great tuberosity, and under the insertion of the *teres minor*, but a little more backward. It is likewise fixed by some oblique fibres in the external inter-muscular ligament.

ANCONÆUS INTERNUS.

THIS muscle is shorter and more fleshy than the *anconæus externus*, and lies toward the inner part of the lower half of the os humeri.

It is fixed above, under the lower extremity of the *teres major*, but a little more backward, and to the internal inter-muscular ligament, which makes a kind of septum between this muscle and the *brachiiæus*. From thence the fibres contracting in breadth, pass toward the tendon of the *anconæus major*, some of them running in between it and the bone, and are inserted in the edge and inner side of that tendon.

ANCONÆUS MINOR.

THIS is a small muscle obliquely triangular, lying in the oblong fossula on the outside of the olecranon.

It is fixed by a small, but pretty strong tendon, in the lower part of the external condyle of the os humeri. From thence the fleshy fibres run down obliquely in a radiated form, and are inserted in the bottom and whole posterior edge of the fossula already mentioned.

*Uses of the Muscles which move the Bones of the Fore-arm on the Os Humeri.*

THE *biceps*, or *coraco-radialis*, bends both bones of the fore-arm, and turns the radius upon the ulna; performing both motions by its insertion in the radius alone. It likewise moves the os humeri on the fore-arm, the scapula on the os humeri, and the os humeri on the scapula.

The *brachiiæus* serves to bend the fore-arm on the os humeri, by its insertion in the ulna, and by the connection of that bone with the radius. It serves also to move the os humeri on the fore-arm.

The *anconæus maximus* serves to extend the fore-arm, by bringing the ulna to a straight line with the os humeri. It serves likewise to extend the os humeri on the ulna, when the last named bone is fixed by some exterior resistance, as when, being laid upon the ground, we rise by supporting ourselves on our hand. In this case likewise, the scapula must be kept steady by the *coraco-brachialis*.

The two lateral *anconæi* co-operate with, and assist the *anconæus maximus*, in extending the fore-arm on the os humeri, and the os humeri on the fore-arm.

The *anconæus minimus* may concur with the other muscles of that name, in extending the fore-arm on the os humeri, and the os humeri on the fore-arm; but its action does not reach to all the degrees of flexion of these bones; for when the fore-arm is very much bent, if we

examine carefully the situation of this muscle, we will find it more disposed to maintain these bones in that posture, by co-operating with the brachialis, than to extend them by assisting the other anconæi.

SECT. VI. *The MUSCLES which move the Radius upon the Ulna.*

SUPINATOR LONGUS *sive* MAJOR.

THIS is a long flat muscle, lying on the external condyle of the os humeri, and on the convex side of the radius from one end to the other.

It is fixed by fleshy fibres to the external inter-muscular ligament, and to the crista of the external condyle of the os humeri, for five or six fingers breadth above the condyle, between the brachialis and anconæus externus. From thence it runs along the whole convex side of the radius, and is inserted by a flat narrow tendon, a little above the styloid apophysis in the angle between the concave and flat sides of the extremity of this bone.

SUPINATOR BREVIS *sive* MINOR.

THIS is a small thin fleshy muscle, surrounding a great portion of the upper third part of the radius.

It is fixed by one end to the lower part of the external condyle of the os humeri, to the external lateral ligament of the joint, to the annular ligament of the radius, and to part of the lateral eminence in the head of the ulna.

From thence it passes obliquely over the head of the radius, covering some part of it; and running down upon, and in some measure surrounding the neck, it turns in under the bicipital tuberosity, and is inserted by the side of the interosseous ligament in the inside of the superior quarter of the bone, and even a little lower.

PRONATOR TERES *sive* OBLIQUUS.

THIS is a small muscle, broader than it is thick, situated on the upper part of the ulna opposite to the supinator brevis.

It is fixed to the internal condyle of the os humeri, partly by fleshy fibres, and partly by a tendon common to it with the ulnaris internus. From thence it passes obliquely before the extremity of the tendon of the brachialis, and reaches to the middle part of the convex side of the radius, where it becomes flat, and is inserted below the supinator brevis by an extremity almost wholly fleshy.

PRONATOR QUADRATUS *sive* TRANSVERSUS.

THIS is a small fleshy muscle nearly as broad as it is long, lying transversely on the inside of the lower extremity of the fore-arm.

It is fixed by one side or edge in the long eminence at the lower part of the internal angle of the ulna, and by

the other in the broad concave side of the lower extremity of the radius.

It has a ligamentary or tendinous frænum belonging to it, one end of which is fixed in the interosseous ligament, the other in the inner edge of the basis of the radius.

*The USES of the Muscles which move the Radius on the Ulna.*

THE supinator longus assists in the motion of supination, and is also a flexor of the fore-arm.

The supinator brevis seems to have no other use than what is expressed by its name; and as it is a short small muscle, it must be very weak.

The pronator teres can have no other action but that of pronation, in the different situations of the radius, whether that bone be in a middle state between pronation and supination, or in the greatest degree of supination; and, in this case, though it is but a small weak muscle, it overcomes the supinator longus.

The pronator quadratus is capable of no other motion but pronation, and it acts with much more force than its congener the pronator teres.

SECT. VII. *The MUSCLES which move the Carpus upon the Fore-arm.*

ULNARIS.

THIS is a long muscle, fleshy at its upper extremity, and tendinous at the other, situated on the outer part of the ulna.

It is fixed by its upper part in the backside of the long or internal condyle of the os humeri, in that part of the olecranon which is next the condyle, along the upper half of the ulna very nearly; and to the middle common tendon of the neighbouring muscle, termed commonly *profundus*.

It runs in the direction of the external angle of the ulna, and ends by a long tendon, in the os pisiforme or orbicular of the carpus, reaching likewise to the os unciniforme, being united to the ligament common to these two bones.

RADIALIS INTERNUS.

THIS is a long muscle very like the foregoing, but situated more obliquely.

Its fleshy portion is fixed, by a short tendon, to the outer and upper side of the inner condyle of the os humeri. From thence it passes obliquely toward the radius; and running along about two thirds of that bone, it forms a long tendon, which passes under a particular annular ligament, and under the insertion of the musculus thenar.

This tendon is at length inserted chiefly in the inside of the basis of the first metacarpal bone, and often in the second likewise, and a little in the first phalanx of the thumb, having first passed through the channel of the os trapezium, which sustains the thumb.

ULNARIS.

## ULNARIS EXTERNUS.

THIS is a long muscle lying on the outside of the fore-arm, fleshy toward the os humeri, and tendinous toward the carpus.

It is fixed above to the external condyle of the os humeri, being there united to the anconæus minor, to the annular ligament of the head of the radius, and to the upper half of the external angle of the ulna. From thence it advances, and forms a tendon, which passes through the external notch at the lower extremity of this bone, on one side of the styloid apophysis.

The tendon, having afterward passed under a particular ligament situated near the os cuneiforme of the carpus, is inserted in the outside of the basis of the fourth metacarpal bone, sending some tendinous filaments to the basis of the little finger.

## RADIALIS EXTERNUS, PRIMUS &amp; SECUNDUS.

THESE are two muscles closely united together, lying along the external angle of the radius, between the os humeri and the carpus, being fleshy near the former, and tendinous near the latter.

The first is inserted above, in the crista of the external condyle of the os humeri, below the insertion of the supinator longus. The second is inserted in the same condyle below the insertion of the first; and in the neighbouring articular ligament. From thence the two fleshy bodies run down very close together; and having reached the middle of the outside of the radius, each of them terminates in a long tendon.

The two tendons accompany each other to the extremity of the radius; and, having passed under a particular annular ligament, they are divided as it were into two cornua; from whence the ancients, who looked upon them as one muscle, gave it the name of *bicornis*.

One of these tendons is inserted anteriorly in the basis of the first metacarpal bone, the other nearly in the same place of the second bone.

## ULNARIS GRACILIS, vulgo PALMARIS LONGUS.

THIS is a small muscle, lying between the os humeri and the carpus, on the inside of the fore-arm; its body being small and slender, its tendon very long and flat.

It is fixed by its fleshy portion, in the small crista of the inner condyle of the os humeri, sometimes closely united to the ulnaris internus. From thence it runs down fleshy for some space, turning a little obliquely towards the middle of the fore-arm, and ends in a long, narrow, thin tendon.

This tendon passes down the middle of the fore-arm, over all the other muscles to which it slightly adheres, and advancing over the large internal annular or transverse ligament of the carpus, is inserted in the surface thereof, sending off some radiated filaments to the aponeurosis palmaris.

## PALMARIS CUTANEUS.

THIS muscle is a small thin plane of fleshy fibres, situated transversely, or more or less obliquely, under the

skin of the large eminence in the palm of the hand, between the carpus and the little finger; its fibres adhering to the skin, and being in some measure interwoven with the membrana adiposa.

These fibres are fixed along the edge of the aponeurosis palmaris, from the large ligament of the carpus toward the little finger; and they run in for some space on the plane of the aponeurosis, but without any connexion with the bones of the metacarpus. Near the aponeurosis, these fibres are more or less tendinous, and some of them often cross each other.

## METACARPUS.

THIS is a very small fleshy muscle, situated obliquely between the large internal annular or transverse ligament of the carpus, and the whole inside of the fourth metacarpal bone.

It is fixed by a small short tendon to the os orbiculare, and to the neighbouring part of the large ligament of the carpus. From thence its fibres run more or less obliquely toward the inside of the fourth metacarpal bone, in the outer edge of which they are inserted. The fibres of this muscle are of unequal lengths, and extend all the way to the articulation of the first phalanx of the little finger with the fourth metacarpal bone, but they have no manner of relation to that finger.

## Uses of the Muscles which move the Carpus on the Fore-arm.

WHEN the ulnaris internus acts alone, or as the principal mover, it brings the hand obliquely toward the internal condyle, and toward the olecranon, though with difficulty.

When it acts together with the radialis internus, it turns the hand equally towards the two extremities of the bones of the fore-arm; and thereby moves not only the carpus in general on the fore-arm, but also the second row of the carpus on the first, and the metacarpal bones on the second.

When it acts with the ulnaris externus, it turns the outer edge of the hand toward the olecranon.

When the ulnaris externus acts with the ulnaris internus, it turns the outer edge of the hand toward the olecranon, as already said.

With the radiales externi, it turns the back of the hand toward the outer condyle.

When this muscle acts alone, it brings the outer edge of the hand obliquely toward the olecranon and the external condyle at the same time.

With the radialis externus, the internus carries the inner edge of the hand, or that next the thumb, toward the extremity of the radius, and toward the fold made by the ulna and os humeri.

Alone, it moves that part of the hand which is next the thumb obliquely, toward the internal angle of the radius.

The radialis externus, together with the radialis internus, turns the inner edge of the hand directly toward the styloid apophysis of the radius.

With

With the *ulnaris externus* it inverts the hand, turning the convex side of the metacarpus toward the lower extremity of the bones of the fore-arm. It likewise moves the second row of the carpus on the first.

This muscle, acting alone, draws obliquely, and toward the external angle of the radius, that portion of the hand which answers to the first metacarpal bone, and to the index.

The *ulnaris gracilis*, commonly called *palmaris longus*, seems to be an assistant to the *ulnaris* and *radialis interni* in bending the wrist; and it seems likewise particularly to assist the *radialis internus* in the motion of pronation.

The metacarpus serves to turn the fourth bone of the metacarpus toward the thumb, and at the same time to increase the convexity of the back of the hand, which is called making *Diogenes's cup*. The fourth bone thus moved carries the third along with it by reason of their connection, which still augments the hollow on one side, and the convexity on the other.

### SECT. VIII. *The MUSCLES which move the Fingers.*

#### FLEXOR POLLICIS LONGUS.

THIS is a long muscle, fixed by short and oblique fleshy fibres to the inside of the upper part of the interosseous ligament, near the radius, and along that bone all the way down to the pronator quadratus. There it terminates in a flat tendon.

This tendon having passed under a particular ligament, runs in between the two portions of the thenar, and then into a sort of groove left between the two sesamoid bones fixed to the basis of the second phalanx of the thumb, on that side which is turned to the palm of the hand. Afterwards the tendon ends in the flat side of the third phalanx, near its basis. It is inclosed in a ligamentary vagina, from the annular ligament to its insertion, and it is divided or slit, so that it appears to be inserted by two extremities adhering together by their edges.

#### EXTENSORES POLLICIS.

THESE are two very distinct muscles, the first or longest of which is sometimes more, sometimes less, and sometimes altogether divided into two, in which case these muscles are three in number. They are situated obliquely between the ulna and convex side of the thumb.

The *extensor primus* is a long muscle, more or less double, in the manner already said. It is fixed above by fleshy fibres, first to the outside of the ulna, near its upper extremity, below the *anconæus minor* and insertion of the *ulnaris externus*; next, to the interosseous ligament under the *supinator brevis*; and, lastly, to the middle part of the outside of the radius.

From thence it runs down and passes anteriorly over the lower part of the radius, and tendons of the *supinator longus* and *radialis externus*, and being gradually di-

vided, it terminates in two long flat tendons, more or less subdivided, which pass together under a particular annular ligament, being only parted by septa or *fiæna* belonging to that ligament.

The first of these two principal tendons is inserted in the edge of the basis of the first phalanx, near the large transverse ligament of the carpus. When this tendon is subdivided, the other portion of it is fixed in that bone of the carpus which sustains the thumb. The other principal tendon, which often belongs to a muscle entirely distinct from the former, is fixed in the convex side of the basis of the second phalanx, where it joins the tendon of the *extensor secundus*.

The *extensor secundus* is shorter than the first. It is fixed to the ulna, below the former, and above the insertion of the *extensor indicis proprius*, and likewise to the neighbouring part of the interosseous ligament. From thence it runs down obliquely on the middle part of the radius, where it has likewise a small adhesion. Afterwards it passes through the small channel in the styloid apophysis of the radius, through the annular ligament belonging to the tendons of the *radialis externus*, and over these tendons, being parted from them by a small ligamentary septum. It is inserted in the convex part of the third phalanx, near its basis.

#### THE NAR.

THIS is a very thick fleshy muscle, in some measure pyriform, lying on the first phalanx of the thumb toward the palm of the hand, the large eminence in which is chiefly formed by it.

It is fixed to the bone which supports the thumb, and to the neighbouring part of the great internal annular ligament of the carpus. It is in some measure bicipital, two distinct portions answering to the two insertions already mentioned. As it runs along the first phalanx, these two portions unite, and, diminishing in thickness, are both inserted by one tendon in the lateral internal part of the head of the first phalanx, in the lateral part of the basis of the second, and in the lateral ligament of that joint.

#### MESOTHENAR.

THIS is a flat, and nearly triangular muscle, lying between the first phalanx of the thumb, and the bottom of the palm of the hand.

It is inserted, by a very broad basis, in the ligament which connects the *os magnum* of the carpus to that which supports the thumb. It is likewise inserted along the internal or angular part of that bone of the metacarpus, which supports the middle finger, and in the small extremity of that which answers to the index.

From thence the fibres contracting to an angle, terminate in a flat tendon of different breadths, which is inserted in that side of the head of the first phalanx of the thumb which is turned to the hollow of the hand, and in the neighbouring part of the basis of the second phalanx, by means of the second sesamoid bone belonging to that joint.

ANTITHENAR *sive* SEMI-INTEROSSEUS POLLICIS.

THIS is a small, flat, fleshy muscle, situated obliquely between the first phalanx of the thumb, and first bone of the metacarpus.

It is fixed by one end toward the basis of the first metacarpal bone, near the first bone of the second row of the carpus. From thence it runs obliquely toward the head of the first phalanx of the thumb, and is inserted in the lateral external part of that bone, or on that side which is turned to the first metacarpal bone. It crosses over the semi-interosseus indicis, this muscle lying toward the back of the hand, and the antithenar toward the palm.

PERFORATUS *vulgo* SUBLIMIS.

THIS is a muscle of a considerable volume, lying along the inside of the fore-arm, fleshy for the greatest part near the articulation of the fore-arm with the os humeri, and near the carpus, terminating in four distinct portions, which become the same number of long small tendons. The name of *sublimis* has been given to it, because it lies almost on the surface of the fore-arm; and that of *perforatus*, from the slits found near the extremities of its tendons.

It is commonly made up of four muscles, closely united by their fleshy portions. It is fixed above to the superior internal parts of the ulna and radius, and to that of the interosseus ligament. A little below the middle of the fore-arm, this large fleshy body is divided into four distinct muscles, which, on the lowest quarter of the fore-arm, end in four flat tendons of different sizes.

These four tendons are inclosed in a common membranous or mucilaginous vagina, which likewise furnishes each tendon with a particular thin vagina. In this manner they advance to the carpus, and pass under the large annular transverse ligament. Beyond this ligament, they spread again in the palm of the hand, still retaining their particular vaginæ, and run between the aponeurosis palmaris and metacarpus, toward the fingers, separating more and more by degrees.

Having reached the heads of the metacarpal bones, they pass under the four arches or fræna formed by the force of the aponeurosis palmaris, and particular septa of the great transverse ligament of the palm of the hand; and then each tendon having got beyond the head of one metacarpal bone, and beyond the basis of the first phalanx, enters the ligamentary vagina on the flat or inner side of that phalanx, and is inserted in the flat side of the second phalanx, near its basis, the membranous vagina accompanying it to its insertion.

In passing along the inside of the first phalanx, the tendon is divided by a long slit, which gives passage to a tendon of the perforans; and from thence the names of these two muscles are taken.

PERFORANS *vulgo* PROFUNDUS.

THIS muscle is very like the former, and is situated much in the same manner; only it lies lower, and is called Vol. I. No. 9.

pered by the perforatus. It is composed of four muscles, which at first seem to make but one mass, and afterwards terminate in four tendons.

The fleshy portions of the first and largest, and also of the second, are fixed in the superior parts of the ulna and interosseus ligament, down to their middle; the fleshy portion of the third is joined to the tendon of the ulnaris internus, by a sort of common aponeurosis; and that of the fourth is fixed along the ulna.

The four tendons have often several small collateral tendons, sometimes five in number, united to the tendons of the neighbouring muscle, as they pass under the large annular ligament of the carpus; but the tendons themselves are separated from the others by thin septa, which form a kind of particular rings. Being thus strengthened, they separate; and running along the palm of the hand in distinct membranous vaginæ, like those of the perforatus, by which they are covered, they enter the ligamentary vaginæ of the first phalanges together with the former; and having passed through the fissures thereof, and through the ligamentary vaginæ of the second phalanges, they are inserted in the flat inner side of the third, near their basis.

## EXTENSOR DIGITORUM COMMUNIS.

THIS is a compound muscle, very much resembling the perforatus and perforans, lying on the outside of the fore-arm, between the ulnaris externus and radialis externus.

It is fixed above, by a tendinous extremity, to the posterior and lower part of the external or great condyle of the os humeri, and, by a tendinous adhesion on each side, to the ulnaris and radialis externus. It has likewise sometimes a small insertion in the radius. It is divided into four muscles, like the perforatus and perforans, and four long, slender, small tendons.

Three of these tendons pass through the common external annular ligament of the carpus; and the fourth, which goes to the little finger, passes through a particular ring of the same ligament.

Afterwards these four tendons separate as they go to the fingers, and in their passage communicate with each other, by oblique tendinous series, chiefly near the heads of the metacarpal bones.

Each tendon having reached the basis of the first phalanx, is slightly inserted therein by some lateral expansions fixed in each side of the basis. From thence it advances to the head of the same phalanx, where it is divided into two flat portions, which, at the articulation of the first phalanx with the second, leave some distance between them. About the head of the second phalanx, they unite again, and are fixed in the convex side of the third phalanx, near its basis.

## EXTENSOR INDICIS PROPRIUS.

THIS is a small long muscle, with a long slender tendon, lying a little obliquely on the lower and outer half of the fore-arm, between the ulna and fore-finger.

It is fixed, by its fleshy body, a little higher than the lowest

lowest third part of the outside of the ulna, below the insertion of the extensor pollicis, and it has likewise a small adhesion to the interosseus ligament. From thence it runs down, ending in a distinct tendon, without any communications, which having passed through the annular ligament of the extensor communis, afterwards joins that tendon which goes to the index.

#### EXTENSOR MINIMI DIGITI PROPRIUS.

THIS is a kind of collateral or auxiliary muscle of the extensor communis, of which it appears almost always to be more or less a portion.

It is fixed along the superior external half of the ulna, from whence its long small tendon runs down in company with the fourth tendon of the extensor communis, all the way to the little finger, where it joins it, and is inserted with it.

#### LUMBRICALES.

THESE are four very small slender muscles, lying in the hollow of the hand, in the same direction with the perforatus and perforans.

They are fixed, by their fleshy bodies, to the tendons of the perforatus on the side next the thumb, near the large annular ligament of the carpus. Near the heads of the metacarpal bones, they become very thin tendons, which accompany those of the perforans through the suræ of the aponeurosis palmaris. Then they pass on to the same sides of the first phalanges, and join the tendons of the extensor communis; each of them being connected with the nearest portion thereof, at the articulation of the first phalanx with the second.

#### INTEROSSEI.

THESE are small muscles, lying between the metacarpal bones, and filling the three interstices left between them, both exteriorly, or towards the back of the hand, and interiorly, or toward the palm of the hand. From this situation they have the name of *interossei*, and have been divided into external and internal. They are commonly reckoned six in number, three external, and three internal.

The first two external interossei are for the most part inserted in the middle finger. They fill the interstices between the three first metacarpal bones, and surround the middle bone all the way to the hollow of the hand. Their tendons are fixed in both sides of the first phalanx, and in both sides of the second tendon of the extensor communis.

The third external interosseus lies in the interstice betwixt the two last metacarpal bones, and is most commonly inserted in the ring finger; its tendon being fixed in that side of the first phalanx farthest from the thumb, and in the corresponding edge of the third tendon of the extensor communis. The fleshy body of this muscle runs in between the two bones toward the hollow of the hand.

The internal interossei are more simple than the former,

and do not lie so much between the bones. The tendon of the first is inserted in the side of the first phalanx of the fore-finger, next the little finger, and in the corresponding edge of the extensor communis. The tendon of the second goes in the same manner to the side of the ring-finger next to the thumb; and the third, to the same side of the little finger.

There are therefore two external interossei for the middle finger, one for the ring finger, but none for the fore and little finger. The middle finger has no internal interossei; but the index, ring finger, and little finger, have each of them one.

#### SEMI-INTEROSSEUS INDICIS.

THIS is a small, short, flat, fleshy muscle, very like the antithenar, or internal semi-interosseus of the thumb. It is situated obliquely on one side of that of the thumb, between the first phalanx thereof, and the first metacarpal bone.

It is fixed by one end to the outside of the basis of the first phalanx of the thumb, and a little to that bone of the carpus by which this phalanx is supported; and by the other end it is fixed near the head of the first phalanx of the index, on that side next the thumb.

#### HYPOTHENAR MINIMI DIGITI.

THIS is a small and pretty long muscle, lying on the backside of the fourth metacarpal bone opposite to the thumb, where, together with the metacarpus, or hypothenar metacarpi, it forms that large eminence over-against the thenar or that of the thumb.

It is fixed by one end in the os orbiculare of the carpus, and a little to the neighbouring part of the large annular ligament. The other end terminates by a short flatish tendon, fixed to that side of the basis of the first phalanx of the little finger which is turned from the thumb.

#### Uses of the Muscles which move the Fingers.

THE perforatus serves to bend the second phalanges of all the fingers except the thumb; and the particular muscles, of which it is made up, may act separately, by reason of their distinct insertions in these phalanges.

They not only bend the second phalanges on the first, but also the first on the metacarpal bones, and the metacarpus and carpus on the fore-arm.

The perforans bends particularly the third phalanges in which it is inserted; and by the same motion it may likewise bend the first and second phalanges.

It may likewise be esteemed an assistant to the ulnaris and radialis interni in great efforts; and these muscles many reciprocally be looked upon as assistants to the perforatus and perforans.

The extensor digitorum communis serves to extend the four fingers, to keep them in any degree of extension, and to moderate their flexion in all the determinate degrees of action of the perforatus and perforans.

Each tendon serves to extend a whole finger, that is, all

all the three phalanges together; and likewise each phalanx by itself, though not with the same facility.

The proper extensors of the fore and little fingers are assistants to two subaltern muscles of the extensor communis that go to these fingers, which consequently we extend separately with more ease than either of the other two. These muscles likewise serve to bring the fingers, in which they are inserted, near the other fingers.

The flexor pollicis longus serves chiefly to bend the third phalanx of the thumb, in which it is inserted by the extremity of its tendon. It likewise bends the second phalanx, by virtue of the ligamentary vagina, through which it passes, as through an annular ligament.

The first extensor of the thumb alone, when there are three, a portion of the first, when there are but two, serves to draw the first phalanx from the palm of the hand, or to keep it at a distance therefrom.

The second of these muscles when there are three, or the second portion of the first when there are but two, serves to extend the second phalanx on the first.

The third when there are three, or the second when there are but two, extends the third phalanx on the second.

When they act all together, they assist each other by the graduated insertions of their small subaltern tendons.

The thenar, by its insertion in the first phalanx of the thumb, serves to draw it from the first bone of the metacarpus, more or less directly, as one of its portions acts more than the other, or as they both act equally.

By the insertion of the large portion in the basis of the second phalanx, by the intervention of the semimoid bone of the same side, it may bend this phalanx laterally on the first, and thereby bring the thumb to a greater distance from the index.

The mesothenar moves the first phalanx of the thumb towards the hollow of the hand, more or less obliquely, as it acts either alone or with the large portion of the thenar, or even with the antithenar. By its insertion in the semimoid bone of the second phalanx, it likewise moves that phalanx on the first, and thereby assists the flexor longus.

The antithenar moves the first phalanx of the thumb toward the first bone of the metacarpus, and thereby presses the thumb laterally against the index. This motion becomes more or less oblique by the co-operation of the mesothenar.

The hypothenar minor serves to separate the little finger from the rest; which motion is commonly called *abduction*. It likewise keeps this finger separated in all situations, that is, in all degrees of flexion or extension.

The interossei may have two different uses, according to their different insertion, and the different situations of the fingers in which they are inserted.

In general, they assist the extensor communis by their insertions in the lateral angles of the rhomboidal fissures; for thereby they act like lateral ropes, which, together with the tendons of the extensor, serve to extend the third phalanx of each finger.

By the same lateral insertions they perform the lateral motions of the fingers, that is, they press them all close

against each other, but do not separate them all, nor move each finger in particular toward, or from, the thumb. In a general separation of all the fingers, the interossei move only the middle and ring fingers; the index and little finger being separated by other muscles. In the motions of the fingers toward the thumb, which is termed *adduction*, they act only on three fingers, the middle, ring, and little fingers. In the contrary motion, or abduction of the fingers, they move likewise three, *viz.* the index, middle, and ring fingers.

The uses of the interossei in particular, whether external or internal, may be different in different subjects, according to the variety of their insertions; and therefore in living bodies nothing can be determined about them.

According to the situation in which they have been described, the first and second external interossei perform alternately the adduction and abduction of the middle finger; the third performs the abduction of the ring-finger; that is, moves it toward the little finger.

The first internal interosseus makes the abduction of the index, or moves it toward the middle finger; the second makes the adduction of the ring-finger, by moving it likewise toward the middle finger; and the third performs the adduction of the little finger, or moves it toward the middle finger.

The use of the semi-interossei indicis is to move the first phalanx of the index, more or less directly, toward the great edge of the metacarpus, by removing it from the middle finger. This motion is not a true adduction of the index toward the thumb.

The lumbrales, by the union of their tendons with those of the interossei, are coadjutors to these muscles, not only in the lateral motions of the four fingers, but also in bending and extending them. In the lateral motions, they co-operate according to their situation in each subject; and it is possible that the variety of their insertions answer to that of the interossei, so that the reciprocal co-operation continues still to be equal.

## SECT. IX. *The MUSCLES which move the Os Femoris upon the Pelvis.*

### PISOAS *sive* LUMBARIS INTERNUS.

THIS is a long thick muscle situated in the abdomen on the lumbar region, adhering to the vertebrae of the loins, from the posterior part of the os ilium to the anterior part near the thigh.

It is fixed above to the last vertebra of the back, and to all those of the loins, that is, to the lateral parts of the bodies of these vertebrae, and to the roots of their transverse apophyses. The insertions in the bodies of the vertebrae are by a kind of digitations, and are very little tendinous.

From thence the muscle runs down laterally over the os ilium, on one side of the iliac muscle, and passes under the ligamentum Fallopii, between the anterior inferior spine of the os ilium, and that eminence which from its situation may be termed *ilio-petinea*.

Before

Before it goes out of the abdomen, it unites with the iliacus, and is sometimes fixed, by a few fleshy fibres, in the outside of the eminence last mentioned. It afterwards covers the fore-side of the head of the os femoris, and is inserted in the fore-part of the little trochanter by an oblique tendon, which is folded double from behind forward.

### ILIACUS.

THIS is a broad thick muscle, lying on the whole inside of the os ilium.

It is fixed by fleshy fibres to the internal labium of the crista ossis ilium, to that of the slope between the two anterior spines, to the insides of these spines, to the superior half of the inside of this bone, and to the neighbouring lateral part of the os sacrum.

All these fibres, contracting by degrees, run obliquely towards the lower part of the musculus psoas, uniting therewith, and being fixed by a kind of aponeurosis to the outside of its tendon all the way to the little trochanter. They cover the head of the os femoris, and some of the lowest are inserted in that bone a little above and behind the little trochanter, and others a little lower down.

The iliacus and psoas, thus united, pass under the ligamentum Fallopii, over the slope or channel, between the anterior inferior spine of the os ilium and eminentia ilio-pectinea, in a sort of ligamentary capsula very smooth and polished.

### PECTINEUS.

THIS is a small, flat, and pretty long muscle, broad at the upper part, and narrow at the lower, situated obliquely between the os pubis and upper part of the os femoris.

It is fixed above by fleshy fibres to all the sharp ridge or crista of the os pubis, and to a small part of the oblong notch or depression on the fore-side of that crista, in which the upper extremity of this muscle is lodged.

From thence it runs down obliquely towards the little trochanter, under and a little behind which, it is inserted obliquely by a flat tendon, between the superior insertion of the vastus internus, and inferior insertion of the triceps secundus, with which it is united.

### GLUTÆUS MAXIMUS.

THIS is a thick broad muscle, lying on the outside of the os ilium and upper part of the os femoris.

It is fixed wholly fleshy to all the lateral posterior parts of the os coccygis and os sacrum; to the ligamentum sacro-sciaticum; to the outside of the tuberosity of the os ilium; and from thence to the external labium of the crista of that bone all the way to its highest part, where this muscle mixes fibres with the glutæus medius.

It is likewise fixed to the inside of the fascia lata, at the places which answer to all the insertions already mentioned, but through a much greater space, and by a

very great number of fleshy fibres, almost in the same manner as we shall see in the external plane of the musculus temporalis. The fibres which end in this fascia become gradually shorter, as they are situated lower.

All these fibres contract in breadth in a radiated manner as they approach to the great trochanter, and afterwards form a strong, flat, pretty broad tendon, about an inch in length, which is inserted a finger's breadth or a little more below the great trochanter, in all that large longitudinal impression at the upper part of the linea aspera on the back-side of the os femoris, between the vastus externus and largest portion of the triceps.

### GLUTÆUS MEDIUS.

THIS is a radiated muscle, almost in the shape of a spread fan. It is pretty thick, and almost as broad as the whole outside of the os ilium, being situated between the crista of that bone and the great trochanter, and covered anteriorly by the fascia lata, and posteriorly by the glutæus maximus.

It is fixed above by fleshy fibres to all that space on the outside of the os ilium, which lies between the external labium of the crista, and the femicircular impression which goes between the superior anterior spine, and the great posterior sinus.

It is likewise fixed in the edge of that ligament which goes between the lower part of the os sacrum and os ilium. Lastly, the inner part of it, which is covered only by the fascia lata, is inserted in the inside of that fascia in the same manner as the glutæus maximus.

From thence all the fibres contract in breadth, more or less, in a radiated manner, as they advance toward the great trochanter, and form a short thick tendon, which mixes a little anteriorly with the tendon of the glutæus minimus; and the most posterior fibres gradually join the side of the tendon of the pyriformis.

The tendon is inserted in the upper convex part of the great trochanter, from the apex of the large superior external rough surface, all the way to the anterior rough surface, encompassing in a manner all that part of the trochanter.

### GLUTÆUS MINIMUS.

THIS is a small, broad, radiated muscle, situated on the outside of the os ilium, under the other two glutæi.

It is fixed above in all that portion of the outside of the os ilium, which lies between the great femicircular line, and another small one, a little above the supraciliary of the cotyloid cavity or acetabulum, running between the anterior inferior spine and the great posterior sinus. It is likewise fixed in the edge of that sinus, in the spine of the ischium, and in the orbicular ligament of the joint of the hip.

From thence its fibres, contracting in breadth, form a short tendon, by which the muscle is inserted in the anterior part of the upper edge of the great trochanter, above the great external convex rough surface in which the glutæus medius is fixed.

### TRICEPS

## TRICEPS PRIMUS.

THIS, with the two following tricipital muscles, are fleshy and flat, and of different lengths, situated between the os pubis and the whole length of the os femoris. The first and second cross each other in such a manner, as that the muscle, which is the first on the os pubis, becomes the second on the os femoris; and the second on the os pubis, is the first on the os femoris. The third muscle keeps its rank.

The triceps primus is fixed above by a short tendon to the tuberosity or spine of the os pubis, and to the neighbouring part of the symphysis, its fibres mixing a little with those of the pectineus. From thence it runs down, increasing in breadth, and is inserted by fleshy fibres interiorly in the middle portion of the linea femoris aspera.

At the lower part of this insertion, a portion of the muscle separates from the rest, and sends off a long tendon, which, together with a like tendon from the triceps tertius, is inserted in the inner condyle of the extremity of the os femoris.

## TRICEPS SECUNDUS.

THIS muscle is fixed above by fleshy fibres, below the superior insertion of the triceps primus, in all the outside of the inferior ramus of the os pubis, as low as the foramen ovale, but seldom so low as the ramus of the os ischium.

From thence it runs down, and is inserted in the upper part of the linea aspera, between the pectineus and triceps primus, mixing a little with each of these muscles.

## TRICEPS TERTIUS.

THIS muscle is fixed above by fleshy fibres to the anterior part of all the short ramus of the ischium, and to a small part of the tuberosity of that bone.

From thence it runs down, and is inserted by fleshy fibres in the linea aspera, almost from the little trochanter, down to the middle of the os femoris. It goes lower down than the first triceps, sending off a separate portion like that of the muscle last mentioned.

These two portions join together, and form a common tendon, which, running down to the lower extremity of the os femoris, is inserted in the back part of the tuberosity of the inner condyle.

PYRIFORMIS *sive* PYRAMIDALIS.

THIS is a small oblong muscle, of the figure of a flat pear or pyramid, from whence it has its name. It is situated almost transversely, between the os sacrum and ischium, being covered and hid by the first two glutæi.

It is fixed to the inferior lateral part of the os sacrum, by fleshy fibres, and to the neighbouring part of the anterior or concave side of that bone, by three digitations lying between the anterior holes. It is likewise fixed by

a small insertion to the ligamentum sacro-sciaticum and edge of the great sinus of the os ilium.

From thence it runs transversely towards the joint of the hip, its fibres contracting in breadth, and ends in a small tendon, which is inserted in the middle of the internal labium of the upper edge of the great trochanter, by two or three branches.

## OBTURATOR INTERNUS.

THIS is a flat muscle, almost triangular, situated in the bottom of the pelvis. It covers the foramen ovale, and almost all the inside of the os pubis and ischium.

It is fixed to the internal labium of all the anterior half of the foramen ovale, a little to the neighbouring part of the obturator ligament; and also both above and below the foramen. It is likewise fixed to the upper half of the inside of the os ischium from the upper oblique notch in the foramen ovale, to the superior part of the great posterior sinus of the os ilium.

From all this extent the fleshy fibres, contracting in breadth, run down below the spine of the ischium, where they go out of the pelvis through the posterior notch of the ischium, and afterwards unite in one large flat tendon, which crossing over that of the pyriformis, unites with it, having first received on each side some additional fleshy fibres from the two gemelli.

## GEMELLI.

THESE are two small, flat, narrow muscles, situated almost transversely one above the other, between the tuberosity of the ischium and the great trochanter, immediately below the pyriformis, and parted by the tendon of the obturator internus.

The superior and smallest gemellus is fixed to the lower part of the spine of the ischium, to the superior part of the small ischiatic notch, and to a rough line, which runs across the outside of the ischium, beginning from the spine, and continued under the acetabulum, where it is bent downward.

The inferior and largest gemellus is fixed to the superior and back part of the tuberosity of the ischium, and to a rough impression which runs across the outside of the ischium from the lower extremity of the ischiatic notch, and is bent upward toward the other line, together with which it forms a sort of irregular semicircle.

Both these muscles have likewise a small insertion in the inside of the ischium, where, being united together by a particular membrane, one of them joins the upper side, and the other the lower side of the obturator internus, a little after it has passed over the notch: They inclose it as in a bag, and continue to be fixed to it by fleshy fibres all the way to its extremity.

## OBTURATOR EXTERNUS.

THIS is a small flat muscle, which fills up the foramen ovale of the os innominatum exteriorly, and reaches

from thence to the great trochanter of the os femoris, behind the neck of that bone.

It is fixed by fleshy fibres to the outer anterior side of the os pubis, all the way to the foramen ovale, to the edge of that hole, next the small ramus of the ischium, and a little to the neighbouring parts of the obturator ligament.

From thence its fibres, contracting in breadth, pass on the fore side of the great ramus of the ischium, under the acetabulum, where a tendon is formed, which continues its course behind the neck of the os femoris toward the great trochanter, and is inserted between the gemelli and quadratus, in a small fossula between the apex of the great trochanter, and the basis of the column femoris.

### QUADRATUS.

THIS is a small, flat, fleshy muscle, of the figure of an oblong square, from whence it has its name. It is situated transversely between the tuberosity of the ischium and the great trochanter.

It is fixed by one extremity along that obtuse line which runs from under the acetabulum, toward the lower part of the tuberosity of the ischium. From thence it runs directly toward the great trochanter, and is inserted in almost all the lower half of the oblong eminence in that apophysis; but chiefly in the small rising or tuberosity in the middle of that eminence.

### MUSCULUS FASCIAE LATÆ.

THIS is a small and pretty long muscle, situated a little obliquely upward and downward on the forepart of the hip.

It is fixed above to the outside of the anterior superior spine of the os ilium, between the insertions of the glutæus medius and sartorius. From thence its fleshy fibres run down a little obliquely backward, forming a very flat body, four fingers breadth in length, and two in breadth.

This body lies between two laminae of the fascia lata, and is inserted therein by short tendinous fibres, which disappear at that place where the fascia adheres to the great trochanter and tendon of the glutæus maximus.

*Uses of the Muscles which move the Os Femoris on the Pelvis.*

THE glutæus maximus serves chiefly, by its posterior portion, to extend the os femoris, and to draw it backward. By its anterior portion, it may co-operate with the rest in performing the abduction of the thigh; but when we sit, it can do this office only by its posterior portion.

By its insertion in the os coccygis, it may on some occasions bring it forward, and hinder it from being thrust too far backward, as in the excretion of hardened fæces, or in difficult births.

The glutæus medius is commonly, but falsely, reckoned an extensor of the thigh. Its use is to separate one

thigh from the other, when we stand, and that more or less directly according to the action of its anterior, posterior, or middle portions.

When we sit, the only use of this muscle is to perform the rotation of the os femoris about its axis, in such a manner, that if the leg be bent at the same time, it shall be separated from the other.

The glutæus minimus has likewise been reckoned an extensor of the thigh, but without any foundation. It assists the glutæus medius in the abduction of the thigh when we stand, and in the rotation when we sit.

The psoas bends the thigh on the pelvis, or brings it forward. It may likewise move the pelvis on the thighs, and hinder it from being carried along with the rest of the trunk, when the body is inclined backward while we sit, having the lower extremities fixed by some external force. In this situation it may likewise move the vertebrae of the loins.

The iliacus is a congener or assistant to the psoas, in bringing the thigh forward and upward. It may likewise move the pelvis in the same manner with the former.

The pectineus is an assistant to the two former muscles in moving both the thigh and the pelvis. It may likewise assist in bringing the thigh inward, or toward the other, whether it be extended or bent at the same time.

The three triceps muscles join in the same use; that is, to move the thigh inward, and bring the two thighs near each other; as when, in riding, we press the thighs close against the saddle; when, in sitting, we hold any thing close between the knees; when we cross the thighs; or when, in standing, we bring the legs close together, in order to jump.

The use of these muscles is likewise to hinder the thighs from separating more than is convenient, especially in great efforts and jerks.

The pyriformis, gemelli, and quadratus, called likewise by the common name of *quadrigemini*, are congeners in their uses; and these have been confined by anatomists to the rotation of the os femoris about its axis from before outward, when we stand or lie at full length; likewise in sitting, or when the thigh is bent in any other posture, they carry the thigh outward, or separate the two thighs from each other when bent.

All the four co-operate in these two uses of rotation and abduction; but they co-operate equally or unequally, according to the different degrees of the extension or flexion of the thigh.

The obturator internus has nearly the same uses with the quadrigemini, in making the rotation of the thigh when extended, and the abduction when bent.

The obturator externus concurs with the internus in the same uses, though in a more simple manner, and in a more uniform direction. It acts chiefly when the thigh is extended more or less.

The musculus fasciæ latæ makes a rotation from before inwards, that is, in a contrary direction to that made by the quadrigemini and obturator internus; and this rotation is not so much confined as that of the quadrigemini, because it may have place whether the thigh be bent or extended.

SECT. X. *The MUSCLES which move the Bones of the Leg on the Os Femoris.*

RECTUS ANTERIOR *sive* GRACILIS ANTERIOR.

THIS muscle is as long as the os femoris; and lies directly along the forefide of the thigh, from whence it has the name of *rectus anterior*.

It terminates above, by a pretty strong tendon, which is divided into two branches, one short and straight, the other long and bent. The short branch, running up in a straight line, is inserted in the anterior inferior spine of the os ilium.

The long branch is inflected backward over the supercilium of the acetabulum, and runs in the direction thereof, from the spine toward the great ischiatic sinus. It is strong and flat, adhering very closely to the bone, and covered by the orbicular ligament and the glutæus minimus.

From thence the muscle runs down wholly fleshy, and partly penniform, some of its fibres meeting above and separating below. It is narrow at the upper extremity, and grows gradually broader toward the middle. Afterwards it contracts again in the same manner, and, at the lower extremity of the os femoris, ends in a flat broad tendon.

VASTUS EXTERNUS.

THIS is a very large fleshy muscle, almost as long as the os femoris, broad at the extremities, and thick in the middle, lying on the outside of the thigh.

Its upper insertion, being something tendinous, is in the posterior or convex rough surface of the great trochanter. It is likewise fixed by a fleshy insertion along the outside of the os femoris for above two thirds of its length downward, in the corresponding part of the linea aspera, and in the neighbouring portion of the fascia lata.

From all this extent the fleshy fibres running downward, and a little obliquely forward toward the rectus anterior, terminate insensibly in a kind of short aponeurosis, which is fixed in all the nearest edge of the tendon of the rectus, in the side of the patella, in the edge of the ligament of that bone, and in the neighbouring lateral part of the head of the tibia.

VASTUS INTERNUS.

THIS muscle is very like the former, and situated in the same manner on the inside of the os femoris.

It is fixed above by a short flat tendon, in the anterior rough surface of the great trochanter, and by fleshy fibres in that oblique line which terminates the basis of the collum femoris anteriorly, on the forefide of the insertions of the psoas and iliacus, in the whole inside of the os femoris, and in the linea aspera on one side of the insertions of the three tricipites, almost down to the internal condyle.

From all this extent the fibres run downward, and a little obliquely forward, and the body of the muscle in-

creases in the same manner as the vastus internus. It terminates below in an aponeurosis, which is fixed in the edge of the tendon of the rectus anterior, in the side of the patella, and of its tendinous ligament, and in the side of the head or upper extremity of the tibia.

CRUREUS.

THIS is a fleshy mass, covering almost all the forefide of the os femoris between the two vasti, which likewise cover the edges of this muscle on each side.

It is fixed to the forefide of the os femoris, from the anterior surface of the great trochanter down to the lowest quarter of the bone, by fleshy fibres which run down successively over each other, between the two vasti, and are partly united to these two muscles, so as not to seem to form a distinct muscle.

It is not so thick as the two vasti; and as it is covered by them on each side, a sort of fleshy channel is formed by all the three, in which the rectus is lodged, covering the forepart of the crureus.

It terminates below in a tendinous aponeurosis, which joins the backside of the tendon of the rectus anterior, and the neighbouring edges of the extremities of the two vasti. Thus, these four muscles form a common tendon, which is inserted in the places already mentioned.

SARTORIUS.

THIS is the longest muscle of the human body. It is flat, and about two fingers in breadth, situated obliquely along the inside of the thigh.

It is fixed above by a very short tendon, in the lower part of the anterior superior spine of the os ilium, before the musculus fasciæ latæ. The beginning of its body lies in the notch between the two anterior spines of that bone.

From thence it runs down obliquely over the vastus internus and other muscles that lie near it, all the way to the inside of the knee, where it terminates in a small tendon, which grows broader near its extremity, and is inserted obliquely and a little transversely in the forepart of the inside of the head of the tibia, near the spine or tuberosity of that bone, immediately above the insertion of the gracilis interior.

GRACILIS INTERIOR *sive* RECTUS INTERIOR.

THIS is a long thin muscle, lying in a straight line on the inside of the thigh, between the os pubis and the knee.

It is fixed in the edge of the inferior branch of the os pubis, near the symphysis, by a broad and very short tendon, on one side of the insertion of the triceps secundus, but a little lower down.

From thence the fleshy fibres contracting a little in breadth, run down to the internal condyle of the os femoris, where they terminate in a thin tendon, which afterwards degenerates into a kind of aponeurosis, and is inserted in the fore-part of the inside of the head of the tibia.

BICEPS.

## BICEPS.

THIS muscle is made up of two portions, one long, the other short, and they end in a common tendon. Both portions are fleshy and considerably thick, being situated on the back and outside of the thigh, between the buttock and ham.

The great portion is fixed above, by a strong tendon, in the posterior and lower part of the tuberosity of the ischium, under the insertion of the inferior gemellus, and close behind that of the semi-nervosus. From thence it runs down toward the lower extremity of the thigh, where it meets the other portion, and joins with it in forming a common tendon.

The small portion is fixed, by fleshy fibres, to the outside of the linea aspera, below its middle, and to the fascia lata, where it forms a septum between the triceps and vastus externus. From thence the fibres run down a little way, and then meeting the great portion, a common tendon is formed between them.

This strong tendon runs down to the outer and back-part of the knee, and is inserted in the lateral ligament of the joint, and in the head of the fibula, by two very short tendinous branches.

## SEMI-NERVOSUS.

THIS is a long muscle, half fleshy and half tendinous, or like a nerve, from whence it has its name. It is situated a little obliquely, on the posterior and inner part of the thigh.

It is fixed above to the posterior part of the tuberosity of the ischium, immediately before, and a little more inward than the biceps. It is afterwards fixed, by fleshy fibres, to the tendon of the biceps, for about the breadth of three fingers, much in the same manner as the coracobrachialis is fixed to the biceps of the arm.

From thence it runs down fleshy toward the lower part of the inside of the thigh, having a sort of tendinous interfection in the inner part of its fleshy portion. Having reached below the middle of the thigh, it terminates in a small, long, round tendon, which runs down to the inside of the knee, behind that of the gracilis, where it expands in breadth.

It is inserted in the inside of the upper part of the tibia, about two or three fingers breadth below the tuberosity or spine, immediately under the tendon of the gracilis internus, with which it communicates.

## SEMI-MEMBRANOSUS.

THIS is a long thin muscle, partly tendinous, from whence it has its name, and situated on the back-side of the thigh, a little towards the inside.

It is fixed above, by a broad tendon or long aponeurosis, in the irregular, obtuse, prominent line which goes from the acetabulum to the tuberosity of the ischium, a little above the insertion of the semi-nervosus, and between those of the gemellus inferior and quadratus.

From thence it runs down fleshy in an oblique direction behind the inner condyle of the os femoris, below which

it terminates in a thick tendon, which is inserted in the posterior and interior side of the inner condyle of the tibia, by three short branches, the first or uppermost of which goes a little toward the inside, the second more backward, and the third lower down.

## POPLITEUS.

THIS is a small muscle, obliquely pyramidal, situated under the ham.

It is fixed above, by a strong narrow tendon, to the outer edge of the inner condyle of the os femoris, and to the neighbouring posterior ligament of the joint. From thence it runs obliquely downward under the inner condyle of the os femoris; it is a flat and pretty thick fleshy body, increasing gradually in breadth, till it is fixed in the back-side of the head of the tibia, all the way to the oblique line or impression observable on that side.

*Uses of the Muscles which move the Bones of the Leg on the Os Femoris.*

THE two vasti and crureus ought to be looked upon as a true triceps, the uses of which, in relation to the bones, are only to extend the tibia on the os femoris, and the os femoris on the tibia. The extension of the tibia on the os femoris happens chiefly when we sit or lie, and that of the os femoris on the tibia when we stand or walk. All the three muscles move the patella uniformly in the direction of the os femoris, on the pulley at the lower extremity of that bone.

The insertion of both the vasti immediately in the head of the tibia, prevents the patella from being luxated laterally on some occasions, in which the muscles may act with more force on one side than on the other, or remain without action, in which case the patella is loose and floating.

The rectus anterior, by its insertion in the patella, is a congener to the last three muscles, and serves to extend the leg. By its insertion in the os ilium, it bends the thigh, and assists the psoas, iliacus, and poëticus, whether the leg be extended or bent. It likewise moves the pelvis forward on the os femoris, and hinders it from falling back when we sit.

The fartorius performs the rotation of the thigh from before outward, whether extended or bent; being an antagonist to the musculus fasciæ latæ, and a congener to the quadrigenius.

It likewise bends the thigh, or raises it forward; it moves the pelvis forward on the femoris; and when the pelvis rests on the two tuberosities of the ischium in sitting, it keeps it in that situation.

Lastly, it bends the leg, whether it performs the rotation of the thigh at the same time or not.

The gracilis internus bends the leg much in the same manner with the fartorius, which it assists in this function, but not in that of turning the leg.

It may likewise assist the triceps in the adduction of the thigh, which it performs with much more facility than it begins the flexion of the leg without the rotation of the thigh.

The semi-nervosus bends the leg, and may likewise bend the thigh on the leg. By its insertion in the tuberosity of the ischium, it likewise extends the thigh on the pelvis, and carries it backward; and may also extend the pelvis on the thigh, when it has been inclined forward with the rest of the trunk; and consequently prevent its being carried too far along with the trunk, when we stoop forward, either standing or sitting.

The semi-membranosus has the same uses with the semi-nervosus. It bends the leg on the thigh, and the thigh on the leg; it extends the thigh on the pelvis, and the pelvis on the thigh, and sustains the pelvis when it is inclined forward.

The two portions of the biceps bend the leg on the thigh, and the thigh on the leg. The superior portion likewise extends the thigh on the pelvis, and the pelvis on the thigh. These four uses in general are common to this muscle with the semi-membranosus, and in some measure with the semi-tendinosus.

The particular use of the biceps, and which seems to belong more to the short portion than to the other, is to perform the rotation of the leg when bent, by which motion the toes are turned outward, and the heel inward.

The popliteus performs the rotation of the leg when bent, in a direction contrary to that of the biceps. The biceps turns the leg from before outward; the popliteus from before inward.

## SECT. XI. *The MUSCLES which move the Tarsus on the Leg.*

### TIBIALIS ANTICUS.

THIS is a long muscle, fleshy at the upper part, and tendinous at the lower, situated on the fore-side of the leg, between the tibia and the extensor digitorum longus.

It is fixed above, by fleshy fibres, in the upper third part of the external labium of the crista tibiæ, and of the inside of the aponeurosis tibialis, or of that ligamentary expansion which goes between the crista tibiæ and the anterior angle of the fibula. It is likewise fixed obliquely in the upper two thirds of the outside of the tibia, or that next the fibula.

From thence it runs down and ends in a tendon, which first passes through a ring of the common annular ligament, and then through another separate ring situated lower down. Afterwards the tendon is fixed, partly in the upper and inner part of the os cuboides, and partly in the inside of the first bone of the metatarsus.

### PERONÆUS MEDIUS *vulgo* PERONÆUS ANTICUS.

THIS is a long muscle, situated anteriorly on the middle part of the fibula.

It is fixed above, by fleshy fibres, to more than the middle third part of the anterior or outside of the fibula, and to the neighbouring part of the aponeurosis tibialis.

It is likewise fixed to a production from the inside of that aponeurosis which runs to the upper part of the ti-

bia, and there serves for a middle septum between this muscle and the extensor digitorum longus.

From thence it runs down and forms a tendon, which going in the direction of the oblique line on the fibula, passes behind the external malleolus, and then through an annular ligament common to it and to the peronæus maximus, and is afterwards inserted in the tuberosity at the basis of the fifth metatarsal bone, sending off a small tendon to the first phalanx of the little toe.

### PERONÆUS MINIMUS.

THIS is a small muscle, commonly thought to be a portion of the extensor digitorum longus, though it is easily separable from it.

It is fixed, by fleshy fibres, in the lower half of the inside of the fibula, between two oblique bony lines, on one side of the lower part of the extensor digitorum longus, to which muscle it is simply contiguous.

From thence it runs down contracting in breadth, and passes with the extensor longus, through the common annular ligament, forming a flat tendon, which soon separates from those of the extensor, and is inserted near the basis of the fifth metatarsal bone.

### GASTROCNEMII.

THESE are two thick, pretty broad, and oblong muscles, situated laterally with respect to each other, in the same plane, under the poples, and forming a great part of what is called the calf of the leg. That which lies next the tibia is called *internus*, and that next the fibula, *externus*; and because they form, as it were, the belly of the leg, they have been termed in Greek *gastrocnemii*.

Each muscle is fixed above, by a flat tendon, to the posterior part of the lower extremity of the os femoris, behind the lateral tuberosity of each condyle, adhering closely to the posterior ligaments of the joint of the knee.

From thence they run down, each forming a large and pretty broad fleshy body, irregularly oval.

About the middle of the leg, they end in a strong, broad, common tendon, which contracts a little in breadth as it descends, and is inserted in the posterior extremity of the os calcis, together with the tendon of the soleus.

### SOLEUS.

THIS is a large, fleshy, flat muscle, nearly of an oval figure, and thicker in the middle than at the edges. It is situated on the back-side of the leg, lower down than the gastrocnemii, by which it is covered; and these three muscles form the calf of the leg.

It is fixed above, partly to the tibia, and partly to the fibula.

Afterwards leaving these two bones, it ends in a broad strong tendon, which, together with that of the gastrocnemii, forms what is called *tend. Achillis*. This strong tendon contracts a little in its passage to the os calcis, and then expanding a little, it is inserted obliquely in the back-side of that bone, all the way to the tuberosity.

TIBIALIS GRACILIS *vulgo* PLANTARIS.

THIS is a small pyriform muscle, situated obliquely in the ham below the external condyle of the os femoris, between the popliteus and gastrocnemius externus; and its tendon, which is long, flat, and very small, runs down on the side of the gastrocnemius internus, all the way to the heel.

The fleshy body, which is only about two inches in length, and one in breadth, is fixed, by a short flat tendon, above the outer edge of the exterior condyle of the os femoris, on one side of the gastrocnemius externus. From thence the fleshy body runs obliquely over the edge of the popliteus, and terminates in a very small, long, flat tendon.

This tendon runs between the body of the gastrocnemius externus and soleus, all the way to the inner edge of the upper part of the tendo Achillis; and from thence continuing its course downward, it joins this tendon, and is inserted, together with it, in the outside of the posterior part of the os calcis, without communicating with the aponeurosis plantaris.

## TIBIALIS POSTICUS.

THIS is a long, fleshy, penniform muscle, broader above than below, situated between the tibia and fibula, on the back-side of the leg, and covered by the extensor digitorum longus.

It is fixed above, by fleshy fibres, immediately under the articulation of the tibia and fibula, to the nearest parts of these two bones, chiefly to the tibia, reaching to the lateral parts of that bone, above the interosseous ligament, which is here wanting.

From thence its insertion is extended below the oblique line or impression in the tibia, over all the neighbouring part of the interosseous ligament, and through more than the upper half of the internal angle of the fibula.

After this, it forms a tendon, which runs down behind the inner malleolus; through a cartilaginous groove and an annular ligament, and, passing under the malleolus, is inserted in the tuberosity or lower part of the os scaphoides.

PERONÆUS MAXIMUS *vulgo* PERONÆUS POSTERIOR.

THIS is a long penniform muscle, lying on the fibula.

It is fixed above to the anterior and outer part of the head of the fibula, and to a small portion of the head of the tibia; then to the outside of the neck of the fibula, to the upper half of the external angle of that bone, and to the aponeurosis tibialis, which at that place makes a septum between this muscle and the extensor pollicis.

From thence turning a little backward, according to the direction of the bone, it forms a considerable tendon, which, running behind the external malleolus, passes through a kind of hollow groove, and through an annular ligament common to it and to the tendon of the peronæus medius, which lies before it.

Afterwards running through the oblique groove in the lower side of the os cuboides, it is inserted in the side of

the basis of the first metatarsal bone, and also a little in the basis of the os cuneiforme majus.

SECT. XII. *The MUSCLES which move the Metatarsus and Toes.*

## EXTENSOR POLLICIS LONGUS.

THIS is a thin single muscle, lying between the tibialis anticus and extensor digitorum longus, by which it is almost hid.

It is fixed to the inside of the fibula, near the interosseous ligament, from the neck down to the lowest quarter of that bone; to the interosseous ligament through the same space, and a little to the lower extremity of the tibia next the fibula.

There it ends in a considerable tendon, which passing through a distinct ring of the common annular ligament, and then through a membranous vagina, is inserted in the basis of the first phalanx of the great toe, and continued from thence up to the second.

## FLEXOR POLLICIS LONGUS.

THIS is a pretty long muscle, situated in the posterior and lower part of the leg.

It is fixed in the lower half of the back-side of the fibula, its insertion reaching almost as far as the external malleolus. The fleshy body advances on the inside of that bone towards the tibia, according to the oblique direction of that side, and ends in a large tendon.

This tendon passes behind the lower extremity of the tibia, toward the inner ankle, then through a small notch in the inner and back-side of the astragalus, and through an annular ligament or ligamentary vagina, continued under the lateral arch of the os calcis.

From thence it advances to the great toe, and passing through the interstice between the two sesamoid bones, in the ligamentary vagina of the first phalanx, is inserted in the lower part of the second.

## THE NAR.

THIS muscle is made up of several portions, and lies on the inner edge of the sole of the foot.

It is fixed, by three or four fleshy fasciculi, to the lower and inner part of the os calcis, os scaphoides, and os cuneiforme majus. It is likewise fixed a little in the annular ligament under the inner ankle, which belongs to the tendon of the flexor longus.

From all these different insertions, the fleshy fasciculi approach each other as they advance forward under the first bone of the metatarsus, and are fixed, partly in the internal sesamoid bone, and partly in the inside of the first phalanx, near its basis.

## ANTITHENAR.

THIS is a small compound muscle, lying obliquely under the metatarsal bones.

It is fixed posteriorly in the lower parts of the second, third, and fourth metatarsal bones, near their basis; in the ligament belonging to the first and second of these bones; in the neighbouring ligaments belonging to the bones of the tarsus; and, lastly, in a lateral aponeurosis of the muscle commonly called *hypotenar*.

All these portions, contracting into a small compass, are inserted in the outside of the external sesamoid bone, and of the first phalanx of the great toe.

### EXTENSOR DIGITORUM LONGUS.

This is a long muscle, fleshy in the upper part, and tendinous in the lower, lying between the tibialis anticus and peroneus maximus.

It is fixed above, by fleshy fibres, in the outside of the head of the tibia, and inside of the head of the fibula; in the upper part of the interosseous ligament, through three fourths of the length of the fibula; and through the same space, in the tendinous septum belonging to the anterior angle of that bone.

It contracts in breadth a little above the annular ligament, and, in passing through it, is divided into three tendons; the first of which is afterwards divided into two. These four tendons are inserted along the upper or convex side of the four small toes.

### EXTENSOR DIGITORUM BREVIS.

This is a small complex muscle, lying obliquely on the convex side of the foot, being likewise termed *pedicus*.

It is fixed in the upper and outer side of the anterior apophysis of the astragalus, and in the neighbouring part of the upper side of that bone. From thence it runs obliquely from without inwards, under the tendons of the peroneus minimus and extensor digitorum longus, being divided into four fleshy portions, which terminate in the same number of tendons.

The first tendon is inserted in the upper or convex part of the first phalanx of the great toe. The other three joining with those of the extensor longus, are inserted along the convex sides of all the phalanges of the three following toes.

### FLEXOR DIGITORUM BREVIS *sive* PERFORATUS PEDIS.

This is the undermost of all the common muscles of the toes, being situated immediately above the aponeurosis plantaris.

It is fixed by fleshy fibres to the anterior and lower part of the great tuberosity of the os calcis; and to the neighbouring part of the upper side of the aponeurosis plantaris.

From thence it runs forward, being divided into four fleshy portions, which terminate in the same number of tendons, split at their extremities, in the same manner as those of the sublimis or perforatus of the hand, and inserted in the second phalanges of the four small toes.

### FLEXOR DIGITORUM LONGUS *sive* PERFORANS PEDIS.

This is a long muscle, fleshy above, and tendinous below, lying on the backside of the leg between the tibia and the flexor pollicis longus, covered by the soleus, and covering the tibialis posterior.

It is fixed above, by fleshy fibres, to a little more than the middle third part of the backside of the tibia near its external angle, below the insertion of the soleus; and also to a kind of ligament which runs down from the middle of the tibia. It afterwards ends in a tendon which passes behind the inner ankle, on one side, and a little behind the tibialis posterior, in a separate annular ligament.

From thence it runs under the sole of the foot, sending off a detachment, by which it communicates with the flexor pollicis longus. There it is divided into four small flat tendons, which go to the third phalanges of the four small toes in the same manner, as the perforans of the hand.

### FLEXOR DIGITORUM ACCESSORIUS.

This is a flat and pretty long fleshy mass, situated obliquely under the sole of the foot.

This muscle is fixed posteriorly by one fleshy portion, in the lower side of the os calcis, and in the anterior tuberosity on that side, and by the other in the neighbouring ligament which joins this bone to the astragalus.

From thence the two portions run obliquely to the middle of the sole of the foot, and there unite in a flat, long, and irregularly square muscular mass, which is fixed to the outer edge of the fasciculus of tendons of the flexor longus, to which it serves as a *stratum* at that place.

### LUMBRICALES.

THESE are four small muscles, situated more or less longitudinally under the sole of the foot.

They are fixed by their fleshy extremities to the four tendons of the flexor digitorum longus near the insertion of the flexor accessorius. The first muscle is fixed to the inside of the first tendon; the second to the tendinous fork formed by the two first tendons; the third, to the tendinous fork made by the second and third tendons; and the fourth, in the same manner to the third and fourth tendons, but commonly most to the third.

From thence these four muscles run to the toes, and there terminate in the same number of small tendons, which are inserted in the first phalanges of the toes, much after the same manner as in the hand.

### TRANSVERSALIS DIGITORUM.

This is a small muscle, which lies transversely under the basis of the first phalanges, and which at first sight appears to be a simple muscular body fixed by one end to the great toe, and by the other to the little toe.

When

When this muscle is carefully examined, we find that it is fixed, by a very short common tendon, to the outside of the basis of the first phalanx of the great toe, conjointly with the antithenar; and, by three different portions or digitations, to the three interosseous ligaments which connect the heads of the four metatarsal bones next the great toe, laterally to each other.

### INTEROSSEI.

THESE are seven small muscles which fill up the four interstices between the metatarsal bones, much after the same manner as in the hand. The four largest are superior, the other three inferior.

### METATARSII.

THIS is a fleshy mass, lying under the sole of the foot. It is fixed, by one end, in the fore-part of the great tuberosity of the os calcis; and running forward from thence, it terminates in a kind of short tendon, which is fixed in the tuberosity and posterior part of the lower side of the fifth bone of the metatarsus.

### PARATHENAR MAJOR.

THIS is a pretty long muscle, forming part of the outer edge of the sole of the foot.

It is fixed backwards by a fleshy body, to the outer part of the lower side of the os calcis, from the small posterior or external tuberosity, all the way to the anterior tuberosity. There it joins the metatarsus, and at the basis of the fifth metatarsal bone separates from it again, and forms a tendon, which is inserted in the outside of the first phalanx of the little toe, near its basis, and near the insertion of the parathenar minor.

### PARATHENAR MINOR.

THIS is a fleshy muscle, fixed along the posterior half of the outer and lower side of the fifth bone of the metatarsus. It terminates under the head of that bone, in a tendon which is inserted in the lower part of the basis of the first phalanx of the little toe.

*Uses of the Muscles which move the Tarsus and the other Bones of the Foot.*

THE tibialis anticus bends the foot, that is, turns the point of the foot toward the leg; which motion is performed by the ginglymoid articulation of the astragalus with the tibia and fibula. It likewise bends the leg on the foot, or hinders its extension.

By its lateral insertion in the os cuneiforme maximum, it moves this bone in particular over the anterior extremity of the os calcis; by which the sole of the foot is turned inward toward the other.

The peronæus medius bends the foot, and hinders the leg from falling back in the same manner as the tibialis anticus. By its insertion in the tuberosity of the fifth metatarsal bone, it turns the sole of the foot outward at

the same time that it bends it, when it acts without the assistance of the tibialis anticus.

The peronæus minimus is an assistant to the medius in the flexion of the foot, in preserving the equilibrium of the leg, and in turning the sole of the foot outward.

THE gastrocnemii and soleus make a kind of triceps; and, by their common tendon, extend the foot, and keep it extended against the strongest resistance. It is by their means that we raise the whole body, even with an additional burden, when we stand a tip-toes; and that we walk, run and jump.

The gastrocnemii, by their insertion in the os femoris, may, in great efforts, move the leg on the thigh, and the thigh on the leg, as assistants to the biceps, femi-membranosus, semi-tendinosus, gracilis internus, and fartorius.

The soleus, by the multitude of its fleshy fibres and its penniform structure, is more proper for strong than large motions, and seems principally to sustain the gastrocnemii in the motions begun by them. The tendinous portions of this muscle and of the gastrocnemii, tho' they form a strong tendon all together, seem nevertheless to slide a little upon each other in the different flexions and extensions of the foot.

Anatomists are not agreed with regard to the use of the tibialis gracilis.

When the tibialis posticus acts alone, it extends the foot obliquely inward. When it acts together with the gastrocnemii and soleus, it changes the straight direction of their motion to an oblique one. When it acts with the tibialis anticus, the sole of the foot is turned more directly inward, or toward the other foot.

When the peronæus longus or maximus acts alone, it may extend the foot hanging freely in the air; but then this extension is obliquely outward. Together with the gastrocnemii and soleus, it likewise changes their direction to an oblique extension outward.

The extensor pollicis longus extends the two phalanges of the great toe; and it may likewise be an assistant to the tibialis anticus.

The flexor pollicis longus not only bends the second phalanx of the great toe, but may likewise serve, in great efforts, as an assistant to the extensors of the tarsus. This muscle is of great use in climbing up a steep place.

The thenar bends the first phalanx of the great toe. When the portion nearest the inner edge of the foot either acts alone, or acts more than the rest, the great toe is separated from the other toes, especially if it be at the same time extended.

The antithenar, acting with the thenar, bends the first phalanx of the great toe. When it acts alone, especially if the great toe is bent, it brings it nearer the other toes, in proportion to the degrees of action of its different portions.

The two extensores digitorum communes concur in extending the four small toes; and, as the extensor longus is not near so fleshy as that of the hand, this difference is made up by the extensor brevis. The longus alone seems to extend the first phalanges; and they both join in the extension of the second and third phalanges; the brevis, by the obliquity of its direction, moderating the action

action of the longus, which otherwise would have turned the toes obliquely the contrary way.

The perforatus or flexor digitorum brevis, bends the second phalanges; and the perforans or flexor longus, the third; the use of these muscles being nearly the same with those of the perforatus and perforans of the hand.

The flexor accessorius is an assistant to the perforans, increasing its force on some occasions. It likewise directs the tendon of that muscle; for by contracting, at the same time that the fleshy belly of the perforans is in action, it makes the tendons go in a straighter line to the toes than they would otherwise do, because of their obliquity.

The lumbricales have nearly the same functions in the foot as in the hand; and they are partly assisted, and partly directed, by the flexor accessorius.

The interossei of the foot have the same uses as in the hand. The first superior muscle brings the second toe near the great toe; the other three bring the second, third, and fourth toes near the little toe. The three inferior muscles move the last three toes toward the other two.

The metatarsus moves the last bone of the metatarsus, much in the same manner as the metacarpus does that of the metacarpus.

The transversalis may assist the metatarsus in this action, which is supposed to be of use to tilers in climbing. The antithenar may likewise concur, and the peroneus minimus may serve to counterbalance these muscles, and to bring the metatarsus back to its natural situation.

THE parathenar major serves particularly to separate the little toe from the rest; and the parathenar minor bends the first phalanx of that toe.

### SECT. XIII. *The MUSCLES employed in Respiration.*

#### DIAPHRAGMA.

THIS is a very broad and thin muscle, situated at the basis of the thorax, and serving as a transverse partition to separate that cavity from the abdomen. For this reason the Greeks termed it *diaphragma*; and the Latins, *septum transversum*. It forms an oblique inclined arch, the fore-part of which is highest, and the posterior part lowest, making a very acute angle with the back.

It is looked upon as a double and digastric muscle, made up of two different portions, one large and superior, called the great muscle of the diaphragm; the other small and inferior, appearing like an appendix to the other, called the small or inferior muscle of the diaphragm.

The great or principal muscle is fleshy in its circumference, and tendinous and aponeurotic in the middle, which, for that reason, is commonly called *centrum nervorum sive tendinosum*.

The fleshy circumference is radiated, the fibres of which it is made up being fixed by one extremity to the

edge of the middle aponeurosis, and by the other to all the basis of the cavity of the thorax, being inserted by digitations in the lower parts of the appendix of the sternum, of the lowest true ribs, of all the false ribs, and in the neighbouring vertebrae.

We have therefore three kinds of insertions; one sternal; twelve costal, six on each side; and two vertebral, one on each side. These last are very small, and sometimes scarcely perceivable. The costal insertions join those of the transversalis abdominis, but do not mix with them, as they seem to do before the membrane which covers them is removed.

The fibres inserted in the appendix ensiformis, run from behind directly forward, and form a small parallel plane.

The first costal insertion runs a little obliquely towards the cartilage of the seventh true rib, a triangular space being left between this and the sternal insertion, at which the pleura and peritonæum meet. The insertion of these fibres is very broad, taking up about two thirds of the cartilage of the seventh rib, and a small part of the bone, from whence it reaches beyond the angle of the cartilage.

The second insertion is into the whole cartilage of the first false rib; the third partly in the bone, and partly in the cartilage of the second false rib; the fourth in the bone, and sometimes a little in the cartilage of the third false rib; the fifth in the bone, and a little in the cartilage of the fourth false rib, being broader than the rest.

The sixth is in the cartilage of the last false rib, and almost through the whole length of the bone. At the head of this rib, it joins the vertebral insertion, which runs from the lateral part of the last vertebra of the back, to the first vertebra of the loins.

The small muscle of the diaphragm is thicker than the other, but of much less extent. It is situated along the fore-side of the bodies of the last vertebra of the back and several of those of the loins, being turned a little to the left hand. It is of an oblong form, representing in some measure a fleshy collar, the two lateral portions of which cross each other, and afterward become tendinous toward the lower part.

The upper part of the body of this muscle is fixed in the slope of the middle aponeurosis of the great muscle. The outer edges of the ala or lateral portions join the posterior plane of the great muscle, and these portions adhere to the body of the last vertebra of the back. The extremities, called likewise *pillars* or *crura*, are inserted by several tendinous digitations in the vertebrae of the loins.

The upper part of the fleshy body is formed by a particular intertexture of fibres belonging to the two alae. These two alae, whereof that toward the right-hand is generally the most considerable, part from each other, and form an oval hole, terminated on the lower part by fibres, detached from the inside of each ala, immediately above the last vertebra of the back. These fibres decussate and cross each other, and afterwards those that come from each ala join that on the other side, so that each of the crura is a production of both alae.

The fibres that come from the left ala, cross over those from the right ala, and this again sends a small fasciculus of fibres over those of the left ala; afterwards the two crura part from each other.

The right crus is larger and longer than the left, and is always inserted in the four upper vertebræ of the loins, and often in the fifth likewise, by the same number of digitations, which become more and more tendinous as they descend, and at length are expanded in form of an aponeurosis. This crus lies more on the middle of the bodies of the vertebræ than on the right side.

The left crus is smaller and shorter, and lies more on the sides of the vertebræ. It is fixed by digitations to the three upper vertebræ of the loins, seldom reaching lower. The lower part of it is expanded in the same manner as the other; and the two expansions sometimes meet together.

The oval opening of this inferior muscle of the diaphragm, gives passage to the extremity of the œsophagus, and the aorta lies in the interstice between the two crura. Immediately above the opening or hole, a thin fasciculus of fibres is sent off to the stomach.

In the middle aponeurosis of the great muscles, a little to the right of the anterior part of the slope, near the small muscle, is a round opening, which transmits the trunk of the lower vena cava. The border or circumference of this opening is very artfully formed by an oblique and successive intertexture of tendinous fibres, almost like the edge of a wicker basket; and is, consequently, incapable either of dilatation or contraction, by the action of the diaphragm.

We find therefore three considerable openings in the diaphragm; one round and tendinous, for the passage of the vena cava; one oval and fleshy, for the extremity of the œsophagus; and one forked, partly fleshy, and partly tendinous, for the aorta. The round opening is to the right-hand, close to the upper part of the right ala of the small muscle; the oval opening is a little to the left; so that the right ala, which is between these two holes, lies almost directly over against the middle of the body of the eleventh vertebra of the back; the tendinous part is under the oval opening, but a little more toward the middle.

### SCALENI.

THESE are compound muscles, irregularly triangular.

The scalenus primus is fixed to the upper part of the outside of the first rib, by two distinct portions, called commonly *branches*; one anterior, the other posterior. The anterior branch is fixed to the middle portion of the rib, about an inch from the cartilage. From thence it runs obliquely upward, and is inserted in the transverse apophysis of the sixth, fifth, and sometimes of the third vertebra of the neck.

The posterior branch is fixed more backward in the first rib, an interstice of about an inch being left between it and the other branch, through which the axillary artery and brachial nerves are transmitted. From thence it runs up obliquely behind the former, and is inserted in all the transverse apophyses of the neck.

The scalenus secundus is fixed a little more backward in the external labium of the upper edge of the second rib, sometimes by two separate portions, and sometimes without any division. The anterior portion is fixed immediately under the posterior portion of the first scalenus, by a short flat tendon, united a little with the first intercostal muscle. From thence it runs up over the posterior portion of the first scalenus, communicating likewise with that muscle, and is fixed by insertions, partly tendinous and partly fleshy, in the transverse apophyses of the four first vertebræ of the neck.

The posterior portion is fixed in the second rib, more backward than the other. From thence it runs up, being divided into two portions, whereof one is inserted in the transverse apophyses of the three first vertebræ of the neck, behind the scalenus primus. The other portion runs up behind the former, and is inserted in the transverse apophyses of the two first vertebræ.

### SERRATUS POSTICUS SUPERIOR.

THIS is a flat thin muscle, situated on the upper part of the back. It is fixed on one side, by a broad aponeurosis, to the lower part of the posterior cervical ligament, and to the spinal apophyses of the two last vertebræ of the neck, and two first of the back.

From thence it runs down a little obliquely forward, and is inserted, by broad fleshy digitations, in the posterior part of the second, third, fourth, and sometimes of the fifth true ribs, near their angles; but sometimes it has no insertion in the second rib.

### SERRATUS POSTICUS INFERIOR.

THIS is a flat thin muscle, lying on the lower part of the back. It is fixed in the last spinal apophysis of the back, and in the three first of the loins, by a broad aponeurosis. From thence it runs up a little obliquely, and is fixed, by fleshy broad digitations, in the last four false ribs. Its insertions, in the lowest rib, is near the cartilage, and, in the other three, near their angles.

### INTERCOSTALES.

THE intercostal muscles are thin, fleshy planes, lying in the interstices between the ribs, their fibres running obliquely from one rib to another. In each interstice lie two planes, an external and an internal, closely joined together, nothing but a thin, fine, cellular, membranous web coming between them.

According to this natural division, there must be forty-four intercostal muscles in the twenty-two interstices left between the twenty-four ribs; and of these there are eleven external, and eleven internal, on each side. The fibres of the external intercostals run down from behind forward, and those of the internal intercostals from before backward; so that the fibres of these two series of muscles cross each other.

The external intercostals extend commonly from the vertebræ to the extremity of the upper labium of the bony portion of each rib, and go no further. The internal

ternal begin forward near the sternum, and end backward at the angle of each rib.

### SUPRA-COSTALES.

THESE muscles are irregularly triangular, and situated on the back-part of the ribs, near the vertebrae.

Each of these muscles is fixed, by one tendinous extremity, in the transverse apophysis, which lies above the articulation of each rib, and to the neighbouring ligament; the first being inserted in the transverse apophysis of the last vertebra of the neck; and the last, in that of the eleventh vertebra of the back.

From thence the fleshy fibres run down obliquely, increasing in breadth as they descend, and are inserted in the back part of the outside of the following rib.

### SUB-COSTALES.

THESE are fleshy planes, of different breadths, and very thin, situated more or less obliquely on the insides of the ribs, near the bony angles, and running in the same direction with the external intercostals.

They are fixed by both extremities in the ribs; the inferior extremity being always at a greater distance from the vertebrae than the superior, and several ribs lying between the two insertions.

### STERNO-COSTALES *vulgo* TRIANGULARIS STERNI.

THESE are five pairs of fleshy planes, disposed more or less obliquely on each side the sternum, and on the inside of the cartilages of the second, third, fourth, fifth, and sixth true ribs.

They are inserted, by one extremity, in the edges of the inside of all the lower half of the sternum. From thence the first muscle on each side runs up obliquely, and is fixed in the cartilage of the second rib. The second runs less obliquely to its insertion in the cartilage of the third rib. The rest are inserted, in the same manner, in the cartilages of the following ribs.

This last muscle is fixed, by one extremity, in the cartilage of the sixth true rib, near the bone, and seems to pass the appendix ensiformis, immediately above the insertion of the diaphragm in that appendix, and to join the muscle on the other side.

#### Uses of the Muscles employed in Respiration.

THE scaleni are sometimes ranked among those which serve for respiration; but they ought rather to be ranked among the muscles which move the vertebrae of the neck; because the articulation of the first rib on both sides, with the first vertebra of the back, seems to serve only for the motion of that vertebra on the rib, and not of the rib on the vertebra.

The serratus posticus superior is disposed to move upwards the three or four upper ribs next the first.

The serratus posticus inferior is still better disposed for depressing and keeping down the last three or four false ribs.

The posterior fibres of the external intercostals are

fixed, by their upper extremities, so near the articulation of the ribs with the vertebrae, that they cannot depress that rib in which they are so inserted; whereas the insertions of their lower extremities in the following rib being at a greater distance from the articulation, they may move that rib upward. And from thence it follows, that all the remaining part of each external intercostal which terminates at the bony extremity of that rib, can only serve to raise the lower rib toward the upper.

The anterior fibres of the internal intercostals are so near the articulation of the ribs with the sternum, that they cannot depress that cartilage in which each of them is inserted; whereas the inferior insertions of these fibres being at a greater distance from the articulation, they are in a condition to raise the cartilages in which they are so inserted. From whence it follows, that all the internal intercostal muscles have the same use with the external, and that they can have no other.

The supra-costales are powerful assistants to the intercostals in their common action, and are therefore very justly termed *levatoros costarum*.

The sterno-costales depress the cartilaginous portions, and anterior extremities of the ribs, especially the superior ribs, except the first; and at the same time draw the cartilages of the inferior ribs near the sternum, by reason of the curvature. They may therefore very well be called *depressores costarum*, as the supra-costales are named *levatoros*.

The sub-costales having the superior extremities of their fibres much more distant from the vertebral articulation of the ribs than the lower extremities, it follows, that they can more easily move the upper than the lower ribs, and consequently that they are assistants to the sterno-costales.

The diaphragm, together with the intercostal muscles, the ribs, sternum, and vertebrae of the back, forms the cavity of the thorax, and it divides this cavity from that of the abdomen.

Its particular use is to be the principal organ of respiration, that is, of the alternate expansion and contraction of the thorax. The other muscles already mentioned are to be considered only as assistants and directors, in order to facilitate and regulate these motions, which, in the ordinary state, are perpetual, but which may, by the action of these other muscles, be accelerated, retarded, or even be suspended for some space of time.

The diaphragm may move when the ribs are at rest, and consequently without the assistance of the muscles which move the ribs; and this motion may be sufficient to keep up the alternate dilatation and contraction of the thorax.

### SECT. XIV. The MUSCLES which move the Head on the Trunk.

#### STERNO-MASTOIDÆUS *sive* MASTOIDÆUS ANTERIOR.

THIS is a long, narrow, pretty thick, and mostly fleshy muscle, situated obliquely between the back part

of the ear, and lower part of the throat. It is in a manner composed of two muscles, united at the upper part through their whole breadth, and separated at the lower.

It has two insertions below, both of them flat, and a little tendinous. The first is in the upper edge of the sternum, near the articulation of the clavicle; the other in the clavicle, at a small distance from the sternum.

The sternal portion passes foremost, and covers the clavicular, both forming one body or belly, which running in the same oblique direction to the apophysis mastoideus, is inserted in the upper and back-part of that process; over which it likewise sends off a very broad aponeurosis, which covers the splenius, and is inserted in the os occipitis.

#### SPLЕНИUS *sq.* MASTOIDÆUS POSTERIOR.

THIS is a flat, broad, oblong muscle, situated obliquely, between the back-part of the ear, and the posterior and lower part of the neck. It is partly single, and partly made up of two portions, one superior, the other inferior.

The superior portion is fixed to the extremities of the three or four lowest spinal apophyses of the neck, and of the first, or first and second, of the back.

It is likewise fixed to the edge of the inter-spinal ligaments of the other vertebrae.

From thence it runs up obliquely toward the mastoid apophysis, partly under the upper extremity of the sterno-mastoideus, and is inserted in the upper part of that process, and along the neighbouring curve portion of the transverse ridge of the os occipitis.

The inferior portion of the splenius is fixed to three or four spinal apophyses of the back, beginning by the second or third. From thence it runs up, being closely united to the other portion, till it reaches the superior and lateral part of the neck, where it separates from it, and is inserted in the transverse apophyses of the three or four superior vertebrae of the neck, by the same number of extremities, a little tendinous, which, however, are sometimes only two in number.

#### COMPLEXUS.

THIS is a pretty long and broad muscle, lying on the posterior lateral part of the neck, all the way to the occiput. It is complicated, by reason of the decussations of its different portions; from which it has its name.

It is fixed below, by small short tendons, to the transverse apophyses of all the vertebrae of the neck, except the first, to which it is fixed only near the root of its transverse apophysis. From thence it runs up obliquely backward, crossing under the splenius, and often communicating with it, by some fasciculi of fibres.

It is afterwards inserted above, by a broad fleshy plane, in the posterior part of the superior transverse line of the os occipitis, near the crista or spine of that bone.

#### COMPLEXUS MINOR *sq.* MASTOIDÆUS LATERALIS.

THIS is a long, slender, narrow indented muscle, lying

along all the side of the neck, up to the ear, where it increases a little in breadth.

It is fixed, by one extremity, in all the transverse apophyses of the neck, except the first, by the same number of digitations or branches, mostly fleshy, and disposed obliquely.

From thence it ascends, and having reached above the transverse apophysis of the first vertebra, it forms a small broad plane, by which it is inserted in the posterior part of the apophysis mastoideus.

#### RECTUS MAJOR.

THIS is a small, flat, short muscle, broad at the upper part, and narrow at the lower, situated obliquely between the occiput and second vertebra of the neck.

It is fixed below to one branch of the bifurcated spine of the second vertebra of the neck, at a tuberosity which is often found at the upper part of that branch. From thence it ascends a little obliquely outward, and is inserted in the posterior part of the inferior transverse line of the os occipitis, at a small distance from the crista, being a little covered by the obliquus superior.

#### RECTUS MINOR.

THIS muscle is like the former, and it has also a small insertion below, in the posterior eminence of the first vertebra. From thence it ascends laterally, and is inserted immediately under the posterior part of the inferior transverse line of the os occipitis, in a superficial fossula on one side of the crista occipitalis.

#### OBLIQUUS SUPERIOR *sq.* MINOR.

THIS muscle is situated laterally between the occiput and first vertebra, being nearly of the same figure with the two recti. It is fixed to the end of the transverse apophysis of the first vertebra; from whence it runs upward and very obliquely backward, and is inserted in the transverse line of the os occipitis, almost at an equal distance from the crista and mastoid apophysis, between the rectus major and complexus minor.

#### OBLIQUUS INFERIOR *sq.* MAJOR.

It is situated in a contrary direction to the obliquus superior, between the first and second vertebra of the neck, resembling that muscle in every thing but the size. It is fixed below to one ramus of the bifurcated spinal apophysis of the second vertebra, near the insertion of the rectus major; from whence it runs obliquely upwards and outward, and is inserted in the end of the transverse apophysis of the first vertebra, under the lower insertion of the obliquus superior.

#### RECTUS ANTICUS LONGUS.

THIS muscle is, in some measure, of a pyramidal figure, lying along the anterior and lateral parts of the vertebrae of the neck, all the way up the basis cranii.

Fig. 2.

Fig. 1.

Fig. 3.

Fig. 4.

Fig. 5.

It is fixed to the anterior parts of the transverse apophysis of the third, fourth, fifth, and sixth vertebræ in a digitated manner. From thence it runs obliquely inward toward the lateral parts of the bodies of the vertebræ, passes on the fore-side of the first and second, without being inserted in them; and, approaching gradually towards the same muscle on the other side, it is inserted near it in the fore-part of the lower side of the apophysis basilaris, or great apophysis of the os occipitis.

### RECTUS ANTICUS BREVIS.

THIS is a small flat muscle, about the breadth of one finger, situated laterally on the anterior part of the body of the first vertebra. It is fixed below to the basis or root of the transverse apophysis of that vertebra, near the anterior eminence.

From thence it runs obliquely upward and inward to a transverse impression in the lower side of the apophysis basilaris of the occipital bone, immediately before the condyle on the same side, being covered by the *rectus anticus longus*.

### TRANSVERSALIS ANTICUS PRIMUS.

THIS is a small, pretty thick, and wholly fleshy muscle, about the breadth of a finger, situated between the basis of the os occipitis and the transverse apophysis of the first vertebra. It is fixed by one end in the anterior part of that apophysis; and from thence running up a little obliquely, it is inserted, by the other end, in a particular impression, between the condyle of the os occipitis and the mastoid apophysis of the same side, behind the apophysis styloides, and under the edge of the jugular fossula.

### TRANSVERSALIS ANTICUS SECUNDUS.

THIS is a small muscle, situated between the transverse apophyses of the first two vertebræ of the neck. It is fixed, by one extremity, very near the middle of the second apophysis, and, by the other, near the root or basis of the first; and therefore it is a muscle of the neck, rather than of the head.

### MUSCULI ACCESSORII.

WE sometimes meet with a small muscle, fixed, by one end, to the extremity of the first transverse apophysis of the neck, near the insertions of the two obliqui, from whence, running up obliquely, it is again inserted behind the mastoid apophysis. This muscle is commonly thought to be a third small transversalis on that side where it is found, but it seems rather to be an additional muscle to the obliquus superior.

*USES of the Muscles which move the Head on the Trunk.*

THE action of the *sterno-mastoidei* is different, according as either both muscles, or only one of them, acts,  
VOL. I. No. 10.

and according to the different situation of the head and trunk.

When we keep the head and trunk straight, whether in standing or sitting, both muscles preserve the head in that posture against any force by which it would otherwise be moved backward.

One of these muscles acting alone, may have the same use, if the force to push the head back be applied between the anterior and lateral parts of it.

They both serve likewise to perform the rotations of the head, that is, to make it turn to either side as on a pivot; and, in this case, when we turn the head to one side, the *sterno-mastoideus* on the other side acts, and not that on the same side.

They both serve, in the next place, to bring the head near the thorax when we lie on the back, or bend backward in sitting. In this case, the sternum, being the fixed point, must remain immovable; but as its connection with the first rib, and the inflexibility of the cartilage of that rib, are not always sufficient for this, the *musculi recti* of the abdomen must lend their assistance in great efforts.

The two *splenii* serve to support the head in an erect posture, whether in standing or sitting; to moderate the flexion of the head forward, and to bring it back again to its natural posture.

They serve alternately to co-operate with either of the *sterno-mastoidei*, for the rotation of the head: Thus when the right *sterno-mastoideus* turns the head, the left *splenius* corresponds with it by its upper part; while the lower part at the same time turns the vertebræ of the neck.

The *complexi* are assistants to the *splenii*, to keep the head straight in sitting or standing, to hinder it from inclining forward, and to raise it when inclined.

The *recti majores*, and *minores postici*, and *obliqui superiores*, turn the head a little backward on the first vertebra of the neck. The *recti majores* contribute most to this motion; and the *minores* seem likewise to hinder the articular membranes from being pinched between the bones in great motions.

The *recti majores* and *minores antici*, and the two *transversales antici*, move the head forward on the first vertebra; and the *recti minores*, and *transversales breves*, likewise defend the capsular ligaments.

The *obliqui inferiores* or *majores* are true rotators of the head, by turning the first vertebra upon the odontoid apophysis of the second; all which alternate motions the head follows, without being hindered in the motions forward and backward in any degree of rotation.

Of the *transversales antici*, the first only move the head in the manner above mentioned; neither can they perform any other motions, their insertions being confined to the os occipitis and first vertebra. The *transversales antici secundi* have no share in the particular motions of the head, but ought rather to be ranked among the muscles which move the vertebræ of the neck.

The *complexi minores* belong to the head only by their superior portions; the other portions belonging rather to the neck. They may serve alternately in the lateral motions of the head, and thereby co-operate with the *splenii*

nius and sterno-mastoidæus of the same side, when these two act together; and they may likewise be of use to preserve the capsular ligaments to which they adhere.

The small accefforii, when they are found, have the same uses with the muscles to which they are supernumerary.

## SECT. XV. *Of the Vertebral Muscles.*

### LONGUS COLLI.

THIS vertebral muscle is made up of several others, situated laterally along the fore-side of all the vertebræ of the neck, and some of the upper vertebræ of the back.

It may be divided into two portions; one superior, consisting of oblique converging muscles; and one inferior, composed of oblique diverging muscles.

The superior portion is covered by the rectus anticus longus of the head. The muscles, of which it consists, are fixed below to all the transverse apophyses that lie between the first vertebra and the last. From thence they run up obliquely, and are inserted in the anterior eminence of the first vertebra, and in the bodies of the three following.

The inferior portion appears almost straight, and yet all the muscles that compose it are diverging, or directed obliquely outward. They are fixed below to the anterior lateral part of the body of the last vertebra of the neck, and of the first three of the back, and sometimes of more. From thence they run upward, and a little obliquely outward, and are inserted near the transverse apophyses of all the vertebræ of the neck, except the first and last.

### TRANSVERSALIS COLLI MAJOR.

THIS is a long thin muscle, placed along all the transverse apophyses of the neck, and the four, five, or six upper apophyses of the back, between the complexus major and minor.

It is composed of several small muscular fasciculi, which run directly from one or more transverse apophyses, and are inserted sometimes in the apophysis nearest to these, sometimes in others more remote, the several fasciculi crossing each other between the insertions of the two complexi, which are likewise crossed by them.

### TRANSVERSALIS GRACILIS *sive* COLLATERALIS COLLI.

THIS is a long thin muscle, resembling the transversalis major in every thing but size, and situated on the side of that muscle.

### SEMI-SPINALIS *sive* TRANSVERSO-SPINALIS COLLI.

THIS name is given to all that fleshy mass which lies between the transverse and spinal apophyses, from the second vertebra of the neck, to the middle of the back.

It is composed of several oblique converging mus-

cles, which may be divided into external and internal.

The external are fixed below to the transverse apophyses of the six, seven, eight, or nine upper vertebræ of the back, by tendinous extremities, which, as they ascend, become fleshy, and mix with each other. Their superior insertions in the neck are six in number, whereof the first, which is tendinous, is in the seventh spinal apophysis; the rest, which are fleshy, are in the five next spinal apophyses.

The internal are shorter and more oblique than the external, and partly covered by them. They are fixed, by their lower extremities, to the transverse apophyses of the three or four upper vertebræ of the back, and to the oblique apophyses of the four or five lower vertebræ of the neck; and, by their other extremities, they are inserted in the six spinal apophyses of the neck.

### SPINALES COLLI MINORES.

THESE muscles lie between the six spinal apophyses of the neck, and between the last of the neck and first of the back, being inserted in these apophyses, by both extremities, on one side of the posterior cervical ligament, which parts them from those on the other side.

### TRANSVERSALES COLLI MINORES.

THESE are very small short muscles, found in the interstices of several transverse apophyses in which they are inserted. They are likewise termed *inter-transversales*.

### SACRO-LUMBARIS.

THIS is a long complex muscle, narrow and thin at the upper part, broad and thick at the lower, representing a kind of flat pyramid. It lies between the spine and posterior part of all the ribs, and along the back-part of the regio lumbaris, all the way to the os sacrum.

Through all this space, it is closely accompanied by the longissimus dorsi, which lies between it and the spinal apophyses of the vertebræ, a narrow, fatty, or cellular line running between them.

It is fixed below, by a broad thin tendinous aponeurosis, to the superior spines of the os sacrum, and to the neighbouring lateral parts of that bone; and, lastly, to the external tubium of the posterior part of the crista of the ilium, all the way to the great tuberosity.

From thence this muscle runs upward, and a little laterally, over all the regio lumbaris; the aponeurosis sending off, from its inside, a mass of fleshy fibres, which are divided, from below upwards, into several large fasciculi, inserted in all the transverse apophyses of the loins.

Afterwards it runs up obliquely over all the ribs, sometimes as high as the two or three lowest vertebræ of the neck, sometimes higher, and sometimes it ends at the first vertebra of the back.

### LONGISSIMUS DORSI.

THIS is a very complex, long, and narrow muscle, something

something like the sacro-lumbaris, but more fleshy and thicker, situated between the spinal apophyses and the muscle just mentioned, from which it is divided by a small, fatty, or cellular line; but at the lower part they are confounded together. It covers the semi-spinalis, or transverso-spinalis dorsi, and the semi-spinalis lumborum. Its upper part lies between the sacro-lumbaris and transversalis colli.

Its inferior insertions are partly by distinct tendinous portions, and by a broad aponeurosis common to it with the sacro-lumbaris; and partly by a large fasciculi of fleshy fibres, which, at first sight, seem to compose one uniform mass. It is fixed, by the long, flat, tendinous portions of different breadths, to the last spinal apophysis of the back, to all those of the loins, and to one or two of the superior spines of the os sacrum. These portions lie at different distances from each other, but are all connected by a thin aponeurosis fixed to their edges.

From thence they run up obliquely, diverging from the apophyses; and, beginning to be fleshy at their inner or anterior sides, they terminate above in small roundish tendons, inserted in the extremities of the seven upper transverse apophyses of the back, and in the neighbouring ligaments of all the true ribs.

The other inferior insertion wholly fleshy, is partly in the inner or fore side of the aponeurosis of the sacro-lumbaris, and partly in the upper portion of the os sacrum, being from thence continued to the great tuberosity of the os ilium.

From thence this uniform mass of fleshy fibres runs up in a course almost direct, crossing the tendinous portions which are more oblique; and join the inferior fibres of the sacro-lumbaris by large fasciculi inserted in the transverse and oblique apophyses of the vertebrae of the loins. The fibres of this portion go afterwards to the ribs, being inserted by planes more or less fleshy, in the lower convex edge of all the false ribs, between the condyles or tuberosities and the angles.

At the sixth or seventh vertebra of the back, one or more of the tendinous portions often communicate with some fasciculi of the semi-spinalis, or transverso-spinalis dorsi.

### SPINALIS DORSI MAJOR.

This is a pretty long and slender muscle, lying upon the lateral part of the extremities of the spinal apophyses of the back.

It is composed of several muscular fasciculi of different lengths, which, crossing each other, are inserted laterally by small tendons in the spinal apophyses from the second, third, or fourth vertebra of the back; and sometimes, though seldom, from the last of the neck, or first of the back, all the way to the first or second vertebra of the loins, with several irregular decussations, which vary in different subjects.

### SPINALES DORSI MINORES.

THESE muscles are of two kinds. Some go laterally from the extremity of one spinal apophysis to another;

being often mixed with the short fasciculi of the spinalis major. The rest lie directly between the extremities of two neighbouring spinal apophyses, being separated from their fellows on the other side by the spinal ligament. They are smaller and thinner than those of the neck, and are properly enough termed *inter-spinales*.

### TRANSVERSALES DORSI MINORES.

SOME particular muscles of this kind are found fixed to the extremities of the three lowest transverse apophyses of the back. The rest are all in some measure continuations of the transversalis major.

### SEMI-SPINALIS *sive* TRANSVERSO-SPINALIS DORSI.

THIS is a fleshy mass, which, from all the spinal and transverse apophyses of the back and loins, is extended into distinct fasciculi over the vertebrae themselves.

It is made up, like that of the neck, of several oblique converging vertebral muscles, the uppermost of which is fixed below to the third transverse apophysis of the back, and above to the first spinal apophysis. The lowest is fixed below to the third transverse apophysis of the loins, and above to the last spinal apophysis of the back.

They may be divided into external, which are first discovered; and internal, which lie immediately on the vertebrae. The external, from the first vertebra to the seventh, inclusively, appear to be longer than the internal, which are covered by them.

### TRANSVERSO-SPINALIS LUMBORUM, SACRÆ VETERIBUS.

THIS muscle is composed of several oblique converging or transverso-spinal muscles, in the same manner as in the back and neck; and it lies between the spinal and oblique apophyses of the loins, reaching to the os sacrum.

The lowest of these muscles are fixed to the superior lateral parts of the os sacrum, to the ligamentum sacro-iliacum, and to the posterior superior spine of the os ilium. The rest are fixed to the three lowest transverse apophyses, and to the four lowest oblique apophyses of the loins, and to their lateral tuberosities. From thence they run up to all the spinal apophyses of these vertebrae, the external, or those that appear first, being longer than the internal, which lie immediately on the vertebrae, especially toward the lower part.

### SPINALES & TRANSVERSALES LUMBORUM.

THERE are some fasciculi which run up from the superior false spines of the os sacrum, to the lower spinal apophyses of the loins, which may be looked upon as so many spinales lumborum majores. There are likewise some spinales minores between the spinal apophyses of the loins, and transversales minores between the transverse apophyses, which are sometimes of a considerable breadth.

### QUADRATUS LUMBORUM *sive* LUMBARIS EXTERNUS.

THIS is a small, oblong, flat muscle, irregularly square, narrower at its upper than at its lower part, lying along the sides of the vertebræ lumborum, between the last false rib and the os ilium.

It is fixed below to the external labium of almost all the posterior half of the crista ossis ilium, to the ligamentum sacro-iliacum, and a little to the os sacrum, by a fleshy plane, the fibres whereof run obliquely backward.

From thence it runs up between the sacro-lumbaris and psoas, by both which it is partly hid, and is inserted in the extremities of all the transverse apophyses of the loins by oblique tendinous digitations. It is likewise fixed by a broad insertion in the twelfth rib, on the inside of the ligament that lies between it and the longissimus dorsi, by which that rib is connected to the first vertebra of the loins.

### MUSCULI OSSIS COCCYGIS.

THESE are small, thin, radiated muscles, lying on the inner or concave side of the os sacrum, and neighbouring parts of the pelvis. They are four in number, two on each side, whereof one is placed more forward, the other more backward; for which reason the first may be termed *coccygeus anterior*, *sive ischio-coccygeus*; the other *coccygeus posterior*, *sive sacro-coccygeus*.

The coccygeus anterior is fixed by a broad insertion in the anterior portion of the small transverse ligament, at the upper part of the foramen ovale of the os innominatum, which is no more than a particular fold of the great transverse ligament of the pelvis. From thence it runs between this great ligament and the musculus obturator internus, and, contracting in breadth, it is inserted in the lower part of the os coccygis.

The coccygeus posterior, or sacro-coccygeus, is fixed to the inner or concave edge of the two first vertebrae of the os sacrum, to the inner and lower edge of the ligamentum sacro-sciaticum, and to the spine of the os ischium. From thence, contracting in breadth, it is inserted in the inside of the os coccygis above the former muscle.

### P SOAS PARVUS.

THIS is a long slender muscle, lying upon the psoas major.

It is fixed above by a short tendon, sometimes to the last transverse apophysis of the back, or higher; sometimes to the first of the loins, and sometimes to both. From thence it runs down wholly fleshy, and more or less complex, on the great psoas, in a direction a little oblique.

Having reached the middle of the regio-lumbaris, or thereabouts, it forms a slender flat tendon, which gradually increasing in breadth, like a thin aponeurosis, runs over the psoas major and iliacus internus, at their union, and from thence down to the symphysis of the os pubis and os ilium, and is inserted chiefly in the crista of the os pubis, above the insertion of the pectineus, sometimes sending an aponeurotic lamina farther down.

### USES of the Muscles which move the Vertebrae.

THE scaleni, when they act on each side at the same time, may assist in bringing the neck forward, when we lean back in any respect. When those of one side act by themselves, they make a lateral inflection, either of all the vertebræ of the neck together, as in bending the middle of the neck; or of some only, as in bending the lower part of the neck alone.

The longi colli bring the neck forward by the lower part of their inferior portions. When one of them acts alone, or acts more than the other, this motion is more or less oblique.

By the upper and greatest part of the lowest portion, they counterbalance the posterior muscles of these vertebræ, and hinder the neck from bending backward by the contraction of the sterno-mastoidæi, when, lying on the back, we raise the head.

The transversalis major, transversalis gracilis, and the little transversales, acting on one side, can have no other use but to bend the neck laterally, and to hinder these inflexions when they act on both sides.

The semi-spinales or transverso-spinales of both sides acting together, extend the neck upon the trunk, to keep it from inclining forward in standing or sitting, and bend it backward. The semi-spinales of one side acting alone, produce the same motions in an oblique direction; and in that case they are assisted by the inferior or vertebral portion of the neighbouring splenius, under which they cross.

The semi-spinales of both sides may likewise serve for the rotation of the neck, but then the inferior splenius of the opposite side must assist them.

The inter-spinales are assistants to the semi-spinales in their mutual action, and may likewise serve to bring back the neck to its natural situation, after small motions of rotation.

The vertebræ of the back are moved by being bent forward, by being extended or straightened, and by being inflected directly or obliquely toward each side. The motion of rotation has no place here, because of the particular structure of the joints of these vertebræ, and their connexion with the ribs, which likewise hinder the flexion backward. Flexion and extension are the two principal motions, and much more apparent than the others.

The flexion of the back forward is not performed by any particular muscles, but depends, both in standing and sitting, on the relaxation of the muscles that extend or straighten it, and keep it in that erect posture.

The two sacro-lumbares maintain the back and the regio-lumbaris in their natural situation when we stand or sit; and by the relaxation of their fibres more or less, the trunk is proportionably bent forward by the weight of the head and breast. They likewise extend the back and loins in all postures, keep them steady and fixed under the weight of burdens, and bend the loins backward.

The longissimus dorsi is an assistant to the sacro-lumbaris, especially to the vertebral portion of that muscle, which it helps very powerfully, both by the multiplicity and insertion of its fibres, in sustaining the vertebræ of the

the back and loins while extended, whether in sitting or standing, and in preventing their sinking under the weight of the body, or of any additional burden. It assists in performing and in counterbalancing all the motions and inflexions of which these vertebræ, especially those of the loins, are capable in all postures of the body.

All the spinales and transverfales of the back and loins belonging to the class of the vertebrales recti, the spinales to the middle muscles, and the transverfales to the lateral, their chief uses must be to assist, moderate, and maintain the motions of extension and lateral inflexion, whether simple and direct, or oblique and compound.

The semi-spinales, or transverso-spinales, being oblique, converging, vertebral muscles, are assistants to the sacro-lumbaris and longissimus dorsi, which they cross on each side.

The quadratus lumborum and psoas parvus are of the same use to the vertebræ of the loins, as the scaleni to those of the neck. When both quadrati act, they keep the lumbar pillar straight, that is, so as not to incline to either side, and then they may assist the recti of the abdomen in the inflexions forward, and the superior portions of the obliqui in lateral inflexions.

They may likewise serve to support the haunches alternately in walking; and, in standing on one foot, the quadratus of the opposite side may support the haunch of that side.

The psoas parvus, serves to sustain the pelvis much in the same manner with the musculi recti of the abdomen, in climbing, &c.

The coccygeus anterior may sustain the coccyx in æquilibrio, and hinder it from being bent backward, and from being luxated in great strains, as in the excretion of hardened feces, &c.

The coccygeus posterior can only serve to replace the os coccygis when it has been forced backward, and to hinder it from being luxated forward.

## SECT. XVI. *The MUSCLES which move the Lower Jaw.*

### MASSETER.

THIS is a very thick fleshy muscle, situated at the back part of the cheek. It seems to be made up of three portions, like a triceps, *viz.* one large and external portion, one middle, and one small and internal.

The external portion is fixed by one tendinous extremity to all the inferior edge of the os malæ, and a little to the neighbouring parts of the os maxillare and apophysis zygomatica of the os temporum. From thence it runs down obliquely backward, being wholly fleshy, and is inserted by the other extremity in the rough impression on the outside of the angle of the lower jaw.

The middle portion is fixed by one end to the lower edge of the whole apophysis zygomatica of the os temporum, and a very little to that of the os malæ. From thence it runs down a little obliquely forward in an opposite direction to the first portion, under which it crosses

the back and loins while extended, whether in sitting or standing, and is inserted by its other extremity in the middle of the inside of the ramus of the lower jaw, near the insertion of the external portion with which it mixes.

The third portion, which is least and most internal, is fixed by one extremity to the inner labium of the lower edge, and also to the inside of almost all the zygomatic arch; and by the other, to the root or basis of the coronoid apophysis, where it mixes wholly fleshy with the insertion of the middle portion.

### TEMPORALIS.

THIS is a broad flat muscle, resembling the quadrant of a circle in figure. It occupies all the semi-circular or semi-oval plane of the lateral region of the cranium, the temporal fossa, and part of the zygomatic fossa. From this situation it has its name.

To conceive justly the insertions of this muscle, it must be observed, that the pericranium is divided into two laminae. The internal lamina, sometimes taken for a particular periosteum, covers immediately all the bony parts of this region. The external lamina separated from the other, is spread out like an aponeurotic or ligamentary tent, by means of its adhesions to the external angular apophysis of the os frontis, to the posterior edge of the superior apophysis of the os male, and to the upper edge of all the zygomatic arch, all the way to the root of the mastoid apophysis.

This muscle is composed of two planes of fleshy fibres, fixed to the two sides of a tendinous plane nearly of the same breadth with them, like a concealed middle tendon; as may be plainly seen by dividing the muscle all the way to the bone, according to the direction of its fibres. The body of the muscle thus formed is inclosed between the two aponeurotic or ligamentary laminae in the following manner.

The internal fleshy plane is fixed, by a broad radiated insertion, to all the semi-circular plane of the cranium, by the intervention of the internal lamina of the periosteum.

Thus it is fixed to the lateral external part of the os frontis, and to its external angular apophysis, to the lower part of the os parietale, to the squamous portion of the os temporis, to the great ala or temporal apophysis of the sphenoidal bone, by which the temporal fossa is formed; and a little to the backside of the internal orbicular apophysis of the os male, which forms part of the zygomatic fossa.

### PTERYGOIDÆUS MAJOR *sive* INTERNUS.

THIS muscle lies on the inside of the lower jaw, almost in the same manner as the masseter does on the outside, being of the same figure with that muscle, only smaller and narrower.

It is fixed above in the pterygoid cavity, chiefly to the inside of the external ala of the apophysis pterygoides.

It runs down obliquely toward the angle of the lower jaw, and is inserted a little tendinous in the inequality

ties on the inside thereof, opposite to the insertion of the masseter.

#### PTERYGOIDÆUS MINOR *sive* EXTERNUS.

THIS is an oblong fleshy muscle, much smaller than the other, and situated almost horizontally between the outside of the apophysis pterygoidea, and the condyloid apophysis of the lower jaw, the subject being considered in an erect posture.

It is fixed by one extremity to the outside and edge of the outer ala of the pterygoid apophysis, filling the fossula which is at the basis of this apophysis, near the basis of the temporal apophysis, of the sphenoidal bone.

From thence it runs backward, and a little outward, into the void space between the two apophyses of the lower jaw, and is inserted anteriorly in the condyloid apophysis, at a small fossula immediately under the inner angle of the condyle. It is also fixed to the capsular ligament of the joint.

#### DIGASTRICUS.

THIS is a small long muscle, situated laterally between the whole basis of the jaw and the throat. It is fleshy at both extremities, and tendinous in the middle, as if it consisted of two small muscles joined endwise by a tendon, and from thence it is called *digastricus* in Greek, and *biventer* in Latin.

It is fixed by one fleshy extremity in the sulcus of the mastoid apophysis. From thence it runs forward, inclining towards the os hyoides, where the first fleshy body ends in a round tendon, which is connected to the lateral part and root of the cornua of that bone by a kind of aponeurotic ligament, and not by a vagina or pulley.

Here the tendon is incurvated, and presently ends in the other fleshy body, which is fixed immediately above the internal labium of the basis of the chin near the symphysis, in a small unequal depression. This insertion is broader than that of the other extremity.

#### Uses of the Muscles which move the Lower Jaw.

THE two temporales acting together, raise the lower jaw, press the teeth in that jaw against the upper teeth, and pull it back when it has been carried so far forward as that the lower incisors get before the upper. They perform the last motion by their most posterior portion, which passes over the root of the zygomatic apophysis, and the other motions by the co-operation of all their muscular radii.

The two masseters serve to raise the lower jaw, and to push the lower teeth against the upper, in which use they co-operate with the temporales. They likewise bring this jaw forward by their external and largest portion; draw it back by their middle portion; and move it laterally by their superior portions acting alternately. By the co-operation of all the three portions, they press the lower teeth against the upper.

Both pterygoidæ interni serve to raise the lower jaw, to bring the lower teeth near the upper, and to move the jaw laterally, as in grinding the food.

The two pterygoidæ externi bring the lower jaw forward, in order to set the lower incisors before the upper; in which action they are antagonists to the posterior portion of the temporales, and the great portion of the masseters. When one of them acts, it carries the chin obliquely forward, or turns it toward the other sides. This oblique motion is performed alternately by these two muscles acting singly.

The two digastrici serve to depress the lower jaw, and to open the mouth.

The force of these muscles is very considerable, as may be shewn by laying the elbow on a table, and leaning with the chin on the hand, while we endeavour at the same time to depress the lower jaw; for as in that case this jaw cannot descend, the digastrici, by their insertions in the apophysis mastoidea, raise the upper jaw, by bending the head backward on the condyles of the lower jaw.

#### SECT. XVII. *The MUSCLES which move the Os Hyoides.*

##### MYLO-HYOIDÆUS.

THIS is a broad, thin, penniform muscle, situated transversely between the internal lateral parts of the basis of the lower jaw, and lying on the anterior portions of the two digastric muscles.

It is made up of two equal fleshy portions, one lying on the right side, the other on the left, both in the same plane, and joined to a small middle tendon, which is inserted anteriorly in the middle of the basis of the os hyoides, and from thence runs directly forward, diminishing gradually in its course.

Each portion is fixed, by fleshy fibres, to the internal lateral part of the lower jaw, between the oblique prominent line and the basis, under the first four dentes molares and caninus. The anterior and greatest part of the other fibres of each portion run obliquely from before backward, to the middle tendon, in which they are regularly fixed, the anterior fibres being the shortest, and a small triangular void space being formed between them and the symphysis of the chin.

The posterior fibres of each portion, which make about a fourth part of the whole, run likewise on each side to the basis of the os hyoides, and are inserted along the lower edge of its anterior or convex side, and from thence a little upward.

##### GENIO-HYOIDÆUS.

THIS is a small and pretty long fleshy muscle, situated between the symphysis of the chin and the os hyoides, close by its fellow.

It is fixed, by its anterior extremity, to a rough, and sometimes prominent surface, on the inner or posterior side of the symphysis of the lower jaw, a little above the chin. From thence it runs backward, and is inserted anteriorly in the upper edge of the basis of the os hyoides,

des, having first sent off a small lateral portion, which is fixed a little higher to the root of the cornu.

### STYLO-HYOIDÆUS.

THIS is a small fleshy muscle, lying obliquely between the apophysis styloides and os hyoides.

It is fixed laterally, by one extremity, to the root or basis of the apophysis styloides, and, by the other, to the os hyoides, at the place where the basis and cornu unite, and likewise to the cornu itself, from whence it has been called *stylo-cornato-hyoidæus*.

### OMOPLATO-HYOIDÆUS *sive* OMO-HYOIDÆUS *vulgo* CORACO-HYOIDÆUS.

THIS is a very long small muscle, much narrower than the sterno-hyoidæus, and situated obliquely on the side of the neck or throat, between the scapula and os hyoides.

It is commonly fixed, by the lower extremity, to the superior costa of the scapula, between the small notch and the angle, and sometimes very near the angle.

From thence it passes over the coracoid apophysis, adhering sometimes to it by a kind of aponeurosis, or membranous ligament, and from this adhesion the name of *coraco-hyoidæus* was given it by some who had not discovered its main insertion.

It is likewise often fixed to the clavica by ligamentary or fleshy fibres; and has sometimes been seen inserted in the whole middle portion of that bone, being inseparably united with the sterno-hyoidæus.

Having passed the clavicle, it is bent forward, and runs between the sterno-mastoideus and internal jugular vein, the small middle tendon being situated in this place. From thence it runs up to its insertion in the inferior lateral part of the basis of the os hyoides, near the cornu, and insertion of the sterno-hyoidæus, which it covers a little.

### STERNO-HYOIDÆUS *sive* STERNO-CLEIDO-HYOIDÆUS.

THIS is a long, thin, flat muscle, broader at the lower than at the upper part, and situated, together with its fellow, on the fore-side of the throat.

It is fixed, by its lower extremity, in the superior and lateral part of the inner or posterior side of the sternum, in the posterior part of the sternal extremity of the clavica, in the transverse ligament which connects these two bones, and in the inner or back-side of the cartilage of the first rib. All these other insertions are more considerable than that in the sternum, which is sometimes scarce perceptible.

From thence it runs up on the fore-side of the aspera arteria, joined to its fellow by a membrane, which forms a sort of linea alba, and is inserted laterally in the lower edge of the basis of the os hyoides.

*Uses of the Muscles which move the Os Hyoides.*

THE mechanism observed in the motions of the os hy-

oides, as well as in those of the scapula, is very particular, and very different from what we find in all the other bones of the human body. All these bones have solid fulcra, on which they are either moved or kept fixed by the proper muscles, after the manner of a lever or otherwise; whereas the os hyoides is merely suspended, having nothing to fix it but these very muscles which move it in different manners.

The mylo-hyoidæus represents a moveable floor or bed, which sustains the tongue with its muscles and glands, and forms the bottom of the cavity of the mouth. When the two portions of this muscle act together, they draw the os hyoides a little forward, and fix it in that situation, raising the whole tongue at the same time, and compressing the glandulæ sub-linguales. If one lateral portion acts more than the other, it puts the os hyoides in an oblique situation, and in a condition to serve as a fixed point for the motions of the tongue.

The genio hyoidæi pull the os hyoides much more forward than the mylo-hyoides; and as they are very narrow, and closely united together, there seems to be very little occasion for one of them to act without the other.

The stylo-hyoidæi move the os hyoides upward and backward in a middle direction, between those in which they lie; and they draw it more upward and backward when they act freely; that is, without being checked or confined by other muscles, in the manner which we shall see hereafter. When one acts more than the other, the bone is moved obliquely.

The omo-hyoidæi, or coraco-hyoidæi, act as the stylo-hyoidæi, in a middle direction between the oblique directions in which they lie, and draw the os hyoides downward and backward, when they are not counterbalanced by the stylo-hyoidæi. When one acts more than the other, the bone is drawn obliquely to the right or left hand.

When these muscles and the stylo-hyoidæi act together, the os hyoides is drawn backward by a direct motion compounded of four oblique motions. This compound motion is directed more upward or more laterally, according to the degree of action of the stylo-hyoidæi, or omo-hyoidæi, or of any one muscle of each pair; and in all these motions the four muscles are counterbalanced by the genio-hyoidæi.

The sterno-hyoidæi draw the os hyoides directly downward, and serve to counterbalance the different motions of the stylo-hyoidæi, omo-hyoidæi, and genio-hyoidæi. They may, in some cases, be assisted by the sterno-thyroidei, and thyro-hyoidæi, as we shall see hereafter.

According to the method commonly observed in complete treatises of myology, the following muscles remain still to be described, *viz.* The muscles of the forehead, occiput, palpebræ, eye, external ear, nose, lips, tongue, uvula, ductus Eustachianus, pharynx, larynx, parts of generation, anus, and bladder; and to these we ought even to add the heart, as Mr Cowper has done in the late edition of his Myotomy. But the description of these will be better understood when we treat of the parts to which they belong. See Part VI.

## EXPLANATION OF PLATE XV.

FIG. 1. The MUSCLES immediately under the common teguments on the anterior part of the body, are represented on the right side; and on the left side the MUSCLES are seen which come in view when the exterior ones are taken away.

A, The frontal muscle. B, The tendinous aponeurosis which joins it to the occipital; hence both named *occipito-frontalis*. C, *Attolens aurem*. D, The ear. E, Anterior auris. FF, *Orbicularis palpebrarum*. G, *Levator labii superioris alaque nasi*. H, *Levator labiorum communis*. I, *Zygomatius minor*. K, *Zygomatius major*. L, *Maffeter*. M, *Orbicularis labiorum*. N, *Depreffor labii inferioris*. O, *Depreffor labiorum communis*. P, *Buccinator*. QQ, *Platyfina myoides*. R R, *Sterno-cleido maffoideus*. S, Part of the trapezius. T, Part of the scaleni.

SUPERIOR EXTREMITY.—U, *Deltoides*. V, *Pectoralis major*. W, Part of the *latiffimus dorfii*. XX, *Biceps flexor cubiti*. Y Y, Part of the *brachiius externus*. Z Z, The beginning of the tendinous aponeurosis, (from the biceps) which is spread over the muscles of the fore-arm. a a, Its strong tendon inserted into the tubercle of the radius. b b, Part of the *brachiius internus*. c, *Pronator teres*. d, *Flexor carpi radialis*. e, Part of the flexor carpi ulnaris. f, *Palmaris longus*. g, Aponeurosis palmaris. 3, *Palmaris brevis*. l, *Ligamentum carpi annulare*. 2 2, *Abductor minimi digiti*. h, *Supinator longus*. i, The tendons of the three extensors of the thumb. k, *Abductor pollicis*. l, *Flexor pollicis longus*. m m, The tendons of the flexores digitorum communis.—The sheaths are entire in the right hand,—in the left cut open, to shew the tendons of the flexor profundus perforating the *sublimis*.

MUSCLES not referred to—in the left superior extremity.—n, *Pectoralis minor*, seu *ferratus anticus minor*. o, The two heads of (x x) the biceps. p, *Coraco-brachialis*. q q, The long head of the triceps extensor cubiti. r r, *Terres major*. ff, *Subscapularis*. t t, *Extensores radiales*. u, *Supinator brevis*. v, The cut extremity of the pronator teres. w, *Flexor digitorum sublimis*. x, Part of the flexor profundus. y, *Flexor pollicis longus*. z, Part of the flexor pollicis longus. 4, *Abductor minimi digiti*. 5, The four lumbricals.

TRUNK.—6, Serrated extremities of the *ferratus anticus major*. 7 7, *Obliquus externus abdominis*. 8 8, The *linea alba*. 9, The umbilicus. 10, *Pyramidalis*. 11 11, The spermatic cord. On the left side, it is covered by the cremaster. 12 12, *Rectus abdominis*. 13, *Obliquus internus*. 14 14, &c. Intercostal muscles.

INFERIOR EXTREMITIES.—a a, The *gracilis*.

b b, Parts of the triceps. c c, *Pectineus*. d d, *Pfoas magnus*. e e, *Iliacus internus*. f, Part of the *glutaeus medius*. g, Part of the *glutaeus minimus*. h, Cut extremity of the *rectus cruris*. i i, *Vastus externus*. k, Tendon of the *rectus cruris*. l l, *Vastus internus*. \* *Sartorius* muscle. \*\* Flehly origin of the tenor vaginæ femoris or membranofus. Its tendinous aponeurosis covers (i), the *vastus externus* in the right-side. m m, *Patella*. n n, *Ligamentum* or tendon from it to the tibia. o, *Rectus cruris*. p, *Crureus*. q q, The tibia. r r, Part of the *gemellus* or *gastrocnemius externus*. fff, Part of the *soleus* or *gastrocnemius internus*. t, *Tibialis anticus*. u, *Tibialis posticus*. v v, *Peronæi* muscles. w w, *Extensor digitorum longus communis*. x x, *Extensor pollicis longus*. y, *Abductor pollicis*.

FIG. 2. The MUSCLES, GLANDS, &c. of the left side of the face and neck, after the common teguments and *platyfina myoides* have been taken off.

a, The frontal muscle. b, *Temporalis* and temporal artery. c, *Orbicularis palpebrarum*. d, *Levator labii superioris proprius*. e, *Levator labiorum communis*. f, *Zygomatius*. g, *Depreffor labii inferioris proprius*. h, *Depreffor labiorum communis*. i, *Buccinator*. k, *Maffeter*. l l, *Parotid gland*. m, Its duct. n, *Sterno-cleido maffoideus*. o, Part of the trapezius. p, *Sterno-hyoideus*. q, *Sterno-thyroideus*. r, *Omo-hyoideus*. s, *Levator fcapulæ*. t t, *Scaleni*. u, Part of the *splenius*.

FIG. 3. The MUSCLES of the face and neck, in view after the exterior ones are taken away.

a a, *Corrugator superciliorum*. b, *Temporalis*. c, Tendon of the *levator palpebræ superioris*. d, Tendon of the *orbicularis palpebrarum*. e, *Maffeter*. f, *Buccinator*. g, *Levator labiorum communis*. h, *Depreffor labii superioris proprius*. i, *Sphincter oris*. k, *Depreffor labiorum communis*. l, Muscles of the os hyoides. m, *Sterno-cleido maffoideus*.

FIG. 4. Some of the MUSCLES of the os hyoides, and submaxillary gland.

a, Part of the *maffeter* muscle. b, Posterior head of the *digrafcic*. c, Its anterior head. d d, *Sterno-hyoideus*. e, *Omo-hyoideus*. f, *Stylo-hyoideus*. g, *Submaxillary gland in situ*.

FIG. 5. The submaxillary gland and duct.

a, *Mufculus mylo-hyoideus*. b, *Hyo-gloffus*. c, *Submaxillary gland extra fitu*. d, Its duct.

## EXPLANATION OF PLATE XVI.

FIG. 1. The MUSCLES immediately under the common teguments on the posterior part of the body are represented in the right side;—and on the left side the MUSCLES are seen which come in view when the exterior ones are taken away.

HEAD.—A A, Occipito-frontalis. B, Attollens aurem. C, Part of the orbicularis palpebrarum. D, Maffeter. E, Pterygoideus internus.

TRUNK.—Right side. F F F, Trapezius seu cucullaris. G G G, Latifimus dorsi. H, Part of the obliquus externus abdominis.

TRUNK.—Left side. I, Splenius. K, Part of the complexus. L, Levator scapulae. M, Rhomboides. N N, Serratus posticus inferior. O, Part of the longissimus dorsi. P, Part of the sacro-lumbaris. Q, Part of the semi-spinalis dorsi. R, Part of the serratus anticus major. S, Part of the obliquus internus abdominis.

SUPERIOR EXTREMITY.—Right side. T, Deltoïdes. U, Triceps extensor cubiti. V, Supinator longus. W W, Extensores carpi radialis longior & brevior. X X, Extensor carpi ulnaris. Y Y, Extensor digitorum communis. Z, Abductor indicis. I 2 3, Extensores pollicis.

SUPERIOR EXTREMITY.—Left side. a, Supra-spinatus. b, Infra-spinatus. c, Teres minor. d, Teres major. e, Triceps extensor cubiti. f f, Extensores carpi radialis. g, Supinator brevis. h, Indicator. I 2 3, Extensores pollicis. i, Abductor minimi digiti. k, Interossei.

INFERIOR EXTREMITY.—Right side. l, Glutæus maximus. m, Part of the glutæus medius. n, Fascialis. o, Gracilis. p p, Abductor femoris magnus. q, Part of the vastus internus. r, Semimembranosus. s, Semitendinosus. t, Long head of the biceps flexor curis. u u, Gastrocnemius externus seu gemellus. v, Tendo Achillis. w, Soleus seu gastrocnemius internus. x x, Peroneus longus & brevis. y, Tendons of the flexor digitorum longus;—and under them \* flexor digitorum brevis. z, Abductor minimi digiti.

INFERIOR EXTREMITY.—Left side. m, n, o, p p, q, r, s, t, v, w w, x x, y, z. Point the same

parts as in the right side. a, Pyramiformis. b b, Gemini. c c, Obturator internus. d, Quadratus femoris. e, Coccygeus. f, The short head of the biceps flexor curis. g g, Plantaris. h, Popliteus. i, Flexor pollicis longus.

FIG. 2. The palm of the left hand after the common teguments are removed, to shew the MUSCLES of the fingers.

a, Tendon of the flexor carpi radialis. b, Tendon of the flexor carpi ulnaris. c, Tendons of the flexores digitorum. d, Abductor pollicis. e e, Flexor pollicis longus. f, Flexor pollicis brevis. g, Palmaris brevis. h, Abductor minimi digiti. i, Ligamentum carpi annulare. k, A probe put under the tendons of the flexor digitorum sublimis; which are perforated by l, the flexor digitorum profundus. m m m, Lumbricales. n, Adductor pollicis.

FIG. 3. A fore-view of the foot and tendons of the flexores digitorum.

a, Cut extremity of the tendo Achillis. b, Upper part of the astragalus. c, Os calcis. d, Tendon of the tibialis anticus. e, Tendon of the extensor pollicis longus. f, Tendon of the peroneus brevis. g, Tendons of the flexor digitorum longus, with the nonus Vesalii. h h, The whole of the flexor digitorum brevis.

FIG. 4. MUSCLES of the Anus.

a a, An outline of the buttocks, and upper part of the thighs. b, The testes contained in the scrotum. c c, Sphincter ani. d, Anus. e, Levator ani. f f, Erector penis. g, Accelerator urinæ. h, Corpus cavernosum urethræ.

FIG. 5. MUSCLES of the Penis.

a a, b, d, e e, f f, h, point the same as in fig. 4. c, Sphincter internus ani. g g, Transversus perinæi.

## PART III.

## OF THE ARTERIES.

THE heart throws the blood into two great arteries; one of which is named *aorta*, the other *arteria pulmonalis*.

Vol. I. No. 10.

The aorta distributes the blood to all the parts of the body, for the nourishment of the parts, and for the secretion of different fluids.

The arteria pulmonalis carries the venal blood through all the capillary vessels of the lungs.

Both these great or general arteries are subdivided into several branches, and into a great number of ramifications. In this part, we shall describe the distributions of the aorta, leaving the pulmonary artery to the particular history of the lungs. See Part VI.

The basis of the heart being very much inclined to the right side, and turned a little backward, the aorta goes out from it in a direct course, nearly over-against the fourth vertebra of the back. Its course is direct with respect to the heart; but with respect to all the rest of the body, it ascends obliquely from the left to the right hand, and from before backward.

Soon after this, it bends obliquely from the right hand to the left, and from before backward, reaching as high as the second vertebra of the back; from whence it runs down again in the same direction, forming an oblique arch. The middle of this arch is almost opposite to the right side or edge of the superior portion of the sternum, between the cartilaginous extremities or sternal articulations of the first two ribs.

From thence the aorta descends in a direct course along the anterior part of the vertebrae, all the way to the os sacrum, lying a little toward the left hand; and there it terminates in two subordinate or collateral trunks, called arteriæ iliacæ.

The aorta is by anatomists generally divided into the aorta ascendens and aorta descendens, though both are but one and the same trunk. It is termed *ascendens*, from where it leaves the heart to the extremity of the great curvature or arch. The remaining part of this trunk from the arch to the os sacrum or bifurcation, already mentioned, is named *descendens*.

The aorta descendens is further divided into the superior and inferior portions; the first taking in all that lies above the diaphragm; the other all that lies between the diaphragm and the bifurcation.

The aorta ascendens is chiefly distributed to part of the thorax, to the head and upper extremities. The superior portion of the aorta descendens furnishes the rest of the thorax; the inferior portion furnishes the abdomen and lower extremities.

The great trunk of the aorta, through its whole length, sends off immediately several branches, which are afterwards differently ramified; and these arterial branches may be looked upon as so many trunks with respect to the other ramifications, which again may be considered as small trunks with regard to the ramifications that they send off.

The branches which go out immediately from the trunk of the aorta, may be termed original or capital branches; and of these some are large and others very small.

The large capital branches of the aorta are these: two arteriæ subclaviæ, two carotides, one cæliaca, one mesenterica superior, two renales, formerly termed emulgentes, one mesenterica inferior, and two iliacæ.

The final capital branches are chiefly the arteriæ coronariæ cordis, bronchiales, œsophagæ, intercostales, diaphragmaticæ inferiores, spermaticæ, lumbares, and sacræ.

These capital branches or arteries are for the most part disposed in pairs; there being none in odd numbers but the cæliaca, the two mesentericæ, some of the œsophagæ, the bronchialis, and sometimes the sacræ.

The aorta gives rise to two small arteries, called coronariæ cordis, which go to the heart and its auricles; one of which is situated anteriorly, the other posteriorly, and sometimes they are three in number.

From the upper part of the arch or curvature, the aorta sends out commonly three, sometimes four large capital branches, their origins being very near each other. When there are four, the two middle branches are termed arteriæ carotides; the other two, subclaviæ; and both are distinguished into right and left.

When there are but three branches, which is oftener the case, the first is a short trunk, common to the right subclavian and carotid, the second is the left subclavian, and the third the left carotid.

The origin of the left subclavian terminates the aorta ascendens.

The carotid arteries run up directly to the head, each of them being first divided into two, one external, the other internal. The external artery goes chiefly to the outer parts of the head and dura mater, or first covering of the brain. The internal enters the cranium, through the bony canal of the os petrosum; and is distributed through the brain by a great number of ramifications.

The subclavian arteries separate laterally, and almost transversely, each toward that side on which it lies, behind and under the claviculæ, from whence they have their name.

The subclavian on each side terminates at the upper edge of the first rib, between the lower insertions of the first scapularis muscle; and there, as it goes out of the thorax, takes the name of arteria axillaris.

During this course of the subclavian artery, several arteries arise from it, viz. the mammaria interna, mediastina, pericardica, diaphragmatica minor five superior, thymica and trachealis.

The thymica and trachealis on each side are, in some subjects, only branches of one small trunk which spring from the common trunk of the right subclavian and carotid.

They are generally small arteries which run sometimes separate, and sometimes partly separate and partly joined.

The subclavian sends off likewise the mammaria interna, vertebrales, cervicales, and sometimes several of the upper intercostales.

The axillary artery, which is only a continuation of the subclavian from where it goes out of the thorax to the axilla, detaches chiefly the mammaria externa, or thoracica superior, thoracica inferior, scapulares externæ, scapularis interna, humeralis or muscularis, &c. Afterwards it is continued by different ramifications, and under different names, over the whole arm, all the way to the ends of the fingers.

The superior portion of the aorta descendens gives off the arteriæ bronchiales, which arise sometimes by a small common trunk, sometimes separate, and sometimes do not come immediately from the aorta. It next sends off the œsophagæ, which may be looked upon as mediastinæ posteriores;

posteriores; and then the intercostales from its posterior part, which in some subjects come all from this portion of the aorta, in others only the lowest eight or nine.

The inferior portion of the descending aorta, as it passes through the diaphragm, gives off the diaphragmaticæ inferiores, or phrenicæ; afterwards it sends off several branches, anteriorly, posteriorly, and laterally.

The anterior branches are the cœliaca, which supplies the stomach, liver, spleen, pancreas, &c. the mesenterica superior, which goes chiefly to the mesentery, to the small intestines, and that part of the great intestines which lies on the right side of the abdomen; the mesenterica inferior, which goes to the great intestines on the left side, and produces the hæmorrhoidalis interna; and lastly, the right and left arteriæ spermaticæ.

The posterior branches are the arteriæ lumbares, of which there are several pairs, and the sacræ, which do not always come from the trunk of the aorta.

The lateral branches are the capsulares and adiposæ, the origin of which often varies; the renales, formerly termed emulgents; and the iliacæ, which terminate the aorta by the bifurcation already mentioned.

The iliac artery on each side is commonly divided into the external or anterior, and internal or posterior.

The internal iliaca is likewise named arteria hypogastrica; and its ramifications are distributed to the viscera contained in the pelvis, and to the neighbouring parts, both internal and external.

The iliac externa, which is the true continuation of the iliac trunk, goes on to the inguen, and then out of the abdomen, under the ligamentum Fallopii; having first detached the epigastrica, which goes to the musculi abdominis recti. Having quitted the abdomen, it commences arteria cruralis, which runs down upon the thigh, and is distributed by many branches and ramifications to all the lower extremity.

We shall now go on to examine particularly all the capital or original branches of the aorta, from their origin, to the entry of them and of their ramifications into all parts of the body.

The CARDIAC or coronary arteries of the heart arise from the aorta immediately on its leaving the heart. They are two in number, and go out near the two sides of the pulmonary artery, which having first surrounded, they afterwards run upon the basis of the heart in form of a kind of crown, or garland, from whence they are called coronariæ; and then pursue the superficial traces of the union of the two ventricles, from the basis of the heart to the apex, and are afterwards lost in the substance of the heart.

The CAROTID arteries are two in number, one called the right carotid, the other the left. They arise near each other, from the curvature of the aorta, the left immediately, the right most commonly from the trunk of the subclavia on the same side.

They run upon each side of the trachea arteria, between it and the internal jugular vein, as high as the larynx, without any ramification. Each of these trunks is afterwards ramified in the following manner.

The trunk having reached as high as the larynx, is

divided into two large branches or particular carotids, one named *external*, the other *internal*, because the first goes chiefly to the external parts of the head, the second enters the cranium, and is distributed to the brain.

The external carotid is anterior, the internal posterior; and the external is even situated more inward, and nearer the larynx, than the other.

The external carotid is the smallest. It runs insensibly outward, between the external angle of the lower jaw, and the parotid gland, which it supplies as it passes. Afterwards it ascends on the fore-side of the ear, and ends in the temples.

In this course it sends off several branches, which may well enough be divided into anterior or internal, and posterior or external; and the principal branches of each kind are these:

The first anterior or internal branch goes out from the very origin of the carotid on the inside; and having presently afterward taken a little turn, and sent off branches to the jugular glands near it, to the fat and skin, it runs transversely, and is distributed to the glandulæ thyroideæ, and to the muscles and other parts of the larynx: It likewise sends some branches to the pharynx and muscles of the os hyoides.

The second anterior branch passes over the nearest cornu of the os hyoides, to the muscles of that bone and the tongue, and to the glandulæ sublinguales; afterwards passing before the cornu of the os hyoides, it loses itself in the tongue, from whence it has been called *arteria sublingualis*.

The third branch, or arteria maxillaris inferior, goes to the maxillary gland, to the styloid and mastoid muscles, to the parotid and sublingual glands, to the muscles of the pharynx, and to the small flexors of the head.

The fourth branch, arteria maxillaris externa, passes anteriorly on the masseter muscle, and middle of the lower jaw, near the chin. Afterwards it runs under the musculus triangularis labiorum, which it supplies as well as the buccinator and the quadratus menti.

It sends of a particular branch, very much contorted, which divides at the angular commissure of the lips, and running in the same manner along the superior and inferior portions of the musculus orbicularis, it communicates on both sides with its fellow, and thereby forms a kind of arteria coronaria labiorum.

Afterwards it ascends towards the nares, and is distributed to the muscles, cartilages, and other parts of the nose, sending down some twigs which communicate with the coronary artery of the lips. Lastly, it reaches the great angle of the eye, and is ramified and lost on the musculus orbicularis palpebrarum, superciliaris, and frontalis. Through all this course, it is named arteria angularis.

The fifth branch, maxillaris interna, arises over-against the condyle of the lower jaw. It passes behind the condyle, and having given off a twig among the musculi pterygoidei, it is divided into three principal branches.

The first branch, or sphæno-maxillaris, goes through the inferior orbital, or sphænomaxillary fissure, to the orbit, after having supplied the musculi peritaphylina,

and

and the glandulous membrane of the posterior nares, through the foramen sphenopalatinum.

It is distributed inferiorly and laterally to the parts contained in the orbit, and detaches a small subaltern branch through the extremity of the superior orbital, or sphenoidal fissure, which enters the cranium, and is spent upon the dura mater.

It sends off likewise another subaltern branch, which passes through the posterior opening of the orbital canal, and having furnished the maxillary sinus and the teeth, goes out by the inferior orbital hole, and on the cheek communicates with the angular artery.

The second branch runs through the canal of the lower jaw, and being distributed to the alveoli and teeth, goes out at the hole near the chin, and loses itself in the neighbouring muscles.

The third branch runs up between the internal and external carotids, passes through the foramen spinale of the sphenoidal bone, and is distributed to the dura mater by several ramifications.

The sixth anterior or internal branch, which is very small, is spent on the musculus masseter.

The first external or posterior branch is named arteria occipitalis. It passes obliquely before the internal jugular vein, and having twigs to the musculus stylo-hyoidæus, stylo-glossus, and digastricus, it runs between the styloid and mastoid apophyses, along the mastoid groove, and goes to the muscles and integuments which cover the os occipitis, turning several times in an undulating manner, as it ascends backwards.

The second external branch spreads itself on the outward ear, by a great many small twigs on each side, several of which run inward, and furnish the cartilages, meatus auditorius, skin of the tympanum, and internal ear.

The trunk of the external carotid ascends afterward above the zygoma, passing between the angle of the lower jaw and parotid gland, and forms the temporal artery, which divides into an anterior, middle, and posterior branch.

The anterior branch of the temporal artery goes to the musculus frontalis, communicates with the arteria angularis, and sometimes gives off a very small artery, which pierces the internal apophysis of the os maxillæ all the way to the orbit. The middle branch goes partly to the musculus frontalis, partly to the occipitalis. The posterior branch goes to the occiput, and communicates with the arteria occipitalis. All these branches likewise furnish the integuments.

The internal carotid artery, leaving the general trunk, is at first a little incurvated, appearing as if either it were the only branch of that trunk, or a branch of the trunk of the external carotid.

It is situated a little more backward than the carotis externa, and generally runs up, without any ramification, as high as the lower orifice of the great canal of the apophysis petrosa of the os temporis. It enters this orifice directly from below upward.

At the end of this canal it is again incurvated from below upward, and enters the cranium through a notch of the sphenoidal bone. Then it bends from behind for-

ward, and makes a third angle on the side of the sella sphenoidal; and again a fourth, under the clinoid apophysis of that sella.

As it leaves the bony canal to enter the cranium, it sends off a branch through the sphenoidal fissure to the orbit and eye, and soon afterwards another through the foramen opticum.

Afterwards the internal carotid runs under the basis of the brain, to the side of the infundibulum, where it is at a small distance from the internal carotid of the other side, and there it commonly divides into two principal branches, one anterior, and one posterior.

The anterior branch runs forward under the brain, first separating from that on the other side, then coming nearer again, it unites with it by an anastomosis, or communication, in the interstice between the olfactory nerves. Afterwards having sent off some small arteries, which accompany these nerves, it leaves its fellow, and divides into two or three.

The first of these branches goes to the anterior lobe of the brain; the second, which is sometimes double, is inverted on the corpus callosum, to which it gives some ramifications, as also to the falx of the dura mater, and middle lobe of the brain. The third goes to the posterior lobe of the brain.

The posterior branch communicates first of all with the vertebral artery of the same side, and then divides into several rami, which run between the superficial circumvolutions of the brain, and are ramified in many different directions on and between these circumvolutions, all the way to the bottom of the sulci.

All these ramifications are covered by the pia mater, in the duplicature of which they are distributed, and form capillary reticular textures in great numbers; and afterwards are lost in the inner substance of the brain.

The SUBCLAVIAN arteries are two in number, one right, the other left; and they arise from the arch of the aorta, on each side of the left carotid, which commonly lies in the middle between them; but when both carotids go out separately, they both lie between the subclavie.

The right subclavian is larger at the beginning than the left, when it produces the right carotid; its origin is likewise more anterior and higher, because of the obliquity of the arch of the aorta. Both of them are distributed much in the same manner, and therefore the description of one may likewise be applied to the other.

The right subclavian, the longest of the two, gives off, first of all, small arteries to the mediastinum, thymus, pericardium, aspera arteria, &c. which are named *mediastinum, thymica, pericardica, and tracheales*.

Afterward this right subclavian, at about a finger's breadth from its origin, often produces the common carotid of the same side; and at a small finger's breadth from the carotid, it gives off commonly three considerable branches, *viz.* the mammaria interna, cervicalis, and vertebralis, and sometimes an intercostal artery, which goes to the first ribs, called *intercostalis superior*.

The arteria thymica communicates with the mammaria interna, and sometimes arises from the anterior middle part of the common trunk of the subclavian and carotid.

The

The thymus receives likewise some rami from the *mammaria interna*, and *intercostalis superior*.

The *pericardiac arifes* much in the same manner with the *thymica*, and runs down upon the *pericardium*, all the way to the *diaphragm*, to which it sends some small ramifications.

The *mediastina arifes* sometimes immediately after the *thymica*, and is distributed principally to the *mediastinum*.

The *trachealis*, which may likewise be named *gutturalis inferior*, runs up from the *subclavia*, in a winding course, along the *aspera arteria*, to the *glandulæ thyroideæ* and *larynx*, detaching small arteries to both sides, one of which runs to the upper part of the *scapula*.

The *internal mammary artery* comes from the anterior and lower side of the *subclavia*, near the middle of the *clavicula*, and runs down, for about a finger's breadth, behind the cartilages of the true ribs, an inch distant from the *sternum*.

In its passage, it sends rami to the *thymus*, *mediastinum*, *pericardium*, *pleura*, and *intercostal muscles*. It likewise detaches other branches through these muscles, and between the cartilages of the ribs, to the *pectoralis major*, and other neighbouring muscular portions; to the *mammæ*, *membrana adiposa*, and *skin*.

Afterwards it goes out at the *thorax*, on one side of the *appendix caeciformis*, and is lost in the *musculus abdominis rectus*, a little below its upper part.

The *cervical artery arifes* from the upper side of the *subclavian*, and is presently afterward divided into two, which come out, sometimes separately, sometimes by a small common trunk. The largest of these two arteries is anterior, the other posterior.

The anterior *cervicalis*, running behind the *carotid* of the same side, is distributed to the *musculus coraco-hyoideus*, *massoideus*, *cutaneus*, *sterno-hyoideus*, and *sterno-thyroideus*; to the *jugular glands*, the *aspera arteria*, the *muscles* of the *pharynx*, *bronchia*, *œsophagus*; and to the anterior muscles which move the neck and head.

The posterior *cervicalis arifes* sometimes a little after the *vertebralis*, and sometimes from that artery. It passes under the *transverse apophysis* of the last vertebra of the neck, and sometimes through a particular hole in that apophysis; and from thence runs up backward in a winding course, on the vertebral muscles of the neck, and then returns in the same manner.

The *vertebral artery goes* out from the posterior and upper side of the *subclavian*, almost opposite to the *mammaria interna* and *cervicalis*. It runs up through all the holes in the *transverse apophyses* of the vertebrae of the neck, and, in its passage, sends off little twigs, through the lateral notches of these vertebrae, to the *medulla spinalis* and its coverings. It also gives arteries to the vertebral muscles, and to other muscles near them.

It sends off a small branch, which is ramified on the outer and posterior parts of the *occiput*, and communicates with the *cervical* and *occipital arteries*. Having afterwards reached the great foramen of the *os occipitis*, it enters the *cranium*, and pierces the *dura mater*.

As soon as it enters the *cranium*, it sends several small

ramifications to the back-part of the *medulla oblongata*, and to the *corpora olivaria* and *pyramidalia*, which are likewise spread on the back sides of the fourth ventricle of the brain, and form the *plexus choroides* of the *cerebellum*.

Afterwards it advances on the *apophysis basilaris* of the *os occipitis*, inclining, by small degrees, toward the vertebral artery of the other side, all the way to the extremity of that apophysis, where they both join in one common trunk.

The *arteria basilaris runs* forward under the great *transverse protuberance* of the *medulla oblongata*, to which it gives ramifications, as well as to the neighbouring parts of the *medulla*.

The *spinal arteries* are two in number, one anterior, and one posterior; both produced by both *vertebrales*, each of which, as soon as it enters the *cranium*, sends out a small branch, by the union of which the posterior *spinalis* is formed. Afterwards the *vertebrales* advancing on the *apophysis basilaris*, or production of the *occipital bone*, detach backward two other small branches, which likewise meet, and, by their union, form the *spinalis anterior*. These *spinal arteries* run down on the fore and back sides of the *medulla spinalis*, and, by small transverse ramifications, communicate with those which the *intercostal* and *lumbar arteries* send to the same part.

The *internal auditory artery* goes off from each side of the *arteria basilaris*, to the organ of hearing, accompanying the *auditory nerve*, having first furnished several small twigs to the *membrana arachnoidea*.

The posterior *meningæa arifes* from the same trunk with the *auditoria interna*, and goes to the back-part of the *dura mater*, on the *occipital* and *temporal bones*, and supplies the neighbouring lobes of the brain.

When the superior *intercostal artery* does not go out from the trunk of the *aorta descendens*, it commonly arifes from the lower side of the *subclavian*, and runs down on the inside of the two, three, or four uppermost true ribs, near their heads, and sends off, under each rib, a branch, which runs along the lower edge, and supplies the *intercostal muscles* and neighbouring parts of the *pleura*.

These branches, or particular *intercostal arteries*, communicate with each other at different distances by small rami, which run upward and downward from one to the other, on the *intercostal muscles*.

The *ductus arteriosus*, which is found only in the *fœtus* and in very young children, arifes from the *aorta descendens*, immediately below the left *subclavian artery*. In adults, this duct is shrunk up and closed, and appears only like a short ligament adhering by one end to the *aorta*, and by the other to the *pulmonary artery*, so that in reality it deserves no other name than that of *ligamentum arteriosum*.

The *bronchial arteries* go sometimes from the fore-side of the superior descending *aorta*, sometimes from the first *intercostal*, and sometimes from the *arteria œsophagæa*. Sometimes they arise separately from each side, to go to each lung, and sometimes by a small common trunk, which afterwards separates towards the right and left hand, at the bifurcation of the *aspera arteria*, and accompany the ramifications of the *bronchia*.

The bronchialis gives a small branch to the neighbouring auricle of the heart, which communicates with the arteria coronaria.

The œsophageæ are generally two or three in number, sometimes but one. They arise anteriorly from the aorta descendens, and are distributed to the œsophagus, &c.

The inferior intercostals are commonly seven or eight on each side, and sometimes ten, when the superior intercostals arise likewise from the aorta descendens; in which case these run obliquely upward.

They arise along the back-side of the descending aorta in pairs, all the way to the diaphragm, and run transversely towards each side, on the bodies of the vertebræ. Those on the right side pass behind the vena azygos; and afterwards they all run to the intercostal muscles, along the lower edge of the ribs, all the way to the sternum, or near it.

They send branches to the pleura, to the vertebral muscles, to those muscles which lie on the out-sides of the ribs, and to the upper portions of the muscles of the abdomen; and they communicate with the arteriæ epigastricæ and lumbares.

Before they take their course along the ribs, each of them detaches one branch between the transverse apophyses on both sides, to the vertebral muscles, and another which enters the great canal of the spina dorsii.

Afterwards each intercostal artery having reached the middle of the rib, or a little more, divides into two principal branches, one internal, the other external. Soon after this division, the arteries that run upon the false ribs, separate a little from them, being gradually bent downward one after another, and are spread upon the abdominal muscles.

The subclavian artery having left the thorax immediately above the first rib, in the interstice left between the portions of the scalenus, then receives the name of *axillaris*, because it passes under the axilla.

In this course it gives off, from its inside, a small branch to the inside of the first rib; and afterwards four or five principal branches, *viz.* the thoracica superior, or mammaria externa, thoracica inferior, muscularis, or scapularis externa, scapularis interna, and humeralis.

The superior thoracica, or external mammary artery, runs down, in a winding course, on the lateral parts of the thorax, and crosses the ribs. It gives branches to the two pectoral muscles, to the mamma, musculus subclavius, serratus major, latissimus dorsi, and to the upper portions of the coraco-brachialis and biceps.

The inferior thoracica artery runs along the inferior costa of the scapula, to the musculus subcapularis, teres major and minor, infra-spinatus, latissimus dorsi, serratus major, and the neighbouring intercostal muscles, communicating with the arteriæ scapulares.

The external scapularis artery passes through the notch in the superior costa of the scapula, to the musculus supra-spinatus and infra-spinatus, teres major and minor, and to the articulation of the scapula with the os humeri.

The internal scapularis arises from the axillary artery near the axilla, and runs backward, to be distributed to the subcapularis, giving branches to the serratus major, to the axillary glands, and to the teres major.

The humeral artery arises from the lower and fore-side of the axillaris, and runs backward between the head of the os humeri and teres major, surrounding the articulation, till it reaches the posterior part of the deltoides, to which it is distributed.

During this course, it gives several branches to the superior portions of the anconæi, to the capsular ligament of the joint of the shoulder, and to the os humeri itself, through several holes immediately below the great tuberosity of the head of that bone.

Opposite the origin of this humeral artery, the axillaris sends off another small branch, which runs in a contrary direction, between the head of the os humeri, and the common upper part of the biceps and coraco-brachialis; and having given branches to the vagina and channel of the biceps, and to the periosteum, afterwards joins the principal humeralis.

The axillary artery having given off these branches, passes immediately behind the tendon of the pectoralis major, where it changes its former name for that of *arteria brachialis*. It runs down on the inside of the arm, over the musculus coraco-brachialis and anconæus internus, and along the inner edge of the biceps, behind the vena basilica, giving small branches on both sides to the neighbouring muscles, to the periosteum, and to the bone.

Between the axilla and middle of the arm, it is covered only by the skin and fat; but afterwards it is hid under the biceps, and runs obliquely forward as it descends; being at some distance from the internal condyle, but it does not reach the middle of the fold of the arm.

Between the axilla and this place, it sends off many branches to the infra-spinatus, teres major and minor, subcapularis, latissimus dorsi, serratus major, and other neighbouring muscles, to the common integuments, and even to the nerves. Below the fold of the arm, it divides into two principal branches, one called *arteria cubitalis*, the other *radialis*.

From its upper and inner part, it sends off a particular branch, which runs obliquely downward and backward over the anconæi, and then turns forward again, near the external condyle, where it communicates with a branch of the arteria radialis.

Immediately below the insertion of the teres major, it gives off another branch, which runs from within outwards, and from behind forward, round the os humeri; and descends obliquely forward, between the musculus brachieus, and anconæus externus, to both which it is distributed in its passage. Having afterwards reached the external condyle, it unites with the branch last mentioned, and likewise communicates with a branch of the arteries of the fore-arm, so that there is here a triple anastomosis.

About the breadth of a finger below this second branch, the brachial artery sends off a third, which runs down towards the internal condyle, and communicates with other branches of the arteries of the fore-arm, as we shall see hereafter.

About the middle of the arm, or a little lower, much about the place where the brachial artery begins to be covered by the biceps, it sends off a branch, which is distributed

distributed to the perosteum, and penetrates the bone, between the musculus brachiius and anconæus internus.

About an inch lower, it gives off another branch, which having furnished ramifications to the anconæus internus, runs over the inner condyle, and likewise communicates with branches of the arteries of the fore-arm.

Having got below the middle of the arm, the brachial artery detaches another branch, which runs behind the inner condyle, in company with a considerable nerve; and having passed over the muscles inserted in this condyle, it communicates with that branch of the cubital artery which encompasses the fold of the arm.

A little lower, it sometimes sends out another branch, which passes on the fore-side of the inner condyle, and then communicates with a branch which runs up from the cubital artery. These three communicating branches are termed *collateral arteries*.

The common trunk of the brachial artery having reached the fold of the arm, runs, together with a vein and a nerve, immediately under the aponeurosis of the biceps, and passes under the *venâ mediana*, detaching branches on each side to the neighbouring muscles.

About a large finger's breadth beyond the fold of the arm, this artery divides into two principal branches, one inner or posterior, named *cubitalis*; the other outer or anterior, named *radialis*.

From this bifurcation, the brachial artery sends branches on each side, to the supinator longus, pronator teres, fat, and skin. It sometimes, though very rarely, happens, that this artery is divided from its origin into two large branches, which run down on the arm, and afterwards on the fore-arm, where they have the names of *cubitalis* and *radialis*.

The cubital artery sinks in between the ulna and the upper parts of the pronator teres, perforatus, ulnaris gracilis, and radialis internus; then leaving the bone, it runs down between the perforatus and ulnaris internus, all the way to the carpus and great transverse ligament, and sends out several branches.

The first is a small artery, which runs inward to the inner condyle, and then turns upward, like a kind of recurrent, to communicate by several branches with the collateral arteries of the arm, already mentioned, and particularly with the third. A little lower down, another small branch goes off, which having run upward a little way, and almost surrounded the articulation, communicates with the second collateral artery of the arm, between the olecranon and inner condyle.

Afterwards, the cubital artery having, in its course between the heads of the ulna and radius, reached the interosseous ligaments, sends off two principal branches, one internal, the other external, called the interosseous arteries of the fore-arm.

The external artery pierces the ligament about three fingers breadth below the articulation, and presently afterwards gives off a branch, which runs up, like a recurrent, toward the external condyle of the os humeri, under the ulnaris externus and anconæus minimus, to which it is distributed, as also to the supinator brevis.

Afterward, this external interosseous artery runs down on the outside of the ligament, and is distributed to the

ulnaris externus, extensor digitorum communis, and to the extensores pollicis indicis and minimi digiti; communicating with some branches of the internal interosseous artery.

Having reached the lower extremity of the ulna, it unites with a branch of the internal interosseous artery, which, at this place, runs from within outward, and is distributed, together with it, on the convex side of the carpus and back of the hand; communicating with the arteria radialis, and with a branch of the cubitalis.

By these communications, this artery forms a sort of irregular arch, from whence branches are detached to the external interosseous muscles, and to the external lateral parts of the fingers.

The internal interosseous artery runs down very close to the ligament, till it reaches below the pronator teres, between which and the pronator quadratus, it perforates the ligament, and goes to the convex side of the carpus and back of the hand, where it communicates with the external interosseous artery, with the radialis and internal branches of the cubitalis.

From the origin of the two interosæe, the cubital artery runs down between the perforatus, perforans, and ulnaris internus, along the ulna, sending branches to the neighbouring parts.

Afterward, it passes over the internal transverse ligament of the carpus, by the side of the os pisiforme, and having furnished the skin, palmaris brevis, and metacarpus, it slips under the aponeurosis palmaris, giving off one branch to the hypothenar minimi digiti, and another, which runs toward the thumb, between the tendons of the flexors of the fingers, and the bases of the metacarpal bones.

It likewise sends off a branch, which, running between the third and fourth bones of the metacarpus, reaches to the back of the hand, where it communicates with the external interosseous artery. Afterwards, having supplied the interosseous muscles, it communicates with the radialis; and they both form an arterial arch, in the hollow of the hand.

This arch sends from its concave side, towards the second phalanx of the thumb, a branch for the lateral internal part thereof, and then ends near the head of the first metacarpal bone, by a communication with the radialis, having first given a branch to the fore-side of the index, and another to the side of the thumb next the former. These communicate, at the ends of the fingers, with the neighbouring branches, as in the other fingers.

This arch sends likewise small twigs to the interosseous muscles, to the lumbricales, palmaris, and to other neighbouring parts; and, lastly, to the integuments.

The radial artery begins by detaching a small branch, which runs upward like a recurrent toward the fold of the arm, and turns backward round the external condyle, communicating with the neighbouring branches from the trunk of the brachial artery.

It runs down along the inside of the radius, between the supinator longus, pronator teres, and the integuments, giving branches to these muscles, and likewise to the perforatus, perforans, and supinator brevis. From thence it runs, in a winding course, towards the extremity of the

the radius, supplying the flexors of the thumb and pronator quadratus.

Having reached the extremity of the radius, it runs near the skin, especially toward the anterior edge of the bone, being the artery which we feel there when we examine the pulse.

At the end of the radius, it gives off a branch to the thenar; and, after having communicated with the arch of the cubital artery in the palm of the hand, and set off some cutaneous branches at that place, it detaches one along the whole internal lateral part of the thumb.

Afterwards it runs between the first phalanx and tendons of the thumb, to the interstice between the basis of this first phalanx, and of the first metacarpal bone, where it turns to the hollow of the hand.

At this turning, it sends off a branch to the external lateral part of the thumb, which having reached the end thereof, communicates, by a small arch, with the branch which goes to the internal lateral part.

It likewise sends branches outward, which run between the two first bones of the metacarpus, and the two tendons of the *radialis externus*; and it communicates with an opposite branch of the cubitalis, together with which it furnishes the external interosseous muscles and integuments of the back of the hand and convex side of the carpus.

Lastly, the radial artery terminates, in its passage over the semi-interosseous muscle of the index, near the basis of the first metacarpal bone, and as it runs under the tendons of the flexor muscles of the fingers, where it is joined to the arch of the cubitalis.

It sends off another branch, which runs along the fore-part of the first bone of the metacarpus, to the convex side of the index, where it is lost in the integuments.

The left **DIAPHRAGMATIC** artery goes out commonly from the aorta descendens, as it passes between the crura of the small muscle of the diaphragm. The right diaphragmatic comes sometimes from the nearest lumbar artery, but most commonly from the cœliaca. These arteries likewise have the name of *arteriæ phrenicæ*.

They appear almost always in several ramifications on the concave or lower side of the diaphragm, and seldom on the upper or convex side. They give small branches to the glandulæ renales, or capsulæ atrabiliaria.

They send likewise small branches to the fat which lies upon the kidneys, from whence they have the name of *arteriæ adiposæ*.

Besides these capital diaphragmatic arteries, there are others of a subordinate class, which come from the intercostales, *mammariæ internæ*, *mediastinæ*, *pericardiæ*, and *cœliaca*.

The cœliac artery arises anteriorly, and a little to the left hand, from the aorta descendens, immediately after its passage through the small muscle of the diaphragm, nearly opposite to the cartilage, between the last vertebra of the back, and the first of the loins. The trunk of this artery is very short; and near its origin, it sends off from the right side two small diaphragmaticæ, though sometimes there is only one, which goes to the right

hand, and is afterwards distributed both ways; communicating with the other arteries of the same name, which come from the intercostales and *mammariæ*. The left branch sends rami to the superior orifice of the stomach, and to the glandula renalis on the same side; the right furnishes the pylorus, and the renal gland on the right side.

Immediately after this, the cœliaca gives off a considerable branch, named *arteria ventriculi coronaria*, and *gastrica*, or *gastrica superior*; and then it presently divides into two large branches, one toward the right hand, named *arteria hepatica*; the other to the left, called *splenicæ*.

The coronary artery of the stomach goes first to the left side of that organ, a little beyond the superior orifice; round which orifice it throws branches, and also to every part of the stomach near it; and these branches communicate with those which run along the bottom of the stomach to the pylorus.

Afterwards it runs on the right side of the superior orifice, along the small curvature of the stomach, almost to the pylorus, where it communicates with the *arteria pylorica*; and turning towards the small lobe of the liver, it gives off some branches to it.

Then it advances, under the *ductus venosus*, to the left lobe of the liver, in which it loses itself near the beginning of the duct, having first given off some small branches to the neighbouring parts of the diaphragm and omentum.

As soon as the hepatic artery leaves the cœliaca, it runs to the upper and inward part of the pylorus, in company with the *vena portæ*, sending off two branches, a small one called *arteria pylorica*, and a large one named *gastrica dextra*, or *gastrica major*.

The pylorica is ramified on the pylorus, and having distributed branches to the neighbouring parts of the stomach, which communicate with those of the right *gastrica*, it terminates on the pylorus, by an anastomosis with the coronary artery of the stomach.

The right gastric artery having passed behind and beyond the pylorus, sends out a considerable branch, named *arteria duodenalis*, or *intestinalis*, which sometimes comes from the trunk of the hepatica, as we shall see hereafter. Afterwards this gastric artery runs along on the right side of the great curvature of the stomach, to the neighbouring parts of which, on both sides, it distributes branches.

These branches communicate with those of the *arteria pylorica*, and of the *coronaria ventriculi*, and with the right *gastro-epiploicæ*, which furnish the nearest part of the omentum, and communicate with the *mesenterica superior*. After this, the right gastric artery ends in the left, which is a branch of the splenicæ.

The duodenal or intestinal artery runs along the duodenum on the side next the pancreas; to both which it furnishes branches, and also to the neighbouring part of the stomach.

The hepatic artery, having sent out the pylorica and right *gastrica*, advances behind the *ductus hepaticus*, toward the *vesicula fellea*, to which it gives two principal branches

branches called *arteria cystica*; and another named *biliaria*, which is lost in the great lobe of the liver.

Afterwards, this artery enters the fissure of the liver, and joins the vena porte, with which it runs within a membranous vagina, called *capsula Glissoni*, and accompanies it through the whole substance of the liver by numerous ramifications, which may be termed *arterie hepaticæ propriae*.

Before it enters the liver, it gives small branches to the external membrane of this viscus, and to the *capsula Glissoni*.

Immediately after the origin of the splenic artery from the *cœliaca*, it runs toward the left hand, under the stomach and pancreas, to the spleen. It adheres closely to the posterior part of the lower side of the pancreas, to which it gives several branches, named *arteria pancreaticæ*.

Near the extremity of the pancreas, under the left portion of the stomach, the splenic artery gives off a principal branch, called *gastrica sinistra* or *minor*, which runs from left to right along the left portion of the great curvature of the stomach, giving branches to both sides of this portion, which communicate with those of the *coronaria ventriculi*.

This gastric artery sends likewise another branch at least to the extremity of the pancreas, which communicates with the other pancreatic arteries. It also supplies the omentum with branches, termed *gastro-epiploicæ sinistrae*; and then it communicates with the right *gastrica*; and from this union, the *gastro-epiploicæ mediz* are produced.

Afterwards, the splenic artery advances towards the spleen, in a course more or less contorted; but before it arrives at that viscus, it gives two or three branches to the large extremity of the stomach, commonly called *vasa brevia*; and one to the omentum, named *epiploica*.

At the spleen, this artery divides into four or five branches, which enter that viscus, after having given some small twigs to the neighbouring parts of the stomach and omentum.

The superior mesenteric artery arises anteriorly from the lower portion of the descending aorta, a very little way below the *cœliaca*, going out a little towards the right hand, but bending immediately afterwards to the left.

Near its origin, it gives off a small branch, which dividing into two, goes to the lower side of the head of the pancreas, and neighbouring part of the duodenum, communicating with the *intestinales* by small arches, and *areolæ* or *malles*.

Afterwards it passes over the duodenum, between this intestine and the meseraic vein, between the two laminae of the mesentery; and then bending in an oblique direction from left to right, and from above downward, by very small degrees, it advances toward the extremity of the ileum. By this incurvation, it forms a kind of long arch, from the convex side of which a great many branches go out.

These branches are sixteen or eighteen in number, or thereabouts, and almost all of them are bestowed on the small intestines, from the lower third part of the duodenum to the *cæcum* and *colona*.

As they approach the intestines, all these branches communicate, first by reciprocal arches; then by *ariolæ* and *malles* of all kinds of figures; from which is detached an infinite number of small ramifications, which surround the intestinal canal, like an annular piece of network.

The first branches from the convex side of the mesenteric arch, which are very short, supply the pancreas and mesocolon, and communicate with the duodenal artery. The last branches go to the *appendicula vermiformis*, and send a portion of an arch to the beginning of the colon.

The considerable branches from the concave side of the mesenteric arch, are seldom above two or three in number; but before they arise, a small ramus goes out to the duodenum, and gives some very small arteries to the pancreas.

The first considerable branch from the concave side of the arch goes into the mesocolon towards the right portion of the colon.

The second principal branch, having run for some space through the mesentery, divides into three rami; the first of which goes to the lower part of the right portion of the colon, the second goes to the beginning of the colon and *intestinum cæcum*.

The third ramus of the second branch, having communicated with the second, gives small twigs to the *cæcum*, *appendicula vermiformis*, and extremity of the ileum.

The lower mesenteric artery goes out anteriorly from the aorta descendens inferior, about a finger's breadth or more above the bifurcation, and below the spermatic arteries; and having run about the length of an inch, or something more, it is divided into three or four branches.

The first or superior branch, about an inch from its origin, divides into two rami; the first of which runs along the left portion of the colon. The second ramus having communicated with the first, runs down upon the same portion of the colon.

The middle branch divides into two rami; one of which passes upward on the extremity of the colon, communicating by arches with the second ramus of the superior branch; the other runs down on the extremity of the same intestine.

The lower branch goes to the second portion of the colon, or to both.

It sends another considerable branch downward, called *arteria hæmorrhoidalis interna*, which runs down behind the *intestinum rectum*, to which it is distributed by several ramifications.

The renal arteries, commonly called *emulgentes*, are ordinarily two in number, and go out laterally from the inferior descending aorta, immediately under the *mesenterica superior*, one to the right hand, the other to the left.

They run commonly without division, and almost horizontally to the kidneys, into the depressions of which they enter by several branches, which form arches in the inner substance of these viscera.

From these arches, numerous small rami go out toward

ward the circumference or outer surface of the kidneys.

Ordinarily, the right renal artery passes behind the vena cava and renal vein on the other side; and the left artery, first behind and then before the vein.

The arteries of the renal glands, which may be termed *arteriæ capsulares*, arise sometimes from the aorta above the *arteria renalis*, and give out the *arteriæ adiposæ*, which go to the fat of the kidneys. Sometimes they come from the trunk of the cœliaca. The right capsular artery comes most commonly from the *arteria renalis* of the same side, near its origin; the left from the aorta, above the *renalis*.

The spermatic arteries are commonly two in number, sometimes more. They are very small, and go out anteriorly from the aorta descendens inferior, near each other, about a finger's breadth below the *arteriæ renales*, between the two mesentericæ, or between the *renales* and *mesentericæ inferiores*.

They send off to the common membrane of the kidney small branches, named *arteriæ adiposæ*; and afterwards they run down upon the psoas muscles, on the fore-side of the ureters, between the two laminae of the peritonæum.

They give several considerable branches to the peritonæum, and communicate both with the mesentericæ and adiposæ. They likewise send small arteries to the ureters.

Afterwards, they pass in men through the tendinous openings of the abdominal muscles in the vagina of the peritonæum, and are distributed to the testicles and epididymis, where they communicate with a branch of the *iliaca externa*.

In women they do not go out of the abdomen, but are distributed to the ovaria and uterus, and communicate with branches of the hypogastrica, at the jagged extremities of the tubæ Fallopiæ.

The lumbar arteries go out posteriorly from the inferior descending aorta, in five or six pairs, or more, much in the same manner with the intercostals.

They may be divided into superior and inferior. The superior send small branches to the neighbouring parts of the diaphragm and intercostal muscles, and supply the place of semi-intercostal arteries.

They are distributed on each side to the psoas muscles, to the quadrati lumborum, and to the oblique and transverse muscles of the abdomen; and by perforating the oblique muscles, they become external hypogastric arteries. They go likewise to the vertebral muscles, and to the bodies of the vertebræ, and enter the spinal canal through the lateral notches, to go to the membranes, &c. forming rings much in the same manner with the intercostals.

The *arteriæ sacre* go out commonly from the back part of the inferior descending aorta, at the bifurcation. They are two, three, or four in number, and sometimes but one. They are ramified on the os sacrum, and on the neighbouring parts of the peritonæum, intestinum rectum, fat, &c. and enter the canal of that bone through the anterior holes, being there distributed toward each side. They likewise send small arteries to the large fasciculi of nerves, which go out through the holes of the os sacrum, and they penetrate the inner substance of that bone.

The inferior descending aorta ends at the last vertebra of the loins, and sometimes higher, in two large lateral branches, one on the right hand, the other on the left, called *arteria iliaca*; each of which is a common trunk to two other arteries of the same name. This bifurcation lies on the anterior and left side of that of the vena cava.

The primitive iliac arteries divaricate gradually as they descend, advancing obliquely toward the anterior and lower part of the ossa ilium, without any considerable ramification for about the breadth of three fingers, except a few very small arteries that go to the os sacrum. They likewise give small arteries to the peritonæum, to the coats of the veins, and to the fat and ureters.

The right iliac trunk passes first on the fore-side of the origin of the left iliac vein, and runs down on the fore-side of the right vein, almost to the place where it goes out of the abdomen, its course being there directed more inwardly. The left trunk goes down likewise before the left vein, but lies a little toward the inside as it leaves the abdomen.

About three fingers breadth from their origin, each iliac trunk is divided into two secondary arteries, one external, the other internal. The external artery has no particular name; the internal is termed *hypogastrica*.

The external iliac on each side runs down on the iliac muscle to the ligamentum Fallopii, under which it goes out of the abdomen. In this course, it gives off only a few small arteries to the peritonæum, and other parts near it; but as it passes out of the abdomen under the ligament, it detaches two considerable branches, one internal, the other external.

The internal branch is named *arteria epigastrica*, and goes out anteriorly from the external iliac. From thence it runs obliquely upward on the tendon of the transverse muscle towards the posterior part of the rectus.

Afterwards the epigastric artery runs up along the posterior or inner side of this muscle, sending ramifications to the tendons of the neighbouring muscles, &c. and then loses itself by a true anastomosis of several ramifications, with the *mammaria interna*.

The external branch of the outer iliac goes off laterally from the outside of that artery under the ligamentum Fallopii, and from thence to the internal labium of the os ilium, where it divides into two, and is ramified on the oblique and transverse muscles of the abdomen communicating with the *arteria lumbaris*.

Besides these two branches, the external iliac gives off a small ramus internally, under the ligament, which runs to the vagina of the spermatic rope; and sometimes another small twig goes from the outside to the os ilium.

The internal iliac or hypogastrica, having run a little more than a finger's breadth inward and backward, bends by small degrees obliquely forward, and toward the outside; and afterwards contracting in its dimensions, it ends in the umbilical artery, which ought to be looked upon as a true continuation of the trunk of the hypogastrica.

This *arteria umbilicalis* ascends on the side of the bladder, and having detached small rami to that viscus and to the neighbouring parts of the peritonæum, &c. it contracts, and in adults is quite closed up above the middle

middle of the bladder. It likewise gives branches to the uterus, and to the neighbouring parts in both sexes. Afterwards it ascends in form of a ligament to the umbilicus, where it joins the umbilical artery on the other side.

From the convex side of the curvature of the hypogastric artery, four or five principal branches commonly go out very near each other, *viz.* iliaca minor, glutæa, sciatica, pudica communis, five pudica hypogastrica, and obtratrix.

The iliaca minor, the most posterior of these branches, and which is often no more than a ramus of the glutæa, passes between the last two lumbar nerves, and divides into two rami, one of which enters the canal of the os sacrum through the lowest large anterior holes; the other passes behind the musculus psoas, to which it gives twigs, and behind the crural nerve, being afterwards distributed to the iliac muscle, and to the middle part of the inside of the os ilium, penetrating into the substance of the bone sometimes by one hole, sometimes by more.

The arteria glutæa is sometimes the largest of all the hypogastric branches. Near its beginning it sometimes sends out the iliaca minor, and sometimes the small ramus that goes from that artery to the os sacrum and other parts fixed to that bone. Afterwards this artery goes out of the pelvis, in company with the sciatic nerve, through the upper part of the great sinus of the os innominatum, below the musculus pyriformis, and is distributed, in a radiated manner, to the glutæus maximus and medius.

In its passage, it gives some branches to the os sacrum, os coccygis, musculus pyriformis, the muscles of the anus, and to the neighbouring parts of the intestinum rectum, forming a particular hæmorrhoidalis interna. It likewise sends twigs to the bladder and parts near it; and detaches a pretty long branch, which runs down with the sciatic nerve.

The arteria sciatica gives first of all some branches to the musculus pyriformis, the quadrigemi, the os sacrum, &c. and even to the inner side of the os ischium. It likewise detaches a branch, which runs under the musculus quadratus, to the articulation of the os femoris.

The pudica communis, called commonly *pudica interna*, arises sometimes by a trunk common to it and to the glutæa, and gives out two principal branches; the first of which passes through the great sinus of the os ilium, in company with the glutæa and sciatica, and then divides into two rami.

The first ramus goes behind the spine of the ischium, between the two ligaments which lie between that bone and the os sacrum; and runs on the inside of the tuberculum ischii, all the way to the origin of the corpus cavernosum penis. There it divides into several arteries, one of which goes to the sphincter ani, under the name of hæmorrhoidalis externa.

The rest are distributed to the neighbouring integuments, to the bulb of the urethra, and to the corpus cavernosum penis; but the last of these arteries, or rather the extremity of this first ramus, runs from behind forward, over the neck of the os femoris, and communicates with a branch of the arteria cruralis.

The second principal ramus, called commonly *arteria pudica externa*, runs between the bladder and intestinum rectum, and is distributed in men to the vesiculæ seminales, neck of the bladder, prostate gland, and neighbouring parts of the rectum.

Afterwards it runs under the os pubis on the side of a considerable vein, which lies directly under the symphysis; and it runs along the penis between this vein and a nerve, being distributed in its passage to the corpus cavernosum, and communicating with the pudica minor, which comes from the cruralis.

This second branch of the pudica major goes off sometimes separately from the hypogastrica, especially in women, being distributed to the lateral parts of the uterus, where it communicates with the spermatic artery, near the jagged extremity of the tuba Fallopiana, and to the neighbouring parts of the vagina, &c.

The arteria obtratrix perforates the obturator muscles, and goes out of the pelvis at the upper part of the ligament of the foramen ovale, having first sent a small branch over the symphysis of the os ilium and os pubis, to the inguinal glands and integuments.

As it passes by the muscles, it divides and is distributed to the pectineus and triceps. It likewise sends out another branch, which communicates with that branch of the sciatica that goes to the articulation of the os femoris; and gives small arteries to the holes in the neck of that bone.

The iliac artery goes out of the abdomen, between the ligamentum Fallopii and tendon of the psoas, at the union of the os ilium and os pubis, and there it takes the name of *arteria cruralis*.

It sends off, first of all, three small branches; one of which, called *pudica externa*, goes over the crural vein to the skin and ligament of the penis, and to the inguinal glands, communicating with the pudica interna. The second goes to the musculus pectineus; and the third to the upper part of the sartorius. All these branches furnish likewise the neighbouring anterior integuments.

Afterwards the crural artery runs down on the head of the os femoris; and, by taking a particular turn, gets on the inside of the crural vein, about three fingers breadth from where it goes out of the abdomen.

In changing its situation, it sends out three considerable branches, one external, one middle, and one internal.

The external branch runs on the upper side of the thigh to the crureus, vastus externus, rectus anterior, musculus fasciæ latæ, and glutæus medius; sending up a ramus to the apex of the great trochanter, which communicates with the first principal ramus of the pudica major and sciatica.

The middle branch runs down on the inside of the thigh between the triceps muscles, to which it gives several rami, one whereof perforates the second muscle, and is distributed to the glutæus maximus, semi-nervosus, semi-membranosus, biceps, and to the neighbouring integuments.

The internal branch runs backward on the quadrigemi, towards the great trochanter; and having detached a ramus, which goes into the joint of the os femoris,

it runs downward, and gives rami to all the muscles that lie on the backside of that bone, one of which enters the bone itself on one side of the *linea aspera*.

Having sent off all these three branches, the *arteria cruralis* runs down between the  *Sartorius*,  *Vastus internus*, and  *triceps*, giving branches to all the parts near it. It is covered by the  *Sartorius* all the way to the lower part of the thigh, where it is inflected backward over the  *triceps tertius* a little above the internal condyle of the  *os femoris*. Afterwards, continuing its course through the hollow of the ham, it is called *arteria poplitea*.

The *poplitea*, while in the ham, is covered only by the integument, sending off branches toward each side, which run up upon the condyles, and communicate with the lower ramifications of the *arteria cruralis*.

It sends rami to the joint of the knee, one of which at least passes between the crucial ligaments. As it runs down, it sends branches to the  *gastrocnemii* and  *popliteus*; and having reached the backside of the head of the tibia, it gives off two branches, one to each side.

The first or internal branch surrounds the fore-part of the head of the tibia, passing between the bone and internal lateral ligament; and besides several other ramifications, sends up a small branch, which communicates with the arteries that lie round the condyles of the  *os femoris*.

The second or external branch runs over the head of the fibula, and between the head of the tibia and external lateral ligament of the knee, surrounding the articulation all the way to the ligament of the patella, and communicating with the branches which lie round the condyles of the  *os femoris*, together with a branch of the first or internal ramus.

Immediately after the origin of these two rami, and before the *poplitea* ends, it sends a small artery down on the backside of the interosseous ligament, very near the tibia, into which it enters by a particular hole a little above the middle portion of the bone.

As the *poplitea* ends, it divides into two principal branches, one of which runs between the heads of the tibia and fibula, passing from behind forwards on the interosseous ligament, where it takes the name of *arteria tibialis anterior*. The second branch divides into two others; one internal and largest, called *arteria peronæa anterior*; the other posterior and smallest, named *arteria peronæa posterior*.

The *tibialis anterior*, having passed between the heads of the tibia and fibula, sends small branches upward and laterally. The superior branches communicate with those rami of the *popliteus* which lie round the articulation; and the lateral branches go to the neighbouring parts. Afterwards this tibial artery runs down on the fore-side of the interosseous ligament, toward the outside of the tibia, between the *musculus tibialis anticus* and *extensor pollicis*.

Having run laterally on the tibia for about two thirds of the length of that bone, it passes on the fore-side under the common annular ligament, and *extensor pollicis*, to the articulation of the foot; giving off several rami both to the right and left hand, which communicate la-

terally with the *tibialis posterior* and *peronæa posterior*, so that these two bones are in a manner surrounded by arteries.

At the joint of the foot, it sends out branches which run between the *astragalus* and *os calcis*, being distributed to the articulation and to the bones of the tarsus.

Having passed the fold of the foot, it sends off, toward both sides, other rami, which communicate with the posterior *tibialis* and *peronæa*; all these branches making a kind of circles round the tarsus.

Afterwards the anterior tibial artery advances on the convex side of the foot, as far as the interstice between the first and second metatarsal bones; between the heads of which it sends a large branch, which perforates the superior interosseous muscles, and, joining the *tibialis posterior*, forms an arch on the side of the foot.

It likewise sends two or three considerable branches over the other metatarsal bones, which go to the rest of the interosseous muscles, integuments, &c. and communicate with each other.

Lastly, This artery terminates by two principal branches, one of which goes to the *thenar* and inside of the great toe; the other is spent upon the outside of the great toe, and the inside of the second toe.

The *tibialis posterior*, called likewise *suralis*, runs down between the *solei*, *tibialis pollicis*, *flexor digitorum communis*, and *flexor pollicis*; giving branches to these muscles, to the tibia, and to the marrow of that bone, through a particular canal in its posterior and upper part.

Afterwards it runs behind the inner ankle, communicating with the *tibialis anterior*, and surrounded by the neighbouring veins; and passes to the sole of the foot between the concave side of the *os calcis* and *thenar muscle*, where it divides into two branches, one large or external, the other small or internal.

The great branch, or *arteria plantaris externa*, passes on the concave side of the *os calcis* obliquely under the sole of the foot, to the basis of the fifth metatarsal bone, and from thence runs in a kind of arch toward the great toe, communicating there with the *tibialis anterior*, which perforates the interosseous muscles.

The convex side of this arch supplies both sides of the last three toes, and the outside of the second toe, forming small communicating arches as in the hand.

The small branch, or *arteria plantaris interna*, having reached beyond the middle of the sole of the foot, is divided into two; one of which goes to the great toe, communicating with the ramus of the *tibialis anterior*; the other is distributed to the first phalanges of the other toes, communicating with the ramifications from the arch already mentioned.

The *arteria peronæa* runs down on the backside of the fibula, between the *soleus* and *flexor pollicis*, to which, and to the neighbouring parts, it gives rami in its passage.

Having reached to the lower third part of the fibula, it sends off a considerable branch, which runs in between the tibia and that bone, passing between their extremities from behind forward, below the interosseous ligament, and is distributed to the integuments of the tarsus.

Lastly,

Lastly, the peronæa continuing its course downward, on the backside of the fibula, as far as the os calcis, forms an arch with the tibialis posterior, between the astragalus and the tendo-achillis.

From thence it runs outward, and a little above the outer ankle communicates with the tibialis anterior by an arch, which sends several small ramifications to the neighbouring parts.

## P A R T IV.

### O F T H E V E I N S.

**T**HE blood, distributed to all parts of the body by two kinds of arteries, the aorta and arteria pulmonaris, returns by three kinds of veins, called by anatomists *vena cava*, *vena portæ*, and *vena pulmonaris*.

The *vena cava* carries back to the right auricle of the heart, the blood conveyed by the aorta to all parts of the body except what goes by the arteriæ coronariæ cordis. It receives all this blood from the arterial ramifications in part directly, and in part indirectly.

The *vena portæ* receives the blood carried to the floating viscera of the abdomen by the arteria cæliaca and the two mesentericæ, and conveys it to the *vena hepatica*, and from thence to the *vena cava*.

The *vena pulmonaris* conveys to the pulmonary sinus, or left auricle of the heart, the blood carried to the lungs by the arteria pulmonaris.

We commonly talk of the *vena cava* in general, as if it were but one vein at its origin, or had but one common trunk; whereas it goes out from the right auricle of the heart by two large separate trunks, in a direction almost perpendicularly opposite to each other, one running upward, called *vena cava superior*; the other downward, called *vena cava inferior*.

The *vena cava superior* is distributed chiefly to the thorax, head, and upper extremities, and but very little to the parts below the diaphragm.

The *vena cava inferior* is distributed chiefly to the abdomen and lower extremities, and but very little to the parts above the diaphragm.

The trunk of each of these two veins sends off, much in the same manner with the arteries, a certain number of principal or capital branches, which are afterwards ramified in different manners. Each trunk terminates afterwards by a bifurcation or a division into two subordinate trunks, each of which gives off other principal branches, ending in a great number of small trunks, rami, and ramifications.

The superior *vena cava* runs up from the right auricle of the heart, almost in a direct course, for about two fingers breadth, lying within the pericardium, in the right side of the trunk of the aorta, but a little more anteriorly.

As it goes out of the pericardium, it is inclined a little to the left hand, and then runs up as high as the cartilage of the first true rib, and a little higher than the

curvature of the aorta. At this place it terminates by a bifurcation or division into two large branches or subordinate trunks, one of which runs toward the left hand, the other toward the right.

These two branches are named *subclavia*, as lying behind the claviculæ.

The trunk of the superior *cava*, from where it leaves the pericardium to the bifurcation, sends out anteriorly several small branches. These branches are the *vena mediastina*, *pericardica*, *diaphragmatica superior*, *thymica*, *mammaria interna*, and *trachealis*.

All these small branches from the trunk of the *cava superior* are termed *dextræ*; and their fellows on the other side, called *sinistræ*, do not arise from the trunk, but from the left *subclavia*.

Posteriorly, a little above the pericardium, the trunk of the superior *cava* sends out a capital branch, called *vena azygos*, or *vena sine pari*, which runs down on the right side of the bodies of the vertebæ dorsæ, almost to the diaphragm; giving off the greatest part of the *venæ intercostales* and *lumbares superiores*.

The two *subclaviæ* run laterally or toward each side, and terminate as they go out of the thorax, between the first rib and clavícula.

The right *subclavian*, which is the shortest of the two, commonly sends out four capital branches; the *jugularis externa*, *jugularis interna*, *vertebralis*, and *axillaris*.

The left *subclavian* being longer than the right, gives off, first of all, the small veins on the left side, answering those on the right side that come from the trunk of the superior *cava*, viz. the *mediastina*, *pericardica*, *diaphragmatica superior*, *thymica*, *mammaria interna*, and *trachealis*.

Next to these small veins, called *sinistræ*, it detaches another small branch, called *intercostalis superior sinistra*, and then four large branches like those from the right *subclavian*, viz. the *jugularis externa*, *jugularis interna*, *vertebralis*, and *axillaris*, which are termed *sinistræ*.

The external *jugular veins* are distributed chiefly to the outer parts of the throat, neck and head; and send a small vein to the arm, named *cephalica*, which assists in forming a large one of the same name.

The internal *jugular veins* go to the internal parts of the neck and head, communicating with the sinuses of

the dura mater, and in several places with the external jugular veins.

The vertebral veins pass through the holes in the transverse apophyses of the vertebrae of the neck, sending branches to the neck and occiput. They form the sinus venales of these vertebrae, and communicate with the sinuses of the dura mater.

The axillary veins are continuations of the subclaviae, from where these leave the thorax, to the axilla. They produce the mammae internae, thoracicae, scapulares or humerales, and a branch to each arm, which, together with that from the external jugularis, forms the vena cephalica.

Afterwards the axillary vein terminates in the principal vein of the arm, called *basilica*; which, together with the cephalica, is distributed by numerous ramifications to all parts of the arm, fore-arm, and hand.

The portion of the inferior vena cava contained in the pericardium is very small, being scarcely the twelfth part of an inch on the fore-part, and not above a quarter of an inch on the back part. From thence it immediately perforates the diaphragm, to which it gives the vena diaphragmaticae inferiores or phrenicae.

It passes next behind the liver, through the great sinus of that viscus, to which it furnishes several branches, termed *vena hepatica*.

In this course it inclines a little toward the spina dorsa and aorta inferior, the trunk and ramifications of which it afterwards accompanies in the abdomen, all the way to the os sacrum.

Thus the inferior cava sends out on each side, in the same manner with the aorta, the vena adiposae, renales, spermaticae, lumbares, and sacrae. Having reached to the os sacrum, it loses the name of cava, and terminating by a bifurcation, like that of the descending aorta, it forms the two vena iliaca.

These iliac veins having given off the hypogastricae, with all their ramifications, to the viscera of the pelvis, and to some other external and internal neighbouring parts, go out of the abdomen, under the ligamentum Fallopii, and there take the name of *vena crurales*.

Each crural vein sends off numerous ramifications to all the lower extremity.

The vena azygos or sine pari is very considerable, and arises posteriorly from the superior cava a little above the pericardium.

It is immediately afterwards bent backward over the origin of the right lung, forming an arch which surrounds the great pulmonary vessels on that side.

From thence it runs down on the right side of the vertebrae dorsa on one side of the aorta, and before the intercostal arteries; and getting behind the diaphragm, it terminates by a very sensible anastomosis, sometimes with the vena renalis, sometimes with a neighbouring lumbar vein, and sometimes immediately with the trunk of the cava inferior.

The vena azygos sends out two or three small veins from the top of the arch, one of which goes to the aspera arteria; the others partly to the aspera arteria, and partly to the bronchia, by the name of vena

bronchiales, accompanying the ramifications of the bronchial artery.

Afterwards the azygos detaches from the extremity of the arch a small trunk common to two or three small veins, called *intercostales superiores dextra*, which bring back the blood from the first three series of intercostal muscles, and from the neighbouring part of the pleura.

These intercostal veins send branches through the intercostal muscles to the ferratus superior pectus, ferratus major, &c. and afterwards they run along the interstices between the ribs, communicating with the vena mammae.

They likewise send small branches backward to the vertebral muscles and canal of the spine, where they communicate with the venal circles, or sinuses which bring back the blood from the medulla spinalis.

As the azygos runs down, it sends off the inferior intercostal veins on the right side, one going to each series of intercostal muscles. These veins run along the lower edges of the ribs, and perforate the muscles by branches, which go to the posterior and external part of the thorax.

They communicate with the vena thoracicae, and most commonly with the mammae interna; and lastly, more or less with each other, by perpendicular branches, near the posterior extremities of the ribs.

The azygos sends off likewise the left intercostal veins, but seldom the whole number; for the superior veins come often from the left subclavian. The inferior intercostal veins, to the number of six or seven, come often from the trunk of the azygos; and running between the aorta and vertebrae, they send off almost the same ramifications with the veins on the right side, and likewise some to the oesophagus.

The azygos, having reached below the last rib, sends off a large branch, which bending outward, perforates the muscles of the abdomen, is ramified between their different planes, and communicates with the like ramifications of the last or last two intercostal veins.

The pectorales internae, are small veins disposed in pairs toward the right and left hand, behind the sternum and parts near it, including the diaphragmaticae superiores, or pericardio-diaphragmaticae, mediastinae, mammae internae, thymicae, pericardicae, and gutturales or tracheales.

The right vena mediastina goes out anteriorly from the trunk of the superior cava, a little above the origin of the azygos; the left comes from the subclavia.

The right superior diaphragmatica, or pericardio-diaphragmatica, comes anteriorly from the root of the bifurcation near the mediastina; and is distributed, by several branches, to the upper, fore, and back parts of the pericardium, communicating with those of the left diaphragmatica. The left superior diaphragmatica comes from the left subclavian, a little below the origin of the mammae.

The right internal mammae arises anteriorly from the vena cava, a little below the angle of the bifurcation. It runs along the nearest internal or posterior edge of the sternum, and on the cartiliginous extremities of the

the right ribs, together with the artery of the same name. Having reached near the diaphragm, it sends it a branch which runs toward the tendinous plane, and communicates with the common diaphragmatic veins.

Afterwards this mammary vein gives small branches to the mediastinum, and others between the ribs to the integuments; of which those that pass between and under the cartilages of the last true ribs, run down on the inner or posterior side of the musculus recti abdominis, being ramified among their fleshy fibres, and communicating with the epigastric veins by several small twigs.

The left internal mammaria arises anteriorly from the left subclavian, opposite to the cartilage or anterior extremity of the first true rib.

The right vena thymica, when it arises separately, goes out from the bifurcation; and when it is wanting, the thymus, from whence it takes its name, is furnished by the gutturalis, or some other neighbouring vein. This vein often reaches no lower than the inferior part of the thymus; and the left vein of the same name comes from the left subclavian, almost opposite to the sternum.

The right pericardiac seems to go out rather from the origin of the right subclavian, than from the trunk of the superior cava. It goes to the upper side of the pericardium, and other neighbouring parts.

The right gutturalis or trachealis goes out from the upper part of the bifurcation, above the mammaria of the same side, sometimes more backward, and sometimes from the subclavia. It is distributed to the glandulæ thyroïdæ, trachea arteria, musculi sterno-hyoidæi, thymus, and glandulæ bronchiales. It communicates, by lateral branches, with the internal jugular vein. The left gutturalis comes from the upper or posterior part of the left subclavian, near its origin.

The right subclavian vein is very short, and its course very oblique, so that it appears to rise higher than the left vein. It sends off, first of all, four large branches, viz. the vertebralis, which is the first and most posterior; the jugularis interna, jugularis externa, and axillaris.

The left subclavian seems to ascend but very little after the bifurcation; and, in this course, it covers the origin of three large arteries, which come from the curvature of the aorta. It sends off four large branches, besides the small pectoral veins, and receives the ductus thoracicus.

It likewise gives off, before its principal division, a small trunk for the left superior intercostals, and this intercostal trunk furnishes likewise the left bronchialis.

Each subclavian vein, near the middle of the clavicle, sends off a branch, called cephalica, which descends near the surface of the body, between the deltoïdes and pectoralis major.

Each external jugular vein arises from the subclavian on the same side, sometimes from the axillaris, and sometimes from the union of these two veins. They run up between the musculus cutaneus and sterno-mastoidæus.

Sometimes they are double from their very origins; and when they are single, each of them divides afterwards into two, one anterior, and the other posterior, or rather superior. The anterior vein goes to the throat

and face, running up toward the angle of the lower jaw, and the posterior goes to the temples and occiput.

The anterior external jugular vein is often a branch of the jugularis interna, and sometimes it comes from the vena axillaris.

It runs up toward the lateral part of the lower jaw, between the angle and the chin, and sends several branches forwards, backwards, and inwards.

Posteriorly it gives, (1.) A large branch on the side of the upper part of the larynx, which communicates with the jugularis interna, and likewise with a large short branch of the jugularis externa posterior. (2.) A small branch, which has the same communication, but which is not always to be found. (3.) Another small branch a little below the lower jaw, which communicates with the jugularis externa posterior.

Anteriorly it sends several branches to the muscles of the larynx, sterno-hyoidæi, thyro-hyoidæ, and to the integuments; and below the larynx it sends communicating branches to the jugularis externa anterior of the other side.

A little higher, opposite to the cartilago-thyroïdes, it gives off a transverse branch, which runs on the anterior and lower part of the musculus sterno-mastoidæi, and communicates with the jugularis of the other side.

The superior and inferior transverse branches communicate on each side by branches more or less perpendicular, and send a small branch to the musculus quadratus of the chin, to the musculus cutaneus and integuments.

It sends another large branch anteriorly toward the symphysis of the lower jaw, which, after having supplied the maxillary glands, is distributed to the digastric muscle, to the chin and under lip.

Interiorly, at the same place, it sends out a large branch, which furnishes the glandulæ sublinguales, runs down toward the cornua of the os hyoides, to communicate with some branches of the jugularis interna, and sends several rami to the tongue, called *venæ raninæ*. It gives off likewise a small branch, which running upon the musculus labiorum triangularis, to the commissure of the lips, is distributed to the neighbouring parts.

The same branch which gives out the *venæ raninæ*, detaches another to the lateral parts of the septum palati, which is distributed to the amygdalæ, and to the uvula, and sends rami forward to the membrane which lines the arch of the palate. Another branch goes out from it to the pterygoïdæus internus, peristaphylini, and cephalopharyngei.

Afterwards the trunk of the anterior external jugular vein runs up on the musculus triangularis, where it receives the name of vena triangularis, in a winding course from the angle of the lower jaw to the great or internal angle of the orbit, sending branches on each side to the muscles and integuments.

The trunk of the vena angularis having reached the bones of the nose, sends out a branch through the lateral cartilages of the nose, which is distributed to the nares; and another which runs down in a winding course to the upper lip.

At the great or inner angle of the eye, the same trunk sends off several other branches; the first of which goes

to the root of the nose, and communicating with its fellow from the other side, gives several small veins to the holes of the ossa nasi.

The second branch runs up on the fore-head, by the name of *vena frontalis*, and is distributed to each side.

The third branch enters the orbit in a winding course, on one side of the cartilaginous pulley, and communicates with the sinuses of the dura mater, by the orbitary sinus of the eye.

The fourth branch goes along the musculus superciliaris and the upper part of the orbicularis, to the small or external angle of the eye, to communicate with the vena temporalis, and with that vein which runs along the lower part of the orbicular muscle.

The posterior or superior external jugular vein runs up toward the parotid gland, and lower anterior part of the eye, giving out several branches toward each side.

At its origin it sends out posteriorly, a principal branch, with its ramifications, to the muscles which cover the scapula and joint of the humerus, commonly called *vena muscularis*.

A little higher, it gives off the vena cervicalis, which goes to the vertebral muscles of the neck.

Near the cervical vein, but a little more outward, it gives off sometimes the small vena cephalica, which runs down between the pectoralis major and deltoïdes, and unites with the vena cephalica of the arm.

Backward it detaches the vena occipitalis, which is distributed to the occiput; it likewise sends out a small vein, which enters the cranium by the posterior mastoid hole, and terminates in one of the lateral sinuses of the dura mater.

Having reached as far as the parotid gland, it forms communications with the anterior external jugular, under the angle of the lower jaw; and then passes through the parotid gland, between that angle and the condyle, giving off a large branch which communicates with another branch common to the internal and anterior external jugulars.

Afterwards it passes before the ear, taking the name of *vena temporalis*, which is distributed to the temples and lateral parts of the head, towards the occiput and forehead.

The temporal vein of one side communicates, above, with its fellow on the other side; before, with the vena frontalis; and behind, with the vena occipitalis. Opposite to the ear, it gives out a large branch, one ramus of which runs under the lower edge of the zygoma, and then returning, communicates with another ramus from the same jugularis, a little below the condyle of the lower jaw.

Behind this condyle, it gives branches to the temporal muscle, to the neighbouring parts of the upper jaw, and to the inside of the lower jaw.

The internal jugular vein is the largest of those that go to the head.

It runs up behind the sterno-mastoidæus and omo-hyoidæus, which it crosses, along the sides of the vertebræ of the neck, by the edge of the longus colli, to the fossula of the foramen lacerum of the basis cranii.

The first branches which it sends off are small, and go

to the thyroid glands. About two fingers breadth higher up, it detaches a middle-sized branch, which runs laterally towards the larynx, and may be named *vena gutturalis*.

This guttural vein divides chiefly into three branches; the lowest of which goes to the thyroid gland and neighbouring muscles; the middle branch to the larynx, musculi thyroïdæi, &c. and the third runs upward to the great communication between the two jugulars.

About the same distance upward, almost opposite to the os hyoides, the internal jugular gives another branch, which sends rami to the muscles belonging to that bone, and others which communicate with the foregoing branch. This other branch runs upward toward the parotid gland and angle of the lower jaw, where it sends communicating branches forward and backward to the two external jugulars.

The internal jugular sends another branch backward, which is distributed to the occiput, where it communicates with a branch of the vertebralis, and, through the posterior mastoid hole, with the lateral sinus of the dura mater.

Afterwards it reaches the foramen lacerum of the basis cranii, bending a little, and sending off small twigs to the pharynx and neighbouring muscles.

The vertebral vein arises posteriorly from the subclavia or axillaris, sometimes by two stems.

The first and principal stem gives out a branch, called *vena cervicalis*, which is distributed to the neighbouring muscles, and afterwards runs up through the holes of the transverse apophyses of the vertebræ colli.

The other item of the vertebral vein runs up on the side of the vertebræ; and having reached the fourth, or sometimes higher, it runs in between the transverse apophyses of that vertebra and the fifth, to join the first or principal stem.

Thus the vertebral vein accompanies the artery of the same name, sometimes in one trunk, sometimes in several stems, through all the holes of the transverse apophyses of the vertebræ colli, all the way to the great foramen occipitale, communicating with the occipital veins and small occipital sinuses of the dura mater.

In its passage it gives off one branch, which enters by the posterior condyloid hole of the os occipitis, and communicates with the lateral sinus of the dura mater.

As these veins run through the holes in the transverse apophyses, they send branches forward to the anterior muscles of the neck, and to the small anterior muscles of the head.

Other branches go likewise outward and backward to the musculi transverseales and vertebrales colli; and inward to the great canal of the spinal marrow, where they form sinuses, which communicate with those on the other side.

These vertebral sinuses are pretty numerous, and placed one above another all the way to the occiput; the lower communicate with the upper; and at the great foramen of the os occipitis there is a communication between them and the occipital sinuses of the dura mater.

The subclavian vein having sent off the branches already described, goes out of the thorax, and passes before

fore the anterior portion of the musculus scalenus, and between the first rib and the clavicle, to the axilla. Through this course it takes the name of *vena axillaris*, and gives off several branches, the chief of which are the venæ musculares, thoracicæ, and vena cephalica.

The musculares, are distributed to the middle portion of the musculus trapezius, to the angularis, infra-spinatus, and subcapularis; and as some of these branches go to the shoulder exteriorly, others interiorly, the venæ scapulares are distinguished into external and internal.

A little before the axillaris reaches the axilla, it sends out the venæ thoracicæ, one of which is superior, called also *mammaria externa*, and the other inferior. It likewise sends rami to the musculus subcapularis, teres major, teres minor, supra-spinatus, latissimus dorsi, serratus major, pectoralis minor, pectoralis major, and to the glands of the axilla.

The axillaris having reached the side of the head of the os humeri, produces a branch, named *vena cephalica*, and afterwards runs along the arm by the name of *vena basilica*.

The cephalic vein, which is a branch of the axillaris, at a small distance from its origin, joins the small cephalica, which runs down from the subclavia, or jugularis externa.

The great cephalica runs down between the tendons of the last mentioned muscles, and along the outer edge of the external portion of the biceps; communicating several times with the vena basilica, and sending small rami on each side, to the neighbouring muscles, fat and skin.

A little below the external condyle of the os humeri, it detaches a branch backward, which runs up between the musculus brachialis and the upper portion of the supinator longus, and afterwards bends back between the os humeri and anconæus externus, where it communicates with some branches of the basilica.

Having reached very near the fold of the arm, it is divided into two principal branches, one long, the other short. The long branch is named *radialis externa*, and the short one may be called *mediana cephalica*, to distinguish it from another mediana, which is a short branch of the basilica.

The external radial vein runs along the radius between the muscles and integuments, giving off branches towards both sides, which communicate with other branches of the same vein, and with some from the basilica.

The mediana cephalica runs down obliquely toward the middle of the fold of the arm, under the integuments, and over the tendon of the biceps, where it joins a short branch of the same kind from the basilica.

From this anastomosis, a considerable branch goes out, which runs down on the fore-arm, uniting on one side with the vena cephalica, and communicating on the other with the basilica, by several irregular areolæ. The name of *mediana* is given to this large branch, as well as to the two short ones, by the union of which it is formed.

From this union of the two lateral medianæ, and sometimes from the origin of the mediana media, a branch goes out, which runs down on the inside of the

fore-arm, opposite to the interosseous ligament, and is called *vena cubiti profunda*. It goes to the neighbouring muscles, and communicates with the other veins of the fore-arm. The mediana cephalica sometimes sends down a long branch, called *radialis interna*, which lies almost parallel to the radialis externa.

Afterwards the cephalica, having reached the extremity of the radius, is distributed, by numerous areolæ, almost in the same course with the radial artery.

A particular branch goes out from it, which runs more or less superficially between the thumb and metacarpus, by the name of *cephalica pollicis*. The areolæ furnish the interosseous muscles and integuments, and communicate with a small ramus from the basilica, called by the ancients *Salvatella*.

The basilic vein sends off first of all, under the head of the os humeri, a pretty large branch, which passes almost transversely round the neck of that bone, from within backward, and from behind outward, running upon the scapula, where it is ramified on the deltoïdes, and communicates with the venæ scapulares externæ. This branch may be named *vena sub-humeralis*, or articularis.

This articular vein sends down two principal branches, one of which runs along the inside of the bone, to which, and to the periosteum, it gives small veins. The other turns forward, toward the middle of the arm between the bone and the biceps, and communicates with the cephalica.

Below the neck of the os humeri, near the hollow of the axilla, and behind the tendon of the pectoralis major, the basilica sends out a considerable branch, which runs down on the side of the brachial artery, and furnishes the neighbouring muscles on both sides. This vein is named *profunda brachii*.

Immediately afterwards, the basilica detaches two or three small veins, which run down very closely joined to the brachial artery, surrounding it at different distances by small twigs which communicate with each other.

These small veins, which often arise from the profunda superior, communicate with the basilica and cephalica; and having reached the fold of the arm, they divide like the artery; and the same divisions are continued along the whole fore-arm.

Afterwards the basilica continues its course along the inside of the os humeri, between the muscles and integuments, forming many communications with the vena profunda and cephalica, and supplying the muscles and integuments.

Having reached the inner condyle, and having sent off obliquely, in the fold of the arm, the mediana basilica, it runs along the ulna, between the integuments and muscles, a little toward the outside, by the name of *cubitalis externa*.

The basilica having at length reached the extremity of the ulna, sends several branches to the convex side of the carpus; one of which, named *Salvatella*, goes to that side of the little finger next the ring finger, having first communicated with the cephalica, by means of the venal areolæ conspicuous on the back of the hand. In the other fingers this vein follows nearly the same course with the arteries.

In general, the external or superficial veins of the forearm are larger than the internal.

The inferior *VENA CAVA* having run down about a quarter of an inch from the right auricle of the heart, within the pericardium, pierces that membrane and the tendinous portion of the diaphragm.

At this place it gives off the *venæ diaphragmaticæ*, or *phrenicæ*, which are distributed to the diaphragm, and appear chiefly on its lower side, one towards the right hand, and one towards the left. The right vein is more backward and lower than the left. The left is distributed partly to the pericardium, and partly to the diaphragm; and sometimes they send rami to the *capsulæ renales*.

The inferior cava having perforated the diaphragm, passes through the posterior part of the great fissure of the liver, penetrating a little into the substance of that viscus, between the great lobe and the lobulus *Spigelii*.

In its passage, it sends off commonly three large branches, called *venæ hepaticæ*, which are ramified in the liver.

Besides these large branches, it sends out some other small ones, either before or immediately after it goes out of the liver.

In the fœtus, as the *vena cava* passes by the liver, it gives off the *ductus venosus*, which communicates with the sinus of the *vena portæ*; and in adults is changed to a flat ligament.

After its passage through the liver, the *vena cava* turns from before backward, and from right to left, toward the *spina dorsæ*, placing itself on the right side of the aorta, which it accompanies from thence downward.

Having got as low as the *arteriæ renales*, it gives off the veins of the same name, termed formerly *venæ emulgentes*.

The right renal runs down a little obliquely, because of the situation of the kidney. The left vein crosses on the fore-side of the trunk of the aorta, immediately above the superior mesenteric artery.

They send up the *venæ capsulares*, which go to the *glandulæ renales*, and downward; the *venæ adiposæ*, which go to the fatty covering of the kidneys; and ordinarily the left renal vein furnishes the left spermatic vein. Afterwards they run to the sinus, or cavity of the kidneys, in the substance of which they are distributed by numerous ramifications.

A little below the renal veins, the trunk of the cava sends out anteriorly, toward the right side, the right *vena spermatica*. The left spermatic vein comes commonly from the left renalis.

In their passage, they send several small branches on each side, to the peritonæum and mesentery, where they seem to be joined by anastomoses with the *venæ mesaraicæ*.

The cava sends likewise off posteriorly the *venæ lumbares*, which commonly arise in pairs. These may be divided into superior and inferior veins.

Their origins vary in different manners. Sometimes the cava gives off a branch to each side below the first vertebra of the loins, which, like a common trunk, furnishes the lumbar veins. This branch communicates with the *azygos*.

Sometimes a considerable branch goes out from the lower extremity of the cava, near the bifurcation, chiefly on the right side, which afterwards running up between the bodies and transverse apophyses of the vertebrae, detaches the *venæ lumbares*, and communicates with the *azygos*.

Sometimes a like branch comes from the beginning of the left *vena iliaca*, and, running up on that side in the same manner, produces the lumbares.

The *venæ lumbares* on one side communicate by transverse branches with those of the other side, and likewise with each other by branches more or less longitudinal. The first and second often go from the *azygos*, and thereby they communicate with the intercostal veins.

The lumbar veins send small capillaries, in their passage, to the substance of the bodies of the vertebrae; and they are distributed to the muscles of the abdomen, *quadratus lumborum*, *psoas*, *iliacus*, &c. They send branches backward to the neighbouring vertebral muscles, and to the canal of the spine, and communicate with the venal sinuses.

The inferior cava, having reached as low as the last vertebra of the loins, and near the bifurcation of the aorta, runs in behind the right iliac artery, and there is divided into two subaltern trunks, called the *right and left iliac veins*.

From this bifurcation of the *vena cava*, the *vena sacra* goes out, and accompanies the artery of the same name in its distribution to the os sacrum, to the nerves which lie there, and to the membranes which cover both sides of that bone.

Each original iliac vein is divided on the side of the os sacrum, much after the same manner as the arteries, into two large trunks.

One of these trunks is named *vena iliaca externa* or *anterior*; the other *interna* or *posterior*.

These veins follow nearly the course and distribution of the iliac arteries, except that the hypogastric vein does not send off the *vena umbilicalis*.

From the common trunk of the iliac veins, and sometimes from the origin of the *iliaca externa*, a particular branch goes out, which is distributed to the *musculus psoas*, *iliacus*, and *quadratus lumborum*; and afterwards sends a ramus on the fore-side of the last transverse apophysis of the loins, to communicate with the last lumbar vein.

The external iliac, a little before it leaves the abdomen, near the ligamentum Fallopii, lying on the *psoas* and iliac muscles, gives off almost the same branches with the artery of the same name, and follows the same course. The chief branches are these:

A little before it goes out of the abdomen, it sends off from the outside, a small branch, which runs up along the crista of the os ilium, and gives branches on each side to the lateral and posterior lower portions of the *musculi abdominis*, to the *musculus iliacus*, &c.

From the inside, before it leaves the abdomen, it sends off the *vena epigastrica*; which having furnished some small rami to the neighbouring conglobated glands, runs up along the inside of the *musculi recti*, on which it is ramified both ways.

Afterwards

Afterwards the vena epigastrica runs upward, and joins the ramifications of the mammae.

Before the iliac vein gets from under the ligamentum Fallopii, it sends several small rami to the neighbouring lymphatic glands; and immediately afterwards, losing the name of iliacæ, it takes that of *cruralis*.

The hypogastric, or internal iliac vein, runs behind the iliac artery, from which the following branches go out.

From the posterior or convex part of the arch, it gives a branch to the superior lateral part of the os sacrum, which is distributed to the musculus facer, or tranverso-spinalis lumborum, and other muscles thereabouts, and to the cavity of the bone, which it enters through the first great hole.

A little lower, on the same side, it sends out another, which is distributed much in the same manner with the former, and enters the second hole.

From the external lateral part of the same arch, a little anteriorly, it sends out a large branch, which runs behind the great sciatic sinus, and is distributed to the musculi glutæi, pyriformis, and gemelli.

Lower down, the same lateral part of the hypogastric vein gives out another large branch, called *obturatrix*; which, having run a little way, detaches several rami, and afterwards reaching the foramen ovale of the os innominatum, perforates the obturator muscles, communicates with the vena cruralis, and is distributed to the musculus pectineus, triceps, and neighbouring parts.

Among the branches sent off by the vena obturatrix, before it perforates the muscles, one is situated exteriorly, which runs toward the sciatic sinus, to the musculus iliacus, the superior part of the obturator internus, and to the os ilium.

Interiorly, the same obturator vein sends off another branch, which is distributed to the ureters, bladder, and internal parts of generation in both sexes.

Lastly, the hypogastric vein runs backward, and goes out of the pelvis, above the ligament which lies between the inferior lateral part of the os sacrum and spine of the ischium.

It next sends a large branch upward to the lower part of the os sacrum, and two or more downward; which, running behind the same ligament, are distributed to the buttocks, anus, neighbouring portion of the musculus pectineus, and to the external parts of generation.

The veins that go to the anus, are termed *hæmorrhoidales externæ*; they that go to the parts of generation, *pubicæ internæ*. The external hæmorrhoidales communicate with the internal veins of the same name, which come from the small vena mesaraica.

The crural vein goes out under the ligamentum Fallopii, on the inside of the crural artery, and immediately gives small branches to the inguinal glands, the musculus pectineus, and parts of generation. These last are termed *pubicæ externæ*, and evidently communicate with the internal veins of the same name.

About an inch below, where it leaves the abdomen, the crural vein produces a large branch, which runs down anteriorly between the integuments and the fartorius,

following the direction of that muscle almost all the way to the inside of the thigh.

This branch having afterwards got beyond the condyles of the os femoris, runs down between the integuments and inner angle of the tibia, to the fore-part of the inner ankle, and is distributed to the foot. All this large branch is named *vena saphena*, or *saphena major*.

After the origin of the saphena, as the trunk of the crural veins runs down, it sinks in between the muscles, and is distributed to all the inner or deep parts of the lower extremity, accompanying the crural artery to the very extremity of the foot.

As the saphena is a vein of very large extent, we shall here describe it altogether, and afterwards return to the vena cruralis.

The vena saphena, in its passage from the inguen to the foot, is covered only by the skin and fat. Immediately after its rise, it gives small veins to the inferior inguinal glands; and then it gives out others more anteriorly, which, running under the integuments, communicate with each other by numerous areolæ.

The saphena, having run down on the thigh, as low as the middle of the fartorius, sends off to the same side several branches, which communicate with each other, and with the superior branches.

Between these upper and lower branches, the saphena sends backward a particular branch; which, after being distributed to the integuments which cover the gracilis internus and triceps, turns backward; and a little below the ham, runs in among the muscles situated there, and communicates with another branch, which may be termed *saphena minor*.

Afterwards the trunk of the great saphena runs down on the inside of the tibia, lying always near the skin; and at the upper part of that bone it sends branches forward, outward, and backward.

The anterior branches go to the integuments on the upper part of the leg; the posterior, to those which cover the gastrocnemii, and communicate with the little saphena; and the external branches are likewise distributed to the fat and integuments, and having reached as low as the middle of the tibia, it sends a communicating branch to the trunk of the great saphena.

From this communication, a branch goes out anteriorly, which runs along the integuments of the tibia all the way to the outer ankle.

As the saphena runs down on the inside of the tibia, it sends out a branch near the middle of that bone, which runs up behind the tendons of the fartorius, gracilis internus, and semi-nervosus, then between the tibia and upper end of the soleus, and is joined by an anastomosis with the crural vein.

At the lower part of the tibia, the saphena produces a considerable branch, which runs obliquely forward over the joint of the tarsus toward the outer ankle, sending off several rami which communicate with each other, and with the trunk of the saphena.

The extremity of this trunk passes on the fore-side of the inner ankle, and runs irregularly under the skin, along

long the interstice between the first two metatarsal bones toward the great toe, where this vein terminates.

The crural vein, having sent off the saphena, and the small branches for the pectineus, &c. as has been said, runs down on the thigh behind the crural artery. Opposite to the little trochanter, it produces two large short branches, or one which afterwards divides into two, whereof one is anterior, the other posterior.

The anterior branch runs more or less transversely forward, to be distributed to the vastus internus, lower part of the pectineus, and of the second triceps, and to the other two muscles of the same name, running in between them as it goes from one to another.

The posterior branch runs more or less transversely backward, and furnishes the glutæi, vastus externus, and beginning of the biceps.

A little below these two branches, about the upper extremity of the vastus internus, the crural vein produces a branch which runs down on the side of the trunk, covering the crural artery, almost as low as the ham, where it is again united to the trunk by an anastomosis. It has the name of *vena sciatica*, from the sciatic nerve which it accompanies.

On the outside of this anastomosis, the crural vein gives off a branch which runs backward between the biceps and neighbouring muscles, and so downward on the backside of the leg a little exteriorly, and very near the skin, all the way to the outer ankle. This vein is termed *saphena minor*, or *externa*.

The little saphena, having got near the integuments in its course downward, gives out a branch which runs backward, and communicates with the great saphena about the middle of the backside of the thigh.

Immediately above and below the ham, this vein sends out other branches, which likewise communicate with the saphena major, and, having run down about one third part of the backside of the tibia, it sends off another branch, which is afterwards re-united to the trunk.

About the beginning of the tendo-achillis, the little saphena runs outward in the integuments, toward the outer ankles, where it terminates in cutaneous ramifications sent to every side.

The crural vein, having detached the little saphena, runs down between the biceps and the other flexors of the leg, closely accompanied by the crural artery, between which and the inner condyle of the os femoris it is situated.

A little above the ham, it takes the name of *vena poplitea*; and as it runs down betwixt the two condyles, it gives branches to the flexor muscles, to the lower and posterior parts of both vasti, and to the fat which lies above the interstices of the two condyles.

It likewise gives off several other branches, one of which runs up laterally between the outer condyle and the biceps, and then turning forward, is ramified in the same manner with the artery.

The vena poplitea runs down immediately behind the muscle of the same name, at the lower part of which it sends off several ramifications to each side, which divide and unite again in different ways; and afterwards it loses its name, being divided into three considerable

branches, called *tibialis anterior*, *tibialis posterior*, and *peronæa*.

The anterior tibial vein, having distributed some small branches from its very beginning to the muscles behind the heads of the two bones of the leg, perforates the interosseous ligament from behind, forward, and runs between the superior portions of the musculus tibialis anticus, and extensor digitorum communis.

As soon as it pierces the interosseous ligament, it distributes small superficial branches to the head of the tibia and fibula, which run to the joint of the knee, and communicate with the lateral branches of the vena poplitea.

Afterwards it divides into two or three branches, which run down together on the fore-side of the interosseous ligament in company with the anterior tibial artery, which they surround at different distances, by small communicating circles.

These branches having reached the lower extremity of the leg, unite in one, which afterwards divides into several, the ramifications of which are distributed to the foot.

The posterior tibial vein gives off, from its beginning, a branch toward the inside, which is distributed to the gastrocnemii and soleus. This vein is named *suralis*.

Afterwards the posterior tibialis runs down between the soleus and tibialis posticus, giving branches to each of them. It is divided in the same manner as the tibialis anterior, into two or three branches, which, as they run, surround the corresponding artery, by small communicating circles formed at different distances.

It continues this course in company with the artery as low as the outer ankle, furnishing the musculus tibialis posticus, and the long flexors of the toes.

Lastly, it passes on the inside of the os calcis, under the sole of the foot, where it forms the *venæ plantares*, by dividing into several transverse arches, which communicate with each other, and with the saphena, and send ramifications to the toes.

The vena peronæa is likewise double, and sometimes triple. It runs down on the inside of the fibula, which it likewise surrounds at different distances, by communicating branches, after the manner of the tibialis posterior.

It runs down as low as the outer ankle, communicating several times with the tibialis posterior, and sending ramifications to the neighbouring portions of the musculus peronæi, and long flexors of the toes.

The vena portæ is a large vein, the trunk of which is situated chiefly between the eminencies on the lower or concave side of the liver.

It may be considered as made up of two large veins, joined almost endwise by their trunks, from each of which the branches and ramifications go out in opposite directions. One of these trunks adheres to the liver, and is ramified in that viscus, its branches accompanying the whole distribution of the hepatic artery.

The other trunk is without the liver, and sends its branches to the viscera, supplied by the rest of the arteria cæliaca, and by the two mesentericæ, that is, to the stomach, intestines, pancreas, spleen, mesentery, and omentum.

The first portion of this vein may be termed *vena*  
*portæ*

*portæ hepatica, superior* or *minor*, the trunk of which is commonly known by the name of *sinus vena portarum*. The other portion may be called *vena portæ ventralis, inferior* or *major*.

The large trunk of the vena portæ inferior, or ventralis, is situated under the lower or concave side of the liver, and joined by an anastomosis to the sinus of the vena portæ hepatica, between the middle and right extremity of that sinus. From thence it runs down a little obliquely from right to left, behind or under the trunk of the arteria hepatica, bending behind the beginning of the duodenum, and under the head of the pancreas.

Having reached to the head of the pancreas, this trunk loses the general name of *vena portæ*, and terminates in three large principal branches, which are distributed, by numerous ramifications, to the viscera already named. The first branch is termed *vena mesaraica, or mesaraica major*; the second, *splénica*; and the third, *hæmorrhoidalis interna, or mesaraica minor*.

The vena mesaraica major appears to be a continuation of the trunk of the vena portæ inferior. The splénica is a capital branch of that trunk; and the hæmorrhoidalis interna has sometimes a common origin with the splénica.

The inferior vena portæ, before the formation of these three branches, sends off from the trunk several small rami, which are commonly the venæ cysticæ, hepatica minor, pylorica, duodenalis, and sometimes the galtrica recta, and coronaria ventriculi.

All these small veins sometimes arise separately; and, in other subjects, some of them go out by small common trunks.

The cystic veins run along the vesicula fellis, from its neck to the bottom; and as they are often no more than two in number, they are called *cysticæ gemellæ*.

The small hepatic vein is commonly a branch of one of the cysticæ.

The vena pylorica arises from the great trunk, almost opposite to the origin of the cysticæ; and sometimes is only a branch of the right galtrica. It passes over the pylorus to the short arch of the stomach, where it is joined, by anastomosis, with the coronaria ventriculi.

The duodenal vein, commonly called *vena intestinalis*, goes out from the great trunk near the cysticæ, and sometimes from the small common trunk of these veins. It is distributed chiefly to the intestinum duodenum, and sends likewise some rami to the pancreas.

The inferior vena portæ, having given off the splénica, changes its name to that of *mesaraica, or mesaraica major*; which often appears to be rather a continuation of the trunk, than of one of the great branches.

It bends toward the superior mesenteric artery, sending off two veins, and afterwards running up over that artery, it accompanies it in those portions of the mesentery and mesocolon which belong to the small intestines, the cæcum, and right portion of the colon.

The first particular branch from this trunk is called *vena colica*. It goes out from the anterior part of the trunk, before it joins the artery, and runs directly to the middle of the colon, where it divides to the right and left, and forms arches. On the left hand, it communicates

with the superior or ascending branch of the hæmorrhoidalis; and on the right, with the second branch of the mesaraica.

This second branch is a little under the first, or colica anterior, and something more towards the right hand. It may be named *gastro-colica*, and is soon divided into two branches, one superior, the other inferior.

The superior branch of the vena gastro-colica sends small veins to the head of the pancreas, and forms the vena galtrica, or gastro-epiploica dextra, which goes from the pylorus to the great curvature of the stomach, and communicates with the galtrica sinistra. In its passage it supplies the stomach and omentum, and communicates with the pylorica, coronaria ventriculi, &c.

The inferior branch of the vena gastro-colica, which may be called *colica dextra*, goes to the right portion of the colon; and from thence to the upper part of the intestine, where it is divided archwise, and communicates with the right branch of the colica anterior, and with a branch of the vena cæcalis.

The trunk of the great mesaraic vein sends out sometimes, opposite to the galtrica, a particular branch to the omentum, called *epiploica dextra*. But almost immediately before it ascends over the mesenteric artery, it produces two large branches very near each other, which pass behind and under the artery, being distributed to the jejunum and part of the ilium by numerous ramifications.

Afterwards the trunk of the mesaraic passes over the superior mesenteric artery, to which it adheres very closely, and from the convex side of its arch sends out several branches, almost in the same manner with the artery.

From the concave side of the mesaraic vein, a little below the origin of the second branch, from the convex side, arises a branch, called *vena cæcalis*, which runs to the beginning of the colon, crossing one of the branches of the superior mesenteric artery.

This caecal vein divides by two arches, the uppermost of which communicates with the lower branch of the vena gastro-colica; the other, after having sent ramifications to the intestinum cæcum and appendicula vermiformis, communicates below with the extremity of the great mesaraic vein.

The splenic vein is one of the three great branches of the vena portæ. It runs transversely from the right to the left, first under the duodenum, and then along the lower side of the pancreas.

In this course it gives off several veins, viz. the vena coronaria ventriculi, pancreaticæ, galtrica, or gastro-epiploica sinistra, and epiploica sinistra. It likewise often gives origin to the hæmorrhoidalis interna, the third capital branch of the vena portæ.

It terminates afterwards by a winding course, being divided into several branches that go to the spleen; one of which produces the small veins called, by the ancients, *vassæ brevissimæ*.

The coronaria ventriculi runs along the small arch of that viscus toward the pylorus, where it joins and becomes continuous with the vena pylorica. In its passage, it gives several rami to the sides of the stomach.

The venæ pancreaticæ are several small branches

sent by the splenica to the pancreas, along its lower side.

The left gastric, or gastro-epiploic vein, goes out from the splenica, at the left extremity of the pancreas; from whence it runs to the great extremity of the stomach, and along the great arch, till it meets the gastrica dextra, which is continuous with the sinistra.

In its passage, it gives several branches to both sides of the stomach, which are distributed by numerous ramifications, form many arcolæ, and communicate with the branches of the coronaria ventriculi.

At a small distance from its origin, this gastric vein sends out a branch, which is distributed to the omentum; and on this account it has been called *gastro-epiploica*.

The vena epiploica sinistra arises at the small extremity of the pancreas, and is ramified on the omentum, all the way to the colon, where it communicates with the hæmorrhoidalis interna.

Lastly, the vena splenica reaches the fissure of the spleen, which it enters through its whole length by several branches. It is from the most posterior of these branches that the veins are sent off to the great extremity of the stomach, formerly known by the name of *vasa brevia*, which communicate with the coronaria ventriculi and gastrica sinistra.

The internal hæmorrhoidal vein is one of the three great branches of the vena portæ, coming ordinarily from the beginning of the vena splenica, and sometimes from the extremity or angle of the bifurcation of the great trunk of the vena portæ.

At a small distance from its beginning, it gives to the duodenum a second vena duodenalis.

Afterwards it is divided into two branches, one superior or ascending, the other inferior or descending. The first runs to the upper part of the arch of the colon, where, after many ramifications, it communicates with a branch of the great mesarica, with the ramifications of the gastro-epiploica sinistra, and with those of the neighbouring epiploica.

The inferior branch runs down on the left portion of the colon, on the lower incurvations of that intestine, and on the rectum, all the way to the anus. In this course, it supplies the mesocolon, and forms arches, which send out numerous small ramifications, which surround these intestines.

This vein has been named *hæmorrhoidalis*, from the tumours often found at its extremity next the anus, which are called *hæmorrhoides*. The word *interna* is added, to distinguish this vein from the hæmorrhoidalis externa, which comes from the vena hypogastrica, and with which this vein communicates by capillary ramifications.

## EXPLANATION OF PLATE XVII.

This plate represents the heart in situ, all the large arteries and veins, with some of the mufcles, &c.

**MUSCLES.**—SUPERIOR EXTREMITY.—a, Mafleter. b, Complexus. c, Diaphragmaticus. d, Os hyoides. e, Thyroid gland. f, Levator fcapulæ. g, Cucularis. h h, The clavicles cut. i, The deltoid mufcle. k, Biceps flexor cubiti cut. l, Coraco-brachialis. m, Triceps extensor cubiti. n, The heads of the pronator teres, flexor carpi radialis, and flexor digitorum fublimis, cut. o, The flexor carpi ulnaris, cut at its extremity. p, Flexor digitorum profundus. q, Supinator radii longus, cut at its extremity. r, Ligamentum carpi tranfverfale. s, Extensores carpi radiales. t, Latiffimus dorfii. u, Anterior edge of the ferratus anticus major. v, v, The inferior part of the diaphragm. w w, Its anterior edge cut. x x, The kidneys. y, Tranfverfus abdominis. z, Os ilium.

**INFERIOR EXTREMITY.**—a, Pfoas magnus. b, Iliacus internus. c, The fleshy origin of the tenor vaginæ femoris. d d, The offa pubis cut from each other. e, Mufculus pectineus cut from its origin. f, Short head of the triceps adductor femoris cut. g, The great head of the triceps. h, The long head cut. i, Vastus internus. k, Vastus externus. l, Crureus. m, Gemellus. n, Soleus. o, Tibia. p, Peroneus longus. q, Peroneus brevis. r, Fibula.

**HEART and BLOOD-VESSELS.**—A, The heart, with the coronary arteries and veins. B, The right auricle of the heart. C, The aorta afcendens. D, The left fubclavian artery. E, The left carotid artery. F, The common trunk which fends off the

right fubclavian and right carotid arteries. G, The carotis externa. H, Arteria facialis, which fends off the coronary arteries of the lips. I, Arteria temporalis profunda. K, Aorta defcendens. L L, The iliac arteries,—which fend off M M, The femoral or crural arteries. N. B. The other arteries in this figure have the fame diftribution as the veins of the fame name.—And generally, in the anatomical plates, the difcription to be found on the one fide, points out the fame parts in the other. 1, The frontal vein. 2, The facial vein. 3, Vena temporalis profunda. 4, Vena occipitalis. 5, Vena jugularis externa. 6, Vena jugularis interna, covering the arteria carotis communis. 7, The vafcular arch on the palm of the hand, which is formed by 8, the radial artery and vein, and 9, the ulnar artery and vein. 10 10, Cephalic vein. 11, Basilic vein, that on the right fide, cut. 12, Median vein. 13, The humeral vein, which, with the median, covers the humeral artery. 14 14, The external thoracic, or mammary arteries and veins. 15, The axillary vein, covering the artery. 16 16, The fubclavian veins, which, with (6 6) the jugulars, forms 17, the vena cava fuperior. 18, The cutaneous arch of veins on the fore-part of the foot. 19, The vena tibialis antica, covering the artery. 20, The vena profunda femoris, covering the artery. 21, The upper part of the vena fapientia major. 22, The femoral vein. 23 23, The iliac veins. 24, 24, Vena cava inferior. 25 25, The renal veins covering the arteries. 26 26, The diaphragmatic veins.

## P A R T V.

## O F T H E N E R V E S.

SECT. I. *Of the NERVES in general.*

THE medullary substance of the brain is employed in forming the white fibrous cords, which are called *nerves*. Within the skull we see the nerves to be the medullary substance continued; and the spinal marrow is all employed in forming nerves.

The nerves are composed of a great many threads, lying parallel to each other, or nearly so, at their exit from the medulla.

This fibrous texture is evident at the origin of most of the nerves within the skull; and in the cauda equina of the spinal marrow we can divide them into such small threads, that a very good eye can scarce perceive them; but these threads, when looked at with a microscope, appear each to be composed of a great number of smaller threads.

How small one of these fibrils of the nerves is, we know not; but when we consider that every, even the most minute part of the body is sensible, and that this must depend on the nerves, (which all conjoined would not make a cord of an inch diameter), being divided into branches or filaments to be dispersed through all these minute parts, we must be convinced, that the nervous fibrils are very small.

The medullary substance, of which the nervous fibrils are composed, is very tender, and would not be able to resist such forces as the nerves are exposed to within the bones, nor even the common force of the circulating fluids, were not the pia mater and tunica arachnoidea continued upon them; the former giving them firmness and strength, and the latter furnishing a cellular coat to connect the threads of the nerves, to let them lie soft and moist, and to support the vessels which go with them.

It is this cellular substance that is distended when air is forced through a blow-pipe thrust into a nerve, and that makes a nerve appear all spongy, after being distended with air till it dries; the proper nervous fibrils shrivelling so in drying, that they scarce can be observed.

These coats would not make the nerves strong enough to bear the stretching and pressure they are exposed to in their course to the different parts of the body; and therefore, where the nerves go out at the holes in the cranium and spine, the dura mater is generally wrapt closely round them, to collect their disgregated fibres into tight firm cords; and that the tension which they may happen to be exposed to may not injure them before they have got

this additional coat, it is firmly fixed to the sides of the holes in the bones through which they pass.

The nervous cords, thus composed of nervous fibrils, cellular coat, pia and dura mater, have such numerous blood-vessels, that, after their arteries only are injected, the whole cord is tinged of the colour of the injected liquor.

A nervous cord has very little elasticity, compared with several other parts of the body. When cut out of the body, it does not become observably shorter, while the blood-vessels contract three eighths of their length.

Nerves are generally lodged in a cellular or fatty substance, and have their course in the interstices of muscles, where they are guarded from pressure; but in several parts they are so placed, as if it was intended that they should there suffer the vibrating force of arteries, or the pressure of the contracting fibres of muscles.

The larger cords of the nerves divide into branches as they go off to the different parts; the branches being smaller than the trunk from which they come, and making generally an acute angle where they separate.

In several places, different nerves unite into one cord, which is commonly larger than any of the nerves which form it. Several nerves, particularly those which are distributed to the bowels, after such union, suddenly form a hard knot considerably larger than all the nerves of which it is made. These knots were formerly called *corpora olivaria*, and are now generally named *ganglions*.

The ganglions have thicker coats, more numerous and larger blood-vessels than the nerves; so that they appear more red and muscular.

Commonly numerous small nerves, which conjointly are not equal to the size of the ganglion, are sent out from it, but with a structure no way different from that of other nerves.

The nerves sent to the organs of the senses, lose there their firm coats, and terminate in a pulpy substance. The optic nerves are expanded into the soft tender webs, the retinae. The auditory nerve has scarce the consistence of mucus in the vestibulum, cochlea, and semicircular canals of each ear. The papillæ of the nose, tongue, and skin, are very soft.

The nerves of muscles can likewise be traced till they seem to lose their coats by becoming very soft; from which, and what we observed of the sensory nerves, there is reason to conclude, that the muscular nerves are also pulpy at their terminations, which we cannot indeed prosecute by dissection.

SECT. II. *Of the particular NERVES.*

It is generally said, that there are forty pair of nerves in all; of which ten come out from the encephalon, and the other thirty have their origin from the spinal marrow.

Of the ten pair of nerves which come from the encephalon, the *first* is the OLFACTORY, which have their origin from the corpora striata, near the part where the internal carotid arteries are about to send off their branches to the different parts of the brain; and in their course under the anterior lobes of the brain, which have each a depression made for lodging them, become larger, till they are extended to the cribriform bone; where they split into a great number of small filaments, to pass through the little holes in that bone; and being joined by a branch of the fifth pair of nerves, are spread on the membrane of the nose.

The tender structure and sudden expansion of these nerves on such a large surface, render it impossible to trace them far; which has made some authors deny them to be nerves: But when we break the circumference of the cribriform lamella, and then gently raise it, we may see the distribution of the nerves some way on the membrane of the nose.

The contrivance of defending these long soft nerves from being too much pressed by the anterior lobes of the brain under which they lie, is singular; because they have not only the prominent orbital processes of the frontal bone to support the brain on each side, with the veins going into the longitudinal sinus, and other attachments bearing it up, but there is a groove formed in each lobe of the brain itself for them to lodge in.—Their splitting into so many small branches before they enter the bones of the skull, is likewise peculiar to them; for generally the nerves come from the brain in disgregated filaments, and unite into cords, as they are going out at the holes of the bones. This contrivance is the best for answering the purpose they are designed for, of being the organ of smelling; for had they been expanded upon the membrane of the nose into a medullary web, such as the optic nerve forms, it would have been too sensible to bear the impressions of such objects—as are applied to the nose; and a distribution in the more common way, of a cord sending off branches, would not have been equal enough for such an organ of sensation.

The *second* pair of nerves, the OPTIC, rising from the thalami nervorum opticorum, make a large curve outwards, and then run obliquely inwards and forwards, till they unite at the fore-part of the sella turcica; then soon divide, and each runs obliquely forwards and outwards to go out at its proper hole in the sphenoid bone, accompanied with the ocular artery, to be extended to the globe of the eye, within which each is expanded into a very fine cuplike web, that lines all the inside of the eye as far forwards as the ciliary circle, and is universally known by the name of RETINA.

Though the substance of this pair of nerves seems to be blended at the place where they are joined; yet observations of people whose optic nerves were not joined, and of others who were blind of one eye from a fault in

the optic nerve, or in those who had one of their eyes taken out, make it appear, that there is no such intimate union of substance; the optic nerve of the affected side only being wasted, while the other was large and plump. And the same observations are contradictory to the doctrine of a decussation of all the nerves, for the disease could be traced from the affected eye to the origin of the nerve on the same side.

These people whose optic nerves were not joined, having neither seen objects double, nor turned their eyes different ways, is also a plain proof, that the conjunction of the optic nerves will not serve to account for either the uniform motions of our eyes, or our seeing objects single with two eyes.

The retina of a recent eye, without any preparation, appears a very fine web, with some blood-vessels coming from its center to be distributed on it; but, after a good injection of the arteries that run in the substance of this nerve, as is common to other nerves, it is with difficulty that we can observe its nervous medullary substance.—The situation of these vessels in the central part of the optic nerve, the want of medullary fibres here, and the firmness of this nerve before it is expanded at its entry into the ball of the eye, may be the reason why we do not see such bodies, or parts of bodies, whose picture falls on this central part of the retina.

The *THIRD PAIR* rise from the anterior part of the processus annularis, and piercing the dura mater a little before, and to a side of the ends of the posterior clinoid process of the sphenoid bone, run along the receptacula, or cavernous sinuses, at the side of the epiphium, to get out at the foramina lacerata; after which each of them divides into branches, of which one, after forming a little ganglion, is distributed to the globe of the eye; the others are sent to the musculus rectus of the palpebra, and to the atollens, adductor, deprimens, and obliquus minor muscles of the eye-ball. These muscles being principal instruments in the motions of the eye-lid and eye-ball, this nerve has therefore got the name of MOTOR OCULI.

The *FOURTH PAIR*, which are the smallest nerves of all, derive their origin from the back-part of the base of the testes; and then making a long course on the side of the annular protuberance enter the dura mater a little farther back, and more externally than the third part, to run also along the receptacula, to pass out at the foramina lacerata, and to be entirely spent on the musculi trochleares, or superior oblique muscles of the eyes. These muscles being employed in performing the rotatory motions, and the advancement of the eye-balls forward, by which several of our passions are expressed, the nerves that serve them have got the name of PAINETICI.

The *FIFTH PAIR* are large nerves, rising from the annular processes where the medullary processes of the cerebellum join in the formation of that tuber, to enter the dura mater near the point of the petrous process of the temporal bones; and then sinking close by the receptacula at the sides of the sella turcica, each becomes in appearance thicker, and goes out of the skull in three great branches.

The *first* branch of the *first* is the OPTHALMIC, which runs through the foramen lacerum, to the orbit, having

having in its passage thither a connection with the sixth pair. It is afterwards distributed to the ball of the eye with the third; to the nose, along with the olfactory, which the branch of the fifth that passes through the foramen orbitarium internum joins, as was already mentioned in the description of the first pair. This ophthalmic branch likewise supplies the parts at the internal canthus of the orbit, the glandula lacrymalis, fat, membranes, muscles, and teguments of the eye-lids; its longest farthest extended branch passing through the foramen superciliale of the os frontis, to be distributed to the forehead.

The second branch of the fifth pair of nerves may be called *MAXILLARIS SUPERIOR*, from its serving principally the parts of the upper jaw. It goes out at the round hole of the sphenoid bone, and sends immediately one branch into the channel on the top of the antrum maxillare; the membrane of which and the upper teeth are supplied by it in its passage. As this branch is about to go out at the foramen orbitarium externum, it sends a nerve through the substance of the os maxillare to come out at Steno's duct, to be distributed to the fore-part of the palate; and what remains of it escaping at the external orbital hole, divides into a great many branches, that supply the cheek, upper lip, and nostril. The next considerable branch of the superior maxillary nerve, after giving branches which are reflected through the sixth hole of the sphenoid bone, to join the intercostal where it is passing through the skull with the carotid artery, and the portio dura of the seventh pair, as it passes through the os petrosum, is sent into the nose by the hole common to the palate and sphenoidal bone; and the remaining part of this nerve runs in the palato-maxillary canal, giving off branches to the temples and pterygoid muscles, and comes at last into the palate to be lost.

The third or *MAXILLARIS INFERIOR* branch of the fifth pair going out at the oval hole of the sphenoid bone, serves the muscles of the lower jaw, and the muscles situated between the os hyoides and jaw: All the salivary glands, the amygdalæ, and the external ear, have branches from it: It has a large branch lost in the tongue, and sends another through the canal in the substance of the lower jaw to serve all the teeth there, and to come out at the hole in the fore-part of the jaw, to be lost in the chin and under lip.

The *SIXTH PAIR*, which is the smallest except the fourth, rises from the fore-part of the corpora pyramidalia; and each entering the dura mater some way behind the posterior clinoid process of the sphenoid bone, has a long course below that membrane, and within the receptaculum at the side of the sella turcica, where it is immersed in the blood of the receptacle: It goes afterwards out at the foramen lacerum into the orbit, to serve the abductor muscle of the eye.—A defect in this nerve may therefore be one cause of a strabismus.—In the passage of this nerve below the dura mater, it lies very contiguous to the internal carotid artery, and to the ophthalmic branch of the fifth pair of nerves. At the place where the sixth pair is contiguous to the carotid, a nerve either goes from each of them in an uncommon way, to wit, with the angle beyond where it rises obtuse, to descend with the artery; and to form the beginning of the

intercostal nerve, according to the common description; or, according to other authors, this nerve comes up from the great ganglion of the intercostal, to be joined to the sixth here.

The *SEVENTH PAIR* comes out from the lateral part of the annular process behind where the medullary processes of the cerebellum are joined to that tuber; and each being accompanied with a larger artery than most other nerves, enters the internal meatus auditorius, where the two large bundles of fibres, of which it appeared to consist within the skull, soon separate from each other; one of them entering by several small holes into the vestibule, cochlea, and semicircular canals, is stretched on this inner camera of the ear in a very soft pulpy substance; and being never seen in the form of a firm cord, such as the other parcel of this and most other nerves become, is called *PORTIO MOLLI*s of the auditory nerve.

The other part of this seventh pair passes through Galen's foramen cæcum, or Fallopius's aqueduct, in its crooked passage by the side of the tympanum; in which passage, a nerve sent from the lingual branch of the inferior maxillary nerve, along the outside of the tuba Eustachiana, and crosses the cavity of the tympanum, where it has the name of chorda tympani, is commonly said to be joined to it. The very acute angle which this nerve makes with the fifth, or the sudden violent reflection it would suffer on the supposition of its coming from the fifth to the seventh, appears unusual; whereas, if we suppose that it comes from the seventh to the fifth, its course would be more in the ordinary way, and the chorda tympani would be esteemed a branch of the seventh pair going to join the fifth, the size of which is increased by this acquisition. This smaller bundle of the seventh gives branches to the muscles of the malleus, and to the dura mater, while it passes through the bony crooked canal; and at last comes out in a firm chord named *PORTIO DURA*, at the end of this canal, between the styloid and mastoid processes of the temporal bone, giving immediately filaments to the little oblique muscles of the head, and to those that rise from the styloid process. It then pierces through the parotid gland, and divides into a great many branches, which are dispersed in the muscles and teguments that cover all the side of the upper part of the neck, the whole face and cranium, as far back as the temples, including a considerable part of the external ear.

The *EIGHTH PAIR* of nerves rise from the lateral bases of the corpora olivaria in disgregated fibres; and as they are entering the anterior internal part of the holes common to the os occipitis and temporum, each is joined by a nerve which ascends within the dura mater from the tenth of the head, the first, second and inferior cervical nerves: This every body knows has the name of the *NERVUS ACCESSORIUS*. When the two get out of the skull, the accessorius separates from the eighth, and descending obliquely outwards, passes through the sterno-mastoid muscle, to which it gives branches, and afterwards terminates in the trapezius and rhomboid muscles of the scapula. In this course it is generally more or less joined by the second cervical nerve.

The large *EIGHTH PAIR*, soon after its exit, gives

nerves to the tongue, larynx, pharynx, and ganglion of the intercostal nerve, and being disjoined from the ninth and intercostal, to which it adheres closely some way, runs straight down the neck behind the internal jugular vein, and at the external side of the carotid artery. As it is about to enter the thorax, a large nerve goes off from the eighth of each side: This branch of the right-side turns round from the fore to the back part of the subclavian artery, while the branch of the left-side turns round the great curve of the aorta; and both of them mounting up again at the side of the œsophagus, to which they give branches, are lost at last in the larynx. These are called the *RECURRENT* nerves, which we are desired to shun in the operation of bronchotomy, though their deep situation protects them sufficiently.

The eighth pair, above, and at or near the place where the recurrent nerves go off from it, or frequently the recurrent themselves, send off small nerves to the pericardium, and to join with the branches of the intercostal that are distributed to the heart; but their size and situation are uncertain.

After these branches are sent off, the *par vagum* on each side descends behind the great branch of the trachea, and gives numerous filaments to the lungs, and some to the heart in going to the œsophagus. The one of the left-side running on the fore-part of the œsophagus, communicates by several branches with the right one in its descent to be distributed to the stomach: The right one gets behind the œsophagus, where it splits and rejoins several times before it arrives at the stomach, to which it sends nerves; and then being joined by one or more branches from the left trunk, they run towards the cœliac artery, there to join into the great semilunar ganglion formed by the two intercostals.

The *NINTH PAIR* of nerves comes from the inferior part of the corpora pyramidalia, to go out of the skull at their proper holes of the occipital bone. After their egress they adhere for some way firmly to the eighth and intercostal; and then sending a branch, that in many subjects is joined with branches of the first and second cervical nerves, to be distributed to the thyroid gland and muscles on the fore-part of the trachea arteria, the ninth is lost in the muscles and substance of the tongue.

The *TENTH PAIR* rises in separate threads from the sides of the spinal marrow, to go out between the os occipitis and first vertebra of the neck. After each of them has given branches to the great ganglion of the intercostal, 8th, 9th, and 1st cervical nerves, it is distributed to the straight, oblique, and some of the extensor muscles of the head.

The branch reflected from the sixth pair, joined possibly by some filaments of the ophthalmic branch of the fifth, runs along with the internal carotid artery, through the crooked canal formed for it in the temporal bone, where the little nerve is very soft and pappy, and in several subjects divides and unites again, and is joined by one or more branches from the fifth particularly of its superior maxillary branch, before it comes out of the skull. As soon as the nerve escapes out of this bony canal, it is connected a little way with the eighth and ninth; then separating from these, after seeming to receive addition-

al nerves from them, it forms a large ganglion, into which branches from the tenth of the head, and from the first and second cervical, enter. From this ganglion the nerves come out again small, to run down the neck along with the carotid artery, communicating by branches with the cervical nerves, and giving nerves to the muscles that bend the head and neck. As the intercostal is about to enter the thorax, it forms another ganglion, from which nerves are sent to the trachea and to the heart; these designed for the heart joining with the branches of the eighth, and most of them passing between the two great arteries and the auricles, to the substance of that muscle.

The intercostal after this consisting of two branches, one going behind, and the other running over the fore-part of the subclavian artery, forms a new ganglion where the two branches unite below that artery, and then descending along the sides of the vertebrae of the thorax, receives branches from each of the dorsal nerves; which branches appearing to come out between the ribs, have given the name of intercostal to the whole nerve. Where the addition is made to it from the fifth dorsal nerve, a branch goes off obliquely forwards; which being joined by such branches from the sixth, seventh, eighth, and ninth dorsal, an anterior trunk is formed, and passes between the fibres of the appendix musculoſa of the diaphragm, to form, along with the other intercostal and the branches of the eighth pair, a large semilunar ganglion situated between the cœliac and superior mesenteric arteries; the roots of which are as it were involved in a sort of nervous net-work of this ganglion, from which a great number of very small nervous threads run out to be extended on the surface of all the branches of those two arteries, so as to be easily seen when any of the arteries are stretched, but not to be raised from them by dissection; and thus the liver, gall-bladder, duodenum, pancreas, spleen, jejunum, ilium, and a large share of the colon, have their nerves sent from this great solar ganglion or plexus.

Several fibres of this ganglion, running down upon the aorta, meet with other nerves sent from the posterior trunk of the intercostal, which continues its course along the sides of the vertebra, they supply the glandulæ renales, kidneys, and testes in men, or ovaria in women; and then they form a net-work upon the inferior mesenteric artery where the nerves of the two sides meet, and accompany the branches of this artery to the part of the colon that lies in the left side of the belly, and to the rectum, as far down as to the lower part of the pelvis.

The intercostal continuing down by the side of the vertebrae of the loins, is joined by nerves coming from between these vertebrae, and sends nerves to the organs of generation and others in the pelvis, being even joined with those that are sent to the inferior extremities.

The *SPINAL NERVES* rise generally by a number of disgregated fibres from both the fore and back part of the medulla spinalis, and soon after form a little knot or ganglion, where they acquire strong coats, and are extended into firm cords. They are distinguished by numbers, according to the vertebrae from between which they come out; the superior of the two bones forming the hole through which they pass, being the one from which the  
number

number is applied to each nerve. There are generally said to be *thirty pair* of them; seven of which come out between the vertebræ of the neck, twelve between those of the back, five between those of the loins, and six from the false vertebræ.

The **FIRST CERVICAL** pair of nerves comes out between the first and second vertebræ of the neck; and having given branches to join with the tenth pair of the head, the second cervical and intercostal, and to serve the muscles that bend the neck, it sends its largest branches backwards to the extensor muscles of the head and neck; some of which piercing through these muscles, run up on the occiput to be lost in the teguments here; and many fibres of it advance so far forward as to be connected with the fibrils of the first branch of the fifth pair of the head, and of the portio dura of the auditory nerve.

The **SECOND CERVICAL** is soon joined, by some branches, to the ninth of the head and intercostal, and to the first and third of the neck; then has a large branch that comes out at the exterior edge of the sternomastoidæus muscle, where it joins with the accessorius of the eighth pair; and is afterwards distributed to the platysma myoides, teguments of the side of the neck and head, parotid gland, and external ear, being connected to the portio dura of the auditory nerve, and to the first cervical. The remainder of this second cervical is spent on the levator scapulæ and the extensors of the neck and head. Generally a large branch is here sent off to join the accessorius of the eighth pair, near the superior angle of the scapula.

The **THIRD PAIR** of the neck passes out between the third and fourth cervical vertebræ; having immediately a communication with the second, and sending down a branch, which being joined by a branch from the fourth cervical, forms the **PHRENIC** nerve. This descending, enters the thorax, between the subclavian vein and artery; and then being received into a groove, formed for it in the pericardium, it has its course along this capsula of the heart, till it is lost in the middle part of the diaphragm. The right phrenic has a straight course; but the left one is obliged to make a considerable turn outwards, to go over the prominent part of the pericardium, where the point of the heart is lodged.—The middle of the diaphragm scarce could have been supplied by any other nerve which could have had such a straight course as the phrenic has.

The other branches of the third cervical nerve are distributed to the muscles and teguments at the lower part of the neck and top of the shoulder.

The **FOURTH CERVICAL** nerve, after sending off that branch which joins with the third to form the phrenic, and bestowing twigs on the muscles and glands of the neck, runs to the arm-pit, where it meets with the **FIFTH, SIXTH, and SEVENTH** cervicals, and **FIRST DORSAL**, that escape in the interstices of the musculi scaleni, to come at the arm-pit, where they join, separate, and rejoin, in a way scarce to be rightly expressed in words; and, after giving several considerable nerves to the muscles and teguments which cover the thorax, they divide into several branches, to be distributed to all the

parts of the superior extremity. Seven of these branches we shall describe under particular names.

1. **SCAPULARIS** runs straight to the *cavitas femilunata* of the upper costa of the scapula, which is a hole, in the recent subject, by a ligament being extended from one angle of the bone to the other, giving nerves in its way to the muscles of the scapula. When it has passed this hole, it supplies the supra-spinatus muscle; and then descending at the anterior root of the spine of the scapula, it is lost in the other muscles that lie on the dorsum of that bone.

2. **ARTICULARIS** sinks downward at the axilla, to get below the neck of the head of the os humeri, and to mount again at the back-part of it; so that it almost surrounds the articulation, and is distributed to the muscles that draw the arm back, and to those that raise it up.

3. **CUTANEUS** runs down the fore-part of the arm, near the skin, to which it gives off branches; and then divides, on the inside of the fore-arm, into several nerves, which supply the teguments there, and on the palm of the hand.

4. **MUSCULO-CUTANEUS**, or *perforans Casseri*, passes through the coraco-brachialis muscle; and, after supplying the biceps flexor cubiti and brachiiæus internus, passes behind the tendon of the biceps, and over the cephalic vein, to be bestowed on the teguments on the outside of the fore-arm and back of the hand.

5. **MUSCULARIS** has a spiral course from the axilla, under the os humeri, and backward to the external part of that bone, supplying by the way the extensor muscles of the fore-arm, to which it runs between the two brachiiæus muscles, and within the supinator radii longus.—At the upper part of the fore-arm, it sends off a branch, which accompanies the supinator longus till it comes near the wrist, where it passes obliquely over the radius, to be lost in the back of the hand and fingers. The principal part of this nerve pierces through the supinator radii brevis, to serve the muscles that extend the hand and fingers, whose actions are not injured when the supinator acts.

6. **ULNARIS** is extended along the inside of the arm, to give nerves to the muscles that extend the fore-arm, and to the teguments of the elbow: Towards the lower part of the arm, it slants a little back-ward, to come at the groove behind the internal condyle of the os humeri, through which it runs to the ulna: In its course along this bone, it serves the neighbouring muscles and teguments; and as it comes near the wrist, it detaches a branch obliquely over the ulna to the back of the hand, to be lost in the convex part of several fingers. The larger part of the nerve goes straight forward to the internal side of the os pisiforme of the wrist; where it sends off a branch which sinks under the large tendons in the palm, to go cross to the other side of the wrist, serving the musculi lumbricales and interossei, and at last terminating in the short muscles of the thumb and fore-finger. What remains of the ulnar nerve, after supplying the short muscles of the little finger, divides into three branches; whereof two are extended along the sides of the sheath of the tendons of the flexors of the little finger, to furnish the concave side of that finger; and the

third branch is disposed in the same way upon the side of the ring-finger next to the little finger.

When we lean or press on the internal condyle of the os humeri, the numbness and prickling we frequently feel, point out the course of this nerve.

7. **RADIALIS** accompanies the humeral artery to the bending of the elbow, serving the flexors of the cubit in its way; then passing through the pronator radii teres muscle, it gives nerves to the muscles on the fore-part of the forearm, and continues its course near to the radius, bestowing branches on the circumjacent muscles. Near the wrist, it sometimes gives off a nerve, which is distributed to the back of the hand, and the convex part of the thumb, and several of the fingers, instead of the branch of the muscular. The larger part of this nerve, passing behind the annular ligament of the wrist, gives nerves to the short muscles of the thumb; and afterwards sends a branch along each side of the sheath of the tendons of the flexors of the thumb, fore-finger, mid-finger, and one branch to the side of the ring-finger, next to the middle one, to be lost on the concave side of those fingers.

Though the radial nerve passes through the pronator muscle, and the muscular nerve seems to be still more unfavourably placed within the supinator brevis; yet the action of these muscles do not seem to have any effect in hindering the influence of these nerves, for the fingers or hand can be bended while pronation is performing vigorously, and they can be extended while supination is exercised.

The manner of the going off of these nerves of the fingers, both from the ulnar and radial, is, that a single branch is sent from the trunk to the side of the thumb and little finger, farthest from the other fingers; and all the rest are supplied by a trunk of a nerve, which splits into two some way before it comes as far as the end of the metacarpus, to run along the sides of different fingers that are nearest to each other.

It might have been observed, that, in describing the posterior branches of the ulnar and muscular nerve, we did not mention the particular fingers, to the convex part of which they are distributed. The reason of this omission is, the uncertainty of their distribution; for though sometimes these posterior branches go to the same fingers, to the concave part of which the anterior branches of the ulnar and radial are sent, yet frequently they are distributed otherwise.

The situation of these brachial nerves in the axilla, may let us see how a weakness and atrophy may be brought on the arms by a long continued pressure of crutches, or such other hard substances on this part; and the course of them from the neck to the arm, may teach us, how much better effects vesicatories, or stimulating nervous medicines, would have, when applied to the skin, covering the transverse processes of the vertebræ of the neck, or at the axilla, than when they are put between the shoulders, or upon the spinal processes, in convulsions or palsies of the superior extremities, where a stimulus is required.

The **TWELVE DORSAL** nerves of each side, as soon as they escape from between the vertebræ, send a branch

forward to join the intercostal, by which a communication is made among them all; and they soon likewise give branches backwards to the muscles that raise the trunk of the body, their principal trunk being extended outwards, to come at the furrow in the lower edge of each rib, in which they run toward the anterior part of the thorax, between the internal and external intercostal muscles, giving off branches in their course to the muscles and teguments of the thorax.

The **FIRST** dorsal, as was already observed, is particular in this, that it contributes to form the brachial nerves; and that the two branches of the intercostal, which come down to the thorax, form a considerable ganglion with it.

The **SIX** lower dorsal nerves give branches to the diaphragm and abdominal muscles.

The **TWELFTH** joins with the first lumbar, and bestows nerves on the musculus quadratus lumborum and iliacus internus.

As the intercostal is larger in the thorax than any where else, and seems to diminish gradually as it ascends and descends, there is cause to suspect that this is the trunk from which the superior and inferior pairs are sent as branches.

The **FIVE LUMBAR** nerves on each side communicate with the intercostal and with each other, and give branches backwards to the loins.

The **FIRST** communicates with the last dorsal, sends branches to the abdominal muscles, to the psoas and iliacus, and to the teguments and muscles on the fore-part of the thigh; while its principal branch joins with the other nerves, to form the crural nerve.

The **SECOND LUMBAR** nerve passes through the psoas muscle, and is distributed nearly in the same way as the former: as is also the **THIRD**.

Branches of the *second, third, and fourth*, make up one trunk, which runs along the fore-part of the pelvis; and, passing in the notch at the fore-part of the great hole common to the os pubis and ischium, is spent on the adductor muscles, and on the teguments on the inside of the thigh. This nerve is called the **OBTURATOR, or POSTERIOR CRURAL NERVE**.

By united branches from the *first, second, third, and fourth* lumbar nerves, a nerve is formed that runs along the psoas muscle, to escape with the external iliac vessels out of the abdomen, below the tendinous arcade of the external oblique muscle. This nerve, which is named the **ANTERIOR CRURAL**, is distributed principally to the muscles and teguments on the fore-part of the thigh. A branch, however, of this nerve runs down the inside of the leg to the upper part of the foot, keeping near to the vena saphæna; in opening of which with a lancet at the ankle, the nerve is sometimes hurt, and occasions sharp pain at the time of the operation, and numbness afterwards.

The **SIXTH PAIR** of the false **VERTEBRÆ** consist each of small posterior branches, sent to the hips, and of large anterior branches.

The *first, second, and third*, after coming through the three upper holes in the fore-part of the os sacrum, join together with the fourth and fifth of the loins, to form

form the largest nerve of the body, which is well known by the name of **SCIATIC** or **ISCHIATIC** nerve: This, after sending large nerves to the different parts of the pelvis, and to the external parts of generation, and the podex, as also to the muscles of the hips, passes behind the great tuber of the os ischium, and then over the quadrigemi muscles, to run down near to the bone of the thigh at its back-part, giving off nerves to the neighbouring muscles and teguments. Some way above the ham, where it has the name of the *popliteau* nerve, it sends off a large branch that passes over the fibula, and sinking in among the muscles on the anterior external part of the leg, runs down to the foot, to be lost in the upper part of the larger toes, supplying the neighbouring muscles and teguments every where in its passage. The larger branch of the sciatic, after giving branches to the muscles and teguments about the ham and knee, and sending a large cutaneous nerve down the calf of the leg, to be lost at last on the outside of the foot and upper part of the lesser toes, sinks below the gemellus muscle, and distributes nerves to the muscles on the back of the leg; among which it continues its course, till passing behind the internal malleolus, and in the internal hollow of the os calcis, it divides into the two plantar nerves: The internal of which is distributed to the toes, in the same manner that the radial nerve of the hand serves the concave side of the thumb and fingers; and the external plantar is divided and distributed to the sole of the foot and toes, nearly as the ulnar nerve is in the palm of the hand, and in the concave part of the fingers.

Several branches of these nerves, that serve the inferior extremities, pierce through muscles.

The **FOURTH**, which, with the two following, is much smaller than the three superior, soon is lost in the vesica urinaria and intestinum rectum.

The **FIFTH** comes forward between the extremity of

the os sacrum and coccygis, to be distributed principally to the levatores ani.

The **SIXTH**, which some think to be only a production of the dura mater, advances forward below the broad shoulders of the first bone of the os coccygis, and is lost in the sphincter ani and teguments covering it.

The size of the nerves of the inferior extremities seems larger proportionally than in the superior extremities; the inferior extremities having the weight of the whole body to sustain, and that frequently at a great disadvantage.—What the effect is of the nerves here being injured, we see daily, when people happen, by sitting wrong, to compress the sciatic nerve, they are incapable for some time after to support themselves on the affected extremity; and this is still more remarkable in the sciatic or hip-gout, in which the member is not only weakened, but gradually shrivels and wastes.

#### USES of the Nerves.

MANY experiments concur in proving, that the nerves are the instruments of sensation. As to the mode of their operation, several different theories have been given. Some suppose, that they are elastic cords, resembling siddle-strings; and that they convey sensations to the brain by a kind of vibratory motion. Others have supposed them to be tubular, and to contain a fluid called *animal spirits*; and that sensation is produced by the motions and counter-motions of this fluid. Many useless volumes have been wrote upon each of these hypotheses.—Another and more recent theory supposes, that the nerves are not tubular, but that they are pervaded by a subtle elastic fluid called *Ether*; and that sensation, &c. are occasioned by the oscillations of that fluid. A few detached and ill-digested scraps of this theory have already appeared in some temporary productions, the principal of which has been sufficiently animadverted upon under the word **ÆTHER**.

## EXPLANATION OF PLATE XVIII.

**FIG. 1.** Represents the inferior part of the brain;—the anterior part of the whole spine, including the medulla spinalis;—with the origin and large portions of all the **NERVES**.

**A A**, The anterior lobes of the cerebrum. **B B**, The lateral lobes of the cerebrum. **C C**, The two lobes of the cerebellum. **D**, Tubercula. **E**, The passage from the third ventricle to the infundibulum. **F**, The medulla oblongata, which sends off the medulla spinalis through the spine. **G G**, That part of the os occipitis which is placed above (**H H**), the transverse processes of the first cervical vertebra. **I I**, &c. The seven cervical vertebrae, with their intermediate cartilages. **K K**, &c. The twelve dorsal vertebrae with their intermediate cartilages. **L L**, &c. The five lumbar vertebrae, with their intermediate cartilages. **M**, The os sacrum. **N**, The os coccygis.

**NERVES**.—**1 1**, The first pair of nerves, named *olfactory*, which go to the nose. **2 2**, The second pair, named *optic*, which goes to form the tunica retina of the eye. **3 3**, The third pair, named *motor oculi*; it supplies most of the muscles of the eye-ball.

VOL. I. No. 11.

**4 4**, The fourth pair, named *pathetic*,—which is wholly spent upon the musculus trochlearis of the eye. **5 5**, The fifth pair divides into three branches.—The first, named *ophthalmic*, goes to the orbit, supplies the lachrymal gland, sends branches out to the forehead and nose.—The second, named *superior maxillary*, supplies the teeth of the upper jaw, and some of the muscles of the lips.—The third, named *inferior maxillary*, is spent upon the muscles and teeth of the lower jaw, tongue, and muscles of the lips. **6 6**, The sixth pair, which, after sending off the beginning of the intercostal or great sympathetic, is spent upon the abductor oculi. **7 7**, The seventh pair, named *auditory*, divides into two branches.—The largest, named *portio mollis*, is spent upon the internal ear.—The smallest, *portio dura*, joins to the fifth pair within the internal ear by a reflected branch from the second of the fifth, and within the tympanum, by a branch from the third of the fifth, named *chorda tympani*.—Vid. fig. 3. near B. **8 8**, &c. The eighth pair, named *par vagum*,—which accompanies the intercostal, and is spent upon the tongue, larynx, pharynx,

rynx, lungs, and abdominal viscera. 9 9, The ninth pair, which are spent upon the tongue. 10 10, &c. The intercostal, or great sympathetic, which is seen from the sixth pair to the bottom of the pelvis on each side of the spine, and joining with all the nerves of the spine;—in its progress supplying the heart, and, with the par vagum, the contents of the abdomen and pelvis. 11 11, The accessorius, which is spent upon the sterno-cleido mastoideus and trapezius muscles. 12 12, The first cervical nerves;—13 13, The second cervical nerves;—both spent upon the muscles that lie on the neck and teguments of the neck and head. 14 14, The third cervical nerves, which, after sending off (15 15, &c.) the phrenic nerves to the diaphragm,—supply the muscles and teguments that lie on the side of the neck and top of the shoulder. 16 16, The brachial plexus, formed by the fourth, fifth, sixth, seventh cervicals, and first dorsal nerves,—which supply the muscles and teguments of the superior extremity. 17 17, The twelve dorsal, or proper intercostal nerves, which are spent upon the intercostal muscles and some of the large muscles which lie upon the thorax. 18 18, The five lumbar pairs of nerves, which supply the lumbar and abdominal muscles, and some of the teguments and muscles of the inferior extremity. 19 19, The sacro-sciatic, or posterior crural nerve, formed by the two inferior lumbar, and three superior of the os fa-

crum.—This large nerve supplies the greatest part of the muscles and teguments of the inferior extremity. 20, The stomachic plexus, formed by the eighth pair. 21 21, Branches of the solar or celiac plexus, formed by the eighth pair and intercostals, which supply the stomach and chylopoetic viscera. 22 22, Branches of the superior and inferior mesenteric plexuses, formed by the eighth pair and intercostals, which supply the chylopoetic viscera, with part of the organs of urine and generation. 23 23, Nerves which accompany the spermatic cord. 24 24, The hypogastric plexus, which supplies the organs of urine and generation within the pelvis.

FIG. 2, 3, 4, 5. Shews different views of the inferior part of the brain, cut perpendicularly through the middle,—with the origin and large portions of all the nerves which pass out through the bones of the cranium,—and the three first cervicals.

A, The anterior lobe. B, The lateral lobe of the cerebrum. C, One of the lobes of the cerebellum. D, Tuber annulare. E, Corpus pyramidale, in the middle of the medulla oblongata. F, The corpus olivare, in the side of the medulla oblongata. G, The medulla-oblongata. H, The medulla spinalis.

NERVES.—1 2 3 4 5 6 7 8 & 9, Pairs of nerves, 10 10, Nervus accessorius, which comes from—11 12 & 13, the three first cervical nerves.

## P A R T VI.

*Of such Parts of the Body as could not properly be described under any of the former general Divisions.*

### SECT. I. *Of the common Integuments.*

#### THE SKIN.

THE skin is a substance of very large extent, made up of several kinds of tendinous, membranous, vascular, and nervous fibres, the intertexture of which is so much the more wonderful, as it is difficult to unfold; for their directions are as various as those of the stuff of which an hat consists.

This texture is what we commonly call leather, and it makes, as it were, the body of the skin. It is not easily torn, may be elongated in all directions, and afterwards recovers itself, as we see in fat persons, in women with child, and in swellings; and it is thicker and more compact in some places than in others.

Its thickness and compactness are not, however, always proportionable; for on the posterior parts of the body, it is thicker and more lax than on the fore-parts; and on the palms of the hands, and soles of the feet, it is both very thick and very solid.

The outer surface of this substance is furnished with small eminences, which anatomists have thought fit to

call *papillæ*, in which the capillary filaments of the cutaneous nerves terminate by small radiated pencils.

These papillæ differ very much in figure and disposition in the different parts of the body, and they may be distinguished into several kinds.

The greatest part of them is flat, of different breadths, and separated by sulci, which form a kind of irregular lozenges. The pyramidal figure ascribed to them, is not natural, and appears only when they are contracted by cold or by diseases.

The papillæ of the palm of the hand, of the sole of the foot, and of the fingers and toes, are higher than on the other parts of the body; but they are likewise smaller, closely united together, and placed as it were endwise, with respect to each other, in particular rows, which represent on the skin all kinds of lines, straight, crooked, waving, spiral, &c. These several lines are often distinctly visible in those parts of the palm of the hand which are next the first phalanges of the fingers.

The red part of the lips is made up of papillæ, representing very fine hairs or villi, closely united together.

There is another particular kind under the nails; the papillæ being there more pointed, or in a manner conical, and turned obliquely towards the ends of the fingers.

Those

Those which are found in the hairy scalp, scrotum, &c. are still of other kinds.

The papillæ of the first and second kinds appear to be surrounded at their bases by a soft mucilaginous and pretty viscid substance, which fills the interstices between them, and represents a kind of net-work or sieve, the meshes or holes of which surround each papilla. This substance is commonly called *corpus reticulare*, or *mosaicum*.

This vascular texture is of various forms and figures in the different parts of the body.

The inner surface of the skin is covered by very small tubercles, commonly called *cutaneous glands*, or *glandulæ miliaires*.

These tubercles are partly fixed in small fossulæ, in the substance of the skin, which answer to the same number of small cavities in the corpus adiposum. Their excretory ducts open on the outer surface of the skin, sometimes in the papillæ, and sometimes on one side of them.

The greatest part of them furnishes sweat, and others a fatty oily matter of different thickneses, as in the hairy scalp, in the back, behind the ears, and at the lower part of the nose, where this matter may be squeezed out, in form of small worms.

Besides these corpuscles, there are other small solid bodies, almost of an oval figure, contained in the substance of the skin. These are the roots or bulbs from whence the hairs arise, and some of them are situated within the inner surface of the skin.

The skin has several considerable openings, some of which have particular names; such as the fissure of the palpebræ, the nares, the mouth, the external foramen of the ears, the anus, and openings of the parts of generation.

Besides these, it is perforated by an infinite number of small holes, called *pores*, which are of two kinds. Some are more or less perceivable to the naked eye; such as the orifices of the milky ducts of the mammæ, the orifices of the excretory canals of the cutaneous glands, and the passages of the hairs.

The other pores are imperceptible to the naked eye, but visible through a microscope; and their existence is likewise proved by the cutaneous transpiration, and by the effects of topical applications; and from these two phenomena, they have been divided into arterial and venal pores.

### THE CUTICULA, OR EPIDERMIS.

THE outside of the skin is covered by a thin transparent web, closely joined to it, which is called *epidermis*, *cuticula*, or the *scarf-skin*.

The substance of the cuticula appears to be very uniform on the side next the skin, and to be composed on the other side of a great number of very fine small squamous laminae, without any appearance of a fibrous or vascular texture, except some small filaments, by which it is connected to the papillæ.

This substance is very solid and compact, but yet capable of being extended and thickened, as we see by

steeping it in water, and by the blisters raised on the skin by vesicatories. It yields very much in swellings; but not so much as the skin, without breaking or cracking.

Hard and reiterated frictions loosen it insensibly, and presently afterward, a new stratum arises, which thrusts the first outward, and may itself be loosened and thrust outward by a third stratum, and so on.

The epidermis adheres very closely to the cutaneous papillæ, from which it may be separated by boiling; or by steeping, for a long time, in cold water.

It adheres still closer to the corpus reticulare, which is easily raised along with it; and they seem to be true portions or continuations of each other.

The epidermis covers the skin through its whole extent, except at the places where the nails lie. It is marked with the same furrows and lozenges as the skin, and has the same openings and pores; and though it may be said to pass the bounds of the skin, where it is continued inward, through the great openings, yet at these places it loses the name of epidermis.

When we examine narrowly the small pores or holes, through which the sweat passes, the epidermis seems to enter these, in order to complete the excretory tubes of the cutaneous glands. The fossulæ of the hairs have likewise the same productions of the epidermis, and it seems to give a sort of coat or bark to the hairs themselves. Lastly, the almost imperceptible ducts of the cutaneous pores are lined by it.

### USES OF THE SKIN.

It is chiefly and properly the filamentary substance, called the body of the skin, which is the universal integument of the body, and the basis of all the other cutaneous parts; each of which has its particular uses.

The skin is able to resist external injuries to a certain degree, and such impressions, frictions, strokes, &c. to which the human body is often liable, as would hurt, wound, and disorder the parts of which it is composed, if they were not defended by the skin.

The papillæ are the organ of feeling, and contribute to an universal evacuation, called insensible transpiration. They likewise serve to transmit from without, inwards, the subtle particles or impressions of some things applied to the skin. The first of these three uses depends on the extremities of the nerves, the second on the arterial productions, and the third on the productions of the veins.

The cutaneous glands secrete an oily humour of different consistences, and they are likewise the origin of sweat.

The epidermis serves to keep the pencils or nervous filaments of the papillæ in an even situation, and without confusion; and it likewise moderates the impressions of external objects.

Another use of the epidermis is to regulate the cutaneous evacuations already mentioned, the most considerable of which is insensible transpiration.

### THE MEMBRANA ADIPOSITA, AND FAT.

THE second universal integument of the human body,

is the membrana adiposa, or corpus adiposum. This is not, however, a single membrane, but a congeries of a great number of membranous laminae, joined irregularly to each other at different distances, so as to form numerous interstices of different capacities, which communicate with each other. These interstices have been named *cellulae*, and the substance made up of them, the *cellulous substance*.

The thickness of the membrana adiposa is not the same all over the body, and depends on the number of laminae of which it is made up. It adheres very closely to the skin, runs in between the muscles in general, and between their several fibres in particular, and communicates with the membrane which lines the inside of the thorax and abdomen.

The structure is demonstrated every day by butchers, in blowing up their meat, when newly killed; in doing which, they not only swell the membrana adiposa, but the air insinuates itself likewise in the interstices of the muscles, and penetrates even to the viscera, producing a kind of artificial emphysema.

These cellular interstices are so many little bags or fatchels, filled with an unctuous or oily juice, more or less liquid, which is called *fat*.

This substance increases in quantity in the body, by rest and good living; and on the contrary, diminishes by hard labour and a spare diet.

The proportional differences in the thickness of this membrana adiposa, are determined, and may be observed to be regular in some parts of the body, where either beauty or use required it.

Thus we find it in great quantities, where the interstices of the muscles would otherwise have left disagreeable hollow or void places; but being filled, and as it were padded with fat, the skin is raised, and an agreeable form given to the part.

In some parts of the body the fat serves for a cushion, pillow, or mattress; as on the buttocks, where the laminae and cells are very numerous.

The fat is likewise of great use to the muscles, in preserving the flexibility necessary for their actions, and in preventing or lessening their mutual frictions.

### THE NAILS.

The substance of the nails is like that of horn, and they are composed of several planes of longitudinal fibres soddred together. These strata end at the extremity of each finger, and are all nearly of an equal thickness, but of different lengths.

The external plane or stratum is the longest, and the rest decrease gradually, the innermost being the shortest; so that the nail increases in thickness from its union with the epidermis, where it is thinnest, to the end of the finger, where it is thickest.

The graduated extremities or roots of all the fibres of which these planes consist, are hollowed for the reception of the same number of very small oblique papillae, which are continuations of the true skin, which having reached to the root of the nail, forms a semilunar fold, in which that root is lodged.

After this semilunar fold, the skin is continued on the whole inner surface of the nail. The fold of the skin is accompanied by the epidermis, to the root of the nail exteriorly, to which it adheres very closely.

Three parts are generally distinguished in the nail, the root, body, and extremity. The root is white and in form of a crescent; and the greatest part of it is hid under the semilunar fold already mentioned.

The crescent and the fold lie in contrary directions to each other. The body of the nail is naturally arched, transparent, and appears of the colour of the cutaneous papillae which lie under it.

The principal use of the nails is to strengthen the ends of the fingers and toes, and to hinder them from being inverted towards the convex side of the hand or foot, when we handle or press upon any thing hard.

### THE HAIRS.

The hairs belong as much to the integuments as the nails. They are a kind of reeds or rushes, the roots or bulbs of which lie toward that side of the skin which is next the membrana adiposa. The trunk or beginning of the stem perforates the skin, and the rest of the stem advances beyond the outer surface of the skin, to a certain distance, which is very various in the different parts of the body.

When the different hairs are examined by a microscope, we find the roots more or less oval, the largest extremity being either turned toward, or fixed in the corpus adiposum.

This oval root is covered by a whitish strong membrane, in some measure elastic; and it is connected either to the skin, to the corpus adiposum, or to both, by a great number of very fine vessels and nervous filaments.

Within the root, we observe a kind of glue, some very fine filaments of which advance toward the small extremity, where they unite and form the stem, which passes through this small extremity to the skin. As the stem passes through the root, the outer membrane is elongated in form of a tube, which closely invests the stem, and is entirely united to it.

The stem having reached the surface of the skin, pierces the bottom of a small fossula between the papillae, or sometimes a particular papilla, and there it meets the epidermis, which seems to be inverted round it, and to unite with it entirely. A sort of unctuous matter transudes through the sides of the fossula, which is bestowed on the stem, and accompanies it, more or less, as it runs out from the skin, in form of an hair.

### SECT. II. *Of the ABDOMEN.*

THE Abdomen begins immediately under the thorax, and terminates at the bottom of the pelvis of the ossa innominata. Its circumference, or outer surface, is divided into regions, of which there are three anterior, *viz.* the epigastric or superior region, the umbilical or middle region, and the hypogastric or lower region. There is but one posterior region, named regio lumbaris.

The

The epigastric region begins immediately under the appendix eniformis, at a small superficial depression, called the pit of the stomach, and ends above the navel at a transverse line, supposed to be drawn between the last false ribs on each side.

This region is subdivided into three parts; one middle, named epigastrium; and two lateral, termed hypochondria. The epigastrium takes in all that space which lies between the false ribs of both sides, and the hypochondria are the places covered by the false ribs.

The umbilical region begins above the navel, at the transverse line already mentioned, and ends below the navel at another transverse line, supposed to be drawn parallel to the former, between the two crista of the os ilium.

This region is likewise divided into three parts; one middle, which is properly the regio umbilicalis; and two lateral, called ilia, or the flanks; and they comprehend the space between the false ribs and upper part of the os ilium on each side.

The hypogastric region is extended downward from the inferior limit of the umbilical region, and is divided into three parts; one middle, called pubis; and two lateral, called inguina, or the groins.

The lumbar region is the posterior part of the abdomen, and comprehends all that space which reaches from the lowest ribs on each side, and the last vertebra of the back, to the os sacrum and neighbouring parts of the ossa ilium. The lateral parts of this region are termed the loins, but the middle part has no proper name in men.

Lastly, the bottom of the abdomen, which answers to the pelvis of the skeleton, is terminated anteriorly by the pudenda or parts of generation, and posteriorly by the clunes and anus. The buttocks are separated by a fossa, which leads to the anus; and each buttock is terminated downward by a large fold, which distinguishes it from the rest of the thigh.

The space between the anus and the parts of generation, is called perinæum, and is divided into two equal lateral parts by a very distinct line, which is longer in males than in females.

The cavity of the abdomen, formed by the parts already mentioned, (all which are covered by the skin and membrana adiposa) is lined on the inside by a particular membrane, called peritonæum. It is separated from the cavity of the thorax by the diaphragm, and terminated below by the musculi levatores ani.

This cavity contains the stomach, and the intestines. It contains likewise the mesentery, mesocolon, omentum, liver, gall bladder, spleen, pancreas, glands of the mesentery, vasa lactea, receptaculum chyli, kidneys, renal glands, ureters, bladder, and the internal parts of generation in both sexes.

The whole fore-part of the abdomen forms an oblong convexity, like an oval vault, more or less prominent in the natural state, in proportion to the quantity of fat upon it, and of food contained in it, or to the different degrees of pregnancy in women. The hypogastric and umbilical regions are more subject to these varieties, than the epigastric region.

The appendix eniformis of the sternum, the cartilaginous portions of the last pair of true ribs, those of the first four pairs of false ribs, all the fifth pair, the five lumbar vertebrae, the ossa innominata, the os sacrum, and os coccygis, form the bony sides of the cavity of the abdomen.

The diaphragm, the muscles called particularly musculi abdominis, the quadrati lumborum, psoa, iliaci, the muscles of the coccyx, and of the intestinum rectum, form the chief part of the circumference of this cavity.

The cavity of the abdomen is of an irregularly oval figure, but still symmetrical. On the fore-side it is uniformly arched or oval, and its greatest capacity is even with the navel, and nearest part of the hypogastrium. On the upper side it is bounded by a portion of a vault, very much inclined. On the back-side, it is in a manner divided into two cavities by the jutting out of the vertebrae of the loins. On the lower side, it contracts gradually all the way to the little edge of the pelvis, and from thence expands again a little as far as the os coccygis and tubercles of the ischium, terminating in the void space between these three parts.

#### PERITONÆUM.

HAVING carefully removed the muscles of the abdomen, the first thing we discover is the peritonæum, a membranous covering, which adheres immediately to the inner surface of the musculi transversi, and of all the other parts of this cavity; and involves and invests all the viscera contained therein, as in a kind of bag.

The peritonæum in general is a membrane of a pretty close texture, and yet very limber, and capable of a very great extension; after which it can recover itself, and be contracted to its ordinary size; as we see in pregnancy, dropsies, corpulency, and repletion.

It seems to be made up at least of two portions, one internal, the other external; which have been looked upon by many anatomists as a duplicature of two distinct membranous laminae. But, properly speaking, the internal portion alone deserves the name of a membranous lamina, as being the main body of the peritonæum. The external portion is no more than a kind of fibrous or follicular apophysis of the internal; and may properly enough be termed the cellular substance of the peritonæum.

The true membranous lamina, commonly called the internal lamina, is very smooth, and polished on that side which is turned to the cavity and viscera of the abdomen, and continually moistened by a serous fluid discharged through almost imperceptible pores.

The cellular substance, or external portion of the peritonæum, adheres very closely to the parts which form the insides of the cavity of the abdomen.

The cellular substance has several elongations, which have been called productions of the peritonæum. Two of these productions accompany and invest the spermatic ropes in males, and the vascular ropes, commonly called the round ligaments, in women. There are other two, which pass under the ligamentum Fallopii, with the

erual vessels, which they involve, and are gradually lost in their course downward.

To these four productions of the cellular substance of the peritonæum, we may add a fifth, which is spread on the neck of the bladder, and perhaps a sixth, which accompanies the intestinum rectum. All these elongations pass out of the cavity of the abdomen, and may be termed external, to distinguish them from others that remain in the abdomen, and are called internal, of which hereafter.

The great blood-vessels, that is, the aorta and vena cava, are likewise involved in this cellular substance of the peritonæum. In a word, it involves immediately and separately all the parts and organs which are commonly said to lie in the duplicature of the peritonæum.

It has, nevertheless, productions of its own, but they are very different from those of the cellular substance; for they run from without, inward, that is, they advance from the convex side of the great bag of the peritonæum, into the cavity of that bag, some more, some less, and also in different manners; as if the sides of a large ball or bladder were thrust inward into the cavity of the ball or bladder.

Of these internal elongations or intropressions of the true lamina of the peritonæum, some are simply folded, like a duplicature; some are expanded like inverted bags or sacculi to contain some viscous; some begin by a simple duplicature, and are afterwards expanded into a cavity, which contains some organ; some are alternately extended in the form of simple duplicatures, and of cavities; and lastly, some form only a small eminence on the inner surface of the great cavity of the peritonæum.

The chief uses of the peritonæum are, to line the cavity of the abdomen, to invest the viscera contained in that cavity as in a common bag, to supply them with particular coats, to form productions, ligaments, connexions, folds, vaginae, &c.

The fine fluid which transudes through the whole internal surface of the peritonæum, prevents the inconveniences which might arise from the continual frictions and motions to which the viscera of the abdomen are exposed either naturally or by external impulses.

## VENTRICULUS, OR STOMACH.

The stomach is a great bag or reservoir, situated partly in the left hypochondrium, and partly in the epigastrium.

The figure of the stomach is like that of a bag-pipe, oblong, incurvated, large and capacious at one end, and small and contracted at the other.

The curvature of the stomach gives us occasion to distinguish two arches in it; one large, which runs along the greatest convexity; and one small, directly opposite to the former. The sides of the stomach, are the two lateral portions which lie between the two arches.

The stomach has two extremities, one large, and one small like a crooked funnel. It has two openings, called the orifices of the stomach, one between the great extremity and the small curvature, the other at the end of the small or contracted extremity. The first opening

is a continuation of the œsophagus; the other joins the intestinal canal, and is called pylorus.

The great extremity of the stomach is in the left hypochondrium, and for the most part immediately under the diaphragm.

The small extremity of the stomach does not reach to the right hypochondrium. It bends obliquely backward toward the upper orifice, so that the pylorus lies about two fingers breadth from the body of the vertebrae immediately under the small portion of the liver, and consequently lower down, and more forward than the other orifice by almost the same distance.

According to this natural situation, the stomach, especially when full, lies so as that the great curvature is turned more upward than downward, and the small curvature more backward than upward.

One of the lateral convex sides is turned upward, the other downward; and not forward and backward, as they appear in dead bodies, where the intestines do not support them in their natural situation.

The stomach is composed of several parts, the chief of which are the different strata which form its substance, to which anatomists give the name of tunicae or coats. These coats are commonly reckoned to be four in number, the outer or common, the fleshy or muscular, the nervous or aponeurotic, and the villous or inner coat; and they are afterwards subdivided several ways.

The first or outermost coat is simply membranous, being one of the internal productions of the peritonæum.

The second or muscular coat is made up of several planes of fibres, which may all be reduced to two, one external, the other internal. The external coat is longitudinal, though in different respects, following nearly the direction of the curvatures and convexities of the stomach; and the internal plane is transversely circular.

Between the outer and inner planes, round the superior orifice, there are two distinct planes, about the breadth of a finger, and very oblique, which surround this orifice in opposite directions, and intersect each other where they meet on the two lateral sides.

Along the middle of each lateral side of the small extremity, there runs a tendinous or ligamentary flat portion, above a quarter of an inch in breadth, which terminates in the pylorus. These two portions lie between the common and muscular coats, and adhere very strongly to the first.

Between the same two coats, there is a cellular substance which adheres very closely to the external coat, and insinuates itself between the fleshy fibres of the second, all the way to the third.

The third coat, called commonly tunica nervosa, sustains, on its convex side, a very large reticular distribution of capillary vessels and nerves. On the concave side, it seems to be of a very loose texture, and as it were spongy or filamentary, containing a great number of small glandular bodies, especially near the small curvature and small extremity of the stomach.

The fourth coat of the stomach is termed villosa, because, when it swims in clear water, some have imagined they saw something in it like the pile of velvet.

These two coats are of a larger extent than the two former,

former, and they join in forming large rugæ on the convex surface of the stomach, the greatest part of which are transverse, though irregular and waving.

In the interstices of these rugæ, there is often found a sort of slimy mucus, with which the whole cavity of the stomach seems likewise to be moistened. This mucus is much more fluid in living bodies, and is supplied by the glands of the stomach. It is termed *succus gastricus* or *stomachicus*.

On the inner surface of the small extremity of the stomach, at the place where it ends in the intestinal canal, we observe a broad, thin, circular border, with a roundish hole in the middle. This hole is the inferior orifice of the stomach, called by the Greeks *pylorus*, which signifies a porter.

This border is a fold or duplicature of the two inner coats of the stomach, the *nervosa* and *villosa*; and it is formed in part by a fasciculus of fleshy fibres fixed in the duplicature of the *tunica nervosa*, and distinguished not only from the other fleshy fibres of the extremity of the stomach, but also from those of the intestines, by a thin, whitish circle, which appears even through the external or common coat, round the union of the stomach and intestines.

The figure of the pylorus is that of a ring, transversely flattened, the inner edge of which, or that next the center, is turned obliquely toward the intestines, like a broad portion of a funnel. This inner edge runs naturally more or less into little plaits or gathers, like the mouth of a purse almost shut. It is therefore a kind of sphincter, which can contract the inferior orifice of the stomach, but seems not capable of shutting it quite close.

The stomach receives in general whatever the mouth sends thither, through the canal of the œsophagus; but its particular use is to receive the aliments, to contain them for a longer or shorter time, in proportion as they are more solid or fluid, and to digest them, that is, to put them in a condition to be turned into that nutritious fluid called chyle.

This operation, which goes by the general name of digestion, and by which chylification begins, is performed partly by the *succus gastricus*, which flows continually from the *tunica villosa*, and partly by the continual contraction and relaxation of the muscular coat.

The pylorus, or fleshy circle of the inferior orifice of the stomach, serves to retain the aliments in it, till they have acquired a sufficient degree of fluidity to pass easily through that opening.

The gentle and alternate motions of the orbicular fibres of the muscular coat, may assist in sending through the pylorus, in the natural way, the aliment that is sufficiently digested. This was called the peristaltic or vermicular motion, by those who believed that it is successively reiterated, like that of earth-worms when they creep.

The situation of the stomach, which is nearly transverse, is likewise of use in making the aliment remain long enough in that cavity, and may serve to make the length of this stay in some measure arbitrary, by means of the different postures of the body; for when we lie on the left side, the aliment must remain longer, than when we lie on the right, &c.

*The Intestines in general, and Intestinum Duodenum in particular.*

BETWEEN the pylorus and the very lowest part of the abdomen, lies a long canal, bent in a great many different directions, by numerous convolutions or turnings, called the *intestina*.

This canal, thus folded and turned, forms a considerable bulk, which fills the greatest part of the cavity of the abdomen; and it is connected, through its whole extent, to membranous productions or continuations of the peritonæum, principally to those called the mesentery and mesocolon.

The incurvations of the intestinal canal form two arches, a small one by which it is connected to the mesentery and mesocolon, and a great one on the opposite side, which lies loose. The whole canal is generally about seven or eight times as long as the body.

The intestines in general are composed of several coats, much in the same manner with the stomach. The first and outermost is a continuation of the mesentery, or of some other elongation or duplicature of the peritonæum.

This is commonly termed the common coat; and it has a cellular substance on its inner surface, like that of the stomach.

The second coat of the intestines is fleshy or muscular, and made up of two planes, one external, the other internal. The external plane is very thin, and its fibres longitudinal; the internal plane is thicker, and its fibres run transversely round the circumference of the intestinal cylinder.

The third coat is called *nervosa*, and is something like that of the stomach. It has a particular plane, which serves as a basis to sustain it, made up of very fine, strong, oblique fibres, which seem to be of the ligamentary or tendinous kind.

This coat sustains two reticular substances which are both vascular, one arterial, the other venal, accompanied by a great number of nervous filaments. These vessels and nerves are productions of the mesenteric vessels and nerves; and as they surround the whole canal of the intestines, some anatomists have formed them into a distinct coat, by the name of *tunica vasculosa*.

The nervous coat sends off from its inner surface a great number of portions of septa, more or less circular, which contribute to the formation of what are called *valvule conniventes*.

The fourth or innermost coat is very soft, and is named *tunica villosa*. It has the same extent with the third coat, which supports it, and it lines all the septa of that third coat.

The small intestines form one continued uniform canal; and though three portions of it have three different names, yet we have no sufficient marks whereby to distinguish them, to fix the precise extent or length of each portion, to settle its just limits.

The first and shortest portion of the whole canal, is called *duodenum*; the second, which is much longer, *jejunum*; and the third, which is still longer than the second, *ileum*.

The duodenum having arisen from the pylorus, is immediately bent a little backward, and obliquely downward; then it bends a second time toward the right kidney, to which it is a little connected, and from thence passes before the renal artery and vein, ascending insensibly from right to left, till it gets before the aorta and last vertebræ of the back. It continues its course obliquely forward, by a gentle turn.

Through this whole course, the duodenum is firmly bound down by folds of the peritonæum, especially by a transverse duplicature which gives origin to the mesocolon.

The villi of this intestine are thicker than in the stomach; but the texture of them in man is not like hairs, as they are commonly represented in figures; but rather like that of a fungous granulated substance, composed of an infinite number of very fine papillæ of different figures, in which we see, through a microscope, a multitude of depressed points or pores, by which their whole surface seems to be pierced.

By the same help we observe, on different places of the inner surface of this intestine, several round villous tubercles, rising like small verucæ at different distances from each other.

This substance sustains an infinite number of capillary vessels, of different kinds; for besides the blood-vessels, we sometimes observe a great number of white filaments which run through it, and end at its inner surface, like so many capillary roots of the vessels, called *vena lactea*.

The internal surface of the duodenum is furnished with a great number of small flat glandular tubercles, raised on the sides, and depressed in the middle, by a kind of fossula; and they are more numerous near the beginning of this intestine than any where else.

These glands appear like little bladders, with the orifices turned toward the cavity of the intestine, and the bodies fixed in the spongy substance next the nervous coat. They furnish a particular viscid fluid.

In the inner surface of the duodenum, almost at the lower part of the first incurvation, and on the shortest side, there is a longitudinal eminence, in the point or apex of which lies a particular opening, which is the orifice of the ductus biliaris, within which the ductus pancreaticus likewise opens.

## INTESTINUM JEJUNUM.

THE jejunum, so called, because it is oftener found empty than the ilium, begins at the last incurvation of the duodenum, and is there connected to the beginning of the mesocolon.

From thence it bends downward from left to right, and obliquely forward, or from the vertebræ, and makes several convolutions, which lie chiefly in the upper part of the umbilical region. Through all this course it is connected to the mesentery.

The jejunum and ilium may be distinguished by dividing both intestines into five parts; and to allow nearly two fifths to the jejunum, and three fifths and a little more to the ilium.

The coats of the jejunum are nearly of the same structure with those of the duodenum, but thinner.

## INTESTINUM ILEUM.

THE convolutions of the intestine ileum surround those of the jejunum on the two lateral and lower sides, and it passes in a winding course from the left side, by the hypogastrum, to the right side, where it terminates a little below the right kidney, joining the intestine crassa.

The structure of the ileum is much the same with that of the jejunum; only the internal duplicatures or valvulæ conniventes decrease gradually both in number and size.

### *The INTESTINA CRASSA in general, and Intestinum cæcum in particular.*

THE great intestines are one continued canal, divided into three portions, like the small ones. This canal begins by a kind of sacculus or bag, which is reckoned the first of the three portions, and called cæcum. The second portion, called colon, is the longest of the three, and is distinguished from them by a great number of particular eminences or convexities, which appear on its outer surface through its whole length. The last portion is named rectum, being more uniform, narrower, thicker, and much shorter than the colon.

The structure of the great intestines is nearly the same with that of the small ones, in regard both to the number and disposition of their coats. They are shorter, and have fewer convolutions, but are much more capacious. The coats in general are stronger, but especially the muscular coat.

The intestine cæcum is only a round short broad bag, the bottom of which is turned downward, and the mouth or opening upward. It lies under the right kidney, and is hid by the last convolution of the ileum. It is about three fingers breadth in length, and its diameter is more than double that of the small intestines.

On one side of the bottom of the cæcum lies an appendix, resembling a small intestine, nearly of the same length with the cæcum, but very slender. It is termed *appendicula vermiformis*, from its supposed resemblance to an earth-worm. Its common diameter is not above a quarter of an inch. By one extremity it opens laterally, and a little obliquely, into the bottom of the cæcum; and the other extremity is closed, being sometimes greater, sometimes smaller, than the rest of the appendix.

Through the membranous or common coat of the cæcum, we see three white ligamentary bands, which adhere very closely both to the outer and muscular coat. One of them is hid by the adhesion of the mesocolon; and all the three divide the cæcum longitudinally into three parts more or less equal.

They all unite in the *appendicula vermiformis*, and cover its whole outer side immediately under the common coat.

## INTESTINUM COLON.

THE colon is the most considerable of all the intestines. From the cæcum, of which it is a continuation, it reaches, in form of an arch, above the umbilical region, and to the lower part of the left hypochondrium. Its continuity is however a little interrupted by the ileum, which advances into the cavity of the colon, and, together with a certain fold of that intestine, forms what is called valvula coli.

The whole convex side of the colon is divided longitudinally into three parts, by three ligamentary bands, continued from those of the cæcum, and of the same structure with these. Two of the three bands run on each side, along the great curvature of the colon; and the third along the small curvature.

These three longitudinal bands do the office of fræna, between which this intestine is through its whole length alternately depressed into transverse folds, and raised into considerable eminences. All the folds are duplicatures, which form portions of valvulæ conniventes in the cavity of the intestine; and the eminences form receptacles, called the cells of the colon.

The common coat, on one side, is a continuation of the mesocolon; and, on the other side, it contributes, by the same continuation, to form the omentum.

The arch of the colon begins under the right kidney, near the haunch. It runs up on the fore side of that kidney to which it is connected, passes under the vesicula fellis, which tinges it with a yellow colour at that place, and continues its course before the first incurvation of the duodenum, to which it adheres, and partly hides it. In this part of its course, therefore, there is a remarkable connexion between the colon, duodenum, right kidney, and vesicula fellis.

From thence the arch of the colon runs before the great convexity of the stomach, and sometimes a little lower; then turns backward under the spleen, in the left hypochondrium; runs down on the fore side of the left kidney, to which it is connected; below this kidney turns toward the vertebræ, and terminates there by a double incurvation, or by two opposite convolutions, which represent in some measure an inverted roman S.

At the place where the cæcum joins the colon, one portion of the circumference of both is depressed, and forms a large fold on the inside, which advances into the cavity of the intestine. It is a little open in the middle, and its extremities are very thick, by reason of the mutual duplicature of the coats of the cæcum and colon.

The extremity of the ileum is as it were grafted in the opening of this fold, and strongly united to its sides by the adhesion of its transverse fibres to the transverse fibres of the cæcum and colon.

This union forms a pretty thick ring, which likewise advances into the common cavity of the cæcum and colon, where it is wrinkled or formed into gathers, almost like the lower extremity of the œsophagus, the pylorus or inside of the anus. Its circumference is more or less oval; and, by a kind of continuity with the com-

mon fold of the cæcum and colon, it forms two productions, which *M. Morgagni* calls the fræna of the valvula coli.

The membranous coat of the extremity of the ileum is continued on the cæcum and colon, without sinking into any fold, at the place where the ileum enters the colon.

This valvula coli is contrived to hinder the return of the excrements into the ileum; it produces this effect partly as a valve, and partly as a kind of sphincter.

The capacious arch of the colon is contracted by both extremities to the regio lumbaris, near the kidneys, by two particular ligaments, one on the right side, the other on the left, which are only small duplicatures of the peritonæum, more or less transverse.

The remaining portion, which forms the two convolutions in form of the roman S, contracts below the left kidney, being narrower there, than lower down. The coats of this portion become gradually thicker and stronger, and likewise the ligamentary bands, which approach each other by degrees, and seem to increase in breadth.

## INTESTINUM RECTUM AND ANUS.

THE last of all the intestines, is named rectum, or the freight gut, which, properly speaking, is a true continuation of the last convolution of the colon; and it is the repository, sink, and common sewer, of the whole intestinal canal.

The rectum having passed below the last vertebra of the loins, to the inside of the os sacrum, is bent backward on that concave side to which it is connected; and having reached the os coccygis, it runs likewise in the direction of that bone, and bends a little forward, terminating beyond the extremity of the coccyx.

The figure of this intestine varies according as it is full or empty. When empty, it is irregularly cylindrical, and links in by a kind of transverse folds; and in that state, it is about three fingers breadth in diameter, more or less. When full, it is wider in proportion to the quantity of feces, wind, or whatever else is contained in it; and it may be extended to the size of a large bladder, so as to represent a kind of stomach.

The membranous coat often contains a great quantity of fat, spread between it and the muscular coat, and forming round the intestine numerous eminences, in the room of the appendices adiposæ of the colon.

The muscular or fleshy coat is very thick; the longitudinal fibres, which in the other intestines are very thin, are in this stronger than the circular fibres of the rest. The ligamentary bands continue to increase in breadth, and to approach each other.

The nervous or filamentous and internal coats, are larger here, than in the other intestines; and when the rectum is empty, they form a great number of waving rugæ in its cavity, which disappear, in proportion as that cavity is filled.

The innermost coat is very improperly termed villosa, and scarce deserves the name of papillaris, because of the smallness of the little corpuscles spread on its surface.

It contains a great number of single or solitary glands; and it is always moistened by a mucus of different consistencies discharged by these glands or folliculi.

Near the extremity of this intestine, the rugæ or folds become in a manner longitudinal; and at last, towards the circumference of the inner margin of the anus, they form little bags or femilunar lacunæ, the openings of which are turned upward, toward the cavity of the intestine. These lacunæ are something like those at the lower extremity of the œsophagus, or upper orifice of the stomach.

At length the extremity of the rectum contracts, and terminates by a narrow orifice called the anus, the sides of which are disposed in close folds or gathers. This extremity of the intestine has several muscles belonging to it, some of which surround it like sphincters, the rest are broad fleshy planes inserted in it, and which being likewise fixed to other parts, sustain it in its natural situation, and restore it to that situation when disturbed by the force necessary for the exclusion of the feces. These latter muscles are termed levatores ani, the first go by the general name of sphincters.

These sphincters are three in number, one intestinal or orbicular, and two cutaneous or oval; whereof one is large, superior, and internal; the other small, inferior, and external.

The intestinal or orbicular sphincter of the anus, consists merely in an augmentation of the inferior portion of the fleshy fibres of the extremity of the rectum.

The cutaneous ligament goes out anteriorly, from the extremity of the os coccygis. It is very slender, and divides into two portions at the orifice of the anus, which run into the membrana adiposa, and are inserted in the skin on each side of the anus, by a kind of expansion; and continuing to divaricate, they are lost on the two sides of the peritonæum.

The interosseous ligament of the ossa pubis is a very strong triangular membrane, fixed by two of its edges in the inferior rami of these bones, all the way up to their common symphysis. The third edge, which is the lowest, is loose; and this whole membrane, the middle of which is perforated by a particular hole, is stretched very tight between the two bones, and under their cartilaginous arch, to which it adheres very closely.

At the lower part of this interosseous ligament, along its whole lower or loose edge, lies a digastric muscle, fixed by its two extremities in the rami of the ossa pubis, its middle tendon lying on the middle of the edge of the ligament.

The cutaneous sphincters have each an anterior and posterior insertion, ending both ways in a kind of point, and comprehending the orifice of the anus between their middle portions.

They are distinguished from each other by their situation, by their size, and by a kind of white cellular line. The greatest of the two appears to be double, and the smallest lies nearest the skin, and adheres most closely to it.

They are inserted backward, partly in the apex of the os coccygis, and partly in the contiguous portion of the os coccygis ligament of that bone. Forward their chief

insertion is in the middle tendon of the transversalis urethra; and they have likewise some connexions to other muscles of the urethra.

The levatores ani are broad, thin, muscular portions, fixed by one extremity of their fleshy fibres round the concave side of the inferior portion of the pelvis, from the symphysis of the ossa pubis, beyond the spine of the ischium. The other extremity of these fibres runs down on each side behind, and under the curvature of the end of the rectum, where they meet together, and unite from the basis of the os coccygis all the way to the margin of the anus.

We ought likewise to remark, that the margin or edge of the anus is formed by the union of the skin and epidermis with the internal coat of the rectum; so that the most superficial portion of that coat seems to be a continuation of the epidermis.

### MESENTERIUM & MESOCOLON.

THIS great bundle of intestines is not left to move at random in the cavity of the abdomen; but artfully bound down by a membranous web, which prevents the intestinal convolutions from being intangled in each other, and from being twisted or compressed in all their different ways of meeting; and yet allows them a gentle floating, but limited motion.

This web is distinguished into two portions; one of which, being very broad and very much plaited, connects the small intestines; the other, which is long and incurvated, does the same office to the greater intestines.

These two portions are in reality only one and the same continuation of the membranous lamina of the peritonæum doubled back upon itself, and they are distinguished only by their breadth. Taken both together, they form a kind of spiral roll, more or less plaited in its circumference. The first portion has retained the name of *mesentery*, the other is termed *mesocolon*.

The mesentery begins at the last incurvation of the duodenum, and runs obliquely from left to right, along the vertebræ of the loins. In this space, the membranous portion of the peritonæum is detached on both hands, produces a duplicature by two elongations or particular laminae applied to each other, and thus forms the mesentery.

It is narrow at its upper and lower parts, but chiefly at the upper. The middle portion is very broad, and the edge of it next the intestines is every where very much plaited. These plaits or folds are only waving inflexions, such as may be observed in the edge of a piece of shamoy, which has been often drawn through the fingers. They make this edge of the mesentery very long, and they run through about one third of its breadth.

The two laminae are joined together by a cellular substance, which contains glands, vessels, and nerves; and in some subjects a great quantity of fat, which keeps the two laminae a distance from each other.

Along the whole circumference of the mesentery, the two laminae are naturally separated, and applied to the two sides of the small intestines, which they invest by their union, or rather reciprocal continuation on the great curvature

curvature of that canal, and carry it as in a scarf or sling. This is what forms the external or membranous coat of the intestines.

The mesocolon is the continuation of the mesentery, which having reached the extremity of the ilium, contracts and changes its name. At this place the particular lamina which is turned to the right side, forms a small transverse fold, called *ligamentum coli dextrum*.

Afterwards the mesocolon ascends towards the right kidney, where it seems to be lost by the immediate adhesion of the colon to that kidney, and to the first incurvation of the duodenum. Then it appears again, and, increasing in breadth, it continues its course almost transversely under the liver, stomach, and spleen, where it begins to turn downward, under the left hypochondrium, toward the kidney on the same side.

Through this whole course, the mesocolon extends in breadth, and forms nearly a transverse femicircular plane, very little plaited at its great circumference. By this circumference or edge, it is connected to the colon; and hides that ligamentary band of this intestine, which runs along its small curvature. By its short or small edge, it forms the triangular case of the duodenum; and by its great edge, the external coat of the colon, in the same manner as the mesentery does that of the small intestines. As it passes under the large extremity of the stomach, it adheres a little to the lower portion of that extremity, as the diaphragm does to the upper.

Having got below the left kidney, it contracts and forms another transverse fold, called *ligamentum celi sinistrum*. Afterwards it expands again, but not so much as in the upper part, and runs down on the left psoas muscle, toward the last vertebrae of the loins. This descending portion is fixed to the convolutions of the colon in the same manner as the superior portion is to the arch of that intestine.

The intestinum rectum is likewise invested by a particular production of the peritonæum, called commonly by the barbarous name of *mesorectum*. This production is very narrow; and, about the middle of the fore-side of the rectum, it forms a transverse femicircular fold, which appears when the intestine is empty, but is lost when it is filled.

### GLANDULÆ MESENTERICÆ, VASA LYMPHATICA & LACTEA.

BETWEEN the laminae of the mesentery, a great number of glands lie scattered through the cellular substance. In the natural state, these glands are something of the figure of lentils or little round beans; some of them being orbicular, others oval, but all of them a little flattened.

These glands are of the number of those that anatomists call *glandulae conglobatae*, the structure of which is not as yet sufficiently known. They seem to be of a cellular substance, surrounded by a very fine membrane or coat, on which, by the help of microscopes, we discover an intertexture of particular filaments.

Besides the blood-vessels which are distributed in a regular manner in the mesenteric glands, and besides many nervous filaments spread through them, we dis-

cover an infinite number of small vessels of another kind running from gland to gland.

These vessels are extremely thin and transparent, and furnished on the inside with numerous valves, which appear on the outside like little small knots very near each other. They go out from each gland by ramifications, as by so many roots, and having formed a small trunk, they are again divided, and enter some neighbouring gland by the same kind of ramifications by which they went out from the former.

They are termed *lymphatic vessels*, because for the most part they contain a very clear, limpid, though mucilaginous serum, called *lymph* by anatomists. But as they have likewise been observed to be filled with a white milky fluid, called *chyle*, they have been called *vasa chylosifera*, or *vasa lactea*. They have the name of *veins*, because their valves are disposed as those of the ordinary blood-veins, and because the fluid which they contain runs from smaller into larger tubes.

They derive their first origin from the tunica villosa of the intestines, and chiefly from that of the small intestines, by a great number of small capillary roots. From these roots there arises, between the coats of the intestines, a kind of rete mirabile, which surrounds almost the whole circumference of the intestinal canal, between the muscular and external coat.

This reticular texture of lacteal vessels keeps close to the external coat, and leaves the canal along with it, on the side of the mesentery, where it forms two planes of ramifications, plainly distinguished from each other by the cellular substance, and adhering closely to the inside of the two membranes of the mesentery. In this separate state they run on the laminae of the mesentery, as far as the first mesenteric glands, where they unite again into one plane.

After this union, the lacteal vessels are distributed almost uniformly through the whole extent of the mesentery, from its circumference to its origin or adhesion to the vertebrae of the back, between the mesenteric glands, which they join, and form frequent anastomoses or communications.

Having passed through the mesentery, the ramifications begin to unite as they approach the spina dorsii, and consequently their number is lessened, and their size increased; and having passed the last mesenteric glands, they terminate about the middle of the adhesion of the mesocolon in small common trunks, which receive a great number of lymphatic vessels from the glandulae lumbaræ, and others below these.

The lacteal vessels which lie between the mesenteric glands and middle adhesion of the mesocolon to the spina dorsii, run down on the body of the inferior aorta, between the extremities of the small muscle of the diaphragm, and terminate in a kind of cistern, called by some *receptaculum chyli*, by others *receptaculum Pecquetii*.

The greatest part of the receptaculum chyli lies behind the right portion of the inferior muscle of the diaphragm, on the right side of the aorta, at the union of the last vertebra of the back with the first of the loins. It is a kind of membranous vesicle, the conformation of which is various in human subjects. Sometimes it is of

an uniform long oval figure, like the vesicula fellis; sometimes it is divided by stricures, into several small roundish bags more or less flattened, and sometimes it surrounds the trunk of the aorta like a collar.

It is composed of very thin coats, and its cavity is divided by small pellicule or membranous septa, the disposition of which is irregular. It is chiefly round the lower part of this receptacle, that the last lacteal vessels are inserted, some on the sides, and some behind the aorta; and they are accompanied by numerous lymphatic vessels. The upper portion is contracted between the aorta and vena azygos, and forms a particular canal, which runs up through the thorax, by the name of *ductus thoracicus*.

### HEPAR & VESICULA FELLIS.

The liver is a large and pretty solid mass, of a dark red colour, a little inclined to yellow, situated immediately under the arch of the diaphragm, partly in the right hypochondrium, which it fills almost intirely, and partly in the epigastrium, between the appendix eniformis and spina dorsa, and terminating commonly in the left hypochondrium.

The figure of the liver is irregular, it being arched or convex on the upper part, unequally concave on the lower, and very thick on the right and back sides. Towards the left and anterior sides its thickness decreases very much, and terminates there by a kind of edge; and it is broader from right to left, than from before backwards.

It may be divided into lateral parts called *lobes*; one of which is termed the *great or right lobe*; the other, the *small or left lobe*. These two lobes are distinguished above, by a membranous ligament; and below very plainly, by a considerable scissure lying in the same direction with the superior ligament.

The eminences on the concave side of the liver belong to the great lobe. The principal eminence is a sort of triangular or pyramidal apophysis situated backward near the great scissure which distinguishes the two lobes.

This triangular eminence is termed *lobulus Spigelii*, or simply the small lobe of the liver. One of its angles advances a considerable way toward the middle of the lower side of the great lobe, and is lost there. Toward the fore-side, there is another eminence less prominent but broader; and to this eminence and the former, the ancients gave the general name of *porta*.

The depressions on the concave or lower side of the liver are four in number. The first is the scissure that separates the two lobes, which runs a-cross the concave side, from the eminences already mentioned, to the anterior edge, where it terminates by a notch of different depths in different subjects. This is termed the *great scissure of the liver*.

The second depression is situated transversely between the two eminences of the great lobe, and filled by the sinus of the vena portæ. The third depression is backward, between the great lobe and lobulus Spigelii, and the vena cava passes through it. The fourth is a kind of sulcus in between the lobulus and small lobe of the liver, which in the fœtus served to receive a venal canal lost in

adults, in whom it appears only as a kind of ligament. This sulcus is in some measure a continuation of the great scissure, and joins the vena cava by an acute angle.

Besides these four depressions, there is one on the fore-part of the great lobe, in which the vesicula fellis is lodged; and it sometimes runs as far as the edge, where it forms a small notch. We may likewise reckon among these depressions, a small superficial cavity in the posterior and lateral part of the lower side of the great lobe, by which it rests on the right kidney; and likewise a superficial cavity in the left lobe, where it runs over the stomach.

Lastly, on the posterior edge of the liver, there is a great sinus common to both lobes, which gives passage to the spina dorsa and œsophagus, near the place where the vena cava descends.

The convex side of the liver is commonly connected to the diaphragm by three ligaments, which are only continuations of the membranous lamina of the peritonæum. One lies near the edge of the extremity of each lobe, and one in the middle, and they are accordingly termed the *right, middle, and left ligaments*. There is a cellular substance in the duplicature of each, in which the blood-vessels and lymphatics run, and which sends off a kind of lamina into the substance of the liver.

The right ligament sometimes connects the great lobe to the cartilages of the false ribs; and the left ligament, or that of the small lobe, is often double, and advances toward the middle ligament. This middle ligament begins low, in the great scissure of the liver, near the eminences called *porta*, and from thence passes thro' the anterior notch and over the convex side of the liver at the union of the two lobes, and is fixed obliquely in the diaphragm.

It is likewise fixed along the upper and inner part of the vagina of the right musculus rectus of the abdomen, in such an oblique manner as to be nearer the linea alba below than above.

Besides these ligaments the great lobe of the liver is likewise connected to the right ala of the tendinous portion of the diaphragm, not by a ligament, but by a broad and immediate adhesion, without the intervention of the membrane of the peritonæum, which is only folded quite round this adhesion, to form the external membrane of all the rest of the body of the liver.

The middle ligament, called improperly *ligamentum hepatis suspensorium*, contains in its duplicature a thick white rope, like a round ligament, which was the umbilical vein in the fœtus. Thus the lower part represents a falx, the convex edge of which is sharp, and the other rounded.

All these ligaments serve to keep the liver in its proper situation, and to hinder it from inclining too much towards either side: But we must not imagine that any of them serve to suspend it; because it is sufficiently supported by the stomach and intestines, especially when they are filled.

When the stomach is empty, or when we fast longer than ordinary, it is a common expression to say *the stomach pinches us*. As the liver is not then sustained by the stomach and intestines, it descends by its own weight, and

Fig. 1.

and chiefly by the means of the middle ligament pulls the diaphragm along with it. It is in that place therefore that we have this uneasy sensation, and not at the superior orifice of the stomach, as is commonly believed.

The liver is composed of several kinds of vessels, the ramifications of which are multiplied in an astonishing manner, and form by the intertexture of their capillary extremities, an innumerable collection of small pulpy, friable corpuscles, which are looked upon to be so many organs designed to separate from the mass of blood a particular fluid termed the *bile*.

The greatest part of these vessels from one end to the other is included in a membranous vagina called *capsula vena portæ*, or *capsula Glissoni*.

The trunk of the *vena portæ* is situated transversely between the broad anterior eminence of the great lobe of the liver, and the root of the lobulus, in a particular fissure, and forms what is called the *sinus of the vena portæ*. From this sinus five principal branches go out, which are afterwards divided into millions of ramifications through the whole substance of the liver.

At this place the *vena portæ* lays down the common office of a vein, and becomes a kind of artery as it enters, and is again ramified in the liver. The extremities of all these ramifications of the trunk of the *vena portæ hepatica* end in the pulpy friable corpuscles which seem to be thick villous folliculi.

Its in these folliculi that the bile is secreted, and it is immediately collected in the same number of extremities of another kind of vessels, which unite by numerous ramifications into one common trunk. These ramifications are termed *pori bilarii*, and the trunk *ductus hepaticus*; and the ramifications of these two kinds of vessels are inverted together by the capsule of the *vena portæ*.

The blood, deprived of this bilious fluid, is reconveyed to the heart by a great number of venal ramifications, which afterwards unite into three principal branches, besides others that are less considerable, that terminate in the *vena cava*, and are all called by the name of *vena hepatica*.

The capillary extremities of the ramifications of the *vena cava*, join those of the *vena portæ*, and accompany them through the liver; and yet the great branches of both veins intersect each other in several places.

The *ductus hepaticus*, or trunk of the *pori bilarii*, having run a little way, joins another canal called *ductus cysticus* or *vesicularis*, because it comes from the vesicula fellis. These two united ducts form a common trunk named *ductus cholidochus*, because it conveys the bile. This duct having reached the incurvation of the duodenum, insinuates itself through the coats of that intestine, and opens into the cavity thereof, not by a round papilla, but by an oblong orifice, rounded at the upper part, and contracted at the lower, like the spout of an ewer, or like a common tooth-picker.

The gall-bladder is a kind of small bag shaped like a pear, that is, narrow at one end and wide at the other. The wide extremity is termed the *fundus* or *bottom*, the narrow extremity the *neck*, and the middle portion the *body*. About one third of the body of the vesicula lies in a depression on the concave side of the liver, from

the trunk or sinus of the *vena portæ*, where the neck is situated to the anterior edge of the great lobe, a little toward the right side, where the bottom is placed.

The gall-bladder is composed of several coats; the outermost of which is a continuation of that which invests the liver, and consequently of the peritonæum.

The second coat is fleshy, and made up of two strata, one longitudinal, the other transverse, the fibres of which have nearly the same irregular direction with those of the stomach; and this disposition of the fibres in these viscera is owing to the different diameters in the several portions of them, and to their incurvation.

These two coats are connected by a cellular substance continued between the body of the vesicula and the liver, all the way, to a whitish stratum, which is looked upon as the third coat of the gall-bladder answering to the *tunica nervosa* of the intestines.

The innermost or fourth coat has on the inside a great number of reticular folds, filled with small lacunæ, like perforated papillæ, especially near the neck of the vesicula where these folds are longitudinal, and afterwards form a kind of small pylorus with plaits of the same nature with those in the great one. These lacunæ are looked upon to be glands.

That side of the body of the vesicula which lies next the liver is connected to that viscus by a vast number of filaments, which run a great way into the substance of the liver; and among these filaments there are some ducts which form a communication between the *pori bilarii* and vesicula. They are most numerous near the neck of the vesicula, and they are named *ductus cyst-hepatici*, or *hepatico-cystici*.

The neck of the vesicula is formed by the contraction of the small extremity; and this neck bending afterwards in a particular manner, produces a narrow canal named *ductus cysticus*.

The neck of the vesicula is nearly of the same structure with the other parts. It has on the inside several reticular rugæ and some folds which appear like fragments of valvulæ conniventes, situated very near each other, from the neck to the contraction of the cystic duct. The first of these folds is pretty broad and large, and almost circular; the next is more oblique, and smaller in size; and the rest diminish in the same manner.

The bile which passes through the *ductus hepaticus* into the cholidochus, may be called *hepatic*; and that which is collected in the vesicula fellis, may be termed *cystic*. The hepatic bile flows continually through the *ductus cholidochus* into the duodenum, whereas the cystic bile flows only by reason of plentitude or by compression.

The uses of the liver shall be explained after the description of pancreas, spleen, and omentum, all these viscera having a great relation to the liver.

## PANCREAS.

THE pancreas is a long flat gland, of that kind which anatomists call *conglomerate*, situated under the stomach, between the liver and the spleen. Its figure resembles that of a dog's tongue; and it is divided into two sides, one superior, the other inferior; two edges, one anterior,

rior, the other posterior; and two extremities, one large, which represents the basis of a tongue, and one small and a little rounded like the point of a tongue.

The pancreas is situated transversely under the stomach, in the duplicate of the posterior portion of the mesocolon. The large extremity is connected to the first incurvation of the duodenum, and from thence it passes before the rest of that intestine, all the way to its last incurvation; so that a great part of the duodenum lies between the pancreas and the vertebræ of the back. The small extremity is fixed to the omentum near the spleen.

The pancreas is composed of a great number of soft glandular molecule, combined in such a manner, as to exhibit the appearance of one uniform mass on the outside, the surface of which is rendered uneven only by numerous small convexities, more or less flattened. When these molecule are separated a little from each other, we find along the middle of the breadth of the pancreas, a particular duct, in which several smaller ducts terminate laterally on each side, like small rami in a stem.

This canal, named *ductus pancreaticus*, or *ductus Virsungi*, is very thin, white, and almost transparent, and the extremity of the trunk opens commonly into the extremity of the ductus cholidochus. From thence it diminishes gradually, and terminates in a point, next the spleen. The small lateral branches are likewise pretty large near the trunk, and very small toward the edges of the pancreas; all of them lying in the same plane like the branches of the common fern.

The pancreatic duct is sometimes double in man, one lying above the other. It is not always of an equal length, and sometimes runs in a winding course, but always in the same plane; and it is nearer the lower than the upper side of the pancreas. It pierces the coats of the duodenum, and opens into the ductus cholidochus, commonly a little above the prominent point of the orifice of that canal; and sometimes it opens immediately into the duodenum.

### S P L E E N.

THE spleen is a bluish mass, something inclined to red, and of a long oval figure, being about seven or eight fingers-breadth in length, and four or five in breadth. It is of a softish substance, and is situated in the left hypochondrium, between the great extremity of the stomach, and the neighbouring false ribs, under the edge of the diaphragm, and above the left kidney.

The inner or concave side is divided by a longitudinal groove or scissure, in two planes or half-sides, one upper, the other lower; and by this groove, the vessels and nerves enter in human subjects. The superior half-side is broader and more concave than the inferior, being proportioned to the convexity of the great extremity of the stomach. The inferior half-side lies backward on the left kidney, and forward on the colon; and sometimes this side of the spleen appears to have two superficial cavities, one answering to the convexity of the stomach, the other to that of the colon. The convex side of the spleen is turned to the left ribs.

It is connected to the stomach, by the vessels called *vasa brevia*; to the extremity of the pancreas, by ramifications of the splenic artery and vein; and to the omentum, by ramifications which the same artery and vein send to the spleen, and which run in the longitudinal groove.

It is connected to the edge of the diaphragm by a particular membranous ligament of different breadths in different subjects, fixed in its convex side, sometimes near the upper edge, and sometimes near the lower.

The structure of the spleen is not easy to be understood in man, and it is very different from that of the spleens of brutes, from which both public and private demonstrations are commonly made.

Its coverings adhere to it so closely in man, that it is difficult to distinguish the common from the proper coat; whereas in some brutes, such as oxen, sheep, &c. we easily find two coats separated by a cellular substance. This covering seems to be no otherwise a continuation of the peritonæum than by the intervention of the omentum and mesocolon.

In man the substance of the spleen is almost wholly vascular. In oxen the substance of the spleen is chiefly reticular, and in sheep it is cellular. In oxen and sheep there are no venal ramifications, but instead thereof only open sinuses disposed like branches, except a small portion of a venal trunk perforated on all sides, at the extremity of the spleen.

In the human spleen we see something like glandular corpuscles, as in those of other animals; and there are numerous venal ramifications through its whole extent. Between these ramifications we every where observe an appearance of extravasated blood, lying in a kind of filamentary transparent and very delicate substance expanded through the whole spleen.

This filamentary substance, having surrounded all the ramifications, terminates in almost imperceptible cells which communicate with each other.

### OMENTUM & APPENDICES EPILOICÆ.

THE omentum is a large, thin, and fine membranous bag, surrounded on all sides by numerous portions of fat, which accompany and even invest the same number of arteries and veins adhering closely to each other.

The greatest part of it resembles a kind of flat purse or a sportsman's empty pouch, and is spread more or less on all the small intestines from the stomach to the lower part of the regio umbilicalis. Sometimes it goes down to the lower part of the hypogastrium, and sometimes does not reach beyond the regio epigastrica. It is commonly plaited or folded in several places, especially between the bands of fat.

It is divided into a superior and inferior, an anterior and posterior, and a right and left portion. The superior portion is in a manner divided into two borders, one of which is fixed along the great curvature or convex side of the arch of the colon, and the other along the great curvature of the stomach. The commissure or union of these two borders on the right side, is fixed to the common ligament or adhesion of the duodenum and colon,

colon, and to the contiguous parts of these intestines. That on the left side is fixed to the longitudinal fissure of the spleen, to the extremity of the pancreas, and to the convex side of the great extremity of the stomach. It is likewise fixed to the membranous ligament which sustains the ductus cholidochus, and connects it to the vena portæ ventralis.

Below these adhesions, the other portions, that is, the anterior, posterior, two lateral and inferior portions, which last is the bottom of the succulus epiploicus, have commonly no fixed connections, but lie loose between the fore-side of the cavity of the abdomen and intestines.

The membrane of the omentum is through its whole extent made up of two extremely thin laminae joined by a cellular substance; the quantity of which is very considerable along the blood-vessels, which it every where accompanies in broad bands, proportioned to the branches and ramifications of these vessels. These cellular bands are more or less filled with fat according to the corpulency of the subject.

Besides this large membranous bag, there is another much smaller, which differs from the large one, not only in size, but also in figure, situation and connexion; and this is the *little omentum*. This small bag is fixed by its whole circumference, partly to the small curvature of the stomach, and partly to the concave side of the liver before the sinus of the vena portæ, so as to surround and contain the prominent portion of the lobulus.

The little omentum is thinner and more transparent than the other, and its cavity diminishes gradually from the circumference to the bottom. Its structure is pretty much the same with that of the great omentum, it being composed of two laminae, with a mixture of the same portions of fat, which are considerably finer than in the other.

The fatty appendices of the colon and rectum appear to be a kind of small omenta or appendices epiploicæ. They are situated at different distances along these intestines, being particular elongations of their common or external coat. They are of the same structure with the great omenta, and there is a cellular substance contained in their duplicature, more or less filled with fat, according as the subject is fat or lean.

#### Uses of the Abdominal Viscera.

THE intestines in general finish what the stomach had begun. The alimentary pulp having been sufficiently prepared by the succus gastricus, or lymph of the stomach, undergoes a further change by the intestinal lymph, bile, and pancreatic juice, by which the milky liquor called *chyle* is produced, and this liquor rendered fluid enough to enter the lacteal vessels through the tunica villosa of the small intestines, while the grosser portion of the aliment continues its course, and becoming gradually thicker as it advances toward the great intestines, is there collected by the name of *feces*.

The valve of the colon, which might more properly be termed *sphincter* or *pylorus* of the ileum, hinders the feces from returning into the small intestines.

The glandular lacunæ of the intestines furnish conti-

nually a kind of mucilage, which not only defends the internal coat from the acrimony of the feces, but serves also to lubricate these feces in proportion to their different degrees of solidity.

The intestinum rectum is the last reservoir of the feces. The great thickness of its muscular coat, and the great number of longitudinal fibres by which this thickness is chiefly formed, enable it to yield to the collected feces to so great a degree, as to represent a large bladder or stomach. The muscoli levatores ani serve to suspend the lower portion of this intestine, especially when full; and it is partly by the contraction of these muscles which overcome the sphincter of the anus, that the feces are discharged out of the body. These sphincters form the third pylorus of the whole alimentary canal.

The mesentery and mesocolon connect the intestines, in such a manner, as that they cannot be twisted or run into knots, without hindering them from sliding and yielding to each other according to the different postures of the body, or according as they are more or less empty or full.

The adhesions of the mesentery form the convolutions of all the small intestines into a large bundle, irregularly round, which fills a great part of the cavity of the abdomen, from the epigastrium downward.

The mesocolon by its adhesion to the colon forms a kind of septum transversum, between the small intestines and the viscera contained in the epigastrium; and this septum supports the liver and stomach under the arch of the diaphragm, just as much as it is sustained by the intestines.

The breadth of the mesentery and mesocolon affords a large extent to the ramifications of the arteries, veins, and nerves, distributed through them by innumerable communications and anastomoses, by means of which any portion of the intestines may be supplied, though the principal branch which leads to it should happen to be compressed or obstructed.

The cellular substance in the duplicature of the mesentery and mesocolon, serves not only for a soft bed to all these ramifications, but also to contain those collections of fat necessary for the formation of the bile; and the cellular substance of the mesentery has likewise one use peculiar to it, which is to invest the lymphatic glands and lacteal vessels, and upon this account it is thicker than that of the mesocolon.

The lacteal vessels being first formed by a copious reticular texture round the circumference of the intestines, resembling the vascular network of that canal, and afterwards uniting every where through the duplicature of the mesentery, with the arterial ramifications which they likewise accompany in many places; it is easy to conceive, that the pulsation of the mesenteric arteries must propel the chyle in the lacteal vessels from the intestines to the receptaculum chyli, that motion being suitable to the direction of their valves.

The liver is the principal organ for the secretion of the bile. The villi of that immense number of glandular cells of which it is composed, filtrate continually from the blood of the vena portæ small drops of bile, which afterwards insinuate themselves into the pori bilarii, an J

are in part lodged in the vesicula fellis, and in part run directly into the duodenum.

The spleen, omentum, appendices epiploicæ, adipose strata of the mesentery, and those of the great intestines, and even the pancreas, with the whole series of glands in the intestinal canal, seem to contribute to the formation of the bile, as so many auxiliary or rather preparatory organs.

The vesicular bile appears to be more exalted than that in the hepatic duct; and by meeting in the ductus cholidochus, they seem to compose a third kind of bile, which without the cylic or vesicular bile would perhaps be too mild, and too acrid without the hepatic. This bile mixes in the duodenum with the pancreatic juice, and with that of the intestinal glands; and from this mixture a fluid results, which is proper to separate the chylous matter from the gross and useless part of the alimentary pulp, as it comes from the stomach.

### RENES & URETERES.

THE kidneys are two pretty solid, glandular bodies, situated in the posterior part of the cavity of the abdomen, on each side of the lumbar vertebræ, between the last false ribs and ossa ileum. The right kidney lies under the great lobe of the liver, and is consequently lower than the left, which lies under the spleen.

The figure of the kidneys resembles that of a large bean, their circumference being convex on one side, and concave on the other. The concave side is turned to the vertebræ, and the convex side the opposite way.

In each kidney we observe a fore and back side, an upper and lower extremity, a great and small curvature, and a convexity and concavity.

The back-side is broader than the fore-side; and the upper extremity is a little broader and more incurvated than the lower. The depression in the small curvature is oblong and uneven, resembling a sinus, surrounded by several tubercles; and as it is turned a little toward the fore-side, this side is something narrower than the other.

The kidneys are surrounded by a very loose membranous and cellular covering, called *membrana adiposa*, because in fat persons the cells of this substance are filled with fat.

The proper coat or membrane of the kidneys is composed of two laminae, between which there is likewise a very fine cellular substance, which may be made sensible by blowing through a pipe between the two laminae.

The external lamina is very thin, and adheres closely to the internal lamina, by means of the cellular substance. The internal lamina penetrates every where, by numerous elongations, into the substance of the kidney, from which it cannot be separated without tearing.

The surface of the external lamina is very smooth, polished and glistening, and it renders the whole surface of the kidney very even and uniform.

The blood-vessels having entered the kidneys, are ramified every way; and these ramifications send out other capillary rami, which go all the way to the surface, where they appear like irregular stars, and furnish the proper membrane of the kidneys.

The proper membrane having surrounded the kidney all the way to the sinus, joins the vessels at that place, and accompanies all their ramifications through the body of the kidney, in form of a vagina or capsula.

We may distinguish three kinds of substances in the kidney; an exterior substance, which is thick, granulated, and in a manner cortical; a middle substance, which is medullary and radiated, called *striata, sulcata, or tubularis*, because it seems to be made up of radiated tubes; and an inner substance, which is only a continuation of the second, and terminates on the inside by papillæ, for which reason it is called *papillaris*.

The papillæ, which are only a continuation of the medullary substance, are often a little paler than that substance. They are ten or twelve in number, very distinct from each other, resembling the same number of cones, with very broad bases and obtuse apices.

At the point of each papilla we see, even without a microscope, in a small depression, several very small holes, through which little drops may be perceived to run when the papillæ are compressed. These are little drops of urine, which being filtrated, partly in the cortical, partly in the medullary or tubular substance, do afterwards pass through the substance of the papillæ, and are discharged by these orifices.

Each papilla lies in a kind of membranous calix or infundibulum, which opens into a common cavity called the pelvis. This pelvis is membranous, being of the same structure with the calices, of which it is a continuation; and its cavity in man is not uniform, but distinguished into three portions, each of which contains a certain number of infundibula or calices, together with the papillæ which lie therein.

At the place where these infundibula surround the bases of the papillæ, they send productions into the medullary or radiated substance of the kidney, which accompany the blood-vessels, and serve for capsule or vagina to all the vascular arches, both arterial and venal, and to their different ramifications, quite through the cortical substance, and as far as the surface of the kidney.

After the infundibula have contracted in a conical form round the apices of the papillæ, each of them forms a small short tube or gullet, which, uniting at different distances along the bottom of the sinus of the kidney, form three large tubes, which go out from the sinus in an oblique direction from above downwards, and immediately afterwards unite into one trunk.

This trunk becomes a very long canal, called the ureter. In men the three tubes supply the place of what is called the pelvis in brutes, and might properly be called the roots or branches of the ureters than the pelvis. The ureters are commonly two in number, one for each kidney.

The situation of the trunk, and of the roots and branches of each ureter, with respect to the renal artery and vein, is in the following manner: The artery is in the upper part of the sinus, and partly before the vein. The vein is about the middle, and between the artery and ureter. The ureter is in the lower part, a little behind the vein, and it is partly surrounded by one branch of the artery.

From

The ureters run down obliquely, and with a very small degree of inflection, from the kidneys to the lateral parts of the inner or anterior side of the os sacrum, and passing between the rectum and bladder they terminate in the last of these viscera.

They are composed of three proper coats; the first of which, that surrounds the rest, is of a whitish colour, and of a very compact filamentary texture, being stretched with difficulty, and appearing like a filamentary substance degenerated. The next coat is of a reddish colour, stronger than the first, and made up of different strata of fibres, which intersect each other; but it is very hard to determine, whether they are muscular, or simply membranous.

### GLANDULÆ RENALES, *vulgo* CAPSULÆ ATRABILARIÆ.

IMMEDIATELY above each kidney, lies a glandular body, called by the ancients capsule atribilariæ; by others capsule renales, renes sucenturiati, and glandulæ renales. They are situated on the upper extremity of each kidney a little obliquely, that is, more toward the inner edge and sinus of the kidney than toward the outer convex edge.

Each gland is an oblong body with three sides, three edges, and two points, like an irregular crescent with its great or convex edge sharp, and the small concave edge broad. Its length is about two thirds of the greatest breadth of the kidney, and the breadth of its middle portion is about one third of its extent between the two extremities, sometimes more, sometimes less. Its colour is a dark yellow.

It has one anterior, one posterior, and one lower side, which last may be termed the basis; and it has one upper, and two lower edges, whereof one is anterior, the other posterior. The upper edge may be called the crista, and the two lower edges the labia.

The surface of these glands is uneven; the fore-side is the broadest, and the lower side or basis the narrowest. Along the middle of the anterior side, a ridge runs from the edge of the inner extremity, a little above the basis, to the point of the other extremity, and divides this side into two equal parts, like the middle rib of the leaf of a tree; and on the lower side, under the basis, there is a kind of raphe or future.

The blood-vessels of these glands come from the arteriæ, and venæ renales, and diaphragmaticæ, and likewise from the aorta and vena cava, from the arteria cæliaca, &c. These vessels are termed the capsular arteriæ and veins; and as they enter the glands, they seem to be invested by a vagina.

In the inside of these capsule, there is a narrow triangular cavity, the surface of which is full of short strong villi of a yellowish colour; but in children it is reddish, and of a dark brown in aged people. The sides of this cavity are connected by a great number of filaments; and they appear to be wholly glandular, that is, to be filled with very fine small follicular corpuscles.

This cavity contains an unctuous viscid liquor, of a yellowish red colour, which with age changes gradually

into a yellowish purple, a dark yellow, and a black yellow; and sometimes it is perfectly black; but even then, if it be spread thin on a large surface, it appears yellow.

The uses of these renal glands have not as yet been discovered; and all that we know about the liquor contained in them, is, that it resembles the bile. They are very large in the fœtus, and diminish in adults.

### VESICA URINARIA.

THE bladder is a kind of membranous and fleshy pouch or bottle, capable of dilatation and contraction, situated in the lower part of the abdomen, immediately behind the symphysis of the ossa pubis, and opposite to the beginning of the intestinum rectum. The figure of it is nearly that of a short oval. It is broader on the fore and back sides, than on the lateral parts; rounder above than below when empty, and broader below than above when full.

It is divided into the body, neck, and bottom; into an anterior, posterior, and two lateral parts. The upper part is termed the fundus or bottom; and the neck is a portion of the lower part, which is contracted like the gullet of some vessels.

The bladder is made up of several coats. That part of the external coat which covers the upper, posterior and lateral sides of the bladder, is the true lamina or membrane of the peritonæum; and the rest of it is surrounded by a cellular substance, by the intervention of which, the peritonæum is connected to the muscular coat.

The proper coats are three in number, one muscular, one nervous, and one villous, which is the innermost. The muscular coat is composed of several strata of fleshy fibres; the outermost of which are mostly longitudinal; the next to these are more inclined toward each hand; and the innermost, more and more oblique; and they become at length almost transverse.

The nervous coat is nearly of the same structure with the tunica nervosa of the stomach.

The internal coat is something granulated and glandular, and a mucilaginous serum is continually discharged through it, which moistens the inner surface of the bladder and defends it against the acrimony of the urine.

At the top of the bladder, above the symphysis of the ossa pubis, we observe a ligamentary rope, which runs up between the peritonæum and the linea alba of the abdomen, all the way to the navel, diminishing gradually in thickness as it ascends. This rope had a particular use in the fœtus, as shall be said in another place. It is sufficient to add here, that it is in part originally a production of the inner coats of the bladder, which production is termed urachus.

This rope is composed likewise of two other ligamentary elongations, which are the extremities of the umbilical arteries. These arteries come from the hypogastricæ, run up by the sides of the bladder, and remain hollow and filled with blood, even in adults, as high as the middle of the bladder, through all which space they likewise send off ramifications. Afterwards they lose their cavity, and become ligamentary as they ascend.

At the upper part of the bladder, they approach each other; and, joining the urachus, form that rope, which may be termed the superior ligament of the bladder.

The lower part of the bladder, which deserves the name of *fundus* much better than the upper part, is perforated by three openings, one anterior, and two posterior. The anterior opening is formed by an elongation of all the proper coats, in form of a gullet, turned much in the same manner with the inner orifice of the rostrum of the head of an alembic. This elongation is called the neck of the bladder, the description of which belongs to that of the parts of generation in men.

The other two openings in the true fundus of the bladder, are formed by the ureters, which, in their course downward already described, run behind the spermatic vessels, and then behind the lower part of the bladder, approaching each other. Each ureter lies between the umbilical artery and vas deferens of the same side, the artery lying on the outside of the ureter, and the vas deferens on the inside.

Afterwards they get between the vasa deferentia and the bladder, crossing these canals: and then at about a finger's breadth from each other, they begin to pierce the coats of the bladder. They run a little way between the muscular and nervous coats, and open into the bladder obliquely, something nearer each other than when they first entered its coats.

The orifices of the ureters in the bladder, are something oval, and narrower than the cavity of the ureters immediately above them. The edge of these orifices is very thin, and seems to be formed merely by the union of the internal coat of the bladder with that of the ureters.

Besides the ligaments already mentioned, there are likewise two small ones, by which the anterior part of the true fundus of the bladder is connected to the ossa pubis, which shall be described with the neck and sphincter after the history of the parts of generation in both sexes.

## THE PARTS OF GENERATION IN MALES.

THE spermatic arteries go out most commonly from the anterior part of the inferior aorta, near each other, and about an inch lower than the arteriæ renales.

They run down obliquely in the posterior part of the abdomen, within the cellular substance of the peritonæum, passing insensibly from behind forward; and so parting gradually more and more from the aorta, they cross over the fore-side of the ureters, and run through the openings or rings of the abdominal muscles, along with the elongations or productions of the cellular portion of the peritonæum.

They are small at their origin; and in their course downward, they give off pretty considerable lateral ramifications to the membrana adiposa, peritonæum, and also to the mesentery.

They sometimes pass through the areolæ, or meshes of the spermatic veins; and before they go out of the abdomen, they are divided into very fine rami, which run

in a more or less winding course, almost parallel to each other.

Afterwards they enter the cellular productions of the peritonæum, which serve them for vaginæ. They do not fluctuate indifferently from one side to the other of these vaginæ; but are connected along their inner surface by thin membranous laminae, which are likewise continuations of the cellular substance of the peritonæum.

The arteries continue the same winding course within these vaginæ, passing before the vasa deferentia, which are likewise contained in them; and at length they terminate by ramifications in the epididymes and testes.

The testes are two glandular bodies, situated near each other, without the abdomen, below the interstice between the groins in an adult. The ancients named them *didymi* or *gemini*. Their size is nearly that of a pigeon's egg, and they are of an oval figure, a little flattened at each side. We may consider in each testicle, two extremities, two edges, and two sides. One extremity is situated forward, and a little upward; the other backward, and a little downward; and their edges lie upward and downward.

At the upper edge, they have each an appendix, called epididymis, together with which it is involved in several coverings; and they are both suspended in a common covering, called the scrotum.

Each testicle is a spermatic gland formed by a vast number of fine whitish tubes, folded and twisted in different manners, and distributed in different fasciculi, between membranous septa; the whole being surrounded by a strong common covering, named *tunica albuginea*.

These septa are disposed longitudinally, divaricating from each other on one side, and approaching on the other. They approach each other along one edge of the testicle, and terminate in a long narrow whitish body, as in a kind of axis.

From thence they divaricate in a regular manner, and are fixed by their opposite edges in the inner surface of the tunica albuginea, of which they appear to be a continuation. This white body may be termed the nucleus of the testicle.

From this description, we see that all these septa are not of an equal breadth; that the interstices between them are in some measure triangular; and that the extent of the small tubes, which lie therein, must be very considerable. They have been reckoned to amount to many cells, by taking the sum of all their several portions; and they may be easily unfolded by a long maceration, which destroys the delicate substance by which all their folds and convolutions are connected and tied down.

All these small canals seem to terminate by a smaller number of common trunks at the white body or nucleus already mentioned; which trunks do afterwards pierce the upper part of the anterior extremity of the testicle, and are disposed in several folds along the lateral external part of the upper edge, all the way to the posterior extremity. From this union arises a long whitish plaited fasciculus or bundle, called epididymis, or appendix to the testicle.

The epididymis thus formed, may be reckoned a production of the testicle, or a kind of testis accessorius; and

and it resembles in some measure an arch supported by its center or frame. It is more contracted at the middle, than at the extremities, by which it is closely united to those of the testicle.

Between its extremities it does not immediately touch the testicle, but is only loosely connected to it, by the duplicature of a very fine and almost transparent membrane, as by a kind of ligament. This membrane is the continuation and duplicature of the tunica albuginea or proper coat of the testicle, which having supplied the place of a ligament to the epididymis afterwards invests it.

The epididymis is flat, a little concave on the under side, or that next the testicle, irregularly convex on the upper side, or that turned from the testicle; and these two sides are distinguished by two angular edges; by the innermost of which, it is connected to the testicle, in the manner already said; but the outer edge and flat side are loose and free.

The anterior extremity or head of the epididymis arises from the testicle; and the posterior extremity or tail, which likewise adheres very closely to it, is incurvated from behind, forward, and a little upward, and contracting by degrees, forms a particular canal, termed vas deferens, which shall be described after the scrotum.

The scrotum is the cutaneous covering of the testes. Outwardly, it is a bag common to both, formed by a continuation of the skin of the neighboring parts, and commonly very uneven, having a great number of rugæ on its outer surface. Interiorly it is fleshy, and forms a muscular capsula for each testicle, termed dartos.

The exterior or cutaneous portion of the scrotum is nearly of the same structure with the skin in general, of which it is a continuation; only it is something finer, and it is likewise plentifully stored with sebaceous glands and bulbs or roots of hairs.

Though it is a common covering for both testicles, it is nevertheless distinguished into two lateral parts by a superficial and uneven prominent line which appears like a kind of suture, and from thence has been termed *raphe*.

This line is a continuation of that which divides in the same manner the cutaneous covering of the penis; and it is continued through the perinæum, which it divides likewise, all the way to the anus. It is only superficial, and does not appear on the inside of the skin.

The inner surface of this cutaneous bag is lined by a very thin cellular membrane, through which bulbs and glands appear very distinctly when we view its inside.

The dartos, or fleshy portion of the scrotum, is a true cutaneous muscle; the fibres of which are for the most part strongly connected to the skin, running through the cellular substance which lies between these two portions in place of a membrana adiposa, but without the least appearance of fat. This muscle is thin, and by the disposition of its fibres forms a bag with two cavities, or two small bags joined laterally to each other, and contained within the cutaneous portion.

The lateral parts of these two bags, which are turned from each other, are longer than those which are joined together; and by this union a septum is formed between the testes, which may be called *mediastinum scroti*.

The *raphe* or suture already mentioned adheres to the

edge of this septum, and thereby braces down the middle of the cutaneous portion, which from thence appears to have in part two cavities.

The aponeurotic or ligamentary expansion of the dartos is fixed in the ramus of the os pubis, between the musculus triceps and the origin of the corpus cavernosum of the same side, all the way to the lower part of the symphysis of these bones.

The vasa deferentia are two white solid flattened tubes, one lying on the right side, the other on the left. From the epididymis, of which they are continuations, each of them runs up in the cellular vagina of the spermatic vessels, as high as the openings in the abdominal muscles; the blood-vessels lying forward, and the vas deferens behind them.

This fasciculus, thus formed by the blood-vessels, vas deferens, and their common covering, is termed the spermatic rope. The covering is smoother on the outer than on the inner side, and for that reason it has been looked upon as a vagina; the internal substance of which is most cellular, and connects all the vessels together, while the external forms a covering to invest them.

The vas deferens having reached the membranous lamina of the peritonæum, where that lamina runs over the orifice of the vagina, separates from the blood vessels, and runs backward, in form of an arch, in the cellular substance of the peritonæum, as far as the nearest side of the bladder.

It passes afterwards behind the body of the bladder, to which it adheres very closely, as also to the lamina of the peritonæum which covers it, and then continues its arched course towards the neck of the bladder, where both vasa deferentia meet, and their arches terminate.

In this course, the vas deferens passes behind and crosses the neighbouring umbilical artery; crosses the extremity of the ureter of the same side, in its passage between that extremity and the bladder; and having got behind the bladder, it meets the vas deferens of the other side between the insertions of the ureters, and they run down together to the neck of the bladder.

This canal, which at the origin of the epididymis is pretty large and plaited, becomes immediately afterward smaller and smoother, and continues in that form till it gets behind the bladder, where it begins again to be larger and more uneven.

It arises from the angular portion or posterior extremity of the epididymis, and from thence runs forward in a very oblique course, on the posterior half of the epididymis, where it is a little incurvated as it joins the back-side of the spermatic vessels.

The cavity of the vas deferens is cylindrical, though the whole tube is flat, and its external circumference oval, and the cavity enlarges as it passes behind the bladder. The termination of these canals must be referred to the history of the urethra.

The particular coverings of the testes are commonly called coats; and they are reckoned to be three in number; the tunica musculo-fasciata, named *crassa*, vaginalis and albuginea. The first two are common to each testicle, and to the spermatic rope that belongs to it; and the third is peculiar to the testicle alone.

The tunica vaginalis is the most considerable of the three, and must be described first, in order to conceive the structure and connection of the cremaster, which is very improperly called a coat. The albuginea has been already described with the testis.

The tunica vaginalis is a continuation of the vagina of the spermatic rope, which, as it approaches the testicle, is gradually dilated, and forms two capsules, one contained within the other, the external being the longest and broadest at bottom; so that there is a void space there left between them, in which the testicle is lodged.

The inner surface of this coat is lined by a fine membrane, which strengthens the bottom of the vagina, and forms a kind of diaphragm, which prevents all communication between the vagina of the spermatic rope and the tunica vaginalis of the testicle.

The cremaster, improperly termed a coat, is a thin muscle or fleshy plane, which runs down round the vagina of the spermatic rope, and terminates in the tunica vaginalis of the testicle.

It surrounds almost the whole vagina, and afterwards expands itself on the upper and external part of the tunica vaginalis, in which it is inserted and lost.

It arises partly from the ligamentum Fallopii, and partly from the lower edge of the internal oblique muscle of the abdomen; and on this account it seems sometimes to arise from the spine of the os ilium.

The corpora cavernosa are two ligamentary and very limber tubes, united laterally to each side, through the greater part of their length, and solid at their two extremities, two of which are connected together, and rounded like the end of a finger; the other two divaricate, like the branches of the greek Y, and diminishing gradually in size after the divarication, terminate in an oblique point. These divaricated and pointed extremities may be called the *roots*, and the round extremities the *heads*.

These two bodies are almost cylindrical, being round, and of an equal diameter from the roots to the heads, where they are in some measure conical. The ligamentary substance of their sides is elastic, and composed of fine close fibres, which are partly transverse, and partly more or less oblique.

The cavity of these ligamentary tubes is entirely filled by a strong cellular or cavernous substance, which does not seem to be a continuation of the substance of the sides. These cells communicate with each other, and are always more or less full of blood, resembling pretty much the cellular substance of the spleen; only with this difference, that the sides of the cells are thicker in these cavernous bodies, and without any additional substance.

By the union of the two corpora cavernosa, two external grooves are formed, one on the upper side, the other on the lower. The lower groove is something broader than the upper, and it is filled through its whole length by a third tube, narrower than the corpora cavernosa, called the urethra.

The roots of the corpora cavernosa are fixed, each, to the edge of the small ramus of the os ischium and os

pubis. They meet at the symphysis of the ossa pubis, where each of them becomes a cylindrical tube, and unites with the other in the manner already said.

The heads or rounded extremities join the basis of a distinct body, called the glans, which is an expansion of the urethra, and closely united to it.

By the union of the corpora cavernosa from their roots to their round extremities or heads, a particular septum is formed by the transverse fibres of both. Between the fibres of this septum several small void spaces are left, by which the corpora cavernosa communicate with each other.

The urethra is the third spongy tube which composes the penis, and it adheres to the corpora cavernosa through the whole length of the inferior groove formed by their union. It differs from the other two, both as it is narrower, and as it forms a true hollow canal. Its substance is spongy or cavernous, except a small portion next the bladder, and its inner and outer surfaces are membranous.

It is at first no more than a membranous canal continued from the anterior opening of the bladder, at the place called the neck of the bladder.

About a finger's breadth and an half from its origin, it joins a cavernous substance like that of the two other tubes, only smaller, which furrounds it through the whole extent of the inferior groove of the corpora cavernosa.

But before this spongy substance begins to furround the urethra, it forms a distinct oblong body, like a pear or onion, which is connected only to the lower convex side of the canal, and afterwards, being split on each side, invests it quite round. This body is called the bulb of the urethra, being larger than any other part of that canal, and divided inferiorly by a very fine membranous septum, into lateral parts; and therefore when it is inflated, it appears to be double or with two heads.

The first portion of the urethra, or that which is not covered by the cavernous substance, and which from the bladder to the bulb is only a membranous canal, is sustained by a large solid whitish mass, of the figure of a chestnut, and situated between the bladder and the bulb of the urethra, its basis being toward the bladder, the apex or point toward the urethra, and the sides lying upward and downward.

This body is termed the prostate, from a greek word that expresses its situation before the vesiculae seminales, and implies a plurality, because it appears to be divided into two lateral lobes, by a hollow groove which runs through its upper side from the basis to the apex. The first portion of the urethra lies in this groove, adhering very closely to the prostate which furrounds it.

The body of the prostate lies on the intestinum rectum, and the apex is under the internal labium of the cartilaginous arch of the ossa pubis. The inner substance is spongy, but very compact; and in each lobe there are several folliculi: which open into the first portion of the urethra, toward the bottom of the groove.

The spongy substance of the urethra, having reached the extremity of the corpora cavernosa, forms a large head, called the *glans*, which crowns the three spongy pillars,

pillars; with this difference however, that it is a continuation of the spongy substance of the urethra, and only adheres to the extremity of the corpora cavernosa without any direct communication.

The figure of the glands is that of a rounded cone, a little flattened at the lower part, and with an oblique prominent basis, the circumference of which is something greater than that of the corpora cavernosa.

The spongy substance of the glands is thick and uniform next the corpora cavernosa; but next the urethra, it is perforated by a continuation of that canal, and is there no thicker than the urethra before the formation of the glands.

Therefore the canal of the urethra does not lie in the middle of the glands, but continues its direct course thro' the lower flat side of it, all the way to the extremity, where it terminates by an oblong orifice.

All the convex surface of the glands is covered by a fine villous substance; and that again by a fine membrane, resembling the red part of the lips. The circumference of the basis of the glands has a double row of small papillæ, which may be reckoned sebaceous glands, from which a thick matter is discharged.

At the bottom of the cavity of the first portion of the urethra, or that which lies within the prostates, there is a small oblong oval eminence, pretty large on the back part, and terminating forward in a point, called *caruncula* or *verumontanum*. The large portion of it is commonly perforated by two holes, sometimes only by one, and very seldom by three; and these are the excretory orifices of the vesiculæ feminales. Each orifice has a small thin membranous border, which may serve for valves to the excretory ducts of the vesiculae.

On each side of the large portion of the caruncula, there are five or six holes ranked in form of a crescent round its lateral parts; which are the orifices of the excretory ducts of the prostates that come from the folliculi already mentioned, and run in an oblique course to the orifices, in a kind of membranous duplicature.

The vesiculæ feminales are soft whitish knotty bodies, about three or four fingers breadth in length, one in breadth, and about three times as broad as thick, situated obliquely between the rectum and lower part of the bladder, in such a manner, as that their superior extremities are at a distance from each other, and their lower extremities united between those of the vasa deferentia, of which they imitate both the obliquity and the incurvature.

They are irregularly round on the upper part, and their breadth decreases gradually from thence. By the union of their lower extremities, they form a kind of fork, the branches of which are broad, and bent like rams horns. These extremities are very narrow, and form a small neck, which runs behind the bladder toward its orifice, and continues its course in the groove of the prostates, through the substance of the contiguous portion of the urethra, till its extremities pierce the caruncula in the manner already said.

The inner substance of the vesiculæ is plaited, and in a manner distinguished into several capsulæ, by contorted folds. Their external surface is covered by a fine

membrane, which serves for a border and frænum to the folds, and is a true continuation of the cellular substance of the peritonæum. The vesiculæ may easily be unfolded, and all their contortions freightened, and by this means they become much longer than in their natural state.

Their inner surface is villous and glandular, and continually furnishes a particular fluid, which exalts, refines, and perfects the semen, which they receive from the vasa deferentia, and of which they are the reservatories for a certain time.

The passage of the vasa deferentia into the vesiculæ is very particular. It was observed, that these canals are incurvated behind the bladder, and that their contracted extremities unite at that place. They unite in an angle, and run between the contiguous extremities of the vesiculæ; and this union is so close, that the adhering portions seem to form only one middle septum, between two small tubes, each of which is formed, partly by the extremity of one vas deferens, and partly by that of the neighbouring vesicula.

This lateral union of the extremities of the vas deferens, and vesicula feminalis on each side, forms likewise a kind of short septum, which terminates in a crescent, like a small semilunar valve, and the extremity of the vas deferens is narrower than that of the vesicula. By this mechanism, the fluid contained in each vas deferens has liberty to enter the contiguous vesicula, but that contained in the vesicula cannot return into the other canal.

Afterwards the two small tubes, formed each by the extremities of the vas deferens and vesicula, run in between the basis of the prostates, and canal of the urethra; and perforating the sides of that canal obliquely, they terminate in the caruncula.

The inside of the canal of the urethra is lined by a fine membrane, full of capillary blood-vessels; and its surface is perforated by a great number of oblong holes or small lacunæ of different sizes, the largest lying near the glands.

These lacunæ, or orifices of the excretory ducts of the same number of small glands, are dispersed through the substance of the urethra. Which ducts run for some way in the spongy substance, along the convex side of the internal membrane of the urethra, and open obliquely from behind, forward into the great canal. The edges of the lacunæ are semilunar, or like a crescent.

A little way from the beginning of the cellular substance of the urethra, we meet with two lacunæ more considerable than the rest, and their ducts are very long. These lacunæ and ducts lead to two glandular bodies, situated on the two convex sides of the spongy substance of the urethra near the bulb. Each of them is about the size of a cherry-stone, but they are oblong and flat, and covered intirely by the muscles called *acceleratores*. These two bodies are commonly called *prostatæ inferiores*.

The cavity of the urethra resembles nearly that of a small writing pen. It is not every where round, and towards the gland becomes broader and flatter on one side, especially in the gland itself, where there is a kind of oval or navicular fossula.

This canal terminates at the extremity of the glands

by a narrow oblong orifice or fissure, which is much less than the rest of the cavity. The commissures of this small fissure are turned one toward the convex, the other toward the flat side of the glans; and the labia of the fissure are its lateral parts; and it seems to be surrounded by fleshy fibres.

The præputium is a continuation of the skin of the penis and scrotum, and it adheres all the way to the basis of the glans. The rest of the cutaneous integument covers the glans without adhesion, and terminates by an opening. This portion is named præputium, and along the whole lower or back side, both of the whole integument in general, and of the præputium in particular, there runs a fine suture, which is a continuation of the raphe of the perinæum and scrotum.

The inner surface of the præputium is lined with a fine membrane from the opening all the way behind the basis of the glans; and the same membrane is folded from behind, forward, round the glans, forming the proper integument thereof, and covering very closely its whole villous surface, as far as the orifice of the urethra, where it joins the membrane, which lines the inside of that canal.

This proper membrane of the glans, and internal membrane of the præputium, form conjointly along the flat part of the glans, from its basis to the orifice of the urethra, a membranous duplicature, which like a septum or mediastinum divides this part into two lateral portions, and limits the motions of the præputium; for which reason it is called *frænum præputii*.

The surface of the internal membrane of the præputium discharges a fluid which prevents it from adhering to the glans.

Several muscles are inserted in the parts which we have described in this paragraph.

The first two muscles are commonly termed ereciores, or acceleratores urinæ. The next two are called acceleratores. The four small muscles, two of which are superior, and two inferior, may be called prostatici.

The ereciores lie along the roots of the corpora cavernosa; each of them being fixed by one extremity very obliquely, in the internal labium of the ramus of the os ischium, from the tuberosity upward. From thence it accompanies the root of the corpus cavernosum, all the way to the symphysis of the ossa pubis, and is fixed by its other extremity in the corpora cavernosa, near their union; where the fibres of both bodies meet, and are reciprocally expanded over both corpora. They lie a little lower, and more interiorly, than the roots of these cavernous bodies.

The musculi transversi, called also triangulares, are two long, narrow, fleshy fasciculi, inserted each by one extremity in the root or beginning of the ramus of the os ischium; from whence they run transversely along the edge of the interosseous ligament of the ossa pubis, as far as the apex of the prostates, where their other extremities meet, and form commonly a kind of digastric muscle, the middle of which gives insertion to the muscles of the urethra, and to the cutaneous sphincters of the anus.

The superior prostatici are two thin planes, fixed in the upper part of the inside of the small rami of the ossa pubis; from whence they are spread over and inserted in the prostates. Their insertions in the ossa pubis are on one side of those of the obturatores interni.

The prostatici inferiores are small transverse planes, each of which is fixed in the symphysis, between the ramus of the os pubis and os ischium, and from thence runs transversely, till it meets its fellow from the other side under the prostates, to which they are both strongly connected, and they serve like a girth to sustain these glands.

#### THE PARTS OF GENERATION IN FEMALES.

THE parts of generation in females are several in number, some of them external, and some internal; and they are all subordinate to one principal internal part, called the *uterus*.

The uterus lies between the bladder and intestinum rectum. It is a body inwardly hollow, outwardly of a whitish colour, of a pretty solid substance, and, except in time of pregnancy, of the figure of a flat flask, being in adults about three fingers breadth in length, one in thickness, and two in breadth at one end, and scarcely one at the other.

The broadest portion is termed the *fundus*, and the narrowest the *neck*. Its situation is oblique, the fundus being turned backward and upward, and the neck forward and downward; the broad sides lie next the rectum and bladder, and the narrow sides are lateral.

The cavity of the uterus is flat, and resembles an oblong triangle, the shortest side of which answers exactly to the fundus, and the two longest sides lie one on the right-hand, the other on the left.

Of the three angles of this cavity, the two which terminate the fundus are perforated each by a narrow duct, which with difficulty admits a hog's bristle. The third angle forms a flat duct wider than the former, which perforates the neck of the uterus lengthwise, and terminates at the extremity of that neck by a transverse opening.

This opening is termed the internal orifice of the uterus; and, in the natural state, is narrower than the duct of the collum uteri, so that only a small stilet can be passed through it. At the edge of this orifice, are several small holes, answering to the same number of glandular corpuscles, which discharge a viscid lymph.

The inner surface of the cavity of the uterus is lined by a very fine membrane, which at the fundus or broad portion is smooth and even, but in the narrow portion which leads to the orifice it is wrinkled in a particular manner.

The portion of this membrane, which covers the bottom of the cavity, is perforated by a great number of considerable holes, through which small drops of blood may be observed to pass when the whole uterus is compressed.

In the narrow part, which answers to the collum, each

side is divided into two lateral parts, by a kind of prominent longitudinal line, which is larger in the upper or anterior side, than in the lower or posterior.

On each side of these two longitudinal lines, there are lines or rugæ obliquely transverse, and disposed like branches, the longitudinal lines representing trunks. Between and round these rugæ, there are small lacunæ, through which a mucilaginous fluid is discharged that closes the orifice of the uterus.

The substance of the body of the uterus is spongy and compact, with a copious intertexture of vessels. Its thickness is nearly equal and uniform in the sides and edges, but the fundus is thicker toward the middle, than toward the two angles, where the thickness decreases gradually. The edges are likewise much thinner near these angles, than near the extremity of the neck.

The uterus is covered by a portion of the peritonæum, which serves it for a coat, and is the continuation of that which covers the bladder and intestinum rectum, running up from the lower and posterior part of the bladder, over the anterior part of the uterus, and from thence over the fundus, and down the backside, and afterwards going to the rectum.

On each lateral part or edge of the uterus, this portion of the peritonæum forms a broad duplicature, which is extended on each side, more or less directly to the neighbouring lateral parts of the pelvis, forming a kind of membranous septum between the anterior and posterior halves of the cavity of the pelvis; and it is afterwards continued in a loose manner with the peritonæum, on the sides of the pelvis.

These two broad duplicatures have the name of *ligamenta lata*, and *vesperitilionum alæ*. The upper edge of each is partly double or folded, forming two small distinct duplicatures.

The laminae of all these duplicatures are connected by a cellular substance, in the same manner as the other duplicatures of the peritonæum; and they contain the Fallopiian tubes, the ovaria, a part of the spermatic vessels, and of those that go to the body of the uterus, the ropes called the round ligaments, the nerves, &c.

The ovaria are two whitish, oval, flat, oblong bodies, situated on the sides of the fundus uteri; to which they are fixed by a kind of short round ligament, and inclosed, together with it, in the duplicature of the posterior pinion of the ligamenta lata.

They are composed of a compact spongy substance, and of several little balls, or transparent vesiculæ, which are called *ova*. The spongy substance surrounds each of these vesiculæ very closely, and seems likewise to furnish them with distinct spongy coverings or calices.

The ligaments of the ovaria lie in the edges of the posterior pinions of the ligamenta lata, much in the same manner as the umbilical vein in the anterior or umbilical ligament of the liver. They are round ropes of a filamentary texture, fixed by one extremity to the corner of the fundus uteri, a little above and behind the level of that fundus. They were formerly believed to be hollow, and looked upon as *vasa deferentia*.

The Fallopiian tubes are two flaccid, conical and vermiform canals, situated more or less transversely on each

side of the uterus, between the fundus and the lateral parts of the pelvis, and included in the anterior duplicatures or pinions of the ligamenta lata.

Each of them is fixed by its narrow extremities in the corner of the fundus uteri, into which it opens, though by so narrow a duct, as hardly to admit a large bristle. From thence their diameter augments by degrees all the way to the other extremity, where it is about one third part of an inch. The body of the tubæ goes in a winding course, and their large extremity is bent toward the ovaria.

These large extremities are irregularly round, and terminate by a narrow orifice, a little plaited, and turned toward the ovarium, where it presently expands in form of a membranous fringe, full of plaits and incisures. These fringes are called the broad ends of the Fallopiian tubes.

These tubes are composed of fleshy fibres, whereof some are longitudinal, and some obliquely circular, with an intertexture of another very fine substance.

The anterior pinions of the ligamentum latum serve for a common or external coat to both tubæ, and also to connect them, in the same manner as the mesentery connects the intestines. From thence the tubæ, and especially their fringes, come to be loose.

The pubes is that broad eminence at the lower part of the hypogastrium, between the two inguina, on which hairs grow at a certain age. This eminence is owing to a particular thickness of the *membrana adiposa* which covers the fore-part of the ossa pubis, and some small portions of the neighbouring muscles.

The longitudinal cavity which reaches from the middle and lower part of the pubes, within an inch of the anus, was by the ancients termed *sinus*; and they called the lateral parts of that cavity *alæ*, which is a more proper name than that of *labia*, commonly given to them. The places where the alæ are joined above and below are termed commissures; and may likewise be called the extremities or angles of the sinus.

The alæ are more prominent, and thicker above than below, and lie nearer each other below than above. They are chiefly composed of the skin, cellular substance, and fat. The exterior skin is a continuation of that of the pubes and inguina. It is more or less even, and furnished with a great number of glandular corpuscles, from which a whitish ceruminous matter may be expressed; and after a certain age it is likewise covered in the same manner with the pubes.

The inner side of the alæ is something like the red portion of the lips of the mouth; and it is distinguished every where from the external side by a kind of line, in the same manner as the red portion of the lips from the rest of the skin; being likewise thinner and smoother than the outward skin. A great number of pores are observable in it, and also numerous glandular corpuscles which furnish a liquor more or less sebaceous.

Near the inner edge of the inner surfaces of the alæ, on each side of the orifice of the canal of the uterus, we find a small hole more visible than the rest. These two holes are termed lacunæ; and they communicate by two small ducts with the same number of follicular bodies lying

ing in the substance of the *alæ*, and which may be looked upon as small prostates answering to the glandule prostaticæ in males. When compressed, they discharge a viscid liquor.

Above the superior commisure, a thin flat ligament runs down from each small branch of the *os pubis*, which penetrates the fat in the substance of each *alæ*, and is lost therein insensibly near the edge. These may be looked upon as the ligamenta suspensoria of the *alæ*. The inferior commisure of the *alæ* is very thin, or like a membranous ligament, and, together with the neighbouring parts of the inner sides, it forms a fossula, termed *navicularis* or *scaphoides*. The space between the inferior commisure and anus, termed *perinæum*, is about a large finger's breadth in length.

The other external parts are situated in the *sinus*, and hid by the *alæ*. Directly under the superior commisure lies the *clitoris*, with its covering called *præputium*. A little lower is the orifice of the *urethra*; and below that is the orifice of the great canal of the uterus. The circumference of this orifice is bordered either by a membranous circle, called *hymen*, or by fleshy portions, termed *caruncule myrtiliformes*. On each side of the *clitoris* begins a very prominent fold like a *crista*, which runs down obliquely on each side of the orifice of the *urethra*. These folds are termed *nymphæ*, and they might likewise be named *crissæ clitoridis*.

The *clitoris* appears at first sight like a small imperforated gland. Its upper and lateral sides are covered by a kind of *præputium*, formed by a particular fold of a portion of the inner side of the *alæ*; which appears to be glandular, and to discharge a certain moisture, and its infide is granulated.

By dissection, we discover in the *clitoris* a trunk and two branches, as in the penis, made up of a spongy substance, and of very elastic coats, but without any *urethra*. The trunk is divided into two lateral parts of a middle septum, from the bifurcation, to the *glans*, where it is insensibly lost.

The bifurcation of the trunk is on the edge of the cartilaginous arch of the *os pubis*; and the branches which resemble the roots of the *corpora cavernosa* are inserted in the inferior rami of these bones, and in those of the *os ischium*, where they terminate by degrees; but there is sometimes a membranous tube on each side, which reaches to the tuberosity of the *ischium*.

The trunk of the *clitoris* is sustained by a *ligamentum suspensorium* fixed in the *symphysis* of the *os pubis*, and containing this trunk in its duplicature, nearly as in the other sex.

Four muscles or *fasciculi* of fleshy fibres are inserted in the trunk of the *clitoris*, two on each side. One of them runs down on the fore side of the neighbouring *corpus cavernosum*, and is inserted by a tendinous or aponeurotic portion, partly in the extremity of the *corpus cavernosum*, and partly in the tuberosity of the *ischium*. These two muscles are called *erectores*.

The other muscle on each side lies under the former, and runs down on the side of the *urethra* and great orifice of the uterus, all the way to the anus; increasing gra-

dually in breadth in its passage, and terminating partly like that which is called *accelerator* in males.

These two muscles surround very closely the lateral parts of the *urethra*, and of the great orifice. They expand very much as they descend, and are spread on the lower and lateral parts of the great orifice; for which reason several anatomists have looked upon them as muscular *splinters*.

The *nymphæ*, *crissæ clitoridis*, or, as they may likewise be termed, *alæ minores* five *internæ*, are two prominent folds of the inner skin of the great or external *alæ*, reaching from the *præputium* of the *clitoris* to the two sides of the great orifice of the uterus. They begin very narrow, and, having increased in breadth in their course downward, they are again contracted at their lower extremity.

They are of a spongy substance, intermixed with glands, several of which may be perceived by the naked eye. Their situation is oblique, their upper extremities lying near each other, and the lower at a much greater distance. In married women they are more or less flaccid and decayed.

By the *urethra* in females, we mean the urinary duct, the orifice of which is between the *nymphæ* below the *glans* of the *clitoris*. The sides of this orifice are a little prominent and wrinkled, and perforated by small lacunæ, from which a viscid or mucilaginous liquor may be squeezed.

The body of the *urethra* is a spongy duct of the same structure as in males, but much shorter, situated directly under the trunk of the *clitoris*, and above the great canal of the uterus, adhering to each of these canals between which it lies, by membranous filaments. It passes under the cartilaginous arch of the *os pubis*, and terminates by an oblique opening at the neck of the bladder.

The great canal is situated below the *urethra*, and above the extremity of the *intestinum rectum*, a little obliquely, being more raised on the inner and back part, than on the outer and fore part.

Its inner or posterior extremity joins the extremity of the body of the uterus, and surrounds its orifice much in the same manner as the *duodenum* surrounds the *pylorus*, or as the *ilium* is surrounded by the *cæcum* and *colon*.

The anterior extremity forms the great orifice, which lies under that of the *urethra*, and above the fossula of the inferior commisure of the *alæ*.

The body of the canal is chiefly made up of a spongy substance, interwoven with numerous blood-vessels; and it is commonly longer and narrower in virgins, than in married women.

Its inner or concave surface, has several transverse rugæ, and is covered by a particular membrane. The rugæ are formed by oblong narrow eminences, incurvated like portions of arches, placed very near each other, and disposed in such a manner as to divide the cavity of the canal into an upper and lower side.

By the union of the extremities of the upper and lower rugæ, a kind of *raphe* or suture is formed on the right and left sides; and both arches are sometimes intersected in the middle, and so form two half-arches.

In general, these arches are very considerable in young persons; become gradually more superficial in married women, and are quite lost in time of delivery.

The inner or posterior extremity of this great canal surrounds the orifice of the uterus, a little obliquely, in such a manner, as that the upper side of the canal lies very near the orifice, and the lower side at a greater distance from it; and this makes the extremity of the uterus appear to advance more into the canal on the lower than on the upper part.

The exterior or anterior extremity of the great canal in virgins, and especially before the first eruption of the menses, is commonly bordered by a circular membranous fold, of different breadths, more or less smooth, and sometimes semilunar, which in some subjects leaves but a very small opening, in others a large opening, and in all renders the external orifice narrower than the rest of the cavity. This fold, called hymen, is formed by the union of the internal membrane of the great canal with that on the inside of the ale, and represents a membranous circle of different breadths, and sometimes uneven.

This membranous circle is commonly ruptured after the consummation of marriage; is quite lost in delivery; and afterwards only some irregular portions of it remain, which, from their supposed resemblance to myrtle leaves, have been termed *earunculæ myrtiformes*. This circle may likewise suffer some disorder by too great a flux of the menses, by imprudence, levity, and other particular accidents.

Each side of the anterior portion of the great canal is covered exteriorly by a thin broad cavernous and vascular plexus, called the plexus cavernosus of that canal. These two planes run down on each side of the clitoris behind the nymphæ, and likewise cover the urethra like a collar, before they are spread on the great canal.

This plexus is strictly united to the muscular portions commonly taken for accelerators or constrictors, lying between these portions and the lateral parts of the urethra and of the great canal.

### SECT. III. *Of the Thorax.*

By the thorax, we commonly understand all that part of the body which answers to the extent of the sternum, ribs, and vertebræ of the back, both outwardly and inwardly.

The thorax is divided into the anterior part called commonly the breast, the posterior part called the back, and the lateral parts called the right and left sides.

The external parts of the thorax, besides the skin and *membrana adiposa*, are principally the *mammæ*, and the muscles which cover the ribs and fill the spaces between them. In the *mammæ* we see the papillæ or nipples, and a small coloured circle, which surrounds them.

The internal parts of the thorax are contained in the large cavity of that portion of the trunk, called the middle venter, or cavity of the breast. This cavity is lined by a membrane named *pleura*, and divided into two lateral cavities by a membranous septum named *mediastinum*, which is a production or duplicature of the *pleura*.

These parts are the heart, pericardium, trunk of the aorta, a portion of the *aspera arteria* and of the *œsophagus*, the *ductus lacteus* or thoracicus, the lungs, &c.

The hard parts, which form the sides of the cavity of the thorax, are the twelve vertebræ of the back, all the ribs, and the sternum. The soft parts, which complete the sides, are the membrane called *pleura*, which lines the cavity, and the muscles *inter-costales*, *sterno-costales*, and *diaphragma*.

All these hard and soft parts taken together represent a kind of cage, in some measure of a conical figure, flattened on the fore-side, depressed on the back-side, and in a manner divided into two nooks by the figure of the vertebræ of the back, and terminated below by a broad arched basis inclined backward. The intercostal muscles fill up the interstices betwixt the ribs, and so complete the sides of the cavity; the basis is the diaphragm, and the *pleura* not only covers the whole inner surface of the cavity, but, by forming the *mediastinum*, divides it into two, one on the right hand, the other on the left.

### M A M M Æ.

THE name of *mammæ*, or breasts, is given to two eminences more or less round, situated in the anterior and a little toward the lateral parts of the thorax.

The body of the *mammæ* is partly glandular, and partly made up of fat; or it is a glandular substance mixed with portions of the *membrana adiposa*, the cellular *pelluculæ* of which support a great many blood-vessels, lymphatics, and serous or lactiferous ducts, together with small glandular *moleculæ* which depend on the former; all of them being closely surrounded by two membranes continued from the *pelluculæ*.

The innermost of these two membranes, which is in a manner the basis of the body of the *mamma*, is thick and almost flat, adhering to the *m. pectoralis major*. The second or external membrane is thinner, forming a particular integument for the body of the *mamma*, more or less convex, and adhering closely to the skin.

The *corpus adiposum* of the *mamma* in particular, is a spongy cluster, more or less interlarded with fat, or a collection of membranous *pelluculæ*, which, by the particular disposition of their outer sides, form a kind of membrane in shape of a bag, in which all the rest of the *corpus adiposum* is contained. The anterior or outer portion of this bag, or that which touches the skin, is very thin; but that side next the *pectoralis major*, is thick.

The glandular body contains a white mass, which is merely a collection of membranous ducts, narrow at their origin, broad in the middle, and which contract again as they approach the papilla, near which they form a kind of circle of communication. They are named *ductus lactiferi*.

The coloured circle or disk is formed by the skin, the inner surface of which sustains a great number of small glandular *moleculæ*. They appear very plainly all over the areola, even on the outside, where they form little flat heights or eminences at different distances quite round the circle.

The tubercle which lies in the center of the areola, is termed papilla, or the nipple. In women with child, or who give suck, it is pretty large, and generally longer or higher than it is thick or broad.

The texture of the nipple is spongy, elastic, and liable to divers changes of consistence, being sometimes harder, sometimes more flaccid. It seems to be made up chiefly of ligamentary fasciculi, the extremities of which form the basis and apex of the nipple.

Between these spongy and elastic fasciculi lie seven or eight particular tubes, at small distances from each other, and all in the same direction. These tubes end at the basis of the papilla in the irregular circle of communication of the lactiferous ducts, and at the apex, in the same number of almost imperceptible holes or orifices.

The use of the mammæ in the nourishment of children is known to all the world: But it is not certainly known what the papillæ and areolæ in males can be designed for. Milk has been observed in them, in children of both sexes.

### PLEURA AND MEDIASTINUM.

The pleura is a membrane which adheres very closely to the inner surface of the ribs, sternum, and muscular inter-costales, sub-costales, and sterno-costales, and to the convex side of the diaphragm. It is of a very firm texture, and plentifully stored with blood-vessels and nerves, in all which it resembles the peritonæum.

The cellular portion goes quite round the inner surface of the thorax, but the membranous portion is disposed in a different manner. Each side of the thorax has its particular pleura, intirely distinct from the other, and making as it were two great bladders, situated laterally with respect to each other in the great cavity of the breast, in such a manner as to form a double septum or partition running between the vertebræ and the sternum, their other sides adhering to the ribs and diaphragm.

This particular duplicature of the two pleuræ is termed mediastinum. The two laminae of which it is made up are closely united together near the sternum and vertebræ; but in the middle, and toward the lower part of the forehead, they are separated by the pericardium and heart. A little more backward they are parted in a tubular form by the œsophagus, to which they serve as a covering; and in the most posterior part, a triangular space is left between the vertebræ and the two pleuræ from above downward, which is filled chiefly by the aorta.

The mediastinum does not commonly terminate along the middle of the inside of the sternum, but inclines toward the left side.

The surface of the pleura turned to the cavities of the breast, is continually moistened by a lymphatic serosity which transudes through the pores of the membranous portion.

The pleura serves in general for an inner integument to the cavity of the thorax. The mediastinum cuts off all communication between the two cavities, and hinders one lung from pressing on the other when we lie on one side. It likewise forms receptacles for the heart, pericardium, œsophagus, &c.

### THYMUS.

The thymus is an oblong glandular body, round on the upper part, and divided below into two or three lobes, of which that toward the left hand is the longest. In the fœtus it is of a pretty large size, less in children, and very little in aged persons.

The greatest part of the thymus lies between the duplicature of the superior and anterior portion of the mediastinum, and the great vessels of the heart; from whence it reaches a little higher than the tops of the two pleuræ, so that some part of it is out of the cavity of the thorax.

Its particular inward structure and secretions are not as yet sufficiently known to determine its uses, which however seem to be designed more for the fœtus than for adults.

### COR.

The heart is a muscular body situated in the cavity of the thorax on the anterior part of the diaphragm, between the two laminae of the mediastinum. It is in some measure of a conical figure, flattened on the sides, round at top, and oval at the basis. Accordingly, we consider in the heart the basis, apex, two edges, and two sides; one of which is generally flat, the other more convex.

Besides the muscular body, which chiefly forms what we call the heart, its basis is accompanied by two appendices called auricles, and by large blood-vessels; all these are included in a membranous capsula, named pericardium.

It is hollow within, and divided by a septum which runs between the edges into two cavities, called *ventriculi*, one of which is thick and solid, the other thin and soft. This latter is generally termed the *right* ventricle, the other the *left* ventricle, though in their natural situation the right ventricle is placed more anteriorly than the left.

Each ventricle opens at the basis by two orifices, one of which answers to the auricles, the other to the mouth of a large artery; and accordingly one of them may be termed the auricular orifice, the other the arterial orifice. The right ventricle opens into the right auricle, and into the trunk of the pulmonary artery; the left, into the left auricle, and into the great trunk of the aorta. At the edges of these orifices are found several moveable pellicule, called valves by anatomists; of which some are turned inward, toward the cavity of the ventricles, called *triglochinæ* or *tricuspidæ*; others are turned towards the great vessels, called *semilunares* or *sigmoidales*. The valves *tricuspidæ* of the left ventricle are likewise termed *mitrales*.

The inner surface of the ventricles is very uneven, many eminences and cavities being observable therein. The most considerable eminences are thick fleshy productions called *columnæ*. To the extremities of these pillars are fastened several tendinous cords, the other ends of which are joined to the valves *tricuspidæ*. There are likewise other small short tendinous ropes along both edges of the septum between the ventricles. These small cords lie in an obliquely transverse situation, and form a kind of net-work at different distances.

The cavities of the inner surface of the ventricles are small deep fossule or lacunæ placed very near each other, with small prominent interstices between them.

The

The fleshy or muscular fibres of which the heart is made up, are disposed in a very singular manner, especially those of the right or anterior ventricle, being either bent into arches or folded into angles.

The fibres which are folded into angles are longer than those which are only bent into arches. The middle of these arches, and the angles of the folds, are turned towards the apex of the heart, and the extremities of the fibres towards the basis. These fibres differ not only in length, but in their directions, which are very oblique in all, but much more so in the long or folded fibres than in the short ones, which are simply bent.

Each ventricle is composed of its proper distinct fibres, but the left ventricle has many more than the right. Where the two ventricles are joined, they form a septum which belongs equally to both.

The fibres which compose the inner or concave surface of the ventricles, do not all reach to the basis; some of them running into the cavity, and there forming the fleshy columns, to which the loose floating portion of the tricuspidal valves is fastened by tendinous ropes.

The valves at the orifices of the ventricles are of two kinds. One kind allows the blood to enter the heart, and hinders it from going out the same way; the other kind allows the blood to go out of the heart, but hinders it from returning. The valves of the first kind terminate the auricular, and those of the second lie in the openings of the great arteries. The first are termed femilunar or sigmoidal valves, the others triglochinic, tricuspidal, or mitral.

The tricuspidal valves of the right ventricle are fixed to its auricular orifice, and turned inward toward the cavity of the ventricle. They are three triangular productions, very smooth and polished on that side which is turned towards the auricle; and on the side next the cavity of the ventricle, they have several membranous and tendinous expansions, and their edges are notched or indented. The valves of the auricular orifice of the left ventricle are of the same shape and structure, but they are only two in number; and from some small resemblance to a mitre, they have been named mitrals.

The femilunar valves are six in number, three belonging to each ventricle, situated at the mouths of the great arteries; and they may be properly enough named *valvulae arteriales*.

The great artery that goes out from the left ventricle, is termed *aorta*. As it goes out, it turns a little toward the right hand, and then bends obliquely backward to form what is called *aorta descendens*.

The trunk of the artery which goes out from the right ventricle is called *arteria pulmonaris*. This trunk, as it is naturally situated in the thorax, runs first of all directly upward for a small space, then divides laterally into two principal branches, one for each lung; that which goes to the right lung being the longest, for a reason that shall be given hereafter.

The auricles are muscular bags situated at the basis of the heart, one towards the right ventricle, the other towards the left; and joined together by an inner septum, and external communicating fibres, much in the same manner with the ventricles; one of them being named the right auricle, the other the left. They are very uneven

on the inside, but smoother on the outside, and terminate in a narrow, flat, indented edge, representing a cock's comb, or in some measure the ear of a dog. They open into these orifices of each ventricle, which are named auricular orifices; and they are tendinous at their opening, in the same manner as the ventricles.

The right auricle is larger than the left, and it joins the right ventricle by a common tendinous opening. It has two other openings united into one, and formed by two large veins which meet and terminate there, almost in a direct line, called *vena cava superior* and *inferior*. The notched edge of this auricle terminates obliquely in a kind of obtuse point, which is a small particular production of the great bag, and is turned toward the middle of the basis of the heart.

The left auricle is a kind of muscular bag or reservoir, of a pretty considerable thickness, and unequally square, into which the four veins open, called *venae pulmonares*, and which has a distinct appendix belonging to it, like a third small auricle. This bag is very even on both sides.

The heart lies almost transversely on the diaphragm, the greatest part of it being in the left cavity of the thorax, and the apex being turned toward the bony extremity of the sixth true rib. The basis is toward the right cavity; and both auricles, especially the right, rest on the diaphragm.

The origin or basis of the pulmonary artery is, in this natural situation, the highest part of the heart on the fore side; and the trunk of this artery lies in a perpendicular plane, which may be conceived to pass between the sternum and *spina dorsii*. Therefore some part of the basis of the heart is in the right cavity of the thorax; and the rest, all the way to the apex, is in the left cavity; and it is for this reason that the mediastinum is turned toward that side.

According to this true natural situation of the heart, the parts commonly said to be on the right side are rather anterior, and those on the left side posterior; and that side of the heart which is thought to be the fore side, is naturally the upper side, and the back side consequently the lower side.

The lower side is very flat, lying wholly on the diaphragm; but the upper side is a little convex through its whole length, in the direction of the septum between the ventricles.

The heart, with all the parts belonging to it, is contained in a membranous capsula, called *pericardium*, which is in some measure of a conical figure, and much bigger than the heart. It is not fixed to the basis of the heart, but round the large veins above the auricles, before they send off the ramifications, and round the large arteries, before their divisions.

The pericardium is made up of three laminae, the middle and chief of which is composed of very fine tendinous filaments, closely interwoven and crossing each other in different directions. The internal lamina seems to be a continuation of the outer coat of the heart, auricles, and great vessels. The trunks of the aorta and pulmonary artery have one common coat which contains them both as in a sheath, and is lined on the inside by a cellular substance, chiefly in that space which lies between  
where.

where the trunks are turned to each other, and the sides of the sheath. There is but a very small portion of the vena cava contained in the pericardium.

The pericardium is closely connected to the diaphragm, not at the apex, but exactly at that place which answers to the flat or lower side of the heart; and it is a very difficult matter to separate it from the diaphragm in dissection.

The internal lamina is perforated by an infinite number of very small holes, through which a serous fluid continually transudes, in the same manner as in the peritoneum. This fluid being gradually collected after death, makes what is called *aqua pericardii*, which is found in considerable quantities in opening dead bodies while they remain fresh. Sometimes it is of a reddish colour, which may be owing to a transudation of blood through the fine membrane of the auricles.

The heart and parts belonging to it are the principal instruments of the circulation of the blood. The two ventricles ought to be considered as two syringes so closely joined together as to make but one body, and furnished with suckers placed in contrary directions to each other, so as that by drawing one of them, a fluid is let in, and forced out again by the other.

The heart is made up of a substance capable of contraction and dilatation. When the fleshy fibres of the ventricles are contracted, the two cavities are lessened in an equal and direct manner, not by any contortion or twisting, as the false resemblance of the fibres to a figure of eight has made anatomists imagine. For if we consider attentively in how many different directions, and in how many places, these fibres cross each other, as has been already observed, we must see clearly, that the whole structure tends to make an even, direct, and uniform contraction, more according to the breadth or thickness, than according to the length of the heart, because the number of fibres situated transversely, or almost transversely, is much greater than the number of longitudinal fibres.

The fleshy fibres thus contracted, do the office of suckers, by pressing upon the blood contained in the ventricles, which blood being thus forced toward the basis of the heart, presses the tricuspid valves against each other, opens the femilunares, and rushes with impetuosity through the arteries and their ramifications, as through so many elastic tubes.

The blood thus pushed on by the contraction of the ventricles, and afterwards pressed by the elastic arteries, enters the capillary vessels, and is from thence forced to return by the veins to the auricles, which, like retirements, porches, or antichambers, receive and lodge the blood returned by the veins during the time of a new contraction. This contraction of the heart is by anatomists termed *systole*.

The contraction or systole of the ventricles ceases immediately, by the relaxation of their fleshy fibres; and in that time the auricles, which contain the venal blood, being contracted, force the blood through the tricuspid valves into the ventricles, the sides of which are thereby dilated, and their cavities enlarged. This dilatation is termed *diastole*.

In this manner does the heart, by the alternate systole and diastole of its ventricles and auricles, push the blood through the arteries to all the parts of the body, and receive it again by the veins. This is called the circulation of the blood, which is carried on in three different manners.

The first and most universal kind of circulation is that by which almost all the arteries of the body are filled by the systole of the heart, and the greatest part of the veins evacuated by the diastole.

The second kind of circulation opposite to the first, is through the coronary vessels of the heart, the arteries of which are filled with blood during the diastole of the ventricles, and the veins emptied during the systole.

The third kind of circulation is that of the left ventricle of the heart; through the venal ducts of which a small quantity of blood passes, without going through the lungs, which is the course of all the remaining mass of blood.

## PULMONES.

The lungs are two large spongy bodies, of a reddish colour in children, greyish in adult subjects, and bluish in old age; filling the whole cavity of the thorax, one being seated in the right side, the other in the left, parted by the mediastinum and heart, and of a figure answering to that of the cavity which contains them; that is, convex next the ribs, concave next the diaphragm, and irregularly flattened and depressed next the mediastinum and heart.

They are distinguished into the right and left lung; and each of these into two or three portions called *lobi*; of which the right lung has commonly three, or two and a half, and the left lung two. The right lung is generally larger than the left, answerably to that cavity of the breast, and the obliquity of the mediastinum.

At the lower edge of the left lung, there is an indented notch or sinus opposite to the apex of the heart, which is therefore never covered by that lung, even in the strongest inspirations, and consequently the apex of the heart and pericardium may always strike against the ribs.

The substance of the lungs is almost all spongy, being made up of an infinite number of membranous cells, and of different sorts of vessels spread among the cells, in innumerable ramifications.

This whole mass is covered by a membrane continued from each pleura, which is commonly said to be double; but what is looked upon as the inner membrane is only an expansion and continuation of a cellular substance.

The vessels which compose part of the substance of the lungs are of three or four kinds; the air-vessels, blood-vessels, and lymphatics, and the nerves. The air-vessels make the chief part, and are termed *bronchia*.

These bronchia are conical tubes, composed of an infinite number of cartilaginous fragments, like so many irregular arches of circles, connected together by a ligamentary elastic membrane, and disposed in such a manner as that the lower easily insinuate themselves within those above them.

They are lined on the inside by a very fine membrane, which continually discharges a mucilaginous fluid; and in the substance of the membrane are a great number of small blood-vessels.

The bronchia are divided in all directions into an infinite number of ramifications, which diminish gradually in size; and as they become capillary, change their cartilaginous structure into that of a membrane.

Each of these numerous bronchial tubes is widened at the extremity, and thereby formed into a small membranous cell, commonly called a vesicle. These cells or folliculi are closely connected together in bundles; each small branch producing a bundle proportionable to its extent and the number of its ramifications.

These small vesicular or cellulous bundles are termed *lobules*; and as the great branches are divided into small rami, so the great lobules are divided into several small ones. The cells or vesicles of each lobule have a free communication with each other, but the several lobules do not communicate so readily.

The lobules appear distinctly to be parted by another cellulous substance, which surrounds each of them in proportion to their extent, and fills up the interstices between them. This substance forms likewise a kind of irregular membranous cells, which are thinner, looser, and broader than the bronchial vesicles.

All the bronchial cells are surrounded by a very fine reticular texture of the small extremities of arteries and veins, which communicate every way with each other.

The blood-vessels of the lungs are of two kinds; one common, called the *pulmonary artery* and *veins*; the other proper, called the *bronchial arteries* and *veins*.

The pulmonary artery goes out from the right ventricle of the heart; and its trunk having run almost directly upward as high as the curvature of the aorta, is divided into two lateral branches, one going to the right-hand, called the *right pulmonary artery*, the other to the left, termed the *left pulmonary artery*. The right artery passes under the curvature of the aorta, and is consequently longer than the left. They both run to the lungs, and are dispersed through their whole substance by ramifications nearly like those of the bronchia, and lying in the same directions.

The pulmonary veins having been distributed through the lungs in the same manner, go out on each side, by two great branches, which open laterally into the reservoir or muscular bag of the right auricle.

Besides these capital blood-vessels, there are two others called the *bronchial artery* and *vein*.

Under the root of each lung, that is, under that part formed by the subordinate trunk of the pulmonary artery, by the trunks of the pulmonary veins, and by the trunk of the bronchia, there is a pretty broad membranous ligament, which ties the posterior edge of each lung to the lateral parts of the vertebrae of the back, from that root all the way to the diaphragm.

The bronchia already described are branches or ramifications of a large canal, partly cartilaginous, and partly membranous, called *trachea*, or *aspera arteria*. It is situated anteriorly in the lower part of the neck, from whence it runs down into the thorax betwixt the two

pleurae, through the upper space left between the duplication of the mediastinum, behind the thymus.

Having reached as low as the curvature of the aorta, it divides into two lateral parts, one toward the right-hand, the other toward the left, which enter the lungs, and are distributed through them in the manner already said. These two branches are called *bronchia*, and that on the right side is shorter than that of the left.

The trachea is made up of segments of circles or cartilaginous hoops, disposed in such a manner, as to form a canal open on the back part, the cartilages not going quite round; but this opening is filled by a soft glandular membrane, which completes the circumference of the canal.

Each circle is about the twelfth part of an inch in breadth, and about a quarter of that space in thickness. Their extremities are round; and they are situated horizontally above each other, small interstices being left between them, and the lower edge of the superior segments being turned toward the upper edge of those next below them.

They are all connected by a very strong elastic membranous ligament fixed to their edges.

The canal of the *aspera arteria* is lined on the inside by a particular membrane, which appears to be partly fleshy or muscular, and partly ligamentary, perforated by an infinite number of small holes, through which a mucilaginous fluid continually passes, to defend the inner surface of the trachea against the acrimony of the air.

This fluid comes from small glandular bodies dispersed through the substance of the membrane, but especially from the glands, something larger than the former, which lie on the outer or posterior surface of that strong membrane, by which the circumference of the canal is completed. The same structure is observable in the ramifications of the trachea from the greatest to the smallest.

At the angle of the first ramification of the trachea arteria, we find on both the fore and back sides, certain soft, roundish, glandular bodies, of a bluish or blackish colour, and of a texture partly like that of the thymus already described, and partly like that of the glandula thyroidea. There are other glands of the same kind, as the origin of each ramification of the bronchia, but they decrease proportionably in number and size. They are fixed immediately to the bronchia, and covered by the interlobular substance; and they seem to communicate by small openings with the cavity of the bronchia.

Respiration is performed by organs of two kinds, one of which may be looked upon as active, the other as passive. The lungs are of the second kind, and the first comprehends chiefly the diaphragm and intercostal muscles.

As soon as the intercostal muscles begin to contract, the arches of the ribs are raised together with the sternum, and placed at a greater distance from each other; by which means the cavity of the thorax is enlarged on the two lateral and anterior sides.

At the same instant the diaphragm is flatted or brought toward a plane by two motions, which are apparently contrary; that is, by the contraction of the diaphragm, and the dilatation of the ribs in which it is inserted. The external surface of the thorax being thus in a manner increased, and the cavity of the bronchia

being at the same time, and by the same means, less resisted or pressed upon; the ambient air yields to the external pressure, and insinuates itself into all the places where the pressure is diminished, that is, into the aspera arteria, and into all the ramifications of the bronchia all the way to the vesicles. This is what is called *inspiration*.

This motion of inspiration is instantaneous, and ceases in a moment by the relaxation of the intercostal muscles; the elastic ligaments and cartilages of the ribs bringing them back at the same time to their former situation. This motion, by which the ribs are depressed and brought nearer each other, is termed *expiration*.

The pulmonary arteries and veins which accompany the bronchia through all their ramifications, and surround the vesicles, transmit the blood through their narrow capillary extremities, and thereby change or modify it, at least in three different manners.

The first change or modification which the blood undergoes in the lungs, is to have the cohesions of its parts broken, to be attenuated, pounded, and, as it were, reduced to powder. The second is, to be deprived of a certain quantity of serum, which transpires through the lungs, and is what we commonly call the *breath*. The third is to be in a manner reanimated by the impression of the air.

### OESOPHAGUS.

THE œsophagus is a canal partly muscular, and partly membranous, situated behind the trachea arteria, and before the vertebrae of the back, from near the middle of the neck, down to the lower part of the thorax; from whence it passes into the abdomen through a particular hole of the small or inferior muscle of the diaphragm, and ends at the upper orifice of the stomach.

It is made up of several coats, almost in the same manner as the stomach, of which it is the continuation. The first coat, while in the thorax, is formed only by the duplicature of the posterior part of the mediastinum, and

is wanting above the thorax and the neck, where the outer coat of the œsophagus is only a continuation of the cellular substance belonging to the neighbouring parts.

The second coat is muscular, being made up of several strata of fleshy fibres.

The third is termed the *nervous coat*, and is like that of the stomach and intestines.

The fourth or innermost coat resembles in some measure that of the intestines, except that instead of the villi it has small and very short papillæ. Through the pores of this coat, a viscid lymph is continually discharged.

The œsophagus from its very beginning, turns a little to the left hand, and naturally runs along the left extremities of the cartilages of the aspera arteria. The thyroid gland, pharynx and larynx, shall be described in another place.

### DUCTUS THORACICUS.

THE thoracic duct is a thin transparent canal, which runs up from the receptaculum chyli, along the spina dorsa, between the vena azygos and aorta, as high as the fifth vertebra of the back, or higher. From thence it passes behind the aorta toward the left hand, and ascends behind the left subclavian vein, where it terminates in some subjects by a kind of vesicula, in others by several branches united together, and opens into the back-side of the subclavian vein near the outside of the internal jugular.

This canal is plentifully furnished with semilunar valves turned upward. Its opening into the subclavian vein in the human body, is, in the place of valves, covered by several pelliculæ, so disposed as to permit the entrance of the chyle into the vein, and hinder the blood from running into the duct. It is sometimes double, one lying on each side, and sometimes it is accompanied by appendices called *pampiniformes*.

FIG. 6. The right testicle intire, and the epididymis filled with mercury.

A, The beginning of the vas deferens. B, The vas deferens ascending towards the abdomen. C, The posterior part of the epididymis, named globus minor. D, The spermatic vessels inclosed in cellular substance. E, The body of the epididymis. F, Its head, named globus major. G, Its beginning from the testicle. H, The body of the testicle, inclosed in the tunica albuginea.

### SECT. IV. Of the BRAIN and its Appendages.

THE name of brain is given to all that mass which fills the cavity of the cranium, and which is immediately surrounded by two membranes called meninges or matres.

This general mass is divided into three particular portions; the cerebrum or brain properly so called, the cerebellum, and medulla oblongata. To these three parts a fourth is added, which fills the great canal of the spina dorsa, by the name of medulla spinalis, being a continuation of the medulla oblongata.

The

The meninges or membranes are two in number. The first is named *dura mater*; the second *pia mater*, which is again divided into two; the external lamina being termed *arachnoides*, the internal retaining the common name of *pia mater*.

### DURA MATER.

THE *dura mater* incloses the brain and all its appendages. It lines the inside of the cranium, and supplies the place of an internal periosteum, being spread in all the holes and depressions, and covering all the eminences in such a manner as to prevent their being hurtful to the brain.

The *dura mater* is made up of two laminae, adhering very closely together; the fibres of both crossing each other obliquely. Their texture is very close and strong, appearing to be partly ligamentary and partly tendinous.

The *dura mater* sticks closely to the cranium by a great number of filaments of the external lamina, which enter the pores of the bones chiefly at the sutures both above and below; and by penetrating these joints, they communicate with the external periosteum.

These adhesions are formed intirely by the external lamina. The internal lamina is very smooth and polished on the inside, which is also continually moistened by a fine fluid discharged through its pores, much in the same manner as in the peritonæum and pleura.

The folds of the *dura mater* are made by the internal lamina; and three of them form particular septa; one of which is superior, representing a kind of mediastinum between the two great lobes of the brain. The second is in a middle situation, like a diaphragm between the cerebrum and cerebellum; the third is inferior, between the lobes of the cerebellum. The superior septum is longitudinal, in form of a scythe, from whence it is termed the *falx of the dura mater*. The middle septum is transverse, and might be called the diaphragm of the brain. The inferior septum is very small, and runs down between the lobes of the cerebellum.

Besides these large folds, there are two small lateral ones on each side of the *fella turcica*, each running from the posterior to the anterior clynoïd apophysis on the same side. These two folds, together with the anterior and posterior parts of the *fella turcica*, form a small fossula in which the pituitary gland is lodged.

The elongations of the *dura mater* are productions of both laminae, which go beyond the general circumference, and pass out of the cranium.

The most considerable of these elongations passes through the great occipital foramen, and runs down the common canal of the vertebrae in form of a tube, lining the inside of that canal, and inclosing the *medulla spinalis*; by the name of the *dura mater of that medulla*. The other elongations accompany the nerves out of the cranium in form of vaginae, which are more numerous than the nervous trunks reckoned in pairs.

There are two particular elongations which form the periosteum of the orbits, together with the vaginae of the optic nerves. These orbital elongations go out by the sphenoidal or superior orbital fissures, and, increa-

sing in breadth in their passage, line the whole cavity of the orbits, at the edges of which they communicate with the pericranium and periosteum of the face.

The elongations of the *dura mater* which accompany the blood-vessels through the foramina of the cranium, unite with the pericranium immediately afterwards. Such, for instance, are the elongations which line the fossulae of the foramina lacera or jugularia, and the bony or carotid canals of the apophysis petrosa, &c.

The *dura mater* contains in its duplicature several particular canals, into which the venal blood not only of that membrane, but of the whole brain, is carried. These canals are termed sinuses, and some of them are disposed in pairs, others in uneven numbers; that is, some of them are placed alone, in a middle situation; others are disposed laterally on each side of the brain. The most ancient anatomists reckoned only four; to which we can now add four times as many.

These sinuses are in the duplicature of the *dura mater*; and their cavities are lined on the inside by particular very fine membranes. They may be enumerated in this manner.

The great sinus of the *falx*, or superior longitudinal sinus, which was reckoned the first by the ancients.

Two great lateral sinuses, the second and third of the ancients.

The sinus called *torcular Herophili*, the fourth of the ancients.

The small sinus of the *falx*, or inferior longitudinal sinus. The posterior occipital sinus, which is sometimes double.

Two inferior occipital sinuses, which form a portion of a circle, and may likewise be called the *inferior lateral sinuses*.

Six sinus petrosi, three on each side, one anterior, one middle or angular, and one inferior. The two inferior, together with the occipital sinuses, complete a circular sinus round the great foramen of the os occipitis.

The inferior transverse sinus.

The superior transverse sinus.

The two circular sinuses of the *fella sphenoidalis*; one superior, and one inferior.

Two sinus cavernosi, one on each side.

Two orbital sinuses, one on each side.

All these sinuses communicate with each other, and with the great lateral sinuses by which they discharge themselves into the internal jugular veins, which are only continuations of these lateral sinuses. They likewise unload themselves partly into the vertebral veins, which communicate with the small lateral or inferior occipital sinuses; and partly into the external jugular veins, by the orbital sinuses which communicate with the venæ angulares, frontales, nasales, maxillares, &c. as the lateral sinuses likewise communicate with the venæ occipitales, &c.

Thus the blood which is carried to the *dura mater*, &c. by the external and internal carotid, and by the vertebral arteries, is returned to the heart by the external and internal jugular and vertebral veins; so that when the passage of the blood is obstructed in any particular place, it finds another way, by virtue of these communications, though not with the same ease.

*Fig. 3.*

## PIA MATER.

THIS membrane surrounds the whole mass of the brain more particularly than the dura mater. It adheres very closely to the brain, and is connected to the dura mater only by the veins which open into the sinuses.

The pia mater is made up of two very fine laminae, the outermost of which covers pretty uniformly all the convex surface of the brain, and lines in the same manner all the concave or inner surface of the dura mater. The internal lamina forms a great number of plicæ, duplicatures, and septa, which insinuate themselves into all the folds and circumsolutions, and between the different strata of the cerebrum and cerebellum.

## CEREBRUM.

THE cerebrum properly so called, is a kind of medullary mass, of a moderate consistence, and of a greyish colour on the outer surface, filling all the superior portion of the cavity of the cranium, or that portion which lies above the transverse septum. The upper part of the cerebrum is of an oval figure, like half an egg cut lengthwise. It is flattened on the lower part, each lateral half of which is divided into three eminences, called lobes, one anterior, one middle, and one posterior.

The substance of the cerebrum is of two kinds, distinguished by two different colours; one part of it, which is softest, being of a greyish or ash colour; the other, which is more solid, being very white. The ash-coloured substance lies chiefly on the outer part of the cerebrum like a kind of cortex, from whence it has been named *substantia corticalis* or *cinerea*. The white substance occupies the inner part, and is named *substantia medullaris*, or simply *substantia alba*.

The cerebrum is divided into two lateral portions, separated by the falx, or great longitudinal septum of the dura mater. They are generally termed hemispheres. Each of these portions is divided into two extremities, one anterior and one posterior, which are termed the lobes of the cerebrum, between which there is a large inferior protuberance which goes by the same name; so that in each hemisphere there are three lobes, one anterior, one middle, and one posterior.

The anterior lie upon these parts of the os frontis which contribute to the formation of the orbits and of the frontal sinuses, commonly called the anterior fossæ of the basis craniî. The posterior lobes lie on the transverse septum; and the middle lobes, in the middle or lateral fossæ of the basis craniî.

Each lateral portion of the cerebrum has three sides; one superior, which is convex; one inferior, which is uneven; and one lateral, which is flat, and turned to the falx. Through the whole surface of these three sides we see inequalities or windings like the circumsolutions of intestines, formed by waving streaks or furrows very deep and narrow, into which the septa or duplicatures of the pia mater insinuate themselves, and thereby separate these circumsolutions from each other.

Near the surface these circumsolutions are at some di-

stance from each other, representing serpentine ridges; and in the interstices between them, the superficial veins of the cerebrum are lodged, between the two laminae of the pia mater, from whence they pass in the duplicature of the dura mater, and so open into the sinuses.

These circumsolutions are fixed through their whole depth to the septa or duplicatures of the pia mater, by an infinite number of very fine vascular filaments.

When they are cut transversely, we observe that the substantia alba lies in the middle of each circumsolution, so that there is the same number of internal medullary circumsolutions as of external cortical ones.

Having cut off the falx from the crista galli, and turned it backward; if we separate gently the two lateral parts or hemispheres of the cerebrum, we see a longitudinal portion of a white convex body, which is named corpus callosum. It is a middle portion of the medullary substance, which under the inferior sinus of the falx, and also a little toward each side, is parted from the mass of the cerebrum, to which it is simply contiguous from one end of that sinus to the other.

The surface of the corpus callosum is covered by the pia mater, which runs in between the lateral portions of this body, and the lower edge of each hemisphere.

The corpus callosum becomes afterwards continuous on each side with the medullary substance, which through all the remaining parts of its extent is intirely united with the cortical substance, and together with the corpus callosum forms a medullary arch or vault of an oblong or oval figure. After which we will observe a medullary convexity much smaller than that which is common to the whole cerebrum, but of the same form; so that it appears like a medullary nucleus of the cerebrum.

Under this arch are two lateral cavities, much longer than they are broad, and very shallow, separated by a transparent medullary septum. These cavities are named the anterior, superior, or great lateral ventricles of the cerebrum.

The lateral ventricles are broad, and rounded at these extremities which lie next the transparent septum. They go from before backward, contracting in breadth, and separating from each other gradually in their progress. Afterwards they bend downward, and return obliquely from behind forward, in a course like the turning of a ram's horn, and terminate almost under their superior extremities. These ventricles are lined with a thin membrane.

The transparent partition or septum lucidum, lies directly under the raphe or suture of the corpus callosum, of which it is a continuation. It is made up of two medullary laminae, more or less separated from each other by a narrow medullary cavity, sometimes filled with a serous substance.

The septum lucidum is united by its lower part, to the anterior portion of that medullary body, called the *fornix* with three pillars.

The fornix being cut off and inverted, or quite removed, we see first of all a vascular web, called *plexus choroides*, and several eminences more or less covered by the expansion of that plexus. There are four pairs of eminences

eminences which follow each other very regularly, two large, and two small. The first two great eminences are named *corpora striata*; and the second, *thalami nervorum opticum*. The four small eminences are closely united together; the anterior being called *nates*, and the posterior *testes*. Immediately before these tubercles there is a single eminence, called *glandula pinealis*.

The *corpora striata* got that name, because in scraping them with the knife we meet with a great number of white and ash-coloured lines alternately disposed, and are only the transverse section of the medullary and cortical laminae, mixed together in a vertical position in the basis of the cerebrum.

They lie in the bottom of the superior cavity of the lateral ventricles, which they resemble in some measure in shape, their anterior parts being near the septum lucidum, from which they separate gradually as they run backward, and diminish in size.

The *thalami nervorum opticum* are so named, because these nerves arise chiefly from them. They are two large eminences placed by the side of each other, between the posterior portions or extremities of the *corpora striata*. Their figure is semi-spheroidal and a little oval; and they are of a whitish colour on the surface; but their inner substance is partly greyish and partly white.

These two eminences are closely joined together, and at their convex part they are so far united as really to become one body, the whitish outer substance being continued uniformly over them both.

Immediately within this whitish common substance these two eminences are closely contiguous till about the middle of their thickness; and from thence they separate insensibly toward the bottom, where by the space left between them a particular canal is formed, named the third ventricle, one extremity of which opens forward, the other backward.

At the bottom these two eminences are elongated downward toward both sides, into two thick, round, whitish cords, which separate from each other like horns, by a large curvature; and afterwards by a small curvature turned forward in an opposite direction to the former, and representing the tip of an horn, they approach each other again. The size of these ropes diminishes gradually from their origin to their anterior reunion.

The tubercles are four in number, two anterior, and two posterior; adhering together as if they made but one body, situated behind the union of the thalami nervorum opticum. Their surface is white, and their inner substance greyish, and are called *nates* and *testes*.

Directly under the place where the tubercles of one side are united to those of the other side, lies a small middle canal, which communicates by its anterior opening with the third ventricle, under the thalami nervorum opticum, and by its posterior opening with the fourth ventricle, which belongs to the cerebellum.

Where the convex parts of the two anterior tubercles join these posterior convex parts of the thalami nervorum opticum, an interstice or opening is left between these four convexities which communicates with the third ventricle, and with the small middle canal. Instead of the

ridiculous name of *anus*, which has been given to this opening, it may be called *foramen commune posterius*.

The glandula pinealis is a small soft greyish body, about the size of an ordinary pea, irregularly round, and sometimes the figure of a pine apple, situated behind the thalami nervorum opticum, above the tubercula quadrigemina. It is fixed like a small button to the lower part of the thalami by two very white medullary pedunculi, which at the gland are very near each other, but separate almost transversely toward the thalami.

It seems to be mostly of a cortical substance, except near the footstalks, where it is something medullary.

Between the basis of the anterior pillar of the fornix, and the anterior part of the union of the optic thalami, lies a cavity or fossula named *infundibulum*. It runs down towards the basis of the cerebrum, contracting gradually, and terminates in a straight course, by a small membranous canal, in a softish body situated in the sella turcica, named *glandula pituitaria*. The infundibulum opens above, immediately before the optic thalami, by an oval hole named *foramen commune anterius*, and consequently communicates with the lateral ventricles.

At the lower part of the thalami nervorum opticum, directly under their union, lies a particular canal, called the *third ventricle* of the cerebrum.

This canal opens forward into the infundibulum under the foramen commune anterius, by which it likewise communicates with the lateral ventricles. It opens backward under the foramen commune posterius, between the thalami and tubercula quadrigemina, opposite to the small middle canal which goes to the cerebellum.

The plexus choroides is a very fine vascular texture, consisting of a great number of arterial and venal ramifications, partly collected in two loose fasciculi, which lie one in each lateral ventricle, and partly expanded over the neighbouring parts, and covering in a particular manner the thalami nervorum opticum, glandula pinealis, tubercula quadrigemina, and the other adjacent parts both of the cerebrum and cerebellum, to all which it adheres.

The pituitary gland is a small spongy body lodged in the sella turcica between the sphenoidal folds of the dura mater. It is of a singular kind of substance, which seems to be neither medullary nor glandular. On the outside it is partly greyish and partly reddish, and white within. It is transversely oval or oblong, and on the lower part in some subjects it is divided by a small notch into two lobes, like a kidney-bean. It is covered by the pia mater as by a bag, the opening of which is the extremity of the infundibulum, and it is surrounded by the small circular sinuses which communicate with the sinus cavernosi.

## CEREBELLUM.

THE cerebellum is contained under the transverse septum of the dura mater. It is broader laterally than on the fore or back sides, flatted on the upper side, and gently inclined both ways, answerable to the septum, which serves it as a kind of tent or ceiling. On the lower side it is rounder; and on the backside it is divided  
into.

into two lobes, separated by the occipital septum of the dura mater.

It is made up, like the cerebrum, of two substances, but it has no circinvolutions on its surface. Its sulci are pretty deep, and disposed in such a manner as to form thin flat strata, more or less horizontal, between which the internal lamina of the pia mater insinuates itself by a number of septa equal to that of the strata.

Under the transverse septum, it is covered by a vascular texture, which communicates with the plexus chorooides. It has two middle eminences called *appendices vermiformes*; one anterior and superior, which is turned forward; the other posterior and inferior, which goes backward. There are likewise two lateral appendices, both turned outward.

Besides the division of the cerebellum into lateral portions or into two lobes, each of these lobes seems to be likewise subdivided into three protuberances, one anterior, one middle or lateral, and one posterior.

When we separate the two lateral portions or lobes, having first made a pretty deep incision, we discover first of all the posterior portion of the medulla oblongata; and in the posterior surface of this portion, from the tubercula quadrigemina, all the way to the posterior notch in the body of the cerebellum, and a little below that notch, we observe an oblong cavity which terminates backward like the point of a writing pen. This cavity is what is called the fourth ventricle.

At the beginning of this cavity, immediately behind the small common canal which lies under the tubercles, we meet with a thin medullary lamina, which is looked upon as a valve between that canal and the fourth ventricle. A little behind this lamina, the cavity grows wider towards both hands, and then contracts again to its first size. It is lined interiorly by a thin membrane, and seems oftentimes to be distinguished into two lateral parts, by a kind of small groove, from the valvular lamina to the point of the calamus scriptorius.

This membrane is a continuation of that which lines the small canal, the third ventricle, infundibulum, and the two great ventricles.

On each side of this ventricle the medullary substance forms a trunk which expands itself in form of laminae through the cortical strata. When one lobe of the cerebellum is cut vertically from above downward, the medullary substance will appear to be dispersed in ramifications through the cortical substance. These ramifications have been named *arbor vite*; and the two trunks from whence these different laminae arise, are called *pedunculi cerebelli*.

### MEDULLA OBLONGATA.

The medulla oblongata is a medullary substance situated from before backward in the middle part of the bases of the cerebrum and cerebellum without any discontinuation, between the lateral parts of both these bases; and therefore it may be looked upon as one middle medullary basis common to both cerebrum and cerebellum, by the reciprocal continuity of their medullary substances, through the great notch in the transverse septum of the

dura mater; which common basis lies immediately on that portion of the dura mater which lines the basis of the cranium. The medulla oblongata is therefore justly esteemed to be a third general part of the whole mass of the brain, or as the common production or united elongation of the whole medullary substance of the cerebrum and cerebellum.

It is extremely difficult, if not altogether impossible, to examine or demonstrate it as we ought, in its natural situation; but we are obliged to do both on a brain inverted.

The lower side of the medulla oblongata in an inverted situation, presents to our view several parts which are in general either medullary productions, trunks of nerves, or trunks of blood-vessels.

The chief medullary productions are these: The large or anterior branches of the medulla oblongata; which have likewise been named *crura anteriora*, femora, and *brachia medullæ oblongatæ*, and *pedunculi cerebri*: The transverse protuberance, called likewise *processus annularis*, or *pons varolii*: The small or posterior branches, called *pedunculi cerebelli*, or *crura posteriora medullæ oblongatæ*: The extremity or cauda of the medulla oblongata, with two pairs of tubercles, one of which is named *corpora olivaria*, the other *corpora pyramidalia*; and to all these productions we must add a production of the infundibulum and two medullary papillæ.

The great branches of the medulla oblongata are two very considerable medullary fasciculi, the anterior extremities of which are separated, and the posterior united, so that, taken both together, they represent a Roman V.

The transverse, annular, or rather semi-annular protuberance, is a medullary production, which seems at first sight to surround the posterior extremities of the great branches; but the medullary substance of this protuberance is in reality intimately mixed with that of the two former. Varolius, an ancient Italian author, viewing those parts in an inverted situation, compared the two branches to two rivers, and the protuberance to a bridge over them both, and from thence it has the name of *pons Varolii*.

The small branches of the medulla oblongata are lateral productions of the transverse protuberance, which by their roots seem to encompass that medullary portion in which the fourth ventricle or calamus scriptorius is formed.

The extremity is no more than the medulla oblongata contracted in its passage backward to the anterior edge of the great foramea of the os occipitis, where it terminates in the medulla spinalis; and in this part of it several things are to be taken notice of. We see first of all, four eminences, two named *corpora olivaria*, and the other two *corpora pyramidalia*. Immediately afterwards, it is divided into two lateral portions by two narrow grooves, one on the upper side, the other on the lower. They both run into the substance of the medulla, as between two cylinders, flattened on that side by which they are joined together.

When we separate these ridges with the fingers, we observe a crucial intertexture of several small medullary cords,

cords, which go obliquely from the substance of one lateral portion into the substance of the other.

The corpora olivaria and pyramidalia are whitish eminences situated longitudinally near each other on the lower side of the extremity or cauda, immediately behind the transverse or annular protuberances. The corpora olivaria are in the middle, so that the interstice between them, which is a kind of superficial groove, answers to the inferior groove of the following portion.

The corpora pyramidalia are two lateral eminences depending on the olivaria. These four eminences are situated on the lower half of the medulla.

The tubercula mammillaria, or papillæ medullares, which are situated very near the production of the infundibulum, have been taken for glands.

These tubercles seem to have some immediate relation to the roots or bases of the anterior pillar of the fornx.

The beak or tube of the infundibulum is a very thin production from the sides of that cavity; and it is strengthened by a particular coat given to it by the pia mater. It is bent a little from behind forward, toward the glandula pinealis, and afterwards expands again round this gland.

The membrana arachnoides, or external lamina of the pia mater, appears to be very distinctly separated from the internal lamina, in the interstices between all these eminences on the lower side of the medulla oblongata, without any visible cellular substance between them.

From this medulla oblongata, arise almost all the nerves which go out of the cranium through the different foramina by which its basis is perforated. It likewise produces the medulla spinalis, which is no more than a common elongation of the cerebrum and cerebellum, and of their different substances; and therefore the medulla oblongata may justly be said to be the first origin or primitive source of all the nerves of the human body.

## MEDULLA SPINALIS.

THE medulla spinalis is only an elongation of the extremity of the medulla oblongata; and it has its name from its being contained in the bony canal of the spina dors; consequently a continuation or common appendix of the cerebrum or cerebellum, as well because of the two substances of which it is composed, as because of the membranes by which it is invested.

The dura mater, after it has lined the whole internal surface of the cranium, goes out by the great occipital foramen, and forms a kind of funnel, in its progress downward through the bony canal of the vertebræ.

The spinal marrow is made up of a cortical and medullary substance, as the cerebrum and cerebellum; but with this difference, that the ash-coloured substance lies within the other; and in a transverse section of this medulla, the inner substance appears to be of the figure of an horse-shoe.

The body of the medulla spinalis runs down all the way to the first vertebra of the loins, where it terminates in a point. The size of it is proportionable to that of

the bony canal, so that it is larger in the vertebræ of the neck than those of the back.

It sends off from both the fore and back sides, at different distances, flat fasciculi of nervous filaments. The anterior and posterior fasciculi having got a little beyond the edge of the medulla, unite in pairs, and form on each side a kind of knots, called *ganglions* by anatomists, each of which produces a nervous trunk. These ganglions are made up of a mixture of cortical and medullary substance, accompanied by a great number of small blood-vessels.

The dura mater, which invests the medulla, sends out on each side the same number of vaginæ as there are ganglions and nervous trunks. These vaginæ are productions of the external lamina; the internal lamina, which is very smooth and polished on the inside, being perforated by two small holes very near each other, where each vagina goes off, through which holes the extremities of each anterior and posterior fasciculus are transmitted; and immediately after their passage through the internal lamina, they unite.

### USES of the BRAIN and its Appendages in general.

MALPIGHI was the first who discovered the brain to be a gland, or an organ fitted to separate some particular fluid from the mass of blood.

The infinite number of small secretory clusters strain or filter the mass of blood carried to them by the numerous ramifications, and separate from it an excessively fine fluid; the remaining blood being conveyed back by the same number of venal extremities, into the sinuses of the dura mater, and from thence into the jugular and vertebral veins.

This subtle fluid, commonly called *animal spirit*, *nervous juice*, or *liquor of the nerves*, is continually forced into the medullary fibres of the white portion of the cerebrum, cerebellum, medulla oblongata, and medulla spinalis; and by the intervention of these fibres supplies and fills the nerves, which are a continuation of them.

## PERICRANIUM.

BESIDES the external integuments of the head, the skin, hair, and cellular substance, there is an aponeurotic expansion which covers the head like a cap, and is spread round the neck and on the shoulders like a riding-hood.

This aponeurosis is very strong on the head, and it appears to be made up of at least two strata of fibres crossing each other. As it is spread on the neck it becomes gradually thinner, and ends insensibly on the clavicles. It sends out a production on each side, from above downward, and from without inward, which having passed over the superior extremity of the musculus sternomastoideus, runs behind that muscle toward the transverse apophyses of the vertebræ of the neck, where it communicates with the ligamenta inter-transversalia.

The external surface of all the bones of the head, as  
well

*Fig. 3.*

*Fig. 1.*

*Fig. 6.*

*Fig. 2.*

*Fig. 4.*

*Fig. 5.*

*Fig. 7.*

*Fig. 9.*

*Fig. 8.*

*Fig. 10.*

well as of all the other bones of the human body, except the teeth, is covered by a particular membrane, of which that portion which particularly invests the cranium is named *pericranium*, and that which invests the bones of the face is simply termed *periosteum*.

The pericranium is made up of two laminae closely united together. The internal lamina, which has by some been taken for a particular periosteum, covers immediately all the bony parts of this region; and the external lamina has been looked upon as a membrane distinct from the internal, and named *pericranium* particularly.

## SECT. V. Of the EYE.

### The GLOBE or BALL of the EYE.

THE globe of the eye is made up of several proper parts, some of which being more or less solid, represent a kind of shell formed by the union of several membranous strata called the *coats* of the globe of the eye; and the other parts being more or less fluid, and contained in particular membranous capsulae, or in the interstices between the coats, are termed the *humours* of the globe of the eye. These capsulae are likewise termed *coats*.

The coats of the globe of the eye are of three kinds. Some form chiefly the shell of the globe; some are additional, being fixed only to a part of the globe; and some are capsular, which contain the humours. The coats which form the shell are three in number. The external is termed *tunica sclerotica* or *cornea*; the middle coat is named *choroides*; and the third or innermost, *retina*. The additional coats are two; one called *tendinosa* or *albuginea*, which forms the white of the eye; and the other, *conjunctiva*. The capsular tunicae are likewise two, the vitrea, and crystallina.

### The COATS of the EYE.

THE most external, thickest, and strongest coat of the eye is the sclerotica or cornea, and it invests all the other parts of which the globe is composed. It is divided into two portions, one called *cornea opaca*, the other *cornea lucida*, which is only a small segment of a sphere, situated anteriorly.

The cornea opaca is made up of several strata closely connected together, and is of an hard compact texture resembling parchment. About the middle of its posterior convex portion, where it sustains the optic nerve, it is in a manner perforated, and thicker than any where else.

The cornea lucida is made up in the like manner of several strata or laminae closely united, and appears to be a continuation of the opaque portion or sclerotica, though of a different texture.

This portion is something more convex than the cornea opaca, so that it represents the segment of a small sphere added to the segment of a greater.

The cornea lucida is perforated by a great number of imperceptible pores, through which a very fine fluid is continually discharged, which soon afterwards evaporates.

The second coat of the globe of the eye is the cho-

roides, which is of a blackish colour, more or less inclined to red, and adheres, by means of a great number of small vessels, to the cornea opaca, from the insertion of the optic nerve, all the way to the union of the two cornea, where it leaves the circumference of the globe, and forms a perforated septum, by which the small segment of the globe is separated from the greater. This portion goes commonly by the particular name of *uvea*, which was formerly given to the whole second coat; and as it is of different colours in several subjects, it has likewise got the name of *iris*.

The anterior portion or perforated septum of the choroides has the name of *uvea*, and the hole near the centre of this septum is called *pupilla*. The anterior lamina of the same septum is termed *iris*, and the radiated plicae of the posterior lamina, *processus ciliares*. Between the two laminae of the uvea, we find two very thin planes of fibres which appear to be fleshy, the fibres of one plane being orbicular, and lying round the circumference of the pupilla, and those of the other being radiated, one extremity of which is fixed to the orbicular plane, the other to the great edge of the uvea.

The plicae or processus ciliares are small radiated and prominent duplicatures of the posterior lamina of the uvea, and their circumference answers partly to that of the white ring of the external lamina. They are oblong thin plates; their posterior extremities, or those next the choroides, being very fine and pointed; the others, or those next the pupilla, broad, prominent, and ending in acute angles.

The space between the cornea lucida and uvea contains the greatest part of the aqueous humour, and communicates by the pupilla with a very narrow space behind the uvea, or between that and the crystalline. These two spaces have been termed the two chambers of the aqueous humour, one anterior, the other posterior.

The third coat of the eye is of a very different texture from that of the other two coats. It is white, soft, and tender, and in a manner medullary, or like a kind of paste spread upon a fine reticular web. It appears to be thicker than the choroides, and reaches from the insertion of the optic nerve, to the extremities of the ciliary radii, being equally fixed to the choroides through its whole extent. At the place which answers to the insertion of the optic nerve, we observe a small depression, in which lies a sort of medullary button terminating in a point; and from this depression blood-vessels go out, which are ramified on all sides through the substance of the retina.

### The HUMOURS of the EYE and their CAPSULAE.

The vitreous humour is a clear and very liquid gelatinous fluid, contained in a fine transparent capsula, called *tunica vitrea*, together with which it forms a mass nearly of the consistence of the white of an egg. It fills the greatest part of the globe of the eye, that is, almost all that space which answers to the extent of the retina, except a small portion behind the uvea, where it forms a fossula, in which the crystalline is lodged.

The tunica vitrea is composed exteriorly of two laminae

are very closely connected, which quite surround the mass of humour, and are immediately applied to the retina, all the way to the great circumference of the cornea ciliaris; but from thence to the circular edge of the fossula of the crystalline, this coat is full of radiated sulci, which contain the proccus ciliares of the uvea.

The internal lamina of the tunica vitrea gives off, through the whole substance of this humour, a great number of cellular elongations or septa.

The radiated sulci of the tunica vitrea, which may be termed *sulci ciliares*, are perfectly black, when the coat is taken out of the body.

The crystalline is a small lenticular body, of a pretty firm consistence, and transparent like crystal. It is contained in a transparent membranous capsula, and lodged in the anterior fossula of the vitreous humour.

The figure of the crystalline is lenticular, but its posterior side is more convex than the anterior, the convexity of both sides being very rarely equal.

The crystalline capsula or coat is formed by a duplicature of the tunica vitrea. The external lamina covers the anterior side of the crystalline mass; the internal lamina covers the backside, and likewise the fossula vitrea, in which the crystalline is lodged.

The anterior portion swells when macerated in water, and then appears to be made up of two pellicular, united by a fine spongy substance.

The aqueous humour is a very limpid fluid, resembling a kind of lymph or serum, with a very small degree of visciditv; and it has no particular capsula like the crystalline and vitreous humours. It fills the space between the cornea lucida and uvea, that between the uvea and the crystalline, and the hole of the pupilla. These two spaces are called the chambers of the aqueous humour, and they are distinguished into the anterior and posterior.

The anterior chamber, which is visible to every body, between the cornea lucida and uvea, is the largest; the other between the uvea and crystalline is very narrow, especially near the pupilla, where the uvea almost touches the crystalline.

#### *The TUNICA ALBUGINEA and MUSCLES of the GLOBE of the EYE.*

THE tunica albuginea, called commonly the *white* of the eye, and which appears on all the anterior convex side of the globe, from the cornea lucida, to the beginning of the posterior side, is formed chiefly by the tendinous expansion of four muscles.

There are commonly six muscles inserted in the globe of the human eye, and they are divided into four recti and two obliqui. The recti are again divided, from their situation, into superior, inferior, internal, and external; and from their functions, into a levator, depressor, adductor, and abductor. The two oblique muscles are denominated from their situation and size, one being named *obliquus superior* or *major*, the other *obliquus inferior*, or *minor*. The obliquus major is likewise called *trochlearis*, because it passes through a small cartilaginous ring, as over a trochlea or pulley.

The *musculi recti* are fixed by their posterior extremi-

ties at the bottom of the orbit near the foramen opticum in the elongation of the dura mater, by short narrow tendons. From thence they run wholly fleshy, toward the great circumference of the convexity of the globe, between the optic nerve and cornea lucida, where they are expanded into flat broad tendons which touch each other, and afterwards unite. These tendons are fixed first of all by a particular insertion in the circumference just mentioned, and afterwards continue their adhesion all the way to the cornea, forming the tunica albuginea.

The superior oblique muscle is fixed to the bottom of the orbit, by a narrow tendon, in the same manner as the recti, between the rectus superior and internus. From thence it runs on the orbit opposite to the interstice between these two muscles, toward the internal angular apophysis of the os frontis, where it terminates in a thin tendon, which having passed through a kind of ring as over a pulley, runs afterwards in a vagina obliquely backward under the rectus superior, that is between that muscle and the globe; and, increasing in breadth, it is inserted posteriorly and laterally in the globe, near the rectus externus.

The ring through which this muscle passes, is partly cartilaginous and partly ligamentary. The cartilaginous portion is flat, of a considerable breadth, and like half a ring. The ligamentary portion adheres strongly to the two ends of the cartilage, and is fixed in the small fossula which lies in the orbit, on the angular apophysis of the os frontis. By means of this ligament, the ring is in some measure moveable, and yields to the motions of the muscle. To the anterior edge of the ring, a ligamentary vagina is fixed, which invests the tendon all the way to its insertion in the globe.

The obliquus inferior is situated obliquely at the lower side of the orbit, under the rectus inferior, which consequently lies between this muscle and the globe. It is fixed by one extremity a little tendinous, to the root of the nasal apophysis of the os maxillare, near the edge of the orbit between the opening of the ductus nasalis, and the inferior orbitary fissure.

From thence it passes obliquely, and a little transversely backward, under the rectus inferior, and is fixed in the posterior lateral part of the globe by a flat tendon, opposite to, and at a small distance from the tendon of the obliquus superior, so that these two muscles do in some measure surround the outer posterior part of the globe.

The rectus superior moves the anterior portion of the globe upward when we lift up the eyes; the rectus inferior carries this portion downward; the internus, toward the nose; and the externus, toward the temples.

When two neighbouring recti act at the same time, they carry the anterior portion of the globe obliquely toward that side which answers to the distance between these two muscles; and when all the four muscles act successively, they turn the globe of the eye round, which is what is called rolling the eyes.

The use of the oblique muscles is chiefly to counterbalance the action of the recti, and to support the globe in all the motions already mentioned. This is evident from their

their insertions, which are in a contrary direction to those of the recti, their fixed points with relation to the motions of the globe being placed forward, and those of the recti backward, at the bottom of the orbit.

The *rectus externus*, by being bent on the globe, not only hinders it from being carried outward, but also prevents the indirect motions of the obliqui from thrusting it out of the orbit toward the temples.

*The SUPERCILIA, and MUSCULI FRONTALES, OCCIPITALES, and SUPERCILIARES.*

The *supercilia*, or eye-brows, are the two hairy arches situated at the lower part of the forehead, between the top of the nose and temples, in the same direction with the bony arches which form the superior edges of the orbits. Their colour is different in different persons, and often in the same person different from that of the hair on the head: the hairs of which they consist are strong and pretty stiff, and they lie obliquely, their roots being turned to the nose, and their points to the temples.

The *supercilia* have motions common to them with those of the skin of the forehead, and of the hairy scalp. By these motions the eye-brows are lifted up, the skin of the forehead is wrinkled more or less regularly and transversely; and the hair and almost the whole scalp is moved, but not in the same degree in all persons. The eye-brows have likewise particular motions which contract the skin above the nose; and all these different motions are performed by the following muscles.

The frontal muscles are two thin, broad, fleshy planes of unequal lengths, lying immediately behind the skin and *membrana adiposa*, on the anterior parts of the forehead, which parts they cover from the root of the nose, and through about two thirds of the arch of the eye-brows on each side, all the way to the lateral parts of the hair on the forehead. At the root of the nose they touch each other as if they were but one muscle; and at this place their fibres are short and longitudinal, or vertical.

These muscles are fixed by the inferior extremities of their fleshy fibres immediately in the skin, running thro' the *membrana adiposa*. They cover the muscular *superciliares*, and adhere closely to them by a kind of intertexture. By the same fibres they seem to be inserted in the angular apophyses of the *os frontis*, and to be blended a little with the muscles of the *palpebræ* and nose. The upper extremities of their fleshy fibres are fixed in the external or convex surface of the *pericranium*. Each of their lateral portions covers a portion of the temporal muscle on the same side, and adheres very closely to it.

The occipital muscles are two small, thin, broad, and very short fleshy planes, situated on the lateral parts of the occiput, at some distance from each other. They are inserted by the inferior extremities of their fleshy fibres in the superior transverse line of the *os occipitis*, and also a little above it. From thence they run up obliquely from behind forward, and are fixed in the inner concave surface of the *pericranium*.

The breadth of these muscles reaches from the posterior middle part of the occiput, toward the mastoid a-

pophysis, and they diminish unequally in length as they approach the apophyses.

These four muscles seem always to act in concert, the *occipitales* being only auxiliaries or assistants to the *frontales*, the office of which is to raise the *supercilia*, by wrinkling the skin of the forehead.

The muscular *superciliares* are fleshy *fasciculi*, situated behind the *supercilia*, and behind the inferior portion of the muscular *frontales*, from the root of the nose to above one half of each *superciliary* arch. They are strongly inserted, partly in the *synarthrosis* of the *ossa nasi*, with the *os frontis*, where they come very near the proper muscles of the nose, and partly in a small neighbouring portion of the orbit. From thence they first run up a little, and afterwards more or less in the direction of the eye-brows. They are made up of several small *fasciculi* of oblique fibres, all fixed by one end in the manner already said, and by the other partly in the lower extremity of the muscles by which they are covered, and partly in the skin of the *supercilia*.

The action of these muscles is to depress the eye-brows, to bring them close together, and to contract the skin of the forehead immediately above the nose, into longitudinal and oblique wrinkles, and the skin which covers the root of the nose into irregular transverse wrinkles.

*The PALPEBRÆ and MEMBRANA CONJUNCTIVA.*

The *palpebræ* are a kind of veils or curtains placed transversely above and below the anterior portion of the globe of the eye; and accordingly there are two eyelids to each eye, one superior, the other inferior. The superior is the largest and most moveable in man. They both unite at each side of the globe, and the places of their union are termed *angles*, one large and internal, which is next the nose, the other small or external, which is next the temples.

The *palpebræ* are made up of common and proper parts. The common parts are the skin, epidermis, and *membrana adiposa*. The proper parts are the muscles, the *tarsi*, the *puncta* or *foramina lachrymalia*, the *membrana conjunctiva*, the *glandula lachrymalis*, and the particular ligaments which sustain the *tarsi*. The *tarsi* and their ligaments are in some measure the basis of all these parts.

The *tarsi* are thin cartilages forming the principal part of the edge of each *palpebra*; and they are broader at the middle than at the extremities. Those of the superior *palpebræ* are something less than half an inch in breadth; but in the lower *palpebræ* they are not above the sixth part of an inch; and their extremities next the temples are more slender than those next the nose.

These cartilages are suited to the borders and curvature of the eye-lids. The lower edge of the superior cartilage and upper edge of the inferior, terminate equally, and both may be termed the *ciliary edges*. The opposite edge of the upper *tarsus* is something semi-circular between its two extremities; but that of the inferior *tarsus* is more uniform, and both are thinner than the *ciliary edges*.

The broad ligaments of the tarsi are membranous elongations formed by the union of the periosteum of the orbits and pericranium along both edges of each orbit. The superior ligament is broader than the inferior, and fixed to the superior edge of the upper cartilage, as the inferior is to the lower edge of the lower cartilage, so that these ligaments and the tarsi, taken alone or without the other parts, represent palpebræ.

The *membrana conjunctiva* is a thin membrane, one portion of which lines the inner surface of the palpebræ. At the edge of the orbit it has a fold, and is continued from hence on the anterior half of the globe of the eye, adhering to the *tunica albuginea*; so that the palpebræ and the forepart of the globe of the eye are covered by one and the same membrane, which does not appear to be a continuation of the pericranium, but has some connection with the broad ligaments of the tarsi.

The name of *conjunctiva* is commonly given only to that part which covers the globe, the other being called simply the *internal membrane* of the palpebræ; but we may very well name the one *membrana oculi conjunctiva*, and the other *membrana palpebrarum conjunctiva*. That of the palpebræ is a very fine membrane adhering very close, and full of small capillary blood-vessels. It is perforated by numerous imperceptible pores, through which a kind of serum is continually discharged.

The conjunctiva of the eye adheres by the intervention of a cellular substance, and is consequently loose, and as it were moveable; and it may be taken hold of and separated in several places from the tendinous coat. It is of a whitish colour; and being transparent, the *albuginea* makes it appear perfectly white: These two coats together forming what is called the *white of the eye*.

The lachrymal gland is white, and of the number of those called *conglomerate glands*. It lies under that depression observable in the arch of the orbit near the temples, and laterally above the globe of the eye. It is a little flattened, and divided as it were into two lobes, one of which lies toward the insertion of the *musculus rectus superior*, the other toward the *rectus externus*. It adheres very closely to the fat which surrounds the muscles and posterior convexity of the eye, and it was formerly named *glandula innominata*.

From this gland several small ducts go out, which run down almost parallel to each other, through the substance of the *tunica interna* or conjunctiva of the superior palpebra, and afterwards pierce it inwardly near the superior edge of the tarsus.

The flat edge of each palpebra is adorned with a row of hairs called *cilia*, or the *eye-lashes*. Those belonging to the superior palpebra are bent upward, and longer than those of the lower palpebra which are bent downward. These rows are placed next the skin, and are not single, but irregularly double or triple. The hairs are longer near the middle of the palpebræ than toward the extremities, and for about a quarter of an inch from the base, where they are quite wanting.

Along the same border of the palpebræ, near the internal membrane, or toward the eye, we see a row of small holes which may be named *foramina* or *puncta ciliaria*.

They are the orifices of the same number of small oblong glands which lie in the sulci, channels, or grooves on the inner surface of the tarsus. These little glands are of a whitish colour; and when squeezed, a sebaceous matter like soft wax, is discharged through the *puncta ciliaria*.

Near the great or internal angle of the palpebræ, the flat portion of their edges terminates in another which is rounder and thinner. By the union of these two edges an angle is formed.

At this place, the extremity of the flat portion is distinguished from the round portion by a small protuberance or papilla, which is obliquely perforated by a small hole in the edge of each palpebra. These two small holes are very visible, and often more so in living than in dead bodies, and they are commonly named *puncta lachrymalia*, being the orifices of two small ducts which open beyond the angle of the eye into a particular reservoir, termed *saeculus lachrymalis*, which shall be described in the article of the nose.

The *puncta lachrymalia* are opposite to each other, and so they meet when the eye is shut. Round the orifice of each of these points, we observe a whitish circle which seems to be a cartilaginous appendix of the tarsus, and which keeps the orifice always open.

The *caruncula lachrymalis* is a small reddish, granulated, oblong body, situated precisely between the internal angle of the palpebræ and globe of the eye. The substance of it seems to be wholly glandular. We discover upon it a great number of fine hairs covered by an oily, yellowish matter; and on the globe of the eye, near this glandular body, we see a semilunar fold, formed by the conjunctiva, the concave side of which is turned to the uvea, and the convex side to the nose.

#### The MUSCLES of the ПАЛПЕБРАЪ.

The muscles of the palpebræ are commonly reckoned to be two, one peculiar to the upper eye-lid, named *levator palpebræ superioris*; the other common to both, called *musculus orbicularis palpebrarum*.

The *levator palpebræ superioris* is a very thin muscle, situated in the orbit above, and along the *rectus superior oculi*. It is fixed to the bottom of the orbit, by a small narrow tendon, near the foramen opticum, between the posterior insertions of the *rectus superior* and *obliquus superior*. From thence its fleshy fibres run forward on the *rectus*, increasing gradually in breadth, and terminate by a very broad aponeurosis in the tarsus of the superior palpebra.

By the *musculus palpebrarum obliquus* we understand all that extent of fleshy fibres, which by a thin stratum surrounds the edge of each orbit, and from thence, without any interruption, covers the two palpebræ all the way to the cilia. Almost all of them have a common tendon situated transversely between the internal angle of the eye and the nasal apophysis of the os maxillare. This is a slender ligamentary tendon, strongest where it is fixed in the bone, and diminishing gradually as it approaches the angle of the palpebræ, where it terminates

at

at the union of the points, or at the extremities of the two tarſi.

This muſcle is divided into four portions, whereof the firſt is that which ſurrounds the orbit. The ſecond portion is that which lies between the upper edge of the orbit and the globe of the eye, and which covers the inferior edge of the orbit below, ſome of its fibres being fixed to both edges of the orbit.

The third portion ſeems to belong more particularly to the palpebræ, and the greateſt part of it is ſpent in the palpebra ſuperior. The fibres of this portion meet at the two angles of the eye, where they appear to make very acute inflexions without any diſcontinuation.

The fourth portion is an appendix to the third, from which it differs chiefly in this, that its fibres do not reach to the angles, and form only ſmall arches, the extremities of which terminate in each palpebra.

All theſe different portions of the orbicular muſcle adhere to the ſkin, which covers it from the upper part of the noſe to the temples, and from the ſupercilium to the upper part of the cheek. When they contract, ſeveral wrinkles are formed in the ſkin, which vary according to the different directions of the fibres.

#### *The Uſes of the Eye, and of its Appendages, in general.*

EVERY body knows that the eye is the organ of viſion. The transparent parts of the globe modify the rays of light, by different refractions; the retina and choroides receive the different impreſſions of theſe rays; and the optic nerve carries theſe impreſſions to the brain. When objects are at a great diſtance or obſcure, the pupilla is dilated; and it is contracted when objects are near, or placed in a great light. The muſcles of the globe of the eye and of the palpebræ perform the motions already deſcribed.

The glandula lachrymalis continually moiſtens the fore-part of the globe of the eye; and the lachrymal ſerum is equally ſpread over that globe by the motions of the ſuperior palpebra, the inner ſurface of which is in a ſmall meſure villous. The union of the two palpebræ directs this ſerum towards the puncta lachrymalia; and the unctuous matter, diſcharged through the foramina ciliaria, hinders it from running out between the palpebræ. The large ſize and viſcid ſurface of the caruncula prevents it from running beyond the puncta, and thus forces it into them.

The ſupercilia may hinder ſweat from falling on the eyes. The ſuperior cilia, which are longer than the inferior, may have the ſame uſe; and they both ſerve to prevent duſt, infects, &c. from entering the eyes when they are only a little open.

### SECT. VI. *The NOSE.*

THE bones of the noſe have already been deſcribed in the ſutures of the bones of the head,

The ſoft parts are the integuments, muſcles, ſacculus lachrymalis, membrana pituitaria, and hairs of the nares.

The internal nares, or the two cavities of the

noſe, comprehend the whole ſpace between the external nares and poſterior openings immediately above the arch of the palate; from whence theſe cavities reach upward as far as the lamina cribroſa of the os ethmoides, where they communicate forward with the ſinus frontales, and backward with the ſinus ſphenoidales. Laterally, theſe cavities are bounded on the inſide by the ſeptum naſium, and on the outſide, or that next the cheeks, by the conchæ, between which they communicate with the ſinus maxillaris.

The particular ſituation of theſe cavities deſerves our attention. The bottom of them runs directly backward, ſo that a ſtreight and pretty large ſtilet may eaſily be paſſed from the external nares, under the great apophyſis of the occipital bone. The openings of the maxillary ſinufes are nearly oppoſite to the upper edge of the oſſa malarum. The openings of the frontal ſinufes are more or leſs oppoſite to, and between the pulleys or rings of the muſculi trochleares; and by theſe marks the ſituation of all the other parts may be determined.

The inferior portion of the external noſe is compoſed of ſeveral cartilages, which are commonly five in number, and of a pretty regular figure. The reſt are only additional, ſmaller, more irregular, and the number of them more uncertain. Of the five ordinary cartilages, one is ſituated in the middle, the other four laterally. The middle cartilage is the moſt conſiderable, and ſupports the reſt, being connected immediately to the bony parts; but the other four are connected to the middle cartilage, and to each other, by means of ligaments.

The ſub-ſeptum, or portion under the ſeptum naſium, is a pillar of fat applied to the inferior edge of the cartilagenous partition, in form of a ſoft moveable appendix. The thickneſs of the alæ naſium, and eſpecially that of their lower edges, is not owing to the cartilages, which are very thin, but to the ſame kind of ſolid fat with which theſe cartilages are covered. The great cartilage is immoveable by reaſon of its firm connection to the bony parts of the noſe; but the lateral cartilages are moveable, becauſe of their ligamentary connections, and they are moved in different manners by the muſcles belonging to them.

The external noſe is covered by the common integuments, the ſkin, epidermis, and fat. Thoſe which cover the tip of the noſe and alæ naſium are a great number of glandular bodies, called *glandula ſebacea*, the contents of which may eaſily be ſqueezed out by the fingers.

Six muſcles are commonly reckoned to belong to the noſe; two recti, called alſo *pyramidales* or *triangulares*; two obliqui, or laterales; and two tranſverſi, or myrtiformes. The noſe may alſo be moved in ſome meſure by the muſcles of the lips, which in many caſes become aſſiſtants to the proper muſcles of this organ.

The muſculus pyramidalis, or anterior, on each ſide, is inſerted by one extremity in the ſynarthroſis of the os frontis and oſſa naſi, where its fleſhy fibres mix with thoſe of the muſculi frontales and ſuperciliares. It is very flat, and runs down on the ſide of the noſe, increaſing gradually in breadth, and terminating by an aponeuroſis, which repreſents the baſis of a pyramid, and is inſerted

inserted in the moveable cartilage which forms the ala of the nares.

The oblique or lateral muscle is a thin fleshy plane, lying on the side of the former. The lateral muscle is fixed by its upper extremity to the apophysis nasalis of the os maxillare, below its articulation with the os frontis, and sometimes a little lower than the middle of the inner edge of the orbit. From thence it runs toward the alar narium, and is inserted in the moveable cartilage, near the os maxillare, being covered laterally by a portion of the neighbouring muscle of the upper lip.

The transverse or inferior muscle, called also *myrtiformis*, is inserted by one end in the os maxillare, near the lower edge of the orbit, much about the place which answers to the extremity of the socket of the dens caninus on the same side. From thence it runs almost transversely upward, and is fixed in the lateral cartilage of the nose, over which it sometimes runs to the ala of the great cartilage, to be inserted there.

The first two pairs of these muscles raise and dilate the ala of the nares when they act; and at the same time raise the upper lip, by reason of their connection with the muscles of that part. They likewise wrinkle the skin on the sides of the nose.

The membrana pituitaria is that which lines the whole internal nares, the cellular convolutions, the conchæ, the sides of the septum narium, and, by an uninterrupted continuation, the inner surface of the sinus frontales and maxillares, and of the ductus lacrymales, palatini, and sphenoidales. It is likewise continued down from the nares to the pharynx, septum palati, &c.

It is termed *pituitaria*, because, through the greatest part of its large extent, it serves to separate from the arterial blood a mucilaginous lymph, called *pituita* by the ancients, which in the natural state is pretty liquid; but it is subject to very great changes, becoming sometimes glutinous or stony, sometimes limpid, &c. neither is it separated in equal quantities through the whole membrane.

When we carefully examine this membrane, it appears to be of a different structure in different parts. Near the edge of the external nares it is very thin, appearing to be the skin and epidermis in a degenerated state. All the other parts of it in general are spongy, and of different thicknesses. The thickest parts are those on the septum narium, on the whole lower portion of the internal nares, and on the conchæ.

On the side next the periosteum and perichondrium it is plentifully strewed with small glands, the excretory ducts of which are very long near the septum narium, and their orifices very visible.

The frontal, maxillary and sphenoidal sinuses open into the internal nares, but in different manners. The frontal sinuses open from above downward, answering to the infundibula of the os ethmoides. The sphenoidales open forwards, opposite to the posterior orifices of the nares; and the maxillares open a little higher, between the two conchæ.

The opening of the sinus maxillaris in some subjects is single, in others double; it lies exactly between the two conchæ, about the middle of their depth.

It is proper here to observe the whole extent of the maxillary sinus. Below, there is but a very thin partition between it and the dentes molares, the roots of which do, in some subjects, perforate that septum. Above, there is only a very thin transparent lamina between the orbit and the sinus. Backward, above the tuberosity of the os maxillare, the sides of the sinus are very thin, especially at the place which lies before the root of the apophysis pterygoidea, through which the inferior maxillary nerve sends down a ramus to the foramen palatinum posterius, commonly called *gustatorium*. Inward, or toward the conchæ narium, the bony part of the sinus is likewise very thin.

The lacrymal facculus is an oblong membranous bag, into which the serous fluid is discharged from the eye through the puncta lacrymalia; and from which the same fluid passes to the lower part of the internal nares. It is situated in a bony groove and canal, formed partly by the apophysis nasalis of the os maxillare and os unguis, partly by the same os maxillare and lower part of the os unguis, and partly by this lower portion of the os unguis and a small superior portion of the conchæ narium inferior.

This bony lacrymal duct runs down for a little way obliquely backward, toward the lower and lateral part of the internal nares on each side, where its lower extremity opens on one side of the sinus maxillaris under the inferior conchæ. The upper part of this duct is only a half canal or groove; the lower is a complete canal, narrower than the former.

The facculus lacrymalis may be divided into a superior or orbital portion, and an inferior or nasal portion. The orbital portion fills the whole bony groove, being situated immediately behind the middle tendon of the musculus orbicularis. The nasal portion lies in the bony canal of the nose, being narrower and shorter than the former.

The orbital portion is disposed at its upper extremity, much in the manner of an intestinum cæcum, and at the lower extremity is continued with the portio nasalis. Towards the internal angle of the eye, behind the tendon of the orbicular muscle, it is perforated by a small short canal formed by the union of the lacrymal ducts.

The nasal portion having reached the lower part of the bony duct under the inferior conchæ, terminates in a small, flat, membranous bag, the bottom of which is perforated by a round opening.

The substance of this facculus is something spongy or cellular, and pretty thick, being strongly united by its convex side to the periosteum of the bony canal.

The ductus incisivii, or naso-palatini of Steno, are two canals which go from the bottom of the internal nares cross the arch of the palate, and open behind the first or largest dentes incisivii. Their two orifices may be distinctly seen in the skeleton at the lower part of the nasal fossæ, on the anterior and lateral sides of the crista maxillares; and we may likewise perceive their oblique passage through the maxillary bones, and lastly their inferior orifices in a small cavity or fossula, called *foramen palatinum anterius*.

The nose is the organ of smelling, by means of the villous portion of the internal membrane, to which the olfactory nerves are chiefly distributed. It is likewise of use in respiration; and the mucilaginous fluid spread over the whole pituitary membrane, prevents the air from drying that membrane, and so rendering it incapable of being affected. The nose serves likewise to regulate and modify the voice, and to this the sinuses likewise contribute. The *faculus lachrymalis* receives the serum from the eyes, and discharges it upon the palate, from whence the greatest part of it runs to the pharynx.

### SECT. VII. *The Ear.*

ANATOMISTS commonly divide or distinguish the ear into external and internal. By the external ear they mean all that lies without the external orifice of the meatus auditorius in the os temporis; and by the internal ear, all that lies within the cavities of that bone, and also the parts that bear any relation thereto.

The greatest part of the external ear consists of a large cartilage very artificially framed, which is the basis of all the other parts of which this portion of the ear is made up. The internal ear consists chiefly of several bony pieces, partly formed in the substance of the ossa temporum, and especially in that portion of it called *apophysis petrosa*, and partly separated from, but contained in a particular cavity of that bone.

The external ear, taken altogether, resembles in some degree the shell of a mussel, with its broad end turned upward, the small end downward, the convex side next the head, and the concave side outward. Two portions are distinguished in the external ear taken all together; one large and solid, called in Latin *pinna*, which is the superior, and by much the greatest part; the other small and soft, called the *lobe*, which makes the lower part.

The forehead is divided into eminences and cavities. The eminences are four in number, called *helix*, *antihelix*, *tragus*, and *antitragus*. The *helix* is the large folded border or circumference of the great portion of the ear. The *antihelix* is the large oblong eminence or rising surrounded by the *helix*. The *tragus* is the small anterior protuberance below the anterior extremity of the *helix*, which in an advanced age is covered with hairs. The *antitragus* is the posterior tubercle below the inferior extremity of the *antihelix*.

The cavities on the forehead are four in number; the hollow of the *helix*; the depression at the superior extremity of the *antihelix*, called *fossa navicularis*; the concha, or great double cavity that lies under the rising termed *antihelix*, the upper bottom of which is distinguished from the lower by a continuation of the *helix* in form of a transverse crista; and lastly, the meatus of the external ear situated at the lower part of the bottom of the concha.

The backside of the external ear shews only one considerable eminence, which is a portion of the convex side of the concha, the other portion being hid by the adhesion of the ear to the os temporis.

The other parts of the external ear, besides the cartilage, are ligaments, muscles, integuments, sebaceous and ceruminous glands, arteries, veins and nerves.

The cartilage of the outward ear is nearly of the same extent and figure with the large solid portion thereof, already mentioned; but it is not of the same thickness, being covered by integuments on both sides. In the lobe or soft lower portion of the ear, this cartilage is wanting.

The external ear is fixed to the cranium, not only by the cartilaginous portion of the meatus auditorius, but also by ligaments, which are two in number, one anterior, the other posterior. The anterior ligament is fixed by one extremity to the root of the apophysis zygomatica of the os temporis, at the anterior and a little toward the superior part of the meatus ossis, close to the corner of the glenoid cavity; and by the other extremity, to the anterior and superior part of the cartilaginous meatus.

The posterior ligament is fixed by one end to the root of the mastoid apophysis, and by the other to the posterior part of the convexity of the concha, so that it is opposite to the anterior ligament.

Of the muscles of the external ear, some go between the cartilages and the os temporis, others are confined to the cartilages alone. Both kinds vary in different subjects, and are sometimes so very thin, as to look more like ligaments than muscles. The muscles of the first kind are generally three in number, one superior, one posterior, and one anterior. The superior muscle is fixed in the convexity of the *fossa navicularis*, and of the superior portion of the concha; from whence it runs up to the squamous portion of the os temporis, expanding in a radiated manner, and is inserted principally in the ligamentary aponeurosis, which covers the posterior portion of the temporal muscle.

The anterior muscle is small, more or less inverted, and like an appendix to the superior. It is fixed by one extremity above the root of the zygomatic apophysis, and by the other in the anterior part of the convexity of the concha.

The posterior muscle is almost transverse, and of a considerable breadth, being fixed by one end to the posterior part of the convexity of the concha, and by the other in the root of the mastoid apophysis.

The small muscles which are confined to the cartilages are only small strata of fibres found on both sides of the cartilages.

The lobe of the ear, or that soft portion which lies under the *tragus*, *antitragus*, and meatus auditorius, is made up of nothing but skin and cellular substance. The meatus auditorius is partly bony, and partly cartilaginous. The bony portion is the longest, and forms the bottom of the canal. The cartilaginous portion is the shortest, and forms the external opening or orifice of the canal.

These two portions joined endwise to each other, form a canal of about three quarters of an inch in length, of different wideness in its different parts, and a little contorted. It is lined on the inside by the skin and cellular membrane, through its whole length; and thus these integuments make up for the breaks in the cartilaginous portion.

portion, and form a kind of cutaneous tube in the other portion.

The skin which covers both sides of the cartilage contains a great number of small glands, which continually discharge an oily whitish humour, collected chiefly near the adhesions of the ear to the head, and under the fold of the helix; and these glands are of the sebaceous kind. The skin which lines the meatus auditorius contains another kind of glands, of a yellowish colour, and which may be plainly seen on the convex side of the cutaneous tube already mentioned.

These glands are disposed in such a manner as to leave reticular spaces between them, and they penetrate a little way into the substance of the skin. They are called *glandulae ceruminosae*, because they discharge that matter which is named *cerumen*, or the *wax of the ear*. The inner surface of the cutaneous tube is full of fine hairs, between which lie the orifices of the ceruminous glands. The first place in which we meet with these glands is on that part of the convex side of the cutaneous tube which supplies the breaks of the cartilaginous meatus.

All the bony parts of the organ of hearing, or bones of the internal ear, being contained in the inferior portions of the ossa temporum; it will be very proper to recollect what has been already said about these, in Part I.

All the bony organ of hearing may be divided into four general parts: 1. The external meatus auditorius; 2. The tympanum or barrel of the ear; 3. The labyrinth; 4. The internal meatus auditorius. It may likewise be divided into immeasurable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called *incus*, *malleus*, *stapes*, and *os orbiculare* or *lenticulare*.

The external auditory passage begins by the external auditory hole, the edge of which is rough and prominent; but backwards towards the mastoid apophysis it appears very much sloped. The passage itself is about half an inch in length, running obliquely from behind forward, in a curve direction, and sometimes winding a little in the middle, like a screw. Its cavity is almost oval, wider at the entry than at the middle, after which it widens again by degrees.

It terminates inwardly by an even circular edge lying in a plane very much inclined, the upper part of it being turned outward, and the lower part inward; so that the whole canal is longer on the lower side than on the upper. The concave side of the circular edge is grooved quite round.

In children this bony canal is wanting, as well as the mastoid apophysis; and the inner circular edge is a distinct ring, which in an advanced age unites intirely, and becomes one piece with the rest. It is termed the *bony circle* in infants, and indeed it is very easily separated from all the other parts.

It would seem therefore, that the whole bony canal in adults is only a prolongation of the bony circle in children; because even in a more advanced age, the whole canal may, without much difficulty, be taken out. The circular groove lies between the mastoid apophysis and the articular fissure or crack.

The tympanum or barrel of the ear is a cavity irregularly semi-spherical, the bottom of it being turned inward, and the mouth joined to the circular groove already mentioned. Both eminences and cavities are observable in it.

The remarkable eminences are three in number; a large tuberosity lying in the very bottom of the barrel, a little toward the back part; and a small irregular pyramid situated above the tuberosity, and a little more backward; the apex of it is perforated by a small hole, and on one side of the basis two small bony filaments are often found in a parallel situation. In the third eminence is a cavity shaped like the mouth of a spoon, situated at the upper and a little towards the anterior part of the bottom of the tympanum.

The principal cavities in the tympanum are, the opening of the mastoid cells or sinuosities; the opening of the Eustachian tube; the bony half-canal; the fenestra ovalis and rotunda; and to these may be added the small hole in the pyramid.

The opening in the mastoid cells is at the posterior and upper part of the edge of the barrel. The cells themselves which end there are dug in the substance of the mastoid process, being very irregular and full of windings and turnings.

The opening of the Eustachian tube is at the anterior and a little toward the upper part of the edge of the barrel. This tube runs from the tympanum, towards the posterior openings of the nasal fossae, and arch of the palate. The bony portion thereof is dug in the apophysis petrosa, along the duct of the carotid apophysis; and when it leaves that, it is lengthened out by the spinal apophysis of the os sphenoides.

The bony half-canal, of which the cavity resembling the mouth of a spoon is the extremity, lies immediately above the Eustachian tube, towards the upper side of the apophysis petrosa, or rather in the very substance of that upper side.

The fenestra ovalis is a hole of communication between the tympanum and labyrinth. It lies immediately above the tuberosity, the upper side of it being a little rounded, the lower a little flatted; and one extremity being turned forward, the other backward.

The fenestra rotunda is something less than the ovalis, and situated in the lower, and a little towards the posterior part of the large tuberosity; the opening of it, which is the orifice of a particular duct in the labyrinth, lying obliquely backward and outward.

The hole in the apex of the pyramid is the orifice of a cavity, which may be named the *sinus of this pyramid*.

The tympanum contains several little bones called the *bones of the ear*. They are generally four in number, denominated from something to which they are thought to bear a resemblance, *viz.* *incus*, *malleus*, *stapes*, and *os orbiculare* or *lenticulare*.

The *incus*, or anvil, resembles, in some measure, one of the anterior grinders with its roots at a great distance from each other; at least it comes nearer to this than to the shape of the anvil. It may be divided into a body and branches. The body is a large substance, the branches

branches or legs are two, one long and one short. The body is turned forward, the short leg backward, and the long leg downward.

The body of the incus is broader than it is thick. It has two eminences, and two cavities between them, much in the same manner as we see in the crown of the first grinders.

The short leg is thick at its origin, and from thence decreasing gradually, it ends in a point. It is situated horizontally, its point being turned backward, and joined to the edge of the malleoid opening of the tympanum.

The long leg, viewed through the external auditory passage, appears to be situated vertically; but if we look upon it either on the fore or backside, we see it is inclined, the extremity of it being turned much more inward, than the root or origin. The point of the extremity is a little flattened, and bent inward like a hook, and sometimes a little hollowed like a kind of ear-picker.

The malleus or hammer is a long bone, with a large head, a small neck, an handle, and two apophyses, one in the neck, the other in the handle.

The top of the head is considerably rounded, and from thence it contracts all the way to the neck. Both head and neck are in an inclined situation, and the eminences and cavities in it answer to those in the body of the incus.

The handle is looked upon by some as one of the apophyses of the malleus; and in that case, it is the greatest of the three. It forms an angle with the neck and head, near which it is something broad and flat, and decreases gradually toward its extremity.

The apophysis of the handle, termed by others the small or short apophysis of the malleus, terminates the angle already mentioned, being extended towards the neck, and lying in a straight line with that side or border of the handle which is next it.

The apophysis of the neck, called also *apophysis gracilis*, is in a natural state very long, but so slender withal, that it is very easily broken, especially when dry; it arises from the neck, and sometimes appears much longer than it really is, by the addition of a small dried tendon sticking to it.

The stapes is a small bone, very well denominated from the resemblance it bears to a stirrup. It is divided into the head, legs, and basis.

The head is placed upon a short flattened neck, the top of it being sometimes flat, sometimes a little hollow.

The two legs taken together, form an arch, like that of a stirrup, in the concave side of which is a groove, which runs through their whole length. One leg is longer, more bent, and a little broader than the other.

The basis resembles that of a stirrup, both in its oval shape, and union with the legs, except that it is not perforated as the stirrups now are, but solid, like those of the ancients. Round its circumference, next the legs, is a little border, which makes that side of the basis appear a little hollow. The other side is pretty smooth, and one half of the circumference is something more curve than the other.

The orbicular or lenticular bone is the smallest bone in the body. It lies between the head of the stapes and

tremity of the long leg of the incus, being articulated with each of these. In dry bones it is found very closely connected, sometimes to the stapes, sometimes to the incus, and might in that state be easily mistaken for an epiphysis of either of these bones.

The labyrinth is divided into three parts, the anterior, middle, and posterior. The middle portion is termed *vestibulum*; the anterior, *cochlea*; and the posterior, the *labyrinth* in particular, which comprehends the three femicircular canals.

The vestibulum is an irregularly round cavity, less than the tympanum, and situated more inward and a little more forward. These two cavities are, in a manner, set back to back, with a common partition-wall between them, perforated near the middle by the fenestra ovalis, by which the cavities communicate with one another.

The cavity of the vestibulum is likewise perforated by several other holes; on the outside, or towards the tympanum, by the fenestra rotunda; on the backside, by the five orifices of the femicircular canals; on the lower part of the fore-side, by two holes, which are the entry of the cochlea; and on the fore-side, towards the internal meatus auditorius, opposite to the fenestra ovalis, by a great many very small holes for the passage of the nerves.

The femicircular canals are three in number, one vertical and superior, one vertical and posterior, and one horizontal. The superior vertical canal is situated transversely with respect to the apophysis petrosa, the convex side or curvature of it being turned upward, and the extremities downward, one inward, the other outward. The posterior vertical canal lies parallel to the length of the apophysis, the curvature being turned backward, and the extremities forward, one upward, the other downward; and the superior extremity of this canal meets and loses itself in the internal extremity of the former. The curvature and extremities of the horizontal canal are almost on a level; the curvature lying obliquely backward, and the extremities forward, ending under those of the superior vertical canal, but a little nearer each other; and the inner being almost in the middle space, between the extremities of the posterior vertical canal.

The horizontal canal is generally the least of the three; the posterior vertical is often, and the superior vertical sometimes, the greatest; all the three canals are larger than a femicircle, forming nearly three quadrants; they are broader at the orifices than in the middle. These orifices open into the back-side of the vestibulum, being but five in number, so that in the posterior part of the vestibulum, two appear towards the inside, and three towards the outside.

The cochlea is a sort of spiral shell, with two ducts, formed in the anterior part of the apophysis petrosa, in some measure resembling the shell of a snail. The parts to be distinguished in it, are the basis, the apex, the spiral lamina, or half septum, by which its cavity is divided into two half-canals; the spindle round which the cochlea turns; and lastly, the orifices and union of the two ducts.

The basis is turned directly inward, toward the internal foramen auditorium, the apex outward, and the axis of the spindle is nearly horizontal.

The basis of the cochlea is gently hollowed, and towards the middle perforated by several small holes. The spindle is a kind of short cone, with a very large basis, which is the middle of the basis of the cochlea. Thro' its whole length runs a double spiral groove, which, through a microscope, shews a great number of pores.

The cochlea makes about two turns and an half from the basis to the apex; and the two ducts, being strictly united together through their whole course, form an entire common septum, which must not be confounded with the half septum or spiral lamina, as is often done. The first might be termed the common septum, the other the particular septum or half-septum.

Both of them are closely joined to the spindle, being thicker there than in any other place. The common septum is complete, and separates the turns entirely from each other; whereas the half-septum in the skeleton is only a spiral lamina, the breadth of which is terminated all round by a very thin border lying in the middle cavity of the cochlea. In the natural state, there is a membranous half-septum, which completes the partition between the two ducts.

The two half-canal turn jointly about the spindle, one being situated towards the basis of the cochlea, the other towards the apex: for which reason they have been termed the one internal, and the other external; the division of them into the upper and lower slight, not being agreeable to the natural state, but liable to convey a very false idea thereof.

The spiral or volute of the cochlea, begins at the lower part of the vestibulum, runs from thence forward to the top, then backward down to the bottom, afterwards upwards and forwards, and so on from the basis which is turned inward, to the apex which is turned outward.

The two half-canal communicate fully at the apex of the cochlea. Their separate openings are towards the basis, one of them being immediately into the lower part of the fore-side of the vestibulum, the other into the fenestra rotunda.

The internal auditory hole is in the backside of the apophysis petrosa, in some measure behind the vestibulum and basis of the cochlea. It is a kind of blind hole, divided into two fossulae, one large, the other small. The large one lies lowest, and serves for the portio mollis of the auditory nerve or seventh pair. The small one is uppermost, and is the opening of a small duct thro' which the portio dura of the same nerve passes.

The inferior fossula is full of little holes, which, in the natural state, are filled with nervous filaments of the portio mollis, which go to the spindle, to the semicircular canals, and to those of the cochlea. It is this fossula which forms the shallow cavity at the basis of the spindle of the cochlea.

The passage for the portio dura of the auditory nerve runs behind the tympanum, and its orifice is the stylo-mastoid hole. It begins by the small fossula, and pierces from within, outwards, the upper part of the apophysis petrosa, making there an angle or curvature. From thence it is inclined backward, behind the small pyramid of the tympanum, and runs down to the stylo-mastoid hole. It communicates likewise, by a small hole, with the sinus

of the pyramid; and lower down, by another hole, with the barrel of the ear.

The internal parts of the ear are chiefly the membrana tympani, the periotemum of the barrel, officula auditus, labyrinth and all its cavities, the membrana mastoidea interna, the muscles of the officula, and the parts which complete the formation of the Eustachian tube.

The Eustachian tube is a canal or duct which goes from the tympanum to the posterior openings of the nares, or nasal fossae, and toward the arch of the palate.

The bony portion of it lies through its whole length immediately above the fissure of the glenoid or articular cavity of the os temporis, and terminates at the meeting of the spinal apophysis of the os sphenoidale with the apophysis petrosa of the os temporis.

The other or mixed portion reaches in the same direction from this place to the internal ala of the apophysis pterygoides, or to the posterior and outer edge of the nares. It is properly divided into four parts, two superior, and two inferior.

The two upper parts or quarters are bony; and of these the innermost is formed by the side of the apophysis petrosa, the outermost by the side of the apophysis spinalis of the os sphenoides, so that the upper half of this portion of the tube is bony. Of the two inferior parts, the internal is cartilaginous, and the external membranous; so that the lower half of this portion of the tube is partly cartilaginous next the os sphenoidale, and partly membranous next the apophysis petrosa.

The Eustachian tube thus formed, is very narrow in the bony part next the ear. The other portion grows gradually wider, especially near the posterior nares, where the inner cartilaginous side terminates by a prominent edge, and the outer side joins that of the neighbouring nostril. The cavity of the tube is lined by a membrane like that of the internal nares, of which it appears to be a continuation.

The situation of the two tubes is oblique, their posterior extremities at the ears being at a greater distance than the anterior at the nares, and the convex sides of the prominent edges are turned toward each other. The openings of the tubes are oval at this place, as is likewise their whole cavity, especially that of the mixed portion.

The membrana tympani is a thin, transparent, flatfish pellicle, the edge of which is round, and strongly fixed in the orbicular groove which divides the bony meatus of the external ear from the tympanum or barrel. This membrane is very much stretched or very tense, and yet not perfectly flat: for on the side next the meatus externus it has a small hollowness, which is pointed in the middle; and on the side next the tympanum it is gently convex, and also pointed in the middle.

This membrane is situated obliquely, the upper part of its circumference being turned outward, and the lower part inward, suitably to the direction of the bony groove already mentioned. It is made up of several very fine laminae, closely united together. The external lamina is in some measure a production of the skin and cuticula of the external meatus; the internal lamina is a continuation of the periotemum of the tympanum; and when the membrane has been first macerated in water, each

each of these laminae may be subdivided into several others.

The depression in the middle of the membrana tympani is caused by the adhesion of the little bone called *malleus*, the handle of which is closely joined to the inside of the membrane from the upper part of the circumference all the way to the center to which the end of the handle is fixed. This handle seems to lie in a very fine membranous duplicature, by means of which it is tied to the membrana tympani, and which serves it for a periosteum.

The periosteum of the tympanum or barrel of the ear produces that of the small bones; it is likewise continued over the two fenestræ, and enters the eustachian tube, where it is lost in the inner membrane of that duct.

The cellulae mastoideæ are very irregular cavities in the substance of the mastoid apophysis, which communicate with each other, and have a common opening towards the inside, and a little above the posterior edge of the orbicular groove. These cells are lined by a fine membrane, which is partly a continuation of the periosteum of the tympanum, and partly seems to be of a glandular structure like a kind of the membrana pituitaria. The mastoid opening is opposite to the small opening of the Eustachian tube, but a little higher.

The ligaments of the ossicula come next in order. The incus is tied by a strong short ligament, fixed in the point of the short leg, to the edge of the mastoid opening. Between the incus and malleus we find a small, thin cartilage. The malleus is connected through the whole length of its handle to the inside of the membrana tympani.

The malleus has three muscles, one external, one anterior, and one internal; and the stapes has one muscle. The external or superior muscle of the malleus, is a thin fasciculus of fleshy fibres lying along the upper part of the bony meatus auditorius, between the periosteum and the other integuments. The outer part of it is pretty broad, and it contracts by degrees as it advances towards the upper part or break of the orbicular groove of the tympanum, into which it enters by a small tendon, above the membrana tympani, and is inserted in the neck of the malleus, near the small eminence or short apophysis of the handle.

The anterior muscle of the malleus, is fleshy, long, and thin. It runs along the outside of the Eustachian tube, to which it adheres very closely through its whole length. Its anterior extremity is fixed in that side of the tube just before the sphenoidal spine; and the posterior extremity ends in a long thin tendon, which runs in the articular or glenoid fissure of the os temporis, through a small oblique notch; in which fissure it enters the tympanum, and is inserted in the long thin apophysis of the malleus. It is partly accompanied by a nerve, which forms what is called the *choria tympani*.

The internal muscle of the malleus is very fleshy and distinct. It lies along the inside of the Eustachian tube, partly on the cartilaginous, and partly on the bony portion, being fixed by one extremity in the apophysis petrosa. Afterwards it runs along the cavity of the bony half-canal of the tympanum, within which cavity it is invested by a portion of a membranous or ligamentary va-

gina, which being fixed to the edges of the half-canal, forms an infirre tube therewith.

At the extremity of this bony half-canal, where we observe the cavity shaped like the mouth of a spoon, this muscle ends in a tendon, which is bent round the transverse bony or ligamentary ridge in the last-named cavity, as over a pulley, and is inserted in the neck of the malleus above the small apophysis, advancing likewise as far as the handle.

The muscle of the stapes is short and thick, and lies concealed within the small bony pyramid at the bottom of the tympanum. The cavity which it fills, touches very nearly the bony canal of the portio dura of the auditory nerve; and it terminates in a small tendon which goes out of the cavity through the small hole in the apex of the pyramid. As it goes through the hole it turns forward, and is inserted in the neck of the stapes on the side of the longest and most crooked leg of that bone.

The three parts of the labyrinth, that is, the vestibulum, semicircular canals, and cochlea, are lined by a fine periosteum, which is continued over all the sides of their cavities, and shuts the two fenestræ of the tympanum.

The periosteum of the two sides of the bony spiral lamina advances beyond the edge of that lamina, and forms a membranous duplicature, which extending to the opposite side compleats the spiral septum.

This septum separates the two half-canals from the basis to the apex; but there it leaves a small opening, by which the small extremities of the half-canals communicate with each other. The large extremity of the external half-canal ends by an oblique turn in the fenestra rotunda, which is shut by a continuation of the periosteum of that canal. The large extremity of the other half-canal opens into the vestibulum; and these two extremities are intirely separated by a continuation of the periosteum.

The ear is the organ of which we can most distinctly unfold the structure, and demonstrate the greatest number of parts, that is, of small machines of which it is made up. We know likewise in general, that it is the organ of hearing; but when we endeavour to discover the uses of each of these parts, that is, how each contributes to the great design of the whole, after having thoroughly examined them, we must be obliged to own, that the greatest part of what the most able philosophers have said upon this subject, is without any real foundation.

## SECT. VIII. *The MOUTH.*

THE mouth may be distinguished into external and internal, and the parts of which it consists may likewise come under the same two general heads.

The parts of the neck still undescribed are only the larynx, pharynx, glandulae thyroideae, and the musculus cutaneus, which really belong to the head; and therefore, instead of making a particular section for so small a number of parts, especially since the larynx and pharynx have so near a relation to the internal parts of the mouth, we are under a necessity of describing them, before proceeding to the mouth in particular.

## THE LARYNX.

THE larynx forms the protuberance in the upper and anterior part of the neck, called commonly *pomum Adami*.

It is chiefly made up of five cartilages, *viz.* Cartilago thyroides, which is the anterior and largest; cricoides, the inferior, and basis of the rest; two arytenoides, the posterior and smallest; and the epiglottis, which is above all the rest. These cartilages are connected together by ligaments, and they have likewise muscles, glands, membranes, &c. belonging to them.

The cartilago thyroidea is large and broad, and folded in such a manner as to have a longitudinal convexity on the fore-side, and two lateral portions, which may be termed *ala*. The upper part of its anterior middle portion is formed into an angular notch; the upper edge of each *ala* makes an arch; and, together with the middle notch, these two edges resemble the upper part of an ace of hearts.

The lower edge of each *ala* is more even, and the posterior edges of both are very smooth, being lengthened out both above and below by apophyses, which are named the *cornua* of the thyroid cartilage.

The cricoid cartilage resembles a thick, irregular ring, very broad on one side, and narrow on the other; or it may be compared to a small portion of a thick tube, cut horizontally at one end, and very obliquely at the other. It is distinguished into a basis and top, into an anterior, posterior, and two lateral sides. The basis is almost horizontal, when we stand; and to this the *apera arteria* is connected; so that the cricoides may be looked upon as the upper extremity of the trachea.

The posterior portion of the cricoides is larger than the rest, and its posterior or convex side is divided by a longitudinal eminence or prominent line into distinct surfaces, for the insertion of muscles. The top is gently sloped above this prominent line, and terminates on each side by a kind of obtuse angle, formed between it and the oblique edge of each lateral portion of this cartilage.

The whole posterior side is distinguished into two lateral portions by two prominent lines, each of which runs down almost in a straight direction from the articular surface at the top, a little below the middle of this side, where it terminates in another articular line a little concave; and near these four articular surfaces there are small tubercles. The two superior surfaces are for the articulation of the cartilages arytenoides; and the two inferior, for the articulation of the inferior cornua or appendices of the cartilago thyroides.

The cartilages arytenoides are two small, equal, similar cartilages, which, joined together, resemble the spout of an ewer, and they are situated on the top of the cricoides. In each, we may consider the basis; cornua; two sides, one posterior and concave, the other anterior and convex; and two edges, one internal, the other external, which is very oblique. The bases are broad and thick, and have each a concave articular surface, by which they are joined to the cricoides.

The cornua are bent backward, and a little toward each other.

The epiglottis is an elastic cartilage, nearly of the figure of a purlain leaf, narrow and thick at the lower part, thin and slightly rounded at the upper part, gently convex on the fore-side, and concave on the back-side. It is situated above the anterior or convex portion of the cartilago thyroides; and its lower extremity is tied by a short, pretty broad, and very strong ligament, to the middle notch in the upper edge of that cartilage. It is perforated by a great number of holes, something like those in the leaves of the hypericum, or St John's Wort, which are hid by the membranes that cover its two sides.

The cartilago thyroides is connected to the cricoides by several short strong ligaments, round the articulations of the two inferior cornua, with the lateral articular surfaces of the cricoides. The apices of the superior cornua are fixed to the posterior extremities of the great cornua of the os hyoides, by slender, round ligaments, about a quarter of an inch in length.

The thyroides is likewise connected to the os hyoides by a short, broad, strong ligament, one end of which is inserted in the superior notch of the cartilage, and the other in the lower edge of the basis of the bone. It has also two ligaments at the middle of the concave side, which belong to the arytenoides.

The cricoides is tied to the lower part of the thyroides by a strong ligament; and by the ligaments already mentioned, to the inferior cornua of that cartilage. Its basis is fixed to the first cartilaginous ring of the trachea arteria, by a ligament exactly like those by which the other rings are connected together; and the membranous or posterior portion of the trachea is likewise fixed to the posterior part of the basis of the cricoides.

The cartilages arytenoides are connected to the cricoides by ligaments, which surround their articulations with the top of that cartilage. Anteriorly the basis of each arytenoides is fixed to one end of a ligamentary cord, which by its other end is inserted about the middle of the concave side of the anterior portion of the thyroides. At their insertions in the thyroides, these two ligaments touch each other, but a small space is left between them, where they are fixed in the two arytenoides, and they seem likewise to have a small adhesion to the top of the cricoides. This is what is called the *glottis*.

Under these two ligamentary cords there are two others, which run likewise from behind forward. The interstice between the superior and inferior cords on each side form a transverse fissure, which is the opening of a small membranous bag, the bottom of which is turned outward, that is, toward the *ala* of the thyroides. These two sacculi are chiefly formed by a continuation of the internal membrane of the larynx, and the inner surface of their bottom appears sometimes to be glandulous.

On the anterior surface of the arytenoid cartilages, there is a small depression between the basis and the convex upper part. This depression is filled by a glandulous body, which not only covers the anterior surface of each arytenoides, but is likewise extended forward from the basis over the posterior extremity of the neighbouring ligamentary cord.

The epiglottis has likewise two lateral ligaments, by which it is connected to the arytenoides, all the way to their points or cornua. It has also a membranous ligament, which running along the middle of its anterior or concave side, ties it to the root or basis of the tongue. This ligament is only a duplicature of the membrane which covers the epiglottis, continued to the neighbouring parts. Lastly, there are two lateral membranous ligaments belonging to it, fixed near the glandulous bodies called *amygdalæ*.

The epiglottis is not only perforated by the regular holes already mentioned, but has likewise a great number of small irregular scissures and breaks, which are so many different lacunæ situated between its two membranes, and filled with small glands, the excretory orifices of which are chiefly on the backside of this cartilage.

The larynx gives insertion to a number of muscles, which shall now be described.

The sterno-thyroidæi are two long, flat, narrow, thin muscles, like ribbons, broader above than below, and situated along that part of the neck which lies between the thyroid cartilage and the sternum. They are covered by the sterno-hyoidæi, and they cover the thyroid glands, passing immediately before them.

Each muscle is fixed, by its lower extremity, partly in the superior portion of the inner or backside of the sternum, partly in the ligament and neighbouring portion of the clavícula, and partly in the cartilaginous portion of the first rib. Sometimes it runs a great way down on the first bone of the sternum, and crosses the muscle on the other side. From thence it runs up on the *aspera arteria*, close by its fellow, passes before the thyroid glands, over the cricoid cartilage; and is inserted, by its upper extremity, in the lower part of the lateral side of the thyroid cartilage, and partly along that whole side.

The thyro-hyoidæi, or hyo-thyroidæi are two flat, thin muscles, lying close by each other, between and above the former. Each of them is inserted, by its upper extremity, partly in the basis, and partly in the neighbouring part of the great cornua of the os hyoides; and by its lower extremity, in the lower part of the lateral side of the thyroid cartilage, immediately above the superior extremity of the sterno-thyroidæi; and both this superior extremity of the last named muscle, and the lower extremity of the thyro-hyoidæus, are, at their place of union, confounded a little with the thyro-pharyngæus inferior.

The crico-thyroidæi are two small muscles, situated obliquely at the lower part of the thyroid cartilage. They are inserted by their lower extremities in the anterior portion of the cricoid cartilage, near each other, and by their superior extremities, laterally in the lower edge of the thyroid cartilage, at a distance from each other.

The two musclicr crico-arytenoidæi posteriores are situated posteriorly at the large or back portion of the cricoïdes, filling almost the two longitudinal surfaces of that portion, and distinguished by the prominent line between these two surfaces. Each of them runs up obliquely, and is inserted, by its upper extremity, in the posterior part of the basis of the arytenoid cartilage of the same side, near the angle of that basis.

The two crico-arytenoidæi laterales are small, and situated more laterally than the former. Each muscle is fixed by one end to the side of the broad part of the cricoïdes, and by the other to the lower part of the side of the neighbouring arytenoides.

The two thyro-arytenoidæi are very broad, each muscle being situated laterally between the thyroïdes and cricoïdes. It is fixed by a broad insertion in the inside of the ala of the thyroid cartilage; and the fibres contracting from thence, run from before backward, and from below upward, towards the neighbouring arytenoid cartilage, in which they are inserted, from the glottis to the angle of the basis.

The arytenoidæi are small muscles lying on the posterior concave sides of the arytenoid cartilages, of which two are called *crucial arytenoidæi*, and one *transverse*.

The crucial muscles run each obliquely from the basis of one arytenoid cartilage, to the middle and upper part of the other, the left muscle covering the right.

The arytenoidæus transversalis is inserted more or less directly, by both extremities, in the two arytenoid cartilages.

The two thyro-epiglotticæi cross the thyro-arytenoidæi, being inserted in the inner lateral part of the thyroïdes, and laterally in the epiglottis.

The aryteno-epiglotticæi are small fleshy fasciculi, each of which is fixed by one extremity in the head of one of the arytenoid cartilages, and by the other in the nearest edge of the epiglottis.

The larynx serves particularly to admit and let out the matter of respiration; and the solidity of the pieces of which it is composed hinders not only external objects, but also any hard thing which we swallow, from disordering this passage. The glottis, being a narrow slit, modifies the air which we breathe; and as it is very easily dilated and contracted, it forms the different tones of the voice, chiefly by means of the different muscles inserted in the cartilages arytenoidæi, to which the other muscles of the larynx are assitants.

The whole larynx is likewise of use in deglutition, by means of its connection with the os hyoides, to which the digastric muscles of the lower jaw adhere; which muscles raise the larynx together with the os hyoides every time we swallow.

The facility of varying and changing the tone of the voice, depends on the flexibility of the cartilages of the larynx, and decreases in proportion as we advance in age, because these cartilages gradually harden and ossify.

The musclicr sterno-thyroidæi serve in general to pull down the thyroid cartilage, and the whole larynx along with it. The thyro-hyoidæi may, as occasion requires, either draw up the larynx toward the os hyoides, or draw that bone downward toward the cartilago thyroïdes.

It is difficult to determine the use of the crico-thyroidæi from their situation. They may either pull the cricoïdes obliquely backward, or the thyroïdes obliquely forward.

Both the lateral and posterior crico-arytenoidæi may separate the arytenoid cartilages, and thereby open or dilate the glottis.

The thyro-arytenoidæi acting together, draw both the

arytenoid cartilages forward, and consequently loosen the glottis, and render it capable of the smallest quaverings of the voice.

The arytenoidæi bring the arytenoid cartilages close together, and press them against each other; and when the cartilages are in this situation, they may at the same time be inclined either forward by the thyro-arytenoidæi, or backward by the crico-arytenoidæi posteriores. By this means the glottis, when shut, may be either relaxed or tense; and in this last case it is intirely shut, as when we hold in our breath in straining.

The general use of the epiglottis is to cover the glottis like a pent-house, and thereby hinder any thing from falling into it when we eat or drink; it serves likewise to hinder the air which we inspire from rushing directly upon the glottis, but by splitting it, as it were, obliges it to enter by the sides, or in an oblique course. The muscles of the epiglottis do not appear to be absolutely necessary for that cartilage; for in deglutition, it may be sufficiently depressed by the basis of the tongue; and it may raise itself again by its own elasticity. The thyro-epiglotticæ and aryteno-epiglotticæ may serve to shut any lateral openings that might remain when the epiglottis is depressed by the basis of the tongue; and the hyo-epiglotticæ may pull it a little forward in strong respirations, as in sighing, yawning, &c.

#### THE PHARYNX.

The pharynx is a muscular and glandular bag, the outer surface of which is closely joined to the inner surface of all that space which is at the bottom of the mouth, behind the posterior nares, uvula, and larynx, and which reaches from the great or anterior apophysis of the os occipitis all the way to the œsophagus, which is the continuation of the pharynx.

Though almost all the muscular or fleshy portions of which the pharynx is composed, concur in the formation of one continued bag or receptacle, they are nevertheless very distinguishable from each other, not only by their different insertions, from which they have been denominated, but also by the different directions of their fibres. The greatest part of them may be looked upon as digastric muscles, the middle tendons of which lie backward in one longitudinal line, which in some subjects appears plainly like a linea alba.

The cephalo-pharyngæi are inserted in the lower side of the apophysis basillaris, or great apophysis of the os occipitis, about the middle of the posterior part. From thence they separate laterally, and sometimes join the stylo-pharyngæi. The linea alba of the pharynx begins by the middle adhesion of these muscles.

The petro-pharyngæi are inserted in the lower part of the extremity of the apophysis petrosa; the spheno-pharyngæi, partly in the os sphenoides, directly above the internal ala of the apophysis pterygoides, and partly in the neighbouring cartilaginous portion of the Eustachian tube; and the petro-pharyngæi, in the edge of the same ala of the apophysis pterygoides. These three muscles on each side run obliquely backward, covering each

other by some fibres, and meet at the linea alba. Their use may be to draw the middle portion or great cavity of the pharynx upward.

The stylo-pharyngæi are inserted interiorly by one extremity in the apophysis, or epiphysis styloides. From thence each muscle runs down obliquely along the lateral part of the pharynx, covering and crossing the other muscles. It extends gradually in breadth as it descends, and forms two principal portions, one superior which is narrow, and one inferior which is broad. The narrow portion is spread among the muscular fibres above the thyroid cartilage, and the broad portion is inserted in the side of that cartilage; and thus the stylo-pharyngæus is partly a true stylo-thyroidæus. These muscles may draw the pharynx laterally upward, especially by their thyroid portions.

The perysphylo-pharyngæi are two small muscles inserted between the uvula and lower extremity of the internal ala of the apophysis pterygoides, and run obliquely backward on the sides of the pharynx. The glosso-pharyngæi are fibres which run along the lateral edges of the tongue, from which they are parted backward, and run down on the sides of the pharynx under the stylo-pharyngæi.

The hyo-pharyngæi in general are those on each side which are inserted in the os hyoides; and they may be reckoned three pairs, the basio-pharyngæi, kerato-pharyngæi minores, and kerato-pharyngæi majores; these denominations being taken from their insertions in the basis, and in the small and great cornua of the os hyoides.

The mylo-pharyngæi is a muscular portion distinct from the genio-glossus, inserted in the side of the pharynx.

The syndesmo-pharyngæi are fasciculi of muscular fibres very distinctly inserted by one end along the ligaments by which the superior cornua of the cartilago thyroïdes are connected to the extremities of the great cornua of the os hyoides. From thence they run backward and meet at the linea alba.

The thyro-pharyngæi are very broad, and each muscle is inserted along the outside of the ala of the cartilago thyroïdes, between the edge of that cartilage and the oblique line in which the thyro-hyoidæi are fixed. From thence they run up obliquely backward, and meet under the linea alba.

The crico-pharyngæi are inserted each in the lower part of the side of the cricoid cartilage. They seem to be appendices of the thyro-pharyngæi, shewing no other marks of distinction but these insertions, and a small difference in direction, because as they run backward they descend a little.

The lowest of these muscular fibres make a complete circle backward, between the two sides of the basis of the cartilago cricoides. This circle is the beginning of the œsophagus, and has been thought by some to form a distinct muscle, called *œsophageus*.

The particular uses of all these muscles are very difficult to be determined. It is certain that those of the middle and lower portions of the pharynx serve chiefly for deglutition.

## THE PALATE, UVULA, &amp;c.

The palate is that arch or cavity of the mouth, furnished anteriorly by the alveolar edge and teeth of the upper jaw, and reaching from thence to the great opening of the pharynx. This arch is partly solid and immovable, and partly soft and moveable. The solid portion is that which is bounded by the teeth, being formed by the two ossa maxillaria, and two ossa palati. The soft portion lies behind the other, and runs backward like a veil fixed to the edge of the ossa palati, being formed partly by the common membrane of the whole arch, and partly by several muscular fasciculi, &c.

The membrane that covers all this cavity is like that which lines the superior and middle portions of the pharynx. It is very thick set with small glands, the orifices of which are not so sensible as in the pharynx, and especially in the rugæ of the superior portion thereof.

This membrane, together with that of the posterior nares, forms, by an uninterrupted continuation, the anterior and posterior surface of the soft portion, or septum palati; so that the muscular fasciculi of this portion lie in the duplicate of a glandulous membrane.

The septum, which may likewise be termed *velum*, or *valvula palati*, terminates below by a loose floating edge, representing an arch situated transversely above the basis or root of the tongue. The highest portion or top of this arch sustains a small, soft, and irregularly conical glandulous body, fixed by its basis to the arch, and its apex hanging down without adhering to any thing, which is called *uvula*.

On each side of the uvula there are two muscular half arches, called *columnæ septi-palati*. They are all joined to the uvula by their upper extremities, and disposed in such a manner; as that the lower extremities of the two which lie on the same side are at a little distance from each other, and so as that one half-arch is anterior, the other posterior, an oblong triangular space being left between them, the apex of which is turned toward the basis of the uvula.

The two half arches on one side, by joining the like half arches on the other side, form the entire arch of the edge of the septum. The posterior half arches run, by their upper extremities, more directly toward the uvula than the anterior. The anterior half arches have a continuation with the sides of the basis of the tongue, and the posterior with the sides of the pharynx. At the lower part of the space left between the lateral half arches on the same side, two glands are situated, termed *amygdalæ*.

The half arches are chiefly made up of several flat fleshy portions, almost in the same manner with the body of the septum. The membrane which covers them is thinner than the other parts of it towards the palate, pharynx, and tongue. Each portion is a distinct muscle, the greatest part of which terminate by one extremity in the substance of the septum and of the half arches, and by the other extremity in parts different from these.

As anatomists used formerly to ascribe all these muscles, as far as they knew them, to the uvula, without

any regard to the septum, they termed them in general either *ptery-staphylini*, or *peri-staphylini*.

The glosso-staphylini are two small muscles, fixed each in the lower and lateral part of the basis of the tongue; from whence they run up obliquely backward along the anterior half arches of the septum palati, and terminate insensibly on each side near the uvula, some of their fibres being spread through the septum.

The pharyngo-staphylini are likewise two small muscles, each of them being fixed by one extremity to the lateral part of the musculi thyro-pharyngæi, as if they were portions detached from these muscles. From thence they run up obliquely forward along the two posterior half arches of the septum, and terminate in the septum above the uvula, where they meet together, and seem to form an entire arch by the union of their fibres.

The thyro-staphylini are two small muscles, which accompany the pharyngo-staphylini very closely, through their whole course, except that their posterior extremities are fixed in the thyroid cartilages near the other muscles. They are inserted in the septum in the same manner with the former.

The sphenio-salpingo-staphylini are each fixed by one extremity, partly to the sphenoidal side of the bony portion of the Eustachian tube, partly to the nearest soft portion of the same tube. From thence it runs toward the external ala of the apophysis pterygoidea, into which one portion of this muscle is inserted. The other portion runs to the end of the ala, and turns round to the forked extremity thereof, as over a pulley, and is afterwards inserted in the septum palati, near the uvula.

The pterygo-staphylinus superior is so named because it has a small insertion in the upper part of the apophysis pterygoidea, besides that in the sphenoidal part of the bony portion of the tube. The pterygo-staphylinus inferior on each side, is a small muscle, inserted by one extremity in the uncus pterygoideus, and by the other in the septum near the uvula.

The petro-salpingo-staphylini, or salpingo-staphylini interni, are those which are commonly called *peri-staphylini interni*. Each muscle is fixed by one extremity, partly to the inner side of the bony portion of the Eustachian tube, or that next the apophysis petrosa, partly along the cartilaginous portion of the same tube. From thence it passes a little way under the soft membranous part, and then, turning toward the septum, is fixed in the edge, and partly in the upper side thereof.

The staphylini, or epistaphylini, are two small fleshy ropes, closely united together, as if they made but one muscle. They are fixed by one extremity in the common point of the posterior edges of the ossa palati, and from thence run downward and backward along the middle of the septum, and likewise along the middle of almost the whole uvula. These muscles have been termed *azygos Morgagnii*, from the discoverer, but he considered them as one muscle. The pterygo-staphylini inferiores are of the same kind, and might be termed *staphylini*, or *epi-staphylini laterales*, and these last, *medii*.

The septum palati serves to conduct the lachrymal lymph, and that which is continually collected on the arch of the palate, into the pharynx. It serves for a

valve to hinder what we swallow, and especially what we drink, from returning by the nares. The uses of the different muscles of the septum are not as yet sufficiently known, nor the different motions of which it is capable.

### THE TONGUE.

THE tongue is divided into the basis and point; the upper and under sides; and the lateral portions or edges. The basis is the posterior and thickest part; the point, the anterior and thinnest part. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow depressed line, called *linea lingue mediana*. The edges are thinner than the other parts, and a little rounded as well as the point. The lower side reaches only from the middle of the length of the tongue to the point.

The tongue is principally composed of very soft fleshy fibres, intermixed with a particular medullary substance, and disposed in various manners. Many of these fibres are confined to the tongue without going any farther, the rest form separate muscles which go out from it in different ways, and are inserted in other parts. All the upper side of the tongue is covered by a thick membrane of a papillary texture, upon which lies another very fine membrane like a kind of epidermis, which is likewise continued over the lower side, but without papillæ.

Three sorts of papillæ may be distinguished in the upper side of the tongue, capitæ, semi-lenticulares, and villosæ. Those of the first kind are the largest, resembling little mushrooms with short stems, or buttons without a neck. They lie on the basis of the tongue in small superficial fossulæ.

They resemble small conglomerate glands seated on a very narrow basis, and each of them has sometimes a small depression in the middle of their upper or convex side. They occupy the whole surface of the basis of the tongue. They are glandular papillæ, or small salival or mucilaginous glands.

We oftentimes observe, about the middle of this part of the tongue, a particular hole of different depths, the inner surface of which is entirely glandular, and filled with small papillæ, like those of the first kind. It is called *foramen cæcum Morgagnii*, as being first described by that author. Since that time M. Vaterus has discovered a kind of salival ducts belonging to it; and M. Heister found two of these ducts very distinctly, the orifices of which were in the bottom of the foramen cæcum near each other. He observed the ducts to run backward, divaricating a little from each other, and that one of them terminated in a small oblong vesicle situated on the side of the small cornu of the os hyoides.

The papillæ of the second kind, or semi-lenticulares, are small orbicular eminences, only a little convex, their circular edge not being separate from the surface of the tongue. When we examine them in a sound tongue, with a good microscope, we find their convex sides full of small holes or pores, like the end of a thimble.

They lie chiefly in the middle and anterior portions of the tongue, and are sometimes most visible on the edges,

where they appear to be very smooth and polished, even to the naked eye.

The papillæ of the third kind, or villosæ, are the smallest and most numerous. They fill the whole surface of the upper side of the tongue, and even the interstices between the other papillæ.

The fleshy fibres of which the tongue is composed, and which go no further than the tongue, may be termed *musculi lingue interiores*; and they are the same which Spigelius named *musculi linguales*. The fibres these muscles consist of are of three general kinds, longitudinal, transverse, and vertical; and each of these situations admits of different degrees of obliquity. The longitudinal fibres point to the basis and apex of the tongue, and seem partly to be expansions of the musculi stylo-glossi, hyo-glossi, and genio-glossi; of which hereafter. The vertical fibres seem likewise to be in part produced by the same genio-glossi, and the transverse by the mylo-glossi.

The musculi exteriores are four in number, and make a part of the body of the tongue.

The mylo-glossi are small fleshy planes, situated transversely, one on each side, between the ramus of the lower jaw, and the basis of the tongue. Their insertion in the jaw is immediately above the posterior half of the mylo-hyoideus, between the prominent oblique line on the inside of the bone, and the dentes molares. From thence they run toward the basis of the tongue, and are lost there on one side of the glosso-pharyngæi.

The stylo-glossi are two long small muscles which run down from the styloid apophyses, or epiphyses, and form two portions of the lateral parts of the tongue. Each muscle is fixed in the outside of the apophysis styloidea by a long tendon. The stylo-hyoideus is the lowest, and the stylo-pharyngæus is in the middle, but more backward.

As it runs down almost opposite to the inside of the angle of the lower jaw, it sends off a pretty broad and short lateral aponeurotic ligament, which being fixed in that angle serves for a frænum, or ligamentum suspensorium, to the muscle in this part of its course. From thence it passes on to the side of the basis of the tongue, where it first of all adheres closely to the lateral portion of the hyo-glossus, and then forms, together with that muscle, a large portion of the side of the tongue.

The hyo-glossi are each inserted in three parts of the os hyoides that lie near each other, in the basis, in the root of the great cornu, and in the symphysis between these two; and on this account the hyo-glossus has been divided by some into two or three distinct muscles, called *basio-glossus*, *cerato-glossus*, and *chondro-glossus*.

It is situated on the inside, and a little lower than the stylo-glossus, with which it forms the lateral part of the tongue. The portion inserted in the basis of the os hyoides lies more anteriorly, and is larger than the other two; that which is inserted in the symphysis is the least, and that inserted in the great cornu the most posterior. This muscle is partly sustained by the mylo-hyoideus, as by a girth; and the anterior portion is distinguished from the rest by the passage of the nerves of the fifth pair, and of the arteries which accompany them.

The genio-glossi are situated close to each other on the

Some of them lie very near the skin, and the rest at a greater distance from it.

As these lymphatic glands differ more in situation than in size or figure, they are commonly enumerated and denominated from the places where they lie; *e. g.*

Glandulæ parotides lymphaticæ,  
Glandulæ maxillares lymphaticæ,  
Glandulæ jugulares, &c.

The lymphatic vessels were discovered more than an hundred years ago. But their nature and origin were not understood till Dr Alexander Monro, present Professor of Anatomy in the University of Edinburgh, published his treatise, *De Venis Lymphaticis Valvulosis*, in the year 1757. In this treatise the Doctor has proved, by many accurate experiments, That the lymphatic vessels are a system of absorbents: That they are not continuations of the arteries or veins; but that they are a distinct system of vessels, destined for absorbing a pellucid liquor called *lymph*, from the different cavities of the body, &c. and for transmitting it to the blood, by the contraction

of their coats, and the pressure of the neighbouring parts. Besides these vessels which accompany the glands, there are others of the same structure found on the several viscera, where no lymphatic glands have hitherto been discovered. We meet with them in very great numbers in the external membrane of the liver, and in the duplicature of the superior membranous ligament of this viscus.

Another sort of vessels termed *lymphatics*, are the small arteries and veins, which, in the natural state, transmit only the serous part of the blood. These vessels differ from the absorbent lymphatics in the smallness of their diameter, and in their structure and situation. All these little arteries and veins are uniform, extremely narrow; and though their sides are not thinner than those of the valvular lymphatics, yet their diameters are generally less. The other lymphatics are full of valves, and very thin, but they are not narrow in proportion. The arterial and venal lymphatics are found on the parts which are naturally white, as on the skin, the white of the eye, &c.

## EXPLANATION OF PLATE XXI.

FIGURE 1. Shews the lachrymal canals, after the common teguments and bones have been cut away.

a, The lachrymal gland. b, The two puncta lachrymalia, from which the two lachrymal canals proceed to c, the lachrymal sac. d, The large lachrymal duct. e, Its opening into the nose. f, The caruncula lachrymalis. g, The eye ball.

FIG. 2. An anterior view of the coats and humours of the eye.

a a a a, The tunica sclerotica cut in four angles, and turned back. b b b b, The tunica choroides adhering to the inside of the sclerotica, and the ciliary vessels are seen passing over—c c, The retina, which covers the vitreous humour. d d, The ciliary processes, which were continued from the choroid coat. e e, The iris. f, The pupil.

FIG. 3. Shews the optic nerves, and muscles of the eye.

FIG. 10. Shews the muscles which compose the fleshy substance of the tongue.

a a, The tip of the tongue, with some of the papillae minimae. b, The root of the tongue. c, Part of the membrane of the tongue, which covered the epiglottis. d d, Part of the musculus hyo-glossus. e, The lingualis. f, Genio-glossus. g g, Part of the stylo-glossus.

## A N C

ANATOMY is also used, in a less proper sense, for the analysing of compound bodies. See ANALYSIS.

ANATOMY, in some old statutes, is used to denote the subject to be anatomized.

ANATOMY, in a figurative sense, is sometimes used for a strict examination of an affair, discourse, or performance.

ANATOMY of plants. See AGRICULTURE, Part I.

ANATORIA, a small city of Greece, upon the river Asopa, five miles from the straits of Negropont.

ANATRON, NATRON, or NATRUM, in natural history. See NATRUM.

ANAUDIA, a term used by some writers to denote dumbness, or the want of the use of speech.

ANAXAGORIA, in Grecian history, an anniversary festival, kept, in honour of Anaxagoras, by the people of Lampfacus.

ANAXIMANDRIANS, in the history of philosophy, the followers of Anaximander; the most ancient of the philosophical atheists, who admitted of no other substance in nature but matter.

ANAZZO, a town in the province of Barri, in the kingdom of Naples.

ANBAR, a city of Asia, situated upon the Euphrates, twenty leagues from Bagdat. It is called by the natives *Hafchemiab*.

ANBURY, among farmers. See AMBURY.

ANCAMARES, a people of S. America, along the river Madeira, which afterwards falls into the river of the Amazons.

ANCARANO, a small city of the ecclesiastical state, in the marquise of Ancona.

ANCASTER, a town of Lincolnshire, near Lincoln, W. long. 30'. N. lat. 52° 50'.

## A N C

ANCENIS, a town of France, in the province of Brittany, W. long. 1° 9'. N. lat. 47° 20'.

ANCESTORS, those from whom a person is descended in a straight line.

ANCESTREL, in law, something that relates to, or has been done by one's ancestors.

ANCHIALUS, a city of Thrace, upon the Euxine sea, by the Turks called *Kiphis*, and by the Greeks *Anchie*.

ANCHILOPS, in medicine, a small tumor in the great angle of the eye, frequently degenerating into an abscess or fistula lachrymalis.

ANCHIO, in geography. See ANCHIALUS.

ANCHOR, in maritime affairs, an extremely useful instrument, serving to retain a ship in its place.

It is a very large and heavy iron instrument, with a double hook at one end, and a ring at the other, by which it is fastened to a cable. It is cast into the bottom of the sea, or rivers; when, taking its hold, it keeps ships from being drawn away by the wind, tide, or currents.

The parts of an anchor are, 1. The ring to which the cable is fastened. 2. The beam or shank, which is the longest part of the anchor. 3. The arm, which is that which runs into the ground. 4. The flouke or fluke, by some called the *palm*, the broad and peaked part, with its barbs, like the head of an arrow, which fastens into the ground. 5. The stock, a piece of wood fastened to the beam near the ring, serving to guide the fluke, so that it may fall right and fix in the ground.

There are several kinds of anchors: 1. The sheet-anchor, which is the largest, and is never used but in violent storms, to hinder the ship from being driven a-shore.

a-shore. 2. The two bows, which are used for ships to ride in a harbour. 3. The stream anchor. 4. The grapnel. See *STREAM-ANCHOR*, and *GRAPNEL*.

The shank of an anchor is to be three times the length of one of its flukes; and a ship of 500 tons hath her sheet-anchor of 2000 weight; and so proportionably for others, smaller or greater. The anchor is said to be *a-peak*, when the cable is perpendicular between the hawse and the anchor. See *HAWSE*.

An anchor is said to *come home*, when it cannot hold the ship. An anchor is *foul*, when, by the turning of the ship, the cable is hitched about the fluke. To *shoot* an anchor, is to fit boards upon the flukes, that it may hold the better in soft ground. When the anchor hangs right up and down by the ship's side, it is said to be a *cock-bell*, upon the ship's coming to an anchor.

The inhabitants of Ceylon use large stones instead of anchors; and in some other places of the Indies, the anchors are a kind of wooden machines, loaded with stones.

**ANCHOR**, in architecture, a sort of carving, something resembling an anchor. It is commonly placed as part of the enrichments of the boustins of capitals of the Tuscan, Doric, and Ionic orders; and also of the boustins of bed-mouldings of the Doric, Ionic, and Corinthian cornices; anchors and eggs being carved alternately through the whole building.

**ANCHOR**, in heraldry, are emblems of hope, and are taken for such in a spiritual, as well as a temporal sense.

**ANCHORAGE**, or **ANCHORING-GROUND**, a place where a ship may cast anchor.

The best anchoring-ground is stiff clay or hard sand; and the best place for riding at anchor is, where a ship is land-locked, and out of the tide.

**ANCHORAGE**, in law, is a duty upon ships for the use of the port or harbour where they cast anchor.

**ANCHORALIS** *proceffus*. See *CORACOIDES*.

**ANCHORED**, or **ANKERED**, is said of a cross, the four extremities of which resemble the flukes of an anchor.

The cross resembles very much the cross-moline; the whole difference between them consisting only in this, that the anchored cross is somewhat sharper at the points than the moline. See *MOLINE*.

**ANCHOVY**, in ichthyology, the English name of the *clupea encrasicolus*. See *CLUPEA*.

**ANCHUSA**, or **ALKANET**, in botany, a genus of the pentandria monogynia class. The corolla is shaped like a tunnel. There are eight species of the *anchusa*; viz. 1. The officinalis, a native of France and the warmer parts of Europe. The root of the officinalis is not now used in medicine; its principal use is for colouring oils, unguents, plasters, &c. 2. The *angustifolia*, a native of Italy and Germany. 3. The *undulata*, a native of Spain. 4. The *orientalis*, a native of the E. Indies. 5. The *virginiana*, a native of Virginia. 6. The *lanata*, a native of Algiers. 7. The *tiactoria*, a native of Montpellier. 8. The

*sempervirens*, or ever-green alkanet, a native of Britain and Spain.

**ANCHYLOBLEPHARON**, among physicians, denotes a cohesion of the eye-lids.

**ANCIENT**. See *ANTIEN*, and *ANTIQUITY*.

**ANCIENTLY**, in some old statutes, a term used to denote seniority.

**ANCLABRIS**, in Roman antiquity, the table whereon the priests eat their portion of the sacrifices.

**ANCLAM**, a town of Pomerania in Germany, situated on the river Pene, in E. long. 14°, and N. lat. 54°, about 45 miles N. W. of Stetin.

**ANCLE**, in anatomy. See *TALUS*.

**ANCOBER**, or **RIO-COBERE**, a river on the coast of Guinea in Africa.

**ANCILIA**, in antiquity. See *ANCYLE*.

**ANCON**. See *OLECRANON*.

**ANCONA**, a sea-port town of Italy, situated on the gulph of Venice, in E. long. 15°, and N. lat. 43° 20'.

It is the capital of a marquisate of the same name, subject to the pope.

**ANCONÆUS**, in anatomy, one of the muscles of the elbow. See *ANATOMY*, p. 197.

**ANCONES**, in architecture, the corners or coins of walls, cross-beams, or rafters.

**ANCONY**, in mineralogy, denotes a bloom of iron fashioned into a flat bar about three feet long, with a square rough knot at each end.

**ANCRE**, a town of Picardy in France, upon a river of the same name, between Corbic and Bapaume.

**ANCRE'E**, in heraldry, the same with anchored. See *ANCHORED*.

**ANCUAH**, a city of the province of Alovahat, in the northern parts of Egypt.

**ANCUBIUS**, among ancient physicians, a term to denote that affection of the eyes in which they seemed to contain sand.

**ANCUD**, a province of Chili in S. America, having on the west the Archipelago of the same name; the Andes on the east; the country of Oforno on the north; and the country of Magellan on the south.

**ANCYLE**, in antiquity, a kind of shield that fell, as was pretended, from heaven, in the reign of Numa Pompilius; at which time, likewise, a voice was heard, declaring that Rome should be mistress of the world as long as she should preserve this holy buckler. It was kept with great care in the temple of Mars, under the direction of twelve priests; and lest any should attempt to steal it, eleven others were made so like, as not to be distinguished from the sacred one. These ancylia were carried in procession every year round the city of Rome.

**ANCYLE**, in surgery, a distortion of the joints.

**ANCYLOGLOSSUM**, among physicians, denotes a contraction of the ligaments of the tongue, hindering speech.

**ANCYLOMELE**, a surgeon's crooked probe. See *PROBE*.

**ANCYLOSIS**, in surgery. See *ANCYLE*.

**ANCYROIDES**, among anatomists. See *CORACOIDES*.

**ANCZAKRICH**, a river of Podolia, which falls into the Black Sea, near Oczakow.

**ANDBATÆ**, in antiquity, a sort of gladiators who, mounted on horseback or in chariots, fought hood-winked, having a helmet that covered their eyes.

**ANDALUSIA**, the most south-west province of Spain, having Eüremadura and New Castile on the north; and Granada, the Straits of Gibraltar, and the Atlantic Ocean, on the south.

**New ANDALUSIA**, a province of Terra Firma, lying on the coast of the Atlantic Ocean, opposite to the Leeward islands, having the river Oroonoco on the west.

**ANDAMAN**, the name of some small islands situated on the east side of the entrance of the bay of Bengal, in E. long. 92°, and N. lat. 15°.

**ANDANAGAR**, a town of the peninsula in India, on this side the Ganges, in the kingdom of Decan.

**ANDANCE**, a town of Languedoc in France, situated near the confluence of the Rhone and the Dome.

**ANDANTI**, in music, signifies, especially in thorough-basses, that the notes are to be played distinctly.

**ANDAYE**, a town in France, upon the Spanish frontiers, within two leagues of St Jean de Luz.

**ANDELI**, a town of Normandy in France, situated upon the Seine, between Paris and Rouen.

**ANDENA**, in old writers, denotes the swath made in mowing of hay, or as much ground as a man could fridle over at once.

**ANDENES**, an island in the north sea, upon the coast of Norway. It is only inhabited by fishermen.

**ANDERENÆ fal**, a name sometimes used for the natrum of the ancients. See **NATRUM**.

**ANDERLECHT**, a fortress of the Austrian Netherlands, about two miles south of Brussels.

**ANDERNACHT**, a city of Germany, situated on the Lower Rhine, in E. long. 7°, and N. lat. 50° 25', about 20 miles south of Cologne.

**ANDERO**, a sea-port town of Spain, in the province of Biscay, about sixty miles west of Bilbao, situated in W. long. 4° 30', and N. lat. 43° 20'. Here the Spaniards build and lay up some of their men of war.

**ANDES**, a vast ridge of mountains which runs almost the whole length of S. America. They are esteemed the highest in the world, being covered with snow in the warmest climates; and from thence called the *Sierras Nevada*, or the *snowy mountains*.

**ANDEVALL**, a small country of Spain, in Andalusia, upon the frontiers of Portugal and Spanish Estremadura.

**ANDEUSE**, a city of Languedoc in France, situated in E. long. 3° 40', and N. lat. 43° 45'.

**ANDORINHA**, in ornithology, an obsolete name of the hirunda. See **HIRUNDA**.

**ANDOVER**, a large market-town in Hampshire, situated about ten miles north-west of Winchester, in W. long. 1° 30', and N. lat. 51° 20'. It sends two members to parliament.

**ANDRACHINE**, in botany, a genus of the monœcia gyanandria class. The calix of the male consists of five leaves; the corolla has five petals; and the stamens, which are also five in number, are inserted into

the stylos. The calix of the female is divided into five leaves; it has no corolla; the styli are three; and the capsule is trilocular, containing two seeds. There are only two species of the andrachne; *viz.* the telepheoides, a native of Italy; and the fruticosia, a native of China.

**ANDREJOS**, a town situated near the Boristhenes, between Muscovy and Poland.

**ANDREW**, or, *Knights of St Andrew*, an order of knights, more usually called the order of the thistle. See **THISTLE**.

*Knights of St Andrew* is also an order instituted by Peter the Great of Muscovy in 1698; the badge of which is a golden medal, on one side whereof is represented St Andrew's cross, with these words, *Cæsar Pierre marquis de tout la Russie*. This medal, being fastened to a blue ribbon, is suspended from the right shoulder. *St Andrew's cross*, one in form of the letter X. See **CROSS**.

*St Andrew's-day*, a festival of the Christian church, celebrated on the thirteenth of November, in honour of the apostle St Andrew.

**St Andrews**, in geography, a town in the county of Fife in Scotland, situated on the German Ocean, in W. long. 2° 25', and N. lat. 56° 20', about 30 miles N. E. of Edinburgh.

St Andrews was formerly an archbishop's see, but at present is chiefly remarkable on account of its university.

**St Andrews** is also the name of a town of Carinthia in Germany, situated in E. long. 15°, and N. lat. 47°, about a hundred miles south of Vienna.

**ANDRIA**, in Grecian antiquity, public entertainments first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta, at which a whole city or a tribe assisted. They were managed with the utmost frugality, and persons of all ages were admitted, the younger sort being obliged by the lawgiver to repair thither, as to schools of temperance and sobriety.

**ANDRIA**, among some naturalists, denotes an hermaphroditical woman. See **HERMAPHRODITE**.

**ANDRIA**, in geography, a town of Italy, in the kingdom of Naples, situated in E. long. 17°, and N. lat. 41° 6'. It is a bishop's see.

**ANDROAS**, or **ANDRODAMAS**, among ancient naturalists, a kind of pyrite, to which they attributed certain magical virtues.

**ANDROGYNOUS**, in zoology, an appellation given to animals which have both the male and female sex in the same individual.

**ANDROGYNOUS baths**, in antiquity, those common to both sexes. See **BATH**.

**ANDROIDES**, in mechanics, a human figure, which, by certain springs, performs several external functions of a man. See **AUTOMATON**.

**ANDROLEPSY**, in Grecian antiquity, an action allowed by the Athenians against such as protected persons guilty of murder. The relations of the deceased were empowered to seize three men in the city or house whither the malefactor had fled, till he were either

- either furrented, or satisfaction made some other way for the murder.
- ANDROLEPSY** is sometimes also used to signify reprisals. See **REPRISAL**.
- ANDROMACHUS'** *treacle*. See **THERIACA**.
- ANDROMEDA**, in astronomy, a northern constellation, consisting of 27 stars, visible to the naked eye, behind Pegasus, Capricorn, and Perseus. See **ASTRONOMY**.
- ANDROMEDA**, in botany, a genus of the decandria monogynia class. The calix is divided into five parts; the corolla is ovated and quinquefid; and the capsule has five cells or divisions. There are nine species of the andromeda, *viz.* the tetragona, hypnoides, and cerulea, natives of Lapland and the Alps; the mariana, paniculata, arborea, and calculata, natives of Virginia; the polifolia, marsh-cistus, or wild rosemary, a native of G. Britain; and the racemosa, a native of Pennsylvania.
- ANDRON**, in Grecian antiquity, denotes the apartment in houses designed for the use of men; in which sense, it stands opposed to *gynæceum*. See **GYNÆCEUM**.
- ANDRONION**, among ancient physicians, a name given to certain troches invented by Andron.
- ANDROPHAGI**. See **ANDROPOPHAGI**.
- ANDROPOGON**, in botany, a genus of the polygamia monœcia class. This genus contains 18 species, *viz.* the caricofum, contortum, divaricatum, nutans, gryllus, insulare, ravenne, alopecuroides, distachyon, schoenanthus, virginicum, bicorne, hirtum, nardus, muticum, ischoemum, fasciculatum, and polydactylon, most of them natives of the Indies.
- ANDROS**, an island in the Archipelago, near the fourth end of Negropont.
- ANDROSACE**, in botany, a genus of the pentandria monogynia class. The umbella of the androsace is inclosed in an involucreum; the corolla is ovated; and the capsule is globular, and consists of one apartment. There are six species of this genus; *viz.* the maxima, a native of Austria; the septentrionalis, a native of Lapland, Russia, and the Alps; the villosa, a native of the Pyrenean mountains; the lactea, a native of Austria; the carnea, a native of Switzerland; and the elongata, a native of Austria.
- ANDROSEMUM**, in botany, a synonyme of several species of hypericum. See **HYPERICUM**.
- ANDROMOTY**, or **ANDRANOTOMY**, the dissection of human bodies. See **ANATOMY**.
- ANDRUM**, a kind of hydrocele, to which the people of Malabar are very subject. See **HYDROCELE**, and **MEDICINE**.
- ANDRYALA**, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is villous; the calix is divided into many equal round pieces; and the pappus is simple and sessile. There are four species of the andryala, *viz.* the integrifolia, a native of France and Sicily; the ragulina, a native of the Archipelagus; the sinuata, a native of Montpellier and Sicily; and the lanata, a native of the southern parts of Europe.
- ANDUXAR**, a city of Andalusia in Spain, situated on the river Guadalquivir, about 32 miles east of Corduba, in W. long. 4°. and N. lat. 37° 50'.
- ANDUZE**. See **ANDEUSE**.
- ANEE**, in commerce, a measure for grain, used in some provinces of France. At Lyons, it signifies also a certain quantity of wine, which is the load an ass can carry at once: Which is fixed at 80 English quarts, wine measure.
- ANEGADA**, one of the Caribbee islands, situated in W. long. 62° 5'. and N. lat. 18°.
- ANELE**, or **ANIL**, in our old statutes, names used for indigo. See **INDIGO**.
- ANEMABO**. See **ANNAMABO**.
- ANEMIUS**, among chemists, an appellation given to a wind-furnace, used in making fire-furnaces for melting and distillation.
- ANEMOMACHIA**, a term used by ancient naturalists for a whirlwind or hurricane.
- ANEMOMETER**, among mechanical philosophers, an instrument contrived for measuring the strength of the wind.
- ANEMONE**, in botany, a genus of the polyandria polygynia class. It has no calix; the petals are from six to nine, and the seeds are numerous. There are 21 species of anemone, most of them natives of Europe, and only the nemorosa and pulsatilla are natives of Britain.
- ANEMOSCOPE**, a machine shewing from what point of the compass the wind blows. It denotes also an instrument invented to foretell the changes of the wind.
- ANET**, a town in the isle of France, upon the river Eure.
- ANETHUM**, in botany, a genus of the pentandria digynia class. The fruit is oval, compressed, and striated. There are only two species of anethum; *viz.* the graveolens, a native of Spain; and the feniculum, fennel, or fennicle, a native of Britain. The seeds of the graveolens are recommended as a carminative. The best preparations of them are, the distilled oil, and a tincture or extract made with rectified spirit.
- ANEURISM**, or **ANEURYSM**, in surgery, a throbbing tumor, distended with blood, and formed by a dilatation or rupture of an artery. See **SURGERY**.
- ANFA**, a city of Africa, in the kingdom of Fez, situated on the sea-coast, between Rabat and Azamar.
- ANGAMALA**, a small city of India, situated upon the river Aicotta, on the Malabar coast.
- ANGARIA**, in Roman antiquity, a kind of public service imposed on the provincials, which consisted in providing horses and carriages for the conveyance of military stores, and other public burdens. It is sometimes also used for a guard of soldiers, posted for the defence of a place. In a more general sense, it is used for any kind of oppression, or services performed through compulsion.
- ANGASMAGO**, a river of S. America. During the reign of the Incas, it bounded the kingdom of Peru on the north, as the river Maule did on the south. See **PERU**.
- ANGEIOGRAPHY**, or **ANGEOLOGY**, among anatomists,

miss the description and history of the several vessels of the human body.

**ANGEIOGRAPHY**, among antiquarians, denotes the description of the various utensils, weights, measures, &c. of the ancients.

**ANGEIOTOMY**, in surgery, a term sometimes used for the opening of a vein or artery.

**ANGEL**, a name given to those spiritual intelligent beings, who are supposed to execute the will of God, in the government of the world.

The existence of angels has been admitted in all religions. The Greeks and Latins acknowledged them under the name of *genii* or *dæmons*; and, in the alcoran, we find frequent mention of them, the Mahometans assigning them different orders and degrees, and different employments, both in heaven and earth. **ANGEL** is likewise a title given to bishops of several churches. In this sense is St Paul understood by some authors, where he says, *Women ought to be covered in the church, because of the angels*; and thus, in the Revelation, *The seven stars are the angels*, that is, bishops, of the seven churches.

**ANGEL**, in commerce, the name of an ancient gold coin in England, of which some are still to be seen in the cabinets of the curious. It had its name from the figure of an angel represented upon it. It was 23½ carats, and weighed four penny-weights. Its value differed in different reigns.

**ANGEL-FISH**, in ichthyology. See **SQUALUS**.

**ANGELIC**, or **ANGELICAL**, an epithet given to whatever belongs to, or partakes of the nature of angels. See **ANGEL**.

**ANGELIC Art**. See **ART**.

**ANGELIC Habit**. See **HABIT**.

**ANGELICA**, in botany, a genus of the pentandria digynia class. The fruit of the angelica is roundish, with three furrows on each side; the corolla is equal, and the petals turned inward at the top. There are four species of angelica, viz. the archangelica, a native of Lapland; the sylvestris, a native of Britain; the purpurea, and the lucida, both natives of Canada. All the parts of the archangelica, but particularly the roots, are aromatic, and used in several alexeterial waters.

**ANGELICA**, in Grecian antiquity, a celebrated dance, performed at their feasts, so called, because the dancers were dressed in the habit of messengers.

**ANGELICS**, in church-history, an ancient sect of heretics, supposed by some to have got this appellation from their excessive veneration of angels; and by others, from their maintaining that the world was created by angels.

**ANGELICS** is also the name of an order of knights, instituted in 1191, by Angelus Flavius Comnenus emperor of Constantinople.

**ANGELICS** is also a congregation of nuns, founded at Milan in 1534, by Louisa Torelli, countess of Guastalla. They observe the rule of St Augustine.

**ANGELITES**, in church-history, an ancient sect of heretics, whose distinguishing tenet was, That the Trinity have no distinct substance, but partake in common of the same divine essence.

**ANGELO**, or **ST ANGELO**, a sea-port town of Apulia in Naples, situated on the gulf of Venice, in 16° 25' E. long. and 41° 20' N. lat. It is also the name of two other small towns in Italy, one situated in the kingdom of Naples, and the other in the province of Urbino.

**ANGELOLATRIA**, among ecclesiastical writers, the adoration or worship of angels.

**ANGELOS**, a fine city of Mexico, situated in 103° W. long. and 19° N. lat. about 75 miles south-east of the city of Mexico.

**ANGELOT**, a gold coin struck at Paris, while subject to the English; so called from the representation of an angel supporting the arms of England and France.

**ANGELUS**. See **ANGEL**.

**ANGER**, a violent desire to be avenged for some supposed injury. See **MORALS**.

**ANGERBURG**, a city of Prussia, in the province of Barteland, upon the river Angerap.

**ANGERMANNIA**, a maritime province of Sweden, lying on the western shore of the Bothnic gulph.

**ANGERMUND**, a town of the duchy of Berg in Germany, situated on the east side of the Rhine, in 6° 20' E. long. and 51° 10' N. lat. It lies about nine miles north of Dusseldorp, and is subject to the elector Palatine.

**ANGERONALIA**, in antiquity, feasts celebrated at Rome in honour of Angerona, the goddess of silence and patience. They were instituted, according to Macrobius, in consequence of a vow, when the people were afflicted with the quinzy. They were held on the 21st of December.

**ANGERS**, a large city of France, capital of the province of Anjou, and situated on the river Loire, in 30° W. long. and 47° 30' N. lat. It is a bishop's see, and has a royal academy for the study of the law chiefly.

**ANGHIERA**, a town of the Milanese in Italy, situated on the east side of the Lago Maggiore, about 40 miles west of Milan, in 9° E. long. and 45° 40' N. lat.

**ANGINA**, in medicine, a violent inflammation of the throat, otherwise called *quinzy*. See **MEDICINE**.

**ANGIOSPERMIA**, in the Linnaean system of botany, denotes those plants of the didynamia class, which have their seeds inclosed in capsules, or seed-vessels. See **DIDYNAMIA**, and **BOTANY**.

**ANGLE**, in geometry, the inclination of two lines meeting one another in a point, and called the *legs* of the angle. See **GEOMETRY**.

**Spherical ANGLE**, that formed by the intersection of two great circles of the sphere. See **TRIGONOMETRY**.

**ANGLES of the eye**, in anatomy, the same with the corners of the eye, called by anatomists *canthi*.

**ANGLER**, a person who practices the art of angling.

**ANGLESEY**, an island on the coast of N. Wales, which sends one member to parliament.

**ANGLICANUS Sudor**, among physicians. See **SUDOR**.

**ANGLICISM**, in style, a manner of speech peculiar to the English language.

**ANGLING**, among sportsmen, the art of fishing with

a rod, to which are fitted a line, hook, and bait.—For the several methods of angling for salmon, trout, carp, tench, perch, flounder, &c. See *Salmon-fishing*, *Trout-fishing*, &c.

**ANGLO-CALVINISTS**, a name given by some writers to the members of the church of England, as agreeing with the other Calvinists in most points, except church-government.

**ANGLO-SAXON**, an appellation given to the language spoken by the English Saxons, in contradistinction from the true Saxon, as well as from the modern English.

**ANGOL**, a city of Chili in S. America, situated in 78° W. long. and 38° S. lat.

**ANGOLA**, a large maritime country on the south-west side of Africa, lying between 10° and 15° E. long. and 5° and 16° S. lat.

The Portuguese have several colonies and considerable settlements on this coast, which does not hinder the other nations of Europe from driving a traffic in slaves with the natives, who are all negroes.

**ANGOLA-feedi**. See *MOLUCCA*.

**ANGON**, in the ancient military art, a kind of javelin used by the French. They darted it at a considerable distance. The iron head of this weapon resembled a flower-de-luce. It is the opinion of some writers, that the arms of France are not flowers-de-luce, but the iron point of the angon, or javelin of the ancient French.

**ANGONEUS**, in anatomy, a name sometimes given to the muscle called *anconaeus*. See page 197.

**ANGOR**, among ancient physicians, a concentration of the natural heat, the consequence of which is a pain of the head, palpitation, and sadness.

**ANGOULESME**, a city of France, situated about 64 miles south-east of Rochelle, in 10° E. long. and 45° 40' N. lat. It is the capital of Angoumois. See the next article.

**ANGOUMOIS**, a province of France, bounded by Poitou on the north, by Limosin on the east, by Perigord on the south, and by Sainctoin on the west.

**ANGOURA**, formerly Ancyra, a large populous city of Natolia, in Asiatic Turkey, situated on the river Melus; E. long. 33°. N. lat. 41° 5'.

**ANGRA**, the principal town of the island of Terceira, one of the Azores. See *AZORES*.

**ANGROGNA**, a town of Piedmont, situated about seven miles west of Pignerol; E. long. 7°. N. lat. 44° 45'.

**ANGUIAN**, or **ENGUEN**, a small town of the Netherlands, between Brussels and Mons.

**ANGUILLA**, in zoology, a synonyme of the nereis acutis, an insect belonging to the order of vermes mollusca. See *NEREIS*. It is also the trivial name of a species of murena or eel. See *MURENA*.

**ANGUILLA**, in geography, one of the Caribbee islands, subject to G. Britain, and situated in W. long. 63°. and N. lat. 18° 15'.

**ANGUILLARA**, a town in the territory of Padua, belonging to the state of Venice.

**ANGUILLARA**, is also a town of St Peter's patrimony, about 18 miles from Rome.

**ANGUILLIFORM**, an appellation given by zoologists, not only to the different species of eels, but to other animals resembling them in shape.

**ANGUINA**, in botany, a synonyme of the trichosanthus. See *TRICHOSANTHUS*.

**ANGUINEAL**, denotes something belonging to, or resembling a snake, anguis.

**ANGUINUM ovum**, among ancient naturalists, a fabulous kind of egg, said to be produced by the saliva of a cluster of serpents, and possessed of certain magical virtues.

**ANGUIS**, or **SNAKE**, in zoology, a genus belonging to the order of amphibia serpentes.—The characters of the anguis are these: They are squamous or scally in the belly and under the tail. There are 16 species of the anguis; viz. 1. The quadrupes: The body of this species is cylindrical, with 14 or 15 longitudinal ash-coloured streaks; the teeth are extremely small; it has no ears; the feet are at a great distance from each other, very short, with five toes and small nails; but the toes are so minute that they can hardly be numbered: It is a native of Java. 2. The bipes, is a native of the Indies; it has 100 scuta on the belly, and 60 on the tail; the scuta are succinea for feet, ranged on both sides; it has two short feet, with two toes, near the anus. In every scale of the bipes there is a brown point. 3. The melægris, is likewise a native of the Indies, and has 165 scuta on the belly, and 32 on the tail: It has small teeth, but no ears. This species has a great resemblance to the former. See Plate XXII. fig. 1. 4. The colubrina, is an inhabitant of Egypt, has 120 scuta on the belly, and 18 on the tail; it is beautifully variegated with pale and yellowish colours. 5. The jaculus, a native of Egypt, has 186 scuta on the belly, and 23 on the tail; the scales on the belly are broad. 6. The maculata, a native of America, has 200 scuta on the belly, and 12 on the tail; it is yellow, and interspersed with ash-coloured lines on the back: The head is small in proportion to the body. See Plate XXII. fig. 2. 7. The reticulata, a native of America, has 177 scuta on the belly, and 37 on the tail; the colour of the scales is brownish, with a white margin. 8. The cerastes, with 200 scuta on the belly, and 15 on the tail, is a native of Egypt. 9. The lumbricalis, a native of America, has 230 scuta on the belly, and 7 on the tail; its colour is a yellowish white. 10. The ventralis, a native of Carolina, has 127 scuta on the belly, and 22 on the tail. 11. The platura; the head is oblong and without teeth; the body is about a foot and a half long, black above and white below; the tail is about one ninth of the length of the animal, much compressed or flattened, and variegated with black and white; the scales are roundish, small, not imbricated, but they cannot be numbered. 12. The laticauda, a native of Surinam, has 200 scuta on the belly, and 50 on the tail; the tail is compressed, acute, pale, with brownish belts. 13. The scytale, a native of the Indies, with 240 scuta on the belly, and 13 on the tail. The head is small and oval, and the eyes are little; the body is cylindrical, about a foot and a half long, covered with oval ob-

- tufe scales: The tail is thick and obtufe like the head; its colour is white, interperfed with brownifh rings; the margins of the scales are of an iron-colour; and the top of the head is blue. See Plate XXII. fig. 3. 14. The eryx, a native of Britain and likewife of America, has 126 feuta on the belly, and 136 on the tail. It is of an afh-colour above, with three black lines interperfed, and blueifh below: It is about a fpan in length, and about the thicknefs of a man's finger. 15. The fragilis, a native of Europe, has 135 feuta on the belly, and 135 on the tail. 16. The ventralis, a native of Carolina, has 127 feuta on the belly, and 223 on the tail. It is of a greenifh afh-colour, and its tail is about thrice as long as its body. According to Linnæus, none of this genus are poifonous.
- ANGULAR**, in a general fenfe, denotes something relating to, or that hath angles. See **ANGLES**.
- ANGULARIS feapulae**, the name by which fome anatomifts call the levator feapulae. See **ANATOMY**, page 194.
- ANGURIA**, in botany, a genus of the monœcia diandria clafs. There are only three fpecies of the anguria, *viz.* the trilobata, pedata, and trifoliata, all natives of America.
- ANGUS**, a fhire or county of Scotland, bounded on the north by the fhire of Merns, on the eaft by the German ocean, on the fouth by the frith of Tay, which divides it from the fhire of Fife, and on the weft by the fhire of Perth.
- This county, which for the moft part is exceeding fertile, is otherwife called Forfarfhire, from its capital Forfar.
- ANGUSTICLAVIA**, in Roman antiquity, a tunica embroidered with little purple fluds. It was worn by the Roman knights, as the laticlavias was by the fenators.
- ANHALT**, a province of the circle of Upper Saxony, in Germany, lying fouthward of the duchy of Magdeburg.
- ANHELATIO**, or **ANHELITUS**, among phyficians, a fhortnefs of breath.
- ANHINGA**, in ornithology, the trivial name of a fpecies of plotus. See **LOTUS**.
- ANHYDROS**, in botany, an obfolete name of the folanum. See **SOLANUM**.
- ANI**, in ornithology, the trivial name of a fpecies of crotophaga. See **CROTOPHAGA**.
- ANIAN**, a large maritime country on the eaftern coaft of Africa, lying between the equator, and 12° N. lat. and between 40° and 50° E. long.
- ANIAN** is alfo the name of a ftrait, fuppofed to lie between the north-eaft of Afa and north-weft of America.
- ANJENGO**, a fmall town and factory on the Malabar coaft, belonging to our Eaft-India company.
- ANIENS**, or **ANIENTE**, a law-term, fignifying to be void, or of no force.
- ANIL**, in botany, a fynonyme of a fpecies of indigofera. See **INDIGOPERA**.
- AMIMA**, among divines and naturalifts, denotes the foul, or principle of life, in animals.
- AKIMA**, among chemifts, denotes the volatile or fpiritous parts of bodies.
- ANIMA hepatis**, is a name by which fome call fal martis, or falt of iron, on account of its fuppofed efficacy in difeafes of the liver.
- ANIMA faturni**, a white powder obtained by pouring diftilled vinegar on litharge, of confiderable ufe in enamelling. See **ENAMEL**.
- ANIMA**, or **ANIMATO**, in mufic, the fame with allegro. See **ALLEGRO**.
- ANIMACHA**, a river of India, in the kingdom of Malabar. It rifes in the kingdom of Calicut, and falls into the ocean fix leagues from Cranganor. It is alfo the name of a town upon the river.
- ANIMADVERSION**, in matters of literature, is ufed to fignify, fometimes correction, fometimes remarks upon a book, &c. and fometimes a ferious confideration upon any point.
- ANIMAL**, in natural hiftory, an organized body endowed with fenfation: Thus, minerals are faid to grow or increafe; plants to grow and live; but animals alone to have fenfation. See **NATURAL HISTORY**.
- ANIMALS**, in heraldry, are much ufed, both as bearings and fupporters. See **HERALDRY**.
- ANIMAL**, ufed adjectively, denotes any thing belonging to, or partaking of the nature of animals. Thus, animal actions, thofe that are peculiar to animals; fuch are fenfation and mufcular motion.
- ANIMAL fpirits**. See **NERVOUS fluid**.
- ANIMAL fystem** denotes the whole clafs of beings endowed with animal life, otherwife called *animal kingdom*.
- ANIMALCULE**, an animal fo minute in its fize, as not to be the immediate object of our fenfes. See **MICROSCOPE**.
- ANIMATED**, or **ANIMATE**, in a general fenfe, denotes something endowed with animal life. It alfo imports a thing to be impregnated with vermin or animalcules.
- ANIME**, in heraldry, a term ufed when the eyes of any rapacious creature are born of a different tincture from the creature itfelf.
- ANIMETTA**, among ecclefiaftical writers, denotes the cloth wherewith the cup of the eucharift is covered.
- ANIMI diliquium**, fainting or fwooning.
- ANINGA**, in commerce, a root which grows in the Antilles iflands, and is pretty much like the China plant. It is ufed by fugar-bakers, for refining the fugar; and is more effectual, and lefs dangerous, than the fublimated of mercury and arfenic.
- ANJOU**, a country, or rather earldom of France, bounded by the province of Maine on the north, by Tourain on the eaft, by Poitou on the fouth, and by Britany on the weft.
- ANISCALPTOR**, in anatomy, a name by which fome call the latiffimus dorf. See page 195.
- ANITERSOR**, in anatomy, another name by which fome call the latiffimus dorf.

ANKER, a liquid measure at Amsterdam. It contains about 32 gallons English measure.

ANN, or ANNAT, in Scots law, is half a year's stipend, which the law gives to the executors of ministers of the church of Scotland, over and above what was due to the minister himself, for his incumbency. See SCOTS LAW, title, *Ecclesiastical persons*.

ANNA, in Roman antiquity, an appellation given to the moon. See the article MOON.

ANNA, in geography, a city of Arabia Petrea, situated on the western shore of the river Euphrates, in  $41^{\circ} 35'$  of E. long. and  $33^{\circ} 30'$  N. lat.

ANNAACIOUS, a people of Brasil, in America, whose country borders on the government of Porto Seguro.

ANNABERG, a small town of Germany, in the province of Misnia, situated near the river Schop, about 11 German miles from Leipzig.

ANNAGH, the name of two towns in Ireland, one in the province of Ulster, and the other in the county of Downe.

ANNALE, in the church of Rome, a term applied to the masses celebrated for the dead during a whole year.

ANNALS, in matters of literature, a species of history, which relates events in the chronological order wherein they happened. They differ from perfect history in this, that annals are a bare relation of what happened every year, as a journal is of what passes every day; whereas history relates, not only the transactions themselves, but also the causes, motives, and springs of actions.

ANNALES, in law. See YEARLINGS.

ANNAMABOE, an English factory on the gold coast, in Guinea, in Africa.

ANNAN, the capital of the shire of Annandale, in Scotland, situated upon a river of the same name, in  $3^{\circ}$  W. long. and  $54^{\circ} 40'$  N. lat.

ANNAPOLIS, the capital of Maryland, a British colony in N. America, in  $78^{\circ}$  W. long. and  $39^{\circ} 25'$  N. lat.

ANNAPOLIS, is also the name of the capital of Nova Scotia, situated in  $64^{\circ}$  W. long. and  $45^{\circ}$  N. lat.

ANNATES, among ecclesiastical writers, a year's income of a spiritual living.

These were, in ancient times, given to the pope through all Christendom, upon the decease of any bishop, abbot, or parish-clerk, and were paid by his successor. At the reformation they were taken from the pope, and vested in the king; and finally, queen Ann restored them to the church, by appropriating them to the augmentation of poor livings.

ANNEALING, or NEALING, the burning or baking glass, earthen ware, &c. in an oven or furnace. See NEALING.

ANNE, or ST ANNE'S-day, a festival of the Christian church, celebrated by the Latins on the twenty-sixth of July, but by the Greeks on the ninth of December. It is kept in honour of Anne, or Anna, mother of the Virgin Mary.

ANNECY, a town of the duchy of Savoy, situated upon a lake of the same name, subject to the king of Sardinia, in  $6^{\circ} 10'$  E. long. and  $46^{\circ}$  N. lat.

ANNEXATION, in law, a term used to imply the uniting of lands or rents to the crown.

ANNI *nubiles*, in law, denotes the marriageable age of a woman, *viz.* after she has arrived at twelve.

ANNIETED, in law, signifies annulled or made void.

ANNIHILATION, the act of reducing any created being into nothing.

ANNIVERSARY, the annual return of any remarkable day. Anniversary days, in old times more particularly, denoted those days in which an office was performed for the souls of the deceased, or the martyrdom of the faints was celebrated in the church.

ANNOBON, an island of Africa, on the coast of Guinea, in  $7^{\circ}$  E. long. and  $1^{\circ} 50'$  S. lat.

ANNO *Domini*, i. e. the year of our Lord, the computation of time from our Saviour's incarnation.

ANNOISANCE, in law, the same with nuisance. See NUSANCE.

ANNOMINATION, in rhetoric, the same with what is otherwise called *paronomasia*. See PARONOMASIA.

ANNONA, in Roman antiquity, denotes provision for a year of all sorts, as of flesh, wine, &c. but especially of corn. Annona is likewise the allowance of oil, salt, bread, flesh, corn, wine, hay, and straw, which was annually provided by the contractors for the maintenance of an army.

ANNONÆ *praefectus*, in antiquity, an extraordinary magistrate, whose business it was to prevent a scarcity of provision, and to regulate the weight and fineness of bread.

ANNONAY, a town of France in the upper Vivares, situated on the river Deume, in  $5^{\circ} 22'$  E. long. and  $45^{\circ} 15'$  N. lat.

ANNOT, a small city in the mountains of Provence in France, in  $7^{\circ}$  E. long. and  $44^{\circ} 4'$  N. lat.

ANNOTATION, in matters of literature, a brief commentary, or remark upon a book or writing, in order to clear up some passage, or draw some conclusion from it.

ANNUA *pensio*, in law, an old writ for granting an annual pension to one of the king's chaplains.

ANNUAL, in a general sense, an appellation given to whatever returns every year, or is always performed within that space of time: Thus we say, The annual motion of the earth, annual plants, &c.

ANNUALRENT, in Scots law, a yearly profit due by a debtor in a sum of money to a creditor for the use of it. See SCOTS LAW, title, *Obligations arising from consent*.

*Right of ANNUALRENT*, in Scots law, the original method of burdening lands with an yearly payment for the loan of money, before the taking of interest for money was allowed by statute. See SCOTS LAW, title, *Heretable and moveable rights*.

ANNUETTES *musculi*, in anatomy, the same with *recti interni minores*. See ANATOMY, Part II.

# A N N U I T I E S.

**A**n Annuity is a sum of money, payable yearly, half-yearly, or quarterly, to continue a certain number of years, for ever, or for life.

An annuity is said to be in arrear, when it continues unpaid after it falls due. And an annuity is said to be in reversion, when the purchaser, upon paying the price, does not immediately enter upon possession; the annuity not commencing till some time after.

Interest on annuities may be computed either in the way of simple or compound interest. But compound interest, being found most equitable, both for buyer and seller, the computation by simple interest is universally disused.

## I. Annuities for a certain Time.

**PROBLEM 1.** Annuity, rate, and time, given, to find the amount, or sum of yearly payments, and interest.

**RULE.** Make 1 the first term of a geometrical series, and the amount of 1 l. for a year the common ratio; continue this series to as many terms as there are years in the question; and the sum of this series is the amount of 1 l. annuity for the given years; which, multiplied by the given annuity, will produce the amount sought.

**EXAMPLE.** An annuity of 40 l. payable yearly, is forborn and unpaid till the end of 5 years: What will then be due, reckoning compound interest at 5 per cent. on all the payments then in arrear?

1      2      3      4      5  
1 : 1.05 : 1.1025 : 1.157625 : 1.21550625; whose sum is 5.52563125 l.; and  $5.52563125 \times 40 = 221.02525 = 221$  l. 0 s. 6 d. the amount sought.

The amount may also be found thus: Multiply the given annuity by the amount of 1 l. for a year; to the product add the given annuity, and the sum is the amount in 2 years; which multiply by the amount of 1 l. for a year; to the product add the given annuity, and the sum is the amount in 3 years, &c. The former question wrought in this manner follows.

40 am. in 1 year.	126.1 am. in 3 years.
1.05	1.05
42.00	132.405
40	40
82 am. in 2 years,	172.405 am. in 4 years.
1.05	1.05
86.10	181.02525
40	40
126 1 am. in 3 years.	221.02525 am. in 5 years.

If the given time be years and quarters, find the amount for the whole years, as above; then find the amount of 1 l. for the given quarters; by which multiply the amount for the whole years; and to the product add

such a part of the annuity as the given quarters are of a year.

If the given annuity be payable half-yearly, or quarterly, find the amount of 1 l. for half a year or a quarter; by which find the amount for the several half-years or quarters, in the same manner as the amount for the several years is found above.

**PROB. 2.** Annuity, rate, and time given, to find the present worth, or sum of money that will purchase the annuity.

**RULE.** Find the amount of the given annuity by the former problem; and then, by compound interest, find the present worth of this amount, as a sum due at the end of the given time.

**EXAMP.** What is the present worth of an annuity of 40 l. to continue 5 years, discounting at 5 per cent. compound interest?

By the former problem, the amount of the given annuity for 5 years, at 5 per cent. is 221.02525; and by compound interest, the amount of 1 l. for five years, at 5 l. per cent. is 1.2762815625

And,  $1.2762815625 \times 221.02525000 = 173$  l. 3 s. 7 d. the present worth sought.

The present worth may also be found thus: By compound interest, find the present worth of each year by itself, and the sum of these is the present worth sought. The former example done in this way follows.

1.2762815625	40.00000000	31.3410
1.21550625	40.000000	32.9080
1.157625	40.000000	34.5535
1.1025	40.0000	36.2811
1.05	40.0000	38.0952

Present worth, 173.1788

If the annuity to be purchased be in reversion, find first the present worth of the annuity, as commencing immediately, by any of the methods taught above; and then, by compound interest, find the present worth of that present worth, rebating for the time in reversion; and this last present worth is the answer.

**EXAMP.** What is the present worth of a yearly pension or rent of 75 l. to continue 4 years, but not to commence till 3 years hence, discounting at 5 per cent.?

.05 : 1 :: 75 : 1500
1.05 × 1.05 × 1.05 × 1.05 = 1.21550625
1.21550625 × 1500.00000 = 1234.05371
1500
1234.05371

265.94629, present worth of the annuity, if it was to commence immediately.

$1.05 \times 1.05 \times 1.05 = 1.157625$ . L. s. d.  
 $1.157625 \times 265.94629 = 229.7344 = 229$  l. 14 s. 8 d.

**PROB. 3.** Present worth, rate and time given, to find the annuity.

**RULE.**

**RULE.** By the preceding problem, find the present worth of 1 l. annuity for the rate and time given; and then say, As the present worth thus found to 1 l. annuity, so the present worth given to its annuity; that is, divide the given present worth by that of 1 l. annuity.

**EXAMP.** What annuity, to continue 5 years, will 173 l. 3s. 7. purchase, allowing compound interest at 5 per cent.

$$.05 : 1 :: 1 : 20 l.$$

$$1.05 \times 1.05 \times 1.05 \times 1.05 \times 1.05 = 1.2762815625$$

$$1.2762815625 \times 20.00000000 = 15.6705$$

$$\frac{20}{15.6705}$$

4.3295 present worth of 1 l. annuity.  
4.329) 173.179 (40 l. annuity. *Ans.*

II. Annuities for ever, or freehold Estates.

In freehold estates, commonly called *annuities in fee-simple*, the things chiefly to be considered are, 1. The annuity or yearly rent. 2. The price or present worth. 3. The rate of interest. The questions that usually occur on this head will fall under one or other of the following problems.

**PROB. 1.** Annuity and rate of interest given, to find the price.

As the rate of 1 l. to 1 l. so the rent to the price.

**EXAMP.** The yearly rent of a small estate is 40 l.: What is it worth in ready money, computing interest at  $\frac{3}{2}$  per cent.

*L. s. d.*

$$\text{As } .035 : 1 :: 40 : 1142.857142 = 1142 \text{ } 17 \text{ } 1\frac{1}{2}$$

**PROB. 2.** Price and rate of interest given, to find the rent or annuity.

As 1 l. to its rate, so the price to the rent.

**EXAMP.** A gentleman purchases an estate for 4000 l. and has  $\frac{4}{2}$  per cent. for his money: Required the rent.

$$\text{As } 1 : .045 :: 4000 : 180 \text{ l. rent sought.}$$

**PROB. 3.** Price and rent given, to find the rate of interest.

As the price to the rent, so 1 to the rate.

**EXAMP.** An estate of 180 l. yearly rent is bought for 4000 l.: What rate of interest has the purchaser for his money?

$$\text{As } 4000 : 180 :: 1 : .045 \text{ rate sought.}$$

**PROB. 4.** The rate of interest given, to find how many years purchase an estate is worth.

Divide 1 by the rate, and the quot is the number of years purchase the estate is worth.

**EXAMP.** A gentleman is willing to purchase an estate, provided he can have  $2\frac{1}{2}$  per cent. for his money: How many years purchase may he offer?

$$.025) 1.000 (40 \text{ years purchase. } \textit{Ans.}$$

**PROB. 5.** The number of years purchase at which an estate is bought or sold, given, to find the rate of interest.

Divide 1 by the number of years purchase, and the quot is the rate of interest.

**EXAMP.** A gentleman gives 40 years purchase for an estate: What interest has he for his money?

$$40) 1.000 (.025 \text{ rate sought.}$$

The computations hitherto are all performed by a single division or multiplication, and it will scarcely be perceived that the operations are conducted by the rules of compound interest; but when a reversion occurs, recourse must be had to tables of annuities on compound interest.

**PROB. 6.** The rate of interest, and the rent of a freehold estate in reversion, given, to find the present worth or value of the reversion.

By Prob. 1. find the price or present worth of the estate, as if possession was to commence presently; and then, by the Tables, find the present value of the given annuity, or rent, for the years prior to the commencement; subtract this value from the former value, and the remainder is the value of the reversion.

**EXAMP.** A has the possession of an estate of 130 l. per annum, to continue 20 years; B has the reversion of the same estate from that time for ever: What is the value of the estate, what the value of the 20 years possession, and what the value of the reversion, reckoning compound interest at 6 per cent.

By Prob. 1.  $.06) 130.00 (2166.8666$  value of the estate.

By Tables 1491.0896 val. of the possession.

$$675.5770 \text{ val. of the reversion.}$$

**PROB. 7.** The price or value of a reversion, the time prior to the commencement, and rate of interest, given, to find the annuity or rent.

By the Tables, find the amount of the price of the reversion for the years prior to the commencement; and then, by Prob. 2. find the annuity which that amount will purchase.

**EXAMP.** The reversion of a freehold estate, to commence 20 years hence, is bought for 675.577 l. compound interest being allowed at 6 per cent.: Required the annuity or rent.

$$\text{By the Tables the amount of } 675.577 \text{ l. } \left. \begin{array}{l} \text{for 20 years, at 6 per cent. is} \\ \end{array} \right\} 2166.8$$

By Prob. 2.  $2166.8 \times .06 = 130.0$  rent sought.

III. Life Annuities.

THE value of annuities for life is determined from observations made on the bills of mortality. Dr Halley, Mr Simpson, and M<sup>rs</sup>. de Moivre, are gentlemen of distinguished merit in calculations of this kind.

Dr Halley had recourse to the bills of mortality at Breslaw, the capital of Silesia, as a proper standard for the other parts of Europe, being a place pretty central, at a distance from the sea, and not much crowded with traffickers or foreigners. He pitches upon 1000 persons all born in one year, and observes how many of these were alive every year, from their birth to the extinction of the last, and consequently how many died each year, as in the first of the following tables; which is well adapted to Europe in general. But in the city of London, there is observed to be a greater disparity in the births and burials than in any other place, owing probably to the vast resort of people thither, in the way of commerce, from all parts of the known world. Mr Simpson, therefore, in order to have a table particularly suited

suit to this populous city, pitches upon 1280 persons all born in the same year, and records the number remaining alive each year, till none were in life.

Dr Halley's table on the bills of mortality at Breslaw.

Age.	Perf. liv.	A.	Perf. liv.	A.	Perf. liv.	A.	Perf. liv.

23	441	47	228	71	64	95	0

It may not be improper in this place to observe, that however perfect tables of this sort may be in themselves, and however well adapted to any particular climate, yet the conclusions deduced from them must always be uncertain, being nothing more than probabilities, or conjectures drawn from the usual period of human life. And the practice of buying and selling annuities on lives, by rules founded on such principles, may be justly considered as a sort of lottery or chance-work, in which the parties concerned must often be deceived. But as estimates and computations of this kind are now become fashionable, we shall here give some brief account of such as appear most material.

From the above tables the probability of the continuance or extinction of human life is estimated as follows.

1. The probability that a person of a given age shall live a certain number of years, is measured by the proportion which the number of persons living at the proposed age has to the difference between the said number and the number of persons living at the given age.

Thus, if it be demanded, what chance a person of 40 years has to live seven years longer? from 445, the number of persons living at 40 years of age in Dr Halley's table, subtract 377, the number of persons living at 47 years of age, and the remainder 68, is the number of persons that died during these 7 years; and the probability or chance that the person in the question shall live these 7 years is as 377 to 68, or nearly as 5½ to 1. But, by Mr Simpson's table, the chance is something less than that of 4 to 1.

2. If the year to which a person of a given age has an equal chance of arriving before he dies, be required, it may be found thus: Find half the number of persons living at the given age in the tables, and in the column of age you have the year required.

Thus, if the question be put with respect to a person of 30 years of age, the number of that age in Dr Halley's table is 521, the half whereof is 265, which is found in the table between 57 and 58 years; so that a person of 30 years has an equal chance of living between 27 and 28 years longer.

3. By the tables, the premium of insurance upon lives may in some measure be regulated.

Thus, The chance that a person of 25 years has to live another year, is, by Dr Halley's table, as 80 to 1; but the chance that a person of 50 years has to live a year longer is only 30 to 1. And, consequently, the premium for insuring the former ought to be to the premium for insuring the latter for one year, as 30 to 80, or as 3 to 8.

PROB. I. To find the value of an annuity of 1 l. for the life of a single person of any given age.

Mons. de Moivre, by observing the decrease of the probabilities of life, as exhibited in the table, composed an algebraic theorem or canon, for computing the value of an annuity for life; which canon I shall here lay down by way of

RULE. Find the complement of life; and, by the tables, find the value of 1 l. annuity for the years denoted by the said complement; multiply this value by the amount

amount of 1 l. for a year, and divide the product by the complement of life; then subtract the quot from 1; divide the remainder by the interest of 1 l. for a year; and this last quot will be the value of the annuity sought, or, in other words, the number of years purchase the annuity is worth.

EXAMP. What is the value of an annuity of 1 l. for an age of 50 years, interest at 5 per cent.

$$\begin{array}{r} 86 \\ \text{50 age given.} \\ \hline 36 \text{ complement of life.} \end{array}$$

By the Tables, the value is, 16.5468

$$\begin{array}{r} \text{Amount of 1 l. for a year,} \quad 1.05 \\ \hline 827340 \\ 165468 \end{array}$$

Complement of life, 36)17.374140(.482615

From unity, viz. 1.000000

Subtract .482615

Interest of 1 l. .05).517385(10.3477, value sought.

By the preceding problem is constructed the following table.

The value of 1 l. annuity for a single life.

Age.	3 per c.	3½ per c.	4 per c.	4½ per c.	5 per c.	6 per c.
9=10	10.87	18.27	16.88	15.67	14.60	12.80
3=11	19.74	18.16	16.79	15.59	14.53	12.75
7=12	19.60	18.05	16.64	15.51	14.47	12.70
13	19.47	17.94	16.60	15.43	14.41	12.65
6=14	19.33	17.82	16.50	15.35	14.34	12.60
15	19.19	17.71	16.41	15.27	14.27	12.55
16	19.05	17.59	16.31	15.19	14.20	12.50
5=17	18.90	17.46	16.21	15.10	14.12	12.45
18	18.76	17.33	16.10	15.01	14.05	12.40

80	2.34	2.31	2.28	2.26	2.23	2.15

The above table shows the value of an annuity of one pound for a single life, at all the current rates of interest; and is esteemed the best table of this kind extant, and preferable to any other of a different construction. But yet those who sell annuities have generally one and a half or two years more value, than specified in the table, from purchasers whose age is 20 years or upwards.

Annuities of this sort are commonly bought or sold at so many years purchase; and the value assigned in the table may be so reckoned. Thus the value of an annuity

of one pound for an age of 50 years, at 3 per cent. interest, is 12.51; that is, 12 l. 10 s. or twelve and a half years purchase. The marginal figures on the left of the column of age serve to shorten the table, and signify, that the value of an annuity for the age denoted by them, is the same with the value of an annuity for the age denoted by the numbers before which they stand. Thus the value of an annuity for the age of 9 and 10 years is the same; and the value of an annuity for the age of 6 and 14, for the age of 3 and 24, &c. is the same. The further use of the table will appear in the questions and problems following.

QUEST. 1. A person of 50 years would purchase an annuity for life of 200 l.: What ready money ought he to pay, reckoning interest at  $4\frac{1}{2}$  per cent.?

L.

By the table the value of 1 l. is 10.8  
Multiply by 200

Value to be paid in ready money 2164.00 *Ans.*

QUEST. 2. A young merchant marries a widow lady of 40 years of age, with a jointure of 300 l. a-year, and wants to dispose of the jointure for ready money: What sum ought he to receive, reckoning interest at  $3\frac{1}{2}$  per cent.?

L.

By the table the value of 1 l. is 12.98  
300

Value to be received in ready money 4194.00 *Ans.*

PROB. 2. To find the value of an annuity for the joint continuance of two lives, one life failing, the annuity to cease.

Here there are two cases, according as the ages of the two persons are equal or unequal.

1. If the two persons be of the same age, work by the following

RULE. Take the value of any one of the lives from the table, multiply this value by the interest of 1 l. for a year, subtract the product from 2, divide the foregoing value by the remainder, and the quot will be the value of 1 l. annuity, or the number of years purchase sought.

EXAMP. What is the value of 100 l. annuity for the joint lives of two persons, of the age of 30 years each, reckoning interest at 4 per cent.?

By the table, one life of 30 years is 14.68  
Multiply by .04  
Subtract the product 5872  
From 2.0000  
Remains 1.4128

And  $1.4128 \times 100 = 141.28$  value of 1 l. annuity.

And  $10.39 \times 100 = 1039$  the value sought.

2. If the two persons are of different ages, work as directed in the following

RULE. Take the values of the two lives from the table, multiply them into one another, calling the result the first product; then multiply the said first product by the interest of 1 l. for a year, calling the result the second product; add the values of the two lives, and from their sum subtract the second product; divide the first

product by the remainder, and the quot will be the value of 1 l. annuity, or the number of years purchase sought.

EXAMP. What is the value of 70 l. annuity for the joint lives of two persons, whereof one is 40 and the other 50 years of age, reckoning interest at 5 per cent.?

By the table the value of 40 years is, 11.83  
And the value of 50 years is, 10.35

First product, 122.4405  
Multiply by .05

Second product, 6.122025

Sum of the two lives, 22.180000  
Second product deduct, 6.122025

Remainder, 16.057975  
And  $16.057975 \times 122.4405 = 1966.76$  value of 1 l. annuity.

70

533.40 value sought.

PROB. 3. To find the value of an annuity upon the longest of two lives; that is, to continue so long as either of the persons is in life.

RULE. From the sum of the values of the single lives, subtract the value of the joint lives, and the remainder will be the value sought.

EXAMP. What is the value of an annuity of 1 l. upon the longest of two lives, the one person being 30, and the other 40 years of age, interest at 4 per cent.?

By the table, 30 years is, 14.68  
40 years is, 13.20

Value of their joint lives, by Prob. 2. } 27.88  
Case 2. is, } 9.62

Value sought, 18.26

If the annuity be any other than 1 l. multiply the answer found as above by the given annuity.

If the two persons be of equal age, find the value of their joint lives by Case 1. of Prob. 2.

PROB. 4. To find the value of the next presentation to a living.

RULE. From the value of the successor's life, subtract the joint value of his and the incumbent's life, and the remainder will be the value of 1 l. annuity; which multiplied by the yearly income, will give the sum to be paid for the next presentation.

EXAMP. A enjoys a living of 100 l. per annum, and B would purchase the said living for his life after A's death: The question is, What he ought to pay for it, reckoning interest at 5 per cent. A being 60, and B 25 years of age?

By the table, B's life is, 13.46  
Joint value of both lives, by Prob. 2. is, 6.97

The value of 1 l. annuity, 6.49  
Multiply by 100

Value of next presentation, 649.00  
The

The value of a direct presentation is the same as that of any other annuity for life, and is found for 1 l. by the table: which being multiplied by the yearly income, gives the value fought.

PROB. 5. To find the value of a reversion for ever, after two successive lives; or to find the value of a living after the death of the present incumbent and his successor.

RULE. By Prob. 3. find the value of the longest of the two lives, and subtract that value from the value of the perpetuity, and the remainder will be the value fought.

EXAMP. A, aged 50, enjoys an estate or living of 100 l. per annum; B, aged 30, is intitled to his lifetime of the same estate after A's death; and it is proposed to sell the estate just now with the burden of A and B's lives on it: What is the reversion worth, reckoning interest at 4 per cent.?

	L.
By the table, A's life of 50 is,	11.34
B's life of 30 is,	14.68
	Sum, 26.02
Value of their joint lives, found by	8.60
Prob. 2. Case 2. is,	17.42 sub.
Value of the longest life,	25.00
From the value of the perpetuity,	25.00
Remains the value of 1 l. reversion,	7.58
Multiply by	100
	758.00

Value of the reversion, 758.00  
 PROB. 6. To find the value of the joint continuance of three lives, one life failing, the annuity to cease.

RULE. Find the single values of the three lives from the table; multiply these single values continually, calling the result the product of the three lives; multiply that product by the interest of 1 l. and that product again by 2, calling the result the double product; then, from the sum of the several products of the lives, taken two and two, subtract the double product; divide the product of the three lives by the remainder, and the quot will be the value of the three joint lives.

EXAMP. A is 18 years of age, B 34, and C 56: What is the value of their joint lives, reckoning interest at 4 per cent.?

By the table, the value of A's life is 16.1, of B's 14.12, and of C's 10.01.

$16.1 \times 14.12 \times 10.01 = 2275.6$ , product of the 3 lives.

	.04
	91.024
	2
	182.048, double product.
Product of A and B, 16.1 $\times$ 14.12 =	227.33
A and C, 16.1 $\times$ 10.01 =	161.16
B and C, 14.12 $\times$ 10.01 =	141.34
Sum of all, two and two,	529.83
Double product subtract	182.048
	347.782
Remainder	347.782
And $347.782 \div 2275.600$ (6.54 value fought).	

PROB. 7. To find the value of an annuity upon the longest of three lives.

RULE. From the sum of the values of the three single lives taken from the table, subtract the sum of all the joint lives, taken two and two, as found by Prob. 2. and to the remainder add the value of the three joint lives, as found by Prob. 6. and that sum will be the value of the longest life fought.

EXAMP. A is 18 years of age, B 34, and C 56: What is the value of the longest of these three lives, interest at 4 per cent.?

By the table, the single value of A's life is,	16.1
single value of B's life is,	14.12
single value of C's life is,	10.01
	Sum of the single values, 40.23
By Prob. 2. the joint value of A and B is,	10.76
joint value of A and C is,	8.19
joint value of B and C is,	7.65
	Sum of the joint lives, 26.60

Remainder,	13.63
By Prob. 6. the value of the 3 joint lives is,	6.54
Value of the longest of the 3 lives,	20.17

Other problems might be added, but these adduced are sufficient for most purposes. The reader probably may wish that the reason of the rules, which it must be owned, are intricate, had been assigned; but this could not be done without entering deeper into the subject than was practicable in this place. See CHANCES.

A N N

ANNUITY of *tiends*, in Scots Law, a certain proportion of the tiends of erected benefices formerly payable to the crown, but now gone into disuse.

ANNULAR, in a general sense, something in the form of, or resembling a ring. It is also a peculiar denomination for the fourth finger, commonly called the *ring-finger*.

ANNULATA, in zoology, an obsolete name of a species of coluber. See COLUBER.

ANNULET, in architecture, a small square member in the Doric capital, under the quarter-round.

A N N

Annulet is also a narrow flat moulding, which is common to divers places of the columns, as in the bases, capitals, &c. It is the same member which Vitruvius calls a *fillet*; Palladio, a *lisel* or *cincture*; Scamozzi, and Mr. Brown, a *supercilium*, *list*, *linea*, *eye-brow*, *square*, and *rabbit*. See ARCHITECTURE.

ANNULET, in heraldry, a mark of distinction which the fifth brother of a family ought to bear to his coat of arms.

The hieroglyphic of the annulet is very various: Some

Some of the ancients used it to denote fervitude; the Romans represented by it liberty and nobility. It is an emblem of secrecy, if it have a seal; and of love, if the cypher, the face, or the arms of the person beloved are engraved upon it.

**ANNULLING**, a term sometimes used for cancelling, or making void, a deed, sentence, or the like.

**ANNUNCIADA**, **ANNUNTIADA**, or **ANNUNTIATA**, an order of knighthood in Savoy, first instituted by Amadeus I. in the year 1409; their collar was of 15 links, interwoven one with another, in form of a true lover's knot, and the motto, F. E. R. T. signifying, *Fortitudo ejus Rhodum tenuit*. Amadeus VIII. gave the name *Annunciada* to this order, which was formerly known by that of *the knot of love*, changing at the same time the image of St Maurice patron of Savoy, which hung at the collar, for that of the Virgin Mary, and, instead of the motto above-mentioned, substituting the words of the angel's salutation.

**ANNUNCIADA** is also the title of several religious orders, instituted at different times, and at different places, in honour of the annunciation. See the next article.

**ANNUNCIATION**, the tidings brought by the angel Gabriel to the Virgin Mary of the incarnation of Christ.

Annunciation is also a festival, kept by the church on the 25th of March, in commemoration of these tidings.

In the Romish church, on this feast, the pope performs the ceremony of marrying or cloistering a certain number of maidens, who are presented to him in the church, clothed in white serge, and muffled up from head to foot: An officer stands by, with purses containing notes of fifty crowns for those who make choice of marriage, and notes of a hundred for those who chafe the veil.

Annunciation is likewise a title given by the Jews to part of the ceremony of the passover.

**ANNUNTIATOR**, the name of an officer in the church of Constantinople. It was his business to inform the people of the festivals that were to be celebrated.

**ANOCTORON**, a term used by some ecclesiastical writers for a church. See **CHURCH**.

**ANOCISTI**, in zoology, an obsolete name of the echinus. See **ECHINUS**.

**ANODYNE**, in pharmacy, a term applied to medicines which mitigate pain.

Among anodynes may be reckoned all relaxing remedies, diluters, and medicines which by any means destroy acrimony, or expel wind, together with the compound medicines of the shops, which pass under this name; such as the anodyne balsam made of Castile soap, opium, camphire, saffron, and spirit of wine.

**ANOLYMPIADS**, in Grecian antiquity, an appellation given by the Eleans to such Olympic games as had been celebrated under the direction of other states besides themselves. See **OLYMPIAD**.

**ANOMOLISTICAL Year**, in astronomy, the time that the earth takes to pass through her orbit: it is also called the periodical year.

The space of time belonging to this year is greater

than the tropical year, on account of the precession of the equinoxes. See **PRECESSION**, and **ASTRONOMY**.  
**ANOMALOUS**, a term applied to whatever is irregular, or deviates from the rule observed by other things of the like nature.

**ANOMALY**, in astronomy, an irregularity in the motion of the planets, whereby they deviate from the aphelion or apogee.

**ANOMIA**, in zoology, a genus of shell-insects belonging to the order of vermes testacea. The ligula is emarginated, and the cilia are fixed to the superior valve; it has two linear brachii longer than the body: The valves of the shell are equal. There are 25 species of the anomia; such of them whose history is known, are all natives of the European seas.

**ANOMOEANS**, in church-history, ancient heretics, who asserted that the Son was of a nature different, and in nothing like to that of the Father.

**ANOMORHOMBOIDIA**, in natural history, a genus of crystalline spars, of no determinate form, easily fissile, but cleaving more readily in an horizontal than in a perpendicular direction, their plates being composed of irregular arrangements of short and thick rhomboidal concretions. See **SPAR**.

**ANONA**, in botany, a genus of the polyandria polygynia class. The calix is three-leaved; the petals are six; the fruit is a roundish berry containing many seeds. There are 8 species of the anona, viz. the muricata, squamosa, reticulata, palustris, glabra, triloba, Asiatica, and Africana. All of them natives of the Indies.

**ANONIS**, in botany. See **ONONIS**.

**ANONYMOS**, in botany, a synonyme of a species of spermacoe and several other plants. See **SPERMACOCE**.

**ANONYMOUS**, something that is nameless, or of which the name is concealed.

**ANONYMOUS**, in chemistry. See **ADIAPHOROUS**.

**ANOREXY**, in medicine, a loathing of meat, or want of appetite.

**ANOT**. See **ANNOT**.

**ANOTH**, one of the Scilly islands. See **SCILLY**.

**ANOUT**, a small island in the Schagerrack, or that part of the sea of Denmark which has Norway on the north, Jutland on the west, and the isle of Zealand on the south; it lies in 13° E. long. and 56° 36' N. lat.  
**ANSA**, a river in Friuli in Italy, which discharges itself into the gulf of Venice.

**ANSÆ**, in astronomy, the parts of Saturn's ring, which are to be seen on each side of that planet, when viewed through a telescope. See **ASTRONOMY**.

**ANSE**, a small town of France in the Lyonnaise, four leagues north of Lyons.

**ANSELWEIGHT**, the same with uncel-weight. See **AUNCEL**.

**ANSELM's Art**, or **ST ANSELM's Art**. See **ART**.

**ANSER**, in ornithology, the trivial name of a species of ans. See **ANS**.

**ANSERES**, the name which Linnæus gives to his third order of birds. This order is distinguished by the following marks: The beak is covered with a smooth skin

skin or membrane, widest at the apex, and full of small holes like a sieve; the toes of the feet are connected by a membrane which enables them to swim; the tibia, or shin-bone, is short and flat. They live upon water-plants, fishes, &c. This order includes 12 genera, viz. the anas, mergus, phaeton, ploutus, rhyncops, dromeda, alca, procellaria, pelecancus, larus, sterna, and columbus. See these articles, and NATURAL HISTORY.

ANSER, in astronomy, a star of the fifth or sixth magnitude, in the milky-way, between the swan and eagle.

ANSE, in astronomy, the same with ansæ. See ANSÆ.

ANSIANACTES, a people of Africa, in the western part of the isle of Madagafcar.

ANSLO, a sea-port town of Norway, and province of Aggerhuys, situated in  $10^{\circ} 12'$  E. long. and  $59^{\circ} 30'$  N. lat.

ANSPACH, or OHNSPACH, a city of Germany, and circle of Franconia, situated in  $10^{\circ} 36'$  E. long. and  $49^{\circ} 22'$  N. lat.

It is the capital of the marquise of Anspach, of which family was the late queen Caroline.

ANSPESSADES, in the French armies, a kind of inferior officer in the foot, below the corporals, but above the common centinels. There are usually four or five of them in a company.

ANSTRUTHER *Easter and Wester*, two royal burghs of Scotland, situated on the south-east coast of the county of Fife, in  $2^{\circ} 25'$  W. long. and  $56^{\circ} 20'$  N. lat.

ANT, in zoology. See FORMICA.

ANTA, in the ancient architecture, a square pilaster, placed at the corners of buildings.

ANTA, in geography, a little city with a harbour, on the coast of Guinea in Africa.

ANTACHATES, in natural history, a bituminous stone, which yields a smell like myrrh, in burning.

ANTACIDS, in pharmacy, an appellation given to all medicines proper to correct acid or four humours: Such are the absorbent and obundent classes, &c.

ANTAGONIST, denotes an adversary, especially in speaking of combats and games.

ANTAGONIST *muscles*, in anatomy, those which have opposite functions, as flexors and extensors, abductors and adductors, &c.

ANTALIS, in zoology, the trivial name of a species of the dentulium. See DENTALIUM.

ANTALGICS, in medicine, the same with anodynes. See ANODYNE.

ANTANACLASIS, in rhetoric, a figure which repeats the same word, but in a different sense; as, *dum vivimus, vivamus*.

ANTANAGOGUE, in rhetoric, a figure by which, when the accusation of the adversary is unanswerable, we load him with the same or other crimes.

ANTANISOPHYLLUM, in botany, a synonyme of a species of Boerhaavia. See BOERHAAVIA.

ANTAPHRODISIACS, in pharmacy, medicines proper to diminish the semen, and consequently extinguish or lessen all desires of venery.

ANTARCTIC, in a general sense, denotes something

opposite to the arctic or northern pole. Hence, antarctic circle is one of the lesser circles of the sphere, and distant only  $23^{\circ} 30'$  from the south pole, which is likewise called antarctic for the same reason.

ANTARES, a star of the first magnitude, otherwise called the *scorpion's heart*. See SCORPION.

ANTE', in heraldry, denotes that the pieces are let into one another in such form as is there expressed; as, for instance, by dove-tails, rounds, swallow-tails, or the like.

ANTEAMBULONES, in Roman antiquity, servants who went before persons of distinction to clear the way before them. They used this formula, *Datè licum domini meo*, i. e. Make room, or way, for my master.

ANTECEDENT, in general, something that goes before another, either in order of time or place.

ANTECEDENT, in grammar, the word to which a relative refers.

ANTECEDENT, in logic, is the first of the two propositions in an enthymema.

ANTECEDENT, in mathematics, is the first of two terms of a ratio, or that which is compared with the other.

ANTECEDENT *signi*, in medicine, such as are observed before a distemper is so formed as to be reducible to any particular class.

ANTECEDENCE, in astronomy, an apparent motion of a planet towards the west, or contrary to the order of the signs.

ANTECESSOR, one that goes before. It was an appellation given to those who excelled in any science: Justinian applied it particularly to professors of civil law; and, in the universities of France, the teachers of law take the title *antecessores* in all their theses.

ANTECURSORES, in the Roman armies, a party of horse detached before, partly to get intelligence, provisions, &c. and partly to chuse a proper place to encamp in. These were otherwise called *antecessores*, and by the Greeks *prodromi*.

ANTEDATE, among lawyers, a spurious or false date, prior to the true date of a bond, bill, or the like.

ANTEDILUVIAN, whatever existed before Noah's flood: Thus, the generations from Adam to Noah are called the *antediluvians*. See DELUGE.

ANTEGO, one of the Caribbee islands, in the Atlantic or American ocean, situated in  $62^{\circ}$  W. long. and  $17^{\circ} 30'$  N. lat. It is about 20 miles long, and as many broad.

ANTEJURAMENTUM, by our ancestors called *juramentum calunnia*, an oath which anciently both accuser and accused were to take before any trial or purgation.

The accuser was to swear that he would prosecute the criminal; and the accused to make oath, on the day he was to undergo the ordeal, that he was innocent of the crime charged against him.

ANTELOPE, in zoology. See CAPRA.

ANTEMURALE, in the ancient military art, denotes much the same with what the moderns call an *out-work*.

**ANTENCLEMA**, in rhetoric, called by the Latins *relatio*, is when the fault is imputed, upon any misfortune happening, to the person to whom it happened.

**ANTENNÆ**, in the history of insects, slender bodies with which nature has furnished the heads of these creatures, being the same with what in English are called *horns* or *feelers*.

**ANTEPAGMENTA**, in the ancient architecture, the jambs of a door. They are also ornaments, or garnishings, in carved work, of men, animals, &c. made either of wood or stone, and set on the architrave.

**ANTEPENULTIMA**, in grammar, the third syllable of a word from the end, or the last syllable but two.

**ANTEPILANI**, in the Roman armies, a name given to the hastati and principes, because they marched next before the triarii, who were called *pilani*.

**ANTEPILEPTICS**, among physicians, medicines esteemed good in the epilepsy.

**ANTEPOSITION**, in grammar, the placing a word first which should stand last.

**ANTEPREDICAMENTS**, among logicians, certain preliminary questions which illustrate the doctrine of predicaments and categories.

**ANTEQUIERA**, a town of Granada, in Spain; situated in W. long. 4° 40', and N. lat. 36° 40', about 25 miles north of Malaga.

**ANTEQUIRA-NOVA**, an episcopal city of New Spain, in America, in the province of Guaxaca.

**ANTERIDES**, in the ancient architecture, buttresses erected to support a wall. See **BUTRESS**.

**ANTERIOR**, denotes something placed before another, either with respect to time or place.

**ANTEROTES**, in natural history, a name given by the ancients to a species of amethyst.

**ANTESIGNANI**, in the Roman armies, soldiers placed before the standards, in order to defend them, according to Lippius; but Cæsar and Livy mention the *antesignani* as the first line, or first body, of heavy-armed troops. The velites, who used to skirmish before the army, were likewise called *antesignani*.

**ANTESTATURE**, in fortification, a small retrenchment made of palisadoes, or saps of earth, with a view to dispute with an enemy the remainder of a piece of ground.

**ANTEVIRGILIAN husbandry**, an appellation given to Mr Tull's new method of horse-hoeing husbandry. See **AGRICULTURE**, Part II.

**ANTHAKIA**, in geography, the same with Antioch. See **ANTIOCH**.

**ANTHELIX**, in anatomy, the inward protuberance of the external ear, being a semicircle within, and almost parallel to the helix. See p. 295.

**ANTHELMINTICS**, among physicians, medicines proper to destroy worms. See **PHARMACY**.

**ANTHEM**, a church-song, performed in cathedral service by choristers who sing alternately.

**ANTHEMIS**, or **CAMOMILE**, in botany, a genus of the syngenesia polygamia superflua class. The receptacle of the anthesis is paleaceous; it has no pappus; the calix is globular. There are 18 species of anthemis, only five of which are natives of Britain, viz.

the nobilis, or sweet-scented camomile; the cotula, or flinking May-weed; the arvensis, or corn-camomile; the maritima, or sea-camomile; and the tinctoria, or common ox-eye. The flowers of the anthemis nobilis are carminative, emolient, and aperient.

**ANTHERÆ**, among botanists, the little roundish or oblong bodies on the tops of the stamina of plants. See **STAMINA**, and **BOTANY**.

**ANTHERICUM**, in botany, a genus of the hexandria monogamia class. The corolla has six petals open at the top; and the capsule is ovated. There are 13 species of anthericum, none of which are natives of Britain, except the calyculatum, or Scottish asphodel.

**ANTHESPORIA**, in antiquity, a Sicilian festival, instituted in honour of Proserpine.

**ANTHESTERIA**, in Grecian antiquity, festivals celebrated in the spring, by the ancient Athenians, in honour of Bacchus, during which the masters feasted their slaves, as the Romans did in the time of the Saturnalia.

**ANTHESTERION**, in ancient chronology, the sixth month of the Athenian year, answering to the latter part of our November and beginning of December.

**ANTHIAS**, in ichthyology, the trivial name of a species of labrus. See **LABRUS**.

**ANTHINE wine**, among the ancients, a kind of wine medicated with the flowers of plants.

**ANTHOCEROS**, in botany, a genus of the cryptogamia class. The calix of the male is sessile, cylindrical, and intire; the antheræ are very long, subulared, and two-valved; the calix of the female is divided into six pieces; the seeds are three. There are only three species of the anthoceros, viz. the punctatus, or spotted anthoceros, a native of Britain; the levis, a native of Europe and America; and the multifidus, a native of Germany.

**ANTHOLOGION**, the title of the service-book used in the Greek church.

It is divided into twelve months, containing the offices sung throughout the year, on the festivals of our Saviour, the Virgin, and other remarkable saints.

**ANTHOLOGY**, a discourse of flowers, or of beautiful passages from any authors.

**ANTHOLOGY** is also the name given to a collection of epigrams taken from several Greek poets.

**ANTHOLYZA**, a genus of the triandria monogamia class. The calix is tubular, irregular, and bent back; the capsule is below the flower. There are four species of the antholyza, viz. the ringens, a native of Æthiopia; the cunonia, a native of Persia; the æthiopia, a native of Æthiopia; and the meriana, a native of the Cape of Good-Hope.

**ANTHONY**, or *Knights of St ANTHONY*, a military order, instituted by Albert duke of Bavaria, Holland, and Zealand, when he designed to make war against the Turks in 1382. The knights wore a collar of gold, made in form of a hermit's girdle, from which hung a stick cut like a crutch, with a little bell, as they are represented in Anthony's pictures.

*St ANTHONY'S fire*, a name sometimes given to the erysipelas. See **ERYSIPELAS**.

**ANTHORA**,

- ANTHORA**, in botany, the trivial name of a species of aconitum. See **ACONITUM**.
- ANTHORISMUS**, in rhetoric, denotes a contrary description or definition of a thing from that given by the adverse party.
- ANTHOS**, a Greek term, properly signifying a flower, but used by some writers to denote rosemary by way of eminence.
- ANTHOS** is sometimes also used for the elixir of gold, as well as for a medicine extracted from pearls.
- ANTHOS phlogophorum**, denotes a certain method of transmuting metals by vitriol.
- ANTHOSATUM acetum**, the vinegar of rosemary flowers.
- ANTHOSPERMUM**, in botany, a genus of the polygamia diœcia class. The calix of the hermaphrodite flower is divided into four parts; it has no corolla; the stamina are four, and the pistilli two; the germen is below the flower. There are two species of anthospermum, *viz.* the æthiopicum, a native of Æthiopia; and the ciliare, a native of the Cape of Good-Hope.
- ANTHOXANTHUM**, in botany, a genus of the dianthia digynia class. The calix is a bivalved gluma, with one flower; the corolla is bivalved, obtuse, and without any awn. There are three species of anthoxanthum, *viz.* the odoratum, or spring-grass, a native of Britain; the indicum, a native of India; and the paniculatum, a native of the southern parts of Europe.
- ANTHRACIS**, **ANTHRACIAS**, or **ANTHRACITIS**, names promiscuously used by ancient naturalists for very different fossils, *viz.* the carbuncle, hematites, and a kind of asteria. See **CARBUNCLE**, &c.
- ANTHRACOSIS**, in medicine, a corrosive scaly ulcer, either in the bulb of the eye or the eye-lids.
- ANTHRAX**, a Greek term, literally signifying a burning coal, used by the ancients to denote a gem, as well as a disease, more generally known by the name of carbuncle. See **CARBUNCLE**.
- ANTHRAX** is sometimes also used for lithanthrax, or pit-coal. See **LITHANTHRAX**.
- ANTHRISCUS**, in botany, the trivial name of a species of tordylium. See **TORDYLIUM**.
- ANTHROPOGLOTTUS**, among zoologists, an appellation given to such animals as have tongues resembling that of mankind, particularly to the parrot kind.
- ANTHROPOGRAPHY**, denotes the description of the human body, its parts, structure, &c. See **ANATOMY**.
- ANTHROPOLATRÆ**, in church-history, an appellation given to the Nestorians, on account of their worshipping Christ, notwithstanding that they believed him to be a mere man.
- ANTHROPOLATRIA**, the paying divine honours to a man, supposed to be the most ancient kind of idolatry.
- ANTHROPOLOGY**, a discourse upon human nature.
- ANTHROPOLOGY**, among divines, denotes that manner of expression by which the inspired writers attribute human parts and passions to God.
- ANTHROPOMANCY**, a species of divination, performed by inspecting the intrails of a human creature.
- ANTHROPOMORPHA**, a term formerly given to the primates, or that class of animals which have the greatest resemblance to the human kind. See **NATURAL HISTORY**.
- ANTHROPOMORHISM**, among ecclesiastical writers, denotes the heresy or error of the Anthropomorphites. See the next article.
- ANTHROPOMORPHITES**, in church-history, a sect of ancient heretics, who, taking every thing spoken of God in scripture in a literal sense, particularly that passage of Genesis in which it is said *God made man after his own image*, maintained, That God had a human shape. They are likewise called *Audeans*, from Audeus their leader.
- ANTHROPOMORPHOUS**, an appellation given to whatever resembles the human form.
- ANTHROPOPATHY**, a figure or expression by which some passion is ascribed to God, which properly belongs only to man.
- ANTHROPOSCOPY**, that part of physiognomy which judges of a man's character, &c. from the lineaments of his body.
- ANTHROPOPHAGY**, the act of eating human flesh. This horrid practice is said to prevail in some parts of Africa and America. But it is greatly to be doubted if ever such a custom existed.
- ANTROPOTHYSLA**, the inhuman practice of offering human sacrifices. See **SACRIFICE**.
- ANTHUM**, in botany. See **EPITHYMUM**.
- ANTHUS**, in ornithology, a synonyme of the louse. See **LOSLIA**.
- ANTHYLLUS**, in botany, a genus of the diadelphia decandria class. The calix is ventricose, and the legumen is roundish. There are 10 species of anthyllus, *viz.* the tetraphylla, montana, cornicina, lotoides, barba jovis, heterophylla, cytisoides, hermanix, and erinacea, all natives of Spain, Italy, and the southern parts of Europe; and the vulnearia, kidney-vech, or lady's finger, a native of Britain.
- ANTHYPHORA**, in rhetoric, a figure of speech; being the counter-part of an hypophora. See **HYPOPHORA**.
- ANTI**, a Greek preposition, which enters into the composition of several words, both Latin, French, and English, in different senses. Sometimes it signifies *before*, as in anti-chamber; and sometimes *opposite* or *contrary*, as in the names of these medicines, antiscorbutics, anti-venereal.
- ANTIÆDES**, in anatomy, a name sometimes used for the glands, more usually called *testis*. See p. 296.
- ANTIDIAPHORISTS**, in church-history, the opposers of the Adiaiphorists. See **ADIAPHORISTS**.
- ANTIBACCHIUS**, in ancient poetry, a foot consisting of three syllables, the two first long, and the last one short; such is the word *ambirë*.
- ANTIBES**, a sea-port town of Provence in France, situated on the Mediterranean, in E. long. 7°, N. lat. 43°, 40'.
- ANTICARDIUM**, in antiquity, the same with scrobiculum cordis.

- ANTICHAMBER**, an outer chamber for strangers to wait in, till the person to be spoken with is at leisure.
- ANTICHRISIS**, among civilians, the same with what in common law is called a *wortgage*. See **MORTGAGE**.
- ANTICHRIST**, among ecclesiastical writers, denotes a great adversary of Christianity, who is to appear upon the earth towards the end of the world. He is called in scripture, *The man of sin, the man of perdition*, &c.
- ANTICHRISTONES**, in ancient geography, an appellation given to the inhabitants of opposite hemispheres.
- ANTICOR**, or **ANTICOEUR**, among farriers, an inflammation in the horse's throat, being the same with the quinzey in mankind.
- ANTICOSTE**, an American island, situated before the mouth of the river St Lawrence, in 64° W. long. and 49° 52' N. lat.
- ANTICUS**, a term used by anatomists, importing, that the part with which it is joined stands before some others: Thus, we meet with *ferratus anticus*, *peroneus anticus*.
- ANTIDESMA**, in botany, a genus of the dioecia pentandria class. The calix of the male consists of 5 leaves; it has no corolla: The calix of the female is entire, gaping a little on one side; it has no corolla, but two styli, and a double valved capsule inclosed in the calix. There is but one species of the antidesma, *viz.* the alexetaria, a native of India.
- ANTIDICOMARLANITES**, in church-history, heretics, who maintained that the Virgin Mary did not preserve a perpetual virginity.
- ANTIDOTE**, among physicians, a remedy taken to prevent, or to cure the effects of poison, &c.
- ANTIENI**, or **ANCIENT**, a term applied to things which existed long-ago: Thus we say, ancient nations, ancient customs, &c.
- ANTIENI**, in a military sense, denotes either the ensign, or the colours.
- ANTIENI**, in ships of war, the streamer or flag borne in the stern.
- ANTIGONIA**, the name of two cities, one in Epirus, now called *Cassra Argiro*, the other in Macedon, now *Geborna*.
- ANTIHECTICS**, in pharmacy, medicines good in hectic disorders.
- ANTILLES**, the same with the Caribbee islands.
- ANTILOGARITHM**, the complement of a logarithm.
- ANTILOGY**, in matters of literature, an inconsistency between two or more passages of the same book.
- ANTILYSSUS Pulv.**, a medicine consisting of equal parts of the lichen cinereus terrestris, and black pepper, reckoned good to prevent the rabies canina.
- ANTIMETABOLE**, in rhetoric, a figure whereby two things are set in opposition to each other.
- ANTIMONARCHICAL**, an appellation given to whatever opposes monarchical government. See **MONARCHY**.
- ANTIMONIALS**, in medicine, preparations of antimony. See **ANTIMONY**, and **CHEMISTRY**.
- ANTIMONIATED**, something impregnated with the virtues of antiaony.
- ANTIMONY**, in natural history, one of the semi-metals. See **CHEMISTRY**, title, *Of metals*.
- ANTINOMIANS**, in church-history, certain heretics who first appeared about the year 1535; so called, because they rejected the law, as of no use, under the gospel-dispensation, with other doctrines equally absurd.
- ANTIOCH**, a town of Syria, formerly its capital, but now in a ruinous condition; situated on the river Orontes, in 37° E. long. and 36° N. lat.
- ANTIOCHENUM**, in botany, a species of convolvulus. See **CONVOLVULUS**.
- ANTIPAGMENTA**. See **ANTEPAGMENTA**.
- ANTIPATHY**, a natural aversion of one body to another, in contradistinction to sympathy. See **SYMPATHY**.
- ANTIPERISTALTIC motion of the intestines**, the reverse of the peristaltic motion. See **PERISTALTIC**.
- ANTIPERISTASIS**, in the peripatetic philosophy, an imaginary intention or heightening of any quality by the opposition of its contrary.
- ANTIPHONY**, in music, the name which the Greeks gave to that kind of symphony which was executed in octave or double octave. It is likewise the answer made by one choir to another, when an anthem is sung between them.
- ANTIPLHRASIS**, in rhetoric, a figure by which in saying one thing we mean the contrary. See **IRONY**.
- ANTIPODES**, in geography, a name given to those inhabitants of the globe that live diametrically opposite to one another. They lie under opposite parallels, and opposite meridians. They have the same elevation of their different poles. It is midnight with the one, when it is noon-day with the other; the longest day with the one is the shortest with the other; and the length of the day with the one is equal to the night of the other. See **GEOGRAPHY**.
- ANTIPOPE**, in the Romish church, one elected pope in an irregular manner, in opposition to another.
- ATIPTOSIS**, in rhetoric, a figure which puts one case for another. See **CASE**.
- ANTIQUARY**, a person who studies and searches after monuments and remains of antiquity.
- There were formerly in the chief cities of Greece and Italy, persons of distinction called antiquaries, who made it their business to explain the ancient inscriptions, and give every other assistance in their power to strangers who were lovers of that kind of learning. There is a society of antiquaries in London, incorporated by the king's charter.
- ANTIQUATED**, something obsolete, out of date, or out of use.
- ANTIQUÉ**, in a general sense, something that is ancient: but the term is chiefly used by sculptors, painters, and architects, to denote such pieces of their different arts as were made by the ancient Greeks and Romans. Thus we say, *an antique bust*, *an antique statue*, &c.
- ANTIQUITY**, signifies times or ages past long ago. Thus we say, *the heroes of antiquity*, &c. It is often used for the works or monuments of the ancients. Researches

- searches into antiquity have frequently been useful. But these researches, unless they are conducted with judgment, are extremely liable to ridicule.
- ANTIRRHINUM**, in botany, a genus of the didymia angiospermia class. The calix consists of five leaves; the basis of the corolla is bent backwards, and furnished with pectoria; the capsule is bilocular. There are 14 species of the antirrhinum, 10 of which are natives of Britain, *viz.* the cymbalaria, or ivy-leaved toad-grafs; the elatine, or sharp-pointed fluellin; the spurium, or round-leaved fluellin; the arvense, or corn-blue toad-flax; the repens, or creeping toad-flax; the monospermum, or sweet-smelling toad-flax; the linaria, or common yellow toad-flax; the minus, or least toad-flax; the majus, or greater snapdragon; and the orontium, or least snapdragon. The linaria is said to be cathartic and diuretic; but it is not used in the shops.
- ANTISAGOGE**, in rhetoric, the same with concessio. See **CONCESSION**.
- ANTISCII**, in geography, people who live on different sides of the equator, whose shadows at noon are projected opposite ways. Thus the people of the north are Antiscii to those of the south, the one projecting their shadows at noon toward the north pole, and the other toward the south pole.
- ANTISCORBUTICS**, medicines good in scorbutical cases.
- ANTISEPTICS**, among physicians, a denomination given to all substances that resist putrefaction. Such as salts of all kinds, vinegar, myrrh, snake-root, pepper, &c.
- ANTISTOECHON**, in grammar, the using one letter instead of another, as *o*lli for *i*lli.
- ANTISTROPHE**, in grammar, a figure by which two things mutually depending on one another, are reciprocally converted; as *the servant of the master, the master of the servant*.
- ANTISTROPHE**, among lyric poets, that part of a song and dance in use among the ancients, which was performed before the altar, in returning from west to east, in opposition to strophe. See **STROPHE**, and **ODE**.
- ANTITACTÆ**, in church-history, a branch of Gnostice, who held, that God was good and just, but that a creature had created evil; and consequently that it is our duty to oppose this author of evil, in order to avenge God of his adversary.
- ANTITHENAR**, in anatomy, a name given to the aductor indicis. See p. 216.
- ANTITHESIS**, contrast, or opposition of words or sentiments; as,
- Though gentle, yet not dull,  
Strong without rage, without overflowing full.*
- ANTITHET**, denotes either a quality or thing set in opposition to its contrary.
- ANTITHETARIUS**, in law, a person who endeavours to acquit himself by charging the accuser with the same fact.
- ANTITRAGUS musculus**, in anatomy, a muscle of the ear. See p. 295. par. 5.
- ANTITRINITARIANS**, a general name given to all

those who deny the doctrine of the Trinity, and particularly to the Arians and Socinians.

**ANTITYPE**, among ecclesiastical writers, denotes a type corresponding to some other type or figure.

**ANTIVARI**, a sea-port town of Albania, situated on the gulph of Venice, in 19° 40' E. long. and 42° 10' N. lat. It is subject to the Turks.

**ANTIVETRIA**, a province or subdivision of Terra Firma, in South America, lying southwards of Carthagena.

**ANTLER**, among sportsmen, a sharp or branch of a deer's attire.

*Brow-ANTLER*, denotes the branch next the head; and, *Be-ANTLER*, the branch next above the brow-antler.

**ANTOECI**, in geography, those inhabitants of the earth who live under the same meridian, and at the same distance from the equator; the one toward the north, and the other toward the south. Hence they have the same longitude; and their latitude is also the same, but of a different denomination. They are in the same semicircle of the meridian, but opposite in parallels. They have precisely the same hours of the day and night, but opposite seasons; and the night of the one is always equal to the day of the other.

**ANTONIAN Waters**, medicinal waters of Germany, very pleasant to the taste, and esteemed good in many chronic and hypochondriac cases.

**ANTONIO**, one of the Cape de Verd islands, subject to the Portuguese, and situated in 26° W. long. and 18° N. lat.

**ANTONOMASIA** a form of speech, in which, for a proper name, is put the name of some dignity, office, profession, science, or trade; or when a proper name is put in the room of an appellative. Thus a king is called his majesty; a nobleman, his lordship. We say the philosopher instead of Aristotle, and the orator for Cicero: Thus a man is called by the name of his country, a German, an Italian; and a grave man is called a Cato, and a wise man a Solomon.

**ANTRIM**, the most north-east county of Ulster, in the king-dom of Ireland. It is also the name of the chief town of the aforesaid county, situated at the north end of Lochneah, in 6° 26' W. long. and 54° 45' N. lat.

**ANTRUM**, among anatomists, a term used to denote several cavities of the body; as the antrum highmorianum, or that in the maxillary or jaw-bone, &c. See p. 162. par. 2.

**ANTWERP**, a beautiful city of the Austrian Netherlands, and capital of the marquisate of the same name. It stands on the eastern shore of the river Scheld, about 25 miles north of Brussels, and in 4° 15' E. long. and 51° 15' N. lat.

**ANTYX**, in antiquity, denotes the circumference, or outermost round of a shield.

**ANVIL**, an iron instrument on which smiths hammer or forge their work, and is usually mounted on a firm wooden block.

**ANUS**, in anatomy, the extremity of the intestinum rectum, or orifice of the fundament. See p. 261. par. 2.

- ANWEILLER**, a small city of France, in the Lower Alface, upon the river Queich.
- ANZAR**, a city of Turquellan, near Catai, where Tamerlane died.
- ANZERMA**, a town of S. America, in the kingdom of Popajan, upon the river Cauca, situated in 47° W. long. and 4° S. lat.
- ANZUGUI**, a town in the island of Japan, upon the bay of Mecao.
- AONIDES**, in mythology, one of the many appellations of the muses, so called from Aonia, a part of ancient Bœotia.
- AORIST**, among grammarians, a tense peculiar to the Greek language, comprehending all the tenses, or rather expressing an action in an indeterminate manner, without any regard to past, present, or future.
- AOUST**, a town of Piedmont in Italy, capital of the duchy of the same name, situated about 50 miles north of Turin, in 7° 10' E. long. and 45° 45' N. lat.
- APAGOGICAL Demonstration**, an indirect way of proof, by shewing the absurdity of the contrary.
- APALACHIAN Mountains**, a ridge of mountains of N. America, lying westward of the British plantations, and extending from 30° to 40° N. lat.
- APAMEA**, or **HAMA**, a town of Syria, situated on the river Orontes, in 38° 30' E. long. and 34° N. lat.
- APAMEA** is also the name of a town of Phrygia, upon the river Marfyas; of a town of Midia, confining upon Parthia; and of a town of Bithynia, called by the Turks *Myrlea*.
- APANAGE**, or **APENNAGE**, in the French customs, lands assigned by a sovereign for the subsistence of his younger sons, which revert to the crown upon the failure of male issue in that branch to which the lands are granted.
- APARINE**, in botany, a synonyme of the utricularia and several other plants.
- APATHY**, a term in philosophy, denoting an utter privation of passion, and an insensibility of pain. Thus the Stoics affected an entire apathy, so as not to be ruffled, or sensible of pleasure or pain.
- APATIZATIO**, a law-term, signifying an agreement.
- APATURIA**, in Grecian antiquity, an Athenian festival, kept in honour of Bacchus. It was during this solemnity that the young people were registered in the respective wards of their fathers.
- APE**, the English name of the simia or monkey. See **SIMIA**.
- APELITES**, Christian heretics in the second century, who affirmed that Christ received a body from the four elements, which at his death he rendered back to the world, and so ascended into heaven without a body.
- APENE**, in antiquity, the chariot in which the images of the gods were carried on solemn occasions.
- APENNAGE**, in the French customs. See **APANAGE**.
- APENNINE**, a vast ridge of mountains, which runs through the middle of all Italy, from Savona, to the very strait that separates Italy from Sicily.
- APENRADE**, a town of Sleswic, or S. Jutland, situated on a bay of the Baltic sea, in 10° E. long. and 55° N. lat.
- APENZEL**, a town of Switzerland, capital of the canton of the same name, and situated in 9° E. long. and 47° 30' N. lat.
- APEPSY**, in medicine, denotes crudity, or a bad digestion.
- APER**, in zoology, a synonyme of the *fus scrofa*. See **SUS**.
- APER** is likewise a trivial name of a species of Zeus. See **ZEUS**.
- APERIENTS**, in the materia medica, an appellation given to such medicines as facilitate the circulation of the humours by removing obstructions.
- The five greater aperient roots of the shops are smallage, fennel, asparagus, parsley, and butcher's broom; as the five lesser ones are grafs, madder, eryngo, capers, and chamomoc.
- APERTURE**, the opening of any thing, or a hole or cleft in any continuous subject.
- APERTURE**, in geometry, the space between two right lines which meet in a point and form an angle.
- APERTURE**, in optics, a round hole in a turned bit of wood or plate of tin, placed within the side of a telescope or microscope, near to the object-glass, by means of which more rays are admitted, and a more distinct appearance of the object is obtained.
- APERTURES**, or **APERTIONS**, in architecture, are used to signify doors, windows, chimneys, &c.
- APERTURA tabularum**, in law-books, the breaking open a last will and testament.
- APERTURA feudi**, in the civil law, signifies the loss of a feudal tenure, by default of issue to him to whom the feud was first granted.
- APETALOSE**, or **APETALOUS**, among botanists, an appellation given to such plants as have no flower-leaves.
- APEX**, in antiquity, the crest of a helmet, but more especially a kind of cap worn by the flames.
- APEX**, among grammarians, denotes the mark of a long-syllable, falsely called a long accent.
- APHACA**, in botany, a synonyme of the lathyrus. See **LATHYRUS**.
- APHÆRESIS**, in grammar, a figure by which a letter or syllable is cut off from the beginning of a word.
- APHÆRESIS**, that part of surgery which teaches to take away superfluities.
- APHANES**, in botany, a genus of the tetrandria digynia class. The calix is divided into eight parts; it has no corolla; and has two naked seeds. There is only one species of aphanes, *viz.* the *arvensis*, or purple-piert, a native of Britain.
- APHELIUM**, or **APHELION**, in astronomy, is that point in any planet's orbit, in which it is furthest distant from the sun, being that end of the greater axis of the elliptical orbit of the planet most remote from the focus where the sun is.
- APHIS**, in zoology, a genus of insects belonging to the order of insecta hemiptera. The rostrum or beak of the aphid is insected; the antennæ or feelers are longer than the thorax; it has four erect wings; the feet are of the ambulatory kind; and the belly often ends in two horns. There are 33 species of the aphid, all

- of which are inhabitants of particular plants; and from this circumstance their trivial names are taken; as *aphis ribis*, *ulmi*, *rosæ*, &c.
- APHORISM**, a maxim, or principle, of a science; or a sentence which comprehends a great deal in a few words.
- APHRATIC**, in the maritime affairs of the ancients, were open vessels, without any decks.
- APHRODISIA**, in antiquity, festivals kept in honour of Venus, the most remarkable of which was that celebrated by the Cyprians.
- APHRODISIACS**, among physicians, medicines which increase the quantity of seed, and create an inclination to venery.
- APHRODITA**, in zoology, an insect of the order of vermes mollusca. The body of the aphrodita is oval, with many small tentacula or protuberances on each side, which serve as so many feet: The mouth is cylindrical, at one end of the body, and capable of being retracted, with two bristly tentacula. There are four species of this insect, *viz.* 1. The aculeata, with 22 tentacula, or feet, an inhabitant of the European seas. See Plate XXII. fig. 4. This figure is taken from the life. It was found on the shore of the frith of Forth, about a mile east from Leith, by Dr Letfom, and by him communicated to the proprietors of this work. Johnston, Seba, and other authors, have given figures of the aphrodita; but they are not so accurate as could be wished. 2. The scabra, of an oblong shape, scabrous on the back, with about 20 tentacula. 3. The squamata, with 24 feet, and scaly on the back. 4. The imbricata, is very like the former, only its scales are more glabrous.
- APHRODITES**, the same with *gemma veneris*. See **GEMMA**.
- APHRONITRE**, in natural history, a name given by the ancients to a particular kind of natrum.
- APHTHÆ**, in medicine, small, round, and superficial ulcers arising in the mouth. The principal seat of this disease, is the extremity of the excretory vessels, salival glands, and, in short, all glands that furnish a humour like the saliva, as the lips, gums, &c.
- APHUA cobites**, in ichthyology. See **GOBIUS**.
- APHYLLANTHES**, or *Blue Montpellier PINK*, in botany, a genus of the hexandria monogynia class. There is but one species, *viz.* the montpelienis, which grows in the high grounds near Montpellier. It is extremely like the *juncus*, only the flower has a corolla.
- APIARY**, a place where bees are kept.
- APIASTELLUM**, or **APIASTRUM**, in botany. See **MELISSA**.
- APIASTER**, in ornithology, the trivial name of a species of the *merops*. See **MEROPS**.
- APICES**, in botany, the same with *antheræ*. See **ANTHERÆ**.
- APIOS**, it botany. See **GLYCINE**.
- APIS**, or the **BEE**, in zoology, a genus of insects belonging to the order of insecta hymenoptera. The mouth is furnished with two jaws, and a proboscis infolded in a double sheath; the wings are four in number, the two foremost covering those behind when at rest: In the anus or tail of the females and working bees, which are of no sex, there is a hidden sting. Linnaeus enumerates no less than 55 species of the apis, *viz.* 1. The longicornis, or hairy yellow bee, with thread-like feelers, about the length of its body. 2. The tumulorum, or black bee, with yellow feet and jaws, and thread-like feelers, about the length of the body. 3. The clavicornis, or black bee, with clavated feelers, about the length of its body, and two yellow belts round the belly. 4. The centuncularis, or black bee, having its belly covered with yellow down. The nests of this species are made of rose-leaves curiously plaited in the form of a matt or quilt. 5. The cineraria, or black bee, with a white hairy breast, and a greenish belt round the belly. The above five species are all natives of Europe. 6. The mexicana, is a brownish bee, with bluish wings, and very large. It is a native of America. 7. The carbonaria, or reddish bee, with darkish green wings; it is about the size of the mellefica, or common honey-bee, and is found in Africa. 8. The retufa, or black bee, has its legs covered with down. 9. The rufa, or brownish bee, with a white front and dusky belly. 10. The bicornis, has two horns on its front, a black head, and a hairy belly. 11. The maxillofa, or black bee, with prominent jaws, short feelers, and a cylindrical belly, covered with a yellow down. 12. The truncorum, or black smooth bee, with a white hairy front, and a yellow belly edged with white. 13. The floriformis, or black bee, with a cylindrical incurvated belly, having two tooth-like protuberances at the anus, and a kind of prickles on the hind-legs. This bee sleeps in flowers. 14. The dentata, or shining green bee, with black wings, and a kind of teeth on the hind thighs. The tongue of this bee is almost as long as its body. The nine last species are all natives of Europe. 15. The cordata, or shining green bee, with a belly shaped like a heart, and wings of a glass-colour. It is a native of the Indies. 16. The helvola, is an oblong reddish bee, with a white belly. 17. The fabriciana, or black bee, with an iron-coloured belly, and two yellow spots. 18. The fuccinea, has a yellow hairy breast, a black belly, and four white belts. The last three are natives of Europe. 19. The zonata, is brownish and hairy, with four bluish belts on the belly. It is a native of the Indies. 20. The ænea, is hairy, and of a copper colour. 21. The cærulefcens, is brownish and hairy, with a greenish belly, margined with white indentations. 22. The mellefica, or honey-bee, is furnished with downy hairs, a dusky-coloured breast, and brownish belly; the tibiae of the hind-legs are ciliated, and transversely breaked on the inside. Each foot of this bee terminates in two hooks, with their points opposite to each other; in the middle of these hooks there is a little thin appendix, which, when unfolded, enables the bees to fasten themselves to glass or the most polished bodies. This part they likewise employ for collecting the small particles of wax which they find upon flowers, and for transmitting them to the middlemost joint of the two hinder feet, in which there is a little cavity, in the shape of a narrow spoon, surrounded by a number of hairs. When they have loaded their thighs with wax, they immediately carry it off to the hive.

hive. The queen and drones, who never collect wax in this manner, have no such cavity. The belly of the bee is divided into six rings or joints. In the inside of the belly there is a small bladder or reservoir, in which the honey is collected, after having passed through the proboscis and a narrow pipe which runs through the head and breast. This bladder, when full of honey, is about the size of a small pea. The sting is situate at the extremity of the belly: It is a horny substance, and hollow within, for transmitting the venomous liquor, which lies in a bladder near the anus, into the wound. The sting is generally left in the wound, and frequently draws after it the poison-bag.

As the mellefica, or honey-bee, is both an useful insect, and endowed with peculiar instincts, we shall give a particular account of its nature and œconomy.

The queen is the only female in a hive; she is distinguished from the others by being taller, more of an oblong figure, and having ten joints in each seeler. She is likewise furnished with a sting. The fuci, males, or drones, are commonly about 1600 in a hive; they have no sting, and their feelers have eleven joints. The operaria, spadones, or working bees, are sometimes 20,000 in a hive; they have fifteen joints in their feelers, and are armed with stings.

After a new swarm is formed, the bees immediately begin to form their cells. They begin their work at the upper part of the hive, and continue it downwards, and from one side to the other. It is not easy to discover the particular manner of their working; for, notwithstanding the many contrivances used for this purpose, there are such numbers in continual motion, and succeed one another with such rapidity, that nothing but confusion appears to the sight. Some of them however have been observed carrying pieces of wax in their talons, and running to the places where they are at work, upon the combs. These they fasten to the work by means of the same talons. Each bee is employed but a very short time in this way; but there is so great a number of them that go on in a constant succession, that the comb increases very perceptibly. Besides these, there are others that run about beating the work with their wings and the hinder part of their body, probably with a view to make it more firm and solid.

The order they observe in the construction of their cells is this: They begin with laying the basis, which is composed of three rhombus's or lozenges. They build first one of the rhombus's, and draw faces on two of its sides; they then add a second rhombus to the first in a certain inclination, and draw two new faces on its two sides; and, last of all, they add a third rhombus to the two first, and raise on the two external sides of this rhombus two other faces; which completes the cell of an hexagonal figure.

Whilst part of the bees are occupied in forming the cells, others are employed in perfecting and polishing those that are new-modelled. This operation is performed by their talons, taking off every thing that is rough and uneven. These polishers are not so desultory in their operations as those that make the cells; they work long and diligently, never intermitting their labour, ex-

cepting to carry out of the cell the particles of wax which they take off in polishing. These particles are not allowed to be lost; others are ready to receive them from the polishers, and to employ them in some other part of the work.

Each comb has two rows of cells opposite to each other, which have their common bases. The thickness of every comb is something less than an inch, and the depth of the cells is about five lines. Almost all the combs are built with cells of this size; except a small number of a larger kind, that are destined for the worms that produce drones.

The bases of all the combs are placed at such a distance from one another, that, when the cells are finished, there is only a space left sufficient for the passage of two bees abreast. These combs are not continued from top to bottom, but are often interrupted, and have openings from one passage to another, which give a more easy and shorter communication.

The queen-bee is generally concealed in the most secret part of the hive, and is never visible but when she lays her eggs in such combs as are exposed to sight. When she does appear, she is always attended by ten or a dozen of the common sort, who form a kind of retinue, and follow her where-ever she goes with a sedate and grave tread. Before she lays her eggs, she examines the cells where she designs to lay them; and if she finds that they contain neither honey, wax, nor any embryo, she introduces the posterior part of her body into a cell, and fixes to the bottom of it a small white egg, which is composed of a thin white membrane, full of a whitish liquor. In this manner she goes on, till she fills as many cells as she has eggs to lay, which are generally many thousands. After the eggs lie four days in the cells, they appear in the form of small caterpillars; and generally lie twisted round, so that the two extremities touch each other. The bees then supply them with a little honey for food, the quantity of which they increase till the eighth day from the birth of the caterpillar. After this, the bees discover no more care about their young; but stop up the mouths of the cells with wax. The embryos lie in this state twelve days, during which time they undergo surprising changes. They first change their situation in the cells, and instead of being rolled up, they extend themselves along, and place their heads towards the mouth of the cell; after this, the head of the worm begins to have a small extension, which is the rudiment of the proboscis: Upon the head there is likewise a black point, and at a little distance from this point, a black streak upon the back: The first lineaments of the feet likewise appear; but they are very small. After the head is formed, and the proboscis lengthened, all the other parts display themselves successively; so that the whole worm or embryo is changed into an aurelia or nymph, which is the fly almost perfect, except that it is yet white and soft, and wants that crust with which it is afterwards covered. By this transformation the worm is stripped of a white thin pellicle, which adheres to the sides of the cell. The young bee being stripped of this pellicle, and all the parts being unfolded by degrees, and changed through successive colours from yellow to black, arrives

*Fig. 1.* ANGUIS MELEAGRIS

*Fig. 2.* ANGUIS MACULATA

*Fig. 3.* ANGUIS SCYTALE

*Fig. 4.* APHRODITA

at perfection on the twentieth day; when she cuts, with her jaws or talons, the covering of wax upon the mouth of the cells, and issues out. When the young bees first get out of the cell, they appear drowsy, but soon acquire agility and command of their members; for they have often been observed to go to the fields, and return loaded with wax the same day that they issued from the cells.

As soon as a young bee quits its cell, one of the old ones takes off the wax-cover, and kneads and employs the wax for some other purpose: Another of them repairs and cleanses the cell, removing the pellicle and other fordes which was left by the young one.

It was observed above, that bees collect their wax from the pollen or farina of flowers, and carry it to the hive. When they arrive there, they support themselves on their two fore-feet, and make a buzz with their wings, thereby warning the bees within to assist them to unload; which they instantly do, each taking a small portion of the wax from the hinder-legs of the loaded ones, till the whole be exhausted. The wax is not only employed for the original construction of the combs and cells, but is collected and laid up in considerable quantities for the purposes of repairing any damage that may happen to the works during the winter, when they have no opportunity of collecting it in the fields, and likewise to stop up the mouths of the cells when full of honey or embryos. Bees have often been observed to dilute their wax, when too hard, by means of some liquor or saliva which they emit upon it, in order to render it soft and pliable for use.

The honey, as well as the wax, is collected from flowers. The honey, however, is extracted from a different part of the flower. In the flowers of many plants there are nectaria, or nectariferous glands, which secrete from the plant a pure transparent liquor, resembling virgin-honey both in taste and appearance, excepting that it is thinner. Perhaps all the change that this nectariferous juice undergoes, by being sucked up, and deposited in the honey-bag of the bee, is, that the more watery parts may probably be absorbed during the small time it remains there. The heat of the hive, after it is deposited in the cells, will still evaporate more of the watery parts, and bring it to the consistence of honey.

When a bee is collecting honey, she no sooner lights upon a flower than she extends her proboscis, and sucks up what she can find: If she cannot find a sufficient quantity to fill her bag in one flower, she immediately flies to another, and thus goes on till she has filled it. She then retires to the hive, goes to the cell, disgorges the honey, and again returns to the fields in quest of more. As the quantity carried home by one bee is but small, it requires the labour of many to fill a cell with honey. When the cells are full, they are immediately closed up with wax, if designed for winter-provision; if not, they are allowed to remain open for the common nourishment of the swarm.

Besides these capital instincts of bees, they are possessed of others, some of which are equally necessary for their preservation and happiness. They anxiously provide against the entrance of insects into the hive, by gluing up with wax the smallest holes in the skep. Some

stand as sentinels at the mouth of the hive, to prevent insects of any kind from getting it. But if a snail, or other large insect, should get in, notwithstanding all resistance, they sting it to death, and then cover it over with a coat of wax, to prevent the bad smell or maggots which might proceed from the putrefaction of such a large animal. Bees are seldom overtaken with bad weather; they seem to be warned of its appearance by some particular feeling. Cold is a great enemy to them. To defend themselves against its effects during a cold winter, they crowd together in the middle of the hive, and buzz about, and thereby excite a warmth which is often perceptible by laying the hand upon the glass-windows of the hive. They seem to understand one another by the motions of their wings. When the queen wants to quit the hive, she gives a little buzz, and all the others immediately follow her example, and retire along with her. They expell the drones before the winter, so that, of several hundreds in a hive, not one can be seen after the month of October. This expulsion always occasions a furious battle between the drones and the working bees; but the latter being greatly superior in number, always prevail.

With regard to Hives, those made of straw are the best, on many accounts: They are not liable to be overheated by the rays of the sun; they keep out cold better than wood or any other materials; and the cheapness renders the purchase of them easy. As the ingenious Mr Wildman's hives are reckoned to be of a preferable construction to any other, we shall give an account of them in his own words.

" My hives," says he, " are seven inches in height, and ten in width. The sides are upright, so that the top and bottom are of the same diameter. A hive holds nearly a peck. In the upper row of straw, there is a hoop of about half an inch in breadth, to which are nailed five bars of deals, full a quarter of an inch in thickness, and an inch and quarter wide, and half an inch asunder from one another; a narrow short bar is nailed at each side, half an inch distant from the bars next them, in order to fill up the remaining parts of the circle; so that there are in all seven bars of deal, to which the bees fix their combs. The space of half an inch between the bars allows a sufficient and easy passage for the bees from one hive to another. In order to give great steadiness to the combs, so that, upon moving the hive, the combs may not fall off, or incline out of their direction, a stick should be run through the middle of the hive, in a direction directly across the bars, or at right angles with them. When the hives are made, a piece of wood should be worked into the lower row of straw, long enough to allow a door for the bees, of four inches in length, and half an inch in height.

" The proprietor of the bees should provide himself with several flat covers of straw, worked of the same thickness as the hives, and a foot in diameter, that so it may be of the same width as the outside of the hives. Before the cover is applied to the hive, a piece of clean paper, of the size of the top of the hive, should be laid over it, and a coat of cow-dung, which is the

“ least apt to crack of any cement-easily to be obtained, should be laid all round the circumference of the hive. Let the cover be laid upon this, and made fast to the hive with a packing-needle and pack-thread, so that neither cold nor vermin may enter.

“ Each hive should stand single on a piece of deal, or other wood, somewhat larger than the bottom of the hive: That part of the stand which is at the mouth of the hive should project some inches, for the bees to rest on when they return from the field. This stand should be supported upon a single post, two and a half feet high; to which it should be screwed very securely, that high winds, or other accidents, may not blow down both stand and hive. A quantity of foot mixed with barley-chaff should be strewed on the ground round the post, which will effectually prevent ants, slugs, and other vermin, from rising up to the hive. The foot and chaff should, from time to time, be renewed as it is blown or washed away: Though, as it is sheltered by the stand, it remains a considerable time, especially if care be taken that no weeds rise through it. Weeds, indeed, should not be permitted to rise near the hive, for they may give shelter to vermin which may be hurtful to the bees.

“ The stands for bees should be four yards asunder; or, if the apiary will not admit of so much, as far asunder as may be, that the bees of one hive may not interfere with those of another hive, as is sometimes the case, when the hives are near one another, or on the same stand: For the bees, mistaking their own hives, light sometimes at the wrong door, and a fray ensues, in which one or more may lose their lives.

“ The person who intends to erect an apiary, should purchase a proper number of hives at the latter part of the year, when they are cheapest. The hives should be full of combs, and well stored with bees. The purchaser should examine the combs, in order to know the age of the hives. The combs of that season are white, those of the former year are of a darkish yellow; and where the combs are black, the hives should be rejected, because old hives are most liable to vermin and other accidents.

“ If the number of hives wanted were not purchased in the autumn, it will be necessary to remedy this neglect after the severity of the cold is past in the spring. At this season, bees which are in good condition will get into the fields early in the morning, return loaded, enter boldly, and do not come out of the hive in bad weather; for when they do, this indicates they are in great want of provisions. They are alert on the least disturbance, and by the loudness of their humming we judge of their strength. They preserve their hives free from all filth, and are ready to defend it against every enemy that approaches.

“ The summer is an improper time for buying bees, because the heat of the weather softens the wax, and thereby renders the combs liable to break, if they are not very well secured. The honey too being then thinner than at other times, is more apt to run out of the cells; which is attended with a double disadvantage, namely, the loss of the honey, and the daub-

“ ing of the bees, whereby many of them may be destroyed. A first and strong swarm may indeed be purchased; and, if leave can be obtained, permitted to stand in the same garden till the autumn; but if leave is not obtained, it may be carried away in the night after it has been hived.

“ I suppose, that in the flocks purchased, the bees are in hives of the old construction. The only direction here necessary is, that the first swarm from these flocks should be put into one of my hives; and that another of my hives should in a few days be put under the old flock, in order to prevent its swarming again.”

Bees never swarm till the hive be too much crowded by the young brood. It is this circumstance that induces a part of the hive to think of finding a more commodious habitation. With this view they single out a queen from among the young, with whom they take wing; and where-ever she leads, the rest follow. They first begin to swarm in May, or in the end of April, but earlier or later according to the warmth of the season. They seldom swarm before ten in the morning, and seldom later than three in the afternoon. We may know when they are about to swarm, by clusters of them hanging on the outside of the hive, and by the drones appearing abroad more than usual: But the most certain sign is, when the bees refrain from flying into the fields, though the season be inviting. Just before they take flight, there is an uncommon silence in the hive; after this, as soon as one takes flight, they all follow. Before the subsequent swarmings, there is a great noise in the hives, which is supposed to be occasioned by a contest whether the young or the old queen should go out. When the bees of a swarm fly too high, they are made to descend lower, by throwing handfuls of sand or dust among them, which they probably mistake for rain. For the same purpose, it is usual to beat on a kettle or frying-pan: This practice may have taken its rise from observing that thunder or any great noise prompts such bees as are in the fields to return home.

When the bees settle in swarming, they collect themselves in a heap, and hang to each other by their feet. When they settle in two separate divisions, it generally proceeds from there being two queens in the swarm. In that case, each cluster of them may be hived separately; or one of the queens must be destroyed, to prevent the commotions which the bees would raise in order to destroy her. All the motions and settling of a swarm are directed by the queen. If she be weak, and fall to the ground, the whole swarm fall down along with her; if she rest upon a branch of a tree, they accompany her; and if the queen be caught into a hive, the swarm will instantly follow her. When a swarm is too few in number for a hive, another may be added, provided the queen belonging to it be destroyed. If that precaution be not taken, a battle will ensue, in which not only one of the queens is killed, but frequently a great many of the working bees.

Several methods of taking the wax and honey, without destroying the bees, have of late been practised. Mr Wildman's fecus both to be the easiest and safest: “ Remove (says he) the hive from which you would take  
“ the

the wax and honey into a room, into which admit but little light, that it may appear at first to the bees as if it was late in the evening. Gently invert the hive, placing it between the frames of a chair, or other steady support, and cover it with an empty hive, keeping that side of the empty hive raised a little which is next the window, to give the bees sufficient light to get up into it. While you hold the empty hive, steadily supported on the edge of the full hive, between your side and your left arm, keep striking with the other hand all round the full hive from top to bottom, in the manner of beating a drum, so that the bees may be frightened by the continued noise from all quarters; and they will in consequence mount out of the full hive into the empty one. Repeat the strokes rather quick than strong round the hive, till all the bees are got out of it, which in general will be in about five minutes. It is to be observed, that the fuller the hive is of bees, the sooner they will have left it. As soon as a number of them have got into the empty hive, it should be raised a little from the full one, that the bees may not continue to run from the one to the other, but rather keep ascending upon one another. So soon as all the bees are out of the full hive, the hive in which the bees are must be placed on the stand from which the other hive was taken, in order to receive the absent bees as they return from the fields. If this is done early in the season, the operator should examine the royal cells, that any of them that have young in them may be saved, as well as the combs which have young bees in them, which should on no account be touched, though, by sparing them, a good deal of honey should be left behind. Then take out the other combs with a long, broad, and pliable knife, such as the apothecaries make use of. The combs should be cut from the sides and crown, as clean as possible, to save the further labour of the bees, who must lick up the honey spilt, and remove every remains of wax; and then the sides of the hive should be scraped with a table-spoon, to clear away what was left by the knife. During the whole of this operation, the hive should be placed inclined to the side from which the combs are taken, that the honey which is spilt may not daub the remaining combs. If some combs were unavoidably taken away, in which there are young bees, the parts of the combs in which they are should be returned into the hive, and secured by sticks, in the best manner possible. Place the hive then for some time upright, that any remaining honey may drain out. If the combs are built in a direction opposite to the entrance, or at right angles with it, the combs which are the furthest from the entrance should be preferred, because there they are best stored with honey, and have the fewest young bees in them.

Having thus finished taking the wax and honey, the next business is to return the bees to their old hive; and for this purpose place a table, covered with a clean cloth, near the stand, and giving the hive in which the bees are a sudden shake, at the same time striking it pretty forcibly, the bees will be shaken

on the cloth. Put their own hive over them immediately, raised a little on one side, that the bees may the more easily enter; and when all are entered, place it on the stand as before. If the hive in which the bees are, be turned bottom uppermost, and their own hive be placed over it, the bees will immediately ascend into it, especially if the lower hive is struck on the sides to alarm them.

The chief object of the bees during the spring and beginning of summer, is the propagation of their kind. Honey during that time is not collected in such quantities as it is afterwards; and on this account it is scarcely worth while to rob a hive before the latter end of June; nor is it safe to do it after the middle of July, lest rainy weather prevent their restoring the combs they have lost, and laying in a stock of honey sufficient for the winter, unless there is a chance of carrying them to a rich pasture.

Mr Wildman, by his dexterity in the management of bees, has lately surprised the whole kingdom. He can order a swarm to light where he pleases, almost instantaneously; he can order them to settle on his head, then remove them to his hand; command them to depart and settle on a window, table, &c. at pleasure. We shall subjoin his method of performing these feats, in his own words: "Spectators (says he) wonder much at my attaching bees to different parts of my body, and wish much to be possessed of the secret means by which I do it. I have unwarily promised to reveal it; and am therefore under a necessity of performing that promise: but while I declare, that their fear and the queen are the chief agents in these operations, I must warn my readers that there is an art necessary to perform it, namely practice, which I cannot convey to them, and which they cannot speedily attain; yet till this art is attained, the destruction of many hives of bees must be the consequence; as every one will find on their first attempt to perform it.

Long experience has taught me, that as soon as I turn up a hive, and give it some taps on the sides and bottom, the queen immediately appears, to know the cause of this alarm; but soon retires again among her people. Being accustomed to see her so often, I readily perceive her at first glance; and long practice has enabled me to seize her instantly, with a tenderness that does not in the least endanger her person. This is of the utmost importance; for the least injury done to her brings immediate destruction to the hive, if you have not a spare queen to put in her place, as I have too often experienced in my first attempts. When possessed of her, I can, without injury to her, or exciting that degree of resentment that may tempt her to sting me, slip her into my other hand, and returning the hive to its place, hold her there, till the bees missing her, are all on wing, and in the utmost confusion. When the bees are thus distressed, I place the queen where-ever I would have the bees to settle. The moment a few of them discover her, they give notice to those near them, and those to the rest; the knowledge of which soon becomes so general, that in a few minutes they all collect themselves round her; and are

“ so happy in having recovered this sole support of their state, that they will long remain quiet in their situation. Nay, the scent of her body is so attractive of them, that the slightest touch of her, along any place or substance, will attach the bees to it, and induce them to pursue any path she takes.

“ My attachment to the queen, and my tender regard for her precious life, makes me most ardently wish that I might here close the detail of this operation, which, I am afraid, when attempted by unskillful hands, will cost many of their lives; but my love of truth forces me to declare, that, by practice, I am arrived at so much dexterity in the management of her, that I can, without hurt to her, tie a thread of silk round her body, and thus confine her to any part in which she might not naturally wish to remain; or I sometimes use the less dangerous way of clipping her wings on one side.

“ I shall conclude this account in the manner of C. Furus Cresinus, who being cited before the Curule Edile and an assembly of the people, to answer to a charge of sorcery, founded on his reaping much larger crops from his small spot of ground, than his neighbours did from their extensive fields, produced his strong implements of husbandry, his well-fed oxen, and a hale young woman, his daughter; and, pointing to them, said, These, Romans, are my instruments of witchcraft; but I cannot shew you my toil, my sweats, and anxious cares. So may I say, These, Britons, are my instruments of witchcraft; but I cannot shew you my hours of attention to this subject, my anxiety and care for these useful insects; nor can I communicate to you my experience, acquired during a course of years.”

We shall conclude this history of the HONEY-BEE with the following experiments for preventing a waste of honey, and preserving the lives of bees during the winter, communicated by a gentleman near the banks of the Tweed. “ I have tried several experiments for preserving the lives of bees during the winter; and tho’ in general with little success, yet I think I have reason to continue, and advise others to follow, what I practised last winter. The method is very simple, and not expensive, for it is no other than keeping the bees in a cold and dark place.

“ My reason for trying this experiment, was my having observed, that a certain degree of cold brought upon the bees a stupor; and that the same degree of cold continued, kept them in the same state, till they were brought into a warmer situation, which immediately restored their life and vigour \*.

\* This observation is confirmed by what Mr White says, *That bees which stand on the north-side of a building, whose height intercepts the sun’s beams all the winter, will waste less of their provisions, almost by half, than others which stand in the sun; for, seldom coming forth, they eat little, and yet in the spring are as forward to work and swarm as those which had twice as much honey in the autumn before.* See the Rev<sup>d</sup>. Mr White’s method of preserving bees. Third edition.

“ With this view I kept two hives shut up in a dark cold out-house, from the middle of September to the middle of April, without ever letting them see light: Upon their being set out in the warmer air, they recovered immediately, and shewed an appearance of more strength than the hives did which had been kept out in the usual way. This appearance of strength continued during the summer, and they multiplied faster than I had ever observed them do before. They were rather later in swarming this year than in former summers; but the fame was the case with many hives in this neighbourhood: and even though this should always happen, yet I think other advantages will do more than overbalance it. Could I go into the country early in the spring, to look after the bees myself, I would bring them into the open air some weeks sooner, carefully attend to the changes of the weather, and shut up the doors of the hive on a bad day: but this degree of care can scarcely be expected from servants and gardeners, who have many other things to attend to.

“ I intend to have four hives put up this season, in the coldest dark place I can find; and as an ice-house is the steadiest and greatest cold we have, one or two of my friends who have ice-houses, have promised to put a hive upon the ice. By all accounts, the cold in Siberia does not kill the bees there; and in Russia, where the winters are extremely severe, bees produce much honey: so I think there is not any danger to be feared from any degree of cold we can expose the bees to.

“ If success continues to attend this experiment of keeping the bees asleep all the winter and spring, without confining their honey, a great point will be gained; especially as Mr Wildman has taught us to take the honey without killing the bees: for, by what I have observed in this country, our bees are lost chiefly by being tempted to go out in a clear sun in the spring, though perhaps a frosty wind blows, and chills them, so as to prevent their being able to return to the hive; or an early warmth induces the queen to lay eggs, and a number of young bees are bred, which consume the little provision left, before the fields can afford any supply.”

#### EXPLANATION of PLATE XXIII.

FIGURE 1. Is the queen bee. 2. Is the drone. 3. Is the working bee. 4. Represents the bees hanging to each other by the feet, which is the method of taking their repose. 5. The proboscis or trunk, which is one of the principal organs of the bees, wherewith they gather the honey and take their nourishment. 6. One of the hind-legs of a working-bee, loaded with wax. 7. A comb, in which the working bees are bred. The cells are the smallest of any. Two of them have the young bees inclosed. A royal cell is suspended on one side. 8. A comb in which the drones are bred, being larger than the former; the young drones being included in several of them; with two royal cells suspended on the side. 9. A similar comb, in which the royal cell is fixed in the middle of the comb; and several common cells are sacrificed to serve as a basis and

*Fig. 10*  
ARANEA TARANTULA

*Fig. 8.*

*Fig. 7.*

*Fig. 9.*

and support to it. In general, the royal cells are suspended on the side of a comb, as in fig. 7, 8. To the side of fig. 9, two royal cells are begun, when they resemble pretty much the cup in which an acorn lies. The other royal cells have the young queens included in them.

The 23d species is the *apis cunicularia*, or hairy bee, with an iron-coloured breast, and yellow belly. This species is very like the *mellefica*; they build their nests in dry sandy places. 24. The *variegata*; the breast and belly are variegated with white and black spots; the legs are of an iron colour. It is a native of Europe. This species sleep in the geranium pænum, or spotted crane's-bill. 25. The *rostrata* is distinguished by the upper lip being inflected, and of a conical shape, and by the belly being invested with bluish belts. They build their nests in high sandy grounds, and there is but one young in each nest. 26. The *argilifosa*, or iron-coloured bee, has an inflected rostrum, and a crooked belly, with one joint. It is a native of Surinam. 27. The *lagopoda* is of a greyish colour, with an emarginated anus. 28. The *manicata*, or black bee, with hairy fore-legs; the belly is spotted with yellow; and the anus is tridentated. 29. The *quatuor-dentata*, is of a dusky colour, with five white belts on the belly, and the anus has four teeth-like protuberances; each intermediate tooth is forked. The last three species are natives of Europe. 30. The *fasciata* has a yellowish back, and a black belt round the edge of each wing; the breast is white; the belly is variegated with black and white; the legs are covered with black hair; and the feelers are green. It is a native of the Cape of Good Hope. 31. The *barbara*, or black bee, with a yellow edging round the breast, is about the size of an ant; the feelers are like threads. It is a native of Barbary. 32. The *conica*, or yellow bee, with an acute conical belly, and the margins of the joints or segments white; it dwells in cavities of the earth. 33. The *annulata*, or black bee, with a black front, and black rings round the legs. 34. The *ruficornis* has two iron-coloured spots on the breast and feelers; the belly is spotted with yellow. 35. The *ferruginea*, or smooth black bee, with the feelers, mouth, belly, and feet of an iron colour. This is a small bee, and supposed to be of an intermediate kind between the bee and wasp. The last three are natives of Europe. 36. The *ichneumonea*; the rostrum or snout is an erect horn; the belly is petiolated and black; and the breast is interspersed with shining gold-coloured sutures or indented lines; the antennæ are green. It is a native of America. 37. The *cariofa* is a yellowish hairy bee; and the feet and front are of a bright yellow colour. It builds in the rotten trees of Europe. 38. The *violacea* is a red bee, and very hairy, with bluish wings. It is a native of Europe. The *violacea* is said to perforate trees, and hollow them out in a longitudinal direction; they begin to build their cells at the bottom of these holes, and deposit an egg in each cell, which is composed of the farina of plants and honey, or a kind of gluten. 39. The *caffra* is also red, and covered with hair; the hind part of the breast and fore-part of the belly are

yellowish. 40. The *carolina* is a red hairy bee, with the upper part of the belly yellow. It is a native of Carolina. 41. The *terrestris* is black and hairy, with a white belt round the breast, and a white anus. It builds its nest very deep in the earth. 42. The *hor-torium* is a black hairy bee, with the fore part of the breast and belly yellow. 43. The *pratorum*, or black hairy bee, with the fore part of the breast yellow, and a blackish anus. 44. The *lapidaria*, or red hairy bee, with a yellow anus. It builds in holes of rocks. 45. The *sylvarum*, or pale hairy bee, with a black belt on the breast, and a reddish anus. 46. The *muscorum*, or yellow hairy bee, with a white belly. It builds in mossy grounds. 47. The *hypnorum*, or yellow hairy bee, with a black belt on the belly, and a white anus. 48. The *lucorum*, or yellow hairy bee, with a white anus. The last eight species are all natives of Europe. 49. The *brasilianorum*, or pale-red hairy bee, with the basis of the thighs black. This is a very large bee, every where covered with a testaceous skin. It is a native of America. 50. The *acervorum* is red and hairy, and builds below ground. 51. The *subterranea* is red and hairy, with a dusky anus; it likewise builds below ground. 52. The *furinamenfis* is a black hairy bee, with the whole belly, excepting the first joint or segment, yellow. It is a native of Surinam. 53. The *stivans*, or black hairy bee, with a yellow breast. 54. The *tropica*, or black hairy bee, with the hind part of the belly yellow. The two last are natives of the warm climates. 55. The *alpina* is a haisy bee, with a black breast, and yellow belly. It inhabits the mountains of Lapland.

**APIUM**, or **PARSLEY**, in botany, a genus of the pentandria digynia class. The fruit is of an oval shape and streaked; the involucre consists of one leaf; and the petals are inflected. There are only two species of apium, *viz.* the *petroselinum*, a native of Sardinia; and the *graveolens*, a native of Britain. The seeds of the *petroselinum* are carminative, and the root is used as an aperient.

**APIVORUS** *Butea*, in ornithology, a synonyme of a species of *falco*. See **FALCO**.

**APLUDA**, in botany, a genus of the polygamia monœcia class. The calix is a bivalved gluma; the floscules of the female are sessile, and the male floscules are furnished with pedunculi; the female has no calix; the corolla has a double valve; there is but one stylus, and one covered sced. The male has three stamina. There are three species of *apluda*, *viz.* the *mutica*, *aristata*, and *zeugitea*, all natives of the Indies.

**APOBATERION**, in antiquity, a valedictory speech or poem made by a person on departing out of his own country, and addressed to his friends or relations.

**APOCALYPSE**, one of the sacred books of the New Testament, so called from its containing revelations concerning several important doctrines of Christianity.

**APOCARPASMUM**, a poisonous drug, otherwise called *carpasmum*.

**APOCHYLISMA**, in pharmacy, the same with **ROB**. See **ROB**.

**APOCOPE**, among grammarians, a figure which cuts off a letter or syllable from the end of a word; as *ingeni* for *ingenii*.

**APOCRISIARIUS**, in antiquity, an officer who delivered the messages of the emperor. He became afterwards chancellor, and kept the seals. It was also a title given to a bishop's resident at court, to the pope's deputy at Constantinople, and to the treasurer of a monastery.

**APOCRUSTICS**, in medicine, the same with repellents. See **REPELLENTS**.

**APOCRYPHAL**, denotes something dubious, and is more particularly applied to such books as are not admitted into the canon of scripture, being either not acknowledged as divine, or rejected as heretical and spurious. The apocryphal books, according to the sixth article of the church of England, are to be read for example of life and instruction of manners; but it doth not apply them to establish any doctrine.

**APOCYNUM**, in botany, a genus of the pentandria digynia class. The corolla is campaniform, or shaped like a bell. There are five species, all natives of America.

**APODICTICAL**, among philosphers, a term importing a demonstrative proof, or systematical method of teaching.

**APODOSIS**, in rhetoric, the same with axiosis. See **AXIOSIS**.

**APODYTERIUM**, in the ancient baths, the apartments where persons dressed and undressed.

**APOGEE**, in astronomy, that point of the orbit of a planet or the sun which is farthest from the earth.

**APOLLINARIAN games**, in Roman antiquity, an appellation given to certain theatrical entertainments celebrated annually in honour of Apollo.

**APOLLINARIANS**, or **APOLLINARISTS**, in church-history, a sect of heretics who maintained, that Jesus Christ had neither a rational human soul, nor a true body.

**APOLLINARIS**, in botany. See **HYOSCYAMUS**.

**APOLLONIA**, in antiquity, an annual festival celebrated by the Ægialians in honour of Apollo.

**APOLLONIA**, in geography, a promontory of Africa, upon the coast of Guinea, near the mouth of the river Mançu.

**APOLOGUE**, in matters of literature, an ingenious method of conveying instruction by means of a feigned relation called a moral fable.

The only difference between a parable and an apologue is, that the former being drawn from what passes among mankind, requires probability in the narration; whereas the apologue, being taken from the supposed actions of brutes, or even of things inanimate, is not tied down to the strict rules of probability. Æsop's fables are a model of this kind of writing.

**APOLOGY**, a Greek term, literally importing an excuse, or defence of some person or action.

**APOMELL**, among ancient physicians, a decoction of honey and vinegar, much used as a detergent, promoter of stool, urine, &c.

**APONEUROSIS**, among physicians, a term sometimes

used to denote the expansion of a nerve or tendon in the manner of a membrane; sometimes for the cutting off a nerve; and, finally, for the tendon itself.

**APONOGETON**, in botany. See **ZANNICHELLIA**.

**APOPHASIS**, a figure in rhetoric, by which the orator, speaking ironically, seems to wave what he would plainly insinuate: as, *Neither will I mention those things, which if I should, you, notwithstanding, could neither confuse nor speak against them.*

**APOPHEGMATIZANTS**, in pharmacy, medicines proper to clear the head from superfluous phlegm, whether by spitting, or by the nose.

**APOPHTHEGM**, a short, sententious, and instructive remark, pronounced by a person of distinguished character. Such are the apophthegms of Plutarch, and those of the ancients collected by Lycothens.

**APOPHYGE**, in architecture, a concave part or ring of a column, lying above or below the flat member. The French call it *le conge d'en bas*, or *d'en haut*; the Italians, *cavo di basso*, or *di sopra*; and also, *il vivo di basso*. The apophyge originally was no more than the ring or ferril, at first fixed on the extremities of wooden pillars, to keep them from splitting; which afterwards was imitated in stone.

**APOPHYSIS**, in anatomy, a process or protuberance of a bone.

**APOPLEXY**, a distemper in which the patient is suddenly deprived of all his senses, and of voluntary motion. See **MEDICINE**, title, *Apoplexy*.

**APORIA**, is a figure in rhetoric, by which the speaker shews, that he doubts where to begin for the multitude of matter, or what to say in some strange and ambiguous thing; and doth, as it were, argue the case with himself. Thus Cicero says, *Whether he took them from his fellows more impudently, gave them to a harlot more lasciviously, removed them from the Roman people more wickedly, or altered them more presumptuously, I cannot well declare.*

**APOSIOPESES**, a form of speech, by which the speaker, through some affection, as sorrow, bashfulness, fear, anger, or vehemency, breaks off his speech before it be all ended. A figure, when speaking of a thing, we yet seem to conceal it, though indeed we aggravate it; or when the course of the sentence begun is so stayed, as thereby some part of the sentence, not being uttered, may be understood; as, *I might say much more, but modestly commands silence.*

**APOSTACY**, the abandoning the true religion. The primitive Christian church distinguished several kinds of apostacy. The first, of those who went over entirely from Christianity to Judaism; the second, of those who mingled Judaism and Christianity together; and the third, of those who complied so far with the Jews as to communicate with them in many of their unlawful practices, without making a formal profession of their religion. But the fourth sort was of those who, after having been sometimes Christians, voluntarily relapsed into Paganism.

**APOSTASIS**, in medicine; the same with abscess. See **ABSCESS**.

**APOSTATE**, one who deserts his religion. Among the

the Romanists, it signifies a man who, without a legal dispensation, forsakes a religious order of which he had made profession. Hence,

**APOSTATA capiends**, in the English law, a writ that formerly lay against a person, who having entered into some order of religion, broke out again, and wandered up and down the country.

**A POSTERIORI**, or demonstration *à posteriori*. See **DEMONSTRATION**.

**APOSTHUME**, or **APOSTEM**, the same with abscess. See **ABSCESS**.

**APOSTIL**, in matters of literature, the same with a marginal note.

**APOSTLE** properly signifies a messenger or person sent by another upon some business; and hence, by way of eminence, denotes one of the twelve disciples commissioned by Jesus Christ to preach the gospel.

The apostles are usually represented with their respective badges: Thus Peter is painted with the keys; Paul, with a sword; Andrew, with a cross; James the greater, with a pilgrim's staff; James the less, with a fuller's pole; John, with a cup and winged serpent flying out of it; Bartholomew, with a knife; Philip, with a long staff, the upper end of which is formed into a cross; Thomas, with a lance; Matthew, with a hatchet; Matthias, with a battle-axe; Simon, with a saw; and Jude, with a club.

**APOSTLES creed**. See **CREED**.

**APOSTLES ointment**. See **OINTMENT**.

**APOSTOLICI**, an early sect of Christians, who pretended to lead their lives in imitation of the apostles. They condemned marriage.

**APOSTROPHE**, in rhetoric, a figure by which the orator, in a vehement commotion, turns himself on all sides, and applies to the living and dead, to angels and to men, to rocks, groves, &c. Thus Adam, in Milton's Paradise Lost,

*O woods, O fountains, hillocks, dales, and bowers,  
With other echo, &c.*

**APOSTROPHE**, in grammar, the contraction of a word by the use of a comma; as *call'd for called, tho' for though*.

**APOTACTITES**, in church-history, a name given to the Apostolici, from the shew they made of renouncing the world more than other men. See **APOSTOLICI**.

**APOTHECARY**, one who practises the art of pharmacy.

**APOTHEOSIS**, in antiquity, a ceremony by which the ancient Romans complimented their emperors and great men, after their death, with a place among the gods. It is described as follows. After the body of the deceased had been burnt with the usual solemnities, an image of wax, exactly resembling him, was placed on an ivory couch, where it lay for seven days, attended by the senate and ladies of the highest quality in mourning; and then the young senators and knights bore the bed of state through the *via sacra* to the old forum, and from thence to the *campus martius*, where it was deposited upon an edifice built in form of a pyramid. The bed being thus placed amidst a quantity of spices and other combustibles, and the knights having made a solemn procession round the pile, the new emperor, with a torch in his hand, set fire to it, whilst an eagle,

let fly from the top of the building, and mounting in the air with a firebrand, was supposed to convey the soul of the deceased to heaven; and thenceforward he was ranked among the gods.

**APOTOME**, in geometry, the difference between two incommensurable lines.

**APOTOME**, in music, the difference between a greater and lesser semi-tone, expressed by the ratio 128 : 125.

**APOZEM**, in medicine, the same with decoction. See **DECOCTION**.

**APPARATUS**, a term used to denote a complete set of instruments, or other utensils, belonging to any artist or machine: thus we say a surgeon's apparatus.

**APPARENT**, in a general sense, something that is visible to the eyes, or obvious to the understanding.

**APPARENT**, among mathematicians and astronomers, denotes things as they appear to us, in contradistinction from real or true: thus we say, the apparent diameter, distance, magnitude, place, figure, &c. of bodies.

**APPARENT heir**, in Scots law, the person entitled to succeed to the estate of a defunct, before he is actually entered. See **SCOTS LAW**, title, *Succession in heritable rights*.

**APPARITION**, in a general sense, denotes simply the appearance of a thing. In a more limited sense, it is used for a spectre or ghost.

**APPARITOR**, among the Romans, a general term to comprehend all attendants of judges and magistrates appointed to receive and execute their orders. Apparitor, in England, is a messenger that serves the process of a spiritual court, or a bacdle in an university who carries the mace.

**APPARURA**, among old law-writers, signifies furniture or tackle, particularly that belonging to a plough.

**APPAUMEE**, in heraldry, denotes one hand extended with the full palm appearing, and the thumb and fingers at full length.

**APPEAL**, in law, the removal of a cause from an inferior to a superior court or judge, when a person thinks himself aggrieved by the sentence of the inferior judge. Appeals lie from all the ordinary courts of justice to the House of Lords. In ecclesiastical causes, if an appeal is brought before a bishop, it may be removed to the archbishop; if before an archdeacon, to the court of arches, and thence to the archbishop; and from the archbishop's court, to the king in chancery.

**APPEAL of main**, is the accusing one that has maimed another.

**APPEARANCE**, in a general sense, the exterior surface of a thing, or that which immediately strikes the senses.

**APPEARANCE**, in law, signifies a defendant's filing a common or special bail, on any process issued out of a court of judicature.

**APPELLANT**, in a general sense, one who appeals. See **APPEAL**.

**APPELLANTS**, in church-history, an appellation given to such of the catholic clergy, as appeal from the constitution unigenitus, to a general council.

**APPELLATIVE**. Words and names are either common or proper. Common names are such as stand for universal ideas, or a whole rank of beings, whether general

- neral or special. These are called *appellatives*. So fish, bird, man, city, river, are common names; and so are trout, eel, lobster; for they all agree to many individuals, and some to many species.
- APPELLEE**, among lawyers, the person against whom an appeal is brought. See **APPEAL**.
- APPENDIX**, in literature, a treatise added at the end of a work, to render it more complete.
- APERCEPTION**, or **ADPERCEPTION**, a term used by Leibnitz and his followers for consciousness.
- APPURTINANCES**, the same with *appurtenances*. See **APPURTENANCES**.
- APPETITE**, in a general sense, the desire of enjoying some object supposed to be conducive to our happiness.
- APPETITE**, in medicine, a certain painful or uneasy sensation, always accompanied with a desire to eat or drink.
- APPLAUSE**, an approbation of something, signified by clapping the hands, still practised in theatres.
- APPLE**, the fruit of the *pyrus malus*, or apple-tree. See **PYRUS**.
- APPLE of the eye**, a name not unfrequently given to the pupil. See p. 280.
- APPLEBY**, the chief town of the county of Westmoreland, situated on the river Eden, in  $2^{\circ} 26'$  W. long. and  $54^{\circ} 30'$  N. lat. It sends two members to parliament.
- APPLICATE**, or **ORDINATE** *applicata*, in geometry. See **ORDINATE**.
- APPLICATION**, in a general sense, is the laying two things together, in order to discover their agreement or disagreement.
- APPLICATION**, in geometry, is used either for division, for applying one quantity to another, whose areas, but not figures, shall be the same; or, for transferring a given line into a circle, or other figure, so that its ends shall be in the perimeter of the figure.
- APPLICATION**, among divines, a term used to signify the same as *imputation*. See **IMPUTATION**.
- APPOGIATURA**, in music, a small note inserted by the practical musician, between two others, at some distance.
- APPOINTE'E**, a foot-soldier, or officer in the French army, who receives a greater pay than others of the same rank, in consideration of his valour or long service.
- APPOINTE'E**, in heraldry, the same as *aguisee*: Thus we say, a cross appointed, to signify that which two angles at the end cut off, so as to terminate in points.
- APPOINTMENT**, in a general sense, the same as *assignment*. See **ASSIGNATION**. In a more restrained sense, it signifies a pension given by princes and noblemen to retain certain persons in their service.
- APPORTIONMENT**, in law, the division of a rent into parts, in the same manner as the land out of which it issues is divided.
- APPOSITION**, in grammar, the placing two or more substantives together in the same case, without any copulative conjunction between them; as, *Ardebat ALEXIM delicias devini*.
- APPRAISING**. See **APPRYISING**.
- APPREHENSION**, in logic, the first or most simple act of the mind, whereby it perceives, or is conscious of some idea. See **PERCEPTION**, and **LOGIC**.
- APPRYISING**, in Scots law, the name of that action by which a creditor formerly carried off the estate of his debtor for payment. It is now abolished, and adjudications are appointed in place of it. See **SCOTS LAW**, title, *Appryings and Adjudications*.
- APPROACH**, or **APPROACHING**, in a general sense, the acceding or coming together of two or more things.
- APPROACHES**, in fortification, the works thrown up by the besiegers, in order to get nearer a fortress, without being exposed to the enemies cannon.
- APPROACHING**, in gardening, the inoculating or ingrafting the sprig of one tree into another, without cutting it off from the parent-tree.
- APPROACHING**, in fowling, a method of getting nearer the birds by means of a machine, made of hoops and boughs of trees, within which the sportsman conceals himself.
- APPROPRIARE** *communiam*, in law, is to discommen, that is, to inclose any parcel of land that before was open and common.
- APPROPRIARE ad honorem**, to bring a manor within the liberty of an honour. See **MANOR**, and **HONOUR**.
- APPROPRIATION**, in law, a severing of a benefice ecclesiastical to the proper and perpetual use of some religious house, or dean and chapter, bishoprick, or college; because, as persons ordinarily have no right of fee simple, these, by reason of their perpetuity, are accounted owners of the fee simple; and therefore are called *propriators*. To an appropriation, after the licence obtained of the king in chancery, the consent of the diocesan, patron, and incumbent, are necessary, if the church be full; but, if the church be void, the diocesan and the patron, upon the king's licence, may conclude.
- APPROXIMATION**, in arithmetic and algebra, the coming nearer and nearer to a root, or other quantity sought, without expecting to be ever able to find it exactly.
- APPUI**, in the menage, the sense of the action of the bridle in the horseman's hand. Thus we say, a horse has no *appui*, when he cannot suffer the bit to bear never so little upon the parts of the mouth. To give a horse a good *appui*, he should be galloped, and put often back.
- APPULSE**, in astronomy, the approach of a planet towards a conjunction with the sun or any of the fixed stars.
- APRICOT**, in botany, the English name of the *prunus Armeniaca*. See **PRUNUS**.
- APRIL**, in chronology, the fourth month of the year, containing only 30 days.
- A PRIORI**, a kind of demonstration. See **DEMONSTRATION**.
- APRON**, in gunnery, the piece of lead which covers the touch-hole of a cannon. See **CANNON**.
- APRIS**, in astronomy, a term used indifferently for either of the two points of a planet's orbit, where it is at the greatest or least distance from the sun or earth.

- Hence the line connecting these points is called the *line of the apsidæ*. See **ASTRONOMY**.
- APsis**, among ecclesiastical writers, denotes the inner part of the ancient churches, answering to the modern choir. It is also used for the bishop's throne, and sometimes for the ambo. See **AMBO**.
- APSYRTUS**, in botany. See **MARRUBIUM**.
- APTE**, a small city of Provence, in France, situated about 25 miles north of Aix, in 5° 20' E. long. and 43° 50' N. lat.
- APTERA**, the term used by Linnæus for his seventh order of insects, comprehending such as have no wings.
- APTHANE**, a title anciently given to the highest degrees of nobility in Scotland. See **THANE**.
- APTOTE**, among grammarians, an indeclinable noun, or one which has no variation of cases.
- APUA**, in ichthyology, an obsolete name of the gobius. See **GOBIUS**.
- APULIA**, or **PUGLIA**, in geography. See **PUGLIA**.
- APUS**, in ornithology, the trivial name of a species of hirundo. See **HIRUNDO**.
- APYCNi Suoni**, in music, sounds distant one or more octaves, and yet concord.
- APYCNOS**, in music, is said of the diatonic genus, on account of its having spacious intervals, in comparison of the chromatic and enharmonic. See **DIATONIC**, **CHROMATIC**, &c.
- APYREXY**, among physicians, denotes the intermission of a fever.
- AQUA**, a term frequently met with in the writings of physicians, chemists, &c. for certain medicines, or menstrua, in a liquid form, distinguished from each other by peculiar epithets; as,
- AQUA alexiteria**, a water distilled from mint, sea-wormwood, and angelica; and said to be good in malignant and pestilential cases.
- AQUA aluminosa**, alum-water, a solution of water and white vitriol; esteemed good in ulcers and cutaneous eruptions.
- AQUA fortis**, a corrosive liquor, made by distilling purified nitre with calcined vitriol, or rectified oil of vitriol, in a strong heat; the liquor, which rises in fumes red as blood, being collected, is the spirit of nitre or aqua fortis; which serves as a menstruum for dissolving silver, and all other metals, except gold. But if sea-salt, or sal ammoniac be added to aqua fortis, it commences *aqua regia*. Aqua fortis is commonly held to have been invented about the year 1300; though others will have it to have been known in the time of Moses. It is serviceable to refiners: in separating silver from gold and copper: to the workers in mosaic, for staining and colouring their woods; to dyers, in their colours, particularly scarlet; and to other artists, for colouring bone and ivory. With aqua fortis bookbinders marble the covers of books, and diamond-cutters separate diamonds from metalline powders. It is also used in etching copper or brass plates. See **CHEMISTRY**, *Of the nitrous acid*.
- AQUA marina**, a name by which the jewellers call the beryl, on account of its sea-green colour. See **BERYL**.
- AQUA mercurialis**, a solution of sublimate of mercury, and a little mercury, in aqua regia.
- AQUA mirabilis**, the wonderful water, is prepared of cloves, galangals, cubebs, mace, cardomums, nutmegs, ginger, and spirit of wine, digested 24 hours, then distilled. It is a good and agreeable cordial.
- AQUA omnium forum**, in pharmacy, the water distilled from the dung of cows, when they go to grass; in English, *All-flower-water*.
- AQUA regia**, an acid corrosive spirit, so called, because it serves as a menstruum to dissolve gold, commonly esteemed the king of metals. Its basis, or essential ingredient, is common sea-salt, the only salt in nature which will operate on gold. It is commonly prepared by mixing common sea-salt, or sal ammoniac, or the spirit of them, with spirit of nitre, or common aqua fortis. See **CHEMISTRY**, title, *Of aqua regia*.
- AQUA secunda**, denotes aqua fortis, which has been used to dissolve fine metal.
- AQUA sulphurata**, the same with gas sulphuris. See **GAS**.
- AQUA vite**, the water of life, a name given to malt spirits in contradistinction from brandy.
- AQUA vitriolica caerulea**, a solution of blue vitriol and alum, with some spirit of vitriol, in water; recommended in inflammatory and putrid cases.
- AQUÆ pavor**, in medicine. See **HYDROPHOBIA**.
- AQUÆDUCT**, in hydraulics and architecture, a conveyance made for carrying water from one place to another. Those of the ancient Romans were surpassingly magnificent. That which Lewis XIV. built near Maintenon, for carrying the Bucq to Versailles, is perhaps the greatest now in the world: It is seven thousand fathoms long, with two thousand five hundred and sixty fathoms of elevation, and contains two hundred and forty-two arcades.
- AQUA-NEGRA**, a small town of the Mantuan, in Italy, situated upon the Chief, in 9° E. long. and 45° 10' N. lat.
- AQUAPENDENTE**, a city of the ecclesiastical state, in Italy, situated upon the river Paglia, abounding in waters.
- AQUARIANS**, in church-history, an ancient sect of heretics, who, under pretence of abstinence, made use of water instead of wine in the eucharist.
- AQUARIUS**, in astronomy, a constellation which makes the eleventh sign in the zodiac, marked thus ♒. See **ASTRONOMY**.
- AQUARTIA**, in botany, a genus of the tetrandria monogynia class. There is only one species, called *aculeata*, a native of Europe.
- AQUATIC**, in natural history, an appellation given to such things as live or grow in the water.
- AQUAVIVA**, a town of the kingdom of Naples, and province of Barri.
- AQUEDUCT**. See **AQUÆDUCT**.
- AQUELEIA**, a patriarchal city of Italy, near the end of the gulph of Venice, situated in 13° 30' E. long. and 46° 20' N. lat.
- AQUEOUS**, in a general sense, something partaking of the nature of water, or that abounds with it.

**AQUEOUS humour**, in anatomy. See p. 239.

**AQUIFOLIUM**, in botany, the trivial name of a species of *Ilex*. See *Ilex*.

**AQUILA**, in ornithology, a synonyme of the falco, or eagle. See *FALCO*.

**AQUILA**, in astronomy, a constellation of the northern hemisphere. See *ASTRONOMY*.

**AQUILA**, in geography, a large city of Abruzzo, in the kingdom of Naples, situated in 14° 20' E. long. and 42° 40' N. lat.

**AQUILEGIA**, or **COLUMBINE**, in botany, a genus of the polyandria pentagynia class. It has no calix; the petals are five, and five horn-like nectaria are inserted betwixt each petal; it has also five separate capsules. There are three species of aquilegia, *viz.* the vulgaris, or common columbine, a native of Britain; the alpina, a native of Switzerland; and the Canadensis, a native of Virginia and Canada. The aquilegia is reckoned to be an aperient, but has long since given way to more powerful medicines.

**AQUILICUM**, or **AQUILICIANA**, in Roman antiquity, sacrifices performed in times of excessive drought, to obtain rain of the gods.

**AQUILINE**, something belonging to, or resembling an eagle: Thus, an aquiline nose is one bent somewhat like an eagle's beak.

**AQUINO**, a ruinous city in the province of Lavoro, in the kingdom of Naples, situated in 14° 30' E. long. and 41° 30' N. lat.

**ARA**, in astronomy, a southern constellation, containing eight stars.

**ARABET**, a town of Turkish Tartary, situated near the Palus Mæotis. It is fortified with two castles; and is the place where the khan keeps his stud of horses, which are reckoned to be about seven thousand in number.

**ARABIA**, a large country of Asia, having Turkey on the north, Persia and the gulf of Persia on the east, the Indian ocean on the south, and the Red sea and isthmus of Suez on the west; and situated between 23° and 60° E. long. and between 12° and 30° N. lat.

Arabia, though subject to a great many different princes, is only considered by geographers as subdivided into the three grand divisions of Arabia Felix, Arabia Deserta, and Arabia Petrea.

**ARABIAN**, or **ARABIC**, in a general sense, something belonging to Arabia: Thus we say, Arabian characters, Arabian language, &c. See *HEBREW*.

**Gum ARABIC**, the name of a gum which distills from the Egyptian acacia tree. It is brought to us from Turkey, in small irregular masses or strings of a pale yellow colour. The true gum-arabic is rarely to be met with in the shops, gum-senega being usually sold in place of it: This resembles the other, but is generally in large rough pieces. The true kind is preferred as a medicine; but the other is cheapest and strongest, and therefore preferred for mechanical uses. It is given, from a scruple to two drams, in hoarseness, a thin acrimonious state of the juices, and where the natural mucus of the intestines is abraded. It is likewise an in-

gredient in the white decoction, chalk julep, and other compositions.

**ARABICI**, a sect of heretics, who held, that the soul both dies and rises again with the body.

**ARABIS**, in botany, a genus of the tetradynamia filiquosa class. The generic mark is taken from four nectariferous glands which lie on the inside of each leaf of the calix. There are eight species of arabis, none of which are natives of Britain, except the thaliana, or coded mouse-ear.

**ARABISM**, in language, an idiom peculiar to the Arabian language.

**ARABLE lands**, those which are fit for tillage, or which have been formerly tilled.

**ARACK**, **ARRACK**, or **RACK**, a spirituous liquor imported from the E. Indies, used by way of dram and its punch. The word *arack* is an Indian name for strong waters of all kinds; for they call our spirits and brandy *Englisb arack*. But what we understand by the name *arack*, is really no other than a spirit procured by distillation from a vegetable juice called *toddy*, which flows by incision out of the cocoa-nut tree. There are divers kinds of it; single, double, and treble distilled. The double distilled is commonly sent abroad, and is preferred to all other aracks of India.

**ARACAN**, the capital city of a small kingdom, situated on the north-east part of the gulf of Bengal, in 93° E. long. and 20° 30' N. lat.

**ARACARI**, in ornithology, the trivial name of a species of ramphastos. See *RAMPHASTOS*.

**ARACH**, the chief city of Arabia Petrea, situated in 49° E. long. and 30° 20' N. lat.

**ARACHIS**, in botany, a genus of the diadelphia decandria class. There is only one species, *viz.* the hypogæa, a native of America. The calix is divided into two parts; and the capsule or pod is cylindrical, and contains two seeds.

**ARACHNOIDES**, in anatomy, an appellation given to several membranes, as the tunic of the crystalline humour of the eye, the external lamina of the pia mater, and one of the coverings of the spinal marrow.

**ARÆOMETER**, an instrument to measure the gravity of liquors, which is usually made of a thin glass ball, with a taper neck, sealed at the top, there being first as much mercury put into it as will keep it swimming in an exact posture. The neck is divided into two parts, which are numbered, that so by the depths of its descent into any liquor, its lightness may be known by these divisions.

**ARÆOSTYLE**, in architecture, a term used by Vitruvius, to signify the greatest interval which can be made between columns.

**ARÆOTICS**, in medicine, remedies which rarefy the humours, and render them easy to be carried off by the pores of the skin.

**ARAF**, among the Mahometans. See *ALARAF*.

**ARAFAT**, a mountain of Arabia, near Mecca, where the Mahometans believe that Abraham offered to sacrifice Ishmael.

**ARAGON**, a province of Spain, having Biscay and the Pyrenean mountains on the north, Catalonia on the

the east, Valencia on the south, and the two Castiles on the west.

**ARAIGNEE**, in fortification, signifies the branch, return, or gallery of a mine. See **MINE**.

**ARALIA**, in botany, a genus of the pentandria pentagynia class. The involucrum is an umbella; the calix has five teeth, and is above the fruit; the corolla has five petals; and the berry has five seeds. There are five species of aralia, all natives of the Indies.

**ARALIASTRUM**, in botany. See **PANAX**.

**ARANDA de Duero**, a city of Old Castile, in Spain, situated on the Duero, between Osma and Valladolid; so called, to distinguish it from another city of the same name, situated upon the Ebro.

**ARANEÆ**, the **SPIDER**, a genus of insects belonging to the order of aptera, or insects without wings. All the species of spiders have eight legs, with three joints in each, and terminating in three crooked claws; eight eyes, two before, two behind, and the rest on the sides of the head. The mouth consists of two claws or talons, denticulated like a saw. A little below the point of the claw, there is a small hole, through which the spider emits a kind of poison. These claws are the weapons with which they kill flies, &c. for their food. The belly or hinder part is separated from the head and breast by a small thread-like tube. The skin or outer surface is a hard polished crust. Spiders have five tubercles or nipples at the extremity of the belly, whose apertures they can enlarge or contract at pleasure. It is through these apertures that they spin a gluey substance with which their bellies are full. They fix the end of their threads by applying these nipples to any substance, and the threads lengthen in proportion as the animal recedes from it. They can stop the issuing of the threads by contracting the nipples, and re-ascend by means of the claws on their feet, much in the same manner as some men warp up a rope. When the common house-spider begins her web, she generally chuses a place where there is a cavity, such as the corner of a room, that she may have a free passage on each side, to make her escape in case of danger. Then she fixes one end of her thread to the wall, and passes on to the other side, dragging the thread along with her, (or rather the thread follows her as she proceeds), till she arrives at the other side, and there fixes the other end of it. Thus she passes and repasses, till she has made as many parallel threads as she thinks necessary for her purpose. After this, she begins again and crosses these by other parallel threads, which may be named the *woof*. These are the toils or snares which she prepares for entangling flies, and other small insects, which happen to light upon it. But, besides this large web, she generally weaves a small cell for herself, where she lies concealed watching for her prey. Betwixt this cell and the large web, she has a bridge of threads, which, by communicating with the threads of the large one, both give her early intelligence when any thing touches the web, and enables her to pass quickly in order to lay hold of it. There are many other methods of weaving peculiar to different species of spiders. But,

as they are all intended for the same purpose, it is needless to give particular descriptions of them.
