	Spectrum	Isochromatic Spectrum	Ordinary Isochromatic Spectrum	Ordinary Isochromatic Spectrum

Such a tabulation shows at a glance the general capability of the plate used. With the ordinary plate we obtain no record of either the green, yellow, or red; with the isochromatic we obtain no record of the red, but one-half the value of the yellow, while with the spectrum plate we are enabled to obtain a record of all colours.

A very pertinent question at this point would be, "Why do we obtain a negative on the ordinary plate if it is not sensitive to the colours which the object presents?" The answer to which is that in nature (fortunately for photography) we are not dealing with pure colours, but with colours which

also contain varying amounts of all the others, and also ultra-violet. Red, for example (in nature), is not red solely, but reflects to the eye also green, blue-violet, and ultra-violet; it appears red simply because that is the hue which it reflects most of. The plate, therefore, is acted upon by these regions (or colours) to which it is sensitive, i.e., the impurities in the colour, and not by the colour itself; hence, when using "ordinary" plates the negative is formed by blue-violet and ultra-violet, and not by the yellows, pinks, and reds.

It is equally obvious that by making use of an isochromatic plate we have a material advantage by the increase in the

Red. Green. Blue-Violet. Ultra-Violet.
Fig. 1.

range of colour sensitiveness, and with the spectrum plate a still greater advantage, because we have a plate sensitive to the entire gamut of colour. This increasing extent of colour sensitiveness is well shown in the accompanying illustrations, which are exposures of the spectrum with the three types of plates enumerated. (Fig. 1.)

The subject is not concluded with such extreme simplicity, however, for although the "iso" and "spectrum" plates are respectively sensitive to green and red, yet the sensitiveness to the blue-violet is by far the strongest, while the ultra-violet is equally strong on all three. In reality, the red and green present an almost equal brightness to the eye, while the blue-violet is very much darker, so that if the plate-sensitiveness were to correspond, then the action would be considerably

changed, and the red and the green present the highest maxima.

In order to obtain this correct relative intensity it is, therefore, customary to cut down the excessive sensitiveness to the blue-violet by means of a colour filter (or "ray filter" as it is popularly termed), whose function is the absorption of a portion of the blue-violet—that is to say, it dims down this hue to such an extent that it is not able to impress itself so strongly as before. Inasmuch as the ultra-violet is invisible to the eye, it is obvious that we do not want its record; hence every ray filter, to be thoroughly effective, must also absorb completely the ultra-violet. It is not possible by sensitising methods alone to obtain a plate wherein the red or green sensitiveness is greater than the blue-violet; and all claims to the contrary are founded upon results from imperfect testing apparatus; for example, exposures made to the prismatic spectrum, or with an abnormal light source strong in red.

How the Ordinary Plate Accentuates the Sitter's Defects,

It will now be readily apparent that, armed with a plate and colour filter, capable (collectively) of representing colours

D Eb F G HK

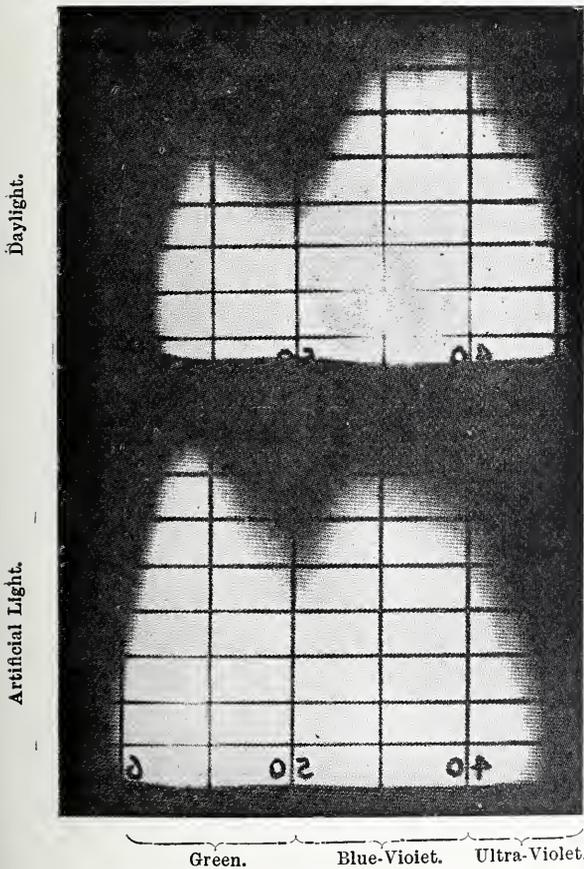

Fig. 2.

in black and white by their relative brightness, the production of prints from such negatives are absolutely certain to be more truthfully correct to visual impression than prints made from another negative obtained by blue-violet and ultra-violet light. Not only is this so, but the "ordinary" plate negative (by reason of its insensitiveness to colour) accentuates strongly every brown freckle and facial blemish, and therefore requires the maximum amount of retouching, while the colour-sensitive plate, simply on account of its very sensitiveness to these colours, renders a result in which retouching is more or less eliminated and dependent upon the amount of correction by the ray filter.

Nothing need be said regarding the improvement in the rendition in the colour of eyes, hair, or costume, because the value of colour-sensitive plates in this respect is now too well known. "Colour-correct" photography is the coming factor in portrait work, just as surely as it has become the premier

factor in landscape, genre, and commercial work. Wise is the man who comes in on the crest of the advancing wave, instead of struggling painfully with the flood.

Drawbacks of the Red-Sensitive Plate.

The "advantages" having been presented, we may glance briefly at the "disadvantages." First, there is the question of speed. It is unfortunately true that a plate may not be specially sensitised for colour without a lowering of the speed to "white light," *i.e.*, daylight. Many photographers, however, make use of artificial light—incandescent gas, acetylene, incandescent electric, and arc. With all such colour-sensitive plates have a marked advantage, because they are making use of a light source which is deficient in the amount of blue-violet and ultra-violet light, compared with daylight, while the red and green are accentuated. That this is so is easily shown by exposures behind, say, a Chapman-Jones or other like form of "plate tester." It will be found that the speed readings of "isochromatic" plates are *higher* than the readings of "ordinary" plates. This is simply due either to the light used or to the yellow-brown colour of the "neutral grey" speed squares. The fairly general use of rapid working modern lenses, however, eliminates the greater portion of this "trouble," and colour filters can readily be obtained to give any amount of correction desired, the principle being that it is obviously better to obtain one-half or even one-quarter correction than no correction at all. Double or triple the present exposure time is a small matter on adult sitters to an operator possessed of modern tools.

The mechanism (so to speak) of the increase in exposure by the use of a "ray filter" is very simple. Suppose, for example, that the speed of any particular colour-sensitive plate be represented by 100 units, of which 15 units are in the red, 15 in the green, 50 in the blue-violet, and 20 in the ultra-violet. If we make use of a ray filter which absorbs only the ultra-violet, then we are cutting off just that 20 units. Consequently, the exposure must be increased to allow of stronger action in the remaining regions to make up the loss. Again, if the filter not only absorbs the ultra-violet, but also reduces the action of the blue-violet to, say, 10 units, we have 20+40=60 units, with a correspondingly greater time increase in the exposure. These figures are simply used as an example.

The second "disadvantage" lies in the very colour sensitiveness of the plate itself, for it necessitates that the red-sensitive plate be handled in total darkness. That it must be so handled is simply a tribute to this sensitiveness; but even this point is well met by the use of tank development, a method coming more and more into general use and favour. It is taking the photographer a long time to appreciate that he can't *help* a plate by watching it develop, and that he can get better and more uniform results by "tank methods" than ever before. Advancement is slow, however, and in this instance by hard travail, verily "there is no pain like the pain of a new idea."

The use of the mercury vapour lamp is not to be commended with colour-sensitive plates, because this light is practically devoid of red. This brings us to a consideration of the difference in "general" sensitiveness of a plate when used with abnormal light sources.

Any light is termed abnormal which differs in its constitution from daylight; that is to say, which has different relative distribution of intensity throughout the different hues. As has already been stated, the artificial illuminants previously mentioned have relatively a stronger action in the red and green than daylight, and this increased intensity is well shown in the spectrum curve prints of Fig. 2, which shows a comparison of the acetylene flame spectrum with daylight on identical plates. The greatly stronger action to the blue-violet is readily apparent in the daylight exposure, and needs no further comment.

R. J. WALLACE.

ON THE INFLUENCE OF BORIC ACID ON THE KEEPING AND WORKING QUALITIES OF THE DIAMIDOPHENOL DEVELOPER.

(A Paper read before the recent Congress of Applied Chemistry.)

SOME years since, a recommendation was made by the present writer as to the use of boric acid in alkaline developers as an excellent means of correcting over-exposure. It was found that boric acid is particularly active when used in conjunction with potassium bromide, and the suggestion was made to use a 10 per cent. solution of potassium bromide saturated with boric acid, this mixture being kept in readiness in the dark-room. This bromo-boric acid solution has been adopted by many, whilst others have informed me that the use of a similar solution has been found of advantage by Dr. Dillaye in the development of bromide prints.

In the course of further experiments on the use of boric acid in conjunction with different developers I have found that, in the case of solutions which work only when containing an alkali, the action of the boric acid is distinctly different from that which is observed in developers such as diamidophenol, which do not require alkali. In the case of the former solutions the boric acid exerts only a notable restraining action on the developer, whilst on the other hand, in the case of diamidophenol made up in the usual way, without bromide but saturated with boric acid, it is found that the effect of the latter on the development is not noticeable. The appearance of the image is restrained so little that in cases of over-exposure the effect is nil. The only distinct advantage is that a diamidophenol developer containing as much as 50 gms. per litre of boric acid keeps much better than the ordinary formula, so that it is not necessary to make up the solution at the time of use. Further, a bath so prepared appears to be sensitive to differences in temperature to a far slighter extent, since the solution has been employed up to a temperature of 77 deg. Fahr. without difficulty.

I find that potassium bromide possesses only a very limited restraining action upon diamidophenol, so that very considerable quantities require to be added in order to correct errors of exposure.

It is, therefore, on this account that bisulphite solution is advisably added to the diamidophenol developer when thus dealing with over-exposure. The bisulphite, however, possesses the property of weakening the reducing power of the developer, and even when present above a certain limit, of almost entirely suppressing its activity. When containing bisulphite, amidol developer, which without such addition possesses a tendency to give weak negatives, gives still less intensity, so that, as Lumière and Seyewetz have recently pointed out, the development is restrained without the contrasts being improved. So

far as concerns the preservation of the solution the small quantity of bisulphite which may be safely added to the diamidophenol solution exerts a very slight influence on the latter, as already shown from the figures given in a previous contribution.

Addition of boric acid by itself to the diamidophenol developer does not possess the drawback of the bisulphite; it does not diminish the reducing power of the amidol, whilst it keeps the bath almost as well as the bisulphite. Used alone, as already stated, the development is restrained only to a very small degree, but it has the advantage of rendering the developer much more sensitive to the action of bromide. Thus the following formula is arrived at:—

Sodium sulphite, cryst.	40 gms.
Boric acid, powder	50 "
Diamidophenol (hydrochloride)	5 "
Water	1,000 ccs.

As examples of the use of this solution, the following times of development are given, the conditions under which the plates were treated being identical in all other respects:—

1. Development with plain diamidophenol developer, as given above, but without boric acid 5 to 6 minutes.
2. Same developer with addition of 3 gms. potass bromide per litre 8 to 9 minutes.
3. Development with diamidophenol and boric acid as given in formula above 6 to 7 minutes.
4. Same developer as in No. 3, but with addition of 3 gms. potass bromide per litre 17 to 20 minutes.

As regards intensity of the denser portions of the negative the four results were the same, but as regards contrast those obtained with bath No. 4, in comparison with the others, showed a greater degree of correction of the over-exposure.

Since it is thus feasible to impart to the cheap diamidophenol developer, by means of addition of large quantities of boric acid, the properties which are possessed only by the more costly developers, it will be clear that the above formulæ should be of value in practice, particularly in the case of the preparation of cinematograph positives, or in making large quantities of bromide prints. Reference should also be made to the fact that the use of a considerable proportion of boric acid in the diamidophenol developer has hygienic reasons for its recommendation, since it greatly diminishes the action of all alkaline developers on the skin to which many persons are liable.

R. NAMIAS.

THE PLATINUM MARKET.—Platinum is likely to be raised in price, according to the measures which the Russian producers are taking. About 95 per cent. of all the platinum in the world comes from the mines of Nijni Taguil and the neighbourhood. The mines are now operated by English, German, French, and Russian companies, but there is now a movement in Russia to keep the platinum production in the hands of a native company or a State enterprise, so as to have Russia benefit by the platinum production instead of foreigners. Last spring (according to a report in the "Scientific American") the Aide of the Minister of Commerce and Industry, M. D. Konvaloff, presided at a meeting of the platinum producers, and the assembly came to the following decision in principle, namely, that all the platinum extracted in Russia should be turned over to a State establishment, which would deliver it to a commission charged

with the sale of the same, and to be composed of seven members, a delegate of the lesser manufacturers, one from the mean, and four from the leading, producers, who handle more than 800 pounds annually, also a Government delegate. This commission will make a reckoning before the end of the fiscal year, and will publish the least price established for the following year. For the first year the price will be 21,000 roubles the pound (\$710 per pound) for 83 per cent. platinum. Upon the products which are turned over to the State establishment there will be allowed an advance of 80 per cent. of the value, at a 5 per cent. interest. It will be forbidden to export crude platinum, and the refining must be done in Russia. This decision is not as yet legalised, but it may be done in the future and it is expected that the price of platinum will be accordingly raised.

ON GENERAL AND LOCAL PHOTOGRAPHS IN MUSEUMS.

(A paper read before the Maidstone Conference of the Museums Association.)

II.

The Second-hand Photograph.

AND exactly the same cause is productive of another difficulty for the collector of photographs. Few, I suppose, in the first instance desire to collect reproductions of every kind of art, ancient as well as modern. Yet before he has long been at work collecting some particular category, he will find himself the involuntary possessor of works of art of all sorts of other categories. If, for instance, he takes in one of the numerous German publications such as *Das Museum* or the French *Les Arts*, he will find that besides the particular school of art which interests him, all other schools will be represented in the plates that come to him month by month. It will frequently happen that the very print he wants is to be found in a casual number of some art magazine, which he therefore buys; but after abstracting the particular print desired he will have on his hands perhaps two or three dozen more, many of them doubtless of no little intrinsic interest, but belonging to altogether different schools and periods from the school and period that he may have selected for his own study. If he keeps these, as he will of course tend to do, and roughly group them together in their proper places, before he realises what he is doing he will find that he is collecting the art of all sorts of periods and of schools which he never intended to regard. Somewhere else, no doubt, there is a student who would gladly relieve him of whole groups of these bye-products of his own search; but until the commercial organisation of the photograph trade is further advanced, no means exist for bringing to each of these persons the knowledge of the existence of the other. This is the reason why masses of photographs are annually destroyed which it only requires a little organisation to make of some definite value. I have frequently inquired of second-hand booksellers and print-dealers and persons who attend the smaller auction sales, why it is that though in almost every house there are to be found volumes and portfolios full of photographs which in due course must frequently find a place in sales, such collections of photographs are hardly ever to be found at the second-hand booksellers' and print-dealers'. The answer I receive is always the same, viz., that the price these things fetch is simply that of old paper, and that they are used mainly for packing for the sake of the cardboard on which they are mounted. One man assured me that he had recently bought for a few pence a great pile of Braun's costly photographs and that they had been simply chopped in half and used to pack the parcels of books that he despatched to different parts of the country. It is only on the very smallest second-hand bookstalls that one may sometimes come across a box labelled "Everything here 1d.," in which you will find photographs. Out of such boxes, which I make it a habit to turn over, I have in my time bought photographs of drawings by old masters which have since disappeared, and of buildings which have since been burnt or restored out of recognition. There is no doubt whatever but that the annual destruction of photographs of real importance to the future historian and student of art is very great indeed. And this destruction is entirely due to the fact that though multitudes of people buy photographs, very few as yet buy and arrange them systematically, and therefore the commercial organisation for photograph collectors does not exist. There are shops, of course, galore where you can buy the ordinary run of current production in the photographic line; and some even where a laudable effort is made to keep negatives of objects, of articles and drawings in private collections. But no trade is alive until the articles it supplies have a second-hand value. It is by the second-hand trade that the health of a trade in new objects can best be tested. The fact that some books at any rate are worth far more second-hand than when they were new; the fact that some pictures increase in value from year to year; that some postage stamps grow more valuable as time goes by, stimulates the collection of such objects and gives vitality to the trade in them. Already there exist, as I have said, a multitude of buyers of photographs whom present arrangements suit well enough, and a small but increasing number of systematic collectors for whom no existing agency caters at all. It is probable that the time has already come when a skilful dealer might commence the trade in second-hand photographs and find no little profit in so doing, especi-

ally if he added the collection and storing of negatives on a systematic plan, to the mere buying in of prints.

Multiply the Small Private Collector.

Nothing is more wasteful nowadays than the way in which negatives are cast aside after they have served a temporary purpose. Owners of private collections are unanimous in describing the photographer as a common nuisance. They are continually being applied to by one person after another for permission to photograph objects which have already been photographed half a dozen times before. If there were some place where negatives after serving their first purpose could be stored, for use again when required, an immense amount of overlapping would be saved. Owners, in fact, would be wise to make the condition when they give permission for any of their pictures to be photographed, that the negative should be loaned for a reasonable fee to any other person who had the owner's permission to apply for it. Still better would it be if owners themselves were to require the negative when done with to be returned to them, and were to keep a series of negatives of objects belonging to them in their own possession or use when required. It is frequently the case that when a collection is dispersed by auction, an illustrated catalogue is published. What happens to the negatives no one knows. The pictures are scattered all over the world, the illustrated catalogues remain for the most part in the hands of dealers and are presently destroyed, and the negatives are presumably broken up before many years have passed, or otherwise cease to exist. In the same way, when a picture or a bronze passes through the hands of a dealer, it frequently happens that he has a photograph made of it; and there is reason to believe that if any central establishment were formed for the preservation of negatives, that many dealers would be willing to transfer such negatives to it for a small price. Thus records would be preserved of fine objects passing through the market, and if they afterwards met with misfortune, as some of them must, these records would be of considerable and sometimes priceless value. There is a well known case of a seal of Hittite workmanship which was offered for sale to a great museum years before the work of the Hittites had been identified. The seal was not recognised to be of interest and importance and was returned to the vendor. But by good luck an impression of it was taken and remained in the museum. Years afterwards, when attention was attracted to Hittite archæology, this impression was recalled and was found to be of the greatest interest. Meanwhile the original seal had utterly disappeared and no one has been able to find a trace of it ever since.

The Value of Rare Photographs.

Such is one of a thousand instances that might be quoted of the possible importance of old reproductions. Nothing is easier than to keep them once they have been made, if only there is a proper place to which to send them where persons are employed to take care of and to arrange them. But, as I have said before, the great preservative agency in all such cases is not first of all the big institutions, it is the small collector. One small collector of course can do little, but as soon as he becomes one of many, the search for these perishable objects is carried on by many pairs of eyes peering about in many places. Competition quickens intelligence; co-operation spreads the knowledge. By degrees, that which is rare becomes recognised as rare, obtains a correspondingly increased value, and leads to more vigorous and persistent efforts of search. The danger of destruction attending a rare thing is diminished the moment it is known to be rare. The only original photograph existing of some important picture, let us say, that has since been burnt, would very properly have the value proportionate to the value nowadays assigned to a rare postage stamp. It is a mere question of the number of people who desire an object that determines its price. At present rare photographs are not particularly desired, because nobody knows anything about their rarity and few people realise their importance. Value in the case of postage stamps may indeed be called fictitious, because the objects themselves are of little intrinsic interest, and it is only the fact that so

many people collect that makes the possession of a particular stamp desirable. But in the case of photographs the intrinsic interest may be very great indeed, and if in addition to intrinsic interest great rarity is added, the value arrived at may be far higher than now seems likely. What has made stamps so much sought after has been the competence of the principal dealers in organising the trade. Few trades indeed are so well organised as is the trade in postage stamps. No trade is so badly organised as that of photographs. Nowadays at least the illustrated postcard has begun to be made a matter of collection. This has been due to the fact that the post-card comes very near to the area pastured over by the stamp collector. Here photography and stamp collecting meet. But illustrated post-cards, when all is said for them that can be, are an indifferent kind of photograph, and do not lend themselves to mounting and classification nearly so well as somewhat larger prints. Their single merit is their cheapness and the elaborate organisation that already exists for their sale. Already a tendency is apparent to increase their size by doubling or quadrupling them, and it is probable that out of this further developments may arise which will be important to the collector of photographs. Italy is the only country where the production and sale of photographs has really been carried to a high degree of perfection. With the catalogues published by the chief Italian photographers at hand, it is easy for anybody to order and obtain photographs of almost any kind of work of art existing in Italy. England is perhaps at the other end of the scale—the country in which photograph publication is least efficiently carried out. The moment you happen to want anything outside the most commonplace range of tourists' photographs in England, you find it almost impossible to obtain it. Most things indeed have been photographed, but the work has been sporadically done and the negatives having served their temporary purpose have been destroyed. In Italy, photography is carried on by large firms who have realised, as English photographers have not, that the great touring public

will buy photographs very freely if they are offered at a reasonable price and are made easily accessible. The ordinary Italian photograph costs 5d.; the corresponding English print costs from one to two shillings. In Italy you can hardly find a building or a picture or any object in a museum of any importance where a photograph is not easily obtainable. But even in the National Gallery in London, half the pictures, if photographed at all, are not easily obtainable in the photographic form. If this is true of the National Gallery, how much truer it is of the provincial museums and private collections will be readily guessed. There is room in England not for one, but for several great photographic publishers to cater to the demands of the large touring public, and still more, of the public that seldom tour, but that desire to possess representations of objects they cannot travel to see. If once these two steps could be taken in England, a proper system of publication on the one hand, and an organisation of the second-hand trade on the other, the number of photograph collectors would rapidly increase and the preservation of records of existing objects of beauty and interest would be efficiently carried out. Not till then will a demand arise for the formation of an historical photographic museum such as I have above proposed. The time will certainly come when that museum or something like it will be made. When it is made, its utility will be so obvious, its importance for all sorts of investigations will be so readily recognisable, that the wonder will be why the making of it was so long delayed. Every collector of photographs who nowadays makes the organisation and arrangement of his collection a matter of personal interest will be contributing to this ultimate development. The mere fact that a man goes and searches over second-hand bookstalls for old photographs is itself a stimulus to the bringing together of such objects by dealers. It is in the hope that I may inspire some of my readers to go more methodically to work in this matter that the present article has been written.

MARTIN CONWAY.

DISCUSSION.*

The President: You have already, by your applause, shown your great appreciation of this communication by Sir Martin Conway. Yesterday, when we were visiting his castle at Allington, the absorbing attraction of the castle rather militated against seeing the collection of pictures he has been speaking of. That was a very great loss. But the compensation for us is that we had so much to see; and the loss is somewhat made up by the pleasure we derived from the artistic and noble work being done at the castle in its restoration. It only makes us doubly under an obligation to Sir Martin Conway that he should have come to us this morning with this delightfully breezy account of his labours in the collection of what may be regarded as representing everything in connection with art. He spoke of it as the dropping of a suggestion amongst us; and I cannot help thinking that to some of us the suggestion came rather like a bomb-shell when he spoke of cutting up rare prints. But we have to remember the main object in view—to acquire a collection on a thoroughly comprehensive scale, which shall deal with the whole subject, and be readily accessible for reference. There is only one way in which this can be achieved, and that is by having one definite uniform standard; and the cutting up principle comes in as a necessity when that is accepted. We have to accede to the rigorous necessity of hardening the heart in this direction. The only thing that strikes me is that there must be some limitation to this cutting up. While Sir Martin Conway was describing his collection and methods, it occurred to me that it is most desirable that there should eventually be established a great national collection, based upon the system so ably expounded by him, and I am tempted to express the hope that the splendid collection of photographic and other records which Sir Martin Conway has already developed upon such comprehensive lines may one day form the nucleus of such a national reference collection.

Mr. J. H. Allchin: A few years ago there was established in this county a Kent Photographic Survey, and steady but slow progress has been made up to the present time. Prints when mounted by the secretary are sent to this institution, and I have the charge of them.

The collection of photographs is divided into architecture, antiquities, archæology, natural history, with sub-divisions, landscapes, historic events, etc. When anything of historical importance is taking place we get someone to take a photograph. When the Maidstone volunteers returned from the Boer War there was a reception at the railway station, and we secured several photographs of their subsequent progress through the town. We obtain photographs of everything we can. The prints are kept here for reference and are mounted on stiff brown paper, as we cannot afford expensive mounts, and if paper is used they do not occupy very much space. A label is attached at the bottom of each sheet, giving the classification of the print, the date, locality, and name of photographer. A great many of the pictures, especially the natural history subjects, have been taken by my colleague, Mr. Elgar. One of very great interest shows the overhanging nests of one of our sand-boring wasps, composed of tubes of grains of sand projecting from the tunnel. The Survey is quite a private association, and has nothing to do with the museum.

Dr. F. A. Bather: I should like to express our great thanks to Sir Martin Conway for his address and to make a suggestion concerning the cutting up of prints. As you say, there must be a limitation. I take it he is collecting these objects not as works of art, but as records of works of art or whatever the subject may be. The word "photograph" implies that he does not regard these reproductions as pictures in themselves. But, of course, the time comes when what was originally described as a photograph may be regarded as a work of art. It is all very well to take prints and cut them in pieces for the sake of convenience; I quite appreciate the point of view. But when the reproduction becomes itself the work of art, Sir Martin Conway would no more think of cutting it in two than of sawing through one of the statues of Notre Dame for the sake of putting it into a cube.

Sir Martin Conway: No, I should have it photographed.

Dr. Bather: I expected that.

Mr. Charles Madeley pointed out that it was scarcely possible to prosecute such a work as Sir Martin Conway was doing in a public institution. Many prints such as he dealt with so drastically had to be treated as works of art in the museum, and the Curator was expected to preserve them with respect. At Warrington it had

* In his introductory remarks Sir Martin Conway stated that by "photographs" he meant all kinds of reproductions (on a flat surface), whether photographs, engravings, or lithographs, &c. This explains some comments made during the discussion which would otherwise appear irrelevant.—Ed.

been found possible to do this. While in many instances they had adopted the principles laid down by Sir Martin, they differed from him in matters of detail. They had adopted a different unit and classified according to subject, so that the pictures formed their own index. When, however, they came to deal with records of objects existing near their own town, they found the geographical interest overpowered the topical interest, and they adopted a geographical arrangement. Sir Martin Conway did not mention it, but he did the same thing himself. When, at Allington Castle the previous day, they came to Sir Martin's end box, they found it devoted to pictures of Allington Castle without chronological arrangement. He hoped Sir Martin would forgive him for giving him away, but they had to do the same at Warrington when they got within a certain distance of their own hearth-stone.

Mr. Richard Quick mentioned that something of the kind was done at Bristol, but they photographed the engravings and placed them on cards to make them uniform with the rest.

Mr. Henry D. Roberts inquired if curators had not already enough work to do. A photographic survey in Sussex had been resuscitated, but he had religiously abstained from having anything to do with it beyond arranging and cataloguing the documents which the members brought in. So far as maps, records, and engravings were concerned, they were carefully photographed by themselves. The unit used was not a topographical one, everything went to its own immediate district.

The President thanked Sir Martin Conway for reading as the concluding paper one which would leave a pleasant impression on the minds of members of the Association.

TREATMENT OF STALE GASLIGHT PAPERS.

[The following article in the current issue of "Photo-Notes" suggests that damp is the main cause of trouble with stale gaslight papers, and the results submitted by the author show pretty clearly that a thorough drying of the paper before use will more or less remedy the effect of staleness if the developer is restrained with extra bromide. It must be remembered that all the cases quoted by him were very bad ones, for the paper, when bought, gave perfectly hopeless results, as evidenced by the specimens sent. The effect produced by the drying process is, however, very marked, and from the results we may reasonably conclude that no trouble would have been met with if the paper had been kept dry all the time. The conclusion to be drawn is obvious. We should exercise greater care in storing gaslight paper, and it would be best to adopt precautions similar to those taken with platinum papers.]

I HAVE always contended that the deterioration of gaslight paper is due mainly to one cause—namely, damp. In the course of a long experience of gaslight papers I have often purchased papers of various makes on which it was impossible to get a good print, the chief fault being absolute lack of contrast, the finished result being flat and grey. In some cases, with papers which were known to be old, the development was unequal, the image coming up in spots, at different rates in different parts.

In Oban in autumn, 1908, I purchased some postcards of a brand I have used more than any other. The first prints made from the packet were excellent in every way. The open packet was then put away in a cupboard, which, by the proprietors of the house, was said to be damp. Some days (certainly not more than a week) later I had occasion to use the same packet of paper with the same negatives, and, notwithstanding a liberal use of 10 per cent. bromide solution in the developer, I could get nothing but exceedingly flat prints. The following evening I put the remainder of the same packet in front of the fire for an hour or two, and then with the same developer (but without bromide) that had been used all along the paper once more gave brilliant results.

About the same time I bought a packet of a very old paper that has been off the market for some years. The dealer from whom I bought it considered it valueless, as he had had it in stock for many years. Merely heated it gave grey results, but by gradually increasing the amount of bromide a clean print was got with terrific contrast, as might be expected when in some cases nearly $\frac{1}{2}$ fl. oz. 10 per cent. bromide solution was added to 4 oz. developer. In some cases the tone of the print was greenish, but it gave a good result when sulphide toned. I subsequently bought up the whole stock of this paper from the dealer and had no further trouble.

These experiments were continued on samples of Rotox paper,

obtained from dealers in Stirling, who had laid it aside as useless, various customers having failed with it. On March 25, 1909, I obtained one packet of above paper (No. 3 thin matt smooth) (packet No. 1 hereafter), and one packet Silvo postcards of same make. Both packets were removed from their envelopes and treated in front of the fire for three to four hours. Prints were then made and developed. Every postcard in the packet gave a perfect print. Two pieces of the paper were tried. The first one was hopeless, being dark grey and covered with irregular white spots. After a further heating for an hour the result was slightly improved.

On March 26, 1909, I obtained another packet of same postcards, of which all that were tried were satisfactory. Another packet of paper, same make, was tried (No. 2 hereafter); it was called No. 1 thin glossy rose.

After developing some six postcards, five drops of bromide were added to the 3 oz. developer and a print made from packet No. 1. It was quite good, though development was irregular, streaky, and spotty, but owing to a somewhat exhausted developer, and the addition of bromide, the image came up slowly, and the spots had almost entirely disappeared when development was finished. The print was practically perfect, but the remains of a large white spot may be seen in the form of a light-coloured patch on the bottom edge. Other prints were successfully made in the same way from the same paper.

Packet No. 2 was then tried with same or similar developer. It yielded satisfactory prints on the whole, but a spot can be noticed in the same place on several prints, showing that some exterior cause was to blame, as the outside print was the worst, and the spot got less and finally disappeared after two or three sheets had been used.

R. A. CRISTAL.

FORTHCOMING EXHIBITIONS.

- September 10 to October 23.—The Photographic Salon. Sec. Reginald Craigie, 5A, Pall Mall East, London, S.W.
 September 23 to October 30.—Royal Photographic Society. Sec., J. McIntosh, 35, Russell Square, London, W.C.
 October 21 to 23.—Rotherham Photographic Society. Secs., H. C. Hemingway, Tooker Road, Rotherham, and F. Sargeant, 17, Aldred Street, Rotherham.
 October 27 to 28.—Watford Camera Club. Sec., W. J. Edmonds, 3, The Parade, Watford.
 November 10 to 13.—Hackney Photographic Society. Sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E.
 November 10 to 13.—Cambridge and District Photographic Club. Entries close October 28. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

- November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
 November 29 to December 2.—Lancaster Photographic Society. Entries close November 20. Sec., Thomas Holt, 4, Parliament Street, Lancaster.
 December 4, 1909, to January 1, 1910.—Southport Photographic Society. Entries close November 15. Sec., J. McLellan, 2, Pilkington Road, Southport.
 December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1910.

- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Photo-Mechanical Notes.

Multi-Colour Machine-Printed Photogravure.

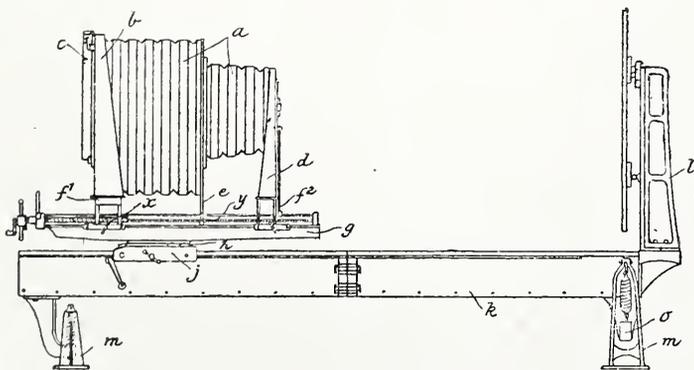

WRITING on the methods employed in this latest development of intaglio printing, Mr. Max Levy states in the "American Photo-engraver": "A screen is employed, usually about 150 lines to the inch, consisting of very thin transparent cross-lines on an opaque ground, and an ordinary positive is used. The screen itself is first printed upon a piece of gelatine tissue, such as is used in carbon printing, and next the negative is printed upon the same tissue. The tissue, then containing the print from the screen and that from the negative, is moistened in cold water and transferred by means of a squeegee to a copper roller, which has been turned accurately true. The design is now etched into the copper roller with perchloride of iron, by what is known as the staging process, as employed in producing a flat photogravure plate, first washing off with cold water the paper upon which the gelatine was coated. If the copper, coated with the gelatine, is immersed in an absolutely saturated solution of chloride of iron no etching will take place, as there is no free water to penetrate the gelatine. If a few drops of water are added, the etching will proceed through the least exposed portions of the gelatine. By slowly adding water the etching will gradually proceed until the more exposed portions have been attacked. The etching can be watched through the transparent gelatine, and when it is completed the gelatine is removed and the design appears on the copper in the shape of little squares, conforming in shape and size to the opaque parts of the screen, but varying in depth in proportion to the action of the solvent. The roll is then ready for printing from on a slightly modified calico press.

Process Cameras.

The main girder of the baseboard or "cradle" (for the camera and copy-board), entirely of metal, is one of the claims in a recent specification (No. 18,263, 1903) of Albert Nixon and Owen Linley, of the Camera Construction Company, Eagle Works, Durham Grove, Hackney, London, N.E.

It is found that girders of narrow section combine in the highest degree economy of material in construction and freedom from vibration and also from sagging and from torsion under the stress of the weight of the camera, which for convenience in practice must usually be made capable of occupying different positions along the length of the girder, and which will also, owing to the movement of the camera bodies, exert a varying torsional stress.

A saddle, also of metal, and similar to the saddle of a lathe, is borne upon the girder and carries the turn-table of the camera.

The saddle is movable along the girder by means of a pinion and a rack, the latter preferably placed with the teeth downwards so as to prevent anything falling upon it.

The saddle may be held down by gibs, preferably three in number, the middle one being loose and capable of being forced forward by a screw or other means, and so serving as a clamp. The action of this clamp is independent of the fitting of the saddle on the girder.

The turn-table consists of a circular metal plate, having its outer edge conveniently at an angle of 45° to its lower face. This turn-table is capable of rotation in three gibs on the saddle, the inner faces of these gibs being curved to fit the outer edge of

the turn-table. One of these gibs is free to move slightly, and can be forced against the turn-table by a screw or other means to clamp it in position.

Lugs, provided with adjustable set screws, project from the saddle, and a projection or projections from the turn-table abuts against these so that the rotation of the turn-table can be arrested at desired points.

The base of the camera is constructed of metal of hollow section on a similar principle to that adopted in the cradle girder, and for lightness it may be tapered in depth towards the ends and deepest at the position where it is desired to fasten it to the turn-table, and provision may be made in the base of the camera for so fastening it conveniently.

The bodies of the camera are of metal, and are attached to metal saddles, which are capable of travelling along the base in a similar way to the saddle on the girder of the stand, and may be capable of being similarly clamped in position.

The back body of the camera may be moved along the base by means of a hollow screw through which a screw for moving the front body passes, so that they have a common axis, and clamps or set screws or other device may be fitted for the purpose of preventing the accidental rotation of these screws.

Exhibitions.

PHOTOGRAPHS BY AMERICAN WORKERS.

At the house of the "Amateur Photographer" there is a highly interesting display of American work which introduces a great number of new names to our notice. The exhibition will be a surprise to many who have come to regard the work of one or two men as the beginning and end of transatlantic talent.

Chas. Booz is an original worker, whose best thing perhaps is "Up the Valley" (8). A child reading a newspaper is the subject of W. D. Brodhun's "Picture-page Reader" (11); awkward material most artistically managed. D. H. Brookins has some capital winter scenes in the city of Chicago, and C. F. Clarke's "Girl and Muff" (20) is a most attractive print. We have already seen the work of W. H. Porterfield this year in London, and the half-dozen things he shows here confirm the good opinion of his powers that we have already expressed. His "Twilight" (25) has but one blemish; the little patch of bright cloud is out of keeping; but he atones for this by a sky truly felt in "The Lowlands of Jersey" (22), which is an eerie moonrise seen through the slender stems of strange looking trees. Wm. T. Knox is with one exception, namely, "Home Portraiture" (31), much too dark for success. We have also some of the large heads by Augustus Thibaudeau, which certainly have distinction in spite of the fact that they appear to resemble bromide wasters. "The City at Night" (6) is by Mr. Richard Witt, the only contributor whose name is prefixed in the "catalog." Mr. Witt has deserved the distinction. The best of F. A. Lidbury's is "Buffalo Harbour—November" (72). Altogether the show gave us a good deal of pleasure.

PHOTOGRAPHS BY MEMBERS OF THE LYCEUM CLUB.

Miss Zaida Ben-Yusuf opens this exhibition with six Japanese photographs and a "Decorative Study" (1), which has nice line and represents a lady holding the inevitable crystal ball, the indispensable accessory of American pictorialists. We think the nicest of the Japanese subjects is "Finishing Touches" (6), a lady on her knees at her toilet, where double lighting has supplied a theme. "Shy" (9) is an exceedingly charming picture of a little girl in the pale manner affected by Mr. Cadby. It is by Mrs. Michael Foster, who shows five other frames. "Italian Mother and Child" (8), is marred by the trembling hands of the mother. Mrs. Cadby's "Girl with Dog" (14) is very attractive, and her life-size "Dog Portrait" (37) striking to a high degree. Miss Warburg shows a portrait of "Henry Lemon, Esq. I.M.S." (17), with which we should be even more pleased were not a hand, a cane, and a leg given over-prominence. Her sea-piece, "A Meeting in the Mist," (43), is harmonious in its feeling and

truth. Mrs. Veley's animals are all excellent, and so is the noble composition of "Silver Birches" (46) by Mrs. Kinder. We must add a word for the interesting views of St. Petersburg and Moscow by Miss S. M. Taylor, and the Alpine pictures of Mrs. Le Blond.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between October 4 to October 9:—

ADVERTISING.—No. 22,621. Invisible photograph advertisement. Albert George Nepean Ford, Inverie, Lower Green, Mitcham, Surrey.

PRINT TRIMMERS.—No. 22,735. Improvements in or relating to trimmers or apparatus for cutting or trimming photographic and other prints, paper, card, cloth, and other like materials and substances. John Merrett, Hill Street, Trowbridge, Wilts.

MAKING PICTURES.—No. 22,776. Improvements in processes of making pictures. Charles William Saalburg, 3, Broad Street Buildings, Liverpool Street, London.

convenient to be able readily to alter this interval, and also to separate the lens for cleaning purposes. For this purpose the mounting in Fig. 1 has been well known for many years. To alter the separation of the middle and back glasses, the back cell can be unscrewed from the middle. In practice, however, it is found that the two cells are sometimes liable to unscrew together from the tube, instead of one remaining fixed and the other unscrewing from it. In another construction shown in Fig. 2 the cells both project outside the tube, right-handed threads are used, and two bolts prevent the flange and the tube respectively from unscrewing from the cells.

In the present invention, as shown in Fig. 3, both right and left-handed threads are used, and one of the cells may be sunk inside the tube, allowing only a small rim to project to facilitate unscrewing for cleaning the glass. The construction is applicable to any lens composed of two or more separated glasses.

It is necessary that the first-glass should be so mounted, either permanently or by means of a detachable cell, as to move as one piece with the tube, and that the second glass should be so mounted, either permanently or by means of a detachable cell, as to move in one piece with the body ring. The flange, or flange adapter, must be mounted by a female screw thread on the body ring, and the tube and body ring connected by screw threads. The tube may carry either a male or female thread, the body ring

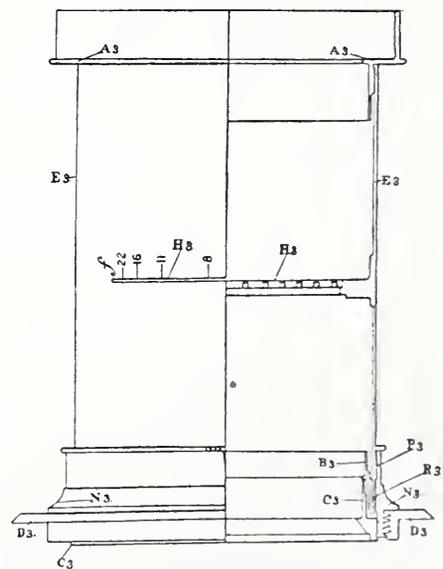

Fig. 3.

PICTURES.—No. 22,777. Improvements in pictures. Charles William Saalburg, 3, Broad Street Buildings, Liverpool Street, London.

PROJECTION APPARATUS.—No. 22,910. Improved apparatus for projecting and enlarging pictures. Ernst Reiners, 22, Gray's Inn Road, London.

POSTCARDS.—No. 23,063. Crystoleum photographic postcards. Harben James Valentine, 41, Reform Street, Dundee.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

LENS MOUNTS.—No. 1,141, 1909 (January 16, 1909). In certain types of lenses used for photographic and other purposes, and more particularly in lenses known as Dallmeyer patent portrait lenses and Dallmeyer stigmatic lenses, the optical construction is such that a small difference in the air interval between the two glasses considerably alters the definition, either at the centre or at the outlying portions of the field of view. For some purposes it is

carrying a female or male thread to correspond, but the thread connecting the body ring and flange must be of opposite hands to that connecting the body ring and tube. That is, there must be a right-handed thread on one and a left-handed thread on the other. It is immaterial which carries the left-hand thread. As a matter of practice it is preferable to cut the flange thread right-handed and the tube thread left-handed. All other threads may be either right or left handed.

Owing to the use of threads of opposite hands on the flange and tube respectively, rotation of the tube for separation of the glasses does not end to unscrew the whole lens from the flange, but actually tends to tighten it. Sinking one of the cells inside, or nearly inside, the tube removes the need for the tube bolt shown in Fig. 2.

As an example, the 3 B Dallmeyer patent portrait lens in brass may be taken. The front cell screws by a right-handed thread at one end of the tube. At the other a casting is soldered on and a male left-hand thread cut. On the inside a right-handed thread is cut in which the middle cell screws.

The body ring carries a male right-handed thread on which the flange screws. Internally a right-handed thread allows the back cell to screw in, and a left-hand thread receives the male thread of the tube.

After the glasses have been adjusted, all parts screwed home, and the flange fixed to a camera front, an increase in separation of the middle and back glasses is made by rotating the lens tube from left to right. By suitable adjustment of the length of the body ring, in the first instance, the glasses may be brought in contact. Rotation will then give any desired separation. Reversal of rotation diminishes the separation.

In the accompanying drawings Fig. 1 represents a well-known mounting of the 3 B Dallmeyer patent portrait lens. The external appearance of one-half and a section of the other half are shown. Three cells are used. The front cell A₁ carrying a hood screws by a right-handed thread into the inside tube E₁, the middle cell B₁, screws by a right-handed thread into the other end of E₁, the back cell C₁, screws by a right-handed thread into B₁. E₁ slides inside an outer tube F₁, and is fitted with rack and pinion K₁. The body ring G₁, is attached to F₁. The flange D₁, screws on to G₁, by a right-handed thread. A diaphragm, H₁, is fixed between A₁ and B₁.

Fig. 2 represents another well-known mounting. The external appearance of one half and a section of the other half are shown. The front cell and hood A₂ screws by a right-handed thread into tube E₂. Middle cell B₂ screws by a right-handed thread into E₂ and back cell C₂ screws by a right-handed thread into B₂. Flange D₂ screws by a right-handed thread on C₂. There is no rack and pinion. H₂ is the diaphragm. K₂ is a bolt fastened to tube E₂ and slipping into a notch L₂ on cell B₂. When shot home K₂ prevents E₂ from being unscrewed from B₂. M₂ is a bolt on flange D₂, slipping into a notch on cell C₂. When shot home M₂ prevents D₂ from being unscrewed from C₂.

Fig. 3 represents the invention. The external appearance of one half and a section of the other half are shown. The front cell and hood A₃ screws by a right-handed thread into tube E₃. Near the other end of E₃ an external left-handed thread P₃ is cut. Below P₃ a short piece of the tube E₃ is left without thread. At the end of E₃ an internal right-handed thread R₃ is cut.

Middle cell B₃ screws into E₃ by R₃. The body ring N₃ screws on the left-handed thread P₃ and carries the flange D₃, which is attached by a right-handed thread. Back cell C₃ is attached to N₃ by a right-handed thread.

The following are constructional details, as shown in Fig. 3:—

Internal diameter of front cell	3.625 inches.
„ length from upper surface of casting on tube to top of tube	4.8 „
„ length of tube	5.6 „
Internal diameter of middle cell	3.55 „
„ depth of middle cell7 „
Internal diameter of body ring	3.9 „
External diameter of portion of body ring on which flange screws	4.25 „
„ Depth of body ring	1.1 „
Internal diameter of back cell	3.5 „
„ depth of back cell7 „
External diameter of tube	3.8 „
External diameter of flange	5.25 „
„ length from iris diaphragm to top of tube	2.9 „
„ length from iris diaphragm to bottom of tube	2.65 „

The flange is attached to the body ring by a screw thread of 14 threads per inch. All other screw threads are 31 threads per inch. Cyril Frederick Lan-Davis, of J. H. Dallmeyer, Ltd., Denzil Road, Neasden, London, N.W.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

MOVING PICTURES.—No. 22,094. Moving picture machines. Mills.
PRINTING FRAMES.—No. 22,311. Automatic printing frames. Edwards.

New Trade Dames.

PHONEMATOGRAPH.—No. 315,060. Electrical or mechanical apparatus for synchronising phonographs with cinematographs and the like apparatus, and transparencies and other accessories relating thereto included in Class 8. Andrew Lincoln Jackson, 118, London Wall, London, E.C., engineer. July 23, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Printing Titles on Negatives.

I have found the following very simple method perfectly satisfactory (writes Mr. J. Gregory in "Photography and Focus" for October 19). The title is first written or printed on a piece of thin parchment paper, underneath which is laid a piece of carbon paper. On turning the parchment paper over, the carbon paper will have marked it with the title reversed. The carbon paper is then laid on the negative in the position selected, the parchment paper put on the top, with the reversed title upwards, and this is then gone over carefully with the pencil. The carbon paper will then set off the reversed inscription on the negative, which, when printed, will show the title the right way round.

How to Carry a Wet Negative.

It sometimes happens (says a writer in "The Amateur Photographer and Photographic News" for October 19) that one wishes to carry away a negative which is just washed, say, from a friend's house, where developing has been done. The negative is laid film side up in a plate-box of its own size, and little props of cardboard, made by bending flat strips at right angles, are stood upright on the film at the extreme corners. They are cut sufficiently long to stand just above the top edge of the box. The cover is now laid carefully on these props, and the whole tied round firmly with string, or secured with a couple of elastic bands. The negative will thus be held down at the bottom of the box, and the film will not be in contact with anything except the ends of the card angles at the extreme edges. These, however, will not cause any damage, because, even if they slightly scratch the film there, it will not affect the printing portions of the negative.

The only precautions to observe in this dodge are to cut off the card strips to equal heights, because if one happens to be decidedly shorter than the others it may fall away from the cover and plate and get on to the film; also the string must be tied round firmly, so that there will be no chance for the strips to work loose. Bearing these points in mind, there is no risk, and valuable time may often be saved.

New Books.

"Photograms of the Year, 1909." London: Dawbarn and Ward Ltd. 2s.

This volume comes to hand in good time this year, so that it able to rank as a running commentary upon the exhibitions rather than as a Christmas gift-book or souvenir. Mr. Snowden Ward to be congratulated upon having triumphed over block makers and printers to such a remarkable extent. As we have said of past issues it is more comprehensive than any one show, a pocket edition of Royal and Salon, and a telescope to show us what photographers across the seas are doing: and the technical qualities of the reproductions are excellent in almost every instance.

We ourselves must take some credit for having furnished Mr. Snowden Ward with a peg upon which to hang, the time- and labor-saving device of reprinting his Convention address as a leader of the book. He says that his address was ridiculed and criticised, but as we remember no other review of it than our own, we add the soft impeachment perforce. "One may, however, ask," says the writer, "that critics should read the matter before demolishing it." We humbly whisper that we did both, whilst we sincerely agree that "there seems no good reason to apologise or withhold the whole or any part of it." It is all good reading and must have been instructive entertainment for many. Certainly it is food for thought for all, and perhaps for the very reason that it came with the weight and authority a Convention address bestows, we were impelled to question its main argument. We believed that it would have been more salutary to show to pictorial photographers where they are weighed in the balance and found wanting than to

them for qualities possessed by few, and, with invidious comparisons, to belittle those whom the outside world call artists, ancient and modern. Photographers as a class cannot be said to be in danger of decline by self-abnegation and dissatisfaction, those never-failing symptoms of the real artistic temperament. If Mr. Snowden Ward were as critical as the ideal critic whom he describes, we should have no quarrel with him, but to our minds he is more moralist than critic, and too solicitous about the effect his words are likely to have upon the one criticised. The milk of human kindness is all very well, but when there is too much, it slops over, and one has to wade through it. Our point was, and still is, that in order to please his audience Mr. Snowden Ward stretched his argument to a breaking-point.

As to the archaic work, which Mr. Ward only ridicules, it has been stated by one of the most sure critics the world ever saw that the true grandeur of Egyptian work has only been apprehended of late years, because it was supposed that its conventionalism was due to simple ignorance of nature and want of skill in art." We might add, on our own part, that conventions in Greek vase paintings, which are such a stumbling-block to Mr. Ward, were contemporary with the finest period of Greek art.

Most of the matter of the address after the point where the writer places the beginning of real art is either outside photography altogether or else relates to mere sentiment as differentiated from art. We do not say that other critics' photographs are not in the same boat with him. It is difficult to see how to speak of photographs without overlooking the fact that they are science made pleasant by good taste. But when Mr. Snowden Ward goes so far as to make the astounding claims of his fourth paragraph it is time to pull up, look around, and take bearings. The cause of pictorial photography is not to be furthered by such arrogant calls for a recognised status. It is not enough, that old justification that photography may be a means of artistic expression. It signifies so little. Gardening and hair-dressing may be means of artistic expression, and indeed they are claimed as art by their votaries.

M. Demachy, in his admirable article referring to France, makes some healthy observations upon the Autochrome and oil workers which we commend to our readers. The article upon Germany, by Matthies-Masuren, deals largely with the Dresden Exhibition, but concludes with a lament that pictorial photography shows no advance in its position ten years ago.

The article upon Spain, by Manuel Mendez Leon, sounds a doleful note on the whole. Amateur societies do not flourish, and publications also have to live a languid and unprosperous life. Nevertheless, the writer assures us that Spain is not asleep, but in the vigour of progressive movement. Pigmentary processes are going strong, and inspiration is forthcoming from a novel feature in exhibitions, "that is, that the person obtaining the prize of honour will nominate the Queen of the Fête, to whom he will offer a pretty artistic insignia, and this lady will distribute the prizes to those who have been favoured with the award of the jury. This is a charming novelty, which I applaud," adds the writer, "and trust it will be adopted by other exhibitions, to which it will add beauty and importance. It is evident that chivalry flourishes still in Spain, even if photography gets languid upon occasion.

As to the contribution by Walter Burke upon Australia we learn that the conditions are much as in Spain in regard to photographic societies, which "seem to languish, and the majority of them are practically dead." But hopeful auguries are set forth by Kodak and Pathé Frères, who appear to have come to stay in Australia.

Then follows the long critique upon the work of the year by the editor. It will no doubt be much read and much valued. Mr. Snowden Ward is always complimentary, always passing votes of thanks, and usually has an excuse at hand as antidote to the venom of his mild objections and heart-to-heart admonitions. In short, it is a part to encourage and exhort, and his essay reads much more like a Sabbath school address than a critique of pictures. Where is the art criticism of a passage like this:—"Mrs. Barton's 'Old Fifer' is one of those fine characters that seem attracted to her, not by instinct. Week after week, until the time of his death the old man walked many miles for the little sympathy and kindness that was awaited him at Rose Cottage, and that he found there on his first call as a wandering musician. A true Bohemian, a true artist in his poor un instructed way, he responded at once to the

interest felt in him by another artist." We are willing to add our dropping tear, but we refuse to accept these moving obituary details as anything to do with art, and we differ *in toto* to the conclusion of the next sentence:—"Sympathy, which is not pity, but which is understanding, is the true alkahest, the universal solvent that converts base metals into gold, and the most invaluable possession of the picture maker." These are the platitudes of the pale young curate and not the trenchant impartial word that should praise or blame and give the reason for either. Similarly we cannot believe that the closing words of the volume will inspire confidence in any one who is hungering and thirsting after art:—"This book closes on a high note, a rich chord of harmony, a combined effort of masterly builder and masterly photographer, to attune our thoughts to the great, the solemn, the eternal truths." It is Ruskinese of the most irritating sort.

"We ought to thank God for the great strong faith that built the enduring fanes, and for the process and the men that can catch some part of their glorious frozen music and bring it to our own easy chair, wherever in the world we may be. A book like this must skip rather irresponsibly over many phases of artward effort and the comment is necessarily disjointed, often inadequate. But the book closes with a great benediction, and the writer of the words cannot do better than wish to every reader that he may receive into his life the message of 'A Pillared Shade,' and feel something of that great peace which passeth all understanding."

By a continuity of ideas one instinctively feels for the threepenny piece and awaits the voluntary.

We are quite sure that Mr. Snowden Ward is himself assured that this attitude towards pictures is the right and proper one, and we are convinced that most of his readers will think so too and derive satisfaction from his remarks. Our sole object in quoting these passages is to substantiate our charge that in such writing art and sentiment is confused: The artistic temperament is callous to story-telling *per se* in pictures, callous to sentiment, callous to moral lessons to be derived or grace and blessings to be received. When it concerns itself with these things it does so only for the worldly advantage in having subject-matter that appeals to minds unable to understand the doctrine of art for art's sake. Art for moral's sake, art for amusement's sake, is art of a bastardised form, always popular, often useful, but contemned by the seeker after art of pure strain. Real art is sensuous; it must fill with desire for the exercise of those faculties that are necessary to its culmination. In fact, art is a lust, and photographers who can neither draw nor paint nor sculpture cannot feel its incitements, though many are now hearing some echoes of its entrancing seductions in oil-printing, which is a little breach in the wall separating art from photography. Those photographers who have succumbed even to this faint beckoning smile of art know that story-telling, character-mongering, picture-making à la Robinson, and sermon-preaching are not art at all. Art is in the blissful and painful *doing*. When all is done the art effort is over—it is the child of art that remains.

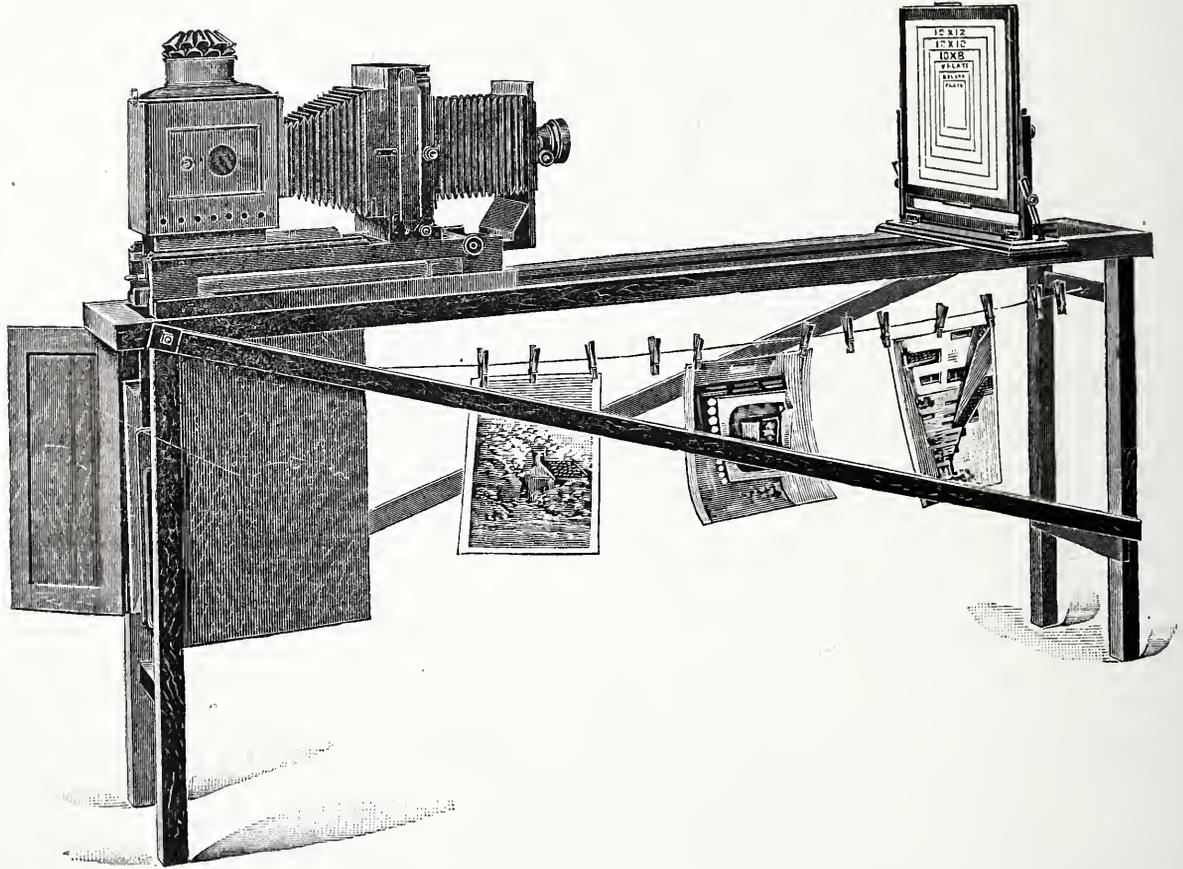

MR. N. S. AMSTUTZ, author of the "Handbook of Photo-Engraving," and well-known both in America and Europe for his researches in process matters, has associated himself with Mr. W. F. Hertzberg, in the establishment of the International Research Company, with headquarters at 1536, Old Colony Buildings, Chicago. They will continue to make scientific investigations of matters pertaining to mechanics, electricity and chemistry.

SOUTHPORT PHOTOGRAPHIC EXHIBITION.—Under the auspices of the Southport Photographic Society an international and open exhibition will be held from December 4, 1909, to January 1, 1910, in the Atkinson Art Gallery, Southport, and will be open to both amateurs and professionals alike. Exhibits will be divided into four sections, namely, pictorial photographs, pictorial photographs in colour, lantern slides, and colour slides, Autochromes, etc., and awards in the form of decorative plaques will be placed at the disposal of the judge, Mr. A. H. Blake. Entries close on November 15, by which date entry forms, together with the necessary fees, must reach the secretary, Mr. J. McLellan, 2, Pilkington Road, Southport, from whom forms and full particulars may now be obtained. A special feature of the exhibition will be the inclusion of the exhibits shown in the British pictorial section of the recent Dresden exhibition.

New Apparatus, &c.

The M.C.C. Enlarging Trestle. Made by the Midland Camera Company, Ltd., Slaney Street, Birmingham.

A new introduction by the Midland Camera Company, of whose many types of enlargers to suit all purses and requirements we have been able to write appreciatively in the past, has been designed with a view to providing a rigid and independent support for the enlarging camera and easel. To the many photographers who are unable to afford the space for a permanent enlarging outfit a piece of apparatus of this kind should be of the greatest service, since the trestle can be taken apart and packed away in comparatively small space, although, when erected for use, the length of the enlarging bench is 6ft. Not only this, the trestle, as shown in the illustration, embodies a light-tight cupboard, which serves for the convenient storage of bromide paper, plates, etc. The easel is supplied mounted on a pair of uprights, which permit of a central swing necessary when making correction of faulty lines in the negative. The space available for the sensitive paper is 16in. square, allowing of 15 x 12

paper being placed either way of the easel. Both easel and enlarger may be readily moved along the trestle, and the operator will find it a convenience to be able to place his enlarger in any position convenient to the place where development is being done, one or other of the spirit incandescent lamps now available making him independent of a gas or electrical connection. The whole apparatus, including the trestle proper, easel, and cupboard, but not the enlarging lantern, is sold at the price of £3. When taken apart for storage the greatest width of the apparatus is 14in., so that not only professional photographers in a small way but also amateurs needing to put their equipment away when done with will find in this new introduction something which very practically supplies their wants.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—The annual supper will be held at the Hotel Boulogne, 27, Gerrard Street, W., on Thursday, October 28. Mr. H. Snowden Ward will occupy the chair, and music will be rendered during the evening by Mr. T. Bennett Griffin's concert party.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 22.

Shotts Camera Club. "Autotype Carbon." Demonstration.

SATURDAY, OCTOBER 23.

Southend-on-Sea Photographic Society. Outing to Stambridge Mill and Temple Sutton.
Worthing Camera Club. Outing to Shoreham.

MONDAY, OCTOBER 25.

Southampton Camera Club. "Autotype Carbon." Demonstration.
South London Photographic Society. "Autotype Carbon." Demonstration.
Leek Photographic Society. "Thornton-Pickard Demonstration." R. Hesketh.
Marylebone Camera Club. "Rule of Thumb v. Mechanical Means of Photography." Dr. F. O'Brian Ellison.

TUESDAY, OCTOBER 26.

Manchester Amateur Photographic Society. "Epping Forest." J. Hayward.
Kinning Park Co-operative Camera Club (Govan). "Autotype Carbon." Demonstration.
Hackney Photographic Society. "York and the North-East Yorkshire Dales." N.E. Ry. Co.

Glasgow Southern Photographic Association. Monthly Lantern Slide Competition.
Leeds Photographic Society. "An Evening with Pictures." Walter Bagshaw.

WEDNESDAY, OCTOBER 27.

Preston (Lune Street) Camera Club. "Autotype Carbon." Demonstration.
Borough Polytechnic Photographic Society. 1909 Affiliation Competition Slide.
Croydon Camera Club. "Travels with the Camera." C. H. Dymond.
Edinburgh Photographic Society. "Bromoil." T. A. Knoblauch.
Sale Photographic Society. "Pin-hole Photography." A. Redfern.
Balham Camera Club. "Carbon Printing. Single and Double Transfer." Tozer.

THURSDAY, OCTOBER 28.

Handsworth Photographic Society. Continuation of Exhibition; with Criticism.
Walter J. Morgan, R.B.A.
Liverpool Amateur Photographic Association. "The Woodlands of Wirral." C. Theodore Green.
L.C.C. School, Bolt Court, E.C. "The Art Work of Durer." S. M. Peartree.

SOUTHAMPTON CAMERA CLUB.—A lecture was given last Monday evening on "Saints, Benedictines, Goths and Vandals," by Mr. B. W. Harvey Piper. The address was illustrated by over one hundred slides, many from recent photographs by prominent workers. The topic of the discourse was the past and present history of the Cathedral and Abbey Church of St. Alban's A

apid sketch describing the early history and the foundation of little church rudely constructed of wattle and mud was given, after which the Abbey Church, built largely at first of Roman bricks quarried from the adjacent and deserted Roman city, was fully described. The church, although restricted to its original narrow dimensions, was so added to that it became one of the longest in England. In 1553 it was sold to the townsfolk, but proved far too large for their requirements, consequently the western part of the nave, being disused, soon fell out of repair. Three centuries of neglect brought the great Abbey Church into sad state of ruinous dilapidation, from which it was rescued by three successive generations of restorers: Lewis Cottingham in the nineteenth century; Sir Gilbert Scott, who evidenced great constructional ability in underpinning the central tower and pushing back into place the long, bulging walls of the nave clerestory; then followed Sir E. Beckett, afterwards Lord Grimthorpe, who expended £140,000 out of his own pocket in reconstruction. Mr. Harvey Piper stated that Grimthorpe's work raised the most commendation that ever raged about an architectural undertaking. A review of the whole exterior was given, and illustrations from ancient engravings in contrast with the recent photographs depicted clearly the effect of the restorations that had taken place. The lecturer then proceeded to conduct the audience through the interior, and made special reference to Trumpington's early English bays at the west end. He also described the discovery of the fragments of the Shrine of St. Alban and its re-erection by the late John Chapple in 1872. The reredos was contrasted with a very similar one at Winchester. Views of the Lady-chapel when desecrated by use as a grammar school brought to an end a most interesting lecture.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The Directors of the Eastman Kodak Company of New Jersey have declared an extra dividend of 2½ per cent. upon the Common Stock of the Company, payable December 1, 1909, to stockholders of record at the close of business on October 30. The usual quarterly dividends will be paid on January 1, 1910.

LEGAL NOTICES.—Joseph Bernard Shepherd, photographer, 27, Queen Street, Rhyl, and Wilson Nair, postcard dealer, 25, Queen Street, Bridlington, have been adjudicated bankrupt. In each case a receiving order was made on the debtor's petition. The first meeting of creditors of Wilson Nair will be held in Scarborough on the 26th inst., and the public examination on November 16.

In the Sheffield Bankruptcy Court on October 14 the public examination was held of John Scott (trading as E. Holt), described as a photographer and postcard publisher, and residing and carrying on business at 50, Hollogate, Rotherham. The debtor said that he commenced business on March last with a capital of between £2 and £3. He attributed his failure to competition, bad weather, and inefficiency of capital. His previous employment was that of a chemist and photographer. The examination was concluded.

Edwin Walkden, photographic dealer and chemist, 129, Ferham Road, Holmes, and now of 30, Broomfield Cottages, The Broom, Rotherham, was publicly examined at the Sheffield Bankruptcy Court on October 14. He estimated his liabilities at £126 and his assets at £25, and attributed his failure to high rent and rates and to bad trade. The examination was concluded.

PHOTOGRAPHIC FRAUDS.—In the Forfar Sheriff Court last week three men—James Muir, George Macfarlane Muir, and Alexander Robertson—were charged with having formed a fraudulent scheme for obtaining money by pretending to a number of people in the Carmyllie district that they were soliciting orders for a firm of portrait specialists in Glasgow; that for the sums of money received they would deliver photographic enlargements in frames; and did so induce persons to pay sums of money, amounting in all to £8 12s., for enlargements and frames, which they did not deliver. The Muirs did not appear, and the charge against Robertson was proceeded with. He pleaded not guilty, and was represented by Mr. James W. Lowson, solicitor, Forfar.

The first witness was David Hume, farmer, Mains of Carmyllie, who spoke to receiving visits from one of the Muirs and Robertson, to whom he gave an order for two frames, and paid a sum of £1 15s. The receipt he received was signed by Robertson.

Mrs. David Gibb, Mains of Carmyllie, also spoke to Robertson and the Muirs calling on her. The men persuaded her to give an order for two frames for two photographs, which they had had enlarged for her, and she handed over £1 19s. 6d. to one of the Muirs. The receipt she received was in Robertson's name.

Mrs. William Gray, from Bankfoot, Arbroath, gave evidence as to her husband having paid 17s. 6d. for an enlargement to Robertson at his lodgings in Arbroath. Several other witnesses were also examined.

Robertson made a statement on his own behalf, and Sheriff Lee, in sending him to prison for ten days, said he thought it was pretty clear that this was not a fraud in which Robertson was the principal, or from whom the idea of carrying out the fraud had emanated.

DISSOLUTIONS OF PARTNERSHIP.—The partnership between Walter Davey, Walter Davey, junior, and Sydney Davey, carrying on business as photographers, under the name of Walter Davey and Sons, at 26, James Street, Harrogate, and at Ashley House, Middleton Street, Llandrindod Wells, Radnor, has been dissolved so far as concerns Walter Davey, who retires. The business will be carried on by the other two partners under the same name as before.

Herbert Button is retiring from Messrs. F. E. Jones and Co., photographic material dealers, 22, Gray's Inn Road, W.C. The business will be carried on by the two other partners, Frederick Ernest Jones and Ernst Makus von Arx.

NEW COMPANIES

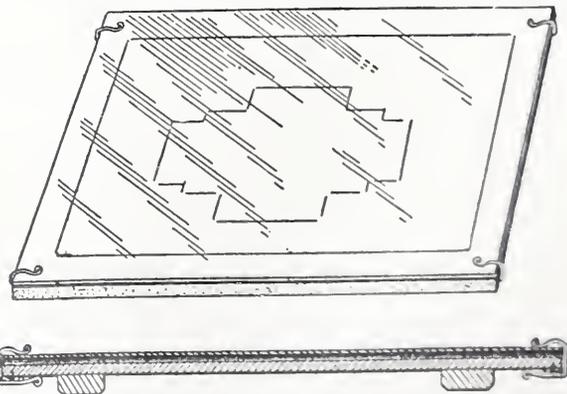

A. E. HUBSCH AND COMPANY, LTD.—Capital, £2,000 in £1 shares. Objects: To take over the business of photographic film merchants and agents, carried on at 3, The Broadway, Ludgate Hill, E.C., as A. E. Hubsch and Company. The first subscribers are:—A. E. Hubsch, 18, Charing Cross Road, W.C.; and H. A. Browne, New Court, Grafton Street, W.; private company. The first directors are: H. A. Browne and A. E. Hubsch, with £500 each per annum as remuneration. Registered office: 18, Charing Cross Road, W.C.

CHERRY KEARTON, LIMITED.—Capital £4,500, in £1 shares (2,000 preference). Objects: To adopt an agreement with C. Kearton and to carry on the business of photographers, publishers, booksellers, advertising agents, etc.

News and Notes.

SIMPLE BLUE-PRINTING FRAME.—For those desiring to make a few small blue prints and having no regular printing frame, the following may prove useful (writes C. L. Swezey, in the "Scientific American").

Secure a piece of ordinary window glass, somewhat larger than

the largest blue print desired. If a piece the same size as your drawing-board can be secured, it will be very convenient. Bind the edges of the glass with adhesive tape, to prevent scratching the tracing or hands. Cover the drawing-board with felt or other heavy cloth, drawing the covering over the edges and fastening with thumb tacks. Make four clips, as shown in the accompanying illustration,

using thin spring brass or wire. The exact size of clips depends on the thickness of board and glass.

In use, the sensitised paper, which can be obtained from dealers in photographic supplies, is laid on the felt, coated side up, the tracing to be copied is placed in position, and covered by glass, which must be clean, then the clips which hold the whole in position are slipped on at the corners.

R.P.S. LECTURES.—The following lectures will be delivered at the New Gallery, at 8 p.m. :—

Saturday, October 23.—“The Romance of Plant Life,” by F. Martin-Duncan.

Monday, October 25.—“A Trip Round the World, via Ceylon, through Australia and Canada,” by C. J. Marshall, A.R.I.B.A.

Thursday, October 28.—“The Catacombs of Rome, and the Early Christian Period,” by S. J. Beckett.

Saturday, October 30.—“Westminster Abbey,” by S. G. Kimber.

THURSDAY EVENINGS AT THE BLENHEIM CLUB.—The photographic lectures at the Blenheim Club will re-commence on Thursday evening, the 28th inst., when Mr. H. W. Fincham will be the speaker, and his subject, “Ely Cathedral, Queen of the Marshlands.” Mr. F. Martin Duncan is arranging these evenings, and a number of very interesting fixtures have been secured, including at least one on the all-absorbent topic of aviation.

MR. E. H. FARROW, who for upwards of nineteen years has carried on business as maker of photographic apparatus at 441, Hornsey Road, has removed to 35, Lichfield Grove, Finchley, London, N.

Correspondence.

- *• We do not undertake responsibility for the opinions expressed by our correspondents.
- *• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

TONING LANTERN SLIDES.

To the Editors.

Gentlemen,—On page 825 of the “Photographic Almanac” for 1907, you describe a process for toning lantern slides. I have been experimenting with that process lately, and although I have not obtained the exact results as there explained, I have turned out some very pretty slides.

By further experimenting I have also discovered that similar results can be obtained by using the chromium intensifier, thus doing away with the necessity of using the highly poisonous mercury bichloride.—Yours, etc.,

WALLACE H. MATHEWS.

[The process described by our correspondent is that first published in the “Amateur Photographer,” and is as follows :—

The slide is first under-developed, and then intensified to the desired depth in mercury and ammonia. It is then well washed and placed for three minutes in a mixture of :

No. 1. Ammonium citrate of iron.....	16 grs.
Water	4 ozs.
No. 2. Potassium ferricyanide	16 grs.
Water	4 ozs.

An equal quantity of each is mixed in a measure glass. To the mixture a few drops of a 10 per cent. solution of nitric acid are added immediately before using.

It is then removed to the final washing, without any apparent change whatever having taken place. On drying, however, the sky will come out a delicate azure blue, the high-lights will be very slightly tinged with blue, and the rest of the slide will present the warm brown tone which follows the intensification process. For certain subjects, notably those with clear skies and a foreground of water, these colours are most effective, the slight tinging of blue in the high-lights of the water appearing only as the natural reflection of the bluer sky.]

Answers to Correspondents.

- *• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C.” Inattention to this ensures delay.
- *• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- *• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

 J. Weir, The Studio, Moffat, N.B. *Photograph entitled, “Sheep Shearing in Upper Annandale, Dumfriesshire.”*

A. M. E.—Dorrett and Martin, 16, Belle Vue Road, Upper Tooting, London, S.W.

W. H.—If your work is chiefly single portraits, head and shoulders, or three-quarter lengths, we think you will be best advised to use one arc, or two if you require to do groups by artificial light. See also reply to “A. E. C.”

GELATINE MOUNTANT.—I wish to use gelatine as a mountant in future, and shall deem it a great favour if you will inform me how to prepare it for use.—IGNORAMUS.

One of the best formulæ is the following, from the “Almanac” :

Nelson's No. 1 gelatine	4 ozs.
Water	16 ozs.

Soften the gelatine in the water, liquefy by heat, and add a little at a time, stirring rapidly.

Methylated spirit	5 ozs.
Glycerine	1 oz.

This is used hot.

A. G.—There is no paper published so far West. The nearest is the “St. Louis and Canadian Photographer,” issued from 911, N. Sixth Street, St. Louis, Mo. ; but, so far as we know, it is not on sale in this country. Write to the above address for a specimen copy. We may tell you that the “British Journal” circulates widely among photographers in Canada and the North-West.

ADVERTISING.—We do not know of anyone offering to advise on the lines suggested. The best reply we can make is to apply to one or both of two firms of printers making a specialty of photographers announcements—viz., Harold Hood, Ltd., St. Bride Works, Middlesbrough; and Walter Pearce and Co., St. George's Press, Brentford. Either of these, we think, would be able to draw up a series of suitable announcements for press or booklet use, and either, of course, is well equipped for printing or supplying any stereos for a newspaper.

PINATYPE.—Would you kindly inform me, through the “Journal,” how prints are finished off in the process known as Pinatype? Perhaps you will be able to understand me more clearly when I quote a few lines which appeared in the “Almanac,” 1909 page 623, which read as follows: “The later process is exactly the same as that for the impressions taken from the positive transparencies in the pinatype process.” Now I am unable to find here anything about the process, so I would like your help. I receive the “Journal” through a newsagent here in Wanganui, New Zealand.—O. BUCKENDALE.

In the pinatype process a “print-plate” is made (from a positive transparency) on a gelatine plate sensitised with bichromate. This print-plate is then dyed with one or other of the special pinatype dyes and prints taken from it by contact only (without light) on

paper coated with gelatine. The materials for the process and booklets of instruction are obtainable from Messrs. Fuerst Bros., 17, Philpot Lane, London, E.C.

E. C.—Your studio is rather short, and as the lamp will always be somewhat near to both sitter and camera we think you would find one of the smaller enclosed arcs sufficiently powerful. We should advise a conical or umbrella-shaped reflector, some six or eight feet across, in the centre of which the lamp is placed. The lamp and reflector should be suspended from a point a little to one side of the ridge, and about nine feet from either end. You will thus be able to work from either end of the studio quite readily. Have a large three-fold screen papered white and mounted on castors. This can be placed under the lamp, and will provide an ample amount of side light. Of course, you will hang the lamp from the solid half of the roof, not the glass half; and if the roof is wood it may be well to cover it just above the lamp with asbestos cloth, or a sheet of iron may be fixed up, with an air space of a couple of inches between it and the woodwork to which it is attached. It is often an advantage to have the lamp on a pulley, with a counterpoise weight, though this is by no means absolutely essential, and with your width of studio you will be able to move both sitter and camera about very considerably in relation to the light. You will need the usual supplementary reflectors and head screens, which you probably already have in your studio.

ENISH.—We should be glad if you would give us the formula or a varnish (matt) for bromide opals, which will allow heavy washes of water-colour to be applied without drying in spots where any quantity of water is used. The present varnish we use is the ordinary "ground glass" or "matt," but although affording an excellent tooth for colour, it does not appear to protect the underneath film. The spots appear in the form of blisters and when dry dark.—SARONY AND Co.

We do not know of a matt varnish other than the ordinary matt varnish, which we should have surmised would have protected the gelatine film sufficiently for it to be worked upon with water-colours. However, we would suggest that you try treating the plates with the aqueous varnish, the formula for which was given in our issue for the 8th inst., before applying the matt varnish. That would possibly get over your difficulty by making the gelatine film less impervious. Possibly, if the gelatine film were thoroughly hardened with formaline before varnishing, it would not blister under the water-colour. If these suggestions will on trial you might try a spirit varnish and dull the surface by rubbing it over with *fine* pumice powder.

BLINDS FOR STUDIO.—I enclose a rough sketch of my studio, and shall be pleased if you will kindly tell me (1) what is the best material and colour for the blinds, and also if my present arrangement can be improved upon. The existing top blinds have gone quite yellow, and I use for the side light nearest camera a blue blind, and for the other half (nearest sitter) two white ones. Is there a better arrangement? (2) I wish also to introduce some work blinds so as to get firelight effects—that, I suppose, would mean a double set. (3) Please advise best "incandescent gas" arrangement for this size studio, and how placed.—STUDIO LIGHTS. The sketch gives no indication of the aspect of the studio, so that we cannot give a definite opinion. But so far as we can judge, the present arrangement should answer very well. 2. A double set will be advisable for convenience in working; very dark green or black will be best for one set. 3. The Tress Company, 4, Rathbone Place, supply a suitable arrangement for the purpose. The apparatus should be so placed as to represent as nearly as possible a high side light.

MATT VARNISH.—I would be greatly helped if you will inform me what to mix with ordinary matt varnish in order to make it more opaque or denser. I saw it mentioned in this column before, but I have searched through the back numbers in vain.—DENSER. A little iodine dissolved in the varnish will increase the depth of colour, or asphaltum may be used, whilst one or other of the spirit-soluble dyes would also serve.

INSURANCE.—Could you tell me if there is any insurance company connected with the photographic profession to insure for sickness, or loss of employment, or old age, or, if not, is there one you

could recommend of sound reputation for business girls? I should feel greatly obliged if you could give me any information.—K. J.

There is no such thing in connection with photography. We should think that the Hearts of Oak Society would be the best, but we do not know if it admits females.

CARBON TROUBLE.—Please find carbon sepia print enclosed. Could you inform me of the cause of the flat-looking shadows? This was a double transfer print, sensitised in a solution bichromate of potash 1 oz., water 40 ozs., for one minute, and dried as usual in five or six hours. Any cause as to its flatness and loss of brilliancy would oblige.—FLAT.

The flatness in the print seems to be due entirely to the negative. It is not vigorous enough for carbon printing. For this process tolerably vigorous negatives are essential if vigorous prints are required. If you intensify the negative a little you will doubtless get better carbon prints from it.

COPYRIGHT.—I sent a local newspaper four photographs of events in the district, which they reproduced in the paper. I did not state a price when I sent them. They sent me payment at the rate of 2s. 6d. per photograph. As I did not consider this enough I sent an account in for them at 5s. each, and a receipt for the payment they had made me as so much on account, together with a letter pointing out that the usual price for press work was 10s. 6d. per print. I have had no reply from them, and I should like to know if I can compel them to pay the fee I have asked for.—PRESS.

You had better apply again for the balance, and if it is not paid you will have to sue for it in the County Court. When photographs are sent to newspapers it is usual to mention the fee to be paid if the pictures are used. Then there can be no dispute about price.

MARION LENS.—Is an old portrait lens marked "Marion à Paris" of any value. It is said to be a 11 plate lens, but as the glasses are only about 2in. diameter, is it not a rather slow one? There is a slot for Waterhouse stops, but as the stops are missing I cannot give exact aperture.—LENS.

We are continually saying that we do not appraise the value of apparatus. However, we may tell you that such a lens as you describe has no market value. We may tell you also that Marions never issued a portrait lens of two inches in diameter as a whole-plate lens. Did you not read the article on the subject of old lenses in our last issue?

A. B.—We think the studies are quite free from objection.

MATT BROMIDE.—I am anxious to know how to work the bromide matt-surface paper by ordinary light, also the toning bath for same? I suppose it can be printed in the same way as the P.O.P.—sunlight or shade printing?—A. B. C.

It is possible, but not practicable, to work bromide by daylight. Why should you want to use the paper in a way quite different from that for which it is intended. The best toning method is the sulphide. See recent articles in these pages.

THE PORTRAIT OF A LADY.—Will you kindly advise me re the following question? Some time ago I photographed a lady and gentleman together, the gentleman paying for a dozen cabinets. Last week the same gentleman called and ordered another dozen, at the same time asking me to put one in the window, and paying so much per week to me for doing so. Since then the lady called and ordered me to remove the photograph from the window, threatening me with legal proceedings if I do not comply with her request. What shall I do? I may add they are not man and wife.—STUDIO.

We advise you to remove the portrait at once, as it is causing the lady annoyance. It is not creditable to the gentleman to wish for the exhibition of the picture to her annoyance, and it is less creditable to you to do so for a weekly payment. If the lady takes legal proceedings against you it will probably land you in heavy law costs, and we may tell you that you will get little sympathy from any respectable photographer.

SPOTS ON PRINTS.—I am enclosing a print which has gone spotty after only about two months, and I am very anxious to find out cause, as I fear there may be some in circulation like it. Some

time ago, probably about same time as this was done, I was troubled with markings on prints of a similar shape, but deep purple in colour, showing up during final washing. They ceased to appear, and I thought no more of it. Now this and a few others have cropped up. Have they any relation to each other, do you think? My first thought is air bubbles during fixing, but as I am a very careful worker and never over-crowd my dishes, I cannot think this is the cause. I use enamel dishes for first and final washing, but never for toning and fixing. Enamel has become broken off in places, and exposes the under-surface. Can that be the cause? The singular thing about it is, I do an enormous number of postcards, and I have never found anything like this. Kindly give me some information in next issue of "Journal."—WHOLE-PLATE SPOTTY.

These spots are not due to air-bubbles, but to specks of some chemical substance. This is evidenced by the dark centre to each spot. From your description of the state of your dishes we should say that the trouble is due to particles of iron from the chipped places in the dishes. Chipped enamel dishes are very unsafe things to use for prints, and you should abandon them. You say nothing about alum, but if you used it the spots can readily be accounted for, as iron and alum together make a slow acting reducer.

PAIRING LENSES.—If I have a 3B. Dallmeyer paired with a cheaper lens, will the focus be identical at all distances? In other words, if two lenses are of identical focal length at infinity, will they require exactly the same bellows extension for all less distances?—BEE.

The camera extensions will most probably not be equal for any distance of the object, but if the lenses are adjusted by packing one of the flanges until both give perfectly sharp focus on, say, a distant object, then the same amount of extra extension will serve for near objects. You may, however, find that the depth differs with the two lenses, as this depends to a very large extent on their degrees of correction.

ARC LIGHT.—I have an arc lamp (medium size). I have tried to take portraits with it, but have not been very successful. One can see they have been taken by artificial light. This shows particularly in the whites of the eyes. For diffusing the light I have tried white cotton, muslin and tissue paper, each separately, and reducing the light till shadows were not shown, by putting a few thicknesses of the various things used. Still they are not what I have seen or would like. I also tried it by having the light reflected from a large screen painted white with Hall's Distemper, with side wings and a piece slanting from the top, but this I think was worse than any, and took up a great lot of room. Is there a diffuser I could buy ready-made that would suit this lamp, or can you tell me of any other things I might try and where they may be had?—LEARNER.

By using such diffusing media as you have been employing you are almost certain to prolong the exposure unnecessarily, and also to destroy the delicate crispness of the modelling of the lightest portions. One thickness of engineer's tracing linen is always sufficient with such a lamp as that you are using. Judging from your remark as to the whites of the eyes showing the character of the lighting, we should imagine you are getting considerable under-exposure. Arrange to have the light a little above and slightly to the front of the sitter, diffused as we have suggested, and for the shadow side have a large grey reflector at least six or eight feet square, and placed partly to the side and partly to the front of the sitter, so that its edge almost comes into the picture. Grey gives a less harsh reflected light than such a dead white as you have been using.

T. C. B.—If there is a registered copyright in the photograph it will be illegal for you to copy it, and if you do, you must take the risk. Whether the copyright is valid or not may depend upon circumstances, and that is a matter on which we can express no opinion. The fact that the photograph is not marked "Copyright" makes no difference. If that is the ground on which you doubt if the copyright is valid, you are quite under a misapprehension.

IDA.—From what you describe we should say that you are suffering from astigmatism, which constant sitting at the retouching desk will probably add to. As you have to depend upon retouching

as a livelihood, we should advise you to consult an experienced oculist without delay. If your means do not enable you to see a specialist, better go to one of the ophthalmic hospitals—say that at Charing Cross. There you will get the best advice free of charge. If spectacles are found to be necessary, you will be able to get them at a very moderate price.

DISTORTION.—Will you please give me your opinion on the enclosed portraits? The lens they were taken with was sold to me, second hand, as a half-plate portrait lens. It is 2½ in. diameter and 5½ in. focus. You will see the pictures are distorted, the nearest part being on a much larger scale than the more distant ones.—J. C. KLEWER.

There is no actual distortion in the pictures, but the perspective is very violent, and that is often called "distortion." It arises from the portraits being taken with a lens of too short a focus for the size of the picture. If you used a lens of the most modern type of similar focus on the same sized plate, the result would be the same.

PATENT QUERY.—Our firm, about a couple of years ago, took a licence to use a certain apparatus and a certain process for an annual payment. We now find that others are working it and paying a royalty. One of those told me that the patent was no good, as was not valid, because the whole thing had been published in the photographic press a dozen years and more back. He also gave me "chapter and verse" for what he said, and we find by reference that it is quite true. Will you please say if, in face of that, we shall still have to pay the licence fees?—V. B.

We fear you will, so long as the patent is not upset. By taking the licence you admitted the validity of the patent, and you cannot now repudiate it. If the validity of the patent is contested by anyone else, and it is ruled invalid, you can then discontinue your payments.

THE LATE MR. E. D. LAVENDER.—It is with regret, which we are sure will be shared by all who knew him, that we have to announce the death of Mr. E. Davey Lavender, F.R.P.S., of Bromley, Kent, which occurred on the 7th inst. Mr. Lavender was at one time a frequent exhibitor of large direct portraits at different exhibitions, in which he gained some of the highest awards, notably at the International Exhibition held in the Crystal Palace in 1889, when he was awarded the gold medal. He took a very active part in forming the now defunct Photographers' Benevolent Association, which came to an end owing to lack of the support from those it was intended to benefit. He was fond of outdoor sports, and was for some time secretary of the Bromley Cricket Club. For the greater part of a century Mr. Lavender carried on a high-class portrait business at Bromley, where he was much respected. We understand that this will be continued by Mrs. Lavender, who has always taken an active part in the business, and by her eldest son.

ENSIGN ROLL-FILM COMPETITION.—Miss E. M. Russell, 43, St. Bourne Terrace, Hyde Park, W., is the winner of the "Ensign" roll-film competition for October. Houghtons Ltd. offer a £1 guinea camera every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free and a competition form is enclosed with every spool of "Ensign" film.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Traill-Taylor lecture will be delivered on November 23 by Professor A. W. Porter, who will take as his subject "The Growth of the Photographic Image." (P. 848.)

Mr. Shaw's "extemporisings," the legitimacy of the straight print, and the fixation of bromide prints figure with other topics in "Correspondence." (P. 849.)

Mr. Cavendish Morton and Mr. A. L. Coburn appear before the committee this week as the authors of "The Art of Theatrical Make-up" in "London" respectively, the latter a portfolio of photogravures. (P. 845 and 833.)

Our contemporary "Printers' Ink," Mr. W. J. Casey lays stress on the increasing use which should be made of photography by advertisers in the general Press, as well as by those who might possibly employ stereoscopic, cinematographic, and other forms of photographic pictures in drawing the public's attention to their goods. (P. 837.)

The slight photography of indoor groups, interiors of factories, etc., having considerable commercial possibilities, the article by Mr. H. Andrews on p. 836 may be offered as a timely reminder of the comparatively simple outfit which is required and of the precautions which are quite essential to success in this class of work.

A recent communication to the R.P.S. by Mr. Arthur Payne describes the method of engraving direct on to the metal plate in the preparation of half-tone blocks, which has been christened "Phototype." (P. 840.)

Etching aluminium, a stop-out medium for fine etching, and a book on colotype, are among the "Photo-Mechanical" topics on p. 843.

The standard methods to be adopted in the recovery of residues in a practical article on p. 841.

The useful purposes to which linoleum or cork-lino may be put—after it makes an excellent facing for the enlarging easel—are mentioned in a note on p. 834.

The German inventors have united in designing and patenting a developing storage bottle. (P. 844.)

The tables, which have been found highly effective by the Kodak Company for the printing, enlarging, and mounting of prints, are described on p. 839.

Two hints on avoiding reflections are given on p. 834.

Some recommendations on making shutters interchangeable with various lenses and cameras which the professional photographer may use are given in an article on p. 835.

EX CATHEDRA.

Photographs at the Goupil Gallery.

In the Regent Street galleries, well known as the Goupil Galleries, a small upper room has been set aside for the photographs by Mr. A. L. Coburn, from which the plates illustrating his "London" have been made. The book is reviewed in another column. We have no hesitation in saying that the originals are incomparably better than the photogravures, in which the results in almost every case have become muddy and heavy. In seeking for more force, Mr. Coburn has lost qualities better worth having, such as delicacy and subtlety, true values and atmosphere. The "London Bridge" is the best subject, and has suffered least; but the great charm of "Hyde Park Corner," its vapour-thickened air, has quite gone in the photogravure, where the omnibus that should gleam out of a foggy ambient is many tones too dark, and has lost its proper place in the scheme. Mr. Coburn's photographs are in remarkably fine company, and they are not a little tried by the works in oil and water-colours by the most advanced artists of to-day, through which the visitor must run the gauntlet before he arrives at the London views. The ground floor galleries are filled with the choicest works, and we advise any who visit the galleries to "do" the whole show whilst they are about it.

* * *

Photographing the Curvature of the Earth.

In these pages we have frequently drawn attention to the value of photography in recording scientific truths. We are, however, reminded by an article in a contemporary that there is a certain amount of danger in this application of photography. It is a matter of common knowledge that we have still with us a few individuals who believe, or profess to believe, that the earth is flat. In support of this theory much use has been made of some photographs produced by Mr. Edgar Clifton, who, we may remark, is not a "flat-earthist" himself. These photographs show a bridge at Salters Sode in Norfolk, as seen from Welney, in Cambridgeshire, along the course of a perfectly straight and level canal six miles long. The bridge was covered with a white sheet, the lower edge of which touched the water; visual observation was made through a telescope, and also a photograph taken with a telephoto lens at a height of two feet above the water, showed the lower edge of the sheet even though, owing to the curvature of the earth, the visible horizon was about five feet above the straight line joining lens and edge of sheet. This result seems to have misled even Mr. Clifton, who says that in his mind "there is little doubt that this canal is absolutely level," and adds: "The most bigoted 'globularist' would not expect the water to rise

above its banks to assume the curved outline which the vast bulk of mankind still associate with the figure of our 'terrestrial ball.' In explanation he suggests that "being situated on an accidentally flat part of the earth's surface, the water, which is trifling in volume, is held in position by gravitation following the flat bottom of the canal." This last argument is beyond us, but we agree with Mr. Clifton that the canal is absolutely level, and we believe it has been proved to be so by actual measurement, but we would remind him that a true level is a curve, and that if the surface had the kind of flatness he seems to assume it would in reality be concave. The whole of Mr. Clifton's remarkable argument is due to disregard of the familiar daily phenomenon of "refraction," which compels the light rays to take a curved path under particular conditions, instead of the straight one they are popularly supposed to follow. In consequence of this phenomenon we are able to see the sun after it has actually sunk below the horizon, while the same cause is responsible for the appearance of mirages. Indeed, Mr. Clifton's photograph is one of the variety of mirage, and all the trouble is due to the fact that he was so near the water level where the air was naturally lying in strata of variable density, and where the light rays had an excessive curvature approximating to that of the earth itself.

* * *

Outlets for Artistic Photography.

The letter from Mr. G. T. Harris which appears on another page makes the altruistic suggestion that photographers might do worse than brighten the depressing atmosphere of a railway waiting room by displaying upon the walls of these apartments examples of their efforts in picture making with the camera. We are not prepared to admit that in every instance the effect would be that sought for, and there is another factor in the case which would probably nip any endeavours in the bud. Wall spaces on the premises of railway stations being the valuable asset for advertising purposes of Messrs. W. H. Smith and Son, it is more than likely that any offers to display alleged works of art in them would be referred to the contractors and would gain admission to the walls only at a price. Nowadays, when everyone advertises by some means or other, we can imagine an agent for the letting of advertisement space raising his eyebrows when told that the motive for showing the photographs displayed was a purely philanthropic one.

* * *

Re-mounting Lens Cells.

A somewhat curious experience was recently reported to us by a friend. It appeared that he possessed a modern lens of good quality mounted in a diaphragm shutter, and, having no use for the shutter, he re-mounted the lens cells in a plain iris mount and sold the shutter. Unfortunately he parted with the shutter before trying the new combination, and when he did try it the result was somewhat startling. He focussed first on an object in the foreground and then racked the camera in so as to change the focus on to a more distant object, but to his surprise the racking-in made the focus worse than before. After several trials he found that to change the focus from one object to another he had to rack out for the greater distance and to rack in for the nearer one, which state of affairs, being contrary to all his previous experience, simply bewildered him. The explanation was, of course, curvature of the field. Though he had appreciated the necessity of preserving the original separation of the two lens cells, yet he had not succeeded in doing it with sufficient accuracy, and as the result, strong curvature of the field was introduced. The nearer object on which he focussed appeared near the centre of

the plate and the more distant one near the margin. When the first object was in focus the image of the other one fell behind the plate instead of in front of it, the curvature being negative or convex to the lens, therefore it was necessary to rack the camera out to get the farther of the two objects into focus. This experience illustrates the danger of shifting lens cells into other mounts, especially when a modern highly corrected objective is in question. Very careful measurements are necessary if the correct adjustments are to be preserved, and it is always best to put the work into the hands of the original maker of the objective. Many good lenses are spoiled by being improperly mounted in diaphragm shutters. In some cases the lens owner makes the change himself on finding that the cells will readily fit the screw threads in the shutter, and when the threads will not fit he appeals to the nearest dealer, who most probably alters the screw thread only, and never discovers that other much more critical adjustments are essential.

* * *

"Cork Lino" for the Enlarging Easel.

Recently we referred to the use of linoleum as a cover for a work-room bench. The same material is, however, eminently useful for a quite different purpose. It is often necessary to let freshly mounted prints dry under pressure, but sometimes the result is marred by unsightly marks produced by the boards used for equalising the pressure. A piece of smooth thick linoleum used in place of the usual board is the best preventive of this trouble, for while it is smooth it is also slightly elastic. For pressing prints we commonly use a large copying press with a pair of linoleum pressure-boards between which the print is placed. A sheet of clean blotting-paper preserves the surface from contact with the linoleum, and so keeps it clean. Another variety of linoleum, known as "Cork Lino," or cork carpet, is also very useful in the workshop. Practically it is an extremely smooth and close-grained variety of cork, backed with strong canvas, and eminently durable. It is adaptable to various purposes. One piece can serve as a cork mat for flasks and beakers which contain hot solutions. Other pieces, fixed to walls or shelves in convenient position will form excellent pincushions for the dark-room pin that are in such constant demand and so seldom to be found. Perhaps, however, the most useful service which it can be put to is that of a covering to the enlarging easel. It should be glued down all over the board, that it may lie quite smoothly, and we then have the luxury of a cork-faced easel into which the feeblest pin can be driven with ease, while the hole vanishes when the pin is withdrawn.

* * *

Photographing Small Interiors.

One of the minor difficulties met with in photographing well-lighted rooms, which are usually a number of pictures on the walls, is the reflection in the glasses of these latter of light objects in other parts of the room. In such cases as this, inspection of the actual subject is a more efficient method of locating unsightly reflection patches than viewing the image on the ground glass. But the point of view must be that of the lens, the operator stooping down in front of the camera and scrutinising his subject from close in front of the lens. In many cases a glaring patch of reflected light may be turned off the plate by tilting the offending picture-frame by means of a ball of paper or a pocket-handkerchief stuffed in behind it. Unfortunately this local tinkering with the subject will not suffice when a number of frames are faced by white or light objects. In this event the most satisfactory remedy is a screen

thin black cloth or lining, which can be easily reared up on a couple of bamboo rods so as to exclude the cause of the trouble entirely. In taking a series of photographs in a picture gallery some such plan as this is almost a necessity.

* * *

Another Experience with Stains.

Though many remedies for stained negatives have been advocated, yet occasionally we come across a stain that refuses to yield to any treatment. Recently we turned out an old negative that was hopelessly stained and quite unprintable, and, as we knew the history of the stain, it seemed to be an interesting subject for experiment. It was a hydroquinone-developed negative, which originally showed a slight yellow stain across one end. In the course of years this stain had spread over the whole negative, and had become of a strong brown colour. Thiocarbamide was tried first, but it failed to touch the stain. We then bleached the negative with bichromate and hydrochloric acid, following this with a bath of chromic acid calculated to dissolve everything out of the film except the silver chloride and the gelatine. After a long soaking the film looked fairly clean, so we washed and re-developed, with the result that the stain reappeared. As a last resource we put the plate in a fixing-bath, and here, for the first time, a certain amount of effect was apparent. The chromic acid had started a certain amount of frilling, and we noticed that the frilled portions of the film were much cleaner than the rest. Frilling was then encouraged, and wherever the hypo got to the back of the film the stain tended to disappear. Evidently this was a case in which the stain was in the parts of the film next the glass, and could not be removed from the top. If we had stripped the film at the start and then operated on the loose film, in all probability we might have been successful in the clearing operations. The remedy would have been a rather desperate one, but sometimes it is necessary to be desperate, so the experience we have described may be useful *in extremis*.

ON LOOKING TO STUDIO APPARATUS.

ANY photographic business, however large or small, is bound to have a variety of cameras. The efficiency of these can be vastly improved in many cases by a little thought. These improvements will be chiefly in the arrangement of the shutter and lens, and in the direction of making these fittings interchangeable. The most generally used type of studio camera of to-day is provided with a grooved front, into which the various lenses on loose panels lift in and out. The panel is generally provided with a fitting upon which the studio shutter is attached. This is a quick method of altering lenses when changing from cabinet to 12 by 10, or what not, but the shutter takes time to detach and attach. We have much simplified matters by screwing inside the camera (covering up the square hole for lens panel) a piece of blackened three-ply wood with a hole in the centre the exact diameter of the largest aperture of the shutter. The shutter is fixed permanently to this, and the lens can be changed even if the plate is ready for exposure, needless to say, re-focussing after changing. The shutter should be large enough to take the largest lens used. We have said above "permanently fixed," but the shutter should be removable when required. For at-home portraits, a really silent shutter is a great boon, and both whole plate and 12 by 10 field cameras are conveniently fitted so that the studio shutter can be used with them. In a large camera this is only a matter of fixing the same shutter catches as for the studio apparatus and placing a brass air-pipe through the lens panel. In a

whole-plate camera, however, the shutter may only just fit, and great care is required in fitting catches. The brass connection almost led us to give up the idea, but the difficulty was overcome by fixing the pipe in the permanent front and cutting a slot in the rising and falling front, similar to that in which the tightening screw works. Only a square-bellows pattern camera will take an inside pattern shutter. For architectural and general work, the extreme rise and swing front of the conical bellows pattern camera make it far superior to the older type. A good lens of the ordinary angle and an extremely wide angle lens are, however, imperative. The loose lens-board type of shutter is to be recommended for general reliability and quickness of alteration, say a whole-plate shutter, big enough to take a 15in. by 12in. lens. This has the disadvantage that it will not fold through the turntable and restricts the cross front, but on the score of convenience and economy it cannot be beaten. Practically, every lens except the 3B portrait should have a lens panel for this shutter, giving a great range of focal length. The quarter-plate lens stopped down will cover the whole plate, as will also a half-plate lens. The wide-angle whole plate comes between these two; thus there is the regular anastigmat and the 15in. by 12in. for long focal length.

The cross front, with the shutter screwed thereon, fits on to the square-bellows whole-plate, when exceptional rigidity is required, and also on to the longer cameras, so that, besides increased efficiency, the cost of an extra shutter, lens panels, and lens flanges is saved. By making a special pattern cross-front and putting two extra grooves on the square-bellows pattern, the studio lens at $f/3$ is available for at-home portraiture—a very great help indeed for groups (of two or three) and babies when combined with the silent shutter as before described. This advantage of the square-bellows camera, i.e., the ability of the solid front to take studio lenses and shutter, should be borne in mind when the respective merits of square or conical bellows pattern are to be determined. With very little work indeed any lens can be made to fit any camera. For copying and other special work it is often desirable to use the field lenses. To avoid purchasing extra flanges, we have one studio camera lens-panel so fitted with the aid of some home-made grooves, velvet, and glue that the various lens-panels of the field shutter will slide on to it.

Should the longer and smaller cameras be out on different work at the same time, shutters for each will be necessary. In that case it is advisable either to have identical shutters or by a little ingenuity to make the lens boards of the smaller shutter fit on to the larger. It will, perhaps, appear rather extravagant to have both types of whole-plate camera, but in this connection we may quote the experience of a correspondent, Mr. Foster Brigham, of Scarborough: "Having by an accident got a camera of each kind, I would not now be without them, each having merits impossible to combine. The accident mentioned was the fact that one square-bellows model had been declared 'unmendable' by the cabinet-maker who has had it several times during the last twenty years. The rack became so loose that the focussing screen moved when the dark slide was inserted and, moreover, the slides leaked slightly. The new camera was ordered with reversing back to take the old slides and also the focal-plane shutter, so that these are again interchangeable. Upon taking the slides to pieces it was found that the velvet light top which is 'unget-at-able' without entirely withdrawing the slide, was worn smooth and shiny. This was replaced with new velvet and slides, and both are now quite as good as new. The slides have always been kept black-leaded to avoid wear, and the brass side clips tightened slightly whenever required. Having some spare time, a too common occurrence in the spring, I removed the

pinion from the camera and found that it was slightly bent. After straightening and screwing on to camera very tight in slightly different position, this also works as in the days of youth."

We have no doubt that there are many dozens of cameras rotting in idleness or thrown away that only require some such simple attention to put them in working order. Brass stays and plates will easily cure slight shakiness. Printing-frames are articles often discarded on account of broken springs or because the angle blocks have become

detached. The latter are easily cut and glued in, whilst spare springs are cheaply purchased. Some of the springs on the cheapest class of printing-frame are almost useless for their purpose. Springs on frames we have had for ten to twenty years are still perfectly "springy" and strong. Some new ones we recently received were more like lead, losing all springiness after bending four or five times. Printing-frames should not be stored higher than a gas flame. The fumes soon destroy all the qualities of the brass, so that springs break like matchwood.

PRACTICAL HINTS ON FLASHLIGHT PHOTOGRAPHY.

Now that the season for flashlight work is here, I wish, if possible, in this short article, to give a few very practical hints and some useful information that will be of some benefit to the professional photographer, so that the average practical man can undertake this class of work with more confidence, and so increase his business. Many have refused this kind of work; indeed, it is not uncommon to find photographers who are absolutely afraid to undertake it at any price. I want, if possible, to make it very clear and plain that it is not so very difficult and dangerous if carried out by a practical man.

First of all, let me emphasise the fact that no one should think of undertaking flashlight unless he be fairly well acquainted with the necessary precautions. There is certainly some danger attached to it, but if the reader will closely follow the instructions here given, and never attempt any experiments with flashlight powder, then the risks are reduced to a minimum.

Let it be said at once that any danger does not apply to the sitters or subjects, but to the man who operates. In an experience of over twelve years with flashlight, during which time I have made considerably over 1,000 exposures, both of indoor and outdoor subjects, I have come in contact with many other workers, but I have never known any accident to happen to anyone except the operator. In some cases he has been severely burnt, and in most instances it can be traced to carelessness. Only once did I ever meet with a slight accident myself—I was burnt slightly—and that was caused through experimenting with a new automatic flashlamp, which went off at the wrong moment.

I intend principally in this article to deal with group flashlight work and indoor commercial work, and shall have little to say about portraiture, because this latter is so very simple and easy after the other. A workroom, or a dinner or children's party, to be taken on, say, a 12 x 10 plate, is not easy, and it is here where the operator has to be quick, have a cool head, and make no mistake.

A Flash Equipment for Practical Work.

For the man who has a good deal of flashlight to do, it is better to have a good lamp, made something after the style of lamp I shall describe; but for only an occasional job it is not at all necessary to have anything elaborate. Really, a pair of borrowed steps and a piece of board about three feet long is all that is necessary; the word flashlamp gives a mistaken idea of what is really wanted. All that is required is something to place the powder on ready to fire. There is not really a perfectly reliable flashlamp on the market that, for large commercial work, I can recommend, and I have tried pretty well every lamp there is, and experimented with every kind of powder. The lamps which I am referring to principally are those for firing off instantaneous powder. Lamps for magnesium powder are not a bit of use for present-day photography; they

are antique, and seldom used now and are practically useless. The kind of lamp which I recommend is one that can be made at home for about ten shillings, and will answer the purpose for a long time without getting out of order. Obtain a piece of match-board about three feet long by about four inches wide, cover this with some sort of metal—aluminium for preference, on account of its lightness.

Insert at the bottom, in the centre, a bush for screwing in a rod, collapsible or otherwise (collapsible for preference), about eight feet in height. A clamp for attaching the rod to a chair or table completes the list of what is required, excepting a taper mounted in holder of decent length. Those who have a lot of flashlight work can quite easily have a more elaborate lamp made on the same lines. The piece of board and pair of steps referred to is what I used for a long while myself some years ago. Never have anything to do with any lamps which act automatically or are fired by batteries or electricity; they may go right for some time, but they are sure to fail later on, and generally at the critical moment. I have heard of more failures from this cause than any other.

The Powder.

Any of the well-known instantaneous combustible powders will answer well, but the powders that I prefer are the "Argentorat" and "Ideal" powders, which have been in use in this country for several years, and can be bought at most dealers at about 4s. 6d. per box of 100 grammes. This is enough for exposures for four 12 x 10 or eight whole-plate negatives. Never be persuaded to try mixing your own powder. The process involves a lot of trouble, is dangerous, and the powder so made is often unreliable. As I have said, at the critical moment of the exposure nothing must go wrong, and there must be no mistake; so always use a good, reliable powder that is well recommended, and, in preference, one of those just mentioned.

Fixing up the Camera.

Assuming that we are to take a dinner-party or a workroom full of people, to be taken on a 12 x 10 plate: arrange to fix the camera fairly high up from the ground. In a large room it is often best to erect the camera on a table. After focussing carefully, stop your lens down to $f/16$, if necessary, but never more than this, or you will require a terrific lot of powder. Nearly all our modern lenses will cover a 12 by 10 beautifully at $f/16$, and there is very seldom occasion to stop down more. If working 1/1 plates $f/11$ should be quite sufficient.

Whilst the focussing is being arranged, if you are lucky enough to have an assistant with you, he can be arranging the flashlamp. An assistant is not at all necessary. I nearly always do all my flashlights quite alone.

Fixing the Lamp.

Erect your lamp as high as possible, and immediately behind the camera. Always remember to get your light high up, and as near to your objects as possible, but never in front of the lens, unless the latter is well shielded from the light; otherwise a fogged plate will be the result, through the light reflecting back into the lens. The plate should now be put in the camera. Always use the fastest plates obtainable: it is useless to use a slow or medium rapidity plate. Now draw your slide, and, last of all, place your powder in position. This sounds perfectly easy, placing the powder in position, but in this operation there is decidedly more art and knack needed than one would imagine. One great thing to remember and aim for is a large sheet of light, rather than an intense concentrated light. This is most important, and essential to good flashlight work. You want your light to carry all over the room, if possible, and this can only be done by placing the powder correctly. On the centre of your lamp, or on your temporary piece of board, place a small piece of gun-cotton (this can be purchased at any wholesale chemist's, and half an ounce will last for years). Use a piece about the size of a small nut, cover this partly with powder, and gently form a trail of powder from end to end of the tray, being careful to see the trail is not broken in any part; otherwise, when ignited, the powder beyond the broken trail will not ignite. One then feels inclined to apply a lighted match with the hand—an act which would prove disastrous to the operator. The amount of powder required is about a quarter of a box (25 grammes). Having previously seen that any near lights are turned off—the lights in the distance will not matter in the least, and will not affect the plate the few seconds the lens is uncapped—you should ask your sitters or party either to look at their work (if a workroom), or else to look just below the camera, and on no account to look at the flash; otherwise they will all appear staring upwards. Nothing remains now but to uncup the lens, and to expose by applying the lighted taper to the exposed piece of gun-cotton: the result will be an instantaneous flash of about a tenth of a second. Your taper-holder should be of good length, so as to allow you to keep as far away as possible from the flash. The majority of the powders contain aluminium, which gives off intense heat, especially when a large flash is used.

One Essential to Success—Dry Powder.

One important thing always to remember is never to have your powder exposed any longer than is really necessary: arrange that it is fired as quickly as possible after having been laid out. If not, there will be a loud report when fired, and the report will be louder the longer the powder is exposed to the atmosphere. If fired as soon as laid out, the powder should go off without any report whatever. If a report does occur, it is liable to give rise to confusion, and may cause certain timid people to be very frightened. Remember, it can be avoided, as can also smoke, to a great extent, if special attention is given to the windows. A great deal depends on the ventilation of the room. If well ventilated, the smoke will go out in a few minutes. No matter how high the room or hall, the smoke will always ascend to the ceiling, and if all the windows are opened for a few minutes, the smoke should soon disappear without descending and causing any inconvenience.

The quantity of powder required will be less than 25 grammes if using the lens at $f/11$, and in proportion less still if using $f/8$, which can be used for half-plates and for single portraits; where the open aperture of the lens can be used, enough to cover a shilling is sufficient. A very large hall will require more powder if it is required to light the whole place well, or if found to be absolutely necessary to stop to $f/22$. Experience only will teach the correct quantity to use.

Development of the Plate.

It will be found that it is very rarely that a flashlight is over-exposed. On the other hand, they will always lean towards under-exposure, so that little or no bromide should be used in the development. Greater care must be used in handling these very fast plates than those in general use. Too much red light will often cause fog, so keep the dish well covered during development.

In this short article I hope to have made it very plain and distinct how good flashlights can be obtained; and all photographers who wish to increase their business would do well to make some attempt to understand this branch of the trade thoroughly, as I believe there are heaps of business to be got in this direction.

H. ANDREWS.

PHOTOGRAPHY IN THE SERVICE OF ADVERTISING.

[The use of the photograph in press, poster, and other forms of advertising is steadily growing, but not as rapidly as one might expect of the large number of photographers "out to make money." If this is due to any misapprehension as to the field open to them on the part of the photographers, we would recommend a perusal of the following article from the two last issues of our advertising contemporary, "Printers' Ink," a journal which we would further suggest for regular study by every photographer and photographic firm interested in improving their methods of publicity. The author, Mr. W. J. Casey, the advertising manager of Messrs. Raines and Co., will doubtless admit that in thus advocating in the advertising press, the greater use of photographic work, he is affording another instance of the "Service that Helps" (Where have we seen that phrase?), since it is the professional photographer who will directly benefit by an increased demand for photographs among advertisers.—Eds. "B.J."]

THIS is a plea for the greater use of the photograph in advertising—both in its half-tone reproduction for illustration and in its actual form for showcard and similar purposes.

The public dearly loves a photograph. All through the big postcard boom it paid its twopences for "real photograph celebrities" compared with the penny or less for the many competing coloured varieties, thus violently upsetting the "penny plain, twopence coloured" theory of values of our childhood.

Public Prefers Photographs.

But strongest of all reasons that I can bring forward is the steadily increasing use of photographs in the editorial pages of the popular press. The managements of these publications gauge the public taste to a nicety, and advertisers may well follow the cue thus given.

As Kenneth Groesbeck puts it in the *Printing Art*, "the advertising value of anything is based on the intensity of the

impression it creates. A photograph, as a general thing, makes better advertising than a drawing. This, when naturalness is desired. If we are illustrating any commonly seen objects, or if figures of people enter into our scheme of illustration, photography is valuable. It convinces by its very accuracy."

And is not "naturalness" the most desirable of attributes in advertising? Is it not more desirable even than the humour that so many advertisers aim at incorporating in their publicity? Ask a woman who has to sweep rooms herself, or (what is seemingly harder work still) who has to direct the servants doing so, her impression of the Hassall "Help" poster. Then ask her what she thinks of the Allenbury mother and child, and you will soon learn which appeals the more strongly. Certainly Allen and Hanburys have run the one subject a long time, but it is quite possible to use photographs, and yet change copy frequently, as witness the excellent half-page of Pearline Soap Powder and the full-page of Washburn-Crosby flour in the American magazines, both of which use a new subject every month. These two advertisers, be it noted, use photographs specially taken—photographs that are made to fit the copy, and not, as are the majority of photographs here used, taken at random and offered to the agents for the article for its name to be worked in and copy written, more or less loosely, around it as opportunity offers.

Who Will Be First?

Who will be the first advertiser to run such a series in our monthlies or weeklies? Obviously the work can only be done by a really good professional photographer, and as such must be well paid for; but even at that, and including payment to the models, the cost would not be nearly so much as that now paid for good pen-and-ink and wash drawings.

I would lay particular stress on this necessity for co-operation between the advertiser and the photographer. Up to the present there has been too much reliance on more or less spasmodic work. I venture to assert that one half of the sum awarded in prizes in the Bovril photographic competition a few years ago (one recognises, of course, that other motives besides the acquisition of photographs were behind the scheme), if spent in commissioning one or other of the West End photographers whose imprints appear below the theatrical photographs in the weekly papers, would obtain such a series of photographs as would create no little attention.

Photographs must be Good.

There is room, too, for more photographs of the article itself than are being used—I mean good photographs of the kind used by Hampton and Maple. The trouble is that too many advertisers think that any photograph is good enough for half-tone reproduction, and that the engraver's artist and fine-etcher can work wonders, and that without extra charge! During the last few years great improvements have been made in photography of coloured objects, and with such a plate as the Wratten Panchromatic and properly adjusted filters, it is possible to photograph even polished mahogany furniture without reflections, and still to show the beauty of the figuring. But for work of this description it will be necessary to call in the photographer who has made a special study of commercial photography; it will not do to entrust the work to the junior clerk who is the proud possessor of a guinea hand-camera.

And how little are photographs used as compared with what they might be.

The Manufacturer at Fault.

The retailer cannot be blamed—except in the case of the companies working a chain of shops—but surely the manufacturer, especially of foodstuffs, who is producing a better article than most of his competitors, might well make use of photographic showcards. For instance, sausage-making—long the

butt of the would-be funny man—could be demonstrated by Messrs. Palethorpe, of Dudley Port, in such a way as to show the product of their model plant immensely superior to the cheaper unlabelled article with which they have to compete. Similarly with the jams produced by Chivers at Histon. A frame with a series of, say, twelve appropriately worded photographs, to be changed daily, would be appreciated by many retailers.

What the Railways are Doing.

The railway companies, whose advertising has been the subject of so much adverse criticism in previous issues of "Printers' Ink," have long realised the value of photographs. Not only have they used small photographs in carriages, but, at the termini in their parcels receiving offices and at the Shepherd's Bush exhibitions, they have used enlargements of such striking size as at once to arrest attention. At Shepherd's Bush this year the London and North Western presented an excellent cinematograph show, while at Earl's Court the Southern and Union Pacific Railway had a very fine exhibit. A small hall was tastefully hung with enlargements, and several times during the day half-hour "talks" were given, illustrated by coloured lanterns and cinematograph films. Thus a "talk" on "San Francisco and its restoration" showed about fifty different slides, and interspersed among them were "moving pictures" depicting a ride on a street car through the busiest part of Frisco, a fire-engine parade, seagulls following a fishing boat from which waste fish are being thrown overboard, an ostrich farm, and an entertainment in a swimming-bath. At the close I remarked to Mr. Erwin, the gentleman in charge of the exhibit, that he had not once mentioned his railway. His reply was interesting. "Oh, that doesn't matter. We want to interest people in California; once they go there, they must travel on our system." Many of our lines have monopolies, or practically so, of desirable resorts—Brighton, Eastbourne, the Norfolk Broads, Lowestoft, the Cornish Riviera—will they follow the Union Pacific example?

Why Not Steamship Companies?

If the railway companies thus realise the value of photographs, why do not the steamship companies use them more? Experts may appreciate the models that are always on show in the office windows of the leading companies, but one doubts if they appeal very strongly to the general public.

The Inexpensive Stereoscope.

Mention has been made of the cinematograph. Lloyds, of newspaper fame, have already a "moving picture" show, and doubtless other firms will soon follow suit. But I have not yet heard of the stereoscope being used for advertising purposes. The councils of seaside resorts, manufacturing firms such as Cadbury's, who, in addition to their model village, must have many interesting views in their factories, might well arrange to have stereoscopes and sets of views in the reading and smoking rooms of hotels, boarding-houses, clubs, etc. In America there is a huge business done in stereoscopic views—Underwood and the H. C. White Company each turn out many thousand weekly. If people will thus buy views on the other side, it may reasonably be argued that they would, were the opportunity offered of doing so free of charge, look at them carefully in this country.

Aids to Recruiting.

It seems to me that photographs depicting life in the army and navy would be very much more attractive as aids to recruiting than the lithographs that one now sees displayed in public places. These all seem to have been designed with the idea that the desired recruit is most likely to be captured by the high

coloured uniforms—but to my mind photographs of the kind that one sees in the sixpenny weeklies, i.e., those showing manœuvres and sports, would, if shown in enlarged form, appeal more strongly to the fighting and sport-loving spirit animating, to a greater or lesser degree, most young Englishmen.

To repeat the quotation I used above, "Photography is valuable. It convinces by its very accuracy." The advertiser should remember this. If he does not, it is "up to" the photographer, the man who has to make his living by it, to remind him of it.
W. J. CASEY.

USEFUL WORKROOM TABLES.

[In arranging and equipping their model studio, the Eastman Kodak Company endeavoured to install only such fixtures as would prove thoroughly practical and convenient and a help in the economy of time and labour. Below we reprint from the September "Studio Light and the Aristo Eagle" a description of the work-room tables.]

THE three tables or work-benches described in this article have thoroughly demonstrated their practical efficiency in three years' constant use, and we have found no necessity for any modifications from the original plans.

It will be noticed that none of the shelving or cupboarding extends entirely to the floor—the free space allowing the floor underneath the benches to be easily swept, and also acts as a protection to the contents of the benches from dampness.

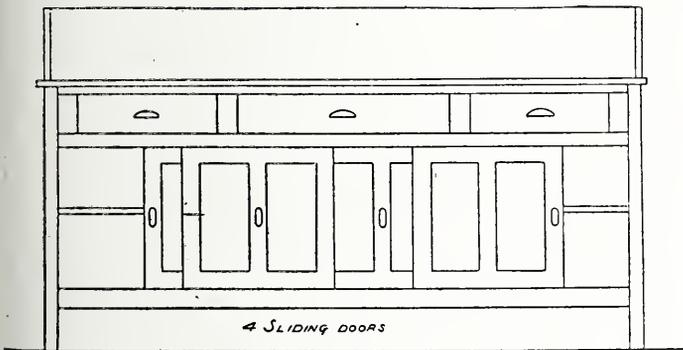

Fig. 1.
Printing-room Table.

The table in the printing-room—see illustration No. 1—is placed against the side wall of the room, just out of range from the light from the printing-window. The top is provided with back and end pieces about twelve inches high. The back forms a handy support for the negatives when sorting for printing, and also prevents any of the negatives from slipping down behind the table and becoming lost or damaged.

We call your attention to the fact that all printing-frames are stored in the lower part of the bench, either in the open shelves at each end or in the enclosed cupboards. This method is far better than sorting the frames on shelves above the

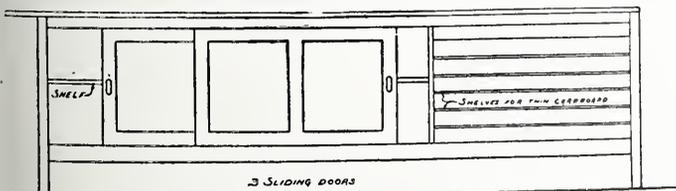

Fig. 2.
Mounting-room Table.

table, as, when stacked above the table, they sometimes come tumbling down, with disastrous results to important negatives. The table is provided with three snugly fitting drawers, equipped with pull handles, for the storage of sensitive paper. In the cupboards beneath ample space is provided for the storage of vignettes, tissues, and other printing necessities.

The table in the mounting-room is of solid construction, and is provided with a broad, perfectly smooth top, which may be covered with white rubber or oilcloth to insure its surface being

always clean, and mounts and prints from damage by soiling. The long shelves for the storage of thin mountboard will be found a great convenience, as the thin stock will remain in perfect condition, and no time need be lost sorting the sheets to locate different colours or weights. The other open shelves may be used for storing dry mounting tissue or paste, and other incidentals for mounting, while the shelving protected by the sliding doors forms an ideal storage place for stock mounts.

The table in the enlarging-room presents some unusual features, which, though simple, greatly facilitate the work when enlarging in large sizes.

By referring to illustration No. 3, it will be noticed that

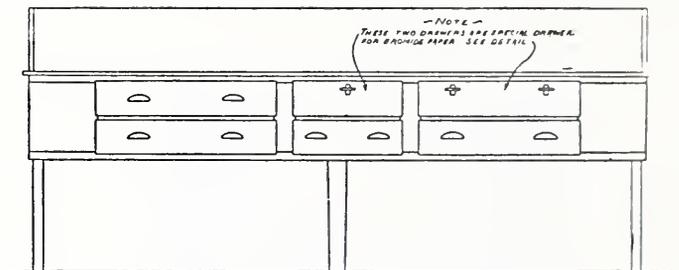

Fig. 3.
Enlarging-room Table.

the top of this table is constructed in the same manner as the table in the printing-room, and for the same reasons. This table is fitted with six drawers for the storage of paper and other incidentals, four of the drawers are of the ordinary type, but the two upper right-hand ones are designed for the storage of bromide paper in large sizes, and are of special construction.

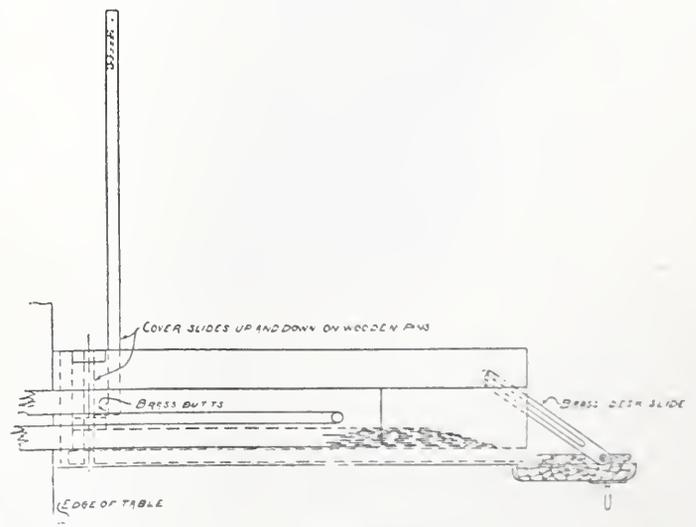

Fig. 4.

Illustration No. 4 affords a profile view of one of these drawers when pulled out. It will be seen that the drawer is provided

with a heavy board cover, which slides up and down on wooden pins, and serves as a weight to keep the paper flat during storage. This cover is provided with a brass flush ring, so that it may be easily lifted up to a vertical position when it is necessary to remove paper for use.

The front of the drawer pulls down, and is supported by a brass desk slide, making the large sizes of paper stored on the bottom of the drawer easy of access, and permitting the

removal of any size sheet without disturbing the remainder. The paper may be stored in this manner in its original enclosures, the size, surface, and grade may be written in the edge extending, thus making it easy to locate and remove any size or grade instantly.

The plans reproduced herewith are reduced from the original scale of three inches to the foot; but they, of course, can be constructed in dimensions to accommodate any space.

A DIRECT PHOTO-ENGRAVING PROCESS.

(A Communication to the Royal Photographic Society's Journal.)

THE illustration on this page is interesting because it is the first half-tone block to be made by photographing the human figure direct upon the prepared metallic (zinc) plate. I exposed the plate in June, 1909, and the exposure was 10 seconds at $f/18$, square stop, with a 65 line Levy screen; the portrait was taken in the open air. Of course, this prolonged exposure does not permit of the practical use of the process by the press photographer at present, but it should be noted that a very slow emulsion was used, and if the most rapid emulsions are found to be suitable for this work, the exposure may be reduced under similar conditions to 1-14th of a second.

The process is protected by Letters Patent No. 28415, 1907, and No. 18775, 1908, in Great Britain.* Patents have also been applied for in the United States of America, Germany, France, Belgium, Austria, and Hungary.

The essential part of the process is the prepared metallic plates, which may be manufactured, stored, and sold ready for use, in a similar manner to ordinary dry plates. Though I have worked with both copper and zinc plates, it seems likely that zinc will be the most useful metal to use as a base. The plates consist of an extremely thin film of a gelatino-bromide

emulsion coated upon a film or substratum of spirit-soluble varnish laid upon the metal plate. The varnish acts as the etching resist and also prevents chemical action between the emulsion and the metal plate. The plates keep well, and may readily be cut to any size by means of a guillotine machine used in the dark room. I have adopted a slow emulsion, of about the same speed as wet collodion, so that I could use a strong yellow light in the dark room in order to study the working details of the process, but it is quite possible that the rapidity of the emulsion may be considerably increased in the future.

The plate is exposed in the process camera in the usual manner, except that as the image does not require to be reversed, no prism is used upon the lens. The exposed plate is developed exactly in a similar manner to an ordinary gelatine dry plate with a glycin developer for about two and a-half minutes, and after rinsing under the tap for half a minute, is immersed for three minutes in a 5 per cent. solution of potassium bichromate, which has the well-known effect of hardening the gelatine in contact with the developed silver. The plate is again rinsed and then developed in hot water like a carbon print, and dried with heat. In parentheses, I may draw attention to the fact that the unexposed silver bromide is not fixed out of the image before the plate is hardened in the bichromate solution, for its presence does not interfere with the effective use of the bichromate solution, and it forms an excellent indicator to show when the lines or dots are thoroughly developed. At this stage the plate carries an image in hardened gelatine imposed upon the acid resist, which is easily removed from the portions unprotected by the gelatine, by immersing the plate in methylated spirit of good quality, 64 O.P., slightly rocking the dish and then rapidly flushing the plate with plenty of water, so as to remove all the spirit from the film before it has time to mix with the water and penetrate through the gelatine film and attack the resist. Under this treatment the acid resist is softened and may be readily removed by carefully wiping the plate with a pad of wet cotton wool. Upon examination, the lines or dots should be found to be quite free from scum, though, if the resist is not completely removed, the plate may be dried and then re-immersed in the methylated spirit and the operation repeated. When a satisfactory result is obtained, the gelatine film may be removed by strong rubbing with a pad of wet cotton wool.

At this stage a negative image is usually obtained which it is necessary to "reverse" into a positive image; though in the making of intaglio line blocks, or in the production of half-tone blocks by copying a continuous tone negative instead of a print made therefrom, this is the whole simple process, and the plate is ready for etching.

But in the larger proportion of blocks it will be necessary to "reverse" the image, and here the operator has the choice of

* "B.J.," 1909, p. 198 and 785.

three different methods. In the first place, he may convert the gelatine image immediately after the first development, and before it is hardened, into a positive, by dissolving the developed layer with an acid permanganate reducer, then re-developing the silver bromide after it has been exposed to light, and, after cleaning the film, proceed to harden the gelatine by means of the bichromate solution. This attractive method is, however, difficult in practice, and it is preferable to convert the negative image into a positive by, in the first place, finishing the plate as if an intaglio line block were required, and then electrolytically depositing copper upon the exposed zinc lines for about ten minutes by means of a very weak electric current and using a warm bath of copper cyanide. The varnish resist prevents the deposition of copper upon those parts of the plate that are protected. When a sufficient coating of copper is obtained—and it is surprising what a thin film forms an efficient etching resist for the nitric acid bath, even when used in a Levy acid blast machine—the plate is cleaned of all traces of the original varnish resist, and may then be etched in the usual manner. The third, and what will probably be the most popular method “reversal,” is to finish the plate as if for the production of a “reversed” block, and then to roll up the plate with a composition roller and middle litho ink thinned with litho varnish, being careful to cover the plate with a thin, even coating of ink. It is necessary to add a little litho varnish to the ink to ensure it remaining sufficiently “tacky” to hold the dragon’s blood after the plate has been immersed in the methylated spirit. After the plate has been rolled up with ink it is immersed in methylated spirit and allowed to lie therein for two minutes, the image subsequently being carefully developed by gently wiping it with a pledget of cotton wool, exactly as in the development of an albumen inked image, over which, however, it has the great advantage that there is no film of albumen between the ink image and the metal. When the plate is developed a picture in greasy ink is obtained upon the zinc plate, and this image may be retouched, dusted with dragon’s blood or bitumen, and etched in the usual manner.

Schedule of Operations.

Development with glycin	2½	minutes.
Rinse with water	½	”
Harden in bichromate solution	3	”
Develop in hot water	2	”
Removing resist.....	2	”
“Reversal” by ink method.....	5	”
	15	”

It should be noted that these times apply to the production of one plate only; when more plates than one are being produced it is possible to work more rapidly. For instance, my own record for the production of twelve half-plate relief-line blocks ready for etching, working single-handed, and including the time of loading the plates into the camera, exposing and develop-

ing them separately, is 2 hours 16 minutes, or an average of 11½ minutes each, against 15 minutes according to schedule time; the reason for this is because considerable time may be saved by dovetailing the operations into each other.

The Paynetype process is not suitable for all kinds of photo-engraving. It will not produce good fine half-tone blocks, and I think that in this direction a 133 line block is about the limitation of the process, and even a block of this grade will not be easily made. But the process has been thoroughly tested under practical conditions, both in a newspaper process studio and a photo-engraver’s establishment, and it was found easy under these conditions to produce excellent line blocks of a reasonable degree of fineness, and also good coarse half-tones that can be made either direct from the original, a negative, or a print. It may be said to be a process that is eminently adapted for newspaper photo-engraving where the speed of working will be a most valuable feature, and for economic reasons, in the production of line blocks in the ordinary photo-engraver’s establishment. Mr. A. J. Newton suggests that it will be an admirable process for making half-tone poster blocks by enlarging from a small half-tone negative direct upon the prepared zinc plate. In addition to its use in the production of printing blocks, this process can be applied in the making of engraved metal plates for use as name-plates, illuminated brasses for churches, engraved dials, engineers’ name-plates, furniture goods, etc., by photographing printed matter, or line sketches, direct on to the metal plate, which is then etched and the intaglio marks filled in with coloured wax. It is interesting to note that the cost of the materials other than the prepared metallic plate is very low, being less than one penny per 12 x 10-inch plate when the process is worked on a commercial scale.

Perhaps I may be permitted to enumerate a few of the advantages possessed by this process. They consist of economy and ease in manipulation, and, principally, in the great saving of time over existing methods. The speed of working is remarkable, for it is possible to develop and etch, with the Levy acid blast machine, a half-tone block in about 15 minutes. It is a really cold process, and therefore suitable for use with zinc plates; it is also a dry plate process, and its beautiful simplicity must appeal to all when they realise that the wet collodion process is finally abolished, and in its place reigns a plate that is supplied to the operator ready for use, and which he has only to lift out of the box and place in the camera. No prism, no sweating of screen, no polishing of metal plates, no fish glue enamel, no printing, and only three cheap solutions, are all features of the Paynetype process.

A set of plates illustrating the steps in the production of a Paynetype block, and also a line block reversed by the electro-deposition of copper, and showing the copper face upon the block, will be found exhibited in the Museum at 35, Russell Square, after the close of the Exhibition at the New Gallery, where they are at the present time. ARTHUR PAYNE.

RESIDUES AND THEIR SAVING.

[Although the remunerative return which attached to the recovery of silver residues in the days of wet collodion and albumen paper no longer holds good, there is, nevertheless, an opportunity for economy, of which probably many photographers making a large turnover do not take advantage. The following article describes the essential methods of saving the silver and gold left unused in photographic materials and solutions.—EDS. “B.J.”]

P.O.P.s contain but comparatively little soluble silver salts which can be washed out; they are very different from albumen paper sensitised at home, but in either case the proceedings are the same. It is well to have a good size vessel to contain the washings, say a large stoneware jar or a paraffin cask with the head removed. When a sufficient quantity has accumulated the silver is precipitated as chloride. It may be as well to mention here that it is only the

first and, perhaps, second waters that contain enough silver to be worth the trouble of recovery. The precipitant of the silver as a chloride, usually recommended, is chloride of sodium (common salt), but in two respects hydrochloric acid is preferable. First, chloride of silver is, to some extent, soluble in a solution of chloride of sodium, and if a large excess of the salt be used some of the chloride of silver may be re-dissolved. Secondly, chloride of silver

precipitated by hydrochloric acid subsides more quickly than does that thrown down by salt. The commercial acid, costing about two-pence a pound, answers quite well for the purpose. If salt be used and there is a difficulty in getting the silver to settle down, an ounce or two of common nitric acid added and well stirred in will cause it to subside more rapidly. When all has settled down the water should be drained off and more washings added until the vessel is again full, when the silver can be precipitated as before. This procedure may be continued until sufficient has accumulated to make it worth while to further deal with it. Silver baths used for sensitising paper, or for collodion plates, are usually renovated or strengthened and used over and over again. But should occasion arrive, that it is required to recover the silver from them, or any other solutions containing nitrate of silver, they may be added to the washing waters. When sufficient chloride has accumulated to make it worth while to deal with it further, the water is drained off closely, and the vessel filled up with fresh water, well stirred up, and allowed to subside. This is repeated two or three times. If the chloride contains much free acid it will neutralise the alkali, carbonate of potash or soda, used by the refiner in reducing it to the metallic state, and perhaps give trouble. The chloride is now emptied out, and dried, and is ready to be sent to the refiner.

Instead of sending the chloride to the refiner, the silver may be reduced to the metallic state and then converted into the nitrate for future use as such. The wet chloride is put into a large basin, and some sulphuric acid added, and, after stirring up, some cuttings of zinc are dropped in and allowed to rest for a day or so, until all the chloride is reduced. After any undissolved zinc has been removed the silver is well washed with water and then dissolved by nitric acid, and crystallised. But as there is but little use for nitrates of silver by photographers at the present time it is better to send the chloride to the refiner for reduction.

Paper Cuttings.

These should be first burnt in an open grate, taking care that none are carried up the chimney. The ash is then collected and put into an old iron pot, or saucepan, which is then put on to a good fire and allowed to incinerate for an hour or two, so as to reduce the bulk to the smallest possible quantity. Unless that is done no correct assay can be made as to the silver they contain. In the case of the cuttings of albumen paper, sensitised at home, if carefully collected and treated in this way, the fine ash usually contains from a third to half its weight of silver. With P.O.P.s the paper is usually surfaced with sulphate of baryta, which is a very heavy substance, therefore the mere weight of the ash, however closely burnt, is no guide whatever as to the quantity of silver it may contain. After the paper ashes have been passed through a sieve to remove any extraneous matters, they are ready for the refiner.

Fixing Solutions.

When only P.O.P.s are used as the printing papers it is in the fixing baths that the greatest portion of the residue must be looked for, whilst in the case of plates this is the sole source. The solutions after use should be emptied into a large receptacle, such as used for the print washings. The silver in hypo solutions is best precipitated as a sulphide. The most convenient precipitant to use is sulphide of potassium—liver of sulphur. A solution of it must be made and added to the hypo, which will throw down a brown precipitate of sulphide of silver. The sulphide of potassium should be added so long as a precipitate is produced, but no longer, as an excess will redissolve it. There is some little difficulty in saying when enough has been used, therefore the best way to proceed is to add a certain quantity and then let what sulphide of silver that has been formed to subside, and then decant a little of the clear liquid, and if the addition of more of the sulphide of potassium solution does not produce a cloudiness it indicates that all the silver in the solution has been thrown down; if it does, more must be used. After the deposit has subsided the supernatant liquor is drained off and the vessel is ready to receive more hypo solution, to be treated as before, and so on until a quantity is collected sufficient to be dried and sent to the refiner.

The treatment of the old fixing baths with the sulphide should be done in the open air on account of the odour—that of rotten eggs. Sulphide of potassium that has long been kept, unless stored in well-

corked and sealed bottles, is almost useless for the purpose. A good test of its quality is its smell—the more it “stinks” the better it is. There are other ways by which the silver may be precipitated from a stock of old fixing baths. One is by putting it into a large carboy, about two-thirds filling it, and then passing a current of sulphuretted hydrogen through it, with occasionally shaking up. With this method there is no risk of any of the sulphide of silver being redissolved. Another way is to add to the solution some cuttings of zinc. That will reduce the silver, but it takes a somewhat long time. Instead of treating the washings from printing, when they are from P.O.P.s, separately, they may be added to the fixing solutions and the silver recovered as a sulphide instead of a chloride. After the sulphide of silver has been dried it is ready for the refiner.

Gold Residues.

In old toning baths, if the gold has been properly apportioned to the number of prints to be toned in them, there should be little or no gold to be recovered from them. However, it is seldom possible to use up all the gold, and the precious metal may be recovered in a fairly pure state as follows:—The old baths are first filtered into a large bottle and a solution of protosulphate of iron, rather strongly acidified with sulphuric acid, added. This will throw down the gold in a metallic state of a brown colour. The precipitate is well washed in several changes of water, finally with distilled, to remove all traces of the iron. The precipitate is then transferred to a Florence flask and well drained. Then a little of a mixture, in the proportion of half a dram of pure nitric acid and two and a half drams of pure hydrochloric acid, is poured in and the flask treated on a sand bath until the gold is dissolved. The whole of the precipitate will not be dissolved, as that consists of chloride of silver, which may be filtered out, and we then have a solution of chloride of gold which may be crystallised and used for making other toning baths; or the acid in it may be neutralised with carbonate of soda and kept as a stock solution. When this is done, after the solution has been neutralised, it is well to add a drop or two of hydrochloric acid to it, as then there is no risk of the gold becoming precipitated by keeping.

SAXONIAN.

ACTINOMETER MEASUREMENTS OF DAYLIGHT.

(A Note by Dr. J. M. Eder in “*Photographisch Korrespondenz*.”)

As is well known, Bunsen and Roscoe employed the darkening of silver chloride paper for the measurement of the intensity of sunlight and diffused daylight, the paper being caused to match a “normal grey” consisting of 1,000 parts of zinc white and 1 part of lamp black, and spread upon paper. The sensitive Bunsen paper was prepared by saturating paper for a period of about five minutes with a solution of about 30gms. of common salt in 1,000 ccs. of water, drying, and floating for two minutes on a 12 per cent. solution of silver nitrate. Professor Wiesner, of the Vienna University employed this method in his studies of the function of light in plant life. He found, in agreement with Bunsen and Roscoe, that a small altitudes the chemical intensity of direct sunlight is remarkably small; at high altitudes of the sun and in mountain districts the ratio

$$\frac{\text{direct sunlight}}{\text{diffused light}}$$

obtains much greater values. Maximilian Samec, in further examining the conclusions of Wiesner, made his experiments at increasing heights above the sea-level from a balloon, and used at first, in addition to the Bunsen paper, a silver-chloride collodion paper and also Andresen's “Rhodamin” paper, which is sensitive into the orange. He found that the quotient

$$\frac{\text{direct sunlight}}{\text{diffused light}}$$

for silver chloride paper at 120 metres above the sea-level and a 53 deg. altitude of the sun is 2.82; at 1,200 metres above sea-level and 61 deg. altitude of the sun, 3.4; and at 4,200 metres above sea-level it was 5.72. The intensity of the diffused light projected upwards from below is increased and then falls off. The intensity of rays of long wave-length, measured with the “Rhodamin b,” is

creased, according to Samec, from 450 to 1,200 metres above sea-level, and remained almost constant at greater heights.

Since the Bunsen normal paper keeps good only one day, I recommended, more than ten years ago, the use of a permanent silver paper for photometric purposes, sensitised with potassium nitrite, and this has been used by Dr. Wiesner and his colleagues in their later actinometric measurements.

The following directions serve for the preparation of a permanent silver chloride paper which may be used in place of the Bunsen normal paper. Some 8-kilo Reeves raw paper is immersed for five minutes in a 3 per cent. solution of common salt, hung up to dry, and then floated for two minutes on a sensitising bath of 12gms. silver nitrate dissolved in 100 ccs. of water, after which it is washed several times in an ample supply of distilled water. It is now placed for five minutes in a solution of 1 part potassium nitrite in 20 parts of water and again hung up to dry. The paper readily assumes the colour of the normal Bunsen tint, which, as is well known, may be read with much greater certainty by employing a yellow or green glass or by making the observation by yellow sodium light. If the Bunsen normal tint be supplemented by darker tints containing a larger proportion of lamp black, these latter serve for the measurements of greater light intensities. The most recent work on the intensity of light at a considerable height above sea-level has been done by Dr. Samec with this Eder normal paper. He ascertained by a number of comparative measurements the relative sensitiveness compared with the Bunsen normal paper, the ratio being .665. Thus measurements made with the nitrite paper when multiplied by this factor of .665 are converted into the units corresponding with the Bunsen normal paper. As an interesting result of this work it may be mentioned that Wiesner and Samec have ascertained the increase of the intensity of the chemically active rays at different heights above sea-level. The increase of intensity at a height of 4,078 metres above sea-level is 47 per cent.; in another case at the height of 3,528 metres the increase was 101 per cent.

J. M. EDER.

Photo-Mechanical Notes.

Collotype Formulæ.

To the correspondent who asks, in reference to our recent note on this process, for formulæ, we would say that several text-books give reliable working formulæ, and to show that there is no magic in it, we give the formulæ now being used by one of the most successful producers of coloured collotypes on the Continent. Substratum.—Dissolve 12 grams gelatine in 400 ccs. distilled water, add 12 ccs. of a concentrated solution of chrome alum and 34 ccs. potassium silicate. Coat in warm room with soft sponge.

Sensitising solution:—

Creutz middle hard gelatine	75 gms.
Water	900 ccs.
Potass. bichromate	12 ccs.

Take 5 ccs. for every 100 square centimetres.

A formula for coarse-grain collotype suitable for lithographic transfers is as follows:—

Gelatine	80 gms.
Water	800 ccs.
Potass. bichromate	12 gms.

Add 2 to 4 gms. gum arabic, according to grain desired.

Take 7 ccs. to every 100 square centimetres.

A Manual of Collotype.

"Manuel pratique de Phototypie." By J. Voirin. Paris: C. Mendel. 2fr.

For those who read French this little book gives very plain and precise instruction for working collotype, with many illustrations of the apparatus employed. An appendix gives a full description of the pedal platen presses introduced by M. Voirin which can be used for collotype, enabling 300 per hour to be printed under very favourable conditions, or easily 1,500 per day of ten hours. The same presses can be used for printing type when required, and therefore

very suitable for either collotypers wanting to print titles, etc., or small printers who want to print collotype postcards.

Fine Etching.

In an article on "Half-tone on Zinc," in the current "Zeitschrift für Reproduktionstechnik," the question of a suitable material for painting-out when fine etching is discussed, and the writer recommends a "Tusche," for which he gives the recipe, on the ground that it is miscible with water, and therefore can be used without having the plate so thoroughly dry as is necessary when a spirit lac or bitumen varnish is used. His formula is as follows:—

Wax	120 gms.
Mutton fat	120 gms.
Marseilles soap	100 gms.
Lampblack	40 gms.
Gum mastic	5 gms.
Shellac	70 gms.
Asphalt	10 gms.
Resin	5 gms.

These ingredients are melted by heat, thoroughly mixed, poured out, and allowed to set. For use, a small piece is taken and thinned to the required consistency with distilled water. The author declares such a paint to be an excellent acid resist.

Exhibitions.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

Viscountess Halifax visited Rotherham and inaugurated, in a very charming manner, the twentieth annual exhibition of the Rotherham Photographic Society in the Drill Hall. The display of pictures is unusually attractive, competitors from all parts of the country having contributed work in the open classes; whilst the members' section is more numerous and artistically represented than usual. A glance through the 600 examples arranged with tasteful effect on the screens which surround the large hall affords evidence that the newest processes are being made use of with the best effect, and some of the oil prints in particular are worthy of careful inspection. In the landscape and seascape class (open), 116 prints are entered, and a fair standard of merit is maintained. Portraiture and figure studies are strong; but architecture shows a little falling off in quality, and is not greatly superior to that in the members' section. There are a few good still life subjects, and colour work, although not a large lot, amply illustrates the progress being made in this branch. Great interest centred in the members' section, which occupied the whole of one side of the hall, and considerable versatility was apparent both in regard to medium and subject. There were the usual lantern-slide classes in both departments. Other interesting material was the selection of prints lent by the Royal Photographic Society Affiliation Committee; a screen of transparencies illustrating "electric splashes" and X-ray work; and the various loans by trade firms. The exhibition, as a whole, is a tribute to the fostering care of the committee, and especially of the secretary, Mr. H. C. Hemmingway.

The judges, Mr. C. B. Keene, F.R.P.S., and Mr. T. A. Scotton, of Derby, made the following awards:—

OPEN CLASSES.

Landscape, seascape, and river scenery.—Silver plaque, "To the Sea," Bertram Cox, Lincoln; bronze plaques, "Nightfall on the Moor," F. Parkin, Sheffield, and "Approaching Storm," Dr. H. G. Paterson, Sheffield. Hon. mention: J. Bell, Sunderland; F. A. Tinker, Sheffield; and G. A. Booth, Preston.

Portraiture, figure studies, and animals.—Silver plaque, "The Oracle," O. C. Wilmot, Sunderland; bronze plaques, "Old Dutch," P. F. Storrs, Birmingham; "A Sylvan Scene," A. W. Walburn, West Hartlepool. Hon. mention: F. W. Menwry, Staines; O. C. Wilmot, Sunderland.

Architecture.—Bronze plaque, "Ray of Light," P. Smedley, Ilkeston. Hon. mention: F. C. Boyes, Theydon Bois, Essex.

Flowers, fruit, and still life.—Bronze plaques, "Clocks," F. A.

Tinker, Sheffield; "Tulips," A. Black, Nottingham. Hon. mention: P. W. Morris, Bushey; J. Dunlop, Motherwell.

Colour work.—Bronze plaques, U. M. Jones, Birmingham; C. H. Parker, Sheffield. Hon. mention: P. D. Prior, Nottingham; G. and D. Smith, Sheffield.

Lantern slides.—Bronze plaques, F. A. Tinker, Sheffield; Alfred Taylor, Whalley, Lancs.

MEMBERS' CLASSES.

Landscape, seascape, and river scenery.—Bronze plaques, F. A. Jordan, Doncaster, and M. Creswick. Hon. mention: S. G. Liversidge, Miss F. A. Eskholme.

Portraiture and figure studies.—Bronze plaque, M. Creswick. Hon. mention: Miss E. H. Tillotson.

Architecture.—Bronze plaques, A. E. Rawson, W. Firth, W. B. Davison. Hon. mention: H. C. Hemmingway.

Flowers, fruit, and still life.—Bronze plaque, F. G. Blackshaw. Hon. mention: A. S. Pye.

Lantern slides.—Bronze plaques, A. S. Pye, R. Chislett.

Boards of Exhibits.—Bronze plaques, A. S. Pye, A. E. Peck. Hon. mention: S. G. Liversidge, Miss E. H. Tillotson.

FORTHCOMING EXHIBITIONS.

September 23 to October 30.—Royal Photographic Society. Sec., J. McIntosh, 35, Russell Square, London, W.C.

November 10 to 13.—Hackney Photographic Society. Sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E.

November 10 to 13.—Cambridge and District Photographic Club. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.

November 29 to December 2.—Lancaster Photographic Society. Entries close November 20. Sec., Thomas Holt, 4, Parliament Street, Lancaster.

December 4, 1909, to January 1, 1910.—Southport Photographic Society. Entries close November 15. Sec., J. McLellan, 2, Pilkington Road, Southport.

December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1910.

April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between October 11 and 16:—

REPRODUCTION.—No. 23,343. Improved negative or positive for reproducing drawings and the like. John Wellesley Ross, 173, Fleet Street, London.

RADIOGRAPHY.—No. 23,455. Method of taking photographs with Röntgen rays. Friedrich Dessauer, 40, Chancery Lane, London.

LENS.—No. 23,491. Improved lens. William Thomas Coulson, 181, Maple Road, Penge, London.

SHUTTERS.—No. 23,493. Improvements in photographic shutters. Arthur Charles Smith, 26, Hanover Street, Peckham, London.

PLATES.—No. 23,538. Improved means applicable for use in exposing, developing, and fixing photographic plates. George Gatton Melhuish Hardingham, Clun House, Surrey Street, Strand, London, for Henry John Barclay, Cape Colony.

CAMERAS.—No. 23,575. Improvements in and relating to photographic cameras. Andrew Macfarlane Dunn, Avorlon, Meikle-riggs, Paisley.

CAMERAS.—No. 23,728. Improvements in or relating to photographic cameras. William Berrell, 33, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

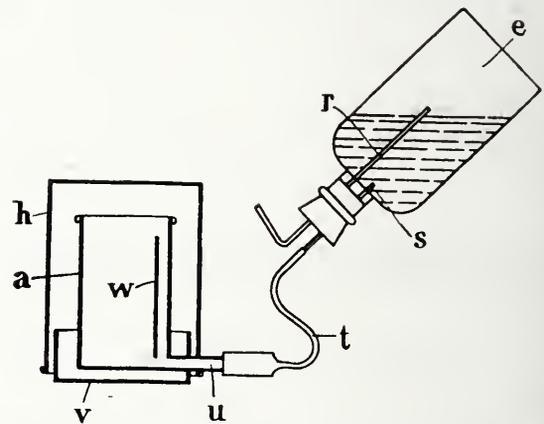

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DEVELOPING APPARATUS.—No. 20,396, 1908 (September 28, 1908).

The invention relates to an improved apparatus for developing photographic plates or films. It consists of a light-proof box or tank, the lower part of which is placed in communication, by means of a flexible pipe, with a vessel containing the necessary developing solution, so that by displacing the container sufficiently above and below the tank the solution would enter or escape. In previous arrangements of the type the container has been of special construction and the solution poured into it from an ordinary bottle.

Now the ordinary solution storage bottle is also employed as the container. This is effected by connecting the flexible pipe to a stopper which is adapted to fit into an ordinary bottle. An ordinary bottle thus serves both as a container and a storing bottle.

In the form of construction shown in the drawing, the tank *a*, which serves for receiving the plates *w* and the liquid for treating

them, has at its bottom a short pipe *u*, to which the vessel *e* for filling the tank *a* is connected by means of a tube *t*. The tank *a* is placed in a second receptacle or tank *v*, through the wall of which the pipe *u* passes. Over the entire apparatus there may be placed a lid or cover *h* in such manner that it forms a light proof joint all round the tank *a* and at the place where the pipe *u* passes through the lid or cover.

In this form of construction the vessel *e* is a bottle having stopper provided with two holes, through one of which a tube *r* passes and extends to about the middle of the bottle, whilst second tube *s*, to which the tube *t* is connected, only just projects through the hole in the stopper.

If the bottle *e* is held in the position shown in the figure it is discharged into the tank *a*, air entering through the tube *r* into the bottle. If the bottle is then placed below the level of the bottom of the tank *a* the liquid runs back into the bottle.—Fel Trüstedt, 82, Berlinerstrasse, Charlottenburg, Johannes Wegener, 137, Invalidenstrasse, Berlin, and Ulrich Wegener, 16, Invalidenstrasse, Berlin.

New Trade Names.

WESTMINSTER (DESIGN).—No. 315,243. Chemical substances used in photography. The Westminster Photographic Exchange, Ltd., 119, Victoria Street, London, photographic chemists. July 1909.

R.P.S. HOUSE EXHIBITION.—An exhibition of the photographic work of Mr. Arthur Marshall, A.R.I.B.A., F.R.P.S., will be opened at 35, Russell Square on November 2.

Analecta.

Extracts from our weekly and monthly contemporaries.

An Adaptation of the Chromium Intensifier.

I have recently been using an adaptation of the well-known chromium intensifier (writes Mr. R. A. Chrystal in "Photography and Focus" for October 26), which I have not seen mentioned in any photographic paper. It consists of making use of the staining properties of the pyro-metol developer. The negative is bleached and washed as usual, then re-developed with normal pyro-metol developer. . . . It is then dipped in water, no more, and stood up or hung up so as to allow the developer to oxidise in the film. In one or two minutes it will have been stained green, the depth depending on the length of exposure to the air. I find that this method surpasses all others I have tried for increasing contrast, as, besides considerable actual intensification, there is great apparent intensification due to the green stain. This method enables one to avail oneself of the advantages of pyro-metol in cases when it is not admissible as the original developer, such as in tank development.

Restoring Old Bromide Paper.

Probably all photographers (writes Mr. A. H. Garner in "The Amateur Photographer and Photographic News" for October 26) experience from time to time the annoyance of finding that their stock of bromide paper, or part of it, has gone stale, and gives fogged, unhealthy looking prints, which are not improved materially by any tinkering with the exposure and development. The following is a quick and easy method of restoration. Mix a weak bath of potassium permanganate, and acidify this with sulphuric acid. Soak the paper in this for a minute, rinse, and transfer to a weak bath of sodium sulphite, leave for another minute, rinse, and make the exposure. The image will develop up clear and strong without trace of fog. In fact, fog seems difficult to get in the developer. Strength of solutions does not seem to be a matter of great moment, but in order to give the method a definite basis the following is suggested as suitable:—

First Bath.

Potass. permanganate.....	5 grs.
Sulphuric acid	30 minims.
Water	10 ozs.

Second Bath.

Soda sulphite	20 grs.
Water	1 oz.

It is necessary to mention that this preliminary treatment reduces the speed of the paper, so that a test exposure will be necessary. A fast bromide paper will require perhaps twice as much exposure, a slower one, probably less than twice as much, as the untreated paper. A trial slip soon determines the best exposure.

New Books.

"The A.B.C. Guide to Autotype Carbon Printing." London: The Autotype Company and Dawbourn and Ward, Limited. 1s. net. In this revised edition of the well-known handbook by the late R. Sawyer the Autotype Company have placed their wide technical knowledge of the carbon process at the service of those working this most admirable photographic method. After a brief historical introduction, a few words are said on the selection of types and on the principles of the single and double transfer methods. Equipment occupies only a few words, whilst the making of the sensitising baths and the manipulation in using them is dealt with in great detail. The use of actinometers and a description of various types and of the merits of each occupy the next section, which is followed by a chapter dealing with development. The variations in treatment needed in working the double-transfer process follow, and the latter part of the book is devoted to the carbon printing-room and equipment for those who work the method on a commercial scale. Both amateur and professional workers of

the carbon process will find the volume free from matter which is not essential to successful practice: in a few words, the authors have emphasised the essential details in carbon printing.

"The Art of Theatrical Make-up." By Cavendish Morton. London: Adam and Charles Black. 5s.

When years ago we saw Mr. Cavendish Morton as the soothsayer in Mr. Tree's "Julius Cæsar" we had never seen him off the stage, and therefore our appreciation of him as a master of make-up was afterwards all the more unqualified. Since then readers of the weekly illustrated papers have had the opportunity of seeing, in a number of Mr. Morton's photographs of himself in different characters, the perfection to which he has brought his art of characterisation, to say nothing of his photography. The present volume is a magnificent demonstration of both. We are given photographs to the number of about a score showing the author "made-up" as the most diverse characters; at the same time in many instances the stages by which these triumphs of characterisation have been secured are shown. The subject is one for which photography is eminently fitted to be the illustrator, but the illustrations are a good deal more than mere camera records; each photograph gains immeasurably by its lighting and composition. Compare the author as Pierrot on page 80 with the portrait of him as Shylock on page 53, or as Iago and Othello on pages 66 and 67 respectively. Perhaps the greatest testimony to Mr. Morton's genius, as an impersonator, is the outdoor portrait of him as Sir Thomas More (page 124), in the Chelsea Pageant last year. Photographers, equally with actors, will derive an immense amount of benefit from a study of the ways in which characters of quite diverse type are treated, and we can recommend this volume most cordially to all who employ the camera for portraiture. As for the author's chapters on the technical make-up, they are brief and to the point, and doubtless provide the information which the theatrical impersonator requires.

"London." By Alvin Langdon Coburn. With an introduction by Hilaire Belloc. London: Duckworth and Co. 25s. net.

So far as we know, Mr. Coburn, in this volume, must be credited with striking a new note in art publishing in that he has issued, through Messrs. Duckworth, a collection of twenty photogravure reproductions of his pictures without relegating any of the work of making the plates or taking the impressions to any other hand. We thus have preserved in these photogravure facsimiles the artist's intentions free from the sophistication which frequently creeps in at the hands of the commercial plate-maker, whose well-intentioned efforts at improvement do not always meet with appreciation. The photogravures measure each 8½ x 6½ inches, and are each mounted on a plain light brown board of 16 x 12 inches. Whether we are to correct our impressions of London from these photographs by Mr. Coburn is another matter. To the present writer London is probably as new an acquaintance as it is to Mr. Coburn, but we certainly cannot admit that the impressions of the majority of the plates are those which constitute the real beauty and fascination of London. If we were to accept the artist's version of "Kensington Gardens, November," as an impression of that most delightful corner of the London parks, famed as a spot of pleasant shades and children's playgrounds, we are compelled to give the go-by to every agreeable recollection we may have of walks in Kensington Gardens. Again, Westminster Abbey, confined behind trees and lamp-posts, is a rendering totally foreign to the position of the Abbey as a landmark in London, whilst we can hardly believe that Mr. Coburn's version is defensible on the grounds of its composition. For London Bridge, in its light tones, and with a truthful rendering of the atmosphere of the Pool, we have nothing but admiration, and Leicester Square on a wet evening is also London to the life, but Mr. Coburn's impression of St. Paul's from the river, of the Temple, and of the Houses of Parliament impresses us as showing a lack of the sense of what constitutes the true glory of these features of London. Mr. Hilaire Belloc's introduction will be read with a great deal of interest. It gives London the place which historically it takes in England, and it shows us in a true perspective the relations of the different towns which make up the modern London.

We might add that the originals of the twenty photogravures are now being shown in the Goupil Gallery, 5, Regent Street.

"The Sinclair Handbook of Photography." Edited by James A. Sinclair. London: James A. Sinclair and Co., Limited. 1s. net.

The very beginner who wishes to start his photography with the greatest chance of success will thank Mr. Sinclair for this volume, and equally the advanced worker can hardly read through its pages without deriving a great deal of information. The book is divided into twenty-three chapters, some few of which are anonymous. The majority are contributed by writers who have made the subjects particularly their own. Among these may be mentioned the article on hand cameras by James A. Sinclair, on flashlight photography by F. J. Mortimer, on carbon printing by H. W. Bennett, and on the Autochrome process by R. Child Bayley. Pigment and oil processes receive a degree of attention which they do not meet with in any other photographic text-book. Thomas Manly writes on ozobrome and oil-ozobrome, R. Demachy on the oil process (described in the contents by an unfortunate printer's error as "the old process"), Mr. Sinclair adds some further notes, whilst the bromoil method is dealt with by C. H. Hewitt. J. C. S. Mummery concludes this orgy of articles on artistic-pigment methods by a very clear description of his manipulation in gum. After these excursions into the intimacies of practical work, we are brought to a calmer frame of mind by the last chapter on law for photographers by E. B. F. Christian, whose theme is, of course, chiefly copyright. The volume gains an added interest by the inclusion of portraits of the authors, and we can heartily commend it as a text-book which contains scarcely a redundant paragraph, and every chapter of which is devoted to a popular branch of present-day photography.

"TRAVEL AND EXPLORATION."—In the November number of "Travel and Exploration" (now edited by Mr. Eustace Reynolds-Ball), Dr. M. Aurel Stein, the famous Asiatic explorer, continues the narrative of his remarkable journey across the Taklamakan Desert. In an article entitled where "East meets West," Mr. Warden Page gives an impressionist sketch of "the European capital" of Morocco. Tangier is a well-worn subject, no doubt, but the writer treats it from an original and novel point of view which invests it with fresh interest. Dr. W. T. Beeby has found a new topic in the mediæval games of North Italy, in which will be found much interesting information. In "Albenga—an Ally of Carthage," a little-known Riviera city of considerable historic interest is well described. We are next taken to the Far East, Mr. Scheltema concluding his narrative of a visit to Tuan Gadis, an ex-Queen of Sumatra. In "Armchair Travel" the most important travel-books of the month are reviewed at some length.

New Materials, &c.

Christmas and New Year Mounts. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

The new list of mounts for the forthcoming season, issued by this old-established firm, runs to twelve pages, and illustrates in a large number of half-tone reproductions the many varieties of folder and slip-in mounts specially designed to accommodate photographs sent as Christmas greetings. While it would be invidious to name particular mounts where there are so many of excellent design, we may perhaps specially refer to Nos. 325 and 327, both folder mounts of linen-surface paper measuring 6½ in. by 3 in., and containing a white inset for the reception of the print. Each mount bears outside a small coloured picture appropriate to the Christmas season, and the mottoes on the two are "Hearty Wishes" (No. 327) and "Every Good Wish" (No. 325). The price in each case is 2s. per dozen, 20s. per gross. Another very tasteful pattern is No. 300, a white Whatman card with a shaded grey deckel-edge, and bearing the gilt motto "Christmas Greetings." This is a slip-in mount with a circular opening 2½ in., the white embossing, gilt decoration, and grey silk binder being all in very nice accord. The price is 2s. 9d. per dozen, 30s. per gross. Colour in the decoration is extensively used on the outside of many of the Fallowfield mounts this year with very good effect. We should mention, also, that mounts

for quite small photographs, from postage-stamp size upwards, are issued by this firm in very great variety. A calendar mount No. 313 deserves mention for its excellent design in brown tints. It provides an oval space for a C.D.V. photograph and carries a tear-off calendar, the price being 3s. 3d. per dozen, or 36s. per gross. Messrs. Fallowfield's list also prices and illustrates the "Bordalace" mounts and the "Photo-fans," both novelties of special application to the photographer's Christmas trade.

WELLINGTON CHRISTMAS POSTCARDS.—Messrs. Wellington and Ward, in accordance with their usual custom, are issuing their series of postcards (bromide, S.C.P., P.O.P., and self-toning), with greetings appropriate to the Christmas season. The cards are issued in regulation (5½ x 3½) and "court" sizes, and are put up in 1s. and 6d. packets.

New Apparatus, &c.

The Phillips Photographic Focussing Scale Chart. Made by W. H. Phillips and Son, 98, Truro Road, Wood Green, London, N.

A very useful chart, allowing of a focussing scale for any lens from 3 in. to 10 in. focus being prepared without any calculation for distances from 5 ft. to 100 ft., has been drawn up by Messrs. W. H. Phillips, and is issued by them at the price of 2s. 7d., post free, in cloth covered case. The chart may also be used as a means of ascertaining the focal length of the lens. This is done by first focussing the lens on an object at a great distance, and marking the position of the lens front on the fixed baseboard of the camera. An object at 5 ft. distance is then focussed, and a second mark made on the baseboard. On comparing the distance between the two marks with the distances on the chart representing the focal extension for 5 ft. and 100 ft., the focal length of the lens being examined may be picked out among those given.

"Cooke" Series II.A *f*/3.5 Portrait Lens. Made by Taylor, Taylor and Hobson, Ltd., Stoughton Street, Leicester.

This new addition to the series of "Cooke" lenses applies the well known construction adopted in these objectives to the production of a portrait lens of the very highest aperture—namely, *f*/3.5. The lens is made only in one focal length—namely, 12 in., intended for making cabinet portraits, and at full aperture it covers the half

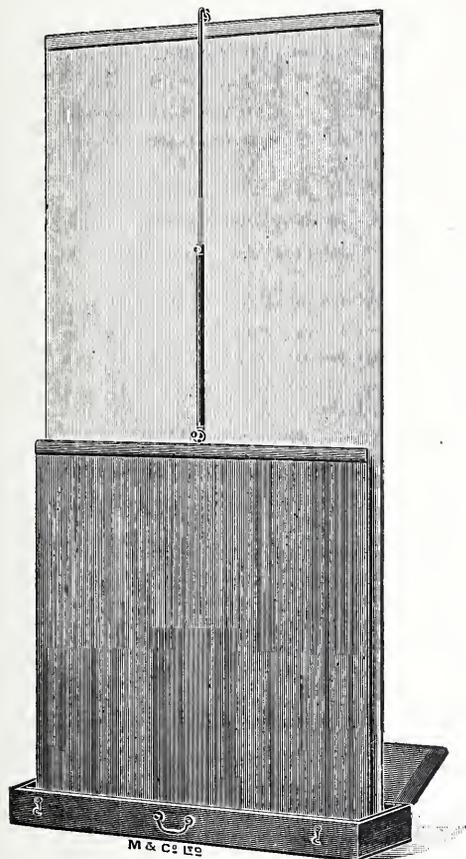

plate perfectly. A lens of this large aperture and focal length necessarily of considerable size, the glass being nearly 3½ in. diameter, and the outside diameter of the flange measuring 5½ in. The lens is supplied with iris diaphragm, whilst the front portion is capable of being separated from the back elements, so as to give a certain amount of diffusion, the makers providing an automatic stop when reverting to the sharpest possible definition. The price of this new "Cooke" is £18.

The "Freckleton" Portable Shading Screen. Made by Marion & Co., Limited, 22 and 23, Soho Square, London, W.

This new and portable accessory for the portrait photographer is equally serviceable in the studio or on the many occasions when a portrait is made at a sitter's home. It consists of a shallow box containing two screens, one of semi-transparent engineer's tracing cloth and the other of an opaque green cloth. Each of these

about 3ft. 6in. in width, and is mounted on a spring roller. The box is fitted with a triple-extension metal rod giving a total height, when extended and fixed, of 8ft. It is erected in the space of a few seconds and either of the screens is supported on it to this full height in the same time; or both may be used together, the opaque screen usually partly extended, where it is necessary to cut off light

in the lower part of the sitter. The containing box thus forms a solid base or support for the screens, which latter, of course, may be replaced by the ordinary background material, when the screen then becomes a very useful accessory to the amateur portraitist of head and shoulders or three-quarter length figures. The price of the apparatus complete, with two screens, as above described, is £1 15s.

CATALOGUES AND TRADE NOTICES.

MARION PLATES.—Messrs. Marion have just issued a booklet of prices and illustrations and formulæ relating to their dry plates. It describes the distinctive feature of each of the eleven varieties of plate, and among other formulæ gives a recommended one for stand development. The booklet is sent free on application to 22-23, Soho square, London, W.

NEWTON'S LANTERN LIST.—Messrs. Newton and Co., 3, Fleet street, may justly claim to retain their pre-eminent position in the lantern trade by the issue of this large list of slides, which runs to over 500 closely printed pages, including a description of sets of slides which, so far as we know, is not approached by any other firm's showing. Educational subjects, relating to every branch of knowledge, are here classified; travel, history, religious pictures present a large number of sets—in fact, it is difficult to name a subject which cannot be found in Messrs. Newton's comprehensive catalogue. The list is sent post free for 1s.

L.C.C. NOTICES.—Willesden District Council has granted certificates that proper means of escape from fire have been provided in the premises of the following firms:—Messrs. T. Illingworth and Sons, photographic factory, Rucklidge Avenue; Imperial Dry Plate Company, works, Ashford Road. The contract of Mr. Jas. T. Hawkins, 38, St. John's Road, Penge, to provide lantern operators and accessories to the L.C.C., was to expire on November 17. It has been renewed to August 31, 1910.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 29.

Paisley Philosophical Institute. "French Slides," A. E. Staley & Co.
Lincoln Amateur Photographic Society. "Sports and Pastimes with the Goetz Anschutz Folding Camera."

SATURDAY, OCTOBER 30.

Kinning Park Co-operative Camera Club (Govan). Outing to Hillington Road.

MONDAY, NOVEMBER 1.

Southampton Camera Club. *Amateur Photographer and Photographic News* Prize Slides.

Watford Camera Club. 1. "Competition." 2. Set of Slides, "The Yorkshire Coast."
New Mills and District Camera Club. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Todmorden Photographic Society. "What Can be Done with a Hand Camera." C. P. Goetz, Ltd.
Richmond Camera Club. "Ensyna." F. Marshall.

Commercial & Legal Intelligence.

PICTORIAL POSTCARDS.—At Marylebone last week, before Mr. Paul Taylor, Agnes Allen, of Praed Street, Paddington, newsagent and seller of sweetstuff, was summoned to show cause why forty pictorial postcards, alleged to be obscene, seized by the police, under a special search warrant, should not be destroyed. Other summonses charged her with exposing to view in the shop window pictorial postcards said to be indecent. Flora Seigel, confectioner, of Praed Street, was similarly summoned in respect to 607 postcards, and also for exposing some of them to view in a shop window.

Mr. Muskett, in opening Allen's case, expressed the hope that the magistrate would support the efforts of the Commissioner of Police to put down the traffic in these pictorial postcards, which was regarded as being of a very degrading and pernicious character. For more than five years the Commissioner had been making these efforts, he said, and until recently they were attended with a great measure of success, for the magistrates, appreciating the gravity of the offence, inflicted very substantial penalties, and ultimately took to sending the offenders to prison.

Mr. Freke Palmer submitted that, while the postcards were for the most part vulgar, they did not come under the designation obscene.

Mr. Paul Taylor imposed upon the defendant a fine of £20, with

£3 3s. costs, or in default two months' imprisonment, and made an order for the cards to be destroyed.

In Seigel's case it appeared that some of the cards were reproductions of fine art studies. Mr. Paul Taylor observed that he regarded some of them as artistic productions of the beautiful originals, but at the same time he did not think that they should be sold, and he should require the defendant to give her assurance that she would not sell them any more. He should order the destruction of the whole of the cards with the exception of these studies, and fine the defendant £40, with £3 3s. costs; in case of default she would have to undergo four months' imprisonment.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—On November 9 the president, Mr. J. C. S. Mummery, will deliver an address, entitled "The Influence of Painting on Photography."

R.P.S. LECTURES.—The following is the closing lecture to be delivered at the New Gallery: Saturday, October 30—"Westminster Abbey," by S. G. Kimber.

RÖNTGEN SOCIETY.—On December 2, Prof. A. W. Porter, B.Sc., will read a paper on "Some Effects of Electrical Discharges on Photographic Plates."

THE SOUTHAMPTON EXHIBITION.—Entries for this exhibition, which comprises technical and colour, as well as pictorial, exhibits, close November 12. Entry forms can be obtained from the hon. secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—Mr. Lewis Lloyd having resigned the secretaryship of the above society, the post is now filled by Mr. S. Wortley, of 10, Newhall Street, Birmingham, to whom all future communications should be addressed.

TRAILL-TAYLOR MEMORIAL LECTURE.—The twelfth Trill-Taylor memorial lecture will be delivered at the Royal Photographic Society, 35, Russell Square, W.C., on Tuesday, November 23, by Professor A. W. Porter, B.Sc., F.R.A.S., who will take as his subject "The Growth of the Photographic Image."

ARC-LAMP DEMONSTRATION AT MANCHESTER.—Messrs. Marion are holding a special demonstration at the Grosvenor Hotel, Manchester, from November 2 to 15, where they are showing the Boardman multicarbon "Northlight" and all their other novelties in labour-saving appliances, and will be glad to receive visits from all interested.

THEFT OF N. AND G. CAMERAS.—At the London Sessions, sentence of three years' penal servitude each was passed on two men, known to the police for previous offences, for feloniously receiving a number of cameras and other articles, valued at £345, which had been stolen from the premises of Messrs. Newman and Guardia, of Rathbone Place.

JOURNALISTIC ENTERPRISE.—If we may judge from one example, American newspapers will soon have to take a back seat in favour of a French photographic journal, a specimen copy of which was recently received at the office of the "British Journal of Photography," addressed to "Monsieur Glaisher," President of the Photographic Society of Great Britain, London.

SIR BENJAMIN STONE, member for East Birmingham and hon. photographer in ordinary to the House of Commons, retires from Parliament at the next election. During the fourteen years he has been at Westminster Sir Benjamin Stone has won the respect and goodwill of all sections of members, and it is proposed to entertain him at a farewell luncheon. Liberals, Nationalists, and Labour members are associating themselves with his Unionist colleagues in the movement in his honour. The gathering is to be held on the 4th of next month.

THE PHOTOGRAPHIC CONVENTION AND THE KENT SURVEY.—Members of the Photographic Convention are earnestly requested to contribute to the photographic record and survey of Kent permanent prints (platinum or carbon) from some of the negatives which they made during the Photographic Convention of this year.

The survey of Kent was well represented by a loan collection in Mr. Bothamley's exhibition at the Convention, and the pictures that it receives are well and carefully housed and indexed in the very fine museum and library at Maidstone. Members who can contribute such prints are invited to send them direct to J. H. Allechin (curator), The Museum, Maidstone.

"THE BEAUTIES OF NORWAY."—The Thursday evening winter lectures in connection with St. Bartholomew's, Dalston Lane, were opened in the Lecture Hall on October 21, when Mr. F. A. Bridge gave an account of his tour in Norway. He described the "land of the midnight sun" in breezy fashion, with many a humorous touch, and brought home some of the wondrous beauties of its mountains, valleys, and fjords by means of magnificent photographs which he had secured. He also showed some exceedingly fine specimens of colour photography. There was a large audience, and his lecture was greatly enjoyed. At the close he was accorded a hearty vote of thanks on the motion of the vicar, the Rev. E. S. Brühl.

PHOTOGRAPHY IN PETERBOROUGH CATHEDRAL.—Writing to the "Times" in reference to an article in that publication, the Dean of Peterborough says:—

"In your article to-day upon this subject it is stated: 'In the case of cathedrals in this country, application has to be made to the dean of each. . . . At most it is necessary to apply by post a day or two beforehand. To avoid disappointment this should always be done.' If the information thus given is as incorrect generally as it is in one particular case, it is not only I who have reason to protest against an invitation published *urbi et orbi* to bombard a dean with superfluous petitions. In this cathedral, at any rate, so long as the exigencies of public worship and decencies which befit a place of worship are duly observed, nobody is hindered from taking photographs, and no 'permit' is required. The desire to take photographs is, I suppose, one of the forms in which interest in what ought to be of interest and public concern finds natural expression, and as such, in my view of the matter, should be welcomed and encouraged.

"The question of Sunday photographing stands, I think, apart. The Sunday services, ranging as they do from early morning until late evening, leave but brief intervals of rest to those who must be in charge, while it is open, of a cathedral building."

AMERICAN PROFESSIONAL PHOTOGRAPHY AT DRESDEN.—It is the unexpected that always occurs (writes "Abel's Photographical Weekly" of the awards to American professional photographers at the Dresden Exhibition). When Pirie MacDonald, early in the year picked the photographers whose pictures he desired to represent American professional photography at the Dresden Exposition, he was fully of the opinion, based on promises made to him by the Exposition authorities, that the collection of pictures sent in by him would be placed *hors concours* or *honoris causa*, or whatever the call it. It was on that basis that he undertook the job, an unprofitable one for him in any case, for there were bound to be hear-burnings and murmurings. Judge of Mr. MacDonald's consternation, then, when along comes a voluminous sheet bearing the honour list of the Exposition and with some nine of the American photographers named for diplomas carrying gold medal honours and fourteen on the silver medal list.* I understand that Mr. MacDonald feels rather badly about the whole matter, as the giving of awards has made many of the participants feel that they were handicapped by not knowing that they were submitting pictures in open competition with the world, and that, with that knowledge, they would or could have made a better showing.

Personally, I don't think much of such a claim, for any man would not submit his very best to this Exposition was not giving square deal either to himself, to Mr. MacDonald, to the Dresden Exposition, or to the cause of American professional photography.

Judged by the accepted standards of our own National Convention exhibitions, the honour list is peculiar. It shows that the Continental valuation of a photograph differs somewhat from our own. And yet there is not the slightest exception one can make to names in the gold medal class. There both the Continental jury and a jury of American photographers would agree, but I think over here, would have placed quite a few of the silver medal pictures in the higher class.

However, the thing is done now, and it only remains for

honoured ones to accept the awards in the spirit they have been given, and to remember that American professional photography took more than its share of honours in its class. Mr. MacDonald is not to blame for any breach of faith or misunderstanding. He acted squarely in the matter from the very beginning, and gave to the world the finest collection of representative American portraiture ever got together.

NEW GERMAN REGULATIONS REGARDING DUTY-FREE SPIRIT.—According to the "Chemist and Druggist," freedom from excise duty is accorded in the case of spirit designed for technical uses, including vinegar making, polishing, heating, cooking, and lighting: also spirit employed in hospitals, lying-in, and other similar establishments, or used in public scientific institutions; the spirit is in general to be denatured according to certain prescribed methods (see below), but in certain instances may be used without denaturing. The use of alcohol in the manufacture of such medicinal preparations as when finished no longer contain spirit is regarded as a technical use, and by medicinal preparations is to be understood not only those for human beings, but also all veterinary preparations. Freedom from tax is withheld in the case of spirit already on the market (im freiem Verkehr), or which contains more by-products of fermentation than one-hundredth part of the weight of contained alcohol. The authorities reserve the right of making exceptions. Denaturing is either complete, i.e., such as to render the spirit undrinkable, or partial, i.e., such as is accompanied by other measures of precaution against misuse. Complete denaturing (provided no other regulations be made by the Federal Council) is effected by adding to every 100 litres of the alcohol 2.5 litres of a mixture of 4 measures of wood spirit and 1 measure of pyridine bases—this is the *general denaturing mixture* (Allgemeines Vergällungsmittel), to which when being made must be added 50 grms. each of oil of lavender and oil of rosemary per litre of the mixture. Complete denaturing may also be carried out by adding 1.25 l. of the general mixture, 0.25 l. of crystal violet solution (strength not stated), and 2 to 20 l. of benzol per 100 l. alcohol. For partial denaturing the following special mixtures (besondere Vergällungsmittel) must be used in the quantities given per 100 litres: (a) For industrial use of all kinds, including the manufacture of medicines named under (d) and (e) and other medicines in which spirit does not exist in the finished product; 5 l. wood spirit and 0.5 l. pyridine bases. (b) For manufacturing brewing glaze and preparing rubber goods: 20 l. shellac solution (1 part shellac to 2 parts alcohol of at least 90 per cent.). The shellac solution must be made under official supervision. (c) For manufacture of celluloid, pegamoid, and synthetic camphor: 1 kilo. camphor and 2 l. turpentine, or ½ l. benzole (d) for manufacture of following: Here follows a long list of pharmaceutical products, such as sulphuric ether, aldehyde, chloral hydrate, scammony, and other resins, alkaloids, glucosides, etc.; further, photographic preparations, collodion, coal tar dyes and their auxiliary and intermediate products, surgical bandages, etc.; 10 l. ether (sulphuric), or 1 l. benzole, or 0.5 l. turpentine, or 0.025 l. bone oil. For manufacture of white lead and acetates (e.g. of lead, etc.), 1 l. benzole or ½ l. turpentine, or 0.025 l. bone oil. For manufacture of acetic acid or vinegar for use above there are special formalities prescribed. Collodion for technical use and made from denatured spirit must contain at least 10 per cent. of nitrated cellulose. (e) For manufacture of chloroform, bromoform, iodoform, and ethyl bromide and brominated iodised fats for medicinal use: 300 grms. chloroform or 300 grms. iodoform or 300 grms. ethyl bromide. (f) For manufacture of vinegar a variety of alternative mixtures are allowed, ranging from 200 l. of 3 per cent. acetic acid or vinegar of that strength to 50 l. of 12 per cent. acetic acid with 100 l. of water, or 30 l. of 10 per cent. acetic acid, 70 l. water, and 100 l. beer. (g) For manufacture of coloured varnishes, stamping and other inks ½ l. turpentine and 0.025 l. bone oil. (h) For manufacture of parquet flooring wax, painters' pitch (resin), etc., ½ l. turpentine. (k) For manufacture of various kinds of varnishes: 2 l. wood spirit and 2 l. petroleum-benzine or ½ l. turpentine. (l) For scientific preparations for educational purposes, 1 l. technically pure methyl alcohol and 1 l. petroleum-benzine. (m) For solid soaps: 1 kilo. castor oil and 400 grms. caustic soda liquor or caustic potash liquor. (n) For lanoline, etc.: 5 petroleum-benzine.

MR. SHAW AND THE LINKS.

To the Editors.

Gentlemen,—Mr. Bernard Shaw has the habit of saying things apparently nonsensical on the surface, but that have a deep underlying truth which those who will patiently think through the surface persiflage will duly find and appreciate.

But there are very many who only resent the surface quibble and refuse to try and see if so clever a speaker and so genuine a thinker could mean other than nonsense. Your reporter seems to have been in some such haste when he refers to Mr. Shaw's example of the carriage-painter, and says that Mr. Shaw's ideal is the smooth and shiny, etc., etc.

It seems quite evident to me that what Mr. Shaw meant to convey, and did indeed plainly say, was that the man who had painted the carriage he saw when he left the Royal Academy had learned his business, knew his trade, had mastered his tools and materials, and was able to do what he set out to do.

The carriage-painter has to so paint his carriage body that it will present a perfectly even surface of great beauty and finish, and will resist rain and weather and hard knocks; this he is able to do from a long apprenticeship, a thorough knowledge of his tools and materials, and a precise knowledge of the end in view; in a word, he has an intelligent idea of what to do and a thorough hand-training in how to do it—*technics in excolsis*.

So much for the craftsman's work Mr. Shaw saw *outside* the Academy; but what of the craftsmen's, or artists', work *inside* the Academy, or at any rate the vast majority of them?

Do they, as did Van Eyck, learn the full use of their tools and materials? When the artist, I mean the painter, sets out to paint sunshine or rain or some elusive atmospheric effect, or some deadly true presentment of local colour in detail or interior work, does he know how to lay on his paint so as to accurately and truthfully and suggestively convey that to us? I wish Mr. Shaw had given one exception, say Clausen, just to show that it was the average exhibitor he was trouncing; but he was perfectly right in saying that the enormous majority of people who paint do not begin to know what mastery of tools and materials means; that they are totally unable to either understand or use them in the same degree of perfection as the painter *outside* the Academy; one is a master of his work, the other the amateur—the butcher.

"The light that never was on land or sea"

appears to be the ideal of the vast majority of both painters and photographers, shown in the too common absence of ability to either visualise or convey real light or atmosphere.

FREDERICK H. EVANS.

"STRAIGHT" PRINTS VERSUS THOSE OBTAINED OTHERWISE."

To the Editors.

Gentlemen,—It is a great pity that such an amount of feeling exists between the advocates of these two phases. That there is a total difference in the work of each cannot be denied, and much of this feeling is, in my opinion, and I believe in the opinion of a good many others, due to the pictorial few who from a ghost of a photograph build up a powerful picture with so much deleted, and so much added, that there is no resemblance whatever to the image formed on the ground glass of the camera.

The straight men are also in arms, and rightly so, when some beautiful photograph is rejected by the hanging committee of some exhibition because it is considered automatic or too systematic in manipulation; while they themselves are in favour of ozobrome or bromoil.

The Royal Academy of Arts is at the disposal of those people who are the cause of such rejection. In the first place because their "paintings" are very often beautiful, and secondly because

the Royal Academy does not accept photographs. If, on the contrary, the exhibition committees wish to continue accepting such work, let them have a special show for the often beautiful work done by the amateur as is evidenced by the excellent show-cards produced as a result of some money competition by the paper manufacturers, and by the editors and judges of photographic periodicals, who are ever willing to give equal encouragement to the "straight" worker. I would impress upon those people who dislike straight work that it is not so easy as they suppose to produce straight prints worthy of pictorial merit.

A visit to an exhibition two or three years ago revealed gems produced by the camera and the man, while now they seem to be produced by the man only. In this case how can they be photographs?

East Dulwich, S.E.

P. FREDERICK VISICK.

PHOTOGRAMS OF THE YEAR.

To the Editors.

Gentlemen,—In recognising your critic's lengthy and kindly remarks upon "Photograms of the Year," may I assure him—he "remembers no other review than our own"—that the presidential address at Canterbury was discussed at some length in columns other than yours.

It is satisfactory to hear that he did read the address, which makes it the more surprising that he should have devoted his best rhetoric to demolishing (as if it were mine) a position exactly opposite to one that I held, and setting in its place (as his own) the thing for which I contended.—Yours faithfully,
H. SNOWDEN WARD.

A DISCLAIMER.

To the Editors.

Gentlemen,—It has been brought to our notice that certain persons, calling themselves the Rotary Photographic Enlargement Co., are canvassing from house to house for orders for enlargements. We have been advised of this matter by householders in the North of London, who were under the impression that the canvassers were sent out by our company. We need hardly say that we know nothing whatever of this concern, and we have never, of course, had anything to do with this class of business.

One of our correspondents sends us a card printed as below:—

The Rotary Photographic
ENLARGEMENT COMPANY.

Branches (London and Provinces).

Branch Office: S. Studholme, Stoke Newington.

We are, Dear Sirs, yours faithfully,

THE ROTARY PHOTOGRAPHIC CO., LTD.

IRIDESCENT MARKS ON SULPHIDE-TONED BROMIDES.

To the Editors.

Gentlemen,—In your issue of August 27 you ask for any experience of iridescent marks on sulphide-toned bromides.

Some years ago I had a large batch of prints spoilt in this way, but from the description in the "B.J." the marks I experienced were of a much worse nature. There was very considerable iridescence in the darker parts. I traced the cause to the use of stale sulphide solution; in fact, the last remnant of the made-up solution. A friend had some trouble since, and on inquiry I found he had in this case also reached the bottom of his sulphide bottle. The last end of a solution of sodium sulphide is frequently of a dirty-green colour, and, of course, should never be used in such condition. I am referring to the usual case where a fair amount of stock solution is made up, lasting possibly many months. The remedy is obvious.—Yours faithfully,
HAROLD SMITH.

Johannesburg, October 4th, 1909.

THE "LITTLE GALLERY" AT BROCKENHURST (SOUTHWESTERN) STATION.

To the Editors.

Gentlemen,—Some few years ago I called attention in these pages to a small collection of portraits, by the late Mrs. Julia Cameron, that had found a rather curious resting-place in a waiting-room at

Brockenhurst Station, in the New Forest. At the time I wrote they were in a somewhat uncared-for condition, and I could not discover any one who seemed interested enough to look after them. On a recent visit to the New Forest I again "did" this Little Gallery, and, to my great satisfaction, I found that the pictures had been most judiciously remounted and reframed, and were altogether in excellent condition. A dark art mount has been laid over the original white cardboard mount, and where any note in Mrs. Cameron's handwriting appeared on the original mount an aperture in the cut-out mount permits of its being seen.

As I was quite curious to know who had taken the matter in hand I captured a stray station official, who goodnaturedly told me that Mrs. Cameron herself had "been down" (*sic*) and seen to them! I thanked him for his information and "tried again" on another platform. This time it was a gentleman in the Isle of Wight, "who comes here reg'lar." There was nothing to cough at in this. But, later on, when mentioning the matter to an acquaintance in Brockenhurst, he said they had been reframed by subscription. Whoever it was that took the matter in hand, he deserves the thanks of all interested in the "old masters" of photography, and I feel sure you will not begrudge me a small portion of your space wherein to call attention both to the existence of the Little Gallery and to its generous renovator (or renovators).

The prints are dated 1870, and appear to be on plain salted paper but on this point I cannot be certain. They are, however, in very good condition. The portraits are:—Robert Browning, Lord Justice James, Charles Darwin, Sir Henry Taylor, D.C.L., H. W. Long fellow, A. Tennyson, Sir J. F. Herschel, G. F. Watts, two Bishop of Winchester, and a second portrait of Sir Henry Taylor. The portraits of Tennyson and Watts are very fine. Ten in number.

One cannot help the reflection that waiting at railway station might be made quite a pleasant interval in railway travel if most stations possessed a Little Gallery of good work. Personally, should be only too glad to supply a railway waiting-room with dozen framed pictures, printed in some permanent process, for by so doing I should feel that I had gained what appears most lacking in photography at the present day, a sphere of future usefulness at a home.—I am, gentlemen, yours faithfully,
G. T. HARRIS.

Sidmouth, S. Devon.

FIXING BATH FOR BROMIDE PRINTS.

To the Editors.

Gentlemen,—In your issue of September 3, under "Ex Cathedra" a drawback of the acid-fixing bath is mentioned—viz., the risk of exhaustion being unnoticed. Personally, I find that the acid-fixing bath (for bromide prints) is a practical necessity. In ordinary use it is not practicable to wash prints thoroughly after developing, and I think one maker says five or six changes. I believe I am right in saying that a mere rinse is the usual practice. In such cases an acid bath is almost a necessity.

There are several ways of easily noticing exhaustion.

1. *The plain acid-hypo.* If a test with blue litmus paper does not give the red colour, distinctly and at once, the acid is certainly exhausted, and it is time to make up a new bath. It will be found that the acid is exhausted before the hypo, when the prints are simply rinsed after developing as mentioned. I am referring to the metol-hydroquinone developer. I have not experimented in this direction with a non-alkaline developer (amidol). Litmus paper is cheap and handy.

2. *Acid-alum-hypo.* If an acid fixing bath is used for hardening chrome alum should be the agent employed. The prints should give that "rubbery" feel to the touch, after a short immersion, less than a minute; and while this is so the bath will not be found to be exhausted. With this bath also there is a change later. The colour of the bath is a very deep blue-green, but clear. On being exhausted the bath is muddy, and, if left, a coloured deposit will settle at the bottom, leaving a clear, colourless solution above. I believe, even at this stage, a considerable quantity of hypo remains, but it is obviously more than high time to renew the bath.

At this stage would be long after the time of the former test mentioned had passed. The bath referred to is the one on page 780 of the "Almanac," which contains a quarter of an ounce or more of chrome alum to the pint.—Yours faithfully,
HAROLD SMITH.

Johannesburg, October 4th, 1909.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- E. McGeachie, Photographer, Pier Road, Dumoon, N.B. Five Photographs of Harry Lauder, and One of a Group containing Harry Lauder, Mrs. Lauder, and Mr. Vallance.
- J. P. Clarke, 34, Castle Street, Llangollen. Photograph of Avelyn Tanqueray, Esq.
- L. E. Richards, The Studio, Suffolk Road, Lowestoft. Photograph of the "Kessingland" Monoplane.
- A. Russell, 6, Wild Street, London Road, Liverpool. Four Photographs of the Sailing Vessel "Kynance."
- S. A. Chandler & Co., 132, Above Bar, Southampton. Two Photographs of the Marathon Race at Bournemouth.
- J. L. Hart, 52, Gainsborough Road, Crewe. Photograph of Group representing "Butterflies," and Photograph of Group representing "Butterflies and Flowers," both at Crewe Pageant, August 8, 1909.
- G. Boucas, 195, High Road, Ilford. Photograph of Little Girl and Dog.

COLOUR-SENSITISING DRY-PLATES.—1. Will you kindly tell me the most suitable dye for sensitising ordinary dry-plates so that their subsequent monochromatic rendering may be as true to nature as possible? The dye should be reasonably easily procurable. It should be simple to use, and should allow of the treated plates being kept some time. 2. I should also like to know if all ultra-violet light from a subject is cut off by a glass lens—and if not, how much is? Will you give me the answer to the latter alternative in wave-lengths ($\mu\mu$)?—PERCY A. TUCKER (Germiston, Transvaal).

1. For full instructions see formulæ in the "B.J." Almanac ("Orthochromatic Formulæ"). A good formula for panchromatic plates is:—

Pinacyanol (1-1,000 solution in alcohol) ...	2 ccs.
Pinaverdol (1-1,000 solution in alcohol) ...	3 "
Water	250 "

Bathe for three minutes and wash for ten minutes in total darkness. If the washing is thorough and the plates are stored in cool, dry place they will keep satisfactorily. The dyes are made by Meister Lucius and Brüning, obtainable from Fuerst Bros., 17, Philpot Lane, E.C. 2. No lens cuts out all the ultra-violet light, the amount cut out depends upon the glass used. Thus microscope cover glass cuts off some of the ultra-violet, while the Jena glass, specially opaque to ultra-violet, allows some to pass beyond 4,000 A.U., which may be regarded as the limit of visibility. Watson's Actinolex lens, made of glass specially transparent to ultra-violet, cuts off at about 3,200 A.U., while Zeiss Protar, Cooke Process, and Goerz Double Anastigmat cut between 3,500 A.U. and 3,600 (Newton and Bull, "R.P.S. Journal," 1906, page 282). Mees and Sheppard show ("Theory of Photographic Processes," page 326) that without and with a screen cutting out the ultra-violet at 3,950 the ratio is as 1 to 2.46 of skylight; using a piece of plate-glass cutting at 3,300 (comparable to a lens) the ratio is as 1 to 1.35.

M. NOTMAN AND SON (Montreal, Canada).—We should recommend you to try one of the enclosed arc lamps, which you will find very actinic. The lamps can be supplied for either direct or alternating current if you specify what you require when ordering, and we think in a studio the size of yours you will do well to get a large size lamp. You will be able to use the same arrangement of light reflected from white screens. You will need to hang the lamp as high as possible, as the arc is a couple

of feet below the point of suspension. You will find this type of lamp quite applicable for printing purposes, and if it is hung over a pulley with a counterpoise weight you will be able to lower it to the floor for convenience in printing. You will not find it necessary to cut off all direct light, nor to throw the whole of the light on to the white reflecting screens. The direct light, however, must be diffused, and for this purpose there is nothing better than a head screen, covered with engineer's tracing linen.

PAINTING BACKGROUNDS.—Could you kindly reply the following demand in the text portion of your paper intended for answers to correspondents? I am painting my own background, but cannot get with oil-colour that beautiful extra matt finish some German and Swiss background painters reach. Could you help me in the matter?—J. MARYNEN (Brussels).

The trouble is due to your using ordinary oil paint, the oil in which causes the colour to dry glossy. To get a matt surface flattening colour must be used. The following will give what you desire:—Mix white lead, lamp-black, and venetian red (or other colour), as sold at oilshops ground in oil, with turpentine to the consistence of ordinary oil paint, or rather thinner, and then add about one-third its bulk of jappanner's gold size. This will dry with a dead surface. The background should previously be painted with oil paints.

COPYING COLOURED MS.—Where a coloured manuscript has to be copied for reproduction by the three-colour process in collotype is more than one negative required—and if so, would you advise as to screens in copyright?—"JOANNI."

Certainly three negatives have to be made. Sets of the three filters are supplied by Sanger-Shepherd and Co., Gray's Inn Passage, London, W.C., and Wratten and Wainwright, Croydon.

TOXO, W. JONES, AND OTHERS.—In our next.

C. J. T.—We are much obliged to you for your letter, but both expedients have been frequently advised in the past.

G. J. PITT.—As you were engaged for a week's trial you are entitled to a full week's pay, and you should sue the people in the County Court for the balance due to you. It is a mean action on their part to try to avoid payment.

PHOTOGRAPHING SHOP FRONTS.—Will you kindly tell me the best way to photograph a shop window, so as to get rid of reflected light? This window is opposite a street, and the back of it has mirrors in each panel.—E. B.

If you can cover the mirrors or dull the surface with, say, a light coating of starch paste, it will help in removing the reflections of objects across the street. If this cannot be done we suggest that you try making an exposure by night by flashlight, which will leave the "reflectable" objects unilluminated.

LENS ON REFLEX CAMERA.—I have a $\frac{1}{2}$ -plate focal-plane reflex camera, to which is fitted a — lens 7.2in. focus, wide angle. It has obtained some very good negatives with this lens and camera, notwithstanding that the makers of the camera inform me that I will be unable to use a lens of such short focus on a reflex camera, and must obtain one of about 9in. focus. Can you inform me how I get such results with this lens? I may say the lens is in a sunk mount, which is in beyond the surface of camera front.—REFLEX CAMERA.

The makers' recommendation to you is made in reference to the mechanical construction of the camera, not to the covering power of the lens. Some reflex cameras will not take a 7in. focus lens in the half-plate size, but if they will there is no reason why a 7in. lens should not be used. A lens of this focal length, particularly of the aperture of $f/8$ or $f/6$, which we suppose yours to be, will cover a half-plate perfectly.

SEMPER EADEM.—The best form of washer for films is one in which the latter are placed in sheaths, and, thus mounted, washed in the same way as plates. Messrs. Houghtons supply a well made apparatus of this kind, the sheaths being given a curved form, so that they retain the films firmly. For prints (which, unlike films, have no sharp corners) there are a number of good washers which do the work of keeping the prints in motion satisfactorily, so long as prints are of moderate size—e.g., not larger than whole-plate.

For larger or even for whole-plates there is nothing better than transference by hand of prints from one dish to another.

DOUBLE-POSE PHOTOGRAPHS.—Would you kindly inform me how to take photographs of a sitter in two or more positions on the same card? A friend of mine would like to be photographed shaking hands with himself.—P. SEYMOUR.

This is done by means of a shutter placed in front of the lens or at a short distance from the plate, one half of the shutter exposing one half of the plate and the other half the other. The subject changes his position between the two exposures. Any dealer can supply.

MARKINGS ON ISO PLATES.—A little while ago I was trying some iso plates backed (plates old), and when developing I rubbed away some of the backing, so that I could see density when developing. On fixing plates and looking at them in white light I found the marks in the image just when I had rubbed away backing, showing exact smears, etc. Would you be so kind as to explain this?—S. H. W.

Without seeing the plates we should say that the result is due to fogging action of an unsafe dark-room light.

BOOK ON PHOTO-ENGRAVING.—In your issue of Friday last, 22nd, you mention the name of Mr. N. S. Amstutz, the author of the "Photo-Engraver's Handbook." I should deem it a great favour if you could inform me as to where I could procure that book, and the price of the same.—J. H. CAMFIELD.

From Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C.; price, 12s. 6d.; post free, 13s.

SPECTROSCOPE.—Where can I obtain a spectroscope that is used for testing three-colour filters, and about what would the cost be? Also, is there a book on the same? Who is it published by, and the price?—F. J. WHITE.

Messrs. Browning (Strand), Penrose, Sanger Shepherd, Griffin, and Hilger (Camden Road) all supply spectroscopes of various types and patterns, and you should consult one of these firms. The cost may be anything from 10s. upwards. You would probably find all you want in R. A. Procter's "The Spectroscope," or C. R. Wood's book with the same title. Messrs. Browning, in the Strand, also have a handbook on the spectroscope. All these are cheap books. We cannot give bookseller or publishers of the first two, as the books are not at present available.

CATHAY.—Boake's sulphite was the kind mentioned. Any dealer can obtain it for you.

DRYING CUPBOARD.—Can you oblige me with sketch or description of a method of heating air before it passes into a drying-box (wood)? I want to command a temperature of 80 to 90 deg. Fahr., in a box of 18in. high by 15in. square. There is a strong outward draught, and bathed plates are in question. Electricity is not available.—D. I.

If you want to draw a current of warm air through the box, the simplest way is to connect the air inlet with a pipe that is twisted into a coil and immersed in a vessel of hot water. You can use small compo tubing for the purpose of making the coil. The tank may conveniently be a biscuit tin filled with water that is kept hot by a gas-burner underneath. Another method is to take a strong tin or iron box (a biscuit tin is again quite serviceable if the joints are rolled and not merely soldered), place it on a tripod with a burner underneath, and then stand the drying-box on the top. By regulating the burner you can easily attain a steady temperature of about 80-90deg. in the drying cupboard, which, of course, must have inlets for fresh air. A description and drawing of a simple drying-box which would serve your purpose are given in "Ferric and Heliographic Processes" (Dawbarn and Ward, 2s.).

WATER-COLOUR.—Apply to the Secretary, Royal Academy of Arts, Burlington House, London, W.

PRESS.—From what you say we judge that the rust has eaten deeply into the steel plate of the rolling-press, in which case it will probably be cheaper to get a new one than to have the present one re-polished. The press-maker, after seeing the plate, will advise you better on this point than we can. When a rolling-press and its plate has to be stored away out of use for a long

time the plate and rollers should be heated and then rubbed over with beeswax. There is then no fear of rust, even if they are kept in a damp place.

J. H. BONE.—The chief advantage of a 10 x 8 R.R. lens, when used for whole-plates, is that it will cover the plate better with a larger stop than a whole-plate one would do. But it must be kept in mind that it will not include so wide an angle of view as the latter would do. That, however, is lot of much moment in taking outdoor groups.

R. J.—You are quite right. Your competitor is acting illegally in styling his process "patent" when he only obtained a provisional protection for it. By doing so he renders himself liable to a penalty of £20. No one must apply the term "patent" to anything for which a patent has not been granted. That applies to photography as it does to anything else.

AMBER VARNISH.—I wish to obtain some amber varnish that dries cold, such as used to be employed for collodion glass positives and negatives in the days when the collodion process was the only one used. I have asked for it at several of the dealers' in London, but none could supply it. Some even said that they had never heard of it, or that there was no such thing.—T. A. CONWAY.

As you cannot obtain the varnish, the only thing to be done is to make it yourself. This you can do by dissolving amber in chloroform to the consistency desired. Chloroform is somewhat costly to use, but that made from methylated alcohol is much cheaper than that made from the unmethylated spirit, and it answers quite as well for varnish-making. What is now used for collodion positives is dammar, dissolved in benzole, and it answers the purpose quite as well for glass positives as that made with amber and chloroform, and, of course, is much cheaper.

COPYRIGHT.—I shall be obliged if you will be good enough to enlighten me as under. A friend has two very fine engravings, and he will be kind enough to lend them to me to copy for specimens for the reception-room. The pictures, I know, are copyright, but I do not intend to sell any copies; all I want them for is to fill up space. I conclude that I shall not be infringing the law. Am I right?—COUNTRY PHOTO.

No; you are decidedly wrong. It is illegal to copy a copyright picture for any purpose whatever. It is also illegal to exhibit publicly a copy of a copyright picture. The Copyright Act is very far-reaching, and completely covers what you propose to do.

SOUTHAMPTON CAMERA CLUB.—The society's year-book, 1909-10, is to hand, and contains all the necessary information for the use of members in a concise and compact form. The winter programme comprises an attractive list of fixtures for the forthcoming session, the varied character of which should appeal to all classes of photographic workers, and ensure a good attendance at all meetings. An interesting feature of the book is the frontispiece, which is a reproduction of a photograph by the secretary, Mr. S. G. Kimber, entitled "Monday," and affords another proof of the versatility of this indefatigable camera worker.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Mr. H. Essenhigh Corke contributes an article dealing with the making of portraits with white backgrounds, a form of portrait photograph now much in vogue and popular, particularly with lady sitters. (P. 855.)

Mr. Rhymer Cook, in an article on page 857, describes the most visible methods in making photographic copies of coins or medals or catalogues, note headings, etc.

The suggestion is made in an editorial note on page 854 of the usefulness of a small clock-dial affixed to a developing or hypo tank. In this, the time at which plates or prints are to be removed can be indicated.

"L.C.C. Training in Photography," "The Fixing Bath for Bromides," "Toning Lantern Slides," "Mr. Shaw and The Links," are among other subjects under "Correspondence." (P. 865.)

In some notes on page 854 a number of cautions are given as to the care of negatives in damp weather.

At the Brighton Police Court last week the amenities of a studio that town formed the subject of a case. (P. 864.)

In reference to the recent issue of a "Monthly Circular" by the affiliation of the Royal Photographic Society, we publish an article on page 858 questioning the usefulness of this publication and criticising some of its contents.

Of hyperfocal distance. (P. 859.)

A patent for animated photography in natural colours has been taken out by Mr. Otto Pfenninger. (P. 860.)

Mr. C. Welborne Piper has made a note of the fact that a plain solution of potassium bichromate, if given time, will intensify a negative to a considerable extent. (P. 857.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. J. H. Pledge published a microscopic and spectroscopic examination of two new forms of colour screen-plate, one the "Dioptrichrome," patented by M. Dufay. (P. 81.)

Mr. Welborne Piper has made an analysis of possible patterns of colour screen-plates in reference to their greater or less opportunity of giving rise to overlap of colour during the successive stages of their manufacture. The plate consisting of parallel bands is superior to all others in this respect. (P. 84.)

Dr. Miethé has recently given some particulars of his methods in taking three-colour photographs from a balloon. (P. 86.)

Some further details of the Stobbe rapid bleach-out method are given on page 88.

EX CATHEDRA.

Insects and Photographs.

In our "Answers" column a query will be found relating to prints that have apparently been spoilt by the attentions of some unknown insect with a taste for gelatine. The print is marked with small white spots which run together in intricate spirals and patterns of all shapes. There is distinct evidence that the spots are dug or nibbled out through the film of the P.O.P. image down to the substratum. In fact, the marks of a sharp angular-pointed mandible are quite apparent under the microscope, though their minuteness also suggests that the creature responsible was one of very small size. It is unusual to meet with this kind of trouble in the case of prints, though it is not an infrequent mishap with negatives. There can be little doubt, however, that the source of the trouble is the same in both cases. Negatives left about on shelves and not stored in boxes are often subjected to the attacks of insects, and there is no reason why prints kept in an equally careless manner should not meet with the same fate.

* * *

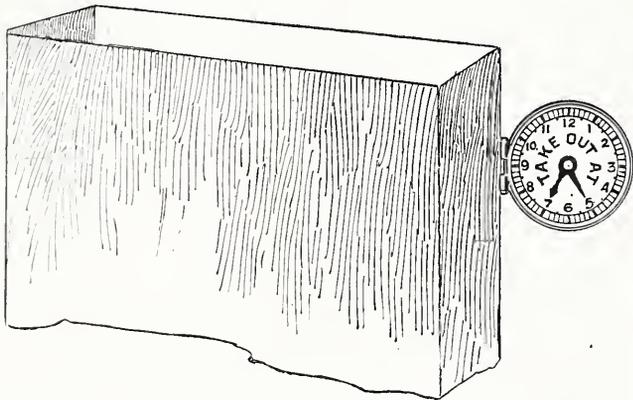

Warm-Toned Lantern Slides.

The succession of lantern slides seen upon the screen at the New Gallery during the R.P.S. Exhibition affords an opportunity of studying a great variety of slides from the technical standpoint. One theory which struck us forcibly this year was the fact that the modern craze for various tones of a more or less warm character is apt to lead to as unpleasant results as the old-fashioned black tones. Simple black and white slides put a severe strain on the eyes in the course of an hour or so, but so also do slides of an aggressively warm tone, while to us a constant change of tone such as we see sometimes is extremely irritating. Photographers generally seem slow to recognise the fact that in a monochrome process such as photography it is only very occasionally that anything is gained by the introduction of decided colour. The moment a departure is made from a neutral tone there is the risk of making a blunder, and the problem of selecting the best colour for a monochrome picture is not one that the photographer is likely to solve satisfactorily unless he has had previous training in colour effects. It is a matter of common experience that the ordinary person who makes no pretence at art knowledge generally shows a marked preference for the rich neutral "photographic purple" of a gold-toned P.O.P. print, and his instinct does not lead him far wrong when it tells him that this is one of the most satisfactory tones for a photograph. A good dark sepia platinotype, or an "engraving black" carbon print, has a tone of a similarly well-appreciated type, while a grey platinum print seldom fails to secure many admirers. In all these cases the tone has the same characteristic of

quiet unobtrusiveness, and with lantern slides tones of similar quality are again the only ones that give universal satisfaction. A red tone is more aggressive on the lantern screen than in a framed picture, and the risk of its quite spoiling the result is far greater. Nowadays, unfortunately, we see few slides of the rich dark purplish-brown neutral tone which at one time everyone aimed at, and the alternating appearance of black tones with washed-out browns and glaring reds is a poor substitute for a succession of quiet slides.

A Development Tank Accessory.

One of those useful devices which should appeal to those practical workers who now make a practice of using the developer in a tank quite apart from what their views may be as to the advantages of development for a fixed time, is a clock dial, fitted with hour and minute hands. Such a dial, in conjunction with an ordinary watch or clock, saves a good deal of attention in the dark room, the worker at the time of pouring on the developer setting the dial on the tank to the time when the plates should be approaching a state of completion, or, if the time method is being

used, setting the clock to the actual time of development which is being adopted. This plan saves the mistakes which are very easily made if the worker's own watch is referred to at the time of starting development and the memory relied upon in the matter of the time at which the plates should be removed. Makers of developing tanks might very easily provide a small dial of this kind which could be hinged to the lid or body of the developing tank—according to its type of construction—and would always be at hand.

SOME DAMP WEATHER CAUTIONS.

MOISTURE in the atmosphere is often quite an unsuspected source of trouble to photographers, though many may not be aware of the full extent of its results. In our variable climate the air is always charged with a certain amount of it. At times it is not sufficient to cause inconvenience, yet on many occasions it becomes a source of trouble. During the continued spell of wet weather which has been experienced in all parts of the kingdom the past few weeks, the air has contained an unusually large proportion of moisture: on some days the atmosphere has been completely saturated with moisture, as proved by the daily weather reports issued by most of the newspapers. For some days in succession the readings of the wet and dry thermometers have been identical, showing that the atmosphere was completely saturated with watery vapour. As the winter advances, the humidity of the atmosphere may be expected to continue, and therefore it may be of service to some to point out some of the effects of excessive atmospheric moisture in the air in connection with photographic work generally.

Everyone knows that platinum paper must be kept absolutely dry, otherwise it will quickly deteriorate; also that the negatives, printing frames, and pads for the latter must be absolutely dry during the time of printing, or first-class results will not be obtained. If a tube of the paper be opened in an absolutely dry atmosphere it will suffer no harm, but if it be opened in a place where the air is almost saturated with moisture it will suffer more or less injury from moisture, particularly if it has been stored in a cold place previously.

Carbon tissue also may be damaged in a similar way, for it is well known that dry gelatine has a great affinity for moisture. The latter is quickly absorbed by it, and will greatly affect its keeping qualities both before and after printing. If, after exposure, the prints are kept in a humid state the so-called "continuing action" will go on very much more rapidly than when they are quite dry. This fact often leads those who are inexperienced in the carbon process to surmise that the prints have been overexposed in the printing, whereas the cause should be sought in the time elapsed between printing and developing. The drying of carbon tissue, after sensitising, is much retarded by excessive moisture in the air; the room in which it is dried must be warmed, otherwise, as a consequence, the solubility of the tissue, as well as its keeping qualities, will be considerably impaired.

We will here digress for a moment to say a few words on the condensation of moisture in the air. Most persons have noticed that when tumblers, wine glasses, and the like are brought from a cold room into a warm one, where a number of persons are assembled, and the air of the apartment is therefore moist from their breath, that dew forms upon the surfaces of the articles. But if the glasses had been as warm or warmer than the room, there would be no condensation whatever. Again, in the case of lantern entertainments, one often sees that a slide on the screen after a minute or two gradually becomes dimmed by moisture condensing upon it, or in some instances on the condensers. This is, among other causes due to the glass being of a lower temperature than the moist atmosphere, and all experienced lanternists take the precaution to warm the condensers as well as the slide before the show commences.

If lenses which have been kept in a cold room are brought into a warm studio, moisture will at once condense upon them and dim their surfaces, and it will be impossible to obtain a brilliant image. This kind of thing is often troublesome when the photographer has to photograph the interior of an artificially heated conservatory or greenhouse. Although there may be comparatively little moisture in the outer atmosphere there is always a considerable amount in buildings of this kind, and as a result dew at once begins to condense on the surfaces of the lenses and thus prevents a brilliant image being obtained until the glasses have been thoroughly cleaned. The condensation may, however, be avoided by warming the lenses, say, by placing them for a time close to the hot-water pipes in the building. Most experienced photographers when they have work of this kind to do, take the precaution to warm the lenses before starting, and then carry them in their pockets so as to avoid their cooling as far as possible.

A very prolific source of trouble due to moisture in the air is the staining of negatives. We are frequently asked how to remove silver stains from negatives that have been printed from on *damp paper*. As often as not, however, the stains are due not to the paper, but to the negative itself being damp at the time the paper was put upon. At the present season of bad light printers have to make the most of every day, and thus the frames are placed out in the open air. Even if this is not done, the places

ch they are exposed is often little better than a shed, is very cold: consequently the negatives get very d also. When they are taken indoors for the paper to be changed, the moisture in the warm room immediately condenses on the cold negatives and on fresh paper being placed in the frame, a film of moisture becomes imprisoned between it and the negative. Some of this being absorbed by the negative and some by the paper, it will readily be seen that after several changes have been made under these conditions the film of the negative has, in all probability, absorbed a considerable amount of moisture and possibly some silver from the paper. This will eventually result in the negative developing stains, though nothing is noticeable at the time. If negatives, after being printed from in these circumstances, are put away without the precaution being

taken to dry them thoroughly, they may readily show, perhaps months afterwards, stains, which are often attributed to their use of damp paper, whereas it was actually the negative that was damp and not the paper. It goes without saying that when negatives are varnished with a spirit or a celluloid solution, they are far less susceptible to the evils of moisture. When they have a thoroughly protective coating, any condensed moisture on the negative is absorbed by the paper, but the print does not suffer therefrom unless it is kept an unduly long time between printing and toning. In conclusion, we would advise everyone after printing in cold weather to warm the negative thoroughly so as to drive off any moisture they may have absorbed before storing them away. If that were always done we should hear less about stained negatives.

THE USE OF WHITE BACKGROUNDS.

At the present time white-background work is exceedingly popular among the better-class clients of the average professional, and such work is produced, I suppose, by most photographers. Those who have not yet adopted this style will find it a good business drawer, but like any other new work

which I will first deal with. Firstly, when ordering a white background for this purpose the photographer should stipulate that it should be a distinctly blue-white, and should have no tendency towards a cream colour. In fact, I find that a distinctly pale blue is even better than pure white. When using the background it should if possible be arranged in such a position that it can be lighted quite independently of the sitter. As strong a light as possible should be thrown on to it, and, if

Fig. 1.

Fig. 2.

possible, it should be tilted towards the skylight instead of being placed perfectly perpendicular.

The lighting of the sitter for such work will naturally depend upon the particular theme of the worker, but for most subjects it will be found better to avoid any great contrasts, and to light the sitter with a full flat lighting, and if very delicate work is desired a reflector upon the shadow side should certainly be employed.

Very fine effects closely resembling pencil drawings can be made of profile heads by placing a black reflection close to the sitter instead of the usual light-coloured reflector. This has the effect of throwing a black shade on to just the outline of

requires a little practice before it becomes easy to produce. Having made a specialty of such work for some time past, I have found out one or two little wrinkles which I hope may be of use to my fellow workers.

The point which will be found most difficult is that even the best of white backgrounds will not, as a rule, photograph as a pure dead white, with the result that when the prints are made the background usually prints as a light grey. There are one or two dodges in the making of the actual background

the profile, and very little after work on the negative will produce results similar to fig. 1.

It is, of course, imperative that for the best results the

Fig. 3.

sitters should be in light clothing, and this fact combined with the use of a full light and the lack of necessity for modelling will allow of very brief exposures, which is always an advan-

Fig. 4.

Prints from the untreated negative (4) and from the same after blocking out the background in the way described in the article.

tage. It is, however, particularly with the whiteness of the background that I now wish to deal.

I do not know just how some workers manage to get purity in the whites, but most photographers to whom I have men-

tioned this matter have told me they have to block the background out. My own method will be found somewhat uncommon, and I trust prove useful. The negative is placed in the printing frame in the usual manner, and then the front of the frame covered with a piece of cardboard, in which is cut a hole rather larger than the part of the negative occupied by the figure just as an ordinary vignetting shape is attached. This hole is then covered with a piece of tracing-paper. The frame is then held up to the light, and the background painted over on the tracing-paper so as to make it quite opaque. The method of doing this will be quite clearly seen in the two small illustrations (figs. 2 and 3).

Any sort of paint will serve for this purpose, such as yellow red, or black water-colour, but perhaps the cheapest method to procure a pound of either yellow or red ochre at the merchant's in the form of a dry powder, and use this with water and just a little gum to prevent it flaking off. Care should be taken to gum the negative into the frame with small strips of paper, or when attending to the painting it will be forgotten that the frame is tilting backwards, and the negative will fall out.

The chief advantage of this method is that the negative itself is not painted upon, and therefore the hard cut out appearance so often seen is avoided. The printing frames used for this purpose should be as shallow as possible, thus avoiding the light spreading and ensuring more accurate results. With a very little practice it will be found possible to block out even such small spaces as between chair legs in this manner, and very much quicker than when actually working on the negative.

Considerable control over various parts can also be exercised by applying light washes of the colour, and thus lightening any excessively heavy shadows, etc.

Fig. 5.

The printing of such subjects should be carried out in a place where the light descends fairly evenly and not from a tall building, which would tend to make the light fall in one direction to a certain extent. In fact, the best

to place the frame in a deep box in a similar manner to that employed when printing from a cracked negative, or easier still, the prints may be made on bromide paper, and thus the short exposure allows the frame to be held at just the right angle to the light. The operation can, with a little practice, be

so carefully carried out that a black background can be entirely vignettted away into a pure white background, and also this method is far quicker as well as softer than actual blocking out.

H. ESSENHUGH CORKE, F.R.P.S.

A NEW METHOD OF CHROMIUM INTENSIFICATION.

THE chromium method of intensification is now well known and very popular, perhaps more so than any other method; it is, however, not generally well known that there is a simpler though much slower method of producing a somewhat similar effect. We need only immerse a negative in a plain solution of potassium bichromate to obtain an appreciable amount of intensification in an hour or so, while several hours' immersion produces a strong effect. Of course the plate requires washing to get rid of the yellow bichromate stain in the shadows. If dried at this stage we obtain an intensified image that is slightly brown in colour. If we immerse in a developer before drying we obtain a much darker and stronger image, while if we apply a hypo bath instead of a developer the extra density disappears, and the final result is much the same as the original image. A

chromium compound of some kind is deposited in or upon the image, but what it is cannot well be determined. It appears to be different from that produced with the ordinary process of chromium intensification and also different from that found in the ozobrome process. It slightly resembles chromic hydrate in some respects, but it is impossible to say that it is the hydrate.

The defects of the process are that strong intensification requires twelve or more hours' soaking in the bichromate, while the final result never seems to be so clean or so black as that produced by the ordinary method. It also seems coarser grained. While I do not recommend the process as having any advantages over the ordinary bleaching method, it is still an interesting one to note from the scientific point of view.

C. WELBORNE PIPER.

PHOTOGRAPHING COINS AND MEDALS.

It occasionally happens that an apparently simple thing in photography is not so easy to carry out successfully as at first sight it may appear to be to those who have had no practical experience in that particular direction, though the thing may be simple enough to those who are familiar with that class of work. It is a no very unusual thing for the ordinary portrait photographer to be called upon to photograph medals, perhaps gained at some recent exhibition, to be afterwards used for advertising purposes, and, when he has done his work to the best of his ability, to find it is not to the satisfaction of his customer, simply because it does not show the design, or, maybe, an inscription on it, sufficiently distinct to answer the purpose for which it is required. Such a result is disappointing to the customer, and also to the photographer, as he has failed to please.

In nine cases out of ten the failure in getting what was required has been entirely due to the lighting of the originals, and nothing else. It has failed to show the design and lettering in the proper degree of relief. It may show it all, it is true, but only as a mere flat surface, and does not convey the idea that it is in more or less high relief. It is our object here to give some practical hints that may be of service to some who are inexperienced in this class of work.

Camera Arrangements.

In the first place, the medals must be secured in position on a suitable background, but it is obvious that the means by which they are secured must not show in the photograph. If the photograph is for reproduction by a mechanical process, in which a reversed negative is necessary, and a reversing mirror or prism is at command, the work is much simplified, as one can only to arrange the things on a sheet of cardboard of suitable tint on the floor, and point the mirror or prism downward, instead of, as usual, sideways. If the prism or mirror is not available, the copying may still be done on the floor, if the camera be arranged so that it points downwards and at right angles to the medals. Then we get, of course, a non-reversed negative, and it is this that is the more generally required. In

either of these methods of procedure it is essential that the greatest attention be paid to the lighting of the originals, for on that the result entirely depends. It must not be from the top, or no relief will be shown in the picture. The dominant light must fall on the medal from the side, and that at a considerable angle to the axis of the lens, or there will be but little relief in the reproduction. This can easily be managed with sheets of brown paper arranged so as to stop off all top light, and the side light from one side.

Mounting Coins Vertically.

In most instances it will be more convenient to the ordinary portrait photographer to copy the objects vertically, and when that system is adopted there must be some means of securing the medals firmly in position. As a rule, their owners will not permit of any kind of cement being used for the purpose, as it might impair the polish on the new medal; therefore some other means must be adopted. A simple one is as follows:—Take a tolerably thick mount of suitable tint, lay the medal on it, and, with a fine-pointed pencil, trace round the edges. Then cut out the centre with a sharp knife, keeping slightly within the pencil-mark. The medal is then pressed into the opening, where it will be held securely. In fixing it into the card, it should not be pressed flush with the mount, otherwise the medal itself will not show in actual relief. The medal, or medals, having been made secure in the mount, and that affixed in a suitable position in the studio, the next point for consideration is the lighting of the object. The best conditions of lighting will be obtained by placing the medal at the side of the window of an ordinary room, or by imitating such lighting in the studio.

If the electric light—arc lamp—is available, that will be very suitable for the illumination of the originals, as it is easy to arrange the rays from it in any direction to suit the subject. If the shadows appear too strong, they may be softened by moving the lamp a little more to the front, or by placing it at a rather greater distance from the object, so as to make the lighting less abrupt.

The best negatives of medals and the like are obtained with a

very full exposure, and a well-restrained developer, so as to get a vigorous image with full details. Backed plates, especially with silver objects, will greatly assist in this direction, and they should always be employed.

Usually a photograph of the obverse and the reverse of a medal is required in one picture. Obviously, they cannot both be taken at the same time; but, if the camera has a repeating back, they may both be done on the same plate by reversing the medal in its mount and then making a second exposure. In practice it will often be found more convenient to take two separate negatives, join them and print them on one piece of paper. The background is blocked out with black varnish; the two negatives are then cut down so that, when placed side by side, they are just the right distance apart. They are then arranged together on the glass of a printing-frame, and the edges secured to it with strips of gum paper. A slip of black paper is then stuck over the juncture, and all is then ready for printing from in the ordinary manner. Very frequently, when medals are required for advertising purposes, electrotypes are made from them, both of the obverse and the reverse sides. When that is done it is obvious that both sides can be photographed at one and the same time.

Photographing Old Coins, etc.

In the above notes we have been dealing more especially with what we have assumed to be comparatively new medals, but it may sometimes happen that ancient coins—gold, silver, or copper—have to be photographed, of which, by reason of their age and the wear they have had, but little of the original figuring can be seen. Here we come to a much more difficult work than the foregoing, for it may be that not only has the design and lettering become almost obliterated, but the surface of the coin is more or less oxidised in parts, while other portions are comparatively bright and reflective. With such subjects as these it is next to impossible to get presentable photographic reproductions. Yet very successful ones are seen in most of the works on numismatics. It may not be generally known, but it is a fact all the same, that these photographs are not taken direct from the coins themselves, but from plaster of Paris casts made from them. In this way is the difficulty got over. The plaster takes no heed of the colour of the coin or of its more or less bright or dead surface. In taking these casts, as a rule, the plaster of Paris is slightly tinted with a dark pigment, such as burnt sienna or umber, but only just sufficient to take off the glaring white of the plaster. When gold, silver, and copper coins are to figure in the same illustration, the plaster should be tinted accordingly—the copper the darkest, the gold a little lighter, and the silver lighter still. When this is done in making the casts the photographic reproduction will indicate to a great extent the difference between the three metals.

The plaster of Paris used for this work must be of the special kind used by modellers, as that sold at oil-shops is much too coarse for the purpose. Although the plaster casts aid the photographer very considerably, the lighting of them is still a most important matter, and it must be done on the same principle as described for photographing direct from the originals, or success will not be attained.

RHYMER COOK.

IMPERIAL INTERNATIONAL EXHIBITION, 1909.—Dallmeyer lenses and apparatus, which have been exhibited in the Machinery Hall, have been awarded a Commemorative Diploma. It will be remembered that at the Franco-British Exhibition, held last year, two grand prizes were awarded to Messrs. J. H. Dallmeyer, Ltd.

MICRO-CINEMATOGRAPHY.—According to newspaper reports, M. Jean Commandon, a young French savant, by combining an ultramicroscopic instrument with a cinematograph, and by running the latter at a speed slightly less than the normal, has been able to obtain photographs in which microbes so small as to be invisible to the eye in the ordinary microscope are seen moving in their natural surroundings.

THE R.P.S. AFFILIATION "CIRCULAR."

THE Executive Committee, which administers the affairs of the Affiliation of Photographic Societies, has commenced the issue of a "Monthly Circular," the first number of which, dated October, appears with 16 pages of text in a cover bearing four pages of advertisements. The contents of the "Circular" are an introductory article on "Our Aims and Objects": a review of the current "Red Book" particulars of Affiliation competitions: announcements of forthcoming society exhibitions: a list of the bookings of Affiliation lectures: an illustrated notice of Mr. J. C. S. Mummery, the first of a series on "The Men who do the Work": notes on society matters: a report of "Red-Book Night" at the R.P.S. Exhibition, and lastly, the "Photographer's Gazetteer," under which heading are given particulars (of places and districts) which are being accumulated under the "Consular" scheme of the Affiliation.

Members of Affiliated societies will naturally be interested in the announcement of the particular service which the "Circular" is to render. This we learn is the communication of "just that personal touch which would bring home to every society secretary the usefulness and importance of united action among the many societies of which we are composed." If this be so it would seem that the first "personal touch" is being deferred for No. 2 of the "Circular," since anything less personal than the "Circular's" announcements it would be difficult to imagine. And when all societies have been personally touched to such an extent that they realise this usefulness and importance, what, we wonder, is the contemplated "united action?" We hope nothing revolutionary hangs behind this dark saying. Not another "reform" of the R.P.S., or anything to strike a blow at the regulations for the admission of Fellows. It all sounds ominous and portentous of history in the making. However, anything may happen in succeeding issues, since (paragraph No. 3 of "Our Aims and Objects") "it is impossible at this time to forecast in detail the exact lines on which the 'Circular' will run, but broadly we may state that all matters of interest to secretaries . . . and indeed, all matters affecting purely society life will be dealt with."

These and other passages rather suggest that the "Circular" is for the reading of secretaries of Affiliated societies. The contents certainly sustain this view, but, on the other hand, the report that the "Circular" is issued to the number of 3,000 belies this charitable assumption—there are about 160 Affiliated societies. Assuming the correctness of the view that the Executive Committee proposes addressing itself to members, as well as to secretaries, thus creating fresh interest in its propaganda—an altogether admirable project—we may legitimately speculate as to the means adopted for bringing it into the hands of members. Apparently the method which is relied upon is that of distribution of the "Circular" at meetings of Affiliated societies, for although among the staff of "The British Journal of Photography" membership of Affiliated societies is represented to a total of six, no copy of the "Circular" reached through these "personal" channels. It would seem that some more direct mode of transit is needed to ensure that members, and particularly those to be stimulated by the "Circular," obtain it. It is probable, too, that the help of members of Affiliated societies would be more effectively enlisted were it more definitely explained in the "Circular" what form that help is to take, and to what end it is to be directed. Paragraph No. 7 of "Our Aims and Objects" returns to this theme, but not very illuminatingly when it says:—"The Executive feel that there is much promise of substantial usefulness in our effort, and rely on the various societies giving us every assistance they can to carry our project to a successful issue." They add (paragraph No. 9), in a last impassioned appeal which has again the better of grammatical construction, "All we need is the personal help of every member of an Affiliated society in making the 'Circular' well known, and assist us in making our scheme one of mutual helpfulness."

Supposing that this aim has been reached, and that every member of every Affiliated society is in possession of the "Circular," what will they find?

1. They will find a review or notice of the 1909-10 "Red Book" which was issued last May. As every member of an Affiliated society received, or should have received, the "Red Book" at the time of its publication, and as every person joining an Affiliated society since then should also have received one, it is difficult to see the relevance of this "notice." It would have been more to the point

had certain errors in the weights and measures section of the "Red Book," pointed out at the time in our pages, been notified for the benefit of those who do possess it.

2. They will learn that the 1908 Affiliation prints, with Mr. W. J. Morgan's criticisms, are still proving a popular society fixture: that only four entries were received for the Affiliation lecture competition, and that the lantern-slide competition secured 529 entries, representing 37 societies.

3. They will learn the rules for the 1909 prints competition.

4. They will see a list of forthcoming society exhibitions, but they will not be able to tell at which of these exhibits other than those by members are admitted. The list is stated to be one of open exhibitions "so far ascertainable," which phrase we presume implies that the societies have been applied to for the information. Therefore we are surprised to see that in a number of instances the particulars contradict those obtained from the societies by ourselves for insertion in the "British Journal Almanac." The Leicester and Leicestershire Photographic Society and the Windsor Camera Club write us positively that they will not hold an open exhibition, whilst the following societies, on being asked to give the date of their exhibition or the month in which it is usually held, providing only that it contains open classes, refrain from filling up this line in the entry form:—Photographic Society of Ireland, Acton Photographic Society, Maidstone Institute and Camera Club, Dover Institute Photographic Society, Hampstead Photographic Society, Sidcup Camera Club, Dukinfield Photographic Society. Yet all these societies are included in the "Circular's" list as those with open exhibitions "so far ascertainable," and in one instance, that of the Doncaster Camera Club, the date of the exhibition is given as November 16 to 19, and a little power down as "not yet fixed." While it may be debated whether an increase in the number of open-class exhibitions is desirable it is at any rate essential for the usefulness of such a list that it shall draw a distinction between those confined to members only and those with open classes.

5. They will learn the bookings for the Affiliation lectures, and thus obtain useful guidance as to the choice open among the very excellent series of illustrated lantern lectures. Secretaries of societies would therefore make a note of this list on pages 6 and 7 of the "Circular."

6. They will see a view of the R.P.S. Exhibition taken from "The Amateur Photographer." Surely it is not suggested that in the "Circular" this reproduction will come before the eyes of any who have not seen it in our contemporary.

7. They will see a "notice" or "character sketch" of Mr. J. C. Mummery. Perhaps we can best describe it as an "appreciation" from the social standpoint of the popular president of the Royal Photographic Society, somewhat in the manner of the paragraphs dealt with to social lions by "Modern Society." This article is supposed to be No. 1 of a series "dealing month by month with an individual society, its method of work as regards programme, exhibition, outings, and other interesting particulars, and we open this phase of our work by a short sketch of our genial R.P.S. president, Mr. J. C. S. Mummery." (Paragraph No 5 of "Our Aims and Objects.") Somehow we feel we would rather have had Mr. Mummery's views on society politics than the unknown writer's supererogatory compliments. Mr. C. F. Inston is to be the subject for No. 2 of the "Circular." The latter will be worth getting if C. F. I. can communicate the secret of the success of the L.A.P.A.

8. They will have their attention called to the tasteful hanging of the R.P.S. Exhibition, to Mr Hall-Edwards' scheme for an exhibition of technical photography, and to the transference of open-class exhibits from one society to another.

9. They will see a report of the Affiliation night at the R.P.S. Club on the occasion of Mr. W. R. Bland's refreshing criticisms of the Affiliation prize lantern-slides, and

10. They will learn that the compilation of the "Photographers' Getteer," made possible by the Affiliation "Consular" scheme, "is making distinct progress." It is now stated that the notes (on places and districts) contained in the "Red Book" is a "very brief summary" of the information placed in the possession of the "Chief Consul," Mr. C. F. Oakden, by the 81 "Consuls." We have, on a previous occasion, expressed our view of this "Consular" scheme, participation in which is certainly a tribute to the generosity of the 81 Consuls if not to their discretion.

Those who, like ourselves, have watched with interest the valu-

able work done by the Affiliation of Photographic Societies desire to know our view of the newly issued "Circular," let us say that we appreciate as much as anyone the value which certain portions of it have for the secretary of any society, Affiliated or not. We must admit that this valuable matter is not a large proportion of the whole, and we think it might quite well appear in the monthly "Photographic Journal" of the Royal Photographic Society, where it would be assured of being brought before every secretary of Affiliated societies with almost clockwork regularity. If the "Circular" is intended, however, for individual members of societies, then we think it essential that it should be brought directly into their hands either from the headquarters of the Affiliation or through the local secretary, irrespective of the members' attendance at the meetings. Apparently the haphazard method of distribution which is relied upon will not at a favourable estimate bring the "Circular" into the hands of more than half the membership of Affiliated societies. In journalism, not to say in the advertising business, a sound motto is that a public does not appreciate what it gets for nothing. That is, we believe, a principle which is the basis of every successful publication, and we would commend to the Executive of the Affiliation the question of making a charge for their publication. They would thus reap the two-fold benefit that the issue would be upon a better financial basis, and that every copy sold would be evidence of a reader who at any rate had given practical manifestation of his interest in the "Circular" by buying it.

OF HYPERFOCAL DISTANCE.

"The reader is told how to calculate the hyperfocal distance."—
Extract from a review of "The Red Book."

I PONDER as I lie in bed
At early morn and evening late,
With wearying insistence,
On all that I have ever read,
That tells one how to calculate
The hyperfocal distance.

My mind with chemistry is fed;
Of art and optics I could prate
For hours with proud persistence;
But on one point my brain is dead.
In vain I pore and cogitate
On hyperfocal distance.

I throw it off; but back am led
To sterile thoughts, with aching pate.
The point still makes resistance.
Aloud I cry that hope is fled,
There is no way to calculate
The hyperfocal distance!

But, lo! a little book of Red!
Societies Affiliated
Do give it its existence.
Its pages through are quickly sped.
Hope doth my bosom agitate
For hyperfocal distance.

Ah! Joy! O Dr. Evershed!
Who at a certain page doth state
(Without expert assistance)
In nutshell neat the question dread.
And clearly doth illuminate
The hyperfocal distance.

ROYAL INSTITUTION.—The 84th Christmas Course of Juvenile Lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Mr. William Duddell, F.R.S., his subject being "Modern Electricity." The Course, which will be experimentally illustrated, commences on Tuesday, December 28, at three o'clock, and will be continued on December 30, 1909, January 1, 4, 6, and 8, 1910.

A DEVICE FOR EMPTYING LOW-LEVEL WASHING TANKS.

A WRITER in the "Scientific American" describes an attachment for a tap supplying water from a company's mains, whereby water lying in tanks, etc., may be drawn off. By providing a simple form of ejector at the tap and connecting one inlet of the ejector to a short piece of hose leading to the sink, the water may be very easily drawn out of the tank into the sink, even though the latter be at a higher elevation. In the accompanying sketch, there is shown a simple contrivance of this character, in which the ejector is formed of a block of wood adapted to be detachably secured to the tap. The ejector includes two passages intersecting at an angle and having a common outlet as shown in section in

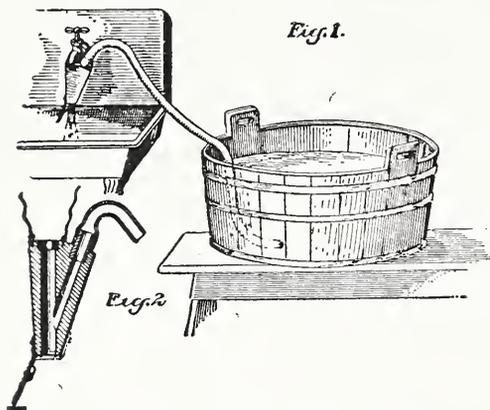

Fig. 2. One of these passages receives a stream of water under pressure from the tap, and the escape of this water from the lower end of the ejector tends to draw water out of the tank through the hose and to deliver the latter to the sink.

The same device may be used for refilling the tank. To secure this object, it is merely necessary to close the lower end of the ejector with a plug or in any other suitable manner. As shown, a short rubber plug is connected to a strap tacked to one side of the block. By inserting the plug within the open lower end of the passage and securing the free end of the strap to a button on the opposite side of the block, as shown in dotted lines, the water will be caused to flow from the tap down through one passage and up through the other to the hose and thence to the washing-tank.

Exhibitions.

FOLKESTONE CAMERA CLUB.

THE first exhibition to be held by this society was open to the public on October 27 and 28, and achieved a degree of success which is highly creditable to the society which started its career only a few months ago and has rapidly risen to a membership of over seventy. For a large part of this success credit must be given to the hon. secretary, Mr. G. C. Sheaff, and the assistant hon. secretary, Mr. Hamilton Smith. The Rev. F. C. Lambert, acting as judge, made the following awards:—

The Mayor's silver cup, for best picture in the exhibition.—G. W. Perkins.

Club's silver plaque, for second best picture in the exhibition.—Hamilton Smith.

Class A—Landscape and Seascape.—G. W. Perkins, silver plaque; Hamilton Smith, bronze plaque; G. Lewis, diploma; J. H. Lewes, diploma; F. C. Skidmore, diploma; H. F. Jackson, diploma.

Class B—Architectural.—T. Hesketh, bronze plaque; G. H. Sheaff, diploma; Hamilton Smith, diploma; G. W. Perkins, diploma; M. R. Hornsby, commended.

Class C—Portrait and Figure Studies.—G. W. Perkins, silver plaque; Hamilton Smith, bronze plaque; G. H. Sheaff, diploma; Hamilton Smith, diploma; Miss Ivy Weston, diploma; C. Clark, commended; C. R. Ogden, commended.

Class D—Still Life and Animal Studies.—C. Clark, bronze plaque; Hamilton Smith, diploma; G. W. Perkins, diploma; M. R. Hornsby, diploma; G. H. Sheaff, commended; C. Clark, commended.

Class E—Lantern Slides.—G. W. Perkins, silver plaque; F. C.

Curtis, bronze plaque; H. R. Hornsby, diploma; Hamilton Smith, diploma awarded for special printing border on slide.

Class G (Beginners' class)—Any subject.—G. H. Sheaff and J. H. Lewes, 1st prize; P. W. Knowles, 3rd prize; G. H. Sheaff, diploma; M. R. Hornsby, diploma; M. R. Hornsby, commended; L. W. Browne, commended; E. Fullagar, commended; P. W. Knowles, commended.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between October 18 to October 23:—

PRINT WASHERS.—No. 23,853. Improvements in device for washing prints and the like. Washington George Rounds, 111, Hatton Garden, London.

NEGATIVES.—No. 24,029. Improvements in process for producing photographic negatives by means of mechanically constructed figures for use as prints. Georg Friedrich Luticke, 49, Burlington Avenue, Kew, Surrey.

CINEMATOGRAPH AUDIENCES.—No. 24,070. Means for regulating the admission and retiral of cinematograph audiences. John Alexander Colquhoun, 45, Station Road, Brixton, London.

DAYLIGHT DEVELOPMENT.—No. 24,085. Improvements in daylight photographic developing tanks and the like. Rodolpho Luchsinger Caballero, 60, Queen Victoria Street, London.

CAMERA.—No. 24,337. Camera fitted with a revolving front, carrying a lens and shutter. Sidney Newman Sedgwick, St. Mary's, Bishopstoke, Hants.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPHY IN COLOURS.—No. 5,945, 1909 (March 12, 1899).

The invention refers to patents in this direction of Lee and Turner (No. 6,202, 1899), Davidson (No. 23,863, 1899), Jumeaux and Davidson (No. 3,729, 1903), Davidson (No. 27,418, 1904), Pfenninge (No. 322, 1905), Smith (No. 26,671, 1906), and Davidson (No. 453, 1908). In the present invention colour discs are used in place of ordinary colour filters or colour screens, each colour disc revolving on its centric or eccentric axis, generally side by side and partly overlapping each other; but the colour discs can also be superposed on one axis and so revolved on one axis, and, whichever way the colour discs are then revolved, they will filter the light as required by the additive method of colour photography, and so provide new means for taking and exhibiting cinematograph pictures, by a two-colour system, by an intermediary system between a two- and three-colour system, and also by a three-colour system.

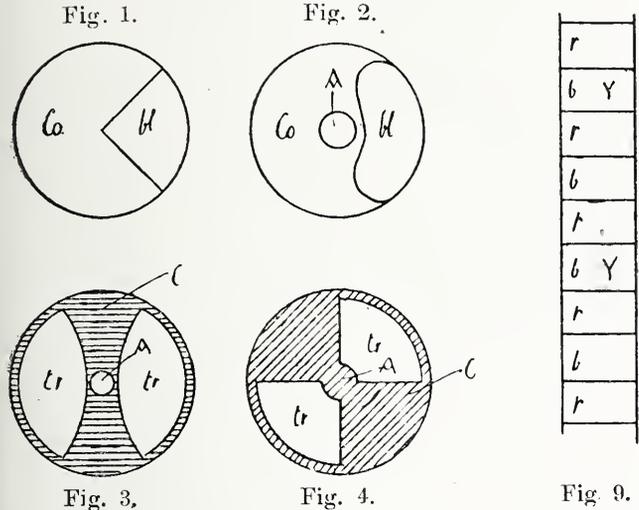

Figs. 1 and 2 represent the new colour disc, which is at the same time a colour filter. Each disc can hold one or several colour filters but in a general way a disc is formed so that it holds only one colour-filter. The disc is of any suitable material, but glass seen a good support for the colour-filter. One-third to one-fourth (*bl*), more or less, of this disc is generally blank (perfectly transparent) and in that case, when the disc holds only one colour-filter, the blank can be formed by cutting away. The colour-disc is therefore formed by a coloured part, *co* and another part *bl*, which latter is generally blank, but can also be coloured, and (if *bl* coloured) is then of a different shade to the main or principal colour on the part *co*. This colour disc may have an opening at *A*, that it can be attached to a revolving axis. The disc can be fitted into a casing best suited for certain requirements.

Two or more such colour discs, each of a different colour, are the components of the present invention for cinematography in colour by the additive method of colour photography. To a two-colour system, a system of intermediary colour-changing movement, shown in Fig. 7, can be added. The colour disc can be adapted to a colour movement, in which the colour discs are revolved on one or on several axes. If three different colour-discs are revolved

one axis or on several axes for the purpose of a scientifically correct three-colour system, then the blank spaces and the coloured spaces of each colour-disc have to be specially arranged or spaced to suit that purpose.

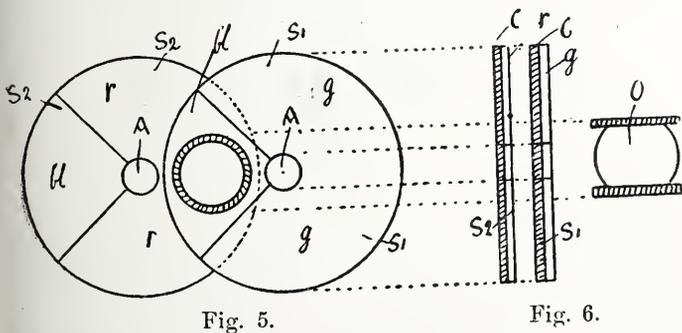

Figs. 3 and 4 show the forms of casings; other forms suggest themselves; *tr* is open or cut out, and *C* is open or solid, *A* is the place where the fixing to the revolving axis may take place.

Figs. 5 (front view) and 6 (side view) show how one can place two circular colour discs in front or at the back of a lens, *O*, disc

S 1 being of green, blue-green, or blue colour (*g*), and disc *S* 2 of red, orange-red, or orange colour (*r*).

Figs. 5 and 6 are repeated in Figs. 7 and 8, with the addition of an eccentric disc *S* 3. This disc *S* 3 is also a colour-disc. Actually it is part of a circular disc, and one can therefore also use a circularly shaped disc in its place; this disc is wholly or partly coloured, say in yellow, or any other colour desirable. The colouring of this disc may be homogeneous, or grating-like, or broken up mosaic-like, to suit the purpose, all in one colour or more than one colour. This third colour-disc does not necessarily revolve with the same rapidity as the other two discs, but can be made to revolve, with or without a casing, so that the other discs are overlapped by it at intervals and in such a manner that the succes-

sive exposures will be influenced, as shown in Fig. 9 or in any similar way.

In Fig. 5 the two colour-discs have the blank space (*bl*) towards the left side. In that case "red" of the disc *S* 2 will be shown in the light cone of the lens *O*. If now we revolve the two discs so that blank (*bl*) is at the top, as shown in Fig. 7, we shall find "red" of disc *S* 2, and "green" of the disc *S* 1, superposed together over the lens *O*. Red and green together form what the colour photographer calls a safe light; by these two colour filters the actinic light is prevented passing. These two-colour filters act, therefore, together precisely the same as an opaque shutter. The third turning movement will show the colour filtering to be that opposite to the one shown in Fig. 5, therefore "green" of the disc *S* 1 will be made to act as light filter to the light cone at *O*. And in the fourth revolving movement, when the blanks (*bl*) are opposite to that shown in Fig. 7, another safe-light, formed by red and green, will be before the focal plane of *O*. The next turning movements are simply a repetition of the above four movements of light-filters and safe-lights acting in succession. Instead of revolving the discs in the same direction, both to the left side or

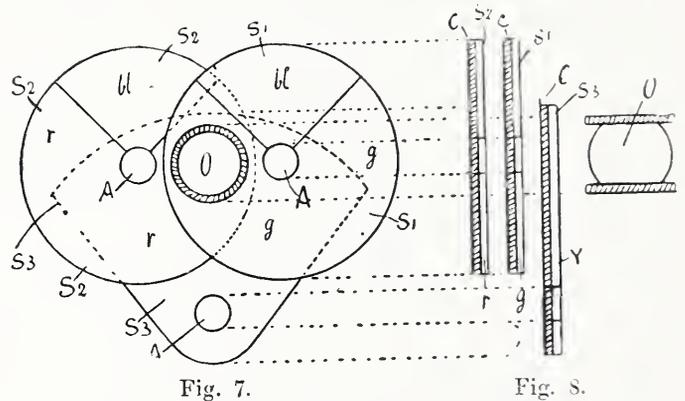

both to the right side, the discs can also be revolved towards each other, one to the left side and one to the right side—the result is exactly the same, or the two discs can be mounted together on one axis, but so that a green space is opposite a red space, and so that both coloured spaces are separated by safe-light.

Generally speaking, if now the third colour-disc *S* 3, which we can suppose to be coloured yellow, passes at intervals through the light cone formed by *O*, when red or blue, or when the colours used in disc *S* 1 and disc *S* 2 are separately over the focal plane, or behind or in front of lens *O*, then red will be coloured to the filter colour orange-red, and blue to blue-green respectively.

To effect the exposures through the discs holding the different colour filters, the mechanical movement can be so arranged that the colour-discs are revolved continually, and then the change of film in the focal plane takes place when the safe-lights are interposed into the light cone; or, the mechanical movement can be so arranged that the colour-discs are wholly or partly stationary during the exposure, but the film in the focal plane and also the colour-discs are moved on when an auxiliary shutter is interposed into the light cone.

By adding a supplementary colour-disc to other two-colour cinematograph apparatus and applying this supplementary colour-disc similar to the disc *S* 2 or *S* 3, one is obviously in a position to improve the respective method.

Two of the colour-discs (say a red and a green disc) can also be fitted, and revolved together on the same axis in such a way that

they act as one shutter, holding two colour-filters and two safe-lights, instead of two colour-filters and two opaque metal spaces. Two of the colour-discs can also be fitted together in such a way that they resemble one colour disc or resemble one colour disc bound up with one transparent cover disc.

With the apparatus in conjunction with a cinematograph camera one is able to take the negative-colour-records for cinematography in colours. Positives printed from negatives thus obtained are projected by a projecting apparatus, to which the apparatus has been fitted, the light-action operating the reverse way. It is taken for granted that the cinematograph operator places behind the colour-discs the right colour records, when we shall have cinematography in colours, and if not in absolute colours of nature, we shall, nevertheless, have a fairly true representation of the objects photographed in their original colours. Otto Pfenninger, 105, Hythe Road, Brighton.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901:—

DAYLIGHT DEVELOPMENT.—No. 24,088. Daylight photographic developing tanks and the like. Luchsinger Caballero.

New Trade Names.

RADIUM.—No. 316,015. Photographic plates and photographic films (undeveloped). Isidore Bernard Davidson. Marlborough House, Basterfield Street, Golden Lane, London, E.C. Fine art publisher. September 1, 1909.

DEVULES.—No. 316,415. Chemical substances used in photographic development. Oppenheimer, Son. and Co., Ltd., 179, Queen Victoria Street, London, E.C., manufacturing chemists. September 18, 1909.

MEGOMO.—No. 316,555. Chemical substances used in manufactures.

photography, philosophical research and anti-corrosives. Nobles and Hoare, 3, Cornwall Road; Stamford Street, London, S.E., varnish and japan manufacturers. September 24, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Silhouettes as Decorative Greeting Cards.

No special photographic procedure is necessary for making silhouette pictures (writes E. W. Jackson in the "Photographic Monthly"). They may be made, in fact, in any ordinary room, by simply photographing the objects against the light, but for best obtainable results we may go to a little more trouble and proceed as follows:—First, procure an old packing-case, such as an empty sugar-box, and knock out the top and bottom. Over one end fasten a sheet of white tissue paper, next place the box on a table near a window with the tissue-paper background towards the window so as to get a good amount of strong and even light. A window facing north is to be preferred, but if the sun does not actually shine on the tissue-paper screen this is not essential. The camera is now placed at the other end of the box, the lens, of course, pointing inside, and the apparatus is complete and ready for use. The flowers, leaves, or whatever we are photographing should usually be placed about half-way inside the box, but if a slight amount of grey tone is desired in the picture (and this is thought by some to be a relief from a large amount of featureless black) the objects may be placed close to the tissue-paper background, or a slightly longer exposure will give a similar result. An opaque cloth may be thrown over the front of the camera, extending to the box; this is to prevent any light entering the lens which does not first come through the tissue-paper screen. A few trials will soon enable one to determine what objects are suitable for this class of photography.

A Reversing Hood for Reflex Cameras.

In some notes on reflex cameras in "Photography and Focus" for November 2, a writer advocates a revolving hood on a reflex camera:—"Figure study work makes one wish that the hood were reversible. We have reversing and revolving camera backs, some of which cannot be brought into use when the plate is ready for action. It seems to me that a reversing hood would often be as great a boon, and should not be difficult or costly. The reflex then could easier be used pointing across the body; and its use, owing to the photographer not facing his model, would not be so perceptible. It could be used at 'eye-level' (also pointing sidewise). The hood could often be revolved when one had not time to close the dark slide, and turn the reversing or revolving back, and this would sometimes make for quicker work. The hood could be used also when the camera was being brought into use as a stand instrument, allowing the plate to be kept ready for instant exposure. Lastly, a revolving hood, fitted to an old-fashioned non-reversing back reflex, would make it, for most purposes, the equal of the latest."

New Materials. &c.

Gevaert Gaslight Paper. Made by Gevaert, Ltd., 26 and 27, Farringdon Street, London, E.C.

A further member of the series of papers manufactured at the Gevaert factory, and now being actively marketed in this country, reaches us in the shape of the gaslight paper known among Continental users of the Gevaert products as "Ridax." In offering a gaslight printing medium to British workers the company have evidently recognised the widespread use which is made of this medium among both amateur and professional workers. The former usually require a paper which gives an enhanced degree of contrast, inasmuch as many negatives are too lacking in contrast to give a really good print on bromide. For such negatives the "Normal" grade of the paper is the one which we would recommend, since it affords a degree of vigour and contrast which certainly in our experience of it makes the very best of a negative which is itself lacking in these qualities. For those, however, who adopt a gaslight paper not primarily from

this motive, but for its ease in manipulation, the "Special" grade is preferable on account of the softer results obtained with it and is the variety which those making a thoroughly good negative will probably elect to use, particularly for portrait and group subjects. Both papers are issued in a variety of surfaces and thicknesses, of which the standard may be taken as the "Thin Matt Smooth" (designated as A), the "Cream Tinted Rough and Smooth" (F and H), and the "Semi-glossy" or "Carbon Surface" (K). The four other varieties, namely, the "Thin Matt Rough" (B), the "Thin Glossy Mauve" (C), the thick or card papers—matt, glossy, and semi-glossy—(D), the "Special Rough White" (E), and the "Cream Special Rough" (G), are the remaining variants of the paper, the qualities of which may be frequently utilised to advantage although, for the generality of work, we believe that the A, F, H, and K should prove amply sufficient. In all instances the paper develops very quickly to a fine black colour in the customary metol-hydroquinone developer, which is that which we used for our trial of the papers submitted to us.

There is one further characteristic of the Gevaert emulsions which will specially appeal to both amateur and professional workers, namely, the production of warm-black to brown tones by means of a diluted developer of the ordinary formula, or preferably a glycin formula made up with the well-known paste prepared according to the method of von Hübl. This preparation, which is very readily made up, keeps for an indefinite time, and is diluted in the proportion of $\frac{1}{2}$ oz. to 15 ozs. of water to make the working developer. For success in obtaining these warm tones by direct development a negative of good contrast is a *sine qua non*, and the warmth of tone may then be adjusted within wide limits by giving a longer time of exposure and a greater or less dilution of the developer. In the case of the above glycin formula it is stated that with the standard dilution mentioned above the exposure only may be varied and a series of warm tones obtained with one and the same solution. In our experience, however, we found it advisable to increase the dilution with the exposure and to add further bromide. In this respect, as well as for its normal qualities of fine colour of image and excellent gradation, the Gevaert paper will repay a trial by those who adopt the gaslight method of printing, or whose business it is to place a paper of reliable quality in the hands of amateur workers. The paper is supplied in packets of cut sizes, in rolls of 12, 25, and 40 inches width, and in gross boxes, all at the standard prices.

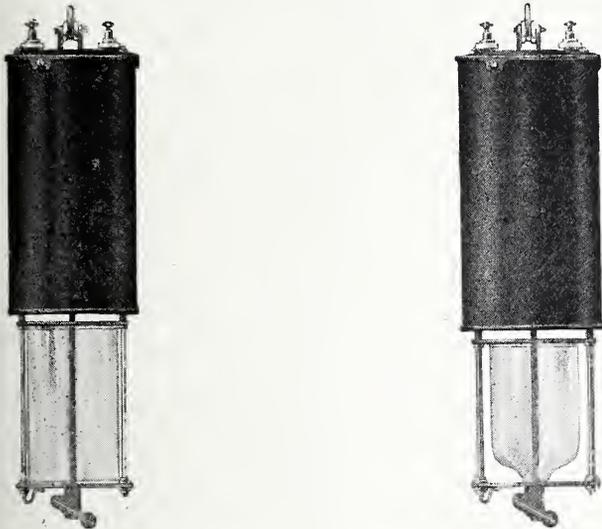

New Apparatus, &c.

The Ensign Arc-Lamp. Sold by Houghtons Limited, 88-89, High Holborn, London, W.C.

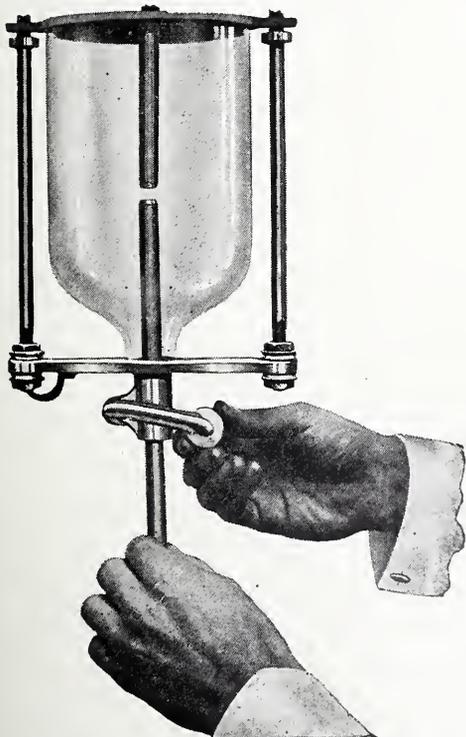

In the most readable presentation of the use of artificial light in the studio, which Messrs. Houghton have just issued under the title "Light in the Studio," they insist on the absolute commercial necessity of the means of taking photographic portraits at any time of day or night and regardless of the weather. That topic, as our readers know, is one which we have many times emphasised in the past, and one, too, which we on one occasion have illustrated by an exhibitio at these offices showing the remarkably excellent portraiture turned out by artificial light. Of late, portraiture by artificial light, and particularly by arc-light, has become so much more general that there is no need to say "remarkably." For all ordinary purposes of professional photography arc-light has proved a perfect substitute for daylight, and at the same time one which is now not an expensive luxury, but within the means of even the small photographer, who by its aid, is enabled to meet a form of competition which is largely based on the ability to take a portrait at any time. Messrs. Houghtons point out the commercial advantage of the arc with almost poignant insistence, but there is not a passage in their argument with which we are not in absolute agreement, for which reason we recommend every professional photographer who is not now a user of arc-light to apply for a copy and consider for himself if his own business may not count upon immense improvement by aid of the modern method of studio lighting. The booklet, to be sure, is issued in reference to a new arc-lamp which Messrs. Houghtons are just issuing, but is none the worse for that, since the arc is a very good

ne and deserves the confidence which the vendors justly claim should be reposed in it as a bringer and improver of business.

The "Ensign" arc-lamp, we must explain, is of the enclosed or violet type, producing a light very rich in ultra-violet rays, and therefore possessing a photographic intensity which is very much greater than would be judged from the brightness to the eyes. Intensity of action on the photographic plate is, of course, the chief essential in a lamp for studio portraiture and printing of negatives, since upon it hinges the question of short exposures. But it is not

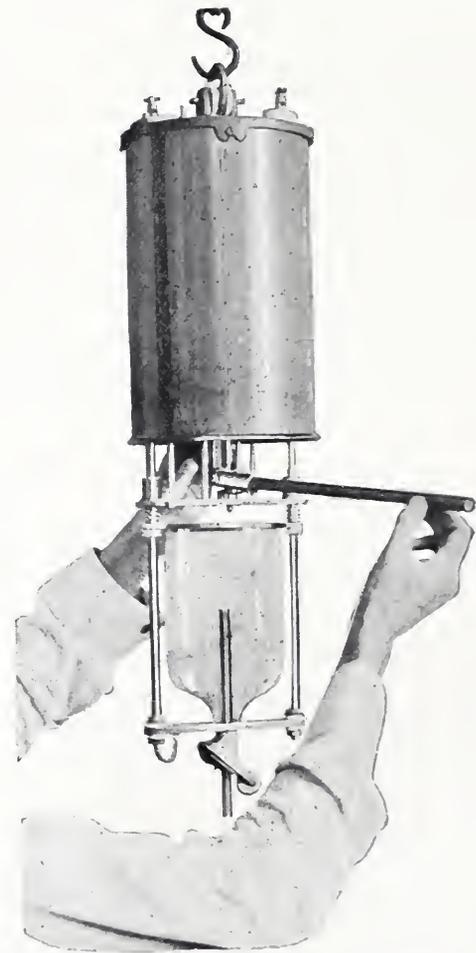

the only factor in the making of an efficient arc-lamp. A second and almost equal qualification is handiness, rapidity of handling, and convenience in use, since upon these depend the speed with which the photographer may bring the light into the most perfect working condition. In this respect, too, the Ensign lamp represents the height of efficiency. As the two first illustrations show, it is made in two patterns—A, with a metal base, and B, with a clear glass chimney-shaped base for the arc chamber. In each pattern the device

changing the carbons and adjusting for combustion of the latter one which is most rapidly employed. The two second drawings show the manipulation which is necessary. When altering the position of the lower carbon or removing this latter altogether, the lever is only to be depressed, when the carbon is at once released. In the case of the upper carbon, the latter is inserted into its holder, as shown in the fourth drawing, and then at once placed in position above the glass chamber. The necessary compensation for combus-

tion is made with the lower carbon, and is done without waiting for the lamp to cool, so that time is not wasted in bringing the lamp just right for working. In thus adopting this very simple hand adjustment the makers have secured freedom from complication of parts, whilst they have sacrificed nothing in the way of ready and rapid working. The lamp is made in three sizes, taking 10, 12, and 14 amperes respectively, each size being made in both A and B patterns, and also for continuous or alternating current. The prices are from £4 15s. to £7 10s. complete, including a variable resistance by which the power of the light may be still further intensified quite conveniently immediately before the exposure.

We should be only misleading any reader who is unacquainted with arc-light portraiture if we were to let him suppose that he has but to hang an arc of this kind in his studio, and, hey presto! he is prepared to make satisfactory portraits. Without what Mr. Samuel Weller would doubtless have described as the "usual trimmings," the arc-lamp is a bad light for portraiture. The light needs diffusion by breaking up or de-concentrating by both reflection and passing through a diffusing screen, that is to say, the outfit of the user should include both an umbrella reflector and diffusing screen suitably attached to the lamp. These very necessary accessories are sup-

plied by Messrs. Houghtons specially for use with the "Ensign" arc. We may, therefore, put down as a model outfit the following apparatus:—

	£	s.	d.
1 lamp, say medium size, continuous current.....	5	5	0
1 tripod support for lamp	2	7	6
1 umbrella reflector	3	10	0
1 diffusing screen to fit on arc-lamp	0	7	6
1 metal shield to cut off all direct light from arc...	0	5	0

£11 15 0

Thus for the sum of £11 15s. the worker obtains an equipment which suffices for a very large proportion of the regular work of a portrait studio. If he does not himself fit up the reflector, he may purchase a stand for the latter, complete with cords, pulleys, and castors, allowing of it being readily moved about the studio, for an additional £2 5s., whilst when using the lamp for printing purposes

a framework rotating on ball bearings and accommodating eighteen whole-plate and 36 half-plate printing frames will cost him £3.3s., say less than £20 in all. The last-named appliance is a particularly labour-saving piece of apparatus, since it gives to the printer the same speed and certainty in his work as it does to the operator in his, and, where a business feels it necessary to restrict its purchase to one lamp only, serves equally well for both purposes. But we have said enough, we hope, to justify our recommendation of application to Messrs. Houghton for their booklet "Light in the Studio."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 5.

Clapham Carlton Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Sutton Photographic Club. "Architectural Photography." A. P. Hoole.
Glasgow Eastern Photographic Association. "Ensyna." F. J. Stedman.
Cowla's Co-operative Society. "Autotype Carbon." Demonstration.

SATURDAY, NOVEMBER 6.

St. Peter's School of Natural History, York. Photographic Society. "Sports and Pastimes with the Goerz-Anschutz Folding Camera."

MONDAY, NOVEMBER 8.

Walsall Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Equitable Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
City of London and Cripplegate Photographic Society. "Flashlight Photography." F. C. Hart.
Marylebone Camera Club. "A Trip through South Devon." E. Markwell.
Leek Photographic Society. "Photographic Facts and Fallacies." T. W. Hawksworth.
South London Photographic Society. Jumble Sale.
Derby Photographic Society. "The Carbon Process." T. A. Scotton.
Southampton Camera Club. The Affiliated Societies' Prize Slides.
Dewsbury Photographic Society. "Autotype Carbon." Demonstration.
Kidderminster and District Photographic Society. "Autotype Carbon." Demonstration.
Larkhall Camera Club. "Autotype Carbon." Demonstration.

TUESDAY, NOVEMBER 9.

Royal Photographic Society. The Presidential Address. "The Influence of Painting upon Photography."
Halifax Camera Club. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Glasgow Southern Photographic Association. "Ensyna." F. J. Stedman.
Widnes Photographic Society. "What Can be Done with a Hand Camera." C. P. Goerz, Ltd.
Glossop Dale Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Worthing Camera Club. "Round about Glasgow and Edinburgh." J. G. Potter.
Manchester Amateur Photographic Society. Members' Slides.
Leeds Photographic Society. "Collections and Recollections of the Land o' Cakes and Plump Spates." Thos. E. Green.
Govan Camera Club. "Autotype Carbon." Demonstration.
Wath and District Photographic Society. "Autotype Carbon." Demonstration.
Keighley and District Photographic Society. "Autotype Carbon." Demonstration.

WEDNESDAY, NOVEMBER 10.

Manchester Amateur Photographic Society. "The Romance of Architecture." James Shaw.
Crompton Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Rochdale Amateur Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Balham Photographic Society. "Ensyna." F. Marshall.
Edinburgh Photographic Society. Lantern Section, Members' Slides. "British Architecture—Early English Gothic." R. Berry.
Croydon Camera Club. "Telephoto Work." Ernest Marriage.
Borough Polytechnic Photographic Society. "Bromide Enlarging." P. Carden.
North Middlesex Photographic Society. "Some Old Towns in Normandy and Brittany." Chas. H. E. West.
Sale Photographic Society. Print Criticisms.
Stoke Photographic Society. "Autotype Carbon." Demonstration.

THURSDAY, NOVEMBER 11.

L.C.C. School, Bolt Court, E.C. "Art in Relation to Commerce." Will Rothenstein.
Longton and District Photographic Society. "Autochromes and Lantern Display." W. Partridge.
Dover Photographic Society. "Dutch Slides." A. E. Staley & Co.

Queen's Park (Glasgow) Photographic Society. "Ensyna." F. J. Stedman.
Brighouse Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Bolton Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Weybridge and District Photographic Society. "Autotype Carbon." Demonstration.

Commercial & Legal Intelligence.

AMENITIES OF A BRIGHTON STUDIO.—Djornette Plummer, of Brighton, was summoned at Brighton Police Court last week for using threats towards Benns Piltin, 5, Brighton Place, a photographer, on October 22.

The Magistrates on the Bench were the Mayor (Alderman Slingsby Roberts) in the chair, Alderman Colbourne, Mr. Horton-Stephens, Councillor Mellor, and Alderman Sendall.

Mr. E. M. Marx appeared for the complainant.

Complainant, a native of Finland, stated that on October 13 he settled terms with defendant as to a dispute about his situation, and it was agreed that witness should work for him for six months at 30s. a week. The first day after the settlement defendant used abusive language to witness and threatened him. On Saturday week defendant said to him, "If you wish to be healthy go away or I will make you ill." He also said, "I shall press you so long until you fall ill, and then you will have to leave." On Friday defendant sent witness to King's Road for a camera, and when witness asked him what camera it was he wanted, he abused witness and ran after him. He was in such a hot temper that witness believed he would have knocked him down if he had not gone away. Later in the day defendant called him opprobrious names in German, and taking up his walking-stick and putting it against his face, said, "If you say one word I'll smash your head in pieces." It was the stick produced, and witness believed it was loaded, adding, "If he struck me on the forehead with that I am sure I should not have come up any more." Defendant was hot-tempered, and witness was afraid of him.

Defendant, who is a man of colour, was cross-examining with the view of showing that complainant did not come to work at the time appointed on the 13th, and that he had to remonstrate with him, when the Mayor intervened to point out to him that all he need deal with were the threats alleged to have been used by him on October 22.

Replying to defendant, complainant denied that when sent for the camera he stood arguing about it and refused to do as he was told instead of fetching it as soon as possible because defendant had a train to catch. Complainant admitted that he was told to stay at the back of the premises and not go into the shop; and asked about occasions when he was in the shop, complainant said he did not go to the back "lest defendant should kill him."

Charles Cyril Mather, who attended on subpoena, said that on the Friday he was working for defendant as manager and saw defendant raise his stick, put it up to complainant's face, and threaten to smash his face, saying, "If you value your face and your place be quiet or I will smash your face."

Cross-examined, he said he had had orders given to complainant to stop in the back, but he did not always stay there. Defendant was seldom at the shop, but they never knew when he was coming.

Answering other questions by defendant, witness said in opinion complainant had something to fear.

Defendant: Why had he something to fear?

Witness: You gave me instructions when he started that I was to "give him hell and work him to death."

What did you say to that?—I laughed.

Answering Mr. Marx, witness said the place at the back was an old workshop, and not fit for anyone to stay in.

In defence, defendant went into the witness-box and said he had several photographic businesses, and on this day sent complainant from the West Street shop to the King's Road shop for a camera. He had first to complain that he was in the shop instead of at the back. Instead of going for the camera at once, complainant argued about it for some time. After he had brought it he "told me back again." Witness was catching a train, and had his coat and stick in his hand, but he denied raising his stick or threatening him in any way.

Cross-examined, he said all he told Mather was that complainant was to do what work he wanted. He denied using the words Mather had alleged, or that he told complainant he had better go away if he wanted to be healthy. As to the place in which defendant was told to work being unsuitable, the premises had only been tenanted temporarily.

After giving evidence, defendant also addressed the Bench, and

at complainant's object in these and other proceedings had been dictate to witness, so that he could do as he pleased instead of obeying witness's orders.

Defendant was bound over in the sum of £10 to keep the peace for six months, and ordered to pay £2 14s. costs (including an advocate's fee) or fourteen days.

AN INVENTOR'S AFFAIRS.—Loss by experiments in connection with patent rotary washing photographic machine was one of the causes ascribed for the failure of George Simper, trading as Mudge and Simper at 10, West Street, Southampton, tin-plate worker. The gross liabilities were put at £601, and the assets at £170. At the first meeting of creditors on October 27, the matter was left in the hands of the Official Receiver.

News and Notes.

MR. SNOWDEN WARD'S LECTURES.—The full prospectus of these lectures on the "Marvels of Photography," "The Humour and Pathos of Dickens," "Shakespeare at Home," and "The Canterbury Pilgrimages," is now obtainable from Mr. Ward, at Hadlow, Kent. Correspondents in America, where Mr. Ward will lecture during the first few months of next year, should address inquiries to 122, East Twenty-fifth Street, New York, U.S.A. The themes of the lectures, it will be seen, are intimately linked with some of the most absorbing phases of English history and English literature, and in each instance the lecturer and his wife stand unrivalled regards the photographic illustrations which they have acquired. Mr. Ward has also prepared an evening of science entertainment (with photography as its subject), into which he introduces a large proportion of demonstration. Mr. Ward speaks from a wide first-hand knowledge of his subjects, and his lectures, both literary and semi-technical, represent the happiest union of personal research and licentious expression.

A STUDIO WARDROBE.—"What do you use that lace curtain for?" asked a visitor in a photograph gallery.

"That isn't a curtain," said the photographer, as he folded up the coarse length of cheap lace; "that's classic drapery for my lady clients who pose as beauties. Look at this, and this."

He pointed to several pictures in the show case where girls who are gotten up to look like actresses or professional beauties had their photographs on exhibition.

"These girls haven't enough money to buy a piece of lace even as cheap as that. They are all employed at the very humblest and poorest paid work, but you would never guess it to look at their pictures. After Miss H—, my assistant, has draped them in that lace, they look as if they had just stepped out of a ballroom or a picture frame. Here is one coming now. Look at her."

She was a bright-faced, olive-skinned foreigner, dressed in a light brown alpaca dress that was hideously unbecoming. Her black hair was strained away from her face in hard braids. She disappeared with Miss H— into a retiring-room, soon to emerge another person. The tight coat-sleeves of her dress were pushed up to her elbow, and her high corsage so folded in to show a round slim throat.

The lace was belted at the waist-line and puffed at the shoulder. The hard braids were let out and left a fluffy effect of crimped hair, transferring an ordinary girl into a very pretty one. The operator then took her in hand to pose for her picture.

"She will send that picture home to her friends in Norway or Sweden, and they will all see how improved she is," said the photographer, with a pardonable glow of pride, "and it doesn't cost them a cent extra for all that fixing up. I have an old fur-lined circular lampshade in my wife's that I use as a background for a winter picture."

"It looks as if the girl had just unfastened it and comes out splendidly, and it gives them an air of comfort and elegance combined. It's a great scheme and sells lots of pictures; but don't give it away to the girls might not like it."—*Detroit Free Press.*

MR. W. R. BLAND.—We read in a Derby newspaper that Mr. W. R. Bland is retiring from the management of the Derby branch of the Union of London and Smith's Bank, after a service of forty-three years. Photographers in all parts of the country who have enjoyed Mr. Bland's pictorial work, no less than his frank criticisms of photographers, men and matters (not to mention photographic pressmen), will wish him many years of leisure and more opportunities for engagement in his favourite pursuit.

Correspondence.

*• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE PHOTOGRAPHIC SECTION OF THE L.C.C. TRADE SCHOOL.

To the Editors.

Gentlemen,—It has come to my ears that a rumour is current in photographic circles that the L.C.C. have placed me—as instructor of the photographic section of the Trade School, Queen's Square—on the retired list. May I use your valuable columns to contradict the rumour and to make known that I have myself placed my resignation in the hands of the Council, as I do not consider that under present existing conditions at the Trade School it is possible either to turn out efficient workers or practical assistants for the trade.—I am, dear sirs, faithfully yours,

BRENDA JOHNSON.

10, Chepstow Place, Bayswater, W.

FIXING BATH FOR BROMIDES.

To the Editors.

Gentlemen,—We note correspondence and Mr. Smith's letter, and suggest that by far the best way for fixing bromide prints is to use an acid fixing bath, and to take particular notice of the amount of area fixed in same. Thus, for postcard work and similar sized prints a certain quantity of acid fixing bath should be used for a given number of cards, and when these have been fixed the solution should be thrown away.

We have adopted this principle in our postcard departments, both hand and automatic, and also for our enlargement and prints department for a large number of years, and have been very well satisfied in every way with the results thereby obtained. The workpeople in charge of the fixing of the prints have to make a note when they have finished every batch as to what has been fixed, and these are calculated out every day, and when the baths have fixed the determined quantity they are replaced with fresh baths after a day's work ready for the next day.—Yours faithfully,

October 29, 1909.

THE HALIFAX PHOTOGRAPHIC COMPANY.

PHOTOGRAPHING THE CURVATURE OF THE EARTH.

To the Editors.

Gentlemen,—Referring to the question of mirage in connection with the "flat earth" photographs, I may say that the suggestion in the opening paragraph of your latest issue has been repeatedly made, but not, as far as I am aware, by anyone who has visited this particular spot. I have in all visited Salters Lode three times, and when there was no general haziness could always see the sheet or bridge through a telescope from Welney. It was also easy to see underneath Welney Bridge from Salters Lode. On one occasion a large surveying level was carefully adjusted on the camera platform, and the lower portion of the sheet was clearly seen against the intersection of the cross wires of the telescope. I should like to add that I feel no special interest in the subject, but only undertook the work in the ordinary way of business on behalf of my employers, Messrs. J. H. Dallmeyer, Limited, to whom Lady Blount had been directed as being experts in telephotographic matters.—Yours faithfully,

EDGAR CLIFTON.

[There need not be any general haziness to render the phenomenon of refraction visible. It is not an exceptional effect, but a universal one that has always to be taken into account when making observations over great distances. In the case of the canal, the effect is no doubt greater than the normal amount, owing to the fact of the observation being made so near the surface of the water. When using a surveying level the distances taken at each observation are usually very short, only a few hundred yards or so, and then refraction can be ignored, but occasionally circumstances make it impossible to set up the instruments repeatedly, and long-distance observations have to be utilised, in which case a correction for refraction is always made. No competent surveyor would dream of taking a six-mile observation without applying the correction, for only in the case of zenith observations can it be dispensed with. The proximity of the water, of course, renders it very difficult, if not impossible, to apply the proper corrections in levelling along the

course of this canal, but it might be utilised as a level datum for a series of observations made at some distance from it, and then its convexity could be demonstrated and measured.—Eds. B.J.]

TONING LANTERN SLIDES.

To the Editors.

Gentlemen,—In your issue of Friday last a correspondent mentions that he has obtained good results with blue toning following chromium intensification. As chromium in my hands has always given a pure black tone I fail to see the object of this; with mercury the tone is sepia, which with the blue sky is very effective.

The following way of getting green tones has not, I think, been published; in fact, I believe it to be original:—

A black-toned slide on the thin side is bleached in bromide and ferricyanide bleacher as usual, and darkened in ammon. sulphide (also called hydrosulphide) and very well washed. It is then put into blue toner and carefully watched, when in two or three minutes it will become green, the yellow of the sulphide image and the blue together forming green. Almost endless shades can be obtained, according to length in blue toner. I find it well to varnish slide with sandrach varnish, as it makes the colours brighter and more transparent.

BLUE TONER.

Iron ammon. citrate	1 grm.
Potass. ferricyanide	2 grms.
Nitric acid	3 m.
Water	2 ozs.

SANDRACH VARNISH

Gum sandrach	1 oz.
Chloroform	8 ozs.

Apply cold.

—Yours faithfully,

10. Annesley Park, Rathmines, Dublin.

October 26, 1909.

R. L. BOYD.

MR. SHAW AND THE LINKS.

To the Editors.

Gentlemen,—Your readers must choose between Mr. Evans's and my own estimate of Mr. Shaw's notions upon carriage painting as applied to oil pictures. Mr. Evans admits himself one of those who "patiently think through the surface persiflage." A fine thing he's arrived at when he is through! His lengthy exposition is quite unnecessary. We all know what Mr. Shaw meant. We are only divided as to whether he spoke from conviction. If he *did* (which I refuse to believe) then he and Mr. Evans are destitute of the merest glimmerings of what artists aim at. The carriage surface is a thing they do *not* desire. Who does—except Mr. Shaw and his prophet? Artists are concerned with matters that apprenticeships of seven, or seven hundred, years could never teach. The biggest fool of them all could get a smooth and shiny surface if he wanted it. But he could not paint a picture by such means, which are those of many coats, each one rubbed down with emery before the next goes on. Imagine, gentlemen, a picture painted by such methods! Does not the "persiflage" by which Mr. Shaw wins his plaudits begin to look rather sorry stuff? The varnish of a carriage door is the antithesis of the peculiar qualities of artists' paint. The varying manner in which the paint is laid on holds the painter's greatest resources. He calls it "handling." Moreover, modern painting is not early painting. Its ideals are quite different. Modern painting is absolutely incompatible with a house-painter's ideals. A picture is not a carriage-door. We do not splash our pictures with mud every day, nor expose them to hail, rain, and storm. If we did, an easily cleanable surface might be worth consideration. As to permanence of colours and grounds, a respectable artist's colourman can in these days look after that much more effectively than the painter himself can.

THE WRITER OF THE ARTICLE.

"STRAIGHT" PRINTS VERSUS THOSE OBTAINED OTHERWISE.

To the Editors.

Gentlemen,—Will you allow me to say, on the point raised by Mr. P. Frederick Visick, that all photographers know it is only once in 100 exposures that photography will, by a straight print from a straight negative, give an absolutely true rendering of the scene before the camera, and that even the image on the ground glass

is often robbed of much of its beauty by having passed through the lens? If a photographer *sees* a picture, and, after photographing it, judiciously retouches his negative or print, until he has produced exactly the effect he *saw*, he may not only produce a photograph, but one which gives the life and beauty of the scene better and truer than any black and white artist can ever hope to do.

If to gain this end he has to shade portions of his bromide print, or keep back some part of his bromoil, he is, in my humble opinion, faking in each case, and as both bromide and bromoil are photographic mediums he is quite justified if his finished photograph is an absolutely true rendering of what he *saw* with his *eyes*, and not what his camera saw.—Yours faithfully,

JOSEPH L. STEPHENS.

97, Freemason's Road, Custom House, E.

REVERSAL METHOD.—Each week brings me the good old "B.J.," the oldest, freshest, and best of them all, and each week it gives me something to think on, something to profit by. Many of the formulæ and methods, curious or useful, have enabled me to experiment to the betterment of my knowledge and appreciation of the beauties, mysteries, and wonders of photography. One process that I tried out recently has not worked out according to plan and specifications, and I write to ask for further and more definite information, if it be not expecting too much from your indulgence. Not long ago you printed an article from a German source, from "Mittelungen," I think it was. It was the description of a method of copying books and manuscripts, by the aid of a mirror directly on bromide paper. The author is made to say that the negative image is desired as a positive, he stops development with a 3 per cent. acetic-acid solution, washes, and with a copper chloride solution removes all the reduced silver, leaving a bromide of silver image, which on being exposed is replaced in the developer and gives a positive image. My trials with a copper chloride solution and a second development invariably resulted in bringing back the image that should have been dissolved out; other words, there was no reversal, as is the case with Mr. Carnegie's bichromate process. Where is the trouble? What the "copper chloride solution," mentioned in the article, composed of? Thanking you in advance for your assistance.—L. R. FRANK, Chicago, Ill., U.S.A.

Copper chloride will not dissolve silver, only convert it to chloride of silver which is afterwards redeveloped with the rest of the film. There appears to be an omission in the article here. After the use of the copper chloride the image could easily be removed by a bath of ammonia, which would dissolve the chloride of silver without touching the bromide; or, as an alternative, 10 per cent. solution of sodium sulphite can be used. This will remove the chloride quickly without appreciably affecting the bromide, but it should not be allowed to act too long. If ammonia is used you must wash well before re-applying the developer. Our experience is that the Carnegie reversal method is the best.

F. AND C. (Detona, Ontario).—There are so many sources of supply that we can best refer you to the advertisement pages of the "British Journal Almanac," from the classified index to which you can judge at once. The 1910 Almanac will be published December 1, close to which date you should be able to obtain in Canada, say, from Messrs. The W. H. Hogg Co., Montreal, J. G. Ramsey and Co., Toronto.

SEPIA TONING.—1. Kindly let me know where I can get a good formula for toning gaslight postcards sepia. 2. Also formula

used in preparing plate glass for making glossy postcards.—
BYRON HARMON (Banff, Canada).

1. There is no better formula than the following, which works with most gaslight papers:

- A Ammonium bromide 100 grs.
- Potass. ferricyanide 300 grs.
- Water 20 ozs.

Keeps moderately well if kept in the dark. Use over and over again until it begins to bleach slowly, i.e., takes longer than two or three minutes.

- B Sodium sulphide, pure 300 grs.
- Water 20 ozs.

Should be mixed fresh for each batch of prints, and any left thrown away. Wash for a minute or two between A and B, for about twenty minutes after B. 2. A suitable preparation for glazing gelatine prints is:

- Beeswax 20 grs.
- Turpentine 1 oz.

- or,
- Spermaceti wax 20 grs.
 - Benzole 1 oz.

A few drops are rubbed over the glass plate with a piece of flannel, and the glass then polished with silk rag or chamois leather.

GREEN TONING.—I have a quantity of green toning to do, and desire to use the vanadium formulæ given in the "Almanac." I have mixed all the chemicals as directed, and obtained clear solution, but I cannot dissolve the vanadium chloride. This I mixed, 20grs. in 20min. hydrochloric acid, made hot with 2ozs. hot water, but it would not dissolve. I then tried it in 1oz. hot hydrochloric acid, but still it would not dissolve. I tried several ways, even boiling it, but no result. I may mention my experiments were with the vanadium by itself, not mixed with the other chemicals. I should feel it a favour if you could help me. Do you think I have not got vanadium supplied me, or what proportions of acid, water, and salt must I use, and how long does it take to dissolve? As I require several gallons of this toner, would you kindly advise me if I can keep stock solutions and what parts to keep separate? I note on page 795, "Almanac" 1907, C. W. Somerville advises vanadium to be kept in solid form and dissolved in 20min. acid, but this I have failed to do.—W. JONES.

It is difficult to reply satisfactorily in a few words. Cold or dilute hydrochloric acid is not much good. You ought to try first evaporating the mixture you have already got to a pasty mass on a water bath. Then, after cooling, add about half its weight, of pure, strong hydrochloric acid, and evaporate again to a pasty mass. To get at the weight of vanadium chloride for calculation you ought now to dry as far as possible in a desiccator over sulphuric acid in a vacuum (about twenty-four hours). Then add one-third the weight to hydrochloric acid (strong), warm gently, and the addition of an equal bulk of distilled water, should make a convenient stock solution all clear blue. To make a green toner on a subsequent occasion, you must repeat all your manipulations exactly as you did before, or you will be very likely to fail, as the exact relative proportions of iron to vanadium and other constituents are very necessary to make a satisfactory green toner. In fact, it is "a deed of some art." If you are not a fairly expert chemical worker, we are sure it is one of those cases where it would be cheaper in the long run to buy one of the green toners on the market.

DOOMY.—In the circumstances you had better write Messrs. R. J. Moss and Sons, 98, Snow Hill, Birmingham, for particulars of an acetylene outfit for studio use.

DEPTH OF DEFINITION.—Kindly inform me how to calculate the depth of definition of a photographic lens, a disc of confusion of 0.1mm. being assumed.—Toxo.

We assume from your question that you want a general rule for finding the permissible movement of the focussing screen back or front of its position for critical focus. This is very simple. Multiply the diameter of the circle of confusion by the ratio of the stop number in use, and the result is the depth of definition when focussing on infinity—that is, the distance by which the camera can be racked in or racked out without losing focus. Thus with $f/8$ and a circle of confusion of 0.1mm. you can rack in or out to the extent of .8mm., which means that the total depth of definition available is 1.6mm. If you wait to allow

for the case of focussing on near objects find the depth of definition for infinitely distant objects in the way just described, and then multiply the result by the total distance from plate to lens node and divide by the focal length. If you have a focussing scale you can do this very simply. In this case measure the extra extension (or extra focal distance) of the camera beyond the infinity mark, divide this by the focal length, and multiply the depth of definition by the result plus 1. To give an example: Suppose we have a 5in. lens working at $f/8$, and that when we have focussed sharply on a near object the camera is extended half an inch beyond the infinity mark. The depth of definition when focussing on infinity is by the rule given, .8mm. Dividing the $\frac{1}{2}$ in. extra extension of the camera by 5in., we get 1-10; therefore, .8mm. multiplied by 1 1-10, which is equal to .88mm., is the depth required. We can therefore rack the camera either in or out for a distance of .88mm. without losing focus. It should be noticed that the fraction 1-10 is also the scale of reduction of the image, in the ratio of image to object, and if we express this by the symbol r , then the depth is always equal to the depth of definition for an infinite distance multiplied by $1+r$. If depth of field is wanted instead of depth of definition page 934 of the "Almanac" gives full particulars.

PRINTS DAMAGED BY INSECTS.—I enclose a photograph printed on — matt P.O.P. toned with gold in phosphate bath. This was taken and finished and delivered to customer in November last year. It has now been returned to me by customer, with two other copies, all of which are gone spotty in the same way as this one. If you look closely into the spots I think you will see that the entire film or image in emulsion has been removed, and, unlike spots caused by chemical deterioration, appear sunk into the print. My own impression is that some insect or other has been feasting on the gelatine, and that this alone is the cause. I have traced photographs put through in the same batch and same lot of paper, and they are perfectly clear. I have done hundreds of prints on this particular paper and never had one fade in any way. All work being done under my personal supervision, I know that washing and fixing were properly done. My customer insists that it is the chemicals. I say it is some mechanical removal of film from paper by what I do not know; but under a strong magnifying glass it is distinctly visible, as minute little "pits" into the print. Then another argument in favour of insects is that all the spots run from outside into the middle, and the middle is least touched. I feel sure it is not the manipulation, but the work of some wretched mite. If you can express an opinion or confirm mine I shall be very grateful.—T. H.

We have not the slightest doubt that these marks are caused by insects nibbling at the film, for in many of the spots the marks of their mandibles can be seen. The film has been dug out with some sharp instrument, and the holes look like chalk that has been chipped repeatedly with a needle point. It is not unlike the work of wasps in some points, but the effect seems too minute for their formidable jaws. Possibly "blackbeetles" are responsible. We should advise you to send the print to Mr. Martin Duncan, who may be able to identify the work of some particular insect, and will, in any case, be interested in the effect. Address, The Martin-Duncan Laboratory, 34, Bradley Gardens, Ealing, W.

LIGHTING.—"The Lighting in Photographic Studios," by P. C. Duchochois, 1s. If you can get it, No. 2 of "The Photo-Miniature: The Pose in Portraiture," is an excellent little book, but out of print. 6d.

ANXIOUS.—We do not know anything of the firm now. It used to be at Regent House, Regent Street, W., but so far as we know is not now in business in London. Better address one of our American contemporaries such as "Wilson's Magazine," 289, Fourth Avenue, New York, U.S.A.

OZOBROME.—Could you give me the number and dates of Ozobrome specifications, and in what issue of the Journal will I find them? —T. DAVIES.

There is only one. No. 17,007, 1905. B.J., June 29, 1906, p. 513. See also B.J. Almanac, 1907, p. 802.

"TRUE-TO-SCALE" PROCESS.—I should be glad if you could enlighten me on the gelatine printing process called "Velography," Ordoverax, or "Westgraph True-to-Scale Process," and many

other similar names, whereby a mass of gelatine compound is melted until in a liquid state, and then run on a sheet of zinc till a thin film is procured, and, when this has set, a ferro-prussiate print is made from an engineer's tracing, and, without washing, is pressed into contact with the gelatine mass. The parts of the print protected by the lines of the drawing are, of course, left yellow, and these parts "etch" the gelatine so that it will take up printer's ink; a piece of tracing linen is then laid on the mass and pressed lightly into contact, the result being a tracing equal in every respect to the original. I have purchased such an outfit, but lately the results have not been as good as previous. Would you kindly enlighten me if possible? 1. The second melting of the gelatine when run on the zinc was not so successful. The gelatine had become a little tacky, but had "fair" results. Why the tackiness? 2. Latterly the gelatine "etched" well, but would not take ink. Why? 3. Do you not think there should be some chemical added to make the etching take ink? 4. Would you kindly tell me the action between the ferro salts and the gelatine mass? 5. Where a line on the drawing is not so dense as to prevent the "ferro" salts from being reduced, as in the case where stencils have been used for the "Drawing No.," these lines get a blue tinge on them, and they will take up the ink, whereas a solid line on the tracing which leaves the line on the blue print yellow will not take the ink. This seems to me to bear out my question No. 3, that the chemical action of the gelatine has become exhausted and needs a chemical addition—say, after each alternate melting; otherwise the action can only take place as described by a slight reduction of the "ferro" salt, which was not so when the gelatine was first used. The makers of the jelly say, "add loz. of water to each lb. of jelly at each melting," which I have done. Also I have tried without the water being added, thinking that it was the water that would not let the "etching" take ink, but this is not so.—"VELO."

1. It is probable that the tackiness may be due either to overheating when re-melting, or the too high temperature of the room where you work. We cannot otherwise account for it. 2. Impossible to say, except, as you surmise, that the small amount of chemical in the gelatine composition has become altered in nature from either the keeping or the re-melting. 3. We do not know that it is advisable to add fresh chemical, but we should think that a certain proportion of new unused composition should be added at every re-melting, and this we understand is what the makers of such compositions usually recommend. 4 and 5. We are afraid we are unable to tell you what the action is between the ferro-salts and the gelatine mass, but it is evident it is some such action as tends to the insolubilisation of the surface of the gelatine.

METOL HYDROQUINONE.—I would be much obliged if you could favour me with a formula for a metol-quinol developer (not containing more metol than necessary), and suitable for general amateur use, that I can make up, ready for dilution, to "1 part developer, 6 parts water, for plates." I have tried several, but the water will not take up the soda; my latest being, 12grms. metol, 45grms. hydroquinone, 1½oz. sulphite, 1½oz. carbonate of soda, and 5 grains potass. bromide, in 4oz. bottle. The result is fairly satisfactory, except the dirty colour is objected to, a clear solution being required.—CONCENTO.

We do not know of a one-solution developer of such a high degree of concentration, and we suggest that it would be better to have a two-solution developer, so that one part of each solution can be added to six parts of water. In the formula you give the carbonate would be in the second bottle, and the solution in the other would then be quite clean.

TELEPHOTO WORK.—I am thinking of taking up telephotography. I have a Goerz-Anschutz ½-plate hand camera, with box extension (which brings up total extension to 14in.), and a Dagor 7in. lens. I had intended to buy the Goerz attachment corresponding to this lens, but I believe this limits magnification to about 6x. Do you think it preferable to get a Staley-Wheeler convertible tele-lens, which gives high and varied magnifications, I believe, within the same compass?—TELE-NOVICE.

If limited to one extension you must use different negative combinations to secure different degrees of magnification. You had

better consult the firm mentioned as to the degrees of magnification obtainable with their attachments for a 14in. extension. You would find a magnification of 6 quite large enough for most purposes, and a smaller one of 3 or 4 would be more generally useful.

C. YATES.—So far as we learn it is not a trying climate. If you care to send us a stamped and addressed envelope we will give you the address of one or two dealers out there who would, no doubt, be pleased to give you their experience.

A TRIAL ENGAGEMENT.—We advertised in your journal for an operator and retoucher, and we engaged one whose references we considered satisfactory. After two days we paid him off, as his retouching was disgraceful. We might mention that his first negative was a cabinet vignette, and, after three attempts, which wasted three hours, it had to be taken off. To give the man every opportunity of showing his ability, we judged his work at the end of the second day when we paid him off, and told him he had misrepresented himself, giving him the two days' money. This being the case, is he justified in demanding the remaining four days?—"EMPLOYER."

Yes; we should say that the man is entitled to his full week's pay. He, it appears, was engaged on a week's trial, so that you could test his abilities and see if he suited your class of work. Apparently he did not, and you could have discharged him at the end of the week without notice. If you can prove that he obtained the trial engagement by wilful misrepresentation, it is possible that he will not recover. That, however, is a matter that the county court judge will decide.

COPYRIGHT.—I should esteem it a great favour if you could give me your opinion on the following case. About three years ago I asked a person to bring his little girl to be photographed for a specimen. They turned out all right, and I gave him some free pictures for his trouble. About a year after I sold a picture of the same subject to a firm for reproduction. The pictures have recently been put on the market by the above firm. Now the father has threatened me, through his solicitor, with an action for damages unless I pay compensation. I may add that he ordered, about a month after he had received the free copies, some more photos for which he paid at the rate of a shilling a month. He has, I believe, registered the copyright as his, but has not done so more than a month ago. Now, seeing that I sold the picture two years ago, can he proceed against me for the infringement committed before registration, or am I liable for the continued publication by the firm after registration? I believe the copyright is mine, but I fear I may have some difficulty in proving it. As action is threatened, and I am not in the financial position to contest same, it would be a considerable relief to me to have an authoritative opinion at your early convenience.—"ANXIOUS."

If the facts be as stated, and you were not paid for taking the portrait, the copyright in it is yours, and you can register it if you like. The fact that the father has now registered the copyright goes for nothing, as it was not his to register, and that the solicitor should know. It looks like "bluff" on his part. The fact that the father subsequently bought some copies of the portrait makes no difference whatever.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Dr. H. D'Arcy Power has brought to a working condition several processes of two-colour printing in bromide, a method which he strongly advocates as providing the photographer with the means of strengthening his pictorial work by the introduction of colour contrasts. (P. 872.)

In an editorial article on p. 870 the principles and methods relating to the hanging of a photographic exhibition are dealt with.

The Presidential address delivered by Mr. Mummery last Tuesday evening at the R.P.S. is reported on p. 882.

A night of night photography with the North Middlesex Society is described more or less accurately on p. 883.

Mr. Marshall's photographs at 35, Russell Square and the exhibition of the Hackney Photographic Society are noticed on p. 878.

An American inventor has devised a system of cinematography in which the pictures are stationary and the audience moves; it is for application to tube railways! (P. 870.)

Sir Benjamin Stone, in retiring from Parliament and the informal office of "hon. photographer," was last week entertained at luncheon and presented with an address. (P. 875.)

The "Architect" has just obtained particulars as to permission to photograph in the English cathedrals. (P. 876.)

Colour screen-plates, films, and cinematographs figure under "Patent News." (P. 878.)

"Mr. Shaw and the Links," "Keeping Films," "Damage of Negatives by Insects," and other vital topics occur under "Correspondence." (P. 885.)

A useful means of subduing the background when photographing machinery is mentioned on p. 875.

A new manual of line-engraving, the proving of half-tone blocks, etching aluminium, and other process topics figure under "Photo-mechanical Notes." (P. 877.)

The London County Council having met with little response from employers in the way of granting opportunities for part-time classes their assistants are contemplating an additional year of compulsory education in a trade school. (P. 870.)

Some of the methods of two leaders of American professional photography have been published. (P. 874.)

There are signs of a less dishonest form of the "free portrait." (P. 869.)

EX CATHEDRA.

The Semi-Free Portrait. From a letter addressed to us by a correspondent in Tunbridge Wells we see that some improvement is discernible in the methods adopted by the "free portrait" fraternity. The old ruse of a portrait for nothing, followed by the demand to purchase a frame, is apparently now too well known to deceive the public any longer, hence the canvasser is now found to be pursuing a less crooked policy and offering at a price of "from 10s. 6d. upwards" a framed "superb crayon drawing." Our quotations are made from the card of receipt for a photograph handed to the wife of our correspondent by the agent of a firm emanating from South Wales. The time-worn dodge of excusing the alleged lowness of price on the ground that a new studio is being opened in the canvassed district is still put forward, and as an address in South Wales is given it may be that the parties intend to abide by their offer. But the "superb crayon drawing" is no doubt the usual cheap enlargement, and the profit to its exploiters depends on the ability of the canvasser to sell a frame at a price more or less disproportionate to its value. Photographers who are harassed by this form of competition require to take notice of these modified tactics, otherwise they may in an unguarded moment make statements which they may have occasion to regret.

* * *

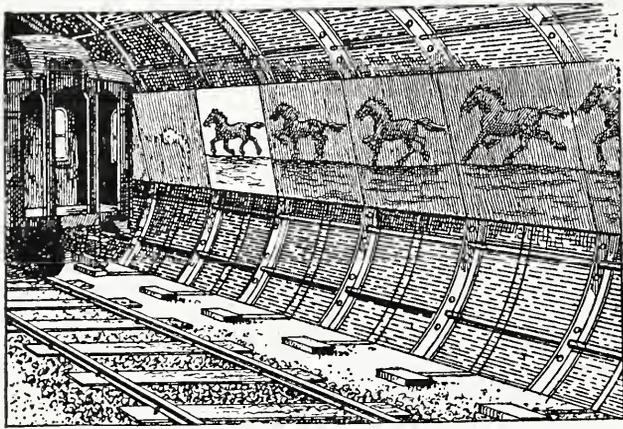

How Not To Advertise. We are glad to see our contemporary, "Abel's Photographic Weekly," commenting on an instance of a very wrong kind of advertising indulged in by a photographer of Cincinnati. The latter issued an announcement in the Press of his town to the following effect:—"The possessor of the only first prize in the city awarded by the National Photographers' Association of America is the title which —, the — Street photographer, proudly bears. The medal, which was awarded to him at the annual convention of the Association at St. Louis, is about two inches in diameter and almost a quarter of an inch thick, the metal being solid gold. On one side are two heads in relief and the name of the Association, while the reverse side bears the name of Mr. —, with the date. Mr. — also has the honour of being one of the very few photographers in the world whose pictures have been approved and hung in the Royal Art Gallery in London." "Abel's Weekly" states that the medal awarded in 1894 was of silver, so that disposes of the "corroborative detail" worthy of Pooch-Bah, whilst as for the "Royal Art Gallery" of London, which has selected our medallist for signal notice, surely this is honour by implication for the R.P.S. We do not believe these fantastic—to use a polite word—methods are at all representative of the American professional, for the latter, as a rule, does not give himself away if he can help it, and.

though he appears to unbend at Conventions, takes a decorous line in his dealings with customers.

* * *

The Tube Railway as a Cinematograph.

The writer who in a recent article on photographic methods in advertising emphasised the greater use of the cinematograph, did not perhaps know of a suggested application of animated photography which assuredly is ingenious enough. An inventor, according to the "Scientific American," has devised a scheme for the cinematograph entertainment of those who travel by tube railway. The motive of his idea can scarcely be other than that of revenue as a means of advertisement. His plan is certainly original. He reverses the order of things which prevail in an ordinary cinematograph. The pictures are stationary, it is the spectators who move and thus view the successive elements of the picture. He proposes to mount a continuous band of pictures at each side of the subway, and have these pictures successively illuminated by means of lamps

placed behind them. The circuits of the lamps would be successively closed by means of a shoe upon the subway car, engaging contact plates at each side of the track. We leave to some of our mathematical readers the pleasure of calculating the "period" and number the pictures must have; say, to entertain the passengers from Holland Park to Bond Street.

The L.C.C. and the Teaching of Photography.

The apprenticeship question in its relation to technical schools is the subject of an exhaustive report by the Education Committee of the London County Council. As regards photography, there is only one class in existence, and this is for girls only. The Committee some time ago made an effort to get employers to allow their apprentices to attend technical classes in the day time, but it is stated that there is not much prospect of establishing part-time classes on any scale commensurate with the need. The Council themselves have, however, set the example to employers by introducing a scheme whereby all youths and boys in their service are to be allowed a certain time off in order to attend education classes. Failing the co-operation of employers in a system of part-time classes, the Committee suggest several steps, including an additional year of compulsory education at a school of an industrial type after the age of 13, an extension of the curriculum of the elementary school to various kinds of manual training, and compulsory half-time classes, under which scheme all employers would be placed under statutory obligation to allow their employees under 17 years of age time off to attend continuation classes. The Council have no power in such a matter, but the Committee recommend them to report to the Board of Education suggesting such a scheme.

A New Gaslight Paper.

We read in an American contemporary a few mornings ago of the purchase by the Eastman Kodak Co. of the Artura Photo Paper Co. of Columbia. A few minutes afterwards a Californian reader of the "B. J.," Mr. George H. Knight, of San Francisco, paid us a call and produced an albumful of prints made, as it happened, on "Artura." They showed us the remarkably fine green tones obtained by direct development of this paper, the introduction of which to English workers will no doubt follow in due course. Our visitor informed us that the paper is issued in varieties other than that of the green tones he showed us, whilst the surface texture is obtainable also in several grades, of which the semi-glossy excellently suits the green toned prints which we examined.

A Stereoscopic Slide of a Comet.

The current number of "Popular Astronomy" contains an interesting article by E. E. Barnard entitled "On the Erroneous Results of a Stereoscopic Combination of Photographs of a Comet." Such photographs are of course taken singly with an interval of an hour or so between the exposures. The writer expresses doubts as to the accuracy of the results owing to the fact that the form must have changed to some extent between the two exposures, hence he suggests caution in accepting all that the stereoscope appears to show. Precisely the same defect exists in other cases in which stereoscopy is similarly employed. For example, stereoscopic views of clouds have been made in just the same way, and it is obvious that a change in the form of the clouds between the two exposures must seriously impair the accuracy of the final results. Such slides may be interesting, but they may also be very deceptive as scientific records, and therefore it is necessary to be cautious in interpreting their indications. An interesting departure in the printing of this article is the fact that the stereoscope slide of the Comet (the Moorhouse Comet of last year) is reproduced twice, so that one print may be cut out and mounted for use in the stereoscope, while the other is preserved in the book for reference. This is an excellent idea, and one that we should like to see carried out more frequently. This slide also presents a curious illusion. The stars are shown by trails, those of the stars of greater magnitude being thick trails, while those of the more distant stars of small magnitude are thin trails. In the stereoscope, the stars of greater magnitude appear distinctly nearer than the others, but this cannot possibly be due to any true stereoscopic effect and must be a perspective illusion, due simply to the evident variation of size.

ON HANGING EXHIBITION PICTURES.

WITH the closing of the Royal and the Salon, and the brief term of the Hackney exhibition, a show which for year past has carried on the interest in pictorial photography, on the closing of the two "great" exhibitions, the season devoted to the exhibition of photographic work throughout the country may be said to commence. With the step which need to be taken to ensure a successful show we do not now propose to deal. In some articles in the "British Journal" a year or two ago these and other society matters were somewhat fully treated. One remark may be made, however, and it is that the chief secret of a strong and interesting exhibition lies in taking time to a very long forelock indeed. In those instances where societies outside of London have succeeded in obtaining good representation of leading work from exhibitors, not only at home but abroad, we have invariably found that the announcements of the societies' activities have been made pretty nearly a full year in advance of the date

the exhibition, and judicious follow-up letters have been employed whenever interest has been shown to have been aroused. Such methods as these, however, are not our theme for the moment, important as they are to the production of a successful exhibition. We are now supposing that all these preliminary measures have been taken, and that therefore the selecting committee has done its work, and, subject to modification by those actually engaged on the hanging, has decided what pictures are to appear on the walls.

The first step to be made is to divide up the wall space into sections, within each of which the frames are to be appropriately placed. It does not follow that each section should be actually divided off from its neighbours in any prominent way, but for purposes of hanging it is an immense assistance to carry out sub-division to a reasonable extent. The spaces thus formed are conveniently indicated by vertical tapes tacked to the walls, whilst as a guide also to uniformity in hanging, a pair of horizontal tapes may be run round the walls to mark the upper and lower limits of the space for the frames, bearing in mind that it will be frequently advantageous to exceed the upper limit, and, on the other hand, to place frames short of the lower limit. This having been done, perhaps the next step is to find a few pictures—say, half a dozen—which, from their size or strong character, are specially fitted for placing in the chief positions in the several sections. In making this selection a further fact requires to be borne in mind, namely, that it is difficult to avoid a patchy and disturbing effect of the walls if frames containing very light prints—or, what amounts to the same thing, light mounts—are intermingled with those in which prints and mounts alike are dark, while it is equally important to avoid massing all the light mounts together in one place and all the dark in others. This destroys the effect of congruity which the exhibition as a whole should have, and while perhaps less objectionable as regards the effect on individual prints than the mingling of light and dark, nevertheless gives the exhibition as a whole a broken-up appearance. The most successful arrangement represents the mean between these two plans, a section composed of the lightest prints being toned down with one or two somewhat darker, whilst those containing the dark prints are relieved by a few of somewhat lighter tones. In working on this system it is almost an absolute necessity that there should be at hand a stock of frames other than those recommended for hanging by the selecting committee from which any particular requirement as to colour or tone may be drawn. Probably every exhibition which is carefully hung contains a few frames which owe their appearance there not to the merits of the individual print but to the service it can render in balancing others hung with it.

As regards arrangement the art of the hanger must be similarly exerted in striking the happy mean between a higgledy-piggledy placing of the frames with regard to balance and a severely symmetrical arrangement in which frames are placed either side of a centre so as to balance each other as equally as possible as regards size and shape. This latter perhaps is the direction in which the inexperienced hanger, who is really taking pains, is most likely to err, but it will be found that once the wall or section of wall has been hung in this way anyone who has had much experience in arranging frames can by a few alterations vastly improve the effect by destroying to some extent the symmetry of arrangement.

As to the practical methods which are to be adopted in arranging prints, the first hint that may be given is to arrange the frames first of all by spreading them out flat on the floor in front of that portion of the wall on which they are to be placed. The angle of floor and wall may be taken as the upper limit of the wall space, and a long

rule or a piece of tape laid on the floor to mark the lower limit. When this plan is adopted various arrangements of the frames may be of course tried without the tedious changes which would be necessary if they had to be attached to the wall in each new position. When they reach the final stage of arrangement and are ready for placing on the walls the following dodge of the expert picture hanger will be found to save a great deal of time and to secure a "straight" position of each print at once. Exhibition frames usually arriving without any plates, rings, or screw eyes, a supply of the latter of quite small size will serve with all but the heavy frames for attachment to the wall. A pair of eyes is screwed into the

back of each frame without troubling whether they are precisely at the same distance from the top edge at each side or not. The eyes are liberally chalked with the ordinary soft chalk used for blackboards, and the frame being held a little tilted forward from the wall, the worker (standing at arms' length) can judge quite accurately whether the picture is straight. When it is, pressure of the two eyes against the wall will leave two chalk marks, and it is then only necessary to drive a thin French nail at an oblique angle into the wall through each chalk mark to provide a pair of supports ensuring the perfectly straight position of the picture. Then again, it is often desirable to hang two or more frames on the same level, to do which the amateur generally depends on a friend at his back, who tells him when the frames appear to be right, but invariably says they are wrong after the nails have been fixed. A piece of tape stretched along the wall and held temporarily with a couple of drawing pins is a much more reliable guide, while it enables the right level to be hit at once without any time wasting trial-and-error efforts. In transferring from the floor to the wall, the centre of the panel, if it is to have a central feature, should be determined and a tape fixed vertically. A plumb line is useful for this. Other vertical lines, if any are in the scheme, should be similarly marked out and also any long horizontal lines. The pictures can then be hung, each in its own place (which operation will take very little time with the aid of the chalk dodge), the tapes pulled down and the panel is finished. Working in this way, the arrangement and hanging of a panel is only a one-man job (unless very large and heavy frames are in question), whereas in the method too often seen in photographic societies, it requires one man to hold a picture straight while another drives in the nails and a third one stands afar off to criticise and suggest alterations. As a rule the three men take three times as long over the job as the one man who knows how to set about it.

BROMIDE PRINTS IN TWO OR MORE COLOURS.

[The following paper, which appears in the current issue of "Camera Craft," was read before a recent meeting of the California Camera Club on the occasion of an exhibition of bromide prints in several colours by the process described by Mr. Power in a later portion of his address. The earlier paragraphs are devoted to an exposition of the author's reason for resorting to two-colour printing as a means of reproducing contrasts of colour.—Eds. "B.J."]

We use photography for two purposes—we use it to represent natural objects with as close an approximation to nature as we can make, and we have also used it in recent years to an increasing extent for the purpose of producing works of art, that is to say, of producing pictures that shall have some esthetic value and shall give some pleasure to the beholder. All photographs produced for this purpose must necessarily conform to the general principles of art and art expression.

I want to say a few words, before we go into the question of colour, upon the elements which are generally conceded to be necessary for the production of any kind of pictorial work. In order that you may have a picture at all, it is always desirable that it include the three fundamental elements. Even in monochrome, in order that you may have a picture of any kind, you need at least two of these; you need that the picture shall express itself by line, and it must also express itself by mass, that is, by relative amounts of light and shade. You cannot have any kind of picture without at least line, and it is desirable to have mass. Many pictures, many pencil drawings, such as Phil May's sketches, and a great deal of illustrating in hard-point, are purely line work, and most beautiful things can be done in that way, but they are merely suggestions.

In nature you always find line, indicated at least; mass always present; and, in addition, colour, which last is usually most compelling to the eye. Sometimes it is line that appeals to you; sometimes light and shade; but more often it is colour. I have no hesitation in saying that nine-tenths of the disappointments in photography are due to the fact that the eye of the inexperienced is attracted by colour in the subject, which cannot be expressed photographically. The painter is capable of expressing all—line, chiaroscuro, and colour. Of these, photography gives absolute line; and in this connection I would remind you that the camera is capable of doing that which is perhaps the most difficult for the painter; it can give texture, texture of cloth and skin, texture of surface, far better than any painter can.

Photographic Falsity in Colour Rendering.

When it comes to the expression of the second element, light and shade, or mass, a photograph is successful if the object photographed is of one colour; but if it is not, the camera fails in expressing the light and shade. It fails because colours ought to be expressed in their proper relation of light and shade, they ought to have their true light values; and yet the influence of colour is often quite independent of light and shade. Two colours may be of exactly the same value, and yet so entirely different in their character, as colours, as to present the strongest kind of contrast. And, when those colours are photographed, that contrast is entirely lost, and the nearer you are to a true rendering of the value the more hopeless is the failure. There is a very general idea that if you use orthochromatic plates you will get a satisfactory picture. It does not take much reasoning to show that this is hopelessly untrue. If you take a picture of an orange against a piece of light purple velvet of the same light value as the orange itself, using an ordinary plate, you will not get the true values at all. The orange will appear intensely black and the violet background will appear very much lighter, an entire falsification of the true relations. Some will say, "We know all about that; but, when a colour screen is used, you will get true values."

If the two colours are really of the same value, and you use a true panchromatic plate with a colour screen—if it is really a true value rendering, you will have no orange upon your plate at all. The nearer you get to true orthochromatism, the worse is the result; you have an entire wiping out, even of the lines of your orange, if your orthochromatism is perfect. This fact is recognised by every artist in black and white. He does not attempt to give true values, not at all. He makes a new standard for himself and represents a certain group of colours by light shades and another by dark shades; he looks upon all these latter elements of the spectrum as so-called cold colours, and represents them by a shade that is very much darker than their true light values.

The Reason for Colours in Prints.

So you see that the camera is not able to give you any true representation of colour. Nor does it give you true light and shade, because of the falsification due to the limitations of the plate. This is why it is desirable to introduce the element of colour into photographs, whether for pictorial or technical purposes. It therefore comes to this, that photography neither presents colour by its true values nor by the arbitrary standards of contrasts used by artists in black and white; and, unless we are to forgo all attempts at rendering the great colour contrasts of nature, we must find a method of introducing colour in our photographic work. Various ways have been tried. There are those who, with dye or paint, colour their photographs; but the result is false and unsatisfactory. It is not the image, but the paper, that is coloured, and the unchanged black of the former degrades the added colour, while the values still remain those of the monochrome original. To the artist a coloured photograph is usually an abomination. Three-colour processes have been much employed in the last few years, multiple-gum, carbon, pinatype, etc., but they are little more successful; the technical difficulties in the way of emulsions, screens, pigments, and registration invariably end in false renderings.

An Empirical Two-Colour Method.

Recognising the futility of attempting to imitate nature with a full palette, it occurred to me to seek a representation of colour effects by the use of two arbitrary tints, one to represent the warm, the other the cold, colours of nature.

We have in nature the fundamental colours, blue-violet, yellow-green, and orange-red, whose combinations produce all the rest. The orange and the red, or, rather, the orange-red and yellow are looked upon by painters as the so-called warm colours; they give you the impression of light, quite independent of their actual values; whereas, the green, blue, and violet give the impression of coldness. If we mix these together having the reds and yellows in excess, we get what is known as tertiary colours, a warm tertiary. If the blues and violet are in excess, we get a cold tertiary; and if we represent in a picture all the warm parts by the former, the cold by the latter, we obtain a result that is in no sense an actual representation of nature; it gives or produces to a certain extent the impression of the original. And, whether we are dealing with a technical subject or a pictorial representation, we obtain a closer approximation, that is, closer to the impression the original makes upon our eyes, than by any representation in plain greys.

When a picture is made in colours, artists are bound by,

at any rate usually follow, certain rules, which have been gradually evolved by experience. It is usual to consider colours in two relations. First, the relation of contrast. Colours as you see them in nature produce effects of contrast which are quite independent of line, quite independent of mass. You look at a field, for example, and you see in one part yellow daisies, and in another, green grass. There is no particular line between the two, no boundary. And perhaps a little further on in the same field there may be a border of trees with yellow foliage like some acacias in the spring, and your eye will follow the colour rather than the contour lines. But if you attempt to represent the scene in black and white only, you will have to follow the boundary lines of the light and shade. You will find that workers in colour are oblivious to the restrictions imposed upon us as photographers. Thus, successful painters are often largely neglectful of composition in mass and line, because colour contrast takes its place. In pictorial photography, you have little control over line and have to accept what nature gives. Gum and oil printing will enable you to change, to some extent, light and shade relation. But when a picture is printed in two contrasting colours, as you see in these examples, the composition is purely dependent upon these introduced colour relations.

In painting, the distribution and relation of colour are made in accordance with laws or principles, the result of experience; although these have primarily to do with the full palette, they can also be applied to our conventional scheme of two tints. For example, it is a principle of modern painting that the primary colours shall not constitute any large portion of a picture without being united by a preponderance of tertiaries. In accordance with this rule, we are precluded from using either primaries or secondaries for our conventional colour; we are restricted to warm tertiaries and cold tertiaries. A warm tertiary may be any combination of the three primary colours with either red or yellow in excess; that is to say, anything between a red chalk and a sepia. For a cool tertiary, anything between olivine and Payne's grey, with an excellent medium in a dark French grey. With two such tints we can suggest most of the effects of a full palette; we can keep the cool tint in the background, the warm forward: we can make a colour contrast between objects and cast shadow; or obtain accent by the sharply contrasting juxtaposition of opposite tints. We can use this power to reinforce existing contrasts in the print or to diminish them; and, if this power be used with the knowledge and skill of an artist, a worthless monochrome may acquire high pictorial value and ideals be realised that were otherwise impossible. Another point to which I would draw attention is this, that if you examine, in a cursory manner, many of the pictures I have placed on exhibition, they will give you the impression of being printed in several colours, the colours proper to the picture. Only by close examination will you perceive that only two are present. The reason for this is that the two colours chosen contain all the primary colours.

Two-Colour Bromides.

My experiments in this direction occurred as far back as 1905, in which year Winthrop Somerville published a note in the "Amateur Photographer," London, on toning a bromide print of calla lilies in such a manner as to leave part brown, part black, and the rest green, the modifiers being sulphide and vandum toning. It was suggested merely as an experiment, without any reference to art possibilities or serious purpose. I reproduced the article in "Camera Craft," tried the method, and did not like the quality of the tints. I then started on a different line. I toned a bromide print with platinum and mercuric chloride to the beautiful sepia that method yields, and then, with a brush, went over selected parts with amidol developer. Wherever it touches there is pro-

duced an intense black. One thus gets a print in sepia for the warm tones and black for the cold. It works well with a certain class of subjects, and the first print I made, now three years old, is on the walls unaffected by light and time. Shortly after this attempt, a method of treating sulphur-toned bromides with a sulpho-cyanide gold bath was published. It converts them into a fine red chalk. Incidentally, in trying it, I found that there might be produced a series of intermediate tones; and, a little while later, it occurred to me to try this bath on a bromide toned in parts with sulphide. The result was a surprise and a revelation. I found that both parts of the picture would tone, but in opposite directions, the black of the silver turning to blue-black, and the brown of the sulphide passing through various shades of brown to red chalk. Therefore, I could get tonal relations running through the blue tertiary for the cold tints, and various shades of red sepia for the warm tints; and I can get it as I want it by stopping the toning at any desired point.

We must be careful to remember that in this process the colour line will dominate our print; therefore, the parts that are changed must be selected with an appreciation of this fact. One of the dangers that you will meet with is the inclination to do a great deal too much, and you will find, sometimes, that the less you do the more effective it will be.

Ozobrome for Multi-Colour Prints.

Now for another method. In ozobrome work you will recollect that the pigment is thrown down upon the surface of the bromide print through the action of the ozobrome solution upon the silver in the print. I reasoned that if I converted the silver in my print into bromide of silver it would no longer act upon the ozobrome solution. If, after I got my deposit of ozobrome, I then locally redeveloped that part which I had previously bleached, that part would take a new piece of ozobrome of any other colour that I desired to put thereon. And so by this means I was able to combine any local colours or tones made in carbon tissue.

Two-Colour Toning in Practice.

Now, to get down to actual practice. Of the three methods described, the one of most general utility is that dependent on sulphuretting and gold toning. The first thing is to study your print and work out beforehand where the second tint is to be placed, remembering that your composition will be controlled by it; also that you must beware of abrupt juxtaposition of the two tints, unless the nature of the picture calls for it. Remember also that colour composition demands that a little of the cool tint appear in the warm portion of the picture, and suggestions of warmth in the cool surfaces, otherwise the effect is unpleasant and crude. These points being determined, you are ready to proceed. The print is usually best handled damp, but quite surface-dry. A little bleach made of a solution of potassium ferricyanide ten per cent. and potassium bromide five per cent. is placed in a saucer, and a camel's or sable's hair brush is charged with a very little of it, using it, in fact, almost dry. With this the outlines of the warm tint are carefully traced, the surface bleaching as the brush passes over it. If at any point it is desirable to unite the cold and warm areas by a colour half-tone, the effect can readily be produced by applying the bleach as a fine stipple. Now wash the print for five minutes in running water; and, if at any point you have bleached beyond the line intended, charge your brush with a little developer and locally redevelop to the desired extent, wash, and place the print in the usual one per cent. sulphide of soda bath for three minutes: wash until free from odour. The bleached parts are now brown, the rest black silver. The print is next immersed in a bath consisting of gold, one grain; ammonium sulpho-cyanide, ten grains;

water, twenty ounces. In this the silver becomes blue-black and the brown sulphide passes through a series of tints to red chalk. The print is to be taken out and washed when the required colour is obtained. If it is desired to carry the change further at one point than at another, the varying degrees are easily obtained by local swabbing with absorbent cotton charged with the gold bath. Finally, let me point out to you that, if the values or even outlines of your bromide print are defective, you can modify them before proceeding to make your colour modification. By a method that I fully described

in the "American Annual of Photography" for 1909, you can modify a bromide print almost as freely as by gum printing. Before proceeding to demonstrate, let me say in conclusion that pictures are only made by artists, and art demands time and skill. It is easier to make daubs in two colours than in one, and they are more unpleasant; but if you care to give the time and study and have in you the sense of the beautiful, you can make better pictures by the method I am advocating than by any existing method of photography.

H. D'ARCY POWER.

POINTERS IN MAKING STUDIO PORTRAIT NEGATIVES.

[An American association of professional photographers has published, through our Philadelphia contemporary, the "Photographic Bulletin," the following notes on the making of portrait negatives in the studio. The hints are drawn up by Charles Wesley Hearn, in collaboration with John H. Garo, a conjunction of authorship which may be taken as representative of some of the very best professional photographic portraiture done in the United States.]

Lighting.

1. Proper balance of light and shadow at time of arrangement of the sitter, correct timing of the exposure, and a little judgment in mixing developer to suit the plate and local conditions, cannot fail to make a fine negative. The more care exercised, the better the results.

2. Light the subject with a soft pure light, i.e., through clean curtains and windows. Dirty skylights and curtains impregnated with dust give blank whites and harsh shadows, without proper values to the planes of the face.

3. Multiplicity of curtains and their complex arrangement are not essential. As much, if not more, can be effected by the proper placement of the sitter's chair.

4. Strong patches of light on face make strong shadows, with the probable result of forcing those parts of the face, arms, etc., unduly forward, destroying their relative position to each other, causing distortion. It is very hard to correctly expose or develop plates in such cases unless done by experts, and they, too, often fail.

5. There is greater latitude in exposure when the lighting is more balanced, i.e., a little over-timed or under-timed exposure does not prevent obtaining good negatives with a little care in developing.

6. Avoid placing the subjects in strong light, even if rendered mellow by the head screen. To be sure you avoid strong shadows, but at the expense of modelling of the planes of the face. The forehead, cheeks, ear, upper lip and chin are all of the same degree of light.

7. A broad light is the best to use for white ground effect; in fact, for any shade of plain grounds, the cases are rare when it is *not* a good light to use. I do not like it for fishy or bulging eyes, nor do I always prefer it to make strong pictures of strong men. I *do not* use it when photographing effeminate youths, but to make women beautiful, to show their beautiful dark or light hair, to render good values of light or dark in clothing. To make dainty effects I know of nothing that so largely aids the operator.

8. Whatever the method of lighting may be, if the chair is so placed that there is only the *slightest* bit of *soft* high-light in the forehead and along the line of the nose, you are not far off in obtaining proper gradation through the face, especially if coming from an angle of from 35 to 45 degrees. Tonality and colour values are easily obtained if the chair is pulled back a little farther still, so that there are no especial high-lights. Be careful about high-lights with subjects possessing greasy complexions, as they are very disturbing.

Developing.

As lighting and developing go hand-in-hand, it is useless to advocate special formulæ for developer without this fact in mind.

1. All plates of recognised merit give standard formulæ as

advisable for their plates. If the results are not satisfactory I have not for some years blamed the plates, but place it where it generally belongs, and that is upon myself. It may be that my light and the method of light employed are not so good for one plate as for some other, or, more probable still, I may have become used to one plate, and can work it better on that account.

2. In working out a formula for any plate it is well (as a basis to start upon) to use their own, and give it a fair and honest trial, being careful to give correct lighting and timing. If you have reason to think that the whites in the negative are too blank for the lighting employed, watch the temperature of developer, strength of developing agent (pyro, etc.), strength of accelerator (soda carbonate, etc.), or if the above appear to be correct, then reduce the developer with a little more water, and see if this does not correct things. In fact, try the *latter plan first*, if the same plate and formulæ have previously been working right at other seasons of the year.

3. Temperature of developer should be about 55 degrees on hot summer days, and about 70 degrees in cold weather. A good plan in summer is to keep your tray during developing in a larger tray containing ice water and lumps of ice, and the bottle of developer in a pitcher of ice water. By this means the solution is cool all the time of development, otherwise in a hot room the temperature of developer rises very high before you are through with the plate.

4. Bromide in summer time is more necessary than at other times of the year, but there is a difference when bromide is used. Test their action with the plate you use. Better, however, try to expose so as to dispense with bromide, as it has a tendency to chalk up the negative. When a plate is over-exposed remove it, rinse well and quickly, and then return to the developer to which bromide has been added. Otherwise the bromide does no good, as the plate is developed before the bromide becomes effective.

5. Acetone sulphite is especially good in the developer if you are troubled with foggy shadows.

6. If weakening the normal developer with water (which does such wonderful things) does not give satisfactory results, reduce slightly the strength of the developing agent, pyro, etc., and see how it works. If you use metol-hydroquinone or edinol-hydroquinone, increase the metol or edinol, and cut out the hydroquinone. If too flat, increase the carbonate. The way of it is this:—Hydroquinone gives density, but unless used by experts, who know how to use it, it also gives blank faces, etc. without modelling. Energy and strength is also imparted by the carbonate of soda opening the pores of the film and making rapid the metallic deposit of silver to the whites of the plate and unless it is itself too strong, it gives what you want without the harshness of the hydroquinone.

7. As you increase or decrease the carbonate, balance the same with the pure sulphite, which proportion varies with different plates, taking about 50 per cent. more sulphite with Cramer to 20 per cent. more with Seed and about 15 per cent. Standard, etc.

8. When balancing the soda solution, do not overlook keeping the developer agent itself in good working condition. Do not forget that you have got to have a good horse or other power to pull that load properly. If the horse is not strong enough you'll have trouble. If the carbonate is too heavy, even if balanced with sulphite (which is used to keep the film clear, and largely aids in the fineness of the deposit in the plate), you will get fog as sure as night follows the day. *Increase of carbonate over the published formula should always be done with caution.*

Fixing and Reducing.

1. Use acid hypo, and *don't* keep it for ever. Fix for several minutes after the film is clear.

2. In my practice I have discontinued reducing with red prussiate of potassium; in fact, reducing at all, if I can help it. I avoid it by developing until my low notes are as desired, and then by rinsing my plates, and occasionally placing in weak sulphite soda solution. I do the rest of the developing with a large camel's hair brush or a large wad of cotton soaked in normal developer, with occasional rinsing; if the developer runs where I want, no other developing.

3. If the *dried* negative still needs reducing, I employ tufts of cotton and alcohol or toothpick and alcohol, but the toothpick is used *without* any cotton on the end of it. I am recently using for larger places, however, turpentine or oil, and pumice or emery powder, and perfectly flat pieces of hardwood or steel, such as are used by engravers for die plates for embossing presses. I make a paste of the oil and pumice on a glass, and work it smooth with the die plate and rub it lightly in the parts of the negative to be reduced.

4. The reason why I have discontinued chemical reduction is because tonality or the removing of undesirable things when effected this way is always at a loss of strength or solidity, with a noticeable and disturbing flatness. By grinding away the film *evenly* this way, or by some other method along these lines, you reduce in tone and preserve quality at the same time.

THE "PHOTOGRAPHER OF PARLIAMENT."

AFTER the next General Election the House of Commons will have to find a new "photographer-in-chief," for Sir Benjamin Stone, the founder and for so many years the occupant of that unofficial position, will no longer be one of its members. The announcement of his intended retirement was received with regret among all parties in the House, and the suggestion that some marked tribute of respect should be paid to one who is not only so generally esteemed but who has made such sterling use of his camera was received with pleasure, and followed up with earnestness. The result was seen on Friday last, when, in the Harcourt Room at the House, Sir Benjamin was entertained at luncheon by a large number of his fellow-members and presented with an illuminated address warmly thanking him "for the kind, considerate, and generous manner" in which he had devoted himself to the presentment of groups and individuals which must be of historic value. Sir John Brunner occupied the chair, and

Mr. Sydney Buxton, as reported in the "Morning Post," made the presentation, and spoke of the value of the photographic work done by their guest. He did not think that as regarded any members of the House Sir Benjamin had really damned them with faint praise, because he made them all good-looking and yet true to life. (Laughter.) Apart from members, he had from time to time given them the opportunity and satisfaction of preserving a permanent record of the visits of colleagues from the Colonies and of distinguished strangers from other countries. He was not sure whether one of the most successful of these photographs was not one of Mark Twain, taken on the Terrace. Then, from the national point of view, Sir Benjamin had rendered a great service in selecting for his studies various ancient and historical landmarks in the country—castles, mansions, and cathedrals—and scenes depicting old customs. There was one

ancient monument which he had photographed, and of which in the next few years, when it has ceased to exist, they would be glad to have a representation—the House of Lords as it was in his time. (Laughter.) But, seriously, they were immensely indebted to Sir Benjamin not only for the pleasure experienced in having him as a fellow-member, but for all that he had done with his camera, and they wished him every possible happiness during the remainder of his life. (Cheers.)

Mr. Cathcart Wason, who, with Mr. Henniker Heaton, has taken a leading part in the presentation movement, then read the address, and stated that among the signatories were Mr. Asquith, Mr. Balfour, Mr. John Burns, Mr. Lloyd George, Mr. Winston Churchill, Mr. Lewis Harcourt, Mr. Henderson, and members from Ireland. He added that he thought it would have given the Speaker great pleasure to have attended that luncheon, but he could not establish a precedent. He had, however, signified his strong approval by signing the address in a prominent place. (Hear, hear.)

Sir Benjamin Stone, in replying, said the severance he had to make was one that he felt keenly. It was a great break in his life, for he was parting from a number of friends whom he greatly esteemed and without any bitterness towards any man in the House. He felt also that there was a break in the interest he had always had in the House itself—in the customs, prejudices, traditions, and history of the House. As to his photographic work, he had pursued it with no kind of assertive selfishness, but he had looked upon it more as part of the common history of the House, and not his own in Parliament. His mind often wandered back to the former history of Parliament and reverted to scenes in Westminster Hall. Again and again he had paced the floor of that hall full of thought, and "amid the spirits and the ghosts" endeavoured to learn something of the scenes that had been witnessed there. How, for instance, he would have liked to have photographed Sir Walter Raleigh, Sir Thomas More, and the famous Duke of Buckingham. Then there was the melancholy scene of Richard II. abdicating, and another of the three Queens kneeling before Henry VIII. and begging for the lives of apprentices condemned to be hanged at the gallows. These were the scenes that went through his mind, and perhaps his photographic interest almost put them into pictures. Coming to modern times, he spoke of the photographs of the men he had been able to take, and his recital included a list of the most eminent Parliamentarians of their day. Pictures of distinguished visitors from other lands were also among his collection, and, as he said, they were pictures of history, suggesting the remark that there ought to be a Government Department to take like account of current history.

The gathering concluded with a vote of thanks to Sir John Brunner for presiding.

A HINT ON PHOTOGRAPHING MACHINES IN WORKSHOPS.

THE following hint on subduing the background of the workshop or other building where a machine is being photographed without resorting to blocking out of the negative is given by a writer in an American journal, "Machinery":—

Some time ago I had to take a photograph of a lathe which had a 28-inch swing and a 56-foot bed, and in one particular it is rather out of the ordinary. Normally there are two complete lathes on the one bed, the headstocks being at the extreme ends and the tailstocks in the middle. One operator is at the back of the machine and one at the front, as usual. The rear lathe has a lead-screw and feed-shaft slightly less than half the length of the bed, while in front the lead-screw and feed-shaft extend along the whole length. The novelty of this arrangement is that the carriage belonging to the rear lathe can be turned around to the front so that both carriages may be at work on the same job, one headstock and one tailstock being, of course, removed. Normally, however, the machine is worked as two independent lathes, and as such was photographed by me and also by a professional photographer whom we generally employed when we wanted an extra good job.

Any one who has tried to block out a negative of a machine which has the shop for a background knows that it is a difficult matter to tell which is the machine and which is the shop. It is always advisable to have a white sheet for a background, so that the outline of the machine is easily discernible; in fact, the writer has taken scores of machines where no blocking out was necessary at all. The white sheet should be gently swayed during exposure

in order to remove all creases and dirty marks which would show if the sheet were still. This method is a good one to adopt if a large enough sheet is available; it is hardly practicable, however, to have a sheet big enough for a 36-foot lathe. The only thing, then, that can be done is to rig up a background that will enable the blocking out of the negative to be done more easily.

When the first photograph of the lathe was taken, a large sheet was suspended from the crane. This was made of a lot of white paper fixed up on cords very much like the family washing, and, in addition, a smaller sheet was held up by three men. It took about an hour to get the background fixed, so that after once dismantling it (this was necessary in order to run the machine) I didn't like the idea of putting it all up again to take the other view; consequently I thought I would only use the small sheet, but instead of keeping it in one position, have the men who were to hold it walk from end to end of the machine during the exposure. This was done, and the idea was a success. It leaves the outlines of the machine well defined, and no time was required in putting up a background.

For all practical purposes it is unnecessary to block this negative out, as the girder work, counter-shaft, etc., rather improve the appearance of the picture, besides giving some idea of the size of the machine.

PHOTOGRAPHY IN ADVERTISING.

BEARING on the recent articles on the greater use of photography for advertising purposes, it gives us pleasure to reproduce herewith a couple of photographs made by the wife of Mr. W. H. Goy, chemist, of 17, Battersea Rise, Clapham Common, which are as admirable an

Advertisement Photograph. By Mrs. W. H. Goy.

example as could be wished of the advertisement photographs which can be made out of quite simple materials. Mrs. Goy's photographs have been designed as advertisements to Wright's coal tar soap, and have, we believe, been taken up by the makers of this article.

Advertisement Photograph. By Mrs. W. H. Goy.

PERMITS TO PHOTOGRAPH.

THE article which appeared in the "Times" on this subject brought a letter from the Dean of Peterborough, pointing out that the information given in the article was incorrect as regarded his cathedral, at least. The "Architect" has, therefore, made special inquiries as to the regulations regarding permission to photograph, sketch, or measure in our cathedrals, and the following particulars may be taken as authentic:—

BRISTOL.—Permits to photograph and sketch given by the Dean. No charge.

CARLISLE.—Permits to photograph, sketch, or measure given by the Dean "on certain necessary conditions."

CHESTER.—Permits to photograph or sketch at the discretion of the Dean on written application, with name and address. No charge except sixpence for entry to choir or lady chapel.

CHICHESTER.—Permission to photograph, sketch, or measure to be obtained from the Dean and Chapter on application to the Chapter Clerk and payment of half-a-crown. A copy of every photograph taken to be sent to the Chapter Clerk.

DURHAM.—Permits to photograph, measure, or draw given by the Dean. No charge.

ELY.—Permission to photograph, sketch, or measure granted to proper applicants for such parts of the cathedral and precincts as are ordinarily accessible to visitors. Application to be made to the Dean or the Canon in residence. No charge at present, but question of a moderate fee is under consideration.

EXETER.—Permits to photograph, sketch, or measure given by the Dean or Canon in residence, under certain regulations which the verger communicates. No charge.

LICHFIELD.—Permits to photograph, sketch, or measure can be obtained on application to the Canon in residence. The use of ladders not allowed, nor the removal of any article of furniture. Regulations now under consideration by the Dean and Chapter, and may possibly be revised.

LINCOLN.—Permits to photograph, sketch, and measure granted for four weeks, and if elsewhere than in the nave for a single payment of sixpence. Special permission required for the higher storeys, and applicant must be accompanied by a workman of the cathedral, for whose time a fee will be charged.

MANCHESTER.—Photographing not allowed. Permits granted for sketching or rubbing brasses on payment of a small fee. Photographs can be bought at a cheap rate, the Dean and Chapter having employed a professional firm "to make a series of beautiful photographs, bringing out all that is best to be seen in the cathedral."

NEWCASTLE-ON-TYNE.—Permission for photographing or sketching to be obtained from the Vicar or the Canon in residence.

OXFORD.—Permission to photograph, sketch, or measure must be obtained from the Dean, or, in his absence, from the Canon in residence.

PETERBOROUGH.—Permits are not required, "except that in the case of elaborate measurements, involving perhaps extra labour or responsibility on the part of the vergers, it might be necessary to make special arrangements."

ROCHESTER.—Permits to photograph, sketch, or measure granted by the Dean on written or personal application. A fee of sixpence charged, unless a series of visits is contemplated, when the fee is somewhat modified.

ST. ALBANS.—Permits granted by the Dean, name and address of applicant being required. No fee charged. Holder must "conform to the necessary regulations."

ST. ASAPH.—Permission to photograph and sketch granted by the Dean on application. No charge.

ST. DAVIDS.—Permits for photographing or sketching are granted by the Dean. Fee for one day, one shilling; for one week, half-a-crown. Permission to take measurements is very rarely asked for and would involve special consideration.

ST. PAUL'S.—Fee of half-a-crown charged for each day's leave to photograph (except in special cases). No flashlight allowed.

SALISBURY.—Permission to photograph, sketch, or measure given to all by the Dean or Canon in residence on application.

SOUTHWARK.—Tickets of permission to photograph, sketch, etc. are obtainable of the Dean's verger at five shillings each.

TRURO.—Permission to photograph given on application, usually by letter, to the Canon in residence. Fee of half-a-crown charged.

WELLS.—Permission given on written application to the Dean or Canon in residence for photographing or sketching, and (in the case of architects) for measuring, without any charge up to the present; but it is not improbable that a small charge may be soon made.

WESTMINSTER ABBEY.—Permission to take photographs is only granted by the Dean in exceptional cases on application to the Chapter Clerk. A fee is paid to the Fabric Fund of five shillings for each view or object photographed within the church.

WINCHESTER.—Permission to sketch or take measurements given on application without charge. Photographers are charged one shilling a day, or half-a-crown a week.

WORCESTER.—Permission to photograph given on application to the Dean or Canon in residence. The use of ladders or other apparatus of that kind would be specially considered as to its reasonability.

YORK.—On application to the Chapter Clerk a permit to photograph is given on payment of half-a-crown for one day; to sketch, measure, or take a rubbing, one shilling. For a period of several days or weeks on special work, special terms are arranged for those who can produce satisfactory references. For the choir, lady chapel, chapter-house, crypt, or any part shut off by gates, an additional charge is made of sixpence. The crypts are electrically lighted, and a small extra is charged for this sometimes. Access to the triforium and the use of ladders and stands allowed only under supervision by the clerk of works.

It is hardly necessary to say that photographing, sketching, and measuring are not allowed in cathedrals on Sunday or during Divine Service; that artificial light is usually forbidden, and the use of ladders or stands or the moving of any article of furniture are only allowed by special permission and under the personal supervision of the clerk of works or other official. It will be gathered from the detailed particulars we give above that great freedom is allowed in our cathedrals to those who wish to study; that the regulations made and the fees charged, where these are in force, are for the purpose of maintaining the decency of the church and of preventing the abuse of the privileges that are granted.

Photo-Mechanical Notes.

A Manual of Line Photo-Engraving.

Messrs. Lund, Humphries, and Co. have just published at 7s. 6d. net a book on "Line Photo-Engraving," by William Gamble, of Penrose and Co. In the 328 pages is contained a description of almost every known method of producing line engravings in which photography enters, and of many processes in which it does not. For instance, instructions are given with regard to drawings on transfer paper and on metal direct, for the production of line etchings. Photo-lithography also receives a considerable share of attention. The author recognises that the very comprehensiveness of his book may puzzle the beginner as to which process is the simplest, for he directs attention in the preface to those chapters which contain the description of current processes; but this encyclopædic character will be of the greatest service to the expert line photo-engraver, who is at all inclined to experiment, for he will find an account of practically all suggested methods, and full instructions for several processes not now much used, if at all, such as the "swelled gelatine" and "wash out" methods, which are capable of turning out work of admirable quality and may still have a future. The book has a frontispiece of tint colour line work, and is copiously illustrated in the text with pictures of "Penrose" apparatus. The book has also a good index.

Proving Half-Tone Blocks.

The improved "Albion" which is now in almost universal use for proving half-tone plates, is gradually being displaced in many establishments by a modified form of gold-blocking press. This is said to possess many advantages, perhaps the chief of them being that it occupies very much less space. The lever being a pull-down vertical bar, the press can stand in a corner of the room with the lever next the wall, and therefore takes up not very much more

space than the size of the plate it will prove. It is said to be three times as strong as an "Albion" of the same size, and the height of the bed is much more comfortable for the prover at his work than in the case of the lower "Albion" bed. There is certainly a future for this press, and we wish there were more English presses to be had instead of German ones. It was an English idea to use the gold blocking press for proving photo-engravings.

Originals for Three-Colour Reproduction.

We receive constant inquiries as to which originals are most suitable for reproduction by three-colour blocks, and whether it is desirable to paint them in the three colours that the block printer will use, viz., yellow, blue-green, and pink. We may say at once that this is not at all desirable, and any artist attempting this will give himself unnecessary trouble—first, in obtaining pigments suitable as to colour and permanency, and, secondly, in producing the colours he wants with mixtures of such pigments. The artist had far better paint with his accustomed pigments and in his accustomed manner, and leave it to the photo-engraver to reproduce his work as nearly as possible. He must remember that it is always and for ever quite impossible to reproduce one medium by another, that is water or oil-colour paint by printing ink: at best it can only be an imitation. Another limitation laid upon three-colour block reproduction is that of narrow contrast range: it is impossible to reproduce contrasts that have a range of more than about 1 to 16 or 20 at the very extreme. It is also very difficult to reproduce very delicate work, so that work especially made for three-colour reproduction should be neither too strongly nor too faintly contrasted, and it should be remembered that these contrasts will be almost always slightly exaggerated in the reproduction. It is also easier to reproduce pictures having fairly well marked regions of colour rather than those in which the colours are vignettted into each other, any sort of boundary or outline being absent. The reason for this is that the production of three-colour blocks is seldom entirely mechanical: if it were, it would not matter, but because neither plates, filters, printing inks, nor manipulation, come up to theoretical requirements a certain amount of fine-etching is always indispensable. This generally necessitates certain parts of the plate being stopped out with acid-resisting varnish, and the more definite these regions are the more likely the etcher is to be successful in treating them.

Another point that is sometimes overlooked is the difficulty of producing an even background of neutral colour. White is, of course, impossible unless the whole of the dots in the background are cut away, and this means a lot of labour, and therefore expense, extra trouble in printing, and very often hard, unsatisfactory edges to the work. On the other hand, to get a neutral colour demands the most exact adjustment of the inks and very slight differences in the size of the dots on one of the plates—or, if these are correct, very slight alteration in the printing conditions will throw the neutral point out, and the background print either too reddish, bluish, or yellowish. Undoubtedly the best sort of originals for three-colour reproductions are those in which form is most important and colour subordinate, so that the slight variations of colour which are almost inevitable in the reproduction will not be a serious matter.

Etching Aluminium.

Inquiries are constantly made as to the best mordant for aluminium, which is a troublesome material at best to etch. We have used the following:—

Alcohol	4 ozs.
Acetic acid	6 ozs.
Butter of antimony (antimony chloride).....	4 ozs.
Water	40 ozs.

Mr. Horgan, in the "Inland Printer," says that experimenters have discarded a complicated formula in favour of a simple bath, made by adding 1 oz. of hydrochloric acid to 20 ozs. of perchloride of iron registering 35 deg. Beaumé, which they state etches the aluminium satisfactorily, though not so quickly.

THE BOLT COURT SCHOOL.—During the rebuilding of the permanent premises in Bolt Court, temporary quarters are to be leased of the Clothworkers' Company in Fleet Street and New Court for the L.C.C. School of Photo-Engraving and Photography.

Exhibitions.

HACKNEY PHOTOGRAPHIC SOCIETY.

ON Wednesday last the 21st annual exhibition of this society was opened at the Hackney Baths, known in its dry state as the King's Hall. The coming of age of the society is an event upon which we offer our congratulations. It is marked by the fact of a record number of entries and a great falling off in the open class. The latter circumstance does not, of course, affect the intrinsic merit of the society, inasmuch as the interest of the show is more completely due to the efforts of the members. We are of opinion that the pictures, on the whole, are more attractive than those of recent exhibitions. The society is, indeed, one of paramount importance in London. Its membership roll numbers 130. It has the advantage of housing its shows perhaps in a finer hall than any other society can boast, and its exhibitions are larger. The present one has 363 entries, exclusive of lantern slides, with a grand total of 520, besides trade and professional exhibits. A liberal orchestral programme has been provided for each of the four days of the exhibition, and, most important point of all, the standard of the work is decidedly a high one.

This year the committee has abandoned the usual classification, and has adopted the novel one of classifying the photographers instead of the photographs. Class A is for competitors who have previously taken more than five awards; Class B for those having previously taken five or fewer awards; Class C for those who have taken none. This obviously sensible arrangement puts competitors upon fairer and more hopeful lines. It will probably be a permanent arrangement, and we commend it to other societies. For the first time, in this age-coming year, there is a class for colour work, the chief exhibitor in which is Colin N. Bennett.

Portraiture is very strong, whereas last year it was practically neglected. Among the most interesting examples are fifteen excellent bromide portraits of the committee, by Stuart Woodhouse, a practically new member. The subject of J. Linley, Esq., B.Sc., who is this year's president, is a work of which anyone might be proud, and is upon the lines of Hollyer's portrait of Walter Crane, which it much resembles. Some multiple gums by Mr. S. W. Shore come very near to success; but in some cases the double tint has proved an embarrassment rather than an advantage. Particularly is this seen in the "Night in May" (13), where the lights and the shadows they cast are not well explained and too variable in colour. Night scenes are the fashion at Hackney. Some are quite fine, and the best is an airy, spacious, and imposing view of Trafalgar Square, by W. H. Witts (188). Mr. Rawlings's "Through a Field Gate" (19) is a choice piece of arrangement of light and dark, and a charming view also. The secretary, Walter Selfe, contributes much excellent work, notably "A Suffolk Landscape" (38), which is finely composed. The trees and snow of Mr. W. A. J. Hensler's "Winter" (48) make one of his best pictorial efforts; but it is run very close by the Alpine scene, "Cloud-Capped Towers" (53), a view of a chalet among mountains. We must mention G. T. Gale's very noble view of "The New Bailey" (111) and R. J. Delf's true "Sunshine in Old Whitby" (411). Space forbids mention of the technical and scientific work, which is, in its way, quite as interesting as the pictorial.

PHOTOGRAPHS BY MR. ARTHUR MARSHALL AT THE R.P.S.

MANY of the pictures in Mr. Marshall's exhibition are already known to our readers. They make a goodly show, and are a tribute to his versatility in methods and catholicity in taste. We are not sure that he is entirely in a position to anathematise the maker of odd and queer pictures. A good half-dozen things might be taken as evidence of his living in a glass house and throwing stones. On the whole, however, his works are charming, and his point of view interesting. We think his reputation will rest upon some of the pretty Dutch girl subjects; the clever street scenes, such as "Shade" (59), and the legitimate snapshots treated with pictorial dignity as in "A Roman Highway" (28) and "A Dusty Day" (56); his best Venetian subjects and the refined figure studies like "Mdlle. P." (54) and "Gertrude Robins" (68).

Mr. Marshall is always on the look-out for the picturesque, for which he has a keen eye. In architectural and street scenes he displays a fine faculty for the beautiful.

We do not know that Mr. Marshall has ever held a one-man show

before, but this one, at any rate, should prove highly beneficial to his reputation, and in many ways interesting to his public. It affords an excellent opportunity of comparing different printing processes as worked by one man. Looking at Mr. Marshall's carbon prints we feel disposed to say that, in his hands, that method has the best results. The bromides are often much fuller of light—sometimes to the point of losing the image in white paper—but they lack the firmness and sureness of gradation which the carbons give. The oil and bromoil prints fall below either by their loss of contrast and liveliness. We think Mr. Marshall could do better in these with a stiffer pigment, more time in pigmentation and severer self-criticising—in short, "straighter" prints.

The manifold sympathies which he advocates as a principle in pictorial work certainly add a charm to his own show, which includes snapshots at bull-fights, and composed devotional works in elaborately and beautifully designed frames. We think he is right. A man who, armed with a reflex camera, only permits himself to photograph one particular variety of subject is obsessed by an exaggerated notion of the importance of his work, and certainly stands confessed a man of narrow sympathies.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between October 25 and October 30:—

DETECTOR.—No. 24,663. Photographic detector. Emma Mary Rose Stevens, 25, Church Stile, Rochdale.

BLUE PRINTS.—No. 24,917. Apparatus for making blue prints. Matthew William Walbank Mackie, 47½, Old Street, London.

CAMERA STANDS.—No. 24,993. Improvements relating to the heads or tops of photographic camera stands. Herbert Edwin Riley and George Frederick Robinson, 24, Temple Row, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR-SCREEN-PLATES.—No. 21,007, 1908 (October 6, 1908). The invention constitutes an addition patent to No. 20,971, 1908,* in which is described a method of making polychromatic screens, where the coloured elements of the screen are produced by emulsifying a liquid in another liquid, in which the former is entirely or practically insoluble.

The present invention relates to improvements in the manufacture of these screens, and by way of example is described a method of producing a three-colour screen consisting of elements of dyed solutions.

Three suitably viscid solutions, for instance of dextrine, are dyed separately with dyes corresponding to the primary colours; thus the first portion may be red, the second green, and the third blue. To each of the three portions can be added such substances as will assist the solution of the dyes, for instance, acid or base, or substances which promote the permanency of the colours, or mordants or reducing substances. The three substances can be of different kinds. For instance, the first a dextrine solution; the second, a gum-arabic solution; and the third, an albumen solution, etc. Each of these portions is then separately emulsified in a viscid solution of, for instance, gum dammar or other appropriate resin, in turpentine oil. (A solution suitable for this purpose may consist of 30 parts of gum dammar and 35 parts of turpentine oil.)

It is mentioned in the prior application that gum dammar and various similar substances (solutions of different resins, balsams, gum resins, etc.) possess a specific emulsifying power, which means that they impart to the small particles, into which the solution

* "B.J.," April 2, 1909, p. 269.

of dextrine, etc., is divided through emulsification, the quality of not re-joining when left at rest.

It has further been found that, by using emulsifying liquids—for instance, gum dammar—of a suitably viscid state, the coloured solutions (in this case the dextrine solutions) will be divided into globules of about uniform sizes, so as to avoid or considerably reduce a subsequent operation in order to separate these globules according to size.

After emulsifying, the gum dammar (or the corresponding substance) must for the greater part be removed, which can be done by repeated dilution and decantation with turpentine oil—i.e., the volatile distillate, or some other solvent, after which the coloured globules are transferred by dilution and decantation, into a volatile liquid, preferably a distillate of petroleum—for instance, benzene. It has been proved that the use of gum dammar as the emulsifying medium and of turpentine oil for the decantation therefrom is especially advantageous for producing the globules, while the subsequent distribution of the latter on the screen support is effected in a better manner if the globules are suspended in a distillate of petroleum, such as benzene. To the volatile liquid is added a small amount of a more or less volatile substance—for instance, petroleum or solid substances, soluble in the volatile liquid in question.

The plate or film, which is to form the support for the screen, can be provided with a thin layer of lac, which is softened by infusion of the liquid in which the emulsified globules are contained. In such case a coating of caoutchouc or gutta-percha is preferable, which has the power of becoming softened or sticky.

The screen-plate or film is prepared by pouring the above-mentioned volatile liquid contained the suspended coloured globules over the same. After some time the globules will settle down, and the undermost layer will adhere to the sticky surface of the plate, while the remainder can easily be rinsed away, for instance, by means of benzene.

In cases where a suitable emulsifying liquid is used for the infusion—for instance, benzene—the above-named coating on the plate can in some cases be dispensed with. If the plate is infused with the benzene containing the coloured globules, and then left for some time, the coloured globules will only adhere to the plate in a single layer. When left at rest the benzene will evaporate quickly, and at the same time the deposited coloured globules will flatten out, so as to cover the whole plate. The less volatile substance, mixed in the benzene, will, however, separate the coloured globules from each other, so as to prevent the colours from diffusing into each other.

After being dried the plate or film is provided with a coating of lac or varnish, after which the sensitive film can be applied to the same. Jens Herman Christensen, Sterrehus, Holte, Denmark.

FILMS.—No. 13,328, 1909 (June 7, 1909). The invention relates to the sensitising of cellulose (viscose) films, prepared from a water solution in particular film obtained from a solution of cellulosic xanthate of soda. Such films are first dipped into a bath of water, so as to swell them. In this state they are at once dipped into a bath of a chloride, bromide, or iodide. Owing to the swollen state of the film at the moment of its immersion into the bath, the salt penetrates into the film instead of merely forming a superficial layer.

The swelling required for the impregnation could be obtained without using the water bath, but using a water solution of the chloride, bromide, or iodide. In this single bath the film would both swell and become impregnated with chloride, bromide, or iodide. After removing it from the salting bath the film can be dried or immediately dipped into a silver or sensitising bath. E. Brandenberger, Thaan, Vosges, France.

WASHING TANK.—No. 8,455, 1909 (April 7, 1909). The invention consists of a tank furnished with a lid, which forms a water-tight joint over the tank, and with a rack for the reception of the plates. There is one tap in the lid for the inlet of water and another at the base of the tank for the outlet. There is also a perforated plate in the lid by which the entering water is broken up into a number of streams. Herbert Frederick, 11, Brynland Avenue, Bishopston, Bristol.

CINEMATOGRAPH MECHANISM.—No. 25,666, 1908 (November 27, 1908). The invention is an automatic extinguisher of cinematograph

films, which has caught fire in the lantern. It is found that when a film is enclosed in a box and is passed through a slit, which is just large enough to take the size of the film, both in thickness and width (the box being closed), and on the film being set on fire outside the box, the flame will not spread farther than the aperture, and will not pass through the slot to the interior of the box, owing to suffocation of the flame. To make it practically useful a round or square box is provided with a closely fitting lid. On the outside of the box is a small square frame, which takes two rollers, preferably made of metal. These two rollers fit very closely into the frame on the four sides, and are separated from one another only just the thickness of a film, but leaving just sufficient room for it to pass through without any friction.

In order to make the box applicable to any existing type of cinematograph, two angular pieces are fixed parallel to one another, forming the letter U upon the box, the angle pieces being grooved on their inside upper edge. By using a suitable plate and screw fixed in the middle, the plate can be slipped into the slots, thus forming a slide, and be fixed by means of the screw up against a spool arm. Leo Kamm, 27, Powell Street, Goswell Road, London, E.C.

CINEMATOGRAPH MECHANISM.—No. 11,546, 1909 (May 15, 1909). The invention relates to the mechanism of a cinematograph camera, and requires the numerous drawings in the specification for its explanation. George William Curtiss, 2,101, Woodland Avenue, Kansas City, Missouri, U.S.A.

CINEMATOGRAPH FILMS.—No. 14,345, 1909 (June 20, 1908). The invention relates to the production of cinematograph pictures (to be viewed by reflected light), printed from half-tone or other photo-mechanical blocks. The chief claim is for a process which consists in producing a printing block, the entire surface of which is occupied by pictures arranged side by side without spaces between, cutting the impressions produced by means of this block into strips and sticking these strips upon a continuous support of sufficient width to leave margins for the reception of the driving perforations, and then forming these perforations in the film. Charles Dupuis, 18, Rue de Paris, Vincennes (Seine), France.

Analecta.

Extracts from our weekly and monthly contemporaries.

Removing Stains from Gaslight and Bromide Prints.

A simple and effective stain-remover for gaslight and bromide prints (writes Mr. N. Morris in "Photography and Focus" for November 9) can be made by dissolving an ounce of hypo and 500 grains of alum in half a pint of boiling water. The hypo should be dissolved first, and the alum then added at once, while the water is still very hot. The print that is to be cleared is first immersed in a hardening solution, made by dissolving 25 grs. of alum in 4 oz. of warm water, and it is left in this bath for five minutes. The solution is then poured off, leaving the print in the same dish. The clearing solution, as above, is divided into two parts; the first, while still hot, is poured over the print, and the dish rocked as in developing a plate. The other part is poured into an enamelled iron dish and put on a gas stove, where it can be kept hot, but not boiling. If the clearing is not completed before the first lot of solution is cold, it may be poured off and the second lot applied, but unless there are a number of prints to be cleared this will very seldom be required. When the clearing is complete the print is placed in a dish of clean water, and any deposit that may have settled on it removed by gently wiping it with a tuft of cotton wool. It is then washed in running water in the usual way. There are two points to note: One is that if the solution is used too hot it will commence to tone the print, and the other that if it is not hot enough it will not work.

Oil Printing by Gaslight.

The extreme sensitiveness to light (writes Mr. H. B. Bradley in "The Amateur Photographer and Photographic News" for

November 9) of the sensitised paper used in oil printing is well known to all oil workers. But that it is rapid enough for printing by incandescent gaslight does not appear to be known to many. To these workers the following may prove interesting:—A half-plate Rodinal developed negative, free from stain and of average density, was selected. A full-plate piece of paper (Autotype Co.'s Special No. 2 Toned) was taken and sensitised with a solution made up of one part saturated solution of ammonium bichromate to two parts methylated spirit.

The sensitised paper was pinned up in a dark cupboard for ten minutes to dry, and then placed for half a minute in a moderately warm oven to drive off any lingering moisture. It was then placed in contact with the negative, and an exposure of one hour was given, at a distance of five inches from an ordinary-size upright incandescent gaslight. A whole-plate frame was used.

At the end of this time the paper was taken out of the frame, quickly washed in several changes of tepid water, and left to soak for twenty minutes in water which was lukewarm. On proceeding to ink up, the print showed signs of over-exposure, taking the ink too readily all over. From commencement to finish the print had taken about two hours. A shorter exposure—say, three-quarters of an hour—would have been sufficient for a good print.

New Books.

Colour Blindness and Colour Perception. Second Edition. By F. W. Edridge-Green, M.D., F.R.C.S. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 5s.

Though this book has no direct bearing on photography yet it contains a great deal of interest to those photographers who make a study of colour. The author has a theory of his own with regard to colour perception, and does not accept either the Young-Helmholtz or Hering theory, and though to this extent he may be looked upon as unorthodox, yet it cannot be denied that he makes out a very strong case for his own theory. So far as we can gather in a first perusal his idea seems to be that colour blindness is a mental, not a visual effect, so that blindness to, say, red does not imply lack of sensitiveness to red in the eye, only a mental lack of perception of the red-sensitiveness. He classifies his subjects according to the number of colour units they can perceive in the spectrum, and points out that normal eyes see only six. A few exceptional persons can see seven, while the different degrees of colour-blindness are classified according to the number of units less than six that can be distinguished. If portions of the spectrum are isolated by a slit of variable width, it will be found that quite an appreciable part of the length of the spectrum appears monochromatic. This forms one of Dr. Edridge-Green's units, six of which form the normally visible spectrums. An interesting digression from the subject of colour applies a similar theory to light and shade. "A person with defective perception of shade will put two shades of grey together as exactly alike when the match is markedly incorrect to a normal-sighted person. This defect is not necessarily associated with diminished colour perception. Observers do not take sufficient account of mental deficiencies of perception when reasoning upon the functions of the senses. Thus we cannot say for certain that a photograph represents the image on the retina; in reality, it may be far more complicated." This we read to mean that the range of gradation from white to black in a photograph may appear too steep to one observer and too gradual to another. By an unfortunate omission the colour plates bear no reference numbers by which they may be identified in the text, so some of the examples are difficult to follow. The book altogether is very interesting, and well worth reading by photographers interested in colour problems, for the author's theories, though very revolutionary, are suggestive in several ways.

THE NEW CAMERA CLUB.—A meeting of those interested in the formation of the New Camera Club will be held at the Gaiety Restaurant, Strand, on Tuesday, the 23rd inst., at 5.30 p.m., at which the Earl of Crawford has kindly promised to preside. All those interested are welcome. A substantial guarantee fund has already been formed.

New Materials, &c.

Phosphate Matt Lantern Plates.—Made by Paget Prize Plate Co., Watford.

With these plates we have the novelty of a matt emulsion upon glass, the result of which is an image that to all appearances is on a very finely ground glass surface. The treatment of the plates is precisely the same as that of the Paget Phosphate paper and clear lantern plates, but in printing a rather longer time must be given. We found that a negative of good P.O.P. printing quality required an exposure of about two minutes at a distance of one foot from an incandescent gas burner to give a dark purple-brown tone, while five minutes gave a good red-brown. A black tone was obtained with 45 seconds exposure, and a good red one with ten minutes. The developer is metol, and acetic acid as used for the paper, and an acid fixing bath applied for one minute, followed by half-an-hour's washing, completes the process. The plates sent to us were of stereoscopic size, and the opalescent matt film gave an excellent effect in the stereoscope. The grain is a little obvious owing to the image and the grain being on the same plane, and both in focus together. Of course, a finely ground surface on the back of the plate is the best way of producing an opalescent background, but to get this effect with ordinary plates we must either make reversed transparencies or use plates ground on the back, both of which complications are inconvenient. Nothing can be more simple than the process of using these Matt Phosphate plates, while the results are excellent. It may be noted that the shadows, though opalescent, are perfectly bright without any of the muddy effects that we so often get on matt paper. We have heard it stated that phosphate emulsions tend to give lights without details, but no such effect is observable with these plates. If exposure and development are both sufficient, whites full of detail are easily obtained. A peculiarity of these plates is the fact that it is apparently difficult to spoil them. The first plate we exposed failed to develop after several minutes treatment, owing to the coldness of the developer. Thinking it was a hopeless case of under-exposure, we took the plate out and let it dry without any washing, but in the drying process the image appeared. On discovering this we took the half-dry plate, treated with some fresh developer, and obtained a black tone result slightly fogged owing to exposure while drying, but free from irregular markings. Another plate by accident was dropped into a dish containing stale developer which only covered half the plate. On observing this we simply poured off the developer and applied fresh, and again secured a result quite free from any markings. Such tricks as these cannot be played with ordinary emulsions, and it is evident that phosphate plates should be a boon to careless workers. It may be worth noting that exposure to air has apparently a strong accelerating effect on the development of these plates; development can therefore be shortened by occasionally lifting out the plate or pouring off the developer at intervals.

"Ensign" Greeting Cards for Photographers. Made by Houghton & Co., Ltd., 88 and 89, High Holborn, London, W.C.

Among the cards which Messrs. Houghtons describe in their newly issued eight-page quarto list, in every instance by aid of half-tone illustration, will be found designs suited to buyers of every degree of taste and pocket. Those who prefer formal designs in the shape of a card without colour or ornate decoration will doubtless select a design such as No. 2,131, consisting of a cream folder embodying a slip-in mount of the same tint, and on which to cover the single word in gold blocking, "Greetings." This is made for quarter-plate prints either upright or oblong, in each case at 1s. per dozen. A step towards the use of more ornate designs is represented by Nos. 2,053 and 2,054 for circle prints of 2½ and 2⅞ inches respectively. These mounts are of cream ivory card with white embossed slip-in folder, and a colour design in cream, gold, and brown, with the words "Good Wishes." The price is 2s. 9d. and 3s. 3d. per dozen. There is more colour in Nos. 2,163 and 2,164 of brown linen-surface paper with dark-brown design and embossed holly berries. The wording is "With All Good Wishes," and this mount is made for prints 3½ by 2½ or quarter-plate, in each case upright and costing 2s. and 2s. 6d. per dozen. A further stage in the use of embossing and colour in the ornamentation of the mounts is represented by No. 2,181—a dark-green mount

for upright postcard prints. The front bears a decorative panel of poppies and gold leaves with the words "Best Wishes." These mounts are sold at 2s. 3d. per dozen. We advise those who are deciding to send Christmas photographic missives to obtain Messrs. Houghtons' list, the illustrations in which very clearly show the design of the card, though they cannot give any idea of the very choice surfaces of paper and colour of design which have been adopted. This is done with great exactness in the short printed description under each illustration. We should mention also the series of calendars suitable for prints from $3\frac{1}{2}$ by $2\frac{1}{2}$ to postcard size, and issued at prices from 2s. 9d. to 3s. 3d. per dozen, in each case allowing of the insertion of a print in a slip-in mount.

"Noctona" (Gaslight) Paper. Made by John J. Griffin and Sons, Limited, Kingsway, London, W.C.

It might be thought by those familiar with the many varieties of "gaslight" papers upon the market that in adding to their number a maker could hardly be expected to contribute anything in the way of simpler manipulation or distinctiveness of quality. But in introducing a new gaslight paper, to be known as "Noctona," Messrs. John J. Griffin and Sons (whose long experience, both as vendors and makers of this type of paper, has stood them in good stead) have certainly sustained their claim to provide the professional—not to say the amateur—worker with further facilities in the practice of this method of printing, whilst at one and the same time they should most assuredly have secured a place in the affections of the dealer by doing this without issuing more than three different brands of the new paper. These three, even, are different only in surface, consisting of "Glossy," "Satin," and "Pearl Matt."

Referring now to the extra simplification of gaslight printing when using "Noctona," it should be explained that with each packet of paper Messrs. Griffin supply a very simple exposure-meter consisting of a multi-strip of graduated tints which is placed between the negative and the printing paper, and an exposure given which should certainly be several times what is judged to be the right time. On developing this print the portions bordering the meter will, of course, be grossly over-exposed, but the sections under the different tints of the meter will—one or other of them—show a correctly exposed and developed picture. The total time during which the paper was exposed is then divided by the number marked on this tint, and the result is the correct exposure for the negative. This method we found to work out quite accurately in practice, and our exposure of the second piece of paper in the packet gave us a print which was as good as could be desired.

Further, in addition to this feature, the "Noctona" paper allows of manipulation which permits of extra contrast or extra softness being obtained according to the negative which is being used or to the character of print desired. If greater contrast is required than is given by correct exposure, the method is to give a longer exposure and remove the print quickly from the developer. Contrary to what users of bromide paper might expect, this method does actually give a considerable increase in the contrast in the print, and is particularly useful when working from negatives which are unduly flat. Treated in the normal way, "Noctona" is very suitable for negatives which print well in P.O.P., and have a fair degree of contrast. It does not give the extra, almost hard, results which many gaslight papers are adjusted for, but the method just mentioned is a valuable means of securing extra contrast when it is required. As regards obtaining softness when working from negatives of extra hard quality the method here again is one which experience with other development papers may at first appear to contradict; the print is given a shorter exposure and allowed to remain longer in the developer. Under these conditions "Noctona" gives a print with full detail but without the strength in the shadows which from such negatives are usually an asset in the print. In making use of this method there is, of course, no limit to the time in which the print may be kept in the developer, but as soon as it is seen to gain no further intensity it is naturally removed. If it has not sufficient depth the remedy is to expose another piece of paper, giving a slightly longer time.

In addition to these qualities, which we think will of themselves recommend the paper to both the amateur and commercial worker, "Noctona" proves an excellent paper for prints to be sulphide-toned, that it may be fairly described as answering to every requirement of a development paper for contact printing. The developer recommended, and the one which we used, is the familiar "Mequin" for-

mula, the composition of which is given in the instructions, whilst the developer is put up in cartols and packets at moderate prices, as is also the acid fixing bath. For this latter, however, we are glad to see that Messrs. Griffin recommend the simple formula of hypo plus a little metabisulphite, than which we know of no better acid bath for either negatives or prints. "Noctona," we should add, is issued at the standard prices, is listed in all sizes up to 15 by 12, and is obtainable also as postcards in packets of eighteen (1s.), one gross and one thousand.

ROTARY CHRISTMAS POSTCARDS.—The Rotary Photographic Company, Ltd., send us specimens of their sensitive postcards for the Christmas season, issued as "Rotox" (gaslight), "Rotograph" (bromide), "Roto" (P.O.P.), and "Rotona" (self-toning). The cards, in the case of each grade, bear reasonable designs in two colours, and include such up-to-date subjects as motor-cars and hand-cameras.

CREAM ANTIQUE SELTONA.—The Leto Photo-Materials Company, Ltd., have just issued a new variety of the antique "Seltona" placed on the market about eighteen months ago. The new paper has the delicate linen-like surface of the ordinary "Antique," but is of cream tint, this colour of ground harmonising excellently with the brown and purplish-brown tones obtained on the paper. For the present this new grade of the renowned self-toning paper is issued in paper only, but postcards and "Boardoids" will appear in due course. The price is that of Seltona itself.

CATALOGUES AND TRADE NOTICES

PROFESSIONAL DISCOUNTS.—The firm of Jonathan Fallowfield sends us a list (prepared for private circulation among bona fide professional photographers) of the discounts allowed off the prices of the chief requisites employed in a studio. The list, in the case of each article, gives a page reference to the indispensable Fallowfield "Annual," where goods are priced, described, and illustrated.

SECOND-HAND APPARATUS.—The Tella Camera Company, of 68, High Holborn, London, W.C., has issued a list of second-hand photographic apparatus, which they are offering at greatly reduced prices. This includes a large variety of cameras (hand, stand, field, and reflex), lenses, tripods, roll-holders, changing-boxes, shutters, enlargers, and lecture lanterns, together with a variety of sundries too numerous to mention, but all of interest to the photographic worker. The firm also draw special attention to a number of half-plate triple extension outfits, which they are now offering at the low price of £2 12s. 6d. Those desirous of obtaining bargains in photographic requisites should apply to the Tella Camera Company at the above address for a copy of this comprehensive list.

FORTHCOMING EXHIBITIONS.

- November 10 to 13.—Hackney Photographic Society. Sec., Walter Selve, 24, Pembury Road, Clapton, London, N.E.
- November 10 to 13.—Cambridge and District Photographic Club. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.
- November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 29 to December 2.—Lancaster Photographic Society. Entries close November 20. Sec., Thomas Holt, 4, Parliament Street, Lancaster.
- December 4, 1909, to January 1, 1910.—Southport Photographic Society. Entries close November 15. Sec., J. McLellan, 2, Pilkington Road, Southport.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.
- 1910.
- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

THE ILLUMINATING ENGINEERING SOCIETY.—The opening meeting of this society will take place on Thursday, November 18, at 8 p.m., at the House of the Royal Society of Arts (18, John Street, Adelphi, London, W.C.), when a brief report of the progress of the Society will be presented by the Hon. Secretary, and the inaugural address will be delivered by Prof. Sylvanus P. Thompson, D.Sc., F.R.S., the first President of the Society.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 12.

Salisbury Camera Club. "Autotype Carbon." Demonstration.
Skipton Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Colne Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Photographic Society of Ireland. "Telephotography." C. P. Goerz, Ltd.
Manchester Amateur Photographic Society. "The Thames Valley." J. McIntosh.
Paisley Philosophical Society. "Ensyna." F. J. Stedman.
Mill Camera Club. *Photography 1909* Lantern Slides.

SATURDAY, NOVEMBER 13.

Manchester Amateur Photographic Society. "Rambles and Scrambles on the Pacific Slope and in the Yellowstone Regions of the Far West." Harold Edgar Young.

SUNDAY, NOVEMBER 14.

South London Photographic Society. Excursion to Wimbledon.

MONDAY, NOVEMBER 15.

Southampton Camera Club. "Picturesque Holland." Rev. John Heath.
Morpeth Y.M.C.A. Camera Club. "Sports and Pastimes with the Goerz-Anschutz Folding Camera."
Southport Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
South London Photographic Society. "Light and Shade." P. Bale Rider.
Leeds Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Stafford Photographic Society. "Ozobrome." Herbert A. E. Hey.
Longridge Camera Club. "Autotype Carbon." Demonstration.
Calceuth Camera Club. "Autotype Carbon." Demonstration.
Catford and Forest Hill Photographic Society. Print and Lantern Slide Competition.
Scarborough and District Photographic Society. "Owre the Border and Awa'." Robert Mackay.

TUESDAY, NOVEMBER 16.

Royal Photographic Society. "Behind Birdland's Veil." Oliver G. Pike.
Barrow Photographic Society. "Autotype Carbon." Demonstration.
Blyth and District Camera Club. "Autotype Carbon." Demonstration.
Padiham Photographic Society. "Autotype Carbon." Demonstration.
Otley and District Camera and Art Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Dumbarton Camera Club. "Ensyna." F. J. Stedman.
Hackney Photographic Society. "Ensyna." F. Marshall.
Nelson Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Manchester Amateur Photographic Society. "Intensification and Reduction." Harry Wade.
Leeds Photographic Society. "The Platinotype Process." The Platinotype Co.
Worthing Camera Club. "Home Portraiture." P. R. Salmon.
Glasgow Southern Photographic Association. Selection of Slides for Federation Lantern Slide Competition.
Seacombe Victoria Photographic Society. "What can be done with a Hand Camera." C. P. Goerz, Ltd.
Birmingham Photographic Society. "One Minute Development." Demonstration. Harold Baker.

WEDNESDAY, NOVEMBER 17.

Croydon Camera Club. "Electric Lights for the Dark Room." W. H. Smith and E. A. Salt.
North Middlesex Photographic Society. "Gaslight Printing." M. Fraser Black. Night Photography Competition.
Borough Polytechnic Photographic Society. Lantern Lecture on 1908 Affiliation Prints.
Woodford Photographic Society. "Gothic Architecture." Grose Lloyd.
Sale Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Darwen Photographic Association. "Printing, Developing, and Toning Velox Paper." W. F. Slater.
Dennistown Amateur Photographic Society. "Ensyna." F. J. Stedman.

THURSDAY, NOVEMBER 18.

Blenheim Club. "Reminiscences of Spain." W. Pringle.
Handsworth Photographic Society. Annual Lantern Slide Exhibition and Competition.
Jarrow Camera Club. "Autotype Carbon." Demonstration.
Eastbourne Natural History Society (Photographic Section). "Stereoscopic Photography." C. P. Goerz, Ltd.
Bolton Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Liverpool Amateur Photographic Association. "Large Prints from Small Negatives." W. F. Slater.
Watford Camera Club. Fakes and Dodges by Members. Holiday Lectures.
L.C.C. School, Bolt Court, E.C. "The Selection of Photographs and Drawings for Illustrated Papers." A. Johnson.
Leek Photographic Society. Open Whist Drive.
Leigh Photographic Society. "Bromoil." S. H. Williams.
Rodley, Farsley, Calverley, and Bramley Photographic Society. "Ozobrome." J. Womersley.
Midlothian Photographic Association. "Light: Its Nature and Use in Photography." Dr. Drinkwater.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 2, the president (Mr. J. C. S. Mummery) in the chair.

At this meeting the new house of the society, at 35, Russell Square, was formally opened. The new premises provide more accommodation than that at the previous home of the society on the other side of

the square. The lecture-room accommodates more sitters than did the room at No. 66, and gives everyone an uninterrupted view of the lantern screen and the lecturer; it also forms an excellent gallery for displays of photographs, and the walls have been provided with a very suitable ground of cool green on which to hang the photographs, a deep frieze of yellow surmounting this space. The society has also built a small studio at the rear of the house on the ground floor, and in the basement has provided ample facilities in the way of workroom, dark-rooms, and enlarging-room, this portion of the premises—like other rooms in the house—being well warmed by radiators, and in other ways comfortably furnished. The library gains in convenience in the new premises, in that the whole of the society's volumes—both books and periodicals—are now placed in the library proper and in the room immediately adjoining it instead of on the floor above, as was necessitated at the old house. No. 35, which, we understand, has been secured by the society on a lengthy lease, will therefore form a most convenient and comfortable headquarters for many years to come. Mr. Arthur Marshall prefaced his address on the one-man show which is now at Russell Square by expressions of congratulation to the society on the fitting and decorations of its new house, and, we are sure, voiced the feeling of every member in referring to the valuable services which had been rendered to the society by its president (Mr. Mummery) in the matter of the interior decoration and other arrangements.

Mr. Marshall's address on the pictures by himself to the number of about eighty, which are now on view, dealt chiefly with the aims he had put before himself in his photographic work. He took exception to the suggestion frequently made that a photographer should confine himself to one class of subject. He had sought to express by photographic means the beauty of many phases of landscape and types of people, which he had sought chiefly in Holland, Spain, and Italy. Mr. Marshall had some frank things to say of styles in photographic pictorialism. "Place an empty barrel on the garden wall, with a geranium beside it, photograph it against the sky, but under-expose it, and when the picture appears on the walls of our leading exhibitions—for it could hardly be refused—some persons will say that it has a 'bold conception of line,' others that 'the masses are well balanced, others, again, that 'it has striking decorative qualities.' The meaning of our art should be to produce pictures, and not freaks—work that would live, and with which we could live." He went on to give instances of criticisms which, he alleged, were misplaced. He criticised critics whose own work was done in one class of subject, those also who wrote, he thought, from a narrow point of view and with deficient observation, and others whose only qualification appeared to be that of literary expression. As to his methods, Mr. Marshall said he did all his work with a reflex camera, a type of instrument which he puts at the head of the list.

In the short discussion which followed, Mr. W. Thomas thought that the critic's comments were invariably in the nature of a revelation of deficiencies in the photograph which the photographer himself could not perceive. Mr. J. C. Warburg expressly commended some of Mr. Marshall's photographs, the predominant charms in which were the effects of light and shade on cobbled pavements. He regarded Mr. Marshall as the prince of pavement-artists. We refer the exhibition in another column, which report, as well as the foregoing account of last week's function, were unavoidably crowded out of our last issue.

Meeting held November 9, the president (Mr. J. C. S. Mummery) in the chair. A large audience attended to hear the presidential address on the subject of the influence of painting on photography. Mr. Mummery, to sum up his argument in a few words, declared that painting had chiefly influenced pictorial photography by reason of the fact that photographers had sought to imitate the methods as well as the effects of painters with resources which were altogether limited. The result had been a series of phases of pictorial photography, each of which was characterised by the pursuit of some method of the painter to an extreme which led workers to avoid the essential qualities of the photograph. While portrait photography had been an immense social boon to humanity, and while landscape work had proved a hobby that led to much social improvement, yet these social qualities were not art. So far as concerned the art influence of photography, he would refer to its effect on painting, for this could not be laid to the credit of the photographer, inasmuch as the methods which were inspired were not theirs, whilst, indeed, there were many who

ioned whether painting had gained by that influence. But in answer to the question whether photography itself could be called an art, it might be said that the prejudice which existed among painters arose from the affectations of photographers, not from the essential failing of photography. There were many ambitious attempts to rival painters, but in many of them the result was a doubtful imitation. Turning to the historical development of photography, the scientific men who were its creators placed its facility of detail and definition first in importance, and thus inspired a reaction in the direction of diffusion, a method which first gained notoriety fifty years ago at the hand of a past president of the society, Sir W. J. Newton. On the principle that the success of any method is its justification, it might be doubted whether diffusion had actually justified itself. Painters invariably delighted in good drawing, and it was that quality in photography which they admitted and the absence of which they regarded as a weakness. Painters studied to suggest detail, even if the labour of actually painting it was impossible, and many artists sacrificed breadth and deliberately sought detail.

A good instance of one phase of pictorial photography which had sprung from the attempt to imitate the methods of painters was that in which combination printing was laboriously used, particularly in figure studies. It appeared satisfying as art to the men of that time, but both in the realm of figure study and in the modified field of landscape work it had rarely shown itself capable of giving values which were correct, and this fact had led those practising it to mask the defect by resorting to obscure definition, a method which had afterwards been further developed to an extreme. When they studied, as they had recently had an opportunity of doing at the Salon, the work of the painter, D. O. Hill, who employed the photographic methods of his day, they saw he made use of photography's rendering of detail and exercised his art on the lines where photography could give him its best help. The modern pictorial worker, however, had seemingly come to be somewhat ashamed of what photography could do, and sought to add something to it, and the gum oil print in monochrome and colours was the latest outcome of this tendency. Fashion had entered very largely into these phases of pictorial work with the camera, but Mr. Mummery declared that we should look for the development of photography as an art along the lines of its own characteristics. One should not be afraid of its origin. The art of photography should be a logical development of its own craftsmanship. Such a status of pictorial work, he concluded, was certainly logical, might be possible, but was not yet.

The subsequent proceedings spared the audience one of those prolonged and frequently tedious discussions of an art topic which are not infrequent at Russell Square. On the proposition of Mr. W. B. Ferguson, seconded by Mr. A. H. Lisett, a vote of thanks was accorded Mr. Mummery for his address.

Some objects of interest were then brought before the meeting. A negative made on an Ilford white label plate, exposed and developed by Mr. Gilbert Walker sixteen years after manufacture, was shown. Its excellent qualities proved an eloquent testimonial to the keeping powers of the emulsion. Four other Ilford plates, now twenty-one years old, remain, and it was suggested that one of them should be exposed and developed by the Secretary, and the remaining three put aside and subjected to the same process at intervals of, say, fifty years. A device by Mr. Gilbert Walker for attaching a focussing magnifier "movably" to the camera was shown. It consisted of a rectangular frame, which could be clipped to the back of the camera. The magnifier was carried on a small panel, which again was mounted in another panel, the full width of the containing frame. One panel had a vertical movement and the other horizontal, the two in conjunction allowing of the magnifier being moved even to the extreme corners of the ground glass. An album of photographs illustrating the Zeiss stereoscopic apparatus and the Zeiss Stereo-Comparator had been presented to the society, and was shown.

IND-LOTHIAN PHOTOGRAPHIC ASSOCIATION.—To a crowded meeting Mr. Inglis Clark gave a most complete explanation and demonstration of the various methods of colour photography. He explained fully by means of diagrams the principles of three-colour combination processes, and showed by micro slides the arrangement of colours on the different single exposure plates, such as the Autochrome, Autochrome, etc. Dr. Clark then dealt with the practical working of the Autochrome process, and advocated a more simple procedure

than usually recommended. He showed that after exposure the plate could be rendered insensitive to colour by immersing in a bath of bisulphite of potash for half a minute and washing for half a minute before developing, which could then be carried out in an ordinary yellow light without fear of fog. For developer the lecturer recommended rodinal, and advised full development, as by this means the greatest brilliancy was obtained. The plate is then reversed in acid bichromate of potash, and afterwards re-developed—which completes the operation.

To prove the thorough practicability of his methods, Dr. Clark exposed by magnesium flash an Autochrome plate on a still-life study, which was developed at once and projected on the screen.

In answer to a question regarding intensification, Dr. Clark said that instead of the usual silver intensifier he preferred to use a dilute solution of bichloride of mercury and blacken with sulphite of soda.

On the conclusion of the practical portion of the demonstration the lecturer projected on the screen over 100 examples of colour photographs of Scottish and Continental scenery under all conditions of light and season, showing the complete power of the colour plate to render all subjects in a pleasing and pictorial manner. A feature of this exhibition was the use of an aluminium screen made by Zeiss, Jena, which, combined with a powerful lantern, gave a most brilliant representation of the various subjects.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—There were strange doings in the West End on Friday evening, October 29. Passers-by in Leicester Square noticed that the gardens, which, after dusk, are usually deserted and still in the midst of all the bustle and turmoil of the theatre world, were occupied by a score or so of strange men. One person looking over the railings suggested that a German band was about to play, but it was only a company of members of the N.M.P.S., who, led by Mr. A. H. Blake, the popular president of the Society of Night Photographers, were making their first endeavours to portray London (or a part thereof) by night. They met at 7 o'clock, and, permission having been obtained by Mr. Blake, entered the gardens, and with fast plates and large apertures set to work to record the fine effects of light and shade obtained through the trees facing those two centres of education, the Empire and Alhambra. The fountain in the centre also came in for a good deal of attention, and those photographing it from the lower side of the gardens had quite a large and, no doubt, appreciative audience. Although the onlookers were numerous on occasion, they were kind and forbore to jeer as they might have done. Perhaps the novelty of the scene or the madness of the photographers rendered them tongue-tied.

After having made a number of exposures the members gradually drifted off in ones and twos to Trafalgar Square, where they were not only known to, but expected, by the police. The N.M.P.S. president had foreseen and prevented possible difficulty by obtaining permission from Scotland Yard for his little band of enthusiasts. There were a few remarks from the onlookers showered through the gloom of the square on the heads of the photographers—remarks more or less witty, but mostly unprintable. Some of the members found this place more to their taste than Leicester Square, for once in the gardens there they had to stop till the custodian let them out. Here was glorious freedom. As soon as a lens was uncapped a word to the next man to look after his camera for a second and the owner was off—where to, goodness knows. What they variously said when they came back to cap their lenses again was that they had been along the Strand a little way for a cigar or down to the Embankment to see if it would be worth while going down there afterwards. Ah, yes! such is night photography.

The Embankment had been in the programme, and it is thought that some members eventually reached there, but the majority adjourned between 9.30 and 10 o'clock to a pre-arranged rendezvous at a well-known Strand hestelry and regaled each other, between the intervals of absorbing refreshment, with tales of what they had done and how they did it—just as fishers and golfers do. One blithe spirit handed round at 10.15 a night photograph of the Embankment as one of that night's taking, but, strange to say, it was not received with the enthusiasm which it no doubt deserved.

On the whole a most enjoyable outing it was, and, in a manner, wholly new to the majority of those present: the notable exception being, of course, Mr. Blake, whose kindness and guidance had

done so much to help the novices on their way. Altogether there were twenty-three members present, who between them exposed about 120 plates. The results are awaited with interest, and perhaps apprehension.

THE PHOTOGRAPHIC CLUB.—The Photographic Club's annual general meeting was held in the club room, Red Cross Hotel, Paternoster Square, on Wednesday, the 3rd inst., Mr. F. A. Bridge in the chair. The report of the committee and the balance-sheet were adopted. The election of the officers and committee for the ensuing year resulted as follows:—Trustees: Messrs. F. A. Bridge and H. Snowden Ward. Committee: Messrs. R. R. Beard, T. W. Derrington, G. Edey, E. W. Foxlee, Hans Müller, Alexander Mackie, E. W. Parfitt, C. H. Skillman. Hon. Sec.: Alexander Corbett.

Commercial & Legal Intelligence.

RHYL PHOTOGRAPHER'S AFFAIRS.—Last week, before Mr. Registrar Glynne Jones, Mr. Tobias, assistant official receiver, publicly examined J. B. O. Shepherd, photographer, Rhyl, touching his bankruptcy, in which on total liabilities of £122 he showed a deficit of £83. The bankrupt, who is 29 years of age, commenced business as a photographer in May, 1904, without capital. He had not had any training in that work, having formerly been a barman. But though he had not a penny in the way of capital, he took premises at a rent of £55 per annum on a lease of seven years.

Asked how he expected to be able to pay his rent under such circumstances, the bankrupt said he was only a young man at the time, and expected to do well, which, as a matter of fact, he did at first. All his takings he took to live on, and admitted that thus to a certain extent he had been living on his creditors.

Asked how he came to reply to a money-lender that his furniture had cost him £250, he said that his house was insured for that amount, and he thought he was justified in stating that. The bulk of the furniture, however, did not belong to him. The furniture taken away was removed after the High Bailiff had taken possession. Nothing was removed before his entry. He knew nothing of the removals, and had not connived at them. They were effected in his absence by his sister-in-law, who claimed them as hers. His father-in-law had also removed some things which he claimed. He would have prevented the removal had he been aware it was intended. His sister-in-law, Mrs. Mary Shepherd, claimed the furniture she took away because she had lent him £3 17s., and saw no way of getting it back.

Mr. Tobias asked that the examination be closed, and intimated that the Official Receiver did not propose to recognise any of the claims to the furniture.

The bankrupt said he was sure his sister-in-law would either return or pay for the furniture she had removed.

The examination was then closed.

WRONGFUL DISTRAINT AT MANCHESTER.—An animadversion on the practice of trading under fancy names was made by Judge Parry at the Manchester County Court last week, in an action in which Mrs. May Astbury, photographic enlarger and dealer, of Grosvenor Street, Manchester, and of other towns, claimed damages for wrongful distraint committed by Robert Gray Briggs, glass dealer, of Leicester.

Mr. Wise, for the plaintiff, said that the matter arose out of the business which formerly belonged to Max Muenzer, a bankrupt. Muenzer sought to assign his various businesses in Manchester and elsewhere to a limited company, because, after lengthy legal proceedings, His Honour found the assignment to have been fraudulent.

The business was then placed in the hands of trustees for the benefit of creditors, and it remained in their possession until March 8 last, when it was purchased by Mrs. May Astbury, who was formerly in Mr. Muenzer's service.

The defendant in the present case supplied glass to the Leicester branch of Muenzer's (which went under the name of the Great Britain Art Company) in November and December, and obtained judgment against that company; but instead of distraining in Leicester, he waited until the transfer and then distrained on Mrs. Astbury's premises in Grosvenor Street, Manchester.

Plaintiff stated that she had continued the business in many places under the name of the Great Britain Art Company, including Leicester, but she denied having had any interest in it before Muenzer became bankrupt.

In reply to his Honour, Mr. Higham, for the defence, said his contention was that Mrs. Astbury was the owner of the Leicester business from the first.

His Honour: It is perfectly amazing to me how people in business will give credit to a "Great Britain Art Co." without finding out who is responsible for its payments. I believe that if a firm were to start under the name of "Undischarged Bankrupts" any amount of credit would be given.

Mr. Higham: Mr. Briggs had previously traded with the company and had been paid.

His Honour: As long as you have got confidence you go on trading with somebody you know nothing about?

Defendant: Yes.

His Honour: And that is business!

Witness added that the reason he made out a bill to "Muenzer Limited," was because the manager told him he would thereby get paid.

His Honour: I daresay you would have made it out in my name if you thought you would have got your money?

Witness: Yes.

His Honour described the case as an extraordinary one. The whole affair had given a great deal of trouble, but one could not altogether blame people who did not want to run straight for trading under fancy names when the trading community encouraged them to do so.

Here was a person dealing for months with a firm without making an effort to find out who was responsible for it. While unscrupulous persons could find such innocent and trusting people they would continue to make money out of them. If Mr. Briggs could afford it, as it amused him, well and good. It was what people called business and after fifteen years listening to that kind of thing he supposed it would go on for many years after he was gone.

However, the onus was upon Mr. Briggs in this case to prove that at the time he sold the goods he was dealing with Mrs. Astbury. He had failed to do that, and there must be judgment for the plaintiff for £8 7s. 6d. and costs.

THE LUMIERE Co.—Speaking on November 2 at an Extraordinary General Meeting of the London Cinematograph Co. (1909), Limited, the chairman, Mr. W. M. Borrodaile, announced a resolution to increase the capital of the company from £50,000 to £200,000. Addressing the shareholders on the expansion of the business and on the objects to which the new resources are to be devoted, he said:—Of course, there was the purchase of the Lumière business for England and the Colonies (Canada excepted). For that we are paying £50,400, half in shares and half in cash. The cash is spread over two months, and the shares are taken at a value of 20s. each, or a premium of 100 per cent. This your directors consider is a valuable contract. The secretary, Mr. Hill, and myself went over to view the business of the Lumière Co., and it struck us as being a very remarkable one. In this connection I may mention that Messrs. Lumière's reputation in the photographic and cinematograph trade is worldwide. They have held from their commencement a commanding position in the industry, and have been instrumental in bringing its development many most important inventions connected with it. They are by far the largest manufacturers of cinematograph films in Europe.

The firm was established in 1883, and its business has been so successful that, besides repaying over 70 per cent. of its issued capital, 4,180,000f., the average yearly dividends have exceeded 25 per cent., and the 100f. shares are quoted on the Paris Bourse at upward of 400f. This must be a very fine house to be associated with, and I say that in England and Ireland I have only seen two firms whose factories are anything equal to theirs—namely, Guinness and Co. Messrs. Lumière certainly have wonderful buildings, while the plants and machinery are of the best, and everything that possibly could be done has been done which will make for the progress of the cinematograph business. We calculate that the profits from the Lumière rights will amount to £22,824 per annum. That is our computation. The figures have been examined by our accountants, who think this is a conservative estimate.

He further announced alterations in the articles of association to

enable us to carry out the contract with Messrs. Lumière by appointing Mr. T. K. Grant, their representative, to be a director of this company. Mr. Grant will be of the greatest use to us on the board, as he has great technical knowledge of the cinematograph, the film, and, in fact, everything connected with the business in all its different branches. Personally, I welcome Mr. Grant on the board because he will probably keep us straight on technical points which we may not quite understand."

FAILURE OF A POSTCARD DEALER.—The first meeting of creditors was held in Scarborough on October 26, in the failure of William Nair, postcard dealer, carrying on business at 25, Queen Street, Bridlington. Gross liabilities were put at £252, due to twenty-six unsecured creditors. The assets were estimated at £14, leaving a deficiency of £238. The causes of failure were ascribed to bad trade during the last two seasons, owing to the weather. The matter was left in the hands of the Official Receiver.

DISSOLUTION OF PARTNERSHIP.—The partnership between Messrs. Sidney Walter Robinson and Otto Bruder, photographers and photographic trade enlargers, 23, High Street, Harlesden, has been dissolved. The business will be carried on by Mr. Robinson, who has changed the name of the firm from Robinson, Bruder, and Co., to Robinson and Co.

LEGAL NOTICE.—A dividend is to be declared in the bankrupt estate of Wm. Tiddy, photographer, 60, Tontine Street, Folkestone. Proofs must be lodged on or before November 20 with the Official Receiver (Mr. J. O. Morris), 68A, Castle Street, Canterbury.

NEW COMPANIES.

CARL ZEISS (LONDON), LTD.—Capital, £10,000, in £1 shares. Formed to acquire and take over as a going concern that part of the business of manufacturers of and dealers in photographic lenses, cameras, microscopes, etc., as is carried on under the style of Carl Zeiss, Jena, at the works at Bittacy Hill, Middlesex, and at Margaret Street, W. The directors are Max Fischer, Professor Doctor Rud. Straubel, Doctor W. Bauersfeld, Doctor P. Fischer, Messrs. Max Poser and Paul Henrichs. Registered office: 17, Basinghall Street, E.C.

THE H.M. ANIMATED PICTURE CO., LTD., registered office, 306, Walworth Road, S.E. Formed to build, or otherwise acquire, theatres, halls, shops, or other buildings, and to provide for the production and representation of animated pictures by cinematograph, bioscope, magic lantern, or by other methods. Capital, £400, in £1 shares. The directors are R. E. Holdon and J. W. Manley, both of 306A, Walworth Road, S.E. Private company.

News and Notes.

THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY passed the following resolution at its meeting on November 3:—"That a vote of thanks be given to the Dean of Peterborough for his kindness and public spirit in deciding to allow photography in Peterborough Cathedral without restrictions."

THE ROYAL SOCIETY OF ARTS has just issued its programme for the forthcoming season, and among the lectures announced are three which have a special photographic interest, and to which we would draw our readers' attention, namely, "Photo-Telegraphy," by Mr. Thorne Baker, to be read on November 24; "Miniatures," by Mr. Cyril Davenport; and "Printing Inks," by Mr. C. G. Zander, the two latter to be read after Christmas.

A GUIDE TO FALMOUTH.—As Falmouth is one of the few English watering-places which can justly lay claim to being both a summer and a winter resort, the little guide book issued by the Corporation that town comes as a seasonable reminder to those who may still be undecided as to where to spend the winter months, and such could do well to send a postcard request for a copy, addressed to the Town Clerk. The booklet, which is well illustrated and contains much interesting information regarding the district dealt with, forms one of the official guides published by the Health Resorts Association, 29, John Street, Bedford Row, London, W.C.

SOUTHPORT PHOTOGRAPHIC EXHIBITION.—In connection with the above exhibition, which, as previously announced in our columns, will be held in the Atkinson Art Gallery, Southport, from December 1909, to January 1, 1910, the committee have decided to extend

the time for receiving entries from November 15 to November 22, by which latter date all forms correctly filled up and accompanied by the necessary fees must reach the hon. sec., Mr. J. McLellan, 2, Pilkington Road, Southport, from whom also the forms may be obtained.

COPYRIGHT IN A SNOW-MAN.—A singular and amusing copyright question is at present being debated in the Berlin Courts. According to a Central News correspondent, one snowy day last winter some enterprising sculptors built a snow-man in the yard of a Press photographer in the likeness of Prince Bülow. The ex-Chancellor was represented in a humorous but characteristic pose, and the work was done so well that the photographer had no difficulty in selling photographs of the snow statue to an illustrated paper. The artists thereupon went to the publishers and demanded payment for their copyright. They were given £2 10s., but were not satisfied, and so the case has come to the law courts, a claim being made also against the photographer. Well-known sculptors have been called in to say whether in their opinions the snow man is a copyright "work of art" or not.

MECHANICALLY-AIDED RETOUCHING.—Mr. E. Belleoudry writes to the "St. Louis and Canadian Photographer":—"I believe you will be interested in a contrivance that I have built, consisting of a retouching desk put on the frame of an old sewing-machine. By working the sewing-machine, which puts in motion a dented rubber wheel, the negative is given a slight forward vibration, and by holding the retouching pencil to the negative, this motion of the negative enables one to retouch in about a third of the time taken ordinarily. I have been using this outfit for the last two months, and I am well satisfied with its time-saving possibilities, although one has to forget the old way of retouching, as the pencil is never in motion. I trust some mechanical genius will put such a machine on the market and make money. He is welcome to the idea, as I find that I have made enough money in the photographic business."

[We can tell Mr. Belleoudry that a device of the kind he names, but much lighter in use, will be shortly put upon the market by an English house.—Eds. "B.J."]

MR. SHAW AND THE LINKS.

To the Editors.

Gentlemen,—Is it perverseness or is it an attack of mental fog that prevents your "Writer of the Article" from seeing that what I meant—and surely said—and what Mr. Shaw meant also, was not that there ought to be a similarity of finish in the carriage-painter's and the landscape-painter's works, but that there ought to exist, but does not, a similarity of knowledge and control of tools and materials? The one, the craftsman, knows what to do and does it; the other, the artist—well, does not.

Mr. Shaw saw in the Academy any number of painters trying to do something they had no real knowledge of or ability for; he went outside the Academy and saw a painter's work, on a carriage-body, which showed a perfect knowledge of what was required, and a perfect mastery in the achievement of it. What is there in that to indict us as insisting that the only ideal for the landscape, etc., artist is the lacquer-like finish of the carriage-body? It is farcical to suppose it either of a clear-headed thinker like Shaw or such a — person as myself. Of course, the analogy must not be carried too far; no one would insist that no paintings should be exhibited that did not evidence an absolute mastery of tools, methods, or materials: but it is the countless instances of rank ineptitude that one tilts at, and that your writer would be the first to inveigh against.

The point at issue is that there are thousands of thousands of people spoiling good canvas yearly, because they have had no real apprenticeship to or training in the craftsman's side of their artistry: and they are bumptious amateurs enough to think they can do without it, and have a right to exhibit their shocking examples of it. If a

carriage-painter were to seek a job having as little knowledge of his tools, methods, and materials as the "artists" Shaw was trouncing have, he would pretty soon get the "chuck" that nine-tenths of the canvas-spoilers ought to.

I happen to know that G. B. S. agrees with me, but even if he did not, your article writer ought not to pervert the clear issue I raised for myself in my letter of last week.—Yours, etc.,

FREDERICK K. EVANS.

To the Editors.

Gentlemen,—To anyone who read your report of Mr. Shaw's lecture attentively it was surely evident that your contributor had misunderstood a portion of it, and, therefore, it was no surprise to one of your readers to see Mr. Evans's correction. It is surprising, though, to find "The Writer of the Article" still unenlightened and taking up your space with irrelevant stuff about rubbing with emery, and so forth. Might I suggest that "The Writer of the Article" should take Mr. Shaw's speech, his own comment on it, and Mr. Evans's letter, into the country with him for a week's meditation? At the end of that time, if he has not discovered that he at first did not understand Mr. Shaw, and that Mr. Evans did, he had better stay another week, and so on until light dawns.—I am, yours,

A. T. C.

To the Editors.

Gentlemen,—There are many admirers of Mr. Shaw, who very charitably construe his "persiflage" into seriousness, and forgivingly accept as fun the quite frank and serious views he advances. They do this rather than suffer their idol to be broken against the hardness of reason. Thus Mr. Shaw gets a double way out of any tight place he may be driven into. There seems to me to be no reason why his words, if they are to be taken seriously, should not be taken as he uttered them. They are certainly appalling enough, but is that any reason why we should give them the benefit of a metaphorical application? That, to my mind, would be real "perversion." He said several times very distinctly that modern painters could not paint; but that carriage painters could. He did not say anything of the ideas or subjects of painting in this connection. If he had there would have been much better analogies than carriage-painting to hammer home his point with. On the contrary, he said that painters should all serve apprenticeships in carriage painters' yards so that they could learn to do their work in the thorough way that carriage-painters did. I submit that he was expressly referring to the actual manner of painting, and that, in his mind, the carriage-door was an ideal for picture painters. Otherwise, why did he mention the carriage-door at all? Now I am prepared to admit that Mr. Shaw was fooling to amuse his audience. Mr. Evans will have it that he was serious underneath. He sees an allusion to portraying "some elusive atmospheric effect," etc., by a proper use of tools and materials in spite of the express desires of Mr. Shaw for an apprenticeship in a carriage-yard! Mr. Evans and A.T.C. are the ones who misunderstand. If they will take Mr. Shaw seriously they must reconcile the carriage apprenticeship with the atmospheric effects. They will find that difficult to do in face of Mr. Shaw's reference to the beautifully prepared canvas of an artist-friend whom he imitated by crying in a loud voice, "Jump on it, jump on it, you can't hurt it, it will last a thousand years." Is jumping on a picture a test for atmospheric effect? I ask Mr. Evans and A.T.C. They will also find it difficult to account for the comparison of Van Eyck's method with modern "loading," etc., which Mr. Shaw described as "laying on with a trowel." Finally, if a power to paint atmospheric effects was meant, and not "surface," they must explain why Mr. Shaw at once slid off into the subject of smooth P.O.P. prints, extolling them together with early painted work.

No, I maintain that your two correspondents do not understand that the clever G.B.S. knows that "trouncing" artists and the Royal Academy, and reviling Sir Joshua Reynolds is a good game to play in an audience who come only to be tickled. It is a trick that always goes down. Their misunderstanding consists in thinking that there is anything beneath the fun. They wish to take him seriously, and therefore they have to hypothecate their "atmospheric effects," etc., in order to save the reputation of their hero. My point is that if they take him seriously what he said was nonsense.

THE WRITER OF THE ARTICLE.

"STRAIGHT" PRINTS VERSUS THOSE OBTAINED OTHERWISE.

To the Editors.

Gentlemen,—In reply to Mr. Stevens, I should like to say that did not refer to retouching the negative or shading the print, which are pure photographic processes; just as legitimate as local reduction or intensification, which they in a manner resemble.

I would emphasise that I called attention to the large number of pictures, or rather, paintings that go to make up so many of our exhibitions, and which, by subtraction and addition of objects, and by an abundance of pigment of various kinds, do not in the least resemble the image as viewed upon the focussing screen. Fortunately such productions are absent from the exhibits of the plate and paper manufacturers as mentioned in my letter; also while these productions are reproduced and awarded prizes in the photographic Press, equal consideration is given to the straight worker.

I give Mr. Stevens to understand that a print may be treated in many ways, many of them giving a better picture than would have otherwise been the case; but there is a limit to such treatment if our result is to be a *photograph*, which must be a piece of work produced by the camera and the man, and in my opinion similar to the one picture of a stereoscopic slide—a totally different production to those referred to.

P. FREDERICK VISICK.

84, Melbourne Grove, East Dulwich, S.E.

A CONCENTRATED ONE-SOLUTION M.Q. DEVELOPER.

To the Editors.

Gentlemen,—We have found the following M.Q. developer quite good, and suggest it as being cheap, clear, and sufficiently concentrated to meet the requirements of your correspondent "Concentro." It is taken from the "Chemist and Druggist" of August 2, 1909.

M.Q. DEVELOPER.

Hydroquinone	5 grms.
Metol	2.5 grms.
Sodium sulphite	80 grms.
Potass carbonate	100 grms.
Potass bromide	2 grms.
Water	500 ccs.

Dissolve the metol first.

For use take one part to four or five parts water.

If sodium sulphite has been dried take 40 grms. only.—Yours truly,

W. L.

12, Earl Grey Street, Edinburgh.

November 5, 1909.

KEEPING FILMS.

To the Editors.

Gentlemen,—In a recent issue you drew attention to the reluctance of some to the use of films. As far as professional photographers are concerned, if I may speak at all for them, I think it is so much because plates are easier to handle, but that so far as I have seen no reliable method has been proposed for their keeping. That they are very much lighter and also simpler on roll exposures goes without saying, but one has had strange misgivings concerning storage. I have tried several methods recommended and have proved hopeless failures, through the great tendency of gelatin to mould when packed with or without paper between them. Some years ago I adopted a method which others may also have tried, but as it has now had ample time for proof, I mention it for the benefit of any who have not tried it—i.e., fix, say, 5 by 4 on half-plate glass, face up, and a strip of stamp-paper top and bottom; then brush over the surface with celluloid varnish and can now be kept either in a grooved box or packed flat against any other negative without any paper between (preferably), and can be printed from just as an ordinary glass negative.—Your

PROFESSION.

DAMAGE OF NEGATIVES BY INSECTS.

To the Editors.

Gentlemen,—In reference to the query of your correspondent "T. H." concerning prints damaged by insects, an experience I had a few months ago may throw some light upon the matter. I was staying at the time at a small town in Norfolk, when the whole district seemed to be overrun by a plague of earwig and

had developed some plates and stood them upon a shelf to dry, little thinking that earwigs were fond of gelatine, though I knew that after dusk they were to be found all over the house; and for three-quarters of an inch all along the edge of the plates they had dug out the gelatine, leaving me the toughest job of spotting what I have ever had.—Yours faithfully,
A. G.
November 8, 1909.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

BURNISHER.—I have an old burnisher, a stylect. Is it of any value and could you tell me where I could sell it, as I am giving up business?—E. HORTON.

It has no market value. This form of burnisher is quite out of date.

DEVELOPER, ETC.—1. Would you kindly inform me if there is a good developer for under-exposed negatives, one that will give black and white (not yellow news)? 2. Correct way to work retouching pencil on negatives? I wish to practise this branch myself.—NALODCT.

1. The best plan with an under-exposed negative is to use a somewhat diluted (i.e., mixed with water) developer. If this is done and solution also kept at about 70°F., one developer is about as good as another, although it is better to employ one—like amidol, rodinal, etc.—which brings out the image as a whole in the first place and brings up density afterwards. Still, pyro will answer equally well, though to avoid stain you should dilute with soda sulphite solution in place of water (soda sulphite, 1 oz.; water, 20 oz.) to avoid stain. 2. We advise you to get "Retouching," by A. Whiting (Dawbarn and Ward, 1s.) or take a course of postal lessons (see our advertisement pages).

THE PORTRAIT OF A WIFE.—Some time ago a gentleman ordered from us an enlargement to be sent to him. In due course the enlargement was sent to him framed. It was sent to him securely packed, but in the transit by rail it was damaged. The gentleman claimed from the railway authorities for the value of the picture, and has received his claim for the full amount. Now, as the authorities say they are returning it to the lost luggage office to sell it, we should be glad if you would let us know if they can legally sell it under these circumstances, seeing it is a portrait of the gentleman's wife. We should be glad if you would kindly let us know in your next week's Journal.—ANXIOUS.

As the railway company have paid for the portrait it seems to be their property, and therefore they can do what they like with it. Probably the company would now sell it to the gentle-

man for a small sum. If not, his best way will be to attend the lost property sale and see if he can buy it.

INTENSIFICATION OF BROMIDES.—For a special purpose we have to intensify some rather faint bromide prints to get the greatest possible density (to transmitted light), but keeping the whites clear. Middle tones can be disregarded. We have tried mercury and ammonia (by the way, does it matter if we omit the hydrochloric?), but though this makes a lot of difference, it is not enough. Then we tried lead nitrate, and this is fine as regards opacity, but all the nitric in the world won't keep a dingy stain off the whites, and this is important. Is there any way of using lead and keeping the whites clean? If not, can Mr. Welborne Piper suggest a method of intensification we might try?—INTENSITY.

We do not know any satisfactory chemical method of dealing with very faint bromide prints, because such an image contains so little silver that there is little to work upon. A bromide that is of a greyish or greenish black tone can easily be intensified to a full black with the chromium intensifier, but this is not powerful enough for a very faint image. If the process is repeated several times a brownish image is produced with fair density to transmitted light. It would, however, be difficult to obtain anything approaching the density given with the lead intensifier. The staining trouble is one that seems very likely to occur on paper, and we fear we can suggest no remedy. Possibly you could obtain the result you want most readily by using the non-transfer ozobrom process. With this you could cover the silver image with a strong carbon black. Hydrochloric acid in very small quantity is a desirable addition to a mercury solution, and in any case the print should be well washed in acid.

FLASHLIGHT.—Having had the pleasure of reading "Hints on Flashlight Photography" in "B.J." of October 29, 1909—1. Could you please give me any more advice that would help me in taking a set of photographs in a coal mine? I am going to use half-plates. 2. Also any advice on half-tone process?—"COAL MINES."

You should try and get the book "Mongst Mines and Miners," by J. C. Burrows and W. Thomas, published in 1895, which contains details of flashlight work in the Cornish mines. One great difficulty was that of getting rid of the smoke after an exposure, but with the greatly improved powders now obtainable and the better ventilation of mines this is less serious. Another cause of failure is condensation of moisture on the lens. It was necessary to put the lens back in the pocket after the view had been arranged, to place it again in position only an instant before making the flash. 2. This is too wide a subject for this column. You had better get "The Half-tone Process," by J. Verfassser (Liffe and Co., 5s.). For lessons there are the L.C.C. School, Bolt Court, Fleet Street, E.C., and the Photographic School, Polytechnic, Regent Street, W., or we could refer you to a probable means of obtaining instruction in Gloucester.

BLEACH-OUT PROCESS.—Can you oblige by giving me further details of the "Bleach-out Process," noted in current issue? I should like to know if dyes are obtainable and where, also fuller details of the process.—W. R. B.

We are sorry we have no further particulars nor any information as to the makers of the dyes. Perhaps a German contemporary, such as "Photographische Industrie," 6, Charlotten Street, Berlin, could assist you if you wrote enclosing International Postal Coupon of 2½d. value for return postage.

GRUBB LENS.—Could you tell me what a Grubb Doublet, No. 2,559, is useful for? Have seen one in a shop window.—E. PITTINGALE.

Without seeing the lens we cannot say. But probably it would be useful for purposes similar to those for which the R.R. is employed.

PERSEVERANCE.—The mirror should be surface silvered. Send it to Mr. M. A. Petitjean, 50, Fonthill Road, Finsbury Park, N.

ENLARGEMENTS.—Can you give me the formula for printing or enlarging on artist canvas by development? I do not want the carbon or bromide process. I remember in France many years ago that a very large firm at Asnières, near Paris, used to make direct canvas prints, and quite as successful as now. They used to print direct on canvas from detached negatives (wet photos) or paper negatives. I wish to do some here. The canvas was cleaned first with weak

ammonia, then salted with a brush, and sensitised in the same manner. Can you give me the formula?—W. M. HARRISON.

Various formulæ have been published for the process, the paper or canvas being salted with bromide, sensitised with silver nitrate, and developed in an acid developer. One formula is:—

Milk	20 ozs.
Glacial acetic acid	$\frac{3}{4}$ oz.

Mix, stir well, and filter, and then add to the filtrate:—

Potassium iodide	140 grs.
Potassium bromide	34 grs.

Paint the solution over the paper and dry as quickly as possible. The prepared paper can be either floated on the following bath, or it may be painted on:—

Silver nitrate	42 grs.
Distilled water	1 oz.
Glacial acetic acid	63 minims.

The paper must be exposed wet, and it is from three to four times slower than slow bromide paper. The developer is:—

Pyro	3 grs.
Water	1 oz.
Glacial acetic acid	40 minims.
Citric acid, 10 per cent. solution	4 drops.

JEE J.—(1) Impossible for us to say. Businesses prosper in all parts of the country. For your class of work locality is not important, particularly if the work is done at a good price. (2) Very crowded, undoubtedly. (3) No. (4) It is the custom of the trade to assume that the customer has the right entrusted to him to have the negative enlarged or printed. Usually it is so, but the law holds the actual reproducer equally liable. The enlarger, no less than the photographer, must use his judgment.

DISPUTED ACCOUNT.—Some three years ago we took a photograph of a well-known local gentleman, he paying for it. Admitted the copyright is his. Now the photograph was a very popular one, and he distributed several dozens. After a time we asked permission to sell the same as postcards. Consent having been obtained, we did so. He has since owed us an account for twelve months, and on our writing and asking for the same writes to us claiming a royalty on the postcards that we have sold. Now we should like to know if he can do this, because nothing was said about royalties when permission was given, and he is rather a bumptious individual and given to trying to do things on the bounce. Also, could you say what would be the usual royalty on postcards, each? The amount is not large, but it is the principle of the thing that we object to, and should like to know how we stand.—H. S.

The copyright undoubtedly belongs to the gentleman, but if he gave you permission to publish the portrait, and nothing was said at the time about royalties, we do not see that he can claim any. However, this is a case for the County Court to decide.

RETURN OF SPECIMENS.—At the beginning of February last I was requested by — and Co., —, to forward specimens of work and references. In my previous reply to their advertisement I had sent copies only, and on the before-mentioned date I sent a batch of platinotype specimens and three original references. I eventually obtained the berth, which was at —, which I held until October 30, when I received a week's notice to leave. I replied the next day accepting the notice, and asking for the return of my specimens and references, and was informed that they had been destroyed, and that they would give me a reference and I could make any specimens. As the studio here is not so good and the clientele moderate I naturally demurred, also as I cannot replace either I am deprived of many good prospects of obtaining another berth at any time I may require one. I now wish to claim damages, and should be glad if you would advise me as to proceedings to take.—H. A. H.

The only proceeding you can take is in the County Court for the value of the pictures, and damages for the non-return of the references. The amount you assess your loss at is very moderate. It would have been better if you had got the pictures and references back at the time you were engaged.

DISPUTED ACCOUNT.—Last year (1908), during July and August, I was requested to do certain photographic work by the manager of

a firm's branch shop for reproduction of postcards. I produced and delivered a certain number at the end of August. After a five months' wait I received pay for one-half, which they published. Now, I have waited fifteen months in all, and when I request a settlement of remainder the head office returns remainder of prints which they have had fifteen months. Both parties deny giving any instructions to me for to do this work. My agreement with all batches was for to reproduce postcard only. I now see they publish a series of views and offer for sale. I find also they wipe my monogram off all cards and views they publish. One print, supposed to be not required, I find published and offered for sale without being paid for. Can I claim, although not registered?—PHOTOGRAPHER.

If the manager, as agent of the firm, gave you the order to take the photographs and supply the copies the firm will have to pay for them. The copyright in the pictures belongs to the firm, and not to you. The County Court will settle the matter if you take the case there.

NOVICE.—Not for general work; the focal-plane folding camera of the Goerz-Auchütz type is about the best for press work.

P. CALLET and others.—In our next.

P. C. L.—1. Thin papier mineral; also matt varnish on back of negative. In both cases worked up with stump or colour. See "Retouching," by A. Whiting (Dawbarn and Ward, 1s.). 2. E. Graber, Tunbridge Wells.

K. ROBERT.—Except that the country is steadily, if not very rapidly, progressing, we are unable to advise you. You might, perhaps, obtain some help from a firm (such as Marions) supplying photographers there.

S. R. J.—An old Lerebour portrait lens will do very well for enlarging with in the lantern. But being 10in. focus it will require an often inconvenient distance between the lantern and the screen when using small negatives. However, with the cabinet size it will be very useful. As you say, it is a good lens for portraiture in the studio, and you will doubtless find it equally as good as an enlarging lens.

BLACKING THE INSIDE OF CAMERA.—My studio camera is what is known as the box form. The inside had become pale by the black wearing off by continual dusting. I reblacked with lamp black mixed with size, but now this wipes off, particularly when a damp cloth is used to remove the dust. Can you please tell me of something that will avoid this trouble?—T. A. WINTERBOURN.

Take some brown hard varnish and dilute it with methylated spirit. To this add some "drop black" and paint over the inside of the camera with it. The best proportions of the black and diluted varnish cannot be definitely given, as all varnishes are not alike, but they are easily arrived at by experiment. It is well to use as much of the varnish as possible with a view to durability, but not sufficient to cause the coating to dry in a way glossy. If it is found to do so the addition of more black will usually prove a remedy. If not, the mixture must be thinned with more methylated spirit.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The "British Journal Almanac." Our publishers desire to announce that the edition (of 25,000) of the "Almanac" is almost exhausted. Dealers and others who have not yet ordered copies are requested to do so without delay.

We very much regret to announce the death of Mr. Frank Bishop, the senior member of the firm of Marion and Co., Ltd. (P. 897.)

The Traill-Taylor lecture will be delivered on Tuesday next, at Russell Square, by Professor A. W. Porter, who will take as his subject "The Growth of the Photographic Image."

Testing the speed of photographic shutters. Messrs. Campbell and Smith, of the National Physical Laboratory, have worked out a method of measuring shutter speeds, which consists in photographing on a moving plate a narrow beam of light reflected from a galvanometer mirror, caused to make angular vibrations very rapidly about an axis parallel to the motion of the plate. A curve is thus obtained on the plate and the length of the exposure is ascertained by counting the number of vibrations recorded. The description of the method and of the apparatus used is given on page 894.

Mr. A. Lockett, in an article on the Dixio method of stereoscopy, deals with the form of stereoscope by which quite large prints may be readily examined, as also transparencies. He suggests that the method is deserving of more attention than is given to it for purposes of portraiture. (P. 891.)

An interesting exhibition of panoramic photographs is being held at the Strand Kodak Gallery. (P. 898.)

Some notes on the working of the carbon process in cold weather are given in an article on page 890.

New material, to be known as "Resinite," has been worked out in Germany, and is said to be suitable for the manufacture of photographic utensils. (P. 897.)

The efficiency of electric light and the use of adhesive masks in air-brush work are among the topics of "Photo-Mechanical Notes." (P. 897.)

EX CATHEDRA.

The Traill-Taylor Lecturer.

Professor A. W. Porter, who is to deliver the Traill-Taylor lecture next Tuesday at the R.P.S., is the Assistant Professor of Physics at University College, London, and the author of many scientific papers, some of which deal with the subject of light. He is co-author (with Professor G. Carey Foster) of a treatise on electricity and magnetism and author of one on mechanics. In recent papers read at the Physical Society and to the British Association at Winnipeg, he has described several novel effects obtained by the action of an electric discharge on photographic plates. In "Nature" of last week a brief account is given of experiments towards the measurement of the refractive index of radium emanation, the chief advance in which is the success obtained in measuring this quantity for extremely small amounts of a gas—a few cubic millimetres alone being required. Although he may be properly described as a mathematical physicist, he has the faculty of clear and luminous exposition and of ably illustrating his theme by well-chosen experiments. Professor Porter has for some time contributed a column on advances in physics to "Knowledge."

* * *

The "B.J." Almanac, 1910.

Within a week's time from Wednesday next—that is to say, on December 1—but not before, the 1910 edition of the "Almanac" will be on sale throughout the United Kingdom. As far as is possible without a fleet of aeroplanes, the publishers will deliver copies simultaneously throughout London and the provinces; at any rate, every purchaser may depend on getting the "Almanac" from his dealer in time for his evening reading on Wednesday, December 1. The "Almanac," it is believed, more than maintains its standard in the way of useful and up-to-date photographic information. The leading article this year has for its subject the use of certain short cuts in making lens-calculations. It is an article which enables the photographer to make any of the usual computations without reference to the tables or formulae—in short, the mental arithmetic of lenses. Other sections of the "Almanac" will, it is hoped, be found of more than ordinary interest, though the physical girth of the volume, despite the most valiant efforts of editor and publishers, has resisted compression.

Local Lights and Safe Lights.

One disadvantage of the existence of so many photographic societies is the fact that they are responsible for the dissemination of much wrong and misleading information of a kind that would never otherwise secure publication. Long ago we remember a lecturer, a shining light and hard-working member of a small local society, holding

forth on the mysteries of enlarging and reducing, and one of the sparkling bits of information that he emitted was that longer exposure was required when reducing because the lens was farther from the negative! This statement was disputed by an argumentative member, but he was, of course, extinguished by the overwhelming authority of the lecturer. In this case, no doubt, experience soon corrected the blunder, for it was somewhat too obvious to live long; but in other cases mistakes of a more insidious nature have been known to live a very long time. An instance of a mistake that ought not to be made in these enlightened times occurred only a week or so ago, when a local lecturer advised the members of his society that they should always make sure that these dark-room lamps were safe, and to ensure safety should use two thicknesses of canary medium for "ordinary" plates and good quality ruby glass for orthochromatic plates. Two thicknesses of canary medium are safe enough for bromide paper or process plates, but they let through enough blue light to fog the much faster "ordinary" in a very brief time, while as for safe ruby glass, we do not know where it is to be obtained. One of the few things about photography that is thoroughly well known nowadays is the philosophy of the "safe light," and there is no excuse for such recommendations as these. The treacherous nature of ruby glass is well enough known to induce everyone to avoid it, while if the generally useful "medium" is employed, we want something much more effective than two thicknesses of "canary" to get even an approximation to safety. It is the great fault of medium that we have to use so much of it that the light can never be anything but very dim. The properly adjusted modern safe light has the advantage that it gives us the maximum light that is consistent with a minimum of risk, and it always pays to adopt the best safe light available.

Royal Society of Painters in Water-colours.

The photographs having all disappeared from the Pall Mall Gallery, the public are now invited to the 153rd exhibition of water-colours. If the Links would but go there still they would find many lessons awaiting them. The finest water-colour work in the world has its home within these walls, and there it bears the stamp of knowledge, power, and sincerity of purpose. Those who boast that the colour-plate may supplant the painting may find their answer in the personal and almost visionary landscapes, which have in them more of what the artist felt than what he saw; such a view, for example, as W. Eyre Walker's "Windermere." An Autochrome would have given something very different from this, and would have been no nearer truth. The Autochrome standpoint is, however, exactly taken by Alfred Parsons, A.R.A., whose astoundingly clever work misses all but the literal reproduction of the scene. Mrs. Laura Knight still goes ahead. No other artist here has quite her naïve and absolutely unfettered attitude of mind. Fresh in ideas, untraditional in her method, she gives us impressions which inspire and astonish at the same time. Robert Anning Bell goes in the opposite direction. He is refined and cultured; but his art grows more and more archaic. The archaistic figures of his "Going to the Hunt" might have come from Botticelli's hand, though their landscape setting is incompatibly modern in the worst sense. We strongly advise those of our readers who are interested in firelight studies to look at the beautiful and exhaustive "Firelight Glow" of J. Walter West. Here are none of the hard shadows nor the lack of middle tones that comes of the lamp in the fender trick. The subject is a charming girl in eighteenth-century costume, who is bathed in a soft rosy light which plays over her form and alternates with cool tones of pearly shade, whilst the distance of the room

is a rich, deep reddish darkness, out of which gleam two immense Oriental vases. We lack space to mention even a tenth part of the things that should be seen for the sake of the lessons they can teach.

* * *

Positives Direct.

A very curious method of producing positives direct in the camera is given in an American contemporary. Generally it appears to be a variation on the various methods that have been proposed involving the removal of the developed negative image with an acid and bichromate solution, and the subsequent development of the remaining silver salt, but the variations introduced seem to be of a very doubtful nature. In the first place, the developed image is to be placed in a solution of boracic acid until it changes from black to red! What the action is or how long it takes is not explained, and it is not at all clear to us why the image should turn red at all, for boracic acid is not likely to affect the reduced silver. This bath is followed by a wash in three changes of a solution containing a mixture of boracic acid and chrome alum, and the plate is then immersed in a solution containing bichromate and nitric acid, cleared in a solution of caustic potash and potassium bromide, washed, exposed, and redeveloped. It is thus apparent that the whole process is only an old and rather ineffective one revived, with sundry additions that seem to serve no purpose. The boracic acid bath can serve no other purpose, so far as we can see, than that of destroying traces of the first developer, and none of the modifications proposed can in any way remedy the fundamental defect of the process, which is that the high-lights of the positive become seriously fogged. This defect was got over by Mr. Carnegie by leaving the red image produced by the bichromate bath *in situ* during the exposure, but the caustic potash bath proposed in the formulæ we are criticising takes away this protection, and leaves the process where it was before this protective device was thought of. This is an excellent example of what a photographic process can become when subjected to a "tinkering" process for the sake of novelty.

—♦—

CARBON PRECAUTIONS IN COLD WEATHER.

THE brief note which occurred in the course of an article last week on the carbon process has been responsible, perhaps, for one or two queries relating to the practice of carbon printing, or rather to the difficulties encountered on a sudden drop in the temperature. We may deal with these together in a further short article instead of taking them separately under "Answers to Correspondents." It must be borne in mind that carbon, like other methods of printing, is considerably affected by the conditions of temperature and moisture of the atmosphere. One of the chief of these is the length of time which the tissue will take to dry after immersion in the sensitising bath when the temperature is low and the air, as it usually is during the winter months, far from dry. When these conditions are at all pronounced, by the time the tissue is dry it has become so insoluble as to be quite unworkable. Even if its solubility is not affected to this extreme degree, the tissue prepared under these conditions nevertheless differs in a marked way from that which has been quickly dried; it shows a greater degree of sensitiveness, does not keep so long, and requires hotter water for its development. The modifications which are thus necessitated are, of course, realised by the expert carbon printer, but those who work the process less regularly may be easily misled as to the causes of what appears to them over-exposure of the prints. It not infrequently happens that in order to hasten the drying of the tissue the latter is placed in a room heated by gas or by a coke stove, and without an

ample amount of ventilation. The fumes from either of these forms of fuel exert a very insolubilising action upon bichromated gelatine, and if the latter be long exposed to their influence the film will become quite insoluble and unworkable. Where a proper drying cupboard is not installed a far more satisfactory plan is to discard the ordinary bichromate solution and to use in its place a spirit sensitiser, such as that prepared by the Autotype Company, containing little or no water. The tissue, after treatment with this bath, will dry in an ordinary room in the course of half an hour, and the danger of insolubilisation is thus avoided.

When the usual bichromate sensitiser is employed it should be borne in mind that gelatine does not absorb a water solution nearly so quickly when the latter is very cold as when the temperature is about 60deg. F. For example, if carbon tissue be immersed in a solution of potash bichromate for, say, three minutes, at 45deg. F., it will absorb far less than at 65 deg. F., and, as a result, will be of much lower sensitiveness. Not only so, but it will yield prints of a quite noticeably harder gradation, and will also require a longer time of printing. The net results often are that prints turn out under-printed, and the delicate tints wash away in the development. One remedy for this state of things is to allow a longer time in the sensitiser. Another is, of course, to raise the temperature of the latter to about 60deg. or 65deg. F. But perhaps the best course in cold weather is to use a sensitiser of greater strength, say 4 or even 5 per cent.—the latter if the negatives are at all of a hard character—in place of the customary 3 per cent.

Another fact which requires to be kept in mind when printing carbons in very dull weather is that bichromated tissue is relatively less sensitive to a weak light than to a strong one. As the exposure is usually timed by means of an actinometer provided with a piece of silver paper (P.O.P.), error in the exposure of the prints may arise from this very cause, the sensitiveness of the silver paper remaining practically the same both in weak and strong lights, and therefore failing to respond to the different behaviour of the carbon tissue. This means that the number of tints on the silver paper which was found suffi-

cient in summer light will not be enough for full exposure in the dull days of winter: a negative which requires, say, four actinometer tints in summer will very likely do with five or even six when printing in a very weak light.

A further danger which must be particularly guarded against in winter weather is dampness of the tissue. The pads of the printing frames should be made quite dry before use, while the frames themselves, when not in use, should be put away in a dry place. It is not uncommon in bad weather to find at the end of the day that certain negatives are still not finished printing. If, however, they are, say, about three parts done, advantage may be taken of the continuing action of the light. The tissues are taken from the frames and placed in an ordinary drawer or box and put away in a moderately dry place till the next day. As a rule, it will then be found on development that they are quite dark enough. To get the full benefit of this continuing action the tissue needs to be kept in a place of moderate warmth, and should not be stored in a calcium tube or other receptacle where traces of moisture will be abstracted from it.

Attention was called above to the fact that gelatine absorbs water much more slowly when it is cold than when it is of a moderate temperature. At this season the water as it comes from the tap is usually at a very low temperature, therefore in mounting the exposed tissue on the support for its development it should be allowed to soak for a longer time than is usually allowed under normal conditions before it is squeegeed on to the support. Also in the case of single transfer papers it is well to soak them for a little longer time than the tissue. If the water from the tap is as low as, say, 35 deg. F., it is a good plan, by addition of warm water, to raise the temperature to about 55 deg. or 60 deg. But this is seldom necessary, as the longer soaking will answer much the same purpose. However, in the case of very thick and rough drawing papers, which at an average temperature require half an hour's or an hour's soaking, it will be a decided advantage to raise the temperature of the water in which they are soaked to 60 deg. F., or higher, as with them even a very long soaking in exceedingly cold water does not always get them in the best condition for working.

STEREOSCOPIC PORTRAITURE.

is somewhat remarkable that so little attention has been directed to the interesting subject of stereoscopic portraiture. The great majority of stereoscopic photographs now produced in this country are, almost without exception, either landscapes, interiors, or street scenes. There was a time, indeed, when portraits for the stereoscope met with a marked appreciation—that was in the palmy days of the Daguerreotype and the eponymous positive. For the last forty years they have, commercially speaking, been practically extinct.

Perhaps the principal reason for this was a lack of comprehension by the earlier photographic artists of the special requirements that have to be fulfilled in order to make a pleasing stereoscopic portrait. The very relief and realism that are so effective in the rendering of a group of statuary, or the presentation of a thatched cottage, will repel rather than attract when applied, in unskilful hands, to the stereoscopic delineation of the human face or figure. Even in its monocular form, a photographic portrait is glaringly and crudely truthful, requiring all the aid of softly rounded lighting and tactful retouching to render it acceptable at once to the sensitiveness of the sitter and the critical inspection of his or her friends. How much more, then, was this the case when these angulari-

ties and projections, already given their full value by artistic lighting and treatment, were still further emphasised by stereoscopic relief, and retouching became either limited in extent or virtually impossible? To this we add the small size of the binocular portraits, the high prices that were demanded for them, and the bulk and clumsiness of the earlier stereoscopes, their decay in popularity becomes easily explicable.

Now, however, that stereoscopic work is again becoming popular, as improved methods and materials render possible the avoidance of many of the earlier obstacles, it is worth while inquiring whether the stereoscopic portrait may not justly hope for a revival of favour. With the simple and ingenious mirror stereoscope, introduced by Professor Léon Pigeon, of Dijon University, all limitations of size at once disappear. Pictures of any dimensions, from the largest to the smallest, may be examined with ease and comfort, either mounted as slides, printed as illustrations in the pages of a book or magazine, or projected on the lantern screen. A further advantage is that, since no lenses are used, the grain of half-tone illustrations or of paper remains inappreciable. Those who perhaps have missed reading the various descriptions of this apparatus that have appeared from time to time may be

reminded that the Pigeon stereoscope, known as the "Dixio," consists of a mirror placed midway between the two halves of the stereogram, one of which has to be reversed as regards left and right. The left hand picture is viewed with the left eye by reflection in the mirror, while the right hand picture is viewed direct by the right eye. The two pictures are, in consequence, seen superimposed, and accordingly coalesce, so that perfect stereoscopic relief results.

In the earlier patterns of the "Dixio" stereoscope the pictures were held in a portfolio, at an angle with one another of about 140 deg., the central mirror being inclined. In the issue of "The British Journal of Photography" for September 10, 1908, the writer pointed out the many advantages which would result if the mirror were perpendicular instead of inclined, and also detachable, among which was the obvious consideration that stereoscopic magazine and book illustrations of any size could be inspected *in situ*, without any need to cut or mutilate the pages, or to hold them at a special angle. M. Pigeon has now kindly informed the writer that he had in fact anticipated this suggestion, and that a new model of his stereoscope, intended primarily for use on the pages of a book, but equally suitable for viewing stereoscopic pictures in any form, had been designed by him and placed upon the Continental market. A full description of the new stereoscope appears in the "Photo-Gazette" for January 25, 1909, and a couple of stereoscopic illustrations for inspection in this manner are included in that periodical, one being the portrait of a lady, and the other an effective study of a sculptor at work in his studio. Fig. 1 shows the appliance placed

Fig. 1.

in position ready for use. It consists of a stout piece of cardboard, A, about 10 inches high, having hinged to it a pair of struts, B and C, which fold up when desired for convenience of carrying. At the top of the card is attached a surface-silvered mirror, D; a small metal piece, E, projects at the side of this, limiting the direction of the left eye and obliging it to look at the mirror, and not directly at the left hand picture. This latter refinement, however, is not indispensable. It is, of course, quite possible to use an ordinary mirror for examining the pictures, and to dispense with the special appliance; but by far the best results are obtained, and the greatest pleasure experienced, when a properly designed mirror stereoscope is brought into service; besides which, it must be remembered that an ordinary mirror with its silvered surface behind the glass gives objectionable multiple reflections, and although these do not in every case prevent its successful employment, the clear, definite image yielded by a surface-silvered mirror must not be expected.

A different stereoscope, but on the same principle as that

previously described, has been constructed by M. Pigeon for the inspection of transparencies. With these, the brilliancy of the lights and the delicate modelling of the half-tones are particularly effective. The most striking results of all, however, are secured with stereoscopic Autochromes, in which we have united not only light and shade with realistic atmosphere and relief, but the very colours of nature. Nothing so perfect has hitherto been obtained in stereoscopy.

The excellent example of stereoscopic portraiture which is here reproduced, by kind permission, should surely act as a spur to British camera workers and a suggestion of what might be done in this direction. Consider for a moment how interesting and attractive portraits of Royalty or of current notabilities would be, if reproduced in large size in our leading illustrated papers; or, to take another example, how altogether charming would be some of the ethereal and filmy studies of fair women, for which Mr. Elwin S. Neame is so deservedly celebrated, if we could view them with all the realism of relief, each gauzy fold of drapery standing out as though floating in air.

A few hints regarding the apparatus and the necessary arrangements for producing stereoscopic portraits may not be out of place. It is well known that a good portrait of any kind cannot be obtained unless the lens used is of sufficiently long focus in respect to the size of plate employed. If we make use of an objective of too short focus for a portrait in which the head occupies an important amount of space, we are obliged to bring the camera too near the sitter; in such a case the perspective becomes disagreeable, those parts nearest to the lens being represented of apparently exaggerated dimensions, while those that are more distant seem to be unduly reduced in size. If, for example, a half-plate head and shoulders portrait is required, it is necessary for satisfactory portraiture to choose a lens of about 12-in. focus, or even more, the rule being that the focal length of the objective should not be less than twice the longer measurement of the picture. For stereoscopic portraiture a pair of lenses of similar focal length are necessary.

Another point to be borne in mind is that the stereoscopic base, or distance between the two lenses, commonly known as the separation, should be sufficiently long with respect to the distance between lens and sitter. The necessity for this will be understood by reference to Fig. 2. Suppose the sitter is placed in front of a tapestry or curtain background AB (a background in which some relief occurs is obviously more suitable for stereoscopic purposes than one of the flat painted description) and that the two lenses C and D are directed towards him. If, then, we choose any point E on the outline or contour of the sitter viewed by either lens, it will be seen that this point masks or hides two points, F and G, on the background in the respective negatives given by the objectives

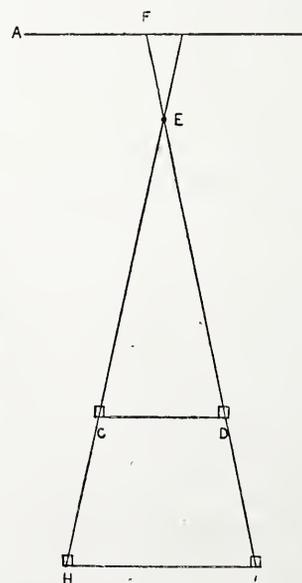

Fig. 2.

and D, these points being adjacent but distinct from each other. It is this perception by the two lenses of different parts of the background behind the sitter, a "seeing round him, as it were, which enables the two pictures when combined by the stereoscope to give a satisfactory impression of relief so that the sitter appears to stand out from the background. The same principle, of course, applies to all the other parts of the stereoscopic picture. If, now, we desire to use lenses

Le Récit.

ILLUSTRATIONS TO ARTICLE BY A. LOCKETT ON "STEREOSCOPIC PORTRAITURE."

By M. L. Chapuis, L'yon.

longer focus, which must be placed further away from the sitter, it is evident that in order to mask the same two points, F and G (or to obtain a similar amount of relief), they must be placed at H and I, in line with C E G and D E F respectively. Or, to put it in other words, the farther the camera is from the sitter, the greater must be the separation or distance between the two lenses, if good relief is required.

This is a convenient fact, because it enables us to use two plates of a good size side by side, either in separate cameras or in a single large camera divided by a central partition. Thus, with a separation of $6\frac{1}{4}$ in., two half-plate cameras with lenses of 12-in. focus could conveniently be placed in juxtaposition on a single stand. For a half-length portrait the lenses would require to be about 8 ft. from the sitter, and the background about 40 in. behind him. For portraits on a smaller scale, a greater distance between sitter and background is recommended. If, however, it is desired to use a single camera divided by a central partition, as commonly employed for stereoscopic work, a 10 in. x 8 in. camera with square bellows will answer admirably for obtaining either ordinary portraits or study heads, with a separation of about 5 in. Using a 10 in. x 8 in. plate, two negatives may be secured on the same plate, measuring 8 in. x $4\frac{7}{8}$ in.—a rather pleasing shape. By employing suitable carriers, it is possible with the same 10 in. x 8 in. camera to take two half-plate or smaller size negatives. The 10 in. x 8 in. camera is more convenient for this purpose than a whole-plate one would be, because half of a whole-plate, $6\frac{1}{2}$ in. x $4\frac{1}{4}$ in., is somewhat too narrow. There is, however, no objection to this size if it be preferred, or the other is not obtainable. The camera front should permit the simultaneous rise or fall of the two objectives, and should also provide for any desired adjustment of the separation. As regards the lenses, if the quality of the results is the only consideration, and price is no obstacle, long focus anastigmats are to be preferred, but excellent work may be done with less expensive objectives. A pair of rapid rectilinears working at $f/8$ may,

for instance, be employed. Tele-objectives deserve a passing mention, as being sometimes used for portraiture, and permitting the use of a relatively short camera extension in proportion to the size of image obtained. Whatever lenses are employed, the two shutters must be made to work in unison, by suitable connection with a single pneumatic bulb.

There are various ways of securing the reversal of the left hand print which need not here be detailed. By far the simplest is to use flat films, which may be printed equally well from either side, or the prints may be made by the carbon process, one by single transfer, and the other by double transfer.

It will be seen that all the operations are simple, requiring neither special apparatus nor objectives, since the ordinary cameras and lenses in everyday use are suitable, or may readily be made so. A removable central partition is easily obtainable; in fact, most cameras were at one time provided with them. If two cameras are employed, it is not necessary that they should be alike, provided the lenses are identical. The application of soft lighting and full exposure to avoid undue harshness of relief is now well understood, while retouching is already reduced to a minimum by photographers permeated with modern views of what constitutes an artistic portrait, and could readily be dispensed with altogether, especially if orthochromatic plates were used.

For some of the facts quoted in this article the writer is indebted to the "Photo-Gazette." It should be stated that the portrait produced herewith was taken by M. L. Chapuis, an artist of Dijon, working in collaboration with Professor Pigeon, the former being responsible for the lighting, posing, and other photographic manipulations, while the latter supervised the arrangement of the apparatus from a scientific and stereoscopic standpoint. A pair of single Zeiss Protar lenses, Series IV., were used, the focal length being $13\frac{3}{4}$ in., and the size of plate 13 x 18 cm.—a little larger than half-plate.

A. LOCKETT.

ON A METHOD OF TESTING PHOTOGRAPHIC SHUTTERS.

[The paper by A. Campbell, B.A., and T. Smith, B.A., read before the Physical Society some time ago, has now been published in the "Philosophical Magazine," and we are therefore at liberty to give the full text and the diagrams shown on the occasion of the paper being read. It should be stated that the method has been worked out in the National Physical Laboratory, and is employed there for making the determinations of the speeds and efficiencies of photographic shutters, which are part of the regular work of this institution.—Eds. "B.J."]

THE importance of having accurate methods of testing photographic shutters is well shown by the number and variety of the methods that have from time to time been proposed and used for this purpose. The method described herein is intended to provide a rapid test, while ensuring the maximum of accuracy. The total duration of exposure for low speeds (say longer than .1 sec.) is determined with an error not exceeding .005 sec., and for high speeds not exceeding .0005 sec. For exceptionally fast exposures measurements can probably be made to within .0001 sec. Attention has been specially directed to the elimination of all calculations, and a permanent record is obtained of each test.

The essential principle of the method consists in photographing on a moving plate a narrow beam of light reflected from a mirror which is forced to make angular vibrations of known frequency about an axis parallel to the direction of motion of the plate. There is thus obtained on the plate a sine curve, and if the light on its way to the plate passes through the shutter, the length of the exposure can be found by counting the number of vibrations recorded on the plate. The method has been rendered practic-

able by the fact that a vibration galvanometer affords a suitable means of imparting the necessary oscillations to the mirror; with this instrument both the amplitude of the vibration and the frequency are under control, and these are points of great importance. Owing to these conditions not being satisfied, and for other reasons, a tuning-fork is not nearly so suitable for imparting vibrations directly to the mirror. When it is desired to find the total duration of the exposure only, the general arrangement is shown in Fig. 1. Light from a point source A

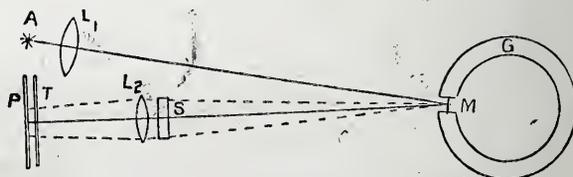

Fig 1.

is reflected by the mirror M of the vibration galvanometer G through the shutter S on to the photographic plate P. The mirror makes oscillations in a horizontal plane, and the ampli-

ude is such that the vibrating beam nearly fills the horizontal diameter of the shutter aperture. The plate falls vertically, and in doing so sets off the shutter. In practice, instead of a point source of light a Nernst lamp is used with its filament vertical, and in front of the plate is placed a narrow horizontal slit T to limit the width of the record on the plate. Lenses L_1 and L_2 are employed to regulate the intensity of the light and the amplitude of the vibration recorded as well as for focussing.

Description of the Special Apparatus Employed.

A special camera has been constructed to hold the shutter S, the lens L_2 , and the slit T (Fig. 1). It is provided with brass ways down which the plate-holder and plate slide, and an adjustable mechanism for setting off the shutter. A side elevation is shown in Fig. 2, and a view of the back in Fig. 3. A is

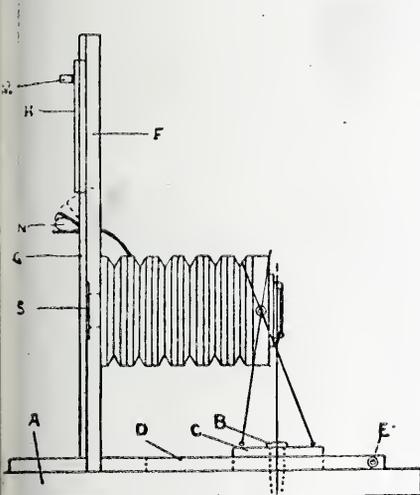

Fig. 2.

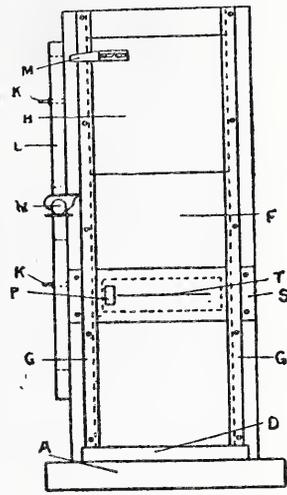

Fig. 3.

the base carrying the whole apparatus, and into it is fixed a vertical pin B. C is a piece of wood in which is bored a hole through which B passes freely. C slides between two portions of the base D of the camera, and can be held in any position by tightening the nuts E. The front of the camera, with the shutter and lens L_2 , is supported by struts from C, and set so that the axis of the pin B, if produced, would pass through the centre of the shutter. By this means the whole vibrating beam of light will be able to pass through the shutter though the whole camera is rotated through a few degrees about B. The back F of the camera is attached rigidly to the base D. The metal plate S carries a narrow horizontal slit T extending the whole width of the plate, and a window P is provided to facilitate focussing. G, G are the grooved metal plates down which the plate-holder H slides. This holder carries a projection M which engages with the upper plate of a ball compressor N; when the holder falls this upper plate is forced down and the pneumatic bulb of the release is compressed. On the return upward journey of the holder the projection passes the compressor freely. The pneumatic release is carried on the movable part L, and may be fixed at any desired height by the butterfly screws K, K. A front view of the apparatus is shown in Fig. 9.

A number of records are taken side by side on one plate. This is secured by rotating the camera about B between each exposure. With this apparatus ten or more records can be made side by side on a 5 in. x 4 in. plate. The base A has grooves cut in it to serve as a guide to the amount of rotation to be given to the camera. In making tests it is possible to make on one plate ten records of the various speeds given by a shutter in one minute.

The Electrical Apparatus.

The vibration galvanometer used is of the moving coil type (as already described by one of us*), and can be readily tuned

to frequencies of 50 or 500 per second. As its mirror is of fair size (50 to 80 sq. mm.), it gives with a Nernst lamp a sufficient amount of light to avoid "tailing off" in the records for quick exposures with rapid plates. The source of current may be an ordinary lighting circuit, the current through a lamp as resistance being made periodically intermittent by means of a wire interrupter, an electrically maintained tuning-fork, or, for the higher frequencies, a microphone hummer. The wire interrupter, which is merely an electrically maintained monochord, can be set to the desired frequency by the help of a tuning-fork; the maintained fork and the hummer give constant and known frequencies, and do not require setting. The pulsating current is led through a primary coil of 50 or 100 turns, and over this is placed a movable secondary coil connected directly to the vibration galvanometer, which is tuned to resonance with the source of current. The amplitude of its vibration can be brought to the desired amount by changing the position of the secondary coil relatively to the primary.

The distance from mirror to plate is usually about 100 cms.

Determination of the Efficiency.

For a more complete test the efficiency, in addition to the total duration of exposure, is determined. If τ denote the total duration of the exposure, T the equivalent exposure, a the area of the shutter aperture at the instant t, and A the maximum opening, we have the relation

$$AT = \int_0^{\tau} a dt ; \text{ the efficiency} = \frac{T}{\tau} = \frac{\int_0^{\tau} a dt}{A\tau}$$

Thus it is necessary to obtain a record of the area of the shutter opening at every instant of the exposure.

For the determination of the efficiency the method employed is essentially that proposed by Sir William Abney, who uses a siren to measure the time. We proceed as follows:—The shutter is removed from the vibrating beam of light (see Fig. 4) so that

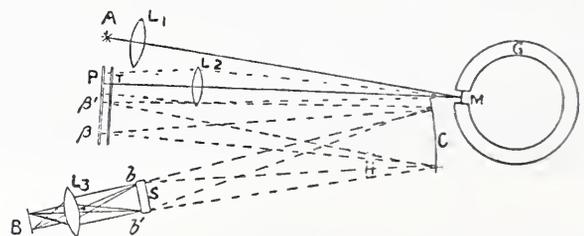

Fig. 4.

a continuous sine curve is recorded over the whole length of the plate, and this curve serves now simply as a time record. A line source of light B is focussed by a lens L_1 on to a narrow horizontal slit $b b'$ placed in a diametral plane of the shutter as close as possible to the shutter-leaves. An image BB' of this

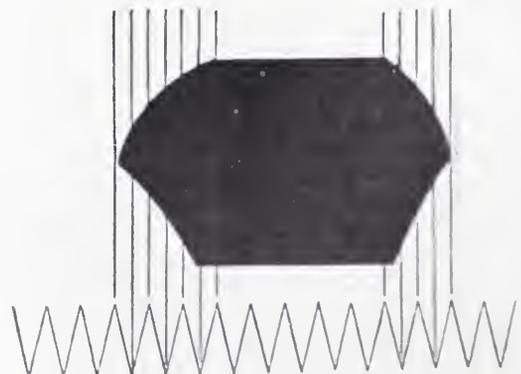

Fig. 5.

slit is formed by the concave mirror C on the photographic plate by the side of the vibrating beam of light. As the plate falls

* "Proc. Phys. Soc.," Vol. XX., and "Phil. Mag.," October, 1907.

† "Proc. Roy. Soc.," A, Vol. LXXVIII., p. 208, 1906.

the shutter is opened as before, and a record is obtained giving at every instant of time the length of slit through which light was passed by the shutter-leaves (Fig. 5). Measurements are then taken of the area of shutter aperture corresponding to a number of lengths of the slit opening. Fig. 6 shows some stages

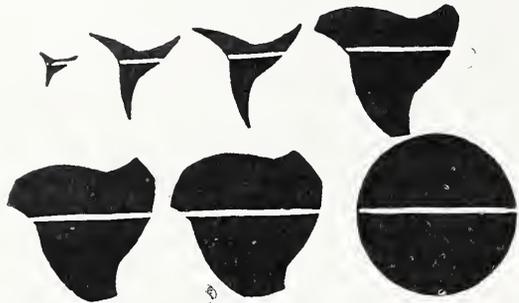

Fig. 6.

in the opening of a particular type of shutter, the white line representing the position of the slit. From a pair of records such as shown in Figs. 5 and 6 a curve is drawn showing at every instant of the exposure the area of the shutter aperture through which light can pass to the plate. It is now evidently

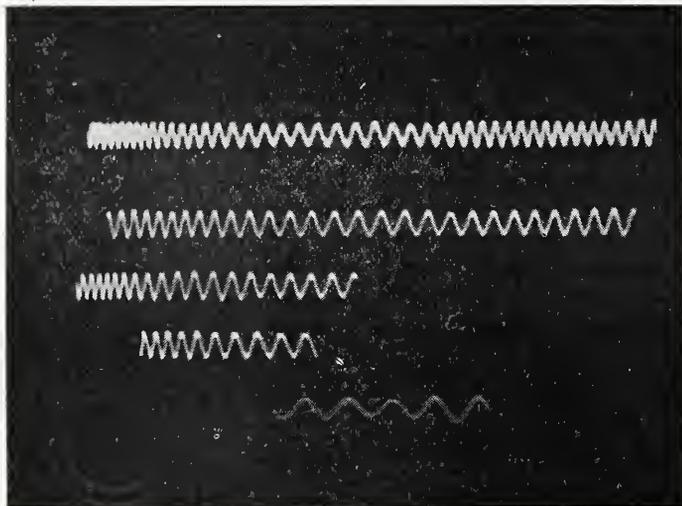

Fig. 7.

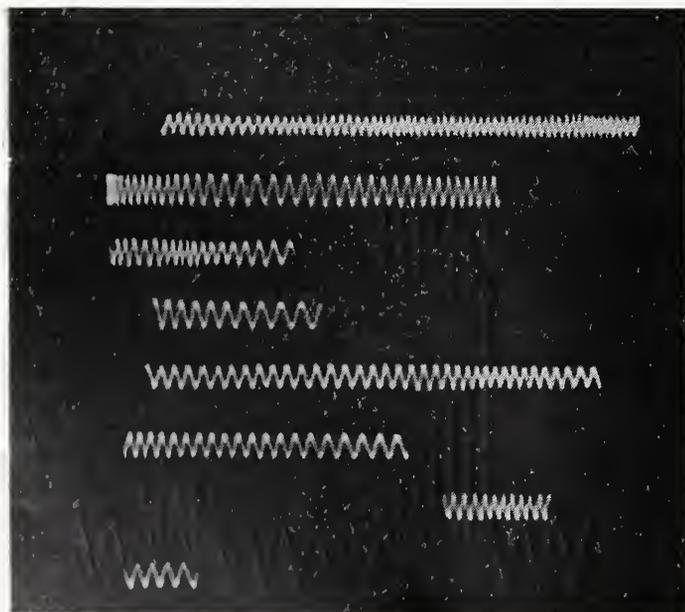

Fig. 7A.

a simple matter to find the amount of light cut off owing to the finite length of time taken by the shutter-leaves to open and close, and hence to calculate the efficiency.

Examples of Records.

A number of shutters of different types have been tested with the apparatus. Figs. 7 and 8 are examples of the records obtained, the former at 50 and the latter at 500 - per second. Figs. 5 and 6 are copies of records obtained in testing the efficiency.

For general use the most convenient frequencies to work with

Fig. 8.

are 50 and 500 - per second, with possibly 2,000 for special work; or perhaps 100 and 1,000 - per second would be suitable. The full advantages that the method offers can only be secured

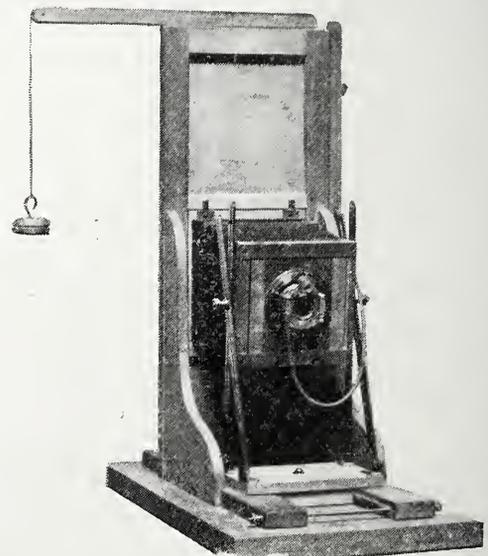

Fig. 9.

by the use of round numbers, such as the above, for the frequencies of the oscillations.

In conclusion, we wish to thank Dr. Glazebrook for the kind interest he has taken in the working out of the method.

A. CAMPBELL, B.A.
T. SMITH, B.A.

CHANGE OF ADDRESS.—Mr. G. Guilbert, successor to Messrs. Romanet and Guilbert, of 26, Red Lion Square, W.C., advises us that the business of the firm will in future be carried on at 40, Hatton Garden, London, E.C.

DEATH OF MR. FRANK BISHOP.

WE very much regret to have to announce the death of Mr. Frank Bishop, which took place on the morning of the 12th inst. at the deceased gentleman's residence, 20, Kensington Crescent, W. Mr. Bishop for many years had occupied a leading position in the photographic trade. His connection with the firm of Messrs. Marion and Co. dated back to nearly fifty years ago. For many years he was a partner in the firm, and its first managing director when the business was converted into a limited company in 1901. Apart from his interest in the ordinary branches of photographic trade, Mr. Bishop interested himself very keenly in the publishing side of photography, and was one of the founders of the Photographic Copyright Union in the year 1893, and retained his active interest in and support of this protective association until the time of his

THE LATE MR. FRANK BISHOP.

ath. It was at the time of the formation of the Union that photographers stood in danger of neglecting their rights in reproductions of their work, and though perhaps their interests are now more actively watched over by the Professional Photographers' Association, the pioneer work in this direction was done by the Copyright Union, and largely by Mr. Bishop. In consequence of ill-health, Mr. Bishop had retired from active management about ten years ago, but he remained a director of Messrs. Marion and Co. to the time of his death. At the funeral, which took place on Monday last, a large number of those who had been associated with him in business were present, and the Professional Photographers' Association was represented by Messrs. F. A. Bridge, Alfred Ellis, H. Fry, and A. Mackie (hon. sec.).

ENLARGING NOTES.—Messrs. Wellington and Ward send us a copy of a very useful booklet issued by them under the title "Enlarging Notes for Use with the Wellington Papers." It concisely describes the merits of the three types of enlarger, but we commend it most for the very emphatic directions for the making and use of developer and toner for the Wellington bromide and S.C.P. papers, for the use of bolting silk, and for the printing-in of clouds. Really, the maker of enlargements wants nothing more in the way of instruction than is here given him for nothing on addressing a postcard to the Wellington Factory at Elstree, Herts.

A NEW MATERIAL FOR PHOTOGRAPHIC UTENSILS.

ACCORDING to a recent paper in the "Zeitschrift für angewandte Chemie," a new material, to be known as "Resinite," has been produced as a condensation product of phenol (carbolic acid) and formaldehyde (formaline). The new material is, in many respects, superior to glass, celluroid, or hard rubber, substances which for one purpose or another are largely used for photographic purposes. Some short account, therefore, of the properties of the new substance may prove of interest. The body is made from a mixture of crystallised carbolic acid and formaldehyde solution, the condensation of which is brought about with potass carbonate, though other neutral or basic salts may be used for the purpose. On heating, a yellowish liquid of high boiling point is obtained. This so-called "Resinite A" contains a good deal of water, and is advocated chiefly for the making of solid utensils from wood, paper, or other porous bodies, since these latter—when impregnated with the solution—are prevented from shrinking and are rendered hard and waterproof.

When "Resinite A" is further distilled, so as to get rid of excess of formaline and water, the residue is that described as "Resinite B." It is obtained by protracted heating of the residue to a temperature of 80 to 200 C. It differs from other condensation products—known as artificial resins—by its non-liability to take fire and its resistance to various chemical bodies, and further to its slight brittleness. The product is of a ruby-red colour and varies more or less in transparency. It shows a shell-like fracture, and may be ground, turned, and polished, although in large pieces it is still somewhat brittle. On this account it is advised to mix it with a certain amount of kieselguhr, talc, or other bodies which diminish its transparency, but render it more elastic. If a certain quantity of acid be incorporated in the mass it becomes more amenable to working, since the long degree of heating can then be reduced to about 15 minutes. In fact, the reaction by direct addition of acid is too rapid, and therefore 20 to 30 per cent. of starch is added in order to give a slower reaction. The acid is removed after setting with soda solution, leaving the "Resinite" softer and easily workable. It is anticipated that if the claims made for "Resinite" are confirmed the material should be found of considerable use for photographic dishes, etc., whilst the "Resinite A" would serve as an excellent means of preparing large wooden dishes or tanks.

Photo-Mechanical Notes.

Masking when Air-brushing.

The old method of masking out an original while air-brushing certain parts of it was to cut out a paper shape and rest upon it small weights, such as coins or bits of lead, to keep in position while the exposed portion was being sprayed. It was naturally more or less troublesome to preserve a sharp edge, as the paper was apt to raise itself and the weights were a nuisance. These troubles can be overcome by the device of cutting the mask out of a slightly adhesive transparent paper, which can then be merely pressed into contact, and will retain its position during the spraying, and is also very easily removed and replaced. A lithographic tracing paper known as "Charbonelle" is sometimes tacky enough; if not, one can easily prepare a paper for oneself by varnishing a suitable tracing paper with a varnish that is tacky when dry.

For many originals it is still necessary to use paper masks, although the newer method of covering with a varnish which is afterwards cleaned off is now used for probably the greater portion of masking work.

Electric Light for Process Workers.

There are a constant succession of new lamps put on the market for process workers, each later type claiming immense superiority over all that have gone before. Very often the vendors are able to support their claims by testimonials from well known firms. But we suggest that these favourable opinions are obtained from operators who frequently have no idea of a comparative test, which, if rigorously carried out, would show there was no real advantage over the lamps superseded, and if any advantage at all was in a direction not suspected.

Users of the arc light want to know the current consumption, as naturally any lamp should be more efficient if it consumes much less

current. To do this one must know the voltage, and the actual amperage of the lamp during burning, not its reputed amperage, which very often is a different thing. Then a calculation can be made as to the cost of the current by multiplying the two together, which gives the watts; 1,000 watts for one hour is the Board of Trade unit against which the charge for current is made.

Then it is necessary to make a photographic test, and see the amount of photographic efficiency which is obtained against a given cost for current.

The writer recently carried out such a test for a lamp, and found that with the same cost for current there was no gain whatever in photographic efficiency; on the other hand, the new lamp was more expensive and much more troublesome to operate.

A point that should not be forgotten is the kind of photographic work required to be done, because one sort of lamp may be much more efficient for one kind of work than another, as for example, the enclosed arc is far superior for ordinary black and white copying, while the open arc is much the best for photographing colour.

Another point is the nearness to which the light may be placed to the original. Thus the ordinary enclosed arc can be placed closer than the open arc, and the flaming arc closer still, while mercury vapour tubes can be placed closest of all. Other things being equal, the lamp that can be placed closest to the copy is naturally the most economical.

Machine-Printed Photogravure.

A reader of the "Photo-engraving Notes" in the "Inland Printer" has written in appreciation of the photogravures machine-printed in colours issued in this country as Mezzochromes. He asks how the work is wiped perfectly from a revolving roller, and why the same principle cannot be applied to a flat plate and do away with the tedious manipulation gone through in wiping a plate by hand? Mr. S. H. Horgan, in reply, states that the Waite die and plate press "inks, wipes and prints at one impression" from a flat plate. It is easier to turn a copper cylinder true than it is to get a plane surface absolutely flat, which would be necessary should the surplus ink have to be removed with a scraper. The ink used in printing photogravures from a cylinder is almost of the consistency of soup, and is called "soup" by rotary photogravure-printers. The bottom of the copper-printing cylinder either turns in a trough of this soup or the liquid ink is supplied with a cylindrical brush or felt to the cylinder. The excess of ink is removed by a scraper, called the "doctor," which has a keen knife-edge. The doctor is given a lateral movement parallel with the axis of the printing cylinder, to which it is pressed tightly. The ink used must be absolutely free from grit, or scratches result on the printing surface. The whole system of printing from an engraved roll is not new, but its application to printing photogravures began in England about ten years ago.

Removing Magnesia from Half-tone Blocks.

Replying in the "Inland Printer" to a correspondent, Mr. S. H. Horgan, the conductor of the photo-engraving column, writes:—"The carbonate of magnesia you buy in powder is likely the powdered mineral magnesite, which, in combination with the iron etching solution and the copper, makes a hard paste in the etched parts that is very difficult to remove. The block magnesia, which you can readily purchase, is oxide of magnesia, produced by burning the metal and then pressing the light fluffy flakes into blocks. When rubbed into an etched plate it shows up the condition of the plate, to a practised eye, even better than a proof. To remove it, begin by getting rid of the stopping-out varnish, which is usually a spirit-varnish and must be removed with alcohol. While the plate is still wet with the alcohol, take it to a sink and pour over a little acetic acid, so as to cover it all over, and sprinkle on the plate a handful of fine table-salt. With a fine bristle nail-brush scrub the plate in the direction of the half-tone dots, allowing the water from the tap to flow while finishing the scrubbing, wash away all traces of the acetic acid, and the plate should be cleared completely of magnesia."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On November 25 a lecture, entitled "Glorious Devon," will be given by Mr. A. J. Woolway, who will show 100 Autochrome lantern illustrations.

Exhibitions.

PANORAMIC PHOTOGRAPHS AT THE KODAK STRAND GALLERY.

THE Kodak Company are now showing at their Strand Gallery, close to Charing Cross Station, a number of panoramic photographs made with the "Cirkut" camera, reviewed not long ago in our pages. The prints are the work throughout of the Notman Photo Company, of Boston, U.S.A., and represent, in almost every instance, well known scenes in European capitals. The great facilities provided by the "Cirkut" type of panoramic camera are very forcibly demonstrated, and perhaps the example which will appeal most to the London visitor is the photograph of Leicester Square, taken from the south-west corner and showing about half of the central garden and more than three-quarters of the surrounding buildings from Messrs. Stagg and Mantle's premises right round the square to beyond the block of the Dental Hospital. The print gives a record of this well-known corner of London which could not be obtained by any single exposure made in the ordinary way. Another equally effective example of the work of the camera is that of the Tower Bridge; whilst two others, which perhaps are not quite so good, are Hyde Park Corner and Piccadilly Circus. A lofty point of view, and one if possible at a considerable distance, naturally favours the most efficient use of the camera, and for that reason the panoramic photographs in Rome, Paris, and Milan have afforded better opportunities to the photographer. Nevertheless, the London subjects amply demonstrate the many applications of this instrument for the purposes of advertising and record photography. We should add that all the prints are made on "Velox" paper, and that the exhibition remains open for a month from the present date.

FORTHCOMING EXHIBITIONS.

- November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 29 to December 2.—Lancaster Photographic Society. Entries close November 20. Sec., Thomas Holt, 4, Parliament Street, Lancaster.
- December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.
- December 15 to 16.—Coves Camera Club. Entries close December 6. Sec., E. E. Vincent, 4, High Street, Coves, I.W.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138 Glasgow Road, Wishaw, N.B.
- 1910.
- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. Georg and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between November 1 and 6:—

SHUTTERS.—No. 25,386. Improvements relating to camera shutters. Alfred Parker and Lucions Charles Knee, 31, Bedford Street Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; and abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH MECHANISM.—No. 22,117, 1908 (October 19, 1908)

This invention relates to cinematograph apparatus of the type in which two shutters are rotated in opposite directions over the two lenses, each shutter having an opening so formed that the pictures are projected on to the screen without an intervening da

period, and with practically uniform lighting. The shutters are constructed with radial slots and wire gauze or other translucent edges, whereby the amount of light transmitted to the screen is kept constant during the rotation of the shutter.

Two shafts cause the alternate motion of two toothed drums which consecutively move a single cinematograph ribbon film of the well-known type, printed according to a predetermined arrangement. One of the lenses is adjustable, and the apparatus admits of the two lenses being concentrated on a single point. The lighting of the pictures projected on the screen may be by means of gas, electricity or other convenient medium. The uniformity of the projection is assured by the double rotary shutter formed of two concentric disc segments each capable of being revolved in the opposite direction to the other (the driving of the shutters being effected by gearing in the well-known manner), and is distinguished by having on each segment a series of narrow radial slots, and a wire-gauze or translucent screen for the purpose of regulating the amount of light passing to the screen. Marius Auguste Ginoux, 15, Rue de Bondy, Paris.

New Trade Dames.

PUREXIDE.—No. 316,604. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Purex, Ltd., Greenford Colour Works, Greenford Road, Greenford Green, Harrow, Middlesex, manufacturers. September 25, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Xylonite Dishes

I like xylonite dishes (writes Mr. P. W. Scott, in "Photography and Focus" for November 16), for more reasons than one. They are not at all likely to break; they pack into a very small space; they are economical of solution, as they are flat, and the plates lie flat upon them; they are easily kept fairly clean; and from their flexible nature they are the easiest of all dishes from which to pick up a negative. Put one thumb on a corner of the plate, and with the other fingers of the hand under the dish pick it up, and the weight of the liquid will cause the dish to bend so that the plate may be picked up at once with the other hand.

New Books.

"L'Arbre dans le Paysage." By J. Carteron. Paris: Chas. Mendel. Price 60 cents.

In this volume of 38 pages the author treats of the tree as the "life of a landscape," and his aim is at a more adequate rendering of trees either as the subject proper of a landscape or as minor constituents of a picture. The little book thus touches a somewhat novel theme of pictorial photography. It is illustrated with reproductions of a few photographs appropriate to its subject.

"Le Diamidophenol Acide en Photographie." By G. Underberg. Paris: Chas. Mendel. Price 60 cents.

This short monograph on the acid diamidophenol developer forms No. 13 of the useful series of text books published by our contemporary, the "Photo Revue," in the pages of which portions of the contents have first appeared. M. Underberg has of late been an unceasing advocate of acid diamidophenol as a universal developer, and in this monograph he gives the formulæ which he has found best, and describes the methods of varying the action of the developer which have seemed advisable. Writing for French readers, he makes use chiefly of soda acid sulphite as an acidifying body, this substance being more generally supplied in France than in this country. Acid sulphite liquor of the standard commercial strength is, however, obtainable here, among others from MM. Lumière.

Metabisulphite of potash and soda might also serve as a source of free or uncombined sulphurous acid, and English workers might experiment in this direction with advantage. M. Underberg has worked out a series of developing solutions prepared from one or two stock solutions, and his recommendations, some of which we have translated in past issues, are evidently the result of painstaking experiment.

"Modern Photography for Amateurs." By J. E. Fearn. Sixth Edition. Revised by C. Welborne Piper. London: L. Upcott Gill. Price 1s. net.

In this re-edition of a popular manual the matter has been brought very closely to date without, however, including anything which has not been fully confirmed. Thus under development, the factorial and time methods are described as well as the Watkins system of correcting for the temperature of the developer. The introduction to each part of the photographic process is commendably by the easiest route—e.g., self-toning papers for the print, pyro-soda for development. The essential and important methods of photography, from the amateur's standpoint, obtain the extended treatment they deserve. Thus enlarging and lantern-slide making, and hand-camera work come in for ample treatment, and the reviser's advice is everywhere very frankly given. The volume does not lay undue stress on the extreme simplicity of photographic processes, but points out the precautions which are really necessary for success. We can cordially commend the volume as a thorough and reliable introduction to photography.

"The Home Life of a Golden Eagle." By H. B. Macpherson. London: Witherby and Co. Price 5s.

Perched somewhere near an eyrie in a wild corner of the Grampians, Mr. Macpherson has crouched for hours at a stretch in the seeping wet, with his eye and that of his camera fixed on the home of a pair of golden eagles a few feet from him. As the result of all this patience in discomfort he has written two diaries—or, rather, one is his and the other is his camera's—between which it would be invidious to make comparisons. Each is an absorbingly interesting record of what he saw of the domestic career of the two birds and their offspring from the time prior to the latter's emergence from the shell until the day when—we quote the last words in the book—"the devoted parents, who for five long months have tended their offspring with loving care, turn on him as on a foe and drive him forth into the outer world." Mr. Macpherson, on his knees, under a pair of hurdles and in a pool of water, and other parts of him exposed to the wind and rain, has watched the parents' solicitude through five months, and has recorded what he saw in a matter-of-fact way which is often horrible from its realism. Easily frightened by a strange object, the eagles know the business of securing food for their youngsters pretty well. Mr. Macpherson's diary consists largely of the stage entrances on to the eyrie of Mr. and Mrs. Eagle carrying for their offspring a tender morsel such as the hind leg of a rabbit, a grouse, plucked and decapitated, or a fat rat—all of which the young bird by the time he was a month or so old had learnt to gulp down, bones and all.

In the 32 excellent plate illustrations the author shows the result not only of his patience and photographic skill, but of his dramatic sense; he has seized upon moments when the affairs of the eagle family were at a crisis, and for this stage-management of his photographs he deserves our congratulations, for the reason that by such means persons who would not read a dry-as-dust treatise are encouraged to learn of "wild Nature's ways."

Though the author cannot be called a literary stylist, his unimpassioned record of what went on at the eyrie is as absorbing as any novel, and we did not lay it down until we had read every word. The book deserves to rank high among the modern natural history works made possible by photography.

PHOTOGRAPHIC CHEMICALS.—No. 101 of the "Photo-Miniature" is devoted to the properties of the chief chemical substances used in photography and the precautions to be observed in their storage and conversion into the photographer's working solution. The arrangement adopted classifies bodies according to their chief purposes, e.g., pyro, sulphite, alkalis, and bromides are grouped and treated together in reference to the making of a developer.

hypo eliminators come next, the cheap and certain permanganate being included among the latter. The materials for gold, platinum, and sulphide toning are next considered, after which the chemicals of intensifiers and reducers and of mountants are the subject of useful notes. The monograph concludes with hints on making solutions, weighing and measuring, and other operations necessary when making up solutions. The issue gives a good deal of information on every-day matters of photographic importance. It is published here by Dawbarn and Ward, and in America by Tennant and Ward, 122, East Twenty-Fifth Street, New York.

New Materials, &c.

"Teb" Christmas Mounts and Cards. Made by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

Messrs. Butcher have this year entered the field of the Christmas mount for photographs with a number of quite novel designs and styles, in addition to retaining their hold upon the less expensive kinds of card, a very great variety of which are illustrated and described in the 24-page list, just issued. Perhaps the best idea of the more popular lines is given by the "Teb" boxes of assorted

The setting for the print consists of two tinted papers, the inner one nicely placed so that more space is left at the bottom than at the top, whilst the inner mount also is of such size that when the print is mounted on it a quite narrow band of the inner mount is left visible all round. In short, the user of the mount obtains the result of multiple mounting without the trouble of himself preparing the tinted surrounds. The whole style of this "Directoire" series deserves every commendation, whilst the prices are moderate—namely, 1s. 6d. per box of six mounts and envelopes in either c.d.v., postcard, or quarter-plate size. In the "Mayfair" series the same leading idea is adopted, but with a slight variation. In these mounts the envelopes are made of linen-surface paper or other delicately figured paper, whilst the mount for the prints consists of a single board $9\frac{1}{2}$ by $7\frac{1}{2}$ inches bearing the one word "Greetings" in unobtrusive gold-blocked lettering. The latter is placed so that the mount may be used either for an upright or landscape picture, and the whole production of these very refined yet ornamental mounts will do credit to the taste of any photographer showing them to his customers or to that of any dealer offering them to amateur workers who may pride themselves on their choice of mounting materials. The "Mayfair" is made in two series, No. VIII. having mounts $8\frac{1}{2}$ by $5\frac{1}{2}$, and including six in the packet, No. IX. of five mounts $9\frac{1}{2}$ by $7\frac{1}{2}$. The price in each case is 2s.

Similarly, in calendars Messrs. Butcher have produced a number

No. 917.

No. 909.

No. 916.

cards sold at 1s. for c.d.v. and quarter-plate size and at 2s. for 5 by 4 prints, in each case containing fifteen mounts. The box itself is turned out in very nice style, tied with green ribbon, and the mounts themselves are as varied in style, design, and colour as can be wished. The majority are folder slip-in mounts, but one or two are made up envelope fashion, the flaps being simply turned down and a touch of adhesive applied when sending the card through the post. This series represents a packet of mounts most saleable to amateurs, and remarkable value for the price charged.

But we must refer more particularly to the quite new departures which Messrs. Butcher have made in photographic Christmas stationery, and particularly the mounts issued under the names of the "Directoire" and the "Mayfair." The former is a box containing six mounts and an envelope for each, the paper used for the envelope in each case matching that for the mount. The mounts are throughout of light tone—white, grey, or cream—with a delicate decoration in faint bands, which gives a very refined effect.

of very choice new series. In the series IV., V., VI.—each issued at the price of 2s.—the calendar mounts are of the slip-in type, taking quarter-plate, c.d.v., and postcard prints respectively; those submitted to us are of dark-green board with a darker vignette margin and provided with a paler green ribbon. In each case the mounts are issued either for upright or horizontal prints, there being an assortment of the two in each packet. In the series VII. of the calendar mounts the prints are pasted on, and this series—for quarter-plate prints only—represents a mount 6 by $6\frac{1}{2}$ inches, the colours being dark green and light brown, whilst the price for eight mounts—in each case bearing a tear-off calendar for the year—is only 1s. In all the foregoing series, equal attention has been given by the makers to the box, so that purchasers are pre-disposed in favour of the mounts by the appearance of the packets.

We might fill several pages of this number with even brief references only to other types of single mounts and calendars as distinct from the packet mounts reviewed above, but we must

content ourselves by pointing to one or two in particular. In No. 909, a calendar mount for postcard (upright or oblong) and for quarter-plate (oblong) prints, the base of the card (the outside measurements of which are 12 by 9 inches) is a delicate grey, with faint banded ornament and with an outside margin of white. The photograph is placed within a border of dark grey, surrounded by a narrow line of black, the final effect being that which is got by the old French method of making a border of wash round the print. The price of this mount complete with white silk cord for hanging and envelope is 3s. 6d. per dozen.

In No. 912, a double-folder mount (paste-on) for upright quarter-plate prints, the inside folder is of semi-matt linen-surfaced paper, whilst the outside is of a rougher-ribbed paper of a slightly darker brown shade, and bearing an embossed cameo relief of a head in profile. In the combination of papers, of silk ribbon which holds the two folders together, and in the printed surround for the photograph, this mount is without a fault, and altogether one of the nicest of the present season. Its price is 3s. per dozen. No. 917 is another paste-on mount in a scheme of most pleasing brown tones. It is a single card with silk cord for hanging, and with the word "Greetings" in white lettering. There are two pasted-on papers, and the mount is made for oblong quarter-plates, and both upright and oblong postcards, the price for the first being 2s. 6d. per dozen, for the two second 3s. per dozen; in each case with brown envelopes to match. This is a very suitable mount indeed for sepia-toned prints. Nos. 920, 921, and 922 are all for slip-in pictures. 920 is made in green and mouse-grey, with a neat gold lettering on the front cover. The print in this mount is slipped into four diagonal cuts in the back cover. The price for prints from $3\frac{1}{2}$ by $2\frac{1}{2}$ to postcard size—in each case four oblong prints—is from 1s. to 1s. 3d. per dozen. In 921 the motto on the front cover—"Best Wishes"—is deeply embossed without white or other foil; there is a tinted border round the slip-in opening, and the mount, with its cord harmonising with the paper, is in very nice taste. Prices, complete with envelopes, from 1s. 6d. to 2s., for prints from $3\frac{1}{2}$ by $2\frac{1}{2}$ to postcard. No. 922 is made in green only, with a fairly deep oval cut-out of grained card. It is provided with a tissue protector to the print, and embossed motto "Greetings" on the front cover. The prices for prints from quarter-plate to postcard are from 2s. to 2s. 6d. per dozen.

Professional photographers in particular should make a note of mounts Nos. 911, 915, 5962, and 916, all of which represent very neat designs, in each case of slip-in mounts provided with tissue protectors and embossed decorated border round the cut-out; 911 at 1s. 3d. a dozen in light brown, neutral grey, and dark green are particularly choice. They are for postcard size, upright, square, and oval—an assortment of these openings being supplied unless otherwise ordered. No. 5962 is for prints 4 by $1\frac{1}{8}$, made in two artistic shades of green and brown with embossed design, inside and out, and gold motto in relief. This card is 1s. 3d. per dozen, as is also No. 916, which is of similar style, but made in Whatman, surface green card, with embossed design in copper, also for prints 4 by $1\frac{1}{8}$. In No. 915 an oval for c.d.v. prints is provided, the card being issued in a delicate ribbed grey paper, with plain embossed medallion and motto in gold. This mount is issued at 1s. 6d. per dozen, including—as is the case, we believe, in every instance to which we have referred—also the envelopes.

These descriptions, we fear, do scant justice to the many excellent novelties which Messrs. Butcher have produced. All these we have examined with much interest, and we are confident that those who would see for themselves what really tasteful designs in Christmas mounts are now obtainable cannot do better than call on Messrs. Butcher or make a selection from the items which we have specially singled out for mention.

"Scales Brand" Flash Powder. Made by Johnson and Sons, 25, Cross Street, Finsbury, London, E.C.

Messrs. Johnson and Sons have just submitted to us a new production of "Scales Brand" Flash Powder, which is sent out packed in a most convenient and safe form suitable for both amateur and professional use. All that is necessary before using is to mix the two powders contained in the cartridges. The mixture is spread out on a tray or some other suitable receptacle, and a small piece

of touch-paper (supplied with every box) is attached, the powder partly covering one end of the touch-paper. The powder is then ignited by lighting the other end of the paper with a lighted taper. When the light reaches the powder the result is a highly brilliant white light, no matter how much powder is used; it all ignites instantaneously.

In the exposure we made with a 6d. box, we found we obtained a well-exposed negative of a large room, proving to us the powder is very economical; the 6d. box is ample to illuminate a large room, or sufficient for two or more portraits. For professionals, the larger size box, price 2s. 6d., is recommended.

The powder seems very free from dust, and there are no unpleasant fumes, and, if anything, less smoke than that from some other powders. The makers have certainly produced a flash powder which is safe and inexpensive.

The Edwards "A. S." (Auto-Screen) Orthochromatic Plate. Made by The Leto Photo Materials Co., Ltd., Roman Wall House, 1, Crutched Friars, London, E.C.

The Leto Company, since its acquirement of the old-established dry-plate works formerly carried on as B. J. Edwards and Co., at Castlebar, Ealing, have introduced a new member of the series of Edwards' plates in addition to maintaining the output of the "Snapshot Iso," "Empire," and other plates. In the new emulsion they have aimed to supply an orthochromatic plate which may be used to give a considerable degree of colour correction without necessitating the use of a filter. In doing this we find, as the result of a number of hand-camera exposures, that they have provided also an emulsion of considerable speed for exposures. In the comparatively dull light of the present week, using a lens of $f/6$ aperture, it gave us fully exposed negatives, the orthochromatic quality of which was evidenced by the good rendering of clouds at the same time as of the foreground of the subject. The plates, like most orthochromatic emulsions, give density easily, and, using a rodinal developer of 1:20 strength with a drop or two of 10 per cent. potassium bromide solution, we found it easy to secure ample density and contrast. There is no doubt that the use of plates such as these, which are issued at the standard prices, will do much to improve the rendering of many subjects undertaken by the amateur worker.

Morgan Self-Adhesive Final Support for Transfer Tissue. Sold by O. Sichel and Co., 42, Bunhill Row, London, E.C.

Messrs. Sichel send us a small sample of this material, prepared specially for the Morgan process of dry-mounting, embossing, and plate-marking at one operation, a departure in mounting methods which we have already reviewed and been able to describe in favourable terms. The self-adhesive paper we find to work well in the carbon process, and, using a small hot press of the ordinary pattern, found it to give perfectly solid adhesion of the print to its mount. The Final support is at present issued in bands of 25in. width and 12ft. length, at 4s., but professional photographers prepared to order cut sizes in quantities should apply to Messrs. Sichel.

ENLARGEMENTS, ETC., BY S. H. FRY.—A new price list has just been issued by Mr. S. H. Fry, of Frisian House, 5, Highbury Grove, London, N., which gives very clearly the charges for bromide and other enlargements, printing in P.O.P., carbon, platinum, and other processes, and of the special lines in mounted and framed enlargements, of which Mr. Fry has made a speciality. The list appears at a time when many photographers doubtless are in the position to place out special orders for the Christmas season, and therefore it is due to Mr. Fry and his staff that we should emphasise our long experience of the excellence and promptness with which all descriptions of photographic work are done. The firm is one which works exclusively for professional photographers and trade houses, and in our long experience of it has maintained a very high standard of output.

New Apparatus, &c.

The "Westminster" Enlarging Easel. Sold by the Westminster Photographic Exchange, Ltd., 119, Victoria Street, Westminster, London, S.W.

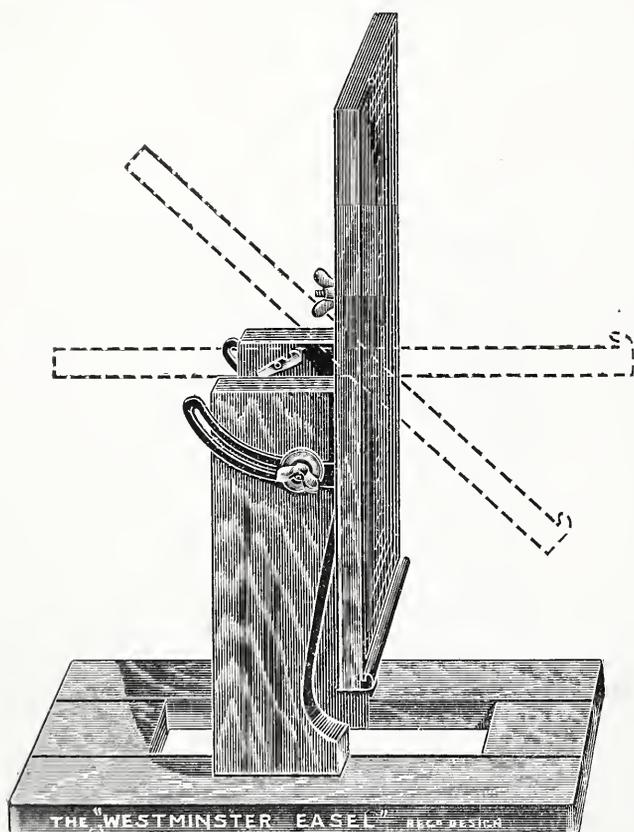

Quite a number of excellent features are embodied in this new piece of apparatus, the design of the Westminster Company, and obtainable only direct from them or through a dealer. The easel accommodates bromide paper up to 15 x 12 size, being marked out for this size and for all others down to lantern plate $3\frac{1}{4} \times 3\frac{1}{4}$ inches), the Westminster Company recognising that an enlarger is as good an apparatus as any for making lantern slides by reduction by artificial light. The lantern plate is simply clipped to the easel by a couple of drawing pins, focussing having previously been done on a piece of Bristol board the approximate thickness of the lantern plate. This, however, is an aside to our object proper, which is to emphasise the special features of the new apparatus. The Westminster easel provides the means of adjusting the bromide paper to the negative and thus dispenses with certain movements of the enlarger. There is no doubt that the proper method of adjusting

amount of tilt can be given, and the lantern is supported quite rigidly. Not only so, but the table, thus provided, forms an excellent support to which may be affixed small articles such as coins, flowers, etc., which may have to be photographed. Lastly, when we have finished enlarging upon it—our present state—we find it of service as a book stand or a copy-holder for the typewriter. The base of the easel is most substantially made in hard wood, whilst the easel itself is made in varnished pine, tongued, and very fully protected against warping. To the amateur worker who goes in for enlarging, the apparatus should prove a boon in the way of saving time and trouble, and giving a degree of certainty to the work. The price is 21s.

A special pattern of the easel is also issued, in which a framed plate-glass front is provided for the bromide paper, whilst the apparatus, as necessitated by the glass front, is of still stronger construction. The price of the special pattern is fixed at 27s. 6d.

The "Maxilyt" Combined Printing and Studio Arc Lamp. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

The requirements, particularly of the photographer in a small

the enlargement on the bromide paper is by moving the paper, and not the negative, in the stage of the enlarger, since the latter plan—in nine cases out of ten—will cause incomplete illumination of the negative. The Westminster easel allows of an up-and-down and rotating movement being given to the bromide paper just as easily as a negative is moved in the stage of a modern enlarger, and the particular virtue of the apparatus lies in the fact that the adjustment is made very conveniently and quickly with one hand, simply by loosening a set screw at the back. A similar screw on the side allows of the easel being tilted forwards towards the lantern or backwards from the lantern through a complete right angle, so that it lies perfectly horizontal. In both cases the easel catches with the support, so that it is automatically brought square with the enlarger. The advantage of the horizontal position is that when the enlargement has been focussed on the face of the easel, the latter can be turned back and the bromide paper pinned firmly in place without any risk of shifting the position of the easel, the pressure being simply vertically downwards instead of a thrust against the easel. Further than this, the movement allows of the apparatus being used as a very efficient and rigid lantern stand for an ordinary optical lantern used in a small room; any desired

way of business, are excellently met in this apparatus, which combines in one instrument a lamp for studio portraiture and for printing, and that at a most moderate price. This is done by making the printing cabinet form the support for the lamp, the arc being very quickly transferred from the lower position in the cabinet to the top of the upright supporting it when used as a studio lamp. If velvet or canvas cover be provided for the printing cabinet the rear end of the support is very conveniently hidden from sitters. The lamp, as we have seen for ourselves, gives a high degree of actinic light, negatives of full printing density giving a P.O.P. print in just over ten minutes. Moreover, the lamp should prove very economical of current, since it works at a consumption of 7 amperes and takes current of from 200 to 240 volts, a resistance included in the price of the lamp allowing of the necessary adjustment or of a greater amount of current being admitted up to 10 amperes. The cabinet allows of frames up to 12 by 10 being accommodated, and the whole outfit is certainly one which will appeal to those who wish to make the

Commercial & Legal Intelligence.

THE "WEST" A VALUABLE CONSIDERATION.—A case of considerable importance to photo artists and to photographers came before the West-London County Court last week in the shape of an action brought by John Hunter, the well-known artist, against Messrs. Clifford and Sons, art publishers, of Haymarket, for an account in connection with the sale of proofs of a picture of his purchased for the nation at the Chantrey Bequest.

Mr. Low, counsel for the plaintiff, said Mr. Hunter painted "My Lady's Garden," which was exhibited at the Royal Academy, and was purchased for the nation by the Chantrey Bequest. The defendants approached Mr. Hunter for permission to reproduce the picture, and he granted a licence on certain terms as to signing artist proofs and receiving royalties on the sale of them. The defendants had sold proofs, and the account now asked for would show what was due to Mr. Hunter under the licence.

Mr. Horace Rowlands, counsel for the defendants, submitted that there was no case, citing the Copyright Act, c. 68, as follows:—"The author (being a British subject, or resident within the dominions of the Crown) of any painting or drawing, or the negative of any photograph, shall have the copyright therein for his life and seven years; but if the same shall be sold or disposed of, or made or executed for a good or valuable consideration, the vendor or author shall not have the copyright therein, unless expressly reserved to him at the time by signed agreement, but it shall belong to the purchaser or person for whom executed, nor shall the vendee or assignee be entitled to the copyright unless expressly so agreed in signed writing."

Here the sale of the picture, said counsel, was an absolute sale of the copyright, unless there was a signed agreement to the contrary. There was no such agreement.

Mr. Low contended this had nothing to do with the original question of reproduction, but was a subject for counterclaim.

Mr. Rowlands: It is a national picture, and anybody can copy it.

Mr. Low said that the defendants had reproduced the picture, the plaintiff had signed the proofs, and the defendants were presumably making money out of it, as the account would show.

The Deputy Judge: He might perhaps recover for signing, but I see no answer to the defendants' objection, and there must be judgment for them, with costs.

Mr. Low said Mr. Hunter would say the copyright was reserved to him. He had the ordinary document from the Tate Gallery.

Judgment was entered as stated.

FRAUD BY A COLLECTOR.—A respectably-dressed man, named Andrew McLochlan (38), of Mellon Street, pleaded guilty at Newport last week to embezzling various sums of money collected for Messrs. A. and G. Taylor, photographers, of Newport. He was collector in the Ebbw Vale and Cwm districts. Mr. Lyndon Cooper, who prosecuted, said Mr. Chalklin, managing partner of the firm, felt compelled to bring the matter into court, as, though the amounts in this case were small, this was the third man in twelve months who had robbed him. From Friday to Wednesday defendant collected and spent £3 16s. 6d., but absconded, and was heard of at Neath. Mr. Chalklin said an industrious man could in that district make 35s. per week clear. Prisoner said he took a drop too much, and then went wrong. Formerly he had a provision business of his own at Swansea, but had a bit of bad luck. His wife (from whom he was separated) and family were still living at Swansea. The Bench in the result took a lenient view, and defendant was fined 30s., with the alternative of 21 days' imprisonment.

OBJECTICNABLE PHOTOGRAPHS.—Walter McIntosh, of Rydevale Road, Balham, was summoned for sending a postal packet containing indecent photographs, contrary to the Post Office Protection Act, 1908. There was also a further summons calling upon the defendant to show cause why 130 photographs seized at his premises should not be destroyed.

Mr. Herbert Muskett supported the summonses on behalf of the Commissioner of Police. Mr. Walter Frampton defended.

Mr. Muskett said that the defendant traded as the Fine Art

Photographers' Publishing Company, and the present proceedings against him were the outcome of certain complaints from people in Australia and other British colonies as to the class of work in which he was dealing. Owing to the persistence of the complaints, Chief-Inspector Stockley, of Scotland Yard, caused a letter to be sent in an assumed name to the defendant, asking for a price list and catalogue. These were forwarded in due course, and they showed that the greater part of the business was of a genuine character, but one section of the catalogue dealt with stereoscopic slides, which were described as "artistic life studies; artists' model and female figure." On October 12 defendant sent on approval fourteen of the slides described in that section, and seven of those had been selected for the purpose of the prosecution. A search warrant was subsequently obtained, and, armed with this, the police went to the defendant's premises and seized 130 other photographs of an exactly similar character.

Mr. Frampton said that if the magistrate agreed with the view of the prosecution that these photographs were indecent, then the defendant would not oppose their being destroyed, and he would undertake not to deal in anything of the kind again. He had a stock of over 30,000 photographs on his premises, and of these the police were only able to bring forth 130, which the defendant had considered artistic and unobjectionable.

It was stated that the defendant was convicted of a similar offence in 1895.

The magistrate observed that the defendant did not appear to have sold these photographs in an indiscriminate manner, and they seemed to form a small part of his business. That being so, he imposed the mitigated penalty of £5 and £5 5s. costs, and ordered the photographs in question to be destroyed.

LEGAL NOTICES.—A first and final dividend of 1s. 2d. in the £ has been declared in the bankruptcy of Percy Hague Mareden, photographer, etc., High Street, Pateley Bridge, Yorkshire.

The Auto Photo Company, Ltd., is being voluntarily wound up in accordance with resolutions passed at the Paris office, 52, Rue de Flandre. Mr. Fournels is the liquidator.

NEW COMPANIES.

THE CINEMATOGRAPH FILM HIRING COMPANY, LTD. Registered November 8, with a capital of £10,000 in £1 shares. Formed to carry on the business of cinematograph and biograph showmen, exhibitors, providers of entertainments and cinematograph pictures, etc., also to enter into an agreement with M. A. Pyke. The signatories are W. W. Cresswell and J. W. Lovett, both of 9, Quality Court, Chancery Lane, W.C. The first directors are Robert A. Lyons, 3, Abingdon Mansions, W., and Montagu A. Pyke, Dewar House, Haymarket, S.W. The registered office is at Dewar House, Haymarket, S.W.

THE LANTERN COMPANY, LTD.—Registered on November 10, with a capital of £720, in £1 shares. Objects: To carry on the business of advertising contractors in all its branches, makers and suppliers of lantern slides, films, plates, etc. Signatories: C. H. K. Chamer, 196, Deansgate, Manchester, and K. E. Hall, Broomefield, Seymour Grove, Manchester. Registered office, 196, Deansgate, Manchester. Private company.

THE LEYTONSTONE PALACE, LTD.—Registered on November 11, with a capital of £1,000 (900 in £1 shares, and 2,000 in 1s. shares). Its objects are to carry on the business of photographers, manufacturers of, and dealers in, photographic cameras, and photographic materials of every kind, particularly in cinematograph films. The subscribers are U. A. Pasqua, 24, Manchester Street, Manchester Square, W., and R. L. Tayler, 30, Moorgate Street, E.C. The first directors are R. L. Tayler, U. A. Pasqua, and F. Mann. Manager director, U. A. Pasqua. Private company.

THE BENOBOB SYNDICATE, LTD.—This company was registered on November 12, with a capital of £15,000 in £1 shares. Its objects are to carry on the business of printers, photographers, photographic chemists, manufacturers of photographic apparatus, etc., and to enter into an agreement with Benno Borzykowski. The subscribers are B. Groner, 48-56, Golden Lane, E.C.; H. Davidson, Basterfield Street, Golden Lane, E.C.; and M. Woolf, 4, Barbican, E.C.

News and Notes.

SOUTH KENSINGTON MUSEUM.—The specimens illustrating the manufacture of high-class lenses shown by Messrs. J. H. Dallmeyer, Ltd., at the Franco-British Exhibition last year, and the Imperial International Exhibition this year, have been presented to the Board of Education. This collection, which was awarded a Grand Prix, is now housed in the Western Hall of the Science Museum, South Kensington, the entrance to which is on the south side near the western end of Imperial Institute Road.

THE NORTH MIDDLESEX EXHIBITION.—Our readers in the North of London should not omit to bear in mind the exhibition of the North Middlesex Society, which will be held from December 1 to 4, in the Hanley Hall, Sparsholt Road, Stroud Green, London, N., opening on the first three days, from 7 to 10, and on the Saturday from 3 to 10. On each evening music or a lecture will be a feature. Mr. A. H. Blake will talk of the "Romance of London Streets" on December 2, and Mr. Martin Duncan of "Wanderings in Zoeland" on December 3.

THE R.P.S. AFFILIATION.—It is announced in the November "Circular" that three societies had been admitted to the Affiliation, viz., the Ashbourne Photographic Society, the Salisbury Camera Club, and the Glasgow and West of Scotland Photographic Association.

A lecture on the simplification and study of pictorial work, by Malcolm Arbuthnot, is in hand, and will shortly be ready for circulation. Negotiations are being made for lectures by eminent men on topical subjects.

A model exhibition prospectus has been drawn up by a special Sub-Committee, and the result of their labours will be printed in an early issue of the "Monthly Circular."

PHOTOGRAPHIC ALLIANCE EXHIBITION.—An exhibition of the Inter-Club Photographic Alliance opened last week at the Blackburn Free Library, by Mr. A. H. Whipple, Director of Education. Mr. B. Ward-Thompson, of Wiltshire, was in the chair. The Alliance was inaugurated at Blackburn last February, and embraces thirteen societies with a radius of eighteen miles from the Town Hall. The pictures for this year's competition (writes "Viewfinder" in the "Lancashire Daily Post") were submitted to Mr. Frank M. Sutcliffe, of Whitby, who officiated as adjudicator. Each society was asked to contribute nine prints by different workers, and ten was the highest number of marks given to any picture. The awarding was as follows:

	Marks.
1.—Blackburn and District Camera Club.....	51
2.—Darwen Photographic Society	47
3.—Nelson Camera Club	45
4.—Burnley Camera Club	44
5.—Nelson Photographic Society	37
6.—Bolton Camera Club	35
6.—Horwich Photographic Society	35
7.—Chorley Photographic Society	31
8.—Preston Camera Club	28
9.—Colne Camera Club	26
10.—Burnley Co-operative Camera Club	24
11.—Padiham Camera Club	21
12.—Preston Scientific P.S.	18

Members of the Blackburn Camera Club have done wonderfully well this season in competitive exhibitions, and they have added another laurel to their wreath by carrying off the Inter-Club championship, which entitles them to hold the Toulmin silver shield for the next twelve months.

THE SINCLAIR OIL AND BROMOIL COMPETITION.—The judges, Messrs. E. T. Holding, Furley Lewis, and J. C. S. Mummery, as a result of their examination of the prints sent in to the above competition, have made the following awards:—First prize, £10, for "A Silhouette" to Frank H. Read, 61, Richmond Road, Twickenham; second prize, £5, for "His Eminence," to F. C. Tilney, Walden, Cheam, Surrey; third prize, £3, for "A Nocturne" to Reginald C. Chapman, 89, Holly Road, Northampton; and seven prizes of £1 each of the following:—H. A. L. Way, for "An Englishman"; W. C. S. Fergusson, for "The Ferry Boat"; Mrs. Ambrose Ralli, for "Sunshine"; Bertram Park, for "Willow Pattern"; R. M.

Cocks, for "Sunset at Rye"; J. T. Tanner, for "Great Yarmouth"; H. Bairstow, for "In Fiesch." A very large number of prints of a high quality were contributed to the competition, and an exhibition in which a selection of these prints will be shown, will be held at 54, Haymarket from November 24 to December 8. Admission to this exhibition will be free, and it will give workers an opportunity of seeing the present position of oil and bromoil work. The exhibition will be open from 10 to 4, excepting Saturdays, when it will close at 1 p.m. Messrs. Sinclair may feel pardonable pride in the fact that the prints in the competition were judged and cheques sent to the successful competitors on the day following that for the last receipt of entries.

TREATMENT OF AN OVER-EXPOSED PLATE.

To the Editors.

Gentlemen,—Recently I was commissioned to photograph the trench for a sewer. In order not to disturb the roadway more than was necessary, the excavation was done in sections, and a tunnel

TRENCH FOR
SEWER.
CLARE, 1909.

run from one section to another. The object was to get a view through from one opening to the next. Owing to the shortness of the openings, and the necessity for placing the camera near to the bottom of the trench, it was impossible to focus or to see the image on the ground glass so as to judge the exposure required, so I

focussed for the distance above ground, planted the camera level with the centre of the pipe, and made two exposures, giving the second plate twice as long as the first. On developing the first plate with my usual developer I found it hopelessly over-exposed. I then soaked the second plate for five minutes in a solution of bromide of potassium, 5 grs. to the oz., mixed this solution with an equal quantity of the developer, and developed the plate, with the result I send you—a result which brought me both cash and credit. I may mention that the cutting was 13ft. deep, the boards shown being the shoring, half-way up, and it has occurred to me that by this procedure I very likely got fuller detail than I should have secured by a correct exposure.

As a "wrinkle" I would add that I had the flat ends of the sewer pipe rubbed over with a piece of chalk.—I am, yours truly,

Clare, Suffolk.

THOS. STOKOE.

November 13, 1909.

A CONCENTRATED ONE-SOLUTION M.Q. DEVELOPER.

To the Editors.

Gentlemen,—I see in your last one or two issues some correspondents asking for a very concentrated M.Q. developer, and in answer there is one given in this number which is not nearly strong enough, as, when diluted, it only contains 1 grain of hydroquinone and $\frac{1}{2}$ grain of metol in the oz., which is on the weak side. If your querists will turn to page 65 of the "Photographic Annual" for this year they will find a very concentrated formula which, when diluted 1 part to 7 parts of water, still contains 3 grains of hydroquinone and $\frac{3}{4}$ grain of metol in the oz.

I will not inflict the formula on you, as it requires the instructions in full to make it up, but I may say that I have made it up dozens of times without a single failure. I do not think such a strong formula has ever before been published, and it might be of interest to your readers to reproduce it.—Yours faithfully,

R. L. BOYD.

10, Annesley Park, Rathmines, Dublin.

November 13, 1909.

[The formula, which appears in Mr. Boyd's name, is as follows:—Warm water, 24 oz.; metol, 24 grs.; hydroquinone, 96 grs. When dissolved, add soda sulphite (crushed small), $1\frac{1}{2}$ oz. By the time the sulphite has dissolved, the whole will be a white, pasty mass. Now add 64 grs. of sodium hydrate (caustic soda), shake well, and in a minute or so you will have a clear concentrated M.Q. solution. One dr. of this, added to 7 drs. of water, will make a developer containing in each ounce:—Metol, $\frac{3}{4}$ gr.; hydroquinone, 3 grs.; sodium sulphite, 2 grs.; sodium hydrate, 2 grs. Can be used half strength for most purposes.

The image appears in 5 to 8 seconds; development usually complete in $1\frac{1}{2}$ or 2 minutes; factor about 16. Diluted 1 dr. to 2 oz. of water and 2 drops of bromide added to each ounce, it makes a first-rate bromide paper developer. The strong solution keeps very well indeed.—Eds. "B.J."]

THE BLEACH-OUT PROCESS.

To the Editors.

Gentlemen,—In No. 2,584, p. 887, you answer that you can give no further information concerning the new bleach-out process. You will find the details in the German Patent Letter, No. 209,993, Klasse 57b, or the inventor, Dr. Hans Stebbe, 12, Robert Schumannstrasse, Leipzig, will give all further information.—Yours very truly,

DR. MEBES.

Berlin, N. 4. Chausseestrasse 105.

COWES CAMERA CLUB.—This club will hold its third open exhibition in the Town Hall, Cowes, I.W., on December 15 and 16, when Mr. S. G. Kimber will perform the work of judging the exhibits. One of the four classes in the open section will be set apart for colour work only, either prints or transparencies, and a number of awards will be placed at the disposal of the judge, in addition to several challenge plaques for special subjects, in both the open and members' classes. Entries close December 6. Further particulars and entry forms may be obtained from the hon. secretary, Mr. E. E. Vincent, 4, High Street, Cowes, I.W.

Answers to Correspondents.

** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

DRAWING REGISTERED:—

The Pansy Portrait Painting Co., "Brompton," 15, Whitehall Road, Thornton Heath, S.E., *Drawing of an Advertisement Design.*

THREE-COLOUR PORTRAITURE.—I should much appreciate your kindly advising me if any firm in London is producing good three-colour portraiture on paper from a gelatine film stained or inked with the necessary three colours. If such work is being done, will you have the kindness to advise me where some specimen prints and the necessary materials can be obtained.—GEO. PENDELL (Callao, Peru).

So far as we know, no one in London is doing such work commercially. You could get good specimens of the process from the Rotary Photographic Co., New Union Street, Moorfields, London, E.C., or from Mr. H. J. Comley, secretary of the Society of Colour Photographers, Surrey House, Stroud, Glos.

COPYING OIL PAINTINGS.—We are requested by a customer to photograph some oil paintings. As ordinary plates would be useless for the purpose, what kind of orthochromatic plates should we require, also what screen, if any, and where obtainable? Could we use, instead of orthochromatic plates, Autochrome transparencies, and thus reproduce the paintings in their natural colours? What lens would be required in either case, and how should we proceed? Any hints on the subject, within the limited space of your valuable journal, would be greatly appreciated by us.—COLOUR.

Most probably you require a panchromatic plate and fairly deep light filter. We cannot say positively without seeing the paintings, but a panchromatic plate, such as the Wratten, will suffice in either case. You should get the shilling book, "The Photography of Coloured Objects," which we reviewed some weeks since. Messrs. Wratten also issue a useful gratis booklet on the subject, and you can get a similar booklet from Messrs. Ilford, Ltd. Of course, you can make a transparency (not a print) in colours on an Autochrome. In either case a good anastigmat lens will suffice, and even a good R.R. lens will probably be quite sufficiently colour corrected.

RETOUCHING (Reply to "J. S. A. C.").—Your work is second-class only. It is merely smoothing up without any special attempt at improving the general modelling. Increase your high-lights more, respect the half-tones, and work with finer and more tender gradation into the shadows. You preserve the likeness well—a strong point in your favour—but avoid obliterating wrinkles to such an extent, and you will be stronger still in this good quality. Why not take some lessons?

H. H. D.—We have no information beyond that in the patent specification, according to which paper is saturated with shellac.

CAMERA.—(1) Can you recommend the ——— folding camera for general professional work—viz., for at home portraiture, interiors of rooms, and exteriors of buildings, or would the absence of a swing back and front be against the camera being used to photograph tall buildings? It is fitted with a rising front.—**BOOTLE.**

(1) It is not the best for the purpose, owing to its insufficient rise of front and inability to take short-focus lenses. You should get a camera of the Sanderson hand-stand type, which is less portable, but possesses the necessary range of movement. Unless you are going to do a good deal of rapid exposure work, you are better without a focal plane shutter. (2) Both are excellent, as good as you can have. A focus of 7in. is best for all-round work on a 5 x 4 plate. For quarter-plate choose 5in., for half-plate 9in., but with camera of the latter size you would find a 5- or 6-inch of frequent use in architectural work.

THE RIGHT TO APPARATUS.—I invented a method by which glass negatives of various thickness could be brought into perfect contact with a collotype plate, this doing away with the use of films and saving the trouble of setting the negatives up in position. I worked this method successfully for about six months. I was then offered a situation as a collotype plate maker by the ———, Limited, of ———. After working there for about two months I introduced my glass negative method, having made the fittings for two frames some time before I was engaged by this firm. I brought them into their works and fitted them to their old frames, and worked them. Later on, I brought out an improvement and protected the whole for six months. I refitted the company's frames with the improvement at my own expense and worked them for about two years. I made the fittings away from the firm, and the company paid nothing whatever in any way. When I came to fit the frames I found I had not fitted a sufficient number of the small rubber blocks with wire stops, so I fitted the few wires to make up the frames in the firm's time. I then put the frames together in the firm's time by sticking the blocks to their glass with fish-glue. The firm found the glass used in the frames. I received nothing whatever for the idea or the material I supplied, but I received notice to leave the company's employ. When I was about to take my fittings away they refused to let me do so, as they said they were attached to their property and some of the blocks were made in their time. Can I legally demand the return of my fittings, or charge them for same, as my property was attached to theirs at their request?—**C. G.**

We are rather inclined to the opinion that you will not be able to recover anything, as you used the contrivance for aiding you in your work while in the firm's employ. However, this is a question you had better refer to a solicitor, who, after hearing the facts, will be better able to advise you than we are. However, it is shabby treatment of the firm not to make you some recompense.

COPYRIGHT.—I took a negative of a very popular clergyman here, which I registered in June, 1900. The sitting was an invitation, and proofs were supplied free. I have sold nearly 1,000 cabinets and also enlargements (nearly 40), so the negative, as you will see, is of value to me. One of the daily papers here published it, and also issued it as a supplement to their weekly paper, with the result that my sale will be completely destroyed. Would you kindly tell me what compensation I should get, or if in the event of taking action (as I may be compelled to do) what kind of case have I? Also, are they liable for both papers—daily and weekly?—**SUPPLEMENT.**

If, as you say, the copyright is yours, as it appears to be, and you did not give the newspaper permission to reproduce the portrait, you can proceed against it for infringement of copyright. You can sue for penalties as well as damages and also obtain an injunction restraining further publication. If you write to the paper saying that you propose taking legal action it will, no doubt, make you a fair offer.

STUDIO.—Will you kindly advise me the best way in which to obtain the side light in my studio, as it's all top light, glass on top measuring 13ft. x 9ft.? I suppose it will have to be done by reflectors, and what material to use, and where to get it? I thought of reflecting with mirrors.—**SIDE LIGHT.**
The only thing to be done is to convert the top light as much as

possible into a side light by means of reflectors. Had the 9ft. dimension been greater the trouble would be less than it is. The best reflectors will be white paper pasted on canvas strained on frames. Glass mirrors are not so good for the purpose. A thin muslin curtain to subdue the direct top light over the head of the sitter will be useful.

WOODLAND LANDSCAPE.—1. Will any plate give the same full scale of gradations that we see in a well-lighted woodland or landscape view? 2. If so, what class of plate, process, ordinary, fast, ortho, panchromatic, with or without filters? 3. If filter is necessary, which is required, Ki, ii, or iii? 4. If full scale can be obtained in negative, what, if any, printing process will reproduce it? 5. Assuming highest light in nature to be a brilliantly lit white cloud or patch of sunlight, and to be represented by 1 (one), what figure will represent deepest shadow, say under heavy foliage of trees at base of a bush? 6. If no negative or print can give same scale, how far will it fall short? Will white paper equal highest light or is it degraded in comparison? Will deepest black in printing process giving longest scale of gradation be as dark as deepest shadow? 7. What was scale used in the original H. and D. experiments, and how did this compare with scale in well-lit landscape?—**TONE.**

1 to 4. No plate will give the great range of contrasts which are actually seen. The best you can do is to use a good plate of medium rapidity, and on it make a negative of plucky quality and print in platinotype or carbon. 5. The range may be from 1 to 200 or more. 6. A negative will give a scale of 1 in 30 or 40. You may choose—you will usually do this—to make the highest light white paper in the print. The deepest shadow will be represented by the deepest black of paper, a tone which is many times lighter than the actual shadow. 7. Messrs. Hurter and Driffield employed a series of known light intensities, obtained by exposing the plate behind a wheel with a series of apertures cut in it. They could thus give a series of exposures greater than the plate could record, and representing more nearly the range of light intensities in a landscape.

COLLODION.—I am anticipating taking up the wet collodion process for making lantern slides. I have made some pyroxyline and collodion by the formula given in the "British Pharmacopœia." and shall be much obliged to you if you will give me a good formula for the iodising solution, one that will be best for lantern slides.—**BEGINNER.**

We may tell you at once that the collodion you have made is of no use for the wet collodion process. The formula given in the "Pharmacopœia" is for surgical purposes, and is of a far too skinny and horney character for photography. As you are a beginner in the wet collodion process, we should advise you to purchase proper photographic collodion (e.g., Mawson's). You will then get the right thing with the proper iodiser. By doing that you will ensure that any failures you may possibly meet with in your first essays are not due to the collodion.

COPYRIGHT LAW IN NEW ZEALAND.—1. Is there a separate Copyright Act for New Zealand? 2. Is this right what the editor of a New Zealand paper tells me after reproducing one of my copyright photographs without permission, viz.:—that under the copyright laws of that country no portrait may be reproduced without the consent of the actual owner (i.e., the person whom it represents), and that whether copyright or not he was justified in reproducing it because he had the permission of the person photographed by me, and that because the mount did not show the name of the photographer (having apparently been cut for a frame) he was doubly justified in reproducing it.—**G. F. B.**

1. Strictly speaking, the Copyright Act of 1862 applies to all the British Colonies and Dependencies, but the formalities differ to some extent, and in most of the Colonies the law is administered with considerable laxity. 2. Under British copyright law, if the copyright was yours the permission of the sitter is not necessary. There is no law requiring the name of the photographer to appear on the photograph. All your editor's statements are untrue.

ALBUMEN PAPER.—Will you kindly tell me the best way to make prints on albumenised paper transparent for the process of

crystoleum painting. Also, if albumenised paper is sold in small quantities and where to obtain it?—CRYSTAL.

A special transparency medium is sold by the dealers. We advise you to purchase, but you can prepare it yourself from—Canada balsam, 5 oz.; paraffin wax, 2 oz.; white wax, 2 oz.; which is melted, the picture immersed, and the whole kept as cool as possible, consistent with remaining fluid. You can purchase albumenised paper from Fallowfield, 146, Charing Cross Road, W.C. No other paper answers so well.

PHOTOGRAPHS OF BUILDINGS.—I should be very much obliged if you could give me any information as to negatives of local buildings, if any one has a right to copy and reproduce them and sell them if they are not copyright?—A READER.

If we understand your query to ask if you are at liberty to photograph local buildings and issue copies, we can tell you that, so far as copyright is concerned, you are at liberty, once you have got the negatives, to do what you like with them. The owners or architects have no copyright in them.

DEXTRINE MOUNTANT.—A formula in "Facts, Figures, and Formulæ" for a dextrine mountant says (pp. 115-7): Dextrine, 25 oz.; alum, 1 oz.; sugar 4 oz.; water, 30 oz.; carbolic acid (10 per cent.), 1½ oz. No instructions are given how to make this up, if to be made up cold or boiled, or in order given, etc. Can you inform me how to make it up, and what sort of sugar to use?—S. E.

We should mix the dextrine in cold water, bring to the boil, and boil for five minutes, then add the sugar and carbolic acid, and finally the alum dissolved in the minimum quantity of hot water (about 2 oz.). We do not advise alum in a mountant, it is a risky constituent, particularly for C.C. prints. The secret of getting a good dextrine paste is to use the best white dextrine, and this, we find, makes the home-made preparation cost practically as much as the excellent pastes on the market. 2. We do not know what the action is. We have tried the method, but have not been led to recommend it.

LESSONS IN CINEMATOGRAPH WORK.—What is the name and address of the school or firm who advertised in the "Journal" some time ago to give lessons in cinematography?—GYWR.

We cannot trace it in our pages. Better address your query to the "Kinematograph Journal."

LOSS OF DENSITY IN FIXING.—I should feel grateful if you will answer me the following through "Correspondence Column" in "Journal":—I am using the paramidophenol developer for bromides, but I find the prints loose in fixing, which I have never had occur with metol.—E. THOMAS.

This simply means under-development. The appearance of the developed image varies considerably with different developers, and you are in this case misjudging the termination of development. We assume that you are using an ordinary fresh fixing bath, and not fixing too long or in a strong light. With a fresh, clean bath there is no actual reduction of the image unless strong light falls on it, or very prolonged soaking is resorted to.

TONING BROMIDES.—(1) When toning bromide prints with platinum the high-lights, and especially the white borders round the picture, get badly stained. I have tried to clear them with a weak solution of hydrochloric acid, and also a 5 per cent. solution of carbonate of soda, but have been unsuccessful. I would deem it a favour if you will kindly let me know how I may overcome this difficulty. (2) Also, are bromide prints, toned with either copper or uranium, permanent?—SIDNEY E. TRELOAR.

(1) You do not say what bath you are using, but if the one given in the "Almanac," page 810, 1909, you will get stained whites, as described in the note to the formula. By adding potassium bromide to the other ingredients you can avoid the stains, but then the tone is a cold, instead of warm, sepia. (2) As a general rule, they may be considered to be of very doubtful permanence, but a good deal depends on the way in which they are kept. If well varnished with celluloid varnish they may last very well indeed, but there is always an element of doubt.

ELECTRIC LIGHT.—I am removing my studio to more convenient premises, and would like to know if I could use an electric lamp for portrait work. The size of the studio at present is about 11ft. wide, 24ft. long, 7ft. to plate, and about 11ft. 6in. to the ridge. I thought of putting the studio 12ft. wide and 8ft. to plate, and

the ridge in proportionate height. Would this be room enough for working the lamp for one or more figures?—ELECTRIC.

We would advise you to get a moderate size lamp of the enclosed arc type, and as these lamps usually have the arc about two feet below the point of suspension, it is well to have your studio fairly lofty. This is always an advantage, as it makes ventilation an easier matter, whether in day or electric light working. The lamp might be hung about three feet from one side of the studio, and as the point of suspension with an eight-foot wall plate would be about 9ft. 6in., giving 7ft. 6in. as the height of the arc, we should regard a slightly higher roof as almost a necessity. If possible, have one side of the roof solid (i.e., not glass), and hang the lamp on that side, protecting the woodwork with a sheet of asbestos. The lamp may be hung about 6ft. in front of the background, and should then give a reasonably good lighting for a group of two or three figures. If possible we should have the width of the studio 14ft. rather than 12ft., as you will then be able to modify the lighting by simply moving the camera more to one side or the other, getting more shadow or more light, according as you move to the shadow or light side of the studio.

CORRUGATED BOARD.—We very much need corrugated board like the enclosed sample, and shall be much obliged if you can favour us with the address of a firm who could supply, as we have failed to get anything like this.—L.YGRA.

Corruganza Manufacturing Company, Summers Town, London, S.W., and Thompson and Norris Manufacturing Company, Ltd., Warple Way, Uxbridge Road, Acton, London, W.

O. T. C.—The results of gold-toning only are not usually so permanent as the use obtained with gold followed by platinum. We should not call the paper as permanent as gaslight, but it is about equal to P.O.P.

L. BALK.—1. Write to the Comptroller of Patents, Southampton Buildings, London, W.C., for the circular of instructions to patentees. The smallest cost is £1 for provisional protection. 2. Fordham and Co., Victoria Works, Walthamstow, London, N.E., and Fourdrinier, Hunt, and Co., 2, Dufferin Street, Bunhill Row, London, E.C.

RIGHT TO PUBLISH.—Your valuable opinion on the following matters will be esteemed. A week or two back I took a photograph of the interior and exterior of a village church a few miles from here for postcards. The sexton of the church let me inside and I got a good picture. I next took a view of the church from the outside, and afterwards took a picture of the vicarage from the roadway. These I printed as postcards, and supplied some copies to a little stationer, etc., in the village, and he soon disposed of a good number and ordered more. The other day the vicar called at the shop and forbade any more being sold. He then came over to me and threatened me with the law if I printed any more copies, as I had taken the pictures without his permission. Please tell me if he can restrain me from selling the prints?—COUNTRY PHOTO.

Go on publishing the pictures. There is no law by which the vicar can prevent you. He might possibly have prevented you from taking the interior of the church had he been present, but having obtained the picture you can do as you like with it. The same with the others. The vicar's threat of the law is simply "bluff" and nothing more.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The "1910 British Journal Almanac" will be published throughout the United Kingdom on Wednesday next, December 1.

We regret to record the death of Dr. W. J. Russell, of whose researches on the action of bodies on the photographic plate in the dark a short account is given on p. 919.

Professor Namias has found that it is practicable to obtain reliefs by exposure of a thick film of bichromated gelatine under a negative by a dry process. The exposed film is heated to a moderate extent and thus attains a certain amount of relief, presumably a good deal more than is often obtained by submitting an ordinary surface-dry negative to similar treatment. (Pp. 909 and 912.)

Some most useful novelties in lights and dark-room lamps were shown last week at the Croydon Camera Club by Messrs. E. A. Salt and W. H. Smith. (P. 924.)

We draw attention in an article on p. 910 to the valuable work rendered possible by photography which is carried out at the "Philadelphia Museums."

A vignetter for the studio camera figures in "Patent News." (P. 920.)

A new scientific society, the work of which is likely to benefit photographic workers, has been formed with the title of the Society of Illuminating Engineers. Professor Silvanus Thompson, the first president, delivered an address last week. (P. 910.)

Some useful suggestions for indicating scale in stereoscopic prints are made by Mr. Martin-Duncan in the current "Photographic Journal." (P. 910.)

Mr. Alfred Watkins, in a lengthy communication to the Royal Photographic Society, has reviewed the methods of time development which have led to the latest method—namely, that of thermo-development, in which allowance is made for the temperature of the developer. (P. 913.)

The experience of an American professional photographer in attracting business is given on p. 918.

The twelfth Traill-Taylor memorial lecture was delivered on Tuesday evening last by Professor A. W. Porter. (P. 924.)

The Royal Photographic Society is to set apart one evening in the month for a discussion of more scientific and technical subjects. (P. 909.)

EX CATHEDRA.

Science at the R.P.S.

In this month's issue of the "Journal of the Royal Photographic Society," a rather important step is announced with regard to the meetings held on the first and third Tuesdays in each month. Under "The Proceedings of Council," it is stated "It has been arranged to devote the meeting held on the third Tuesday in each month to scientific and technical subjects, and, as it will be assumed that all who attend have expert knowledge of the subjects announced, elementary introductions will be considered unnecessary. At the meeting on the first Tuesday in each month, subjects of a less advanced character will be dealt with on practical lines." From this we gather it is intended that the third Tuesday shall be a strictly scientific meeting, at which important matters can be discussed in an adequately scientific manner, neither lecturers nor those joining in the discussion being expected to "talk down" to the level of the less advanced members of the audience. Hitherto the knowledge that many of the members present are not conversant with the subject has been a severe handicap to the speakers, and has done much towards nullifying the value of both lecture and discussion. An evening is none too long, and, under ordinary conditions, a good half of the time is wasted in dealing with elementary matters with which all those likely to join in the discussion are already perfectly familiar. This must be the case in any society that concerns itself with a variety of subjects, unless some arrangement such as that now adopted by the R.P.S. is in force. It is absurd to spoil the value of a discussion for the sake of those who do not understand it, and as the R.P.S. exists for the purpose of advancing photography, it is obviously a right move to ensure that once a month scientific subjects shall have the chance of being adequately dealt with. Apparently this new arrangement does not come into force until after Christmas, as the first meeting to which it applies seems to be on January 18, when Dr. E. J. Spitta will open a discussion on "The Illumination of the Object in Photo-Micrography."

* * *

Gelatine Reliefs by Contraction.

On another page we give a paper by Professor Namias on a property of bichromated gelatine that has hitherto passed unnoticed. It is that the film, after exposure to light, undergoes such a change that it is materially affected by a dry heat: the parts that have been exposed contract to a less extent than do those that have been protected from it, so that when the film has been exposed, say, under a negative and is afterwards subjected to heat alone an image in more or less relief is obtained. It is well known that gelatine, whether bichromated or not, contracts greatly when subjected to heat, but so far as we call to mind it has not before been pointed out, in the case of

bichromated gelatine, that contraction is retarded by the light's action. It would seem from what Professor Namias says that this novel property might be turned to useful account in the production of gelatine reliefs for different purposes. If so, it will be less troublesome to work than some of the well-known methods now in use. The author of the paper says that the relief obtainable by his process is not so high as that got by the swelled gelatine method, but for some purposes a very high relief is not at all necessary. The process seems simplicity itself. A metal plate is coated with a thick film of bichromated gelatine, and dried. It is then printed, and afterwards subjected to a tolerably high temperature, when those portions that have been more or less protected by the negative contract to a greater extent than the others, and so an image in relief is obtained. The presence of moisture in the "dry" film is an essential in the working of the process, and this the author of the paper ensures by the addition of glycerine to the gelatine solution with which the metal plates are coated. There is one point that occurs to us in reading the instructions for working the process. Professor Namias directs that, after the plates are sensitised, they should be put away to dry spontaneously. In the case of the thick film of gelatine given in the formula, which film is sensitised by soaking it for fifteen minutes in a tolerably strong solution of the bichromate of ammonia, it will take an unusually long time to dry at this time of year. Such a film as this is (in thickness and condition) very analogous to one for the Woodburytype process, and in the protracted drying would become quite insoluble in warm water, and useless. It would be interesting to know if a film dried so that it becomes insoluble in warm water has its power of contraction by heat similarly affected. Professor Namias' process will doubtless receive attention by those interested in bichromated gelatine photography, for there is certainly some novelty in it.

* * *

Standards of Illumination.

The photographic community has reason to feel gratified by the formation of the Society of Illuminating Engineers, the objects of which, as stated at the inaugural meeting held on Thursday in last week at the Royal Society of Arts, are the study of using light to the best advantage in both indoor and outdoor lighting, emphasising the need of standards of illumination, and encouraging the scientific study of the field of work coming next to the science of light production as distinguished from its effective and economical employment. Professor Sylvanus Thompson, the first president of the society, in delivering his address, dwelt most emphatically on the new era just opening for illumination as an art. The public interest demanded a scientific measurement of illumination, and that could now be given with the candle-foot as a unit. It would be one of the objects of the society to fix standards of illumination of workshops, schools, libraries, and studios, and to impress upon public bodies as well as upon individuals the need of certain specifications being complied with. Under the secretaryship of Mr. Leon Gaster, editor of the "Illuminating Engineer," the society promises to enter upon a sphere of great usefulness.

* * *

Stereoscopic Photographs of Small Specimens.

In an article by Mr. Martin Duncan on "Stereo-Photography in Geological Research," which appears in the current "Photographic Journal," two valuable suggestions are made with regard to the photography of such objects as fossils, etc. The first is that the work should always be carried out to a fixed standard scale of reduction, the author recommending distances of 50 and 100 centimetres (20 and 40 inches respec-

tively) from the lens as a suitable standard to adopt. The second suggestion is that a separate tray or support should be made of a graduated rule on the same standard scale of reduction, so that the object may at any time be approximately measured by laying the scale transversely over the other slide. Both these are excellent ideas, but it cannot be too strongly insisted that a scientific photographic record loses half its value if no scale is indicated. The author makes an alternative suggestion to the effect that a scale may be photographed together with the object, and he objects to this on the ground that the inclusion of the scale rather spoils the appearance of the slide. We would suggest that the least objectionable method of including a scale is to use a background faintly ruled in squares together with a "floor-cloth" similarly ruled. When photographing small specimens, both background and floor-cloth may consist of a piece of ruled cardboard bent at a right angle. If the specimen is placed right in the angle so that it touches both surfaces, a very good idea of the size of the object in three dimensions can be obtained in the stereoscope.

* * *

Portraits at the New Gallery.

The New Gallery is now occupied with the exhibition of the Society of Portrait Painters. To photographers it must appear a marvellously diverse and catholic show, for although confined strictly to portraiture it embraces such variety in matters of point of view, motive, arrangement, and treatment that a professional camera portraitist need to his own work and that of his competitors, can but see in it another proof of the limitations of his own methods. The newest developments come from Wm Orpen, A.R.H.A., who continues his series of small scale figures taking their natural and usual place in various interiors. In this he goes one point beyond Hogarth, who used the interior as a background, and often grouped the figures. Even his "conversation" pieces lacked the commonplace naturalism of Mr. Orpen's peers at domestic intimacy. Sargent has also done this sort of work, but in a less intimate way. The most striking of Mr. Orpen's here shown is "A Portrait" (22) of a lady reclining amongst the cushions of a lounge in her bedchamber. She is a mere accessory to the scene which boasts as its chief motive the gorgeous four-posted bed with its hanging and tester. The painting of this interior reaches the high water mark of Mr. Orpen's skill. Its colour and tonal harmonies, and in the perfect presentation of the bright but gentle light that pierces the shadowy recesses, the picture will stand as a great achievement. T. B. Kaminerton's "Portrait of a Lady" (65) is quite photographic in its realistic force.

PHOTOGRAPHY IN A GREAT PUBLIC WORK

THE paper read by Sir Martin Conway before the recent Congress of the Museums Association has brought us a budget of literature from Mr. Fred D. Maesch, the photographer of the "Philadelphia Museum," an institution established only in 1894, but now engaged upon many of the able departments of public commercial work. Unlike the ideal institution which Sir Martin Conway forebadowed the object of which was to provide a record of the art of all nations, the "Philadelphia Museum" (we follow the American friends in using the singular verb after the title) has for its object the collection and classification of specimens and photographs for the purpose of promoting the commerce of America with foreign lands, and securing of disseminating through the United States a wider knowledge of the customs and conditions of the nations of the world. It would lead us too far from our present purpose which is to draw attention to the great work which has been

made of photography in this work, to enlarge upon the many forms of activity which the "Museums" has shown. Suffice it to say that, apart from its work in collecting and exhibiting specimens and photographs, it publishes a weekly and monthly periodical aiming to interest foreign buyers in American goods, organises a translation department through which manufacturers may ensure the correctness of literature which they send to foreign customers, contains a library specially selected for giving the merchant a knowledge of new and possible markets, and in several other ways forms a centre of contact between manufacturers and United States Consuls. In this great work the camera has been very largely employed. Mr. Maisch tells us that the "Museums" collection of photographs now amounts to 5,000, all of which are catalogued and cross-referenced, whilst the yearly accession to this number amounts to 2,000 prints. The subjects of these are not only towns, countries, and types of people, but include also photographs of means of transport, and of methods of production of raw products in countries which are as yet in an uncivilised or semi-civilised state, the collections being accumulated with the object of showing manufacturers and exporters the conditions of foreign markets.

With characteristic American foresight, the resources of the "Museums" have been applied to the education of the American boy and girl in these branches of commercially valuable knowledge. The "Museums" has organised series of lectures, which are delivered within its buildings in connection with visits which detachments of students from the schools make to the galleries. But, realising that such a form of instruction can be only local, under a monetary grant from each State a large series of lectures have been prepared—in each case with lantern illustrations—and are sent out, slides, manuscript, lantern, and even the lantern screen, to schools from the Atlantic to the Pacific coast, the cost to the school being only the carriage to and from Philadelphia. But going even further than this, the "Museums" makes up specimen cases for use in elementary and secondary schools of all grades and designed to reach the scholars by actual exhibition the nature of commercial products, of the means taken to prepare them for the market, and of the uses which are made of them. Each specimen case consists of labelled examples of the raw, re-dried, and manufactured products, interspersed to an almost equal proportion with actual photographs showing, for example, the natural surroundings of the raw material, the conditions of growing and harvesting, and of the processes of refining. Perhaps we can best illustrate the form which this eminently practical method of education takes by quoting the contents of one shelf of a case dealing with tea and sugar.

Sugar cane.

Raw cane sugar.

Photographs.

Cutting sugar cane, Hawaii.

Pressing sugar cane, Java.

Sugar factory, Java.

Map.

Geographic distribution of cane and beet sugar.

Raw beet sugar.

Grape sugar.

Tea, green and black.

Photographs.

Tea-leaves, flowers and fruits.

Picking tea, Japan.

Preparing tea, pan-firing, Japan.

Map.

Geographic distribution of tea and cacao.

In a recent issue of the "Photographic Times," Mr. Maisch has dealt in particular with these educational de-

partments of the "Museums," and we reproduce from his article a half-tone illustration showing the shelf arrangement of one of these exhibition cases, the subject in this case being the cocoon and its uses. Others which we would equally like to reproduce deal with cotton and its bye-products, and silk from the cocoon to the fabric, in

each case employing photographs in conjunction with the actual specimens, and impressing upon the mind of the scholar by means of the map, which is not very clearly shown in the right-hand corner of the drawing, the geographical distribution of the products—in other words, the opportunities for American trade.

WATER SUPPLY IN WINTER.

THE recent spell of cold weather, accompanied as it has been in all parts of the United Kingdom by frost and snow, has been quite sufficient to remind us all that winter is at hand. Our present object is to give some practical hints, or reminders, that may be the means of saving, by a few precautionary measures being taken, some of the inconveniences that may arise from the stoppage of water supply, surely one of the greatest inconveniences that a studio can experience in winter. It practically puts a stop to business—or at least to printing operations—and customers are not always easily convinced that climatic influences are the cause of the delay in the execution of their orders. It is only those who have actually experienced these troubles that can realise them to their full extent. It is true that it has not been often during the past decade or so that we have had very inclement weather of long duration. Some of our older readers will well remember the winter we had some few years ago—the hard frost that lasted unbroken for many weeks, and the troubles thereby incurred. Some, perhaps, realised how this might have been avoided had a few simple precautions been taken beforehand. Not only is business impeded by a frozen water supply, but considerable damage may be done by burst pipes and the water flooding the premises when a thaw sets in, if the fracture is not discovered beforehand and the injury repaired. The really simple precautions should be taken without delay. In the first place, all exposed pipes should receive protection. If out of doors, and if detached from the building, they may be bound round with hay-bands, which may be had at any livery stables, or where horses are kept, for a few pence. A couple of thicknesses of these will usually afford ample protection. If the pipes are attached to a wall, of course, they cannot be dealt with in this way, but the hay bands may be laid along them, and secured closely by a piece of sacking nailed over them. At most ironmongers' a special kind of felt is sold for the protection of water pipes against frost, and this material being an excellent non-conductor of heat, is very effective, while at the same time it is very inexpensive. Angles or sharp bends in the pipes should receive special attention, for it is at such points that the water is prone to freeze first. The

outside pipes having been made secure, the main cock from the street should receive attention. The space in the ground in which it is usually situated should be filled up with some old flannel or blanket, which is one of the best non-conducting mediums we can well have; failing that, hay firmly pressed in will answer well. The water meter, if there is one, should be similarly protected. Some supply pipes from the main in the street to the house are laid very close to the surface, and in very inclement weather there is a risk of their becoming frozen. In this case it is a good plan to put some more earth over them so far as the premises extend, or, better still, six inches or so of stable manure; with that there need be little fear that frost, however severe, will reach the pipes.

If the above precautions be taken, there is small risk of the outside pipes getting frozen; but those inside the building must not be neglected, the more especially if the workrooms through which they pass are not always kept above the freezing point of water. In many cases the water is supplied to a cistern, which is sometimes fixed in a more or less exposed place. When this is the case the ball-cock should be specially protected, as its freezing would often be almost as bad as being quite frozen out. This may be done by binding it over with the special felt sold for such purposes. A good way, in the case of the water being drawn from a cistern, of protecting the pipes from it to the workrooms is to empty them every night after the day's work is done, while keeping the water in the tank for the next day's use. This can be done in the following way:—There is obtained a piece of iron barrel, say half an inch in diameter (obtainable of any gasfitter), and of sufficient length to reach a little above the level of the water when the tank is full. One end is wound round with a piece of rag so as to make it fit the outlet pipe from the cistern. This is then plugged in, and when all the lower taps are opened the pipes will be emptied, when, of course, there will be nothing to freeze. If the outlet from the tank were plugged with a solid plug, the pipes would remain full, even though all the taps were open, but the pipe plug supplies a vent by admitting air, so that the water runs out at the taps. In the morning the tube is removed, when the supply to the taps is restored. It is at night that the pipes freeze, as it is scarcely possible

for them to do so in the daytime when they are continually being drawn from and the water is in constant motion.

If perchance, through insufficient precaution, a pipe gets frozen, it should at once be carefully examined throughout its length, to find out if it has burst anywhere. A burst can be detected by the feel, as the pipe will always be considerably bulged at the part. When that is discovered, the aid of a plumber should at once be sought to do the needful. Failing this aid, the photographer can make a temporary repair himself as follows:—The pipe should be gently pulled away from the wall, and the ice picked out at the fracture with, say, a bradawl. Then with a couple of hammers (one used as an anvil), by gently tapping, the fractured edges can be brought neatly together. Some white and red lead are then mixed together and spread as a thick plaster on a piece of calico. This is then bound tightly over the place, and then the plaster is wound over with several layers of thick tape, and this bound tightly on with string. A fractured pipe thus temporarily repaired will last for weeks, or months, if the work is carefully done.

If it should happen that a burst has not been found out until a thaw revealed it, and the water is flooding the place, the best procedure in the emergency is to batter up the pipe a few inches from the break with a hammer. This treatment, though it will slightly increase the plumber's bill, will often save a lot of expense and annoyance in the shape of damaged ceilings, soaked walls, and other troubles. Sometimes the ceilings are not only stained by the water, but come down altogether, and in the case of walls that have become saturated with the water, they may take even months before they become sufficiently dry to be re-papered.

Freezing of the water in the pipes may generally be avoided by leaving all the taps dribbling during the night; but this water companies object to, if they find it out though, of course, they do not demur if the water is paid for by meter! The main object of the foregoing is to remind readers that, by taking a few simple precautions at the right time, much trouble may often be avoided. Although at the end of the winter they may be found unnecessary, still the trouble expended has been but trivial; while if the season happens to turn out severe, the labour of the preventive measures will be amply repaid.

MAKING RELIEFS ON BICHROMATED GELATINE BY A CONTRACTION PROCESS.

(A paper in "Eder's Jahrbuch.")

BICHROMATED gelatine, as is well known, possesses the property, after exposure to light, of losing its ability to swell up in water. On this fact are based the methods for the preparation of reliefs by photographic means. Another method for the production of gelatine reliefs is based upon the further property of bichromated gelatine to become insoluble in warm water on exposure to light. In the process for the making of a gelatine relief, which is described below, neither the swelling method nor that based on dissolution of the gelatine is employed. In the course of a series of experiments on the making of reliefs by the swelling method, I have noticed a characteristic which bichromated gelatine assumes on exposure to light. This is a kind of contraction which the gelatine undergoes when it is subjected to moderate dry heat. A film of gelatine rendered insoluble by exposure to light and moderately warmed over a lamp contracts to an appreciably less extent than one not affected by light. As a result of this, if one has upon the same metal plate a film consisting partly of light-affected gelatine and partly of that which has not been exposed, and if this film be heated, there is produced a species of relief in the parts

which have not been exposed. And this relief occurs not only in the parts of the film which have been most strongly affected but also throughout the gradation of the subject. I have noticed that the contraction which takes place, and the relief thereby produced, are more marked the damper the film. The process would thus appear to be a species of fusion (melting) of the normal gelatine in presence of a sufficient, but small quantity of water. The gelatine, which has become insoluble even at a considerable temperature does not absorb water, and therefore cannot undergo this melting process, and therefore the contraction which occurs in these parts is considerably less.

The Gelatine Coating Mixture.

The gelatine film (on the plate) must be actually dry, otherwise it could not be exposed under a negative or a drawing, but even in the so-called dry state the gelatine still retains sufficient moisture to give rise to the production of relief. In order to secure uniform results, and also to enhance the depth of the relief, it is an advantage, it has been found, to add a small quantity of glycerine to the gelatine. Glycerine has the same

effect as water, but is free from the drawback of evaporating, and owing to its hygroscopic nature it also reduces the tendency of water to leave the film, and thus assists the production of the relief. In practice the following method is used. A solution of gelatine is prepared as follows:—

Gelatine (emulsion or collotype)	30 gms.
Water	100 ccs.
Glycerine	5 ccs.

This solution is prepared on the water bath and warmed until a froth forms on the surface. The mixture is then filtered, avoiding further frothing as much as possible, through very fine muslin. Any froth now remaining on the surface should be skimmed off with a piece of card. The solution is now heated to 120 to 140 deg. F., and applied on to a polished and cleaned zinc plate, which has been previously warmed and placed perfectly level. The zinc plate may be given an edging of wax in order to prevent the solution running over. The quantity of gelatine mixture for a plate 4 by 3 inches is 30 ccs. (1 oz.). Naturally, the higher the degree of relief required the thicker must be the gelatine film, and therefore the maximum quantity of gelatine solution is applied to the plate. Any air-bubbles are removed with a bit of card whilst the mixture is still liquid. The solution should be allowed to stand in a place free from draughts, otherwise the coating will be striated and the plate will be of no use. When the gelatine has set the plates are transferred to an ordinary drying-box and put away to dry free from dust. When coated they keep for an unlimited time.

Sensitising.

In order to render the coated plates sensitive they are immersed in the following solution:—

Ammonium bichromate	60 gms.
Water	1,000 ccs.
Ammonia	To render the solution pale yellow.

In this bath the plates remain for 15 minutes. Sensitising can be done in a fairly bright light, providing that the dish is kept covered. The plates are then put away to dry spontaneously in the dark. They are then printed under a strong near negative of good contrast. Pressure in the printing-machine must be strong in order to bring the whole of the plate in contact with the negative, and therefore the screw form of printing-frame should be used. Printing is done in sunlight or in ordinary bright daylight, and will take from 10 to 30

minutes according to the light and the character of the negative. In ordinary diffused daylight five times the exposure must be given.

As no indication can be obtained during printing of the progress of exposure an actinometer must be used, but it is much simpler to judge of printing by the appearance of the metal plate projecting round the edges of the negative, for which reason a plate larger than the negative should be used. These edges should become chocolate-brown in colour.

Heating to Get Relief

After printing the plate requires only to be heated, for which purpose it is mounted on a whirler and rotated over a gas or spirit flame. Care should be taken not to employ a degree of heat which will scorch the gelatine. As soon as heating is begun it is seen that the gelatine, in the parts protected from the action of light, greatly contracts. This is noticeable in a less degree in the half-tones, whilst the parts of the print corresponding to the deepest shadows of the negative remain unaltered. The heating is stopped at this point, as further heating will have the effect of reducing instead of increasing the relief.

Although the relief thus obtained is not great, still it is very exact throughout the subject. The reliefs keep indefinitely, and can be used without further treatment for taking impressions in wax, or for producing castings in a readily fusible metal. Impressions in plaster of Paris may also be made, although this is the least desirable method, as the water in the mixture of plaster can easily cause the swelling of the film. The process is one possessing no difficulties, and provides the worker with a ready means of making quickly reliefs of monograms, etc., and it may be used for decoration by electrotyping and similar processes. Although the relief is less than that obtained by a swelled gelatine process, the process is much easier and quicker, and the matrixes are quite permanent. By means of solutions of aniline dyes made up with a mixture of water and alcohol the gelatine film can be dyed and small decorative zinc plates prepared in this way. This process is thus suited for the reproduction of drawings which are prepared specially for reproduction by the swelled gelatine method. Portrait negatives may also be used when they are taken in profile, and particularly when they show strong effects of lighting.

R. NAMIAS.

THERMO-TIME DEVELOPMENT.

[In a communication to the "Photographic Journal," published on the 20th inst., Mr. Alfred Watkins, under the title, "Some Recent Aids to Development," has given the following very useful review of the methods of allowing for variation in the temperature of the developing solution when developing by the time (non-inspection) system.—Eds. "B.J."]

ALTHOUGH in a sense all methods of development may be termed time development, I think it will be conceded that the term only applies only where results are controlled solely by time, without modifying that time from an examination of the plate during the latter period of the development.

Probably the systematic application of time development commenced with the memorable paper of Hurter and Drifffield (*Journal Soc. Chem. Industry*, May, 1890). In this paper they pointed out that the degree of contrast between the tones of a negative could be settled—to an extent amply sufficient for practical purposes—by variation of time only, without any need to vary the composition of the developer to attain the same end. They also (in this or in subsequent papers) made obvious the fact that a given brand of plate developed at a standard temperature with a standardised developer for a standard time will always give (within limits of error of manufacture in the plate) a standard amount of printing contrast between two

standard tones in the subject, and that this rule is (within limits) independent of time of exposure.

There followed from this the obvious fact that, given the standard conditions enumerated above, a uniform and settled time of development will in all cases be right in practice, except where, for reasons connected with special subjects and the limited range of gradation available in printing papers, it is desired to increase or lessen the contrast between two standard tones of the subject.

This simple method of time development was the one adopted in the first place by Messrs. Kodak for their film tanks, they providing a standard film and a standard developer, and asking the photographer to make an attempt to standardise temperature by adding (in cold weather) hot water to that used to dissolve the developing powders.

But in practice it is extremely difficult, if not impossible, for an ordinary photographer to work at the same temperature all

the year round. The only way is either to keep the whole of the room at the standard temperature, or to use a water bath ensuring an equable temperature. Merely to heat or cool the developer before pouring it into a dish or tank and on to plates or films all at a different temperature introduces large and serious errors. When it is considered that with an average developer (temp. coeff. 1.9) the right time of development at 50 deg. F. is just double the right time at 70 deg. F. (and these are variations often met with), it will be seen that temperature is all important in time development.

It was to allow for variations in temperature that I devised (in 1893) factorial development, and it has come into extensive use; for the time of appearance has been found in practice to make an accurate indication of changes in the energy of the developer due to temperature. But this method does not come within the scope of the present paper; and for some years I have felt that, useful as it is, it must gradually make way for simple time development in which calculated allowances are made for temperature variations. The newer method can most conveniently be designated Thermo-Development, to distinguish it from time development at a fixed temperature, and from Factorial Development. All three are, of course, time methods.

It may be useful to glance rapidly at the stages by which thermo-development has been introduced.

Commandant Houdaille in 1903 published an observation that a variation in temperature of 1 deg. C. means a variation of 5 per cent. in the appearance of the image and total duration of development. It will be noted that there is here an indication of utilising an observation of the time of appearance for the purpose of drawing up a table of development times for different temperatures.

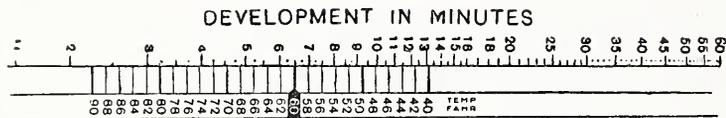

Fig. 1.

In the "Photographic Journal," March, 1905, Howard and Ferguson gave a graphic method of determining the time of development at different temperatures, and this was followed by mathematical papers by Sheppard and Mees and by Ferguson, the last ("Photographic Journal," May, 1906) giving very complete equations and formulæ for calculating times at different temperatures. During 1906 tables of times at different temperatures for a specified developer appeared both in America (G. M. Alves, "Photo Beacon," June) and England (H.M.T.S., "Focus," November 14).

It should be noted here that these tables, and tables constructed from the Ferguson formula could only be applicable to a specified brand of plate or film, different emulsions varying enormously in their speed of development with the same developer. It was at this point I commenced in 1907 the improvements (or inventions) which are the chief subject-matter of this paper.

The starting point was my discovery that a table of times and temperatures calculated by the Ferguson (and Houdaille) formulæ could be accurately represented by a logarithmic scale of figures representing time, placed in contact with an even division scale of temperatures. For the benefit of the non-mathematical reader I should explain that in a logarithmic scale the figures are placed at such distances apart that an equal distance multiplies or divides by the same amount at all parts of the scale. Thus, the distance between 1 and 2 (doubling the value) is exactly the same as the distance between 5 and 10 (again doubling the value).

Such a scale has this distinct advantage over a mere table of times and temperatures: that by making it relatively movable, it can be adjusted for any plate, or for a diluted form of the same developer.

Fig. 1 represents such a scale constructed for a developer of temperature coefficient 1.9. The making of such scales for a particular plate and developer is quite simple, and requires only two trials to find the correct times for a given contrast at two temperatures, for when these two temperatures are marked against their times on the logarithmic scale, all other temperatures can be marked in to form an even division scale without making a calculation of any kind.

Before proceeding further it seems desirable to glance at the three factors in this matter, and to examine methods of estimating variations in time caused by variations of these factors.

Factor No. 1—The Plate.

Different emulsions require widely different development times in order to attain the same standard of contrast with the same developer.

The trial to ascertain this time is made by exposing a plate behind a revolving sector in a H. and D. exposing apparatus, to develop this plate (in sections) for three different times, to measure in a photometer the density of the gradations of each slip, and to plot each out on a H. and D. diagram to ascertain its Hurter and Driffield development factor or gamma (γ). From these three results it is not difficult to find the time for γ 1, or whatever the standard of steepness adopted. In my own practice, I find the time by a graphic method. I take a fan-shaped series of lines equally spaced (similar to those of Fig. 6) and figure them for development factors .8, .9, 1., 1.1

Fig. 2.

and so on. By applying a movable log scale (the slide from slide rule) to this diagram, so that the two times of the trial come against the two resulting factors, the time for the standard factor can be read off.

One great difficulty sometimes occurs at this point. The method assumes that the emulsion is capable of attaining development factor over the standard of γ 1. But in some cases of rapid plates the highest development factor attainable (or gamma infinity) is very near or less than γ 1. In such a case a new standard of a lesser development factor has to be taken.

Of course the temperature of development is carefully noted and the corresponding time for 60 deg. is calculated on a thermo-calculator to be described presently.

These times (for 60 deg. F. with my standard time developer) vary from 2¼ minutes for some of the slow-speed plates to 11¼ minutes for some of the rapid (exposure speed) plates, and for convenience in giving information regarding the development speed of plates—divide them into seven groups according to their time of development. These groups, with the average time (as above) in minutes are given below, the code letters being founded on the words quick, slow, and medium.

VQ	Q	MQ	M	MS	S	VS
2¼	3	4	5	6½	8½	11¼

It will be seen later on that instead of advising the user to give different times for these different classes of plates I have found it more convenient to give different dilutions of the developers for the different groups, the time of development for 60 deg. F. being the same (6½ minutes) for all.

I am bound to point out that it is impossible to say that a

given brand of plate will always be in the same group, and, indeed, the development speed of a plate will often fall off (requiring longer time) by keeping. Since I published this plan of grouping development speeds it has been adopted, in modified form, by Messrs. Burroughs and Wellcome.

It will be convenient here to describe a small developing tank holding three plates (Fig. 2) which I have found convenient for developing plates for three different times without cutting them into slips. It is a plain upright zinc tank with grooves to take three plates. Outside is a down spout or tube, open at the top, closed at the bottom, but with a bottom communication to the tank. Developer poured into this spout flows in at the bottom of the tank. The three trial times of development are decided upon, and enough developer to fill the tank is divided into three parts, each in a separate measure. The group times given under the code letters are (for convenience) taken. For example, the times selected may be (if the plate or plates are supposed to be slow developers) 4, 6½, and 11¼ minutes.

The first third of the developer is poured in at 0 minute. The second part of the developer is poured in at 11¼—6½ minutes = equals 4¾ minutes.

their temperature coefficient is different, and they require different temperature scales for calculation.

It is therefore most important to ascertain the temperature coefficient of a developer, and it must be done before it can be supplied with a scale for calculation. It is one of the difficulties in giving information about thermo development that intending users cannot grasp the fact that the same scale or table of times cannot apply to widely different developers, even if the alkali is so adjusted as to bring them to the same energy at 60 deg. F.

The temperature coefficient of a developer is the ratio of time between correct development at temperatures 10 deg. C. (18 deg. F.) apart. A temperature coefficient of 1.5 means that the ratio between the time at, say, 60 deg., to that at 42 deg. is as 1 is to 1.5.

Fortunately, it is not at all difficult to ascertain the temperature coefficient of a developer; taking advantage of the fact that the time of appearance of a given tone is affected by temperature in the same ratio as the time of development is affected. I use a water bath, a shallow tin tank in a felt-lined wood case with a felt-lined cover. The tank is filled with water at

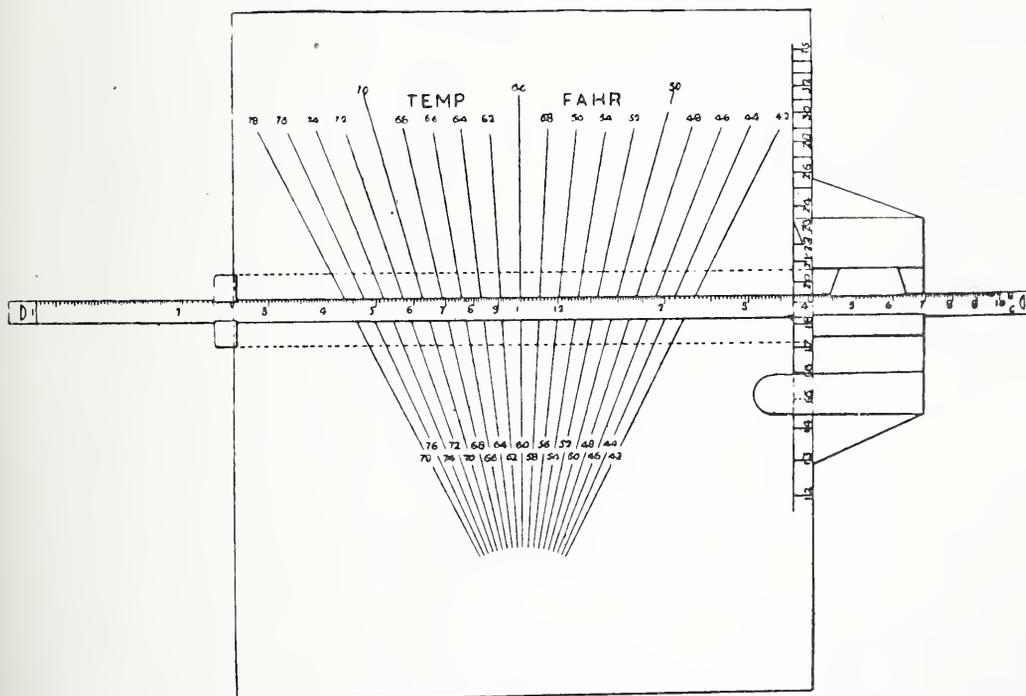

Fig. 3.

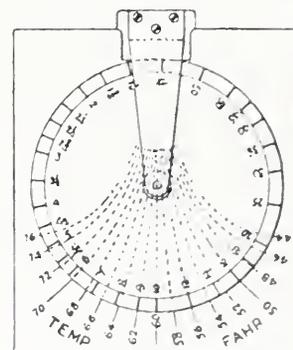

Fig. 4.

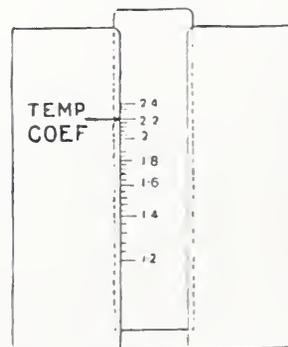

Fig. 5.

The third part of the developer is poured in at 11¼ — 4 minutes = 7¼ minutes from commencement.

The developer is poured off and the plates washed at 11¼ minutes (the longest time).

It will be seen that development will have been for the required 4, 6½, and 11¼ minutes on the three sections of the plates, and three different brands can be developed at one time. The tank must not be rocked or moved. It is shown in Fig. 2 in section and plan.

Factor No. 2—The Developer.

For thermo development it is necessary to test two distinct attributes of a developer, namely, its *temperature coefficient*, and its *energy* or development speed.

To show the difference between these attributes, a metal developer and a hydroquinone developer can be so adjusted in amount of alkali that they require the same time at 60 deg. F.—say 5 minutes. But try them both at 42 deg. F., and the metal would only require about 7½ minutes, while the hydroquinone would require about 11½ minutes. In other words,

the desired temperature, say 75 deg. for the warm trial and 50 deg. for the cold trial. Two stamped tin dishes float on the water. In the one is placed a slip of the exposed plate, in the other some of the developer, and the lid is put on for a time to allow all to attain a uniform temperature, a thermometer in the bath being noted before and after. The plate and amount of exposure is unimportant (a few seconds to a gas jet with the shutter of dark slide half drawn). The dark-room light is arranged to throw a good light on the developing dish, the developer poured on, and the time of appearance in seconds carefully noted. It is often well to make a second trial at the same temperature. The trial at the other temperature is then made, temperature being again carefully noted.

The two times of appearance and the two temperatures being known, it is easy to find the temperature coefficient on either of the thermo calculators illustrated in Figs. 3, 4, and 5. The two motions of either instrument are so adjusted that the two times coincide with the lines of the two temperatures: when this is done the indicator at the side of the straight line instrument or at the back of the more compact circular instrument,

indicates the temperature coefficient. Or it may be done on the diagram Fig. 6 (borrowed from the Watkins' Manual). A slip of paper is laid against the logarithmic scale and the two times marked off; this slip is then laid over the diagram, and adjusted so that the two marks touch the lines of the two temperatures. The point where the paper slip intersects the radial temperature lines is marked with the right temperature coefficient.

Temperature Coefficients.

I am afraid that investigation and trials are not yet sufficient to make it possible to give a reliable list of temperature coefficients of different developers. Besides, the addition of bromide seems to alter the coefficient, but the amount of bromide present does not seem to make much difference. Dilution seems to have an uncertain effect, but does not greatly alter the coefficient, in some cases not at all. As a rule, the plate used does not affect the coefficient, and it is possible that the few exceptions are those plates which contain soluble bromides.

I have found hydroquinone the most perplexing developer, and have found the different coefficients of different formulæ and tablets to range from 1.4 up to 2.25. Sheppard and Mees make it 2.20 and 2.80 with different plates.

The following are a few results. Those marked B. and W. are coefficients deduced from the temperature tables recently published by Messrs. Burroughs and Wellcome for their tabloid developers:—

Pyro soda, "Manual" formula without bromide (Watkins)	1.5
Pyro soda, "Manual" formula with bromide (Watkins) ...	1.9
Pyro soda, H. and D. formula without bromide (Ferguson)	1.48
Pyro soda, Kodak powders (Watkins)...	1.9
Pyro soda, tabloid (B. and W.)...	2.15
Pyro soda, tabloid, Ilford formulæ (B. and W.) ...	2.04
Rodinal (Watkins) ...	1.9
Azol (Watkins) ...	1.9
Victol (Watkins) ...	1.9
Certinal (Watkins) ...	1.9
Metol quinol, time developer (Watkins) ...	1.9
Metol quinol, tabloid (B. and W.) ...	1.86
Glycin tabloid (B. and W.) ...	2.3
Rytol tabloid (B. and W.) ...	1.84
Rytol tabloid (Watkins)...	2.2
Hydroquinone tabloid (B. and W.) ...	2.3
Hydroquinone tabloid (Watkins) ...	2.25
Paramidophenol tabloid (B. and W.) ...	2.4
Amidol tabloid (B. and W.) ...	2.06
Ortol tabloid (B. and W.) ...	2.06

It must be noted that the temperature coefficient of a developer must be decided before a scale or a table of times can be fitted to it. That is, a different scale or table is required for different developers, unless the adjustable instruments illustrated in Figs. 3 and 4 are used, or the diagram Fig. 6.

But even when the temperature co-efficient is ascertained, the time for a stated temperature depends upon the amount of alkali or the concentration of the solution. There is therefore a second attribute to be tested, namely, the energy.

Energy of Developer.

This requires a standard brand of plate (whose development classification in the Watkins group is known) to be exposed in the H. and D. exposing apparatus, and developed for two or three different times in the way already described under the heading "Plate." The object of the trial is to find the time of development which gives the standard development factor 1. The trial is made as near 60 deg. F. as convenient, and the resulting time (ascertained on the thermo calculator as described) is translated into the time for 60 deg., this time being right for plates of the same Watkins group as the one tested. The times for other groups (at 60 deg. F.) can be estimated by proportion, using the table already given. There is an expedient for saving time

in ascertaining the development factor of an exposed slip, which is, I think, new. In the usual way a H. and D. slip has to be measured in each of its gradations and the result plotted out on a H. and D. diagram before its development factor (the γ , or gamma, of our mathematical friends) can be ascertained. But if the inertia of a plate is once known, and a single exposure of ten times that inertia be made to the same light with which the plate was tested, the density of the single exposed tone will be the same value as the development factor.

Factor No. 3—the Temperature

The third and final factor in estimating time of development has already been treated under the other headings. An ordinary thermometer is used to ascertain the temperature, and if the developer and water used for dilution has already stood for some time in the room, there is no need to dip it in the solution, a test of the air-temperature being sufficient. The improvement by which I apply the logarithmic time scale direct to the thermometer tube without marking a temperature scale at all will, I think, much simplify matters.

Practical Application.

The thermo calculators illustrated in Figs. 3, 4, and 5 are intended for laboratory, not popular, use.

But the diagram Fig. 6 can be used by any non-scientific photographer for drawing up a table of times and temperatures for the plate and developer he fancies. He must ascertain by trial the time at a cold temperature which gives him the result he wants, and also the time at a warm temperature giving the same result. A strip of note-paper is taken, and the two ascertained times marked on the edge of it by means of the logarithmic scale. This strip is then applied to the temperature lines, keeping it parallel to the logarithmic scale, and adjusted until the two marks on it coincide with the two temperatures at which the trials were made. The position of each temperature line is then marked on the edge of the strip and the temperature figure written opposite it. The point at which the strip intersects the fan-shaped lines is marked on the diagram with the temperature coefficient of the developer tested. The marked strip of paper is again applied to the logarithmic scale, so that the temperatures of the tests again coincide with their right times; and from these adjacent scales a complete table of times and temperatures is written out for the future use of the photographer. Another way of attaining the same end where the temperature coefficient of a developer is known is to use either of the thermo calculators, setting it to the coefficient, make of one a test of the developer and plate at any temperature, and use this in future to set the instrument reading off the time for any other temperature.

Commercial Applications

There is a decided demand for still more definite and simplified information than that hitherto indicated, so that the use of a stated brand of plate and a stated developer can be told the exact time to develop that plate with that developer at any temperature without making any trials for himself.

For this purpose I devised the time developer illustrated Fig. 7 used in conjunction with the code letters already described under the heading "Plate." Every plate made in England is marked on the speed card (issued by the firm which handles my inventions) with these code letters, indicating the development speed of the plate, and by them actual times of development are also indicated.

On the label of the bottle the time and temperature scale illustrated in Fig. 1 is given. Up to the present date the temperature scale is on a separate band of paper revolvable round the bottle, and to use the scale the 60 deg. mark is set to the time given for the code letter of the plate, a standard dilution of the developer (1 dram to 1 oz.) being used. Thus on a plate marked M the 60 deg. pointer is set to 5 minutes, and

BUSINESS PRINCIPLES FOR THE PHOTOGRAPHER.

(A paper in the "Philadelphia Bulletin of Photography.")

ALL members of the profession will concede that it is necessary for the photographer to be an artist if he is to instil into his work the proper degree of feeling. But when we consider the talent of the photographer from a business standpoint we do not find it so well developed. Of course, there are exceptions, but it is generally conceded that the majority of portrait workers are indifferent business men. We may, perhaps, attribute this fact to the innate feeling which every worker has, or should have, for the art itself. In many cases this is so great as to engulf all thoughts of business, as well as other work which may have its origin outside of the studio workrooms.

If the photographer is located in one of the smaller towns, and it is to such that these words are addressed chiefly, the business part of the profession is not so important. Even then, however, one cannot make the mistake of thinking that work will come to him without an effort. If you desire to increase the volume of business being done it is up to you to *hustle*. To a certain extent an artist must create demand for his product. Of course, there are the children, lovers, and some others, for whom pictures must be made, but there are lots of people who need "coaxing," those who keep delaying until a more opportune time, which in many cases never arrives. It is to tell how you may possibly increase the output of pictures from your studio that this article is written.

First, let me say that I do not consider the field of work limited to studio portraiture alone. I have taken up home portraiture work with much success, and, in fact, at one time followed this exclusively. If your outfit contains a good flash lamp you can secure very pleasing pictures of children in their natural home surroundings. Indeed, you will, doubtless, find that better results can be secured in this way than if the subjects were brought to the studio. Then there are the old people. During the wintry months it is hard to get them far from the warm, cosy fireplace, but if you specialise on home portraiture, say just after the holidays, you will succeed in making a number of negatives of such subjects. Let the people know you are doing this work, and then get their orders for sittings.

Making pictures for illustrative purposes offers a remunerative field of work. There is always a demand for photographs representing original ideas or depicting anything out of the ordinary. Do not overlook the opportunities in out-door view work. People want this class of work done, and if you don't get out for it others will.

The watchword in photography is "hustle," and, above all, be on the lookout for new ideas. Study your customers. Find out their tastes, and then cater to the demand. Do not neglect taking up a certain kind of work because, in your opinion, it is not to be classed with portraiture. On the other hand, no greater mistake could be made than to do a grade of work which does not appeal to your trade, although you may think it artistic. Remember that you are making pictures to sell, and not for your own enjoyment.

I shall herein devote considerable space to the value of advertising, which, as a factor in creating business, cannot be overlooked. Of course, there are, even in this age of competition, those who look upon advertising as a needless waste of effort, not to say money. My own experience, however, teaches me that one cannot overestimate the returns resulting from a systematic campaign of advertising.

Before taking up this matter further, it should be stated that it is necessary to exercise great care in keeping up the standard of your work, for it is on this principle that one's reputation is made or upheld. In my own practice I deliver no work which might in any way be improved by a re-sitting. I am aware that there are some who will say that their patrons cannot detect the difference between good work and that of

an inferior grade. But if they cannot, perhaps some friends more critical will pass their opinion on the photograph in question, and when the customer's confidence in your ability to do uniform work is shaken, it is a difficult matter to restore it. If you are able to turn out the best work and do justice to this ability, the quality of your work will be your best advertisement. You may then have no fear in making "quality" a leader in your newspaper advertising, and if you have a competitor, people will sit up and take notice. But it is the height of folly to advertise in this manner unless your work will uphold it.

Not only through the circulation of his work may the photographer be open to praise or criticism, but the show case at the entrance of his establishment may exert its force either to repel or attract customers. In the first place, the case of samples should be kept clean. The glass should be washed at frequent intervals, and the interior kept free from dust, and, as to the pictures, let them be your best. Have a variety not only in poses, but styles of mountings and finish. I have in mind a photographer's show case in which, at present, are displayed nine pictures arranged in three parallel rows of three pictures each. The prints are all cabinet square in size and, with one exception, are mounted on a white card of the same style. It is needless to comment on the unattractiveness of such a display.

In my advertising considerable stress is laid upon the question of variety. People are constantly on the lookout for something different, and they welcome new ideas in the photograph as well as other lines. My samples include about sixty different styles in cards and folders, and my customers are at liberty to choose from any of these. Appropriate mounts for aristos or platinum, mounted solid or otherwise, are shown. Right here is where I believe a great many photographers are in error. They follow a short-sighted policy in their belief that their trade will not warrant getting out samples in the more expensive styles. Their specimens merely include the regular grade of staples. Oftentimes, in my own experience, I have been surprised by the demand evinced among certain ones for the higher grade work. A picture, if ever so good, will strike the customer's fancy much quicker if finished in a more elaborate style, and the better work will bring better prices. People are not having pictures made every day. Consequently, when they visit your studio they are, in many cases, willing to pay good money for something a little above the ordinary.

In speaking of the photographer's display case, the necessity of changing the prints often should be emphasised. A merchant would be open to ridicule, indeed, if the same goods were to be seen displayed in his show windows from month to month. Then why is it that so many portrait workers look upon this matter with indifference? People wish not only to examine your work often, but if they find new samples shown at intervals of every few weeks they will get the idea that a good business is being done.

There are various ways to give the public the impression that you are a successful business man. Always make it a point to be engaged in some work whenever in the studio, and do not neglect your dress. You will find it to your advantage to wear good clothes in the studio as well as on the street. A good appearance, more than aught else, gives the impression that you are enjoying prosperity. Don't be seen lounging around the streets, since if you wish to get business you must appear businesslike.

I find there is an inclination on the part of some to "knock" their business. They are sometimes heard lamenting the fact that things are slow, and instead of hustling all the more, they allow themselves to become discouraged. The public is not

going to boost the photographer if he himself does not exert any efforts in his behalf. In answer to inquiries, say, "Business is fine," "Couldn't be better," or something to the same effect.

In regard to advertising, don't do this at infrequent intervals, but keep your name and business constantly before the public. Make a yearly contract for space in your home paper, and then keep plugging away. Change the copy each week, and it will not be long before you commence getting results. Some think because returns fail to come right on the start they should give up. This is wrong, for benefits from use of the advertising columns will come only with constant "hammering." During the dull season following the holidays it would seem rather useless to invest money in advertising. But think a moment. Is not the stimulation of trade the main purpose in advertising? Hence the greater need for this at a time when business is quiet. If your name is constantly before the public they will not forget you, and when photographs are desired you will be given the preference.

In my advertisements particular emphasis is given quality. Since I have a competitor in the field, I consider this a good subject on which to talk. For example, I announced some time ago that in my advertisements each week would be named one essential element of a first-class picture, such as artistic posing, correct lighting, etc. In this manner I was able to make up quite catchy as well as effective little advertisements. But I will say again, if you contemplate following this method, you cannot afford to retract from the high quality of your work, even so far as one picture is concerned. I know a photographer in one of the smaller towns who is very particular in keeping up the standard of his work. Within the radius of twenty miles there are several villages, in one or two of which are photographers more or less indifferent to their work. The result is that members of the community will go miles that they may have their work done by the first-mentioned artist. Such is the merit resulting from a reputation, but foolish is the photographer who, having eventually succeeded in securing the bulk of the trade, will jeopardise his business by turning out work known to be not up to the usual standard. It is a difficult proposition, indeed, to dispute the value of good sound advertising coupled with high grade work upon the photographer's part.

It has been a frequent occurrence for different ones to speak to me regarding pictures they wished to have made. In some cases there seemed, however, an inclination for these same people to seemingly forget the matter or delay unusually long in calling for a sitting. A plan was, therefore, adopted and put into execution at times when business was a little quiet in the studio. A quantity of circulars were printed. These called the prospective customers' attention to the fact that I would be pleased to make his or her picture, and incidentally a word or two was said as to the good quality of my work. As an inducement for them to call at once for a sitting an offer was made to include, free of charge, with the regular order, one high grade folder. In most cases people will not neglect taking advantage of this offer.

Strictly speaking, the public, as a whole, does not look upon pictures as an absolute necessity. Hence, advertising, that is, constantly having your name before the public, to say nothing of any new business methods practised, are of great value in the photograph profession.

In my opinion, no worker will ever find it of profit to cut prices in an effort to get extra business. As before stated, those desiring pictures are willing to pay a fair price for work that is good. But should they at any time secure cut rates, they will expect the same thing at the next sitting.

As I am about to conclude these remarks, another thought occurs to me. Should work of yours ever receive recognition from any source, or an occurrence out of the ordinary take

place in your photographic work, it is well to have a note made of it in the local paper.

The principle of competition is the overcoming of one's competitors. By this is not meant that you are to resort to questionable methods in an effort to attain this result. The producing of clean, uniform work of a high grade quality is sure to bring its reward. And if you will employ the most up-to-date business methods, and be quick to follow up any advantage gained, the confidence of the entire community will eventually be secured.

With the thought in mind that an account of a few of my methods might be of benefit to others, I have been led to write this article. In conclusion, it is hoped that this article may therefore fulfil its purpose in contributing, if in a small measure only, to the success of fellow-workers.

G. W. N.

DEATH OF DR. W. J. RUSSELL, F.R.S.

Photographers will learn with regret of the death of Dr. W. J. Russell, Ph.D., F.R.S., which took place on Friday, November 12.

Born in 1830, Dr. Russell took his degree at Heidelberg, and was for many years lecturer on chemistry at St. Bartholomew's Hospital. Well known to chemists by his researches on the atomic weights of nickel and cobalt, the estimation of urea, and his report jointly with Sir W. Abney on the "Fading of Water Colours," photographers will remember him best by the work which occupied the later years of his life.

From 1897 to 1908 he published a series of papers dealing with the action of substances of all kinds upon a photographic plate in the dark; a subject upon which nothing was then known. The metals were first investigated and divided into those able to produce a developable image upon a plate in the dark and those which could not do so, the former being arranged in the order of their activity. Dr. Russell showed later that the active metals all formed hydrogen peroxide as a product of their oxidation when a clean surface was exposed to ordinary air. Hydrogen peroxide was found to act with remarkable vigour on a plate, a solution of 1 in 1,000,000 of water being strong enough to affect a plate placed above it for twenty-four hours. Not only this, but the activity was able to pass through media such as gelatine, guttapercha, celluloid, etc., and, in the case of very thin media, with but little blurring of the picture. Moisture was usually the carrier of the peroxide in these cases, but some volatile substances were able to act in its place, e.g., camphor in the instance of celluloid. Subsequent investigations showed that most organic substances which oxidised in the air acted on a plate in the dark, and in some cases it was possible to prove the production of hydrogen peroxide. The woods, for instance, were all active, and gave a very remarkable series of pictures of great sharpness, the picture in some cases being quite different to that seen with the eye or under the microscope.

Many of the vegetable oils, the terpenes, the resins (but not the true gums), coal, and most fibres of vegetable origin, if unbleached, were all shown to be more or less active. The "rosin" resins were less active than ordinary resins, amber being only slightly so, and the oldest formed coals, such as cannel, possessed but little activity. Thus, as these natural products become more completely oxidised, they are less able to act on a plate in the dark.

These actions were shown to be chemical, and to have no relation to emanations of the radium type. They were unable to pass through the thinnest glass or lead foil; through mica or aluminium foil of a thickness of 1-1,000 inch; on the other hand, they could be carried along a tube and round corners: were stimulated in an atmosphere of oxygen, and completely prevented from taking place in one of carbon dioxide. A further point of interest was the remarkable increase in activity of many of the organic products when exposed to the sunlight or arc lamp.

It was found to be thus possible to stimulate perfectly inactive printed matter from the seventeenth century so that it gave a distinct picture in the dark: the quantity of unoxidised matter remaining in the printing ink must have been infinitesimal. Amber, the resins, oils, and woods all behaved in this manner, but the metals and coals were not affected by exposure to the light.

Dr. Russell showed that this stimulation was caused by the blue

end of the spectrum, and there seems to be but little doubt that oxidation was thus promoted and a supply of hydrogen peroxide formed.

In Dr. Russell photographers have thus lost a patient and original investigator; there is much to learn from his researches, and in his papers will be found a wealth of information which should be of great value to both makers and users of plates.

FORTHCOMING EXHIBITIONS.

- November 25 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 29 to December 2.—Lancaster Photographic Society. Sec., Thomas Holt, 4, Parliament Street, Lancaster.
- December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.
- December 15 to 16.—Coves Camera Club. Entries close December 6. Sec., E. E. Vincent, 4, High Street, Coves, I.W.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.
- 1910.
- January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.
- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between November 8 and November 13:—

- SHUTTER.**—No. 25,715. Air-regulated automatic camera shutter. Thomas Henry Carruthers, 153, Sharrow Vale Road, Sheffield.
- APPARATUS.**—No. 25,724. Improvements in apparatus to facilitate the contact between two bands, flexible or otherwise, for making photographic or other reproductions. Charles Raleigh, Birkbeck Bank Chambers, Southampton Buildings, London.
- PRINTING FRAMES.**—No. 25,797. Improvements in or connected with photographic printing frames and the like. Herbert Malcolm MacCallam, 58, St. Vincent Street, Glasgow.
- CAMERA STANDS.**—No. 25,941. Improvements in or relating to the heads or tops of photographic camera stands. David Henry Robinson, 24, Temple Row, Birmingham.
- COLOUR PHOTOGRAPHY.**—No. 25,998. Improvements in colour photography. Rudolf Ruth, Birkbeck Bank Chambers, Southampton Buildings, London.
- DEVELOPING.**—No. 26,117. Photographic and developing apparatus. George Chae Beidler, 33, Cannon Street, London.
- STEREOSCOPY.**—No. 26,135. Improved stereoscopic apparatus for use with photographs. Auguste Jules Touppillier, 285, High Holborn, London.
- DEVELOPING.**—No. 26,194. Improvements in and relating to means for developing photographic plates, films, and the like. Percy Albert Craven, 16, Warmington Road, Herne Hill, London.
- STAMP PHOTOGRAPHS.**—No. 26,208. Improved method for the production of stamp and panel photographs and the like. Harry Reginald Ellis Coker and Frank Victor Hemery, 1, Hanover Street, Peckham, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STUDIO VIGNETTER.—No. 27,229, 1908 (December 15, 1908). The invention relates to a vignetter for use with a camera, its object

being to enable the vignetting screen to be adjusted by the operator while still looking at the image on the focussing screen.

In order to obtain the desired effect with accuracy and speed it is necessary that the vignetting screen has four distinct movements—viz.:

1. A movement towards and away from the camera.
2. A vertical movement.
3. A movement across the lens horizontally.
4. A swinging movement which will not displace the serrated edge of the screen towards or away from the camera to an appreciable extent.

The serrated vignetting screen is mounted in a triple frame, one of which frames enables the screen to move vertically, another allows of horizontal movement, and the third supports the screen on trunnions situated at or near the top or serrated edge of the screen to allow of the swinging movement of the screen. By mounting the screen at its upper edge instead of at the centre the screen may be swung without moving the serrated edge thereof appreciably nearer to or away from the lens after setting the screen at the proper distance from the camera.

The movements of the screen are effected as follows:—The triple frame which supports the screen is attached to a piece of wood or metal, which is secured to a rod or tube, which slides in a tube of wood. This may be readily attached to or removed from the camera board by means of a suitable catch. The tube and the piece to which the triple frame is attached are grooved to receive strings or wires, by means of which the operator is enabled to adjust the screen.

To enable the operator to adjust the distance of the screen from the camera one end of a wire is attached to the camera end of the inner tube, this wire is passed through an eye attached to the tube which is attached to the camera board, and is brought back to the hand of the operator; on pulling this wire the screen is moved away from the camera. A second wire is attached to the camera end of the inner rod or tube, and is led through an eye in the spring catch to the hand of the operator. By pulling on this cord, string, or wire, the catch is released, and the screen moved towards the camera.

The movement of the screen across the lens is effected by cords, which act on Bowden wires attached to the outer screen frame, which latter moves in a cross slide secured to the piece of wood or metal, which is attached to the inner tube or rod.

The movement of the screen in a vertical direction is effected by cords or strings, which, by means of Bowden wires attached thereto, actuate a plunger which raises and lowers the frame carrying the screen.

Finally, the swinging movement of the screen is effected by means of cords or strings, which actuate Bowden wires forming part of one of the trunnions which support the screen.

These cords or strings which effect the vertical, horizontal, and swinging movements of the screen, are led from the frames through grooves in the supporting tube and the piece of wood or metal supporting the cross slide, to apertures in a piece of wood attached to the camera board, being passed through suitable weights to keep them taut as the screen is moved away from the camera, or towards the same.

The cords and weights are placed close to the hand of the operator, and, pulling on one cord or string, moves the screen in one direction, whilst pulling on the other cord or string attached to the same part of the apparatus moves the screen in the opposite direction.

The ends of the strings may be connected to a controller instead of hanging loose, and one may use Bowden wires throughout, instead of cords or strings, or partly cords or strings and partly Bowden wires. Alexander Good, 103, Whitestile Road, Brentford.

PLATE CINEMATOGRAPH.—No. 16,441, 1909 (August 11, 1908). The invention consists of a cinematographic apparatus for the continuous exposure and projection of photographic plates. It embodies the combination of a movable carriage carrying the plates with a drum provided on its periphery, with a cam forming a helicoidal incline with a half pitch to the right and a half pitch to the left. This constitutes a continuous path, displacing the carriage alternately from left to right, and from right to left, the forward movement being produced at intervals separated by a given period of stoppage. The helicoidal

incline is divided for this purpose into parts at right angles to the generating lines of the drum, separated by parts oblique to these generatrices, the perpendicular parts corresponding to the periods of exposure of the plate, and the inclined parts to the period during which the plate is conveyed for changing the view in one and the same horizontal row. The carriage is appropriately guided by means of rollers. Rene Achille Robin, 62, rue d'Allemagne, Paris.

PNEUMATIC PRINTING FRAMES FOR PLANS.—No. 43,790, 1909 (February 26, 1909). The invention consists of a pneumatic printing frame, in which is used (in combination with a deeply recessed outer frame carrying the glass surface) a flexible backing sheet, having inner and outer stiffened layers of material surrounding the orifice of the suction tube. The inner layer is formed with passages leading from the orifice to the edge of the stiff material; a separate removable holding frame is adapted to fit within the deep recess of the outer frame, and rotatable levers are provided, having inclined surfaces working on inclines on the holding frame. There are also means for exhausting the air from between the sheet and the glass surface. A. W. Penrose and Company, Ltd., and William Gamble, 109, Farringdon Road, E.C.

CINEMATOPHONOGRAPH.—No. 23,153, 1908 (October 30, 1909). This invention relates to an improved means for securing synchronous movement in moving picture and talking machines, by a modification of the method according to which these are employed. By this method discs over which hands move to indicate the respective speeds has been proposed to photograph into the machine film a disc, index hand, or part, moved by the cinematograph, and to project upon the screen at the time of reproduction an image of an object such as a disc or index hand moved by the talking machine, the intention being that the operator of the cinematograph machine may drive his machine at a speed to accord with that of the talking machine by watching two index hands and keeping that of the cinematograph equal with that of the talking machine.

According to the present invention the projection of the second image of the talking machine is not required, and a very great simplification in the working is thus introduced. This is effected by photographing a visible speed indicator or the like moved by the talking machine directly into the film, so that an accurate record of the speed of the latter is obtained in the film, and in projecting nothing more is required than for the operator of the machine to keep it synchronous with the talking machine by comparing the photographed index with the index of the talking machine when the latter is reproducing, and accelerating or slowing down accordingly. William George Barker and William Cecil Jeapes, 117, Charing Cross Road, London.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901:—

APPARATUS.—No. 25,724. Apparatus to facilitate the contact between two bands, flexible or otherwise, for making photographic or other reproductions. Raleigh.

New Trade Names.

SYLVAX.—No. 316,738. A chemical preparation for use in photography. Augustus Harry Garner, 34, Nicholas Lane, London, accountant. September 30, 1909.

LINEN CLOTH FOR ENLARGEMENTS.—To prepare such for enlargements or copies in oil it is first washed with a wet cloth and afterwards coated with—

Warm water	300 ccs.
Common salt	4.5 grams.
Gelatine	0.4 grams.
Acetic acid	10 drops.

When dried, which may be done by heat, 3 to 4 grams of ammonio-nitrate of silver are rubbed over it with a sponge and once again after drying, when it is ready to be printed under a negative. After printing, the unaffected silver is to be washed out and the picture fixed in hypo.

Analecta.

Extracts from our weekly and monthly contemporaries.

Loss of Light by Reflection from the Glasses of Lenses.

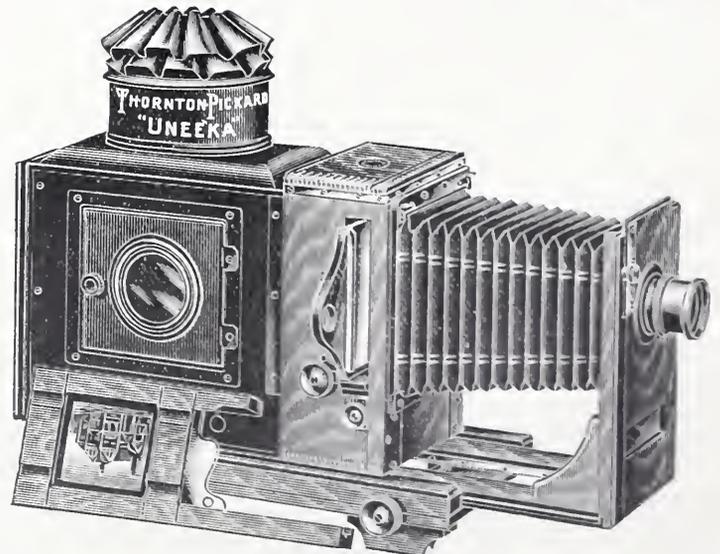

I believe there is a sort of unwritten custom (writes Mr. T. Bolas, in "The Amateur Photographer and Photographic News" for November 23) among working opticians to allow 5 per cent. for the loss of light at each reflecting surface, whether from air to glass or from glass to air; at any rate, this estimate may be taken as approximately correct for average lenses and average polish and finish. To give some kind of documentary support to this estimate, I may refer to page 79 of the 1899 edition of Dr. Rohr's classic work on the photographic lens ("Theorie und Geschichte des photographischen Objectives"). The loss by reflection due to two surfaces is taken as about 9½ per cent.; four surfaces, somewhat over 18 per cent.; and six surfaces almost 25 per cent.

In order to prevent misunderstanding, it may be well to point out that a single landscape lens has two air surfaces, but no air gap, a cemented doublet has four air surfaces, and one air gap; a three-element system, as a triplet, has two air gaps and six air surfaces; a four-element system has three air gaps and eight air surfaces; a five-element system has four air gaps and ten air surfaces. Element in this paragraph stands for a unit having two air surfaces, and the unit may be a single glass or a cemented group.

New Apparatus, &c.

Thornton-Pickard "Uneeka" and "Royal Ruby" Enlargers. Made by the Thornton-Pickard Manufacturing Company, Ltd., Altrincham, Cheshire.

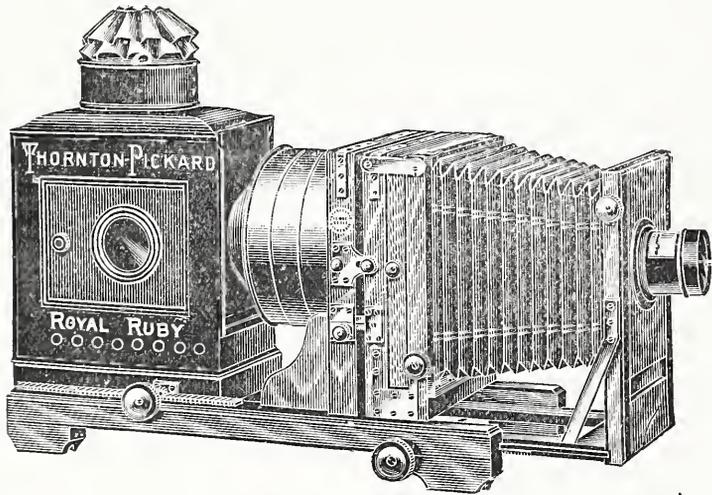

The "Uneeka" fills a gap in enlargers, since it provides, at a moderate price, a lantern for the enlargement of 3½ x 2½ negatives, and is equally efficient when used for projecting ordinary lantern slides or for science demonstrations in the open stage afforded by the removal of the bellows. It is fitted with 4¼ in. condenser, mounted in a mahogany box, in which also is the negative or lantern slide stage, the box resting on the base of the lantern and secured in place by a screw inserted from below and readily withdrawn when it is required to polish the condensers. The stage allows of the central swing of the negative, rise and fall, and rotating movements, in each case by rack and pinion, whilst the negative may

also be adjusted sideways. Although made primarily for the 3½ x 2½ size, the lantern is fitted with negative carrier to hold a quarter-plate, part of which may thus be enlarged, whilst an inner carrier serves to hold the 2.5/16 x 1¼ negative, now coming largely into use in what we may call the "ultra-pocket" cameras. The carrier being removed, the stage takes the "Merito" lantern-slide

carrier, and then serves equally well as a projection lantern, whilst the ready removal of the bellows from its support at each end allows of pieces of scientific apparatus, troughs, etc., to be placed in the optical system. The apparatus is strong, but weight is removed from all portions where it fails to give strength, so that the lantern is surprisingly light. Complete with achromatic projection lens, lantern slide carrier, and tray, but without light, the price is £5.

In the "Royal Ruby" the Thornton-Pickard Company have embodied many of the excellencies of their cameras in an enlarging apparatus, all the movements of which—and they include everything which an enlarger can be expected to do—are actuated by rack and pinion. Thus the lantern body, the three separate movements of the negative carrier (tilt, rise and fall, and rotatory), together with the rise and fall of the lens, are fitted with rack and pinion, the pinion head in several instances serving also to lock the moving part. The lens front and the condenser frame are rigidly held by right-angled stays, whilst the bellows may be completely removed and the

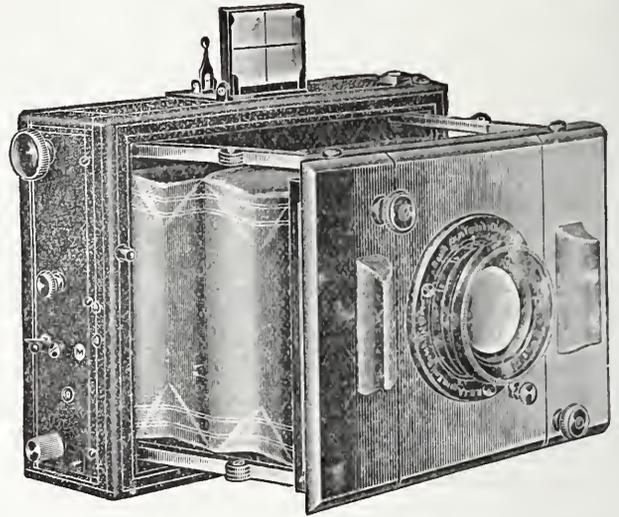

lantern used for optical and scientific projection. One excellent feature of the series is that the negative carrier of each lantern is built large enough to hold a negative of the next larger size; though the whole negative is not completely covered by the condenser, parts may nevertheless be enlarged. The price of the enlarger, complete with condenser and portrait objective, is £10 10s. in quarter-plate, £11 15s. in 5 x 4 and postcard, and £14 10s. in half-plate. The very convenient movements and excellent workmanship of the instrument deserve every commendation. A separate frame is provided to replace the negative carrier, when the "Merito" lantern-slide carrier is being used. This, together with extra 4½ condenser and the slide carrier, costs 25s. in quarter-plate, 5 x 4, and postcard sizes, 30s. in half-plate.

Busch Folding Focal-Plane Cameras. Made by the Emil Busch Optical Company, 35, Charlotte Street, Hatton Garden, London, E.C.

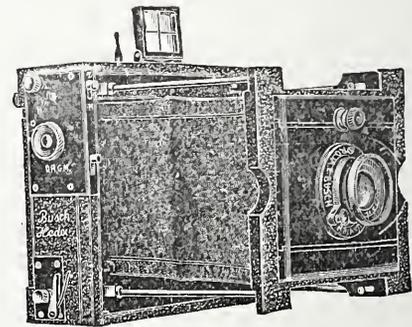

Two new models of the convenient folding focal-plane cameras have been placed on the market by the Busch Company, the first, the "Planor," being a further improvement of the camera hitherto marketed under that name. The lens board is most rigidly supported by four stout metal struts, each hinged half way between front and back, and giving the highest degree of rigidity to the front board. The camera is very easily and quickly collapsed by simple pressure on the hinges. It is quickly opened simply by pulling out the pair of clips seen on either side of the lens in the drawing. The camera is fitted with two-way rising front, giving both a rise and fall of one inch the vertical way of the plate, in addition to rise and fall the landscape way of the plates. The shutter is very simple and rapid in its manipulation, the slit being adjusted by winding the blind until the upper part of the aperture is level with the top of the plate, when pressure of a knob on the left of the camera allows of the slit being enlarged or contracted by winding a small head on the right just above the winding key. The adjustment for alteration of tension is provided in the usual way, the two in conjunction giving speeds up to 1-1,000 sec. Time exposures are very simply obtained by opening the slit to the full

width of the plate, when pressure on the release opens the shutter and a second pressure closes it. Mention should also be made of the brake attachment for the shutter, convenient at times for still further slowing down the slowest speeds given by the shutter. In several points the details of construction make for convenience. For example, the catch for the dark slide or focussing screen is

operated by pressing down the lever instead of raising it, an improvement which, although of minor importance, nevertheless conduces to smoothness of working. The camera is provided with strong bushes for adjustment to the tripod, and complete with three excellent double plate-holders, with pull-out shutters and Busch "Detective" Aplanat, the price is £8 10s. 6d. With "Omnia" anastigmat, Series III., No. 2B, the price is £9 10s. The camera can also be adapted to carry the "Premo" film pack at the price of 12s., whilst extra double plate-holders are obtainable at 10s. each.

The "Heda" is a still cheaper variety of the camera sold at the low price, complete with three single metal slides and Busch Aplanat, f/8, of £5 7s. 6d. The extension in this case is provided by four metal rods, and certainly gives a very rigid front board. Rise and fall of front are provided the vertical way of the plate, whilst the lens board is further made rotatable, so that the rise and fall can be obtained either way of the plate. The shutter, with the exception

of the brake attachment, is the same as that fitted to the "Planor." Adjustments of the width of the slit and for time exposures are made as with the "Planor," and the "Heda," like the "Planor," is also fitted with direct-vision finder. The cameras, both of which are listed at present only in the quarter-plate size, are most efficient instruments of their type, and may be recommended for the many descriptions of hand camera photography, particularly that of rapidly moving objects.

"Excelsior" Metal Tripods. Sold by F. G. Phillips, 12, Charterhouse Street, London, E.C.

Three patterns of very portable telescopic tripods are supplied under this name, each in a series of six or seven sizes, affording a total length of leg when fully extended of from 44in. to 58in. The A pattern of extra strong type is composed of round brass tubes with an outer tube of black or nickel; the B pattern is similar, but somewhat lighter, whilst the C is fitted with aluminium tubes and is thus extremely light. In each case the tripod is fitted with

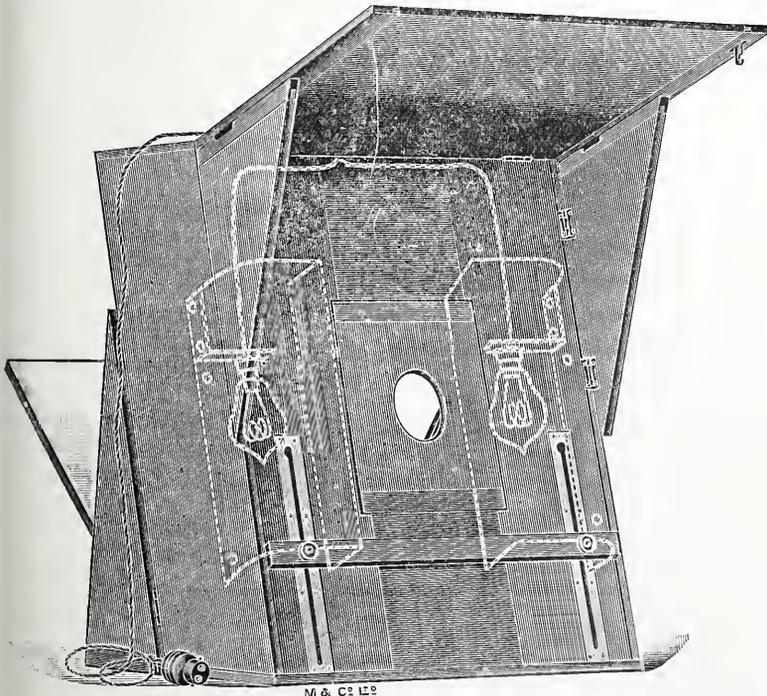

double-spring catches lying loose in the tubes and, therefore, not liable to get broken off; moreover, the tubes engage only at the ends, so that they work very free when opening and closing; further, the head of the tripod is reversible, one side being fitted

with the English standard screw and the other with the Continental. The prices of these very portable and rigid tripods range from 7s. 6d. for an A pattern, 44in. when extended, to 18s. for a C pattern, extending to 50in.

The Robinson Professional Retouching Desk. Sold by Marion and Co., 22-23, Soho Square, London, W.C.

In this new desk for the professional retoucher the makers have employed two of the metallic filament lamps, thus providing the user with a constant, powerful, and inexpensive light, which has the further advantage that it does not heat the retouching room unduly. The construction of the lamp affords a perfectly adequate shading of the light, whilst the stage of the desk is made to accom-

modate negatives from the smallest up to 12 x 10. The whole apparatus is very strongly made, and, as we might expect from a photographer of the long experience of Mr. Ralph W. Robinson, its design fully provides for the most effective retouching practice. Complete with the two lamps, flexible connection, and adapter serving to connect the latter to any ordinary electric light, the price is 65s.

New Materials, &c.

"Vitramic" Photographic Enamels. Made by J. W. Beaufort, The Studio, Easy Row, Birmingham.

We have received some examples of these photographic enamels from Mr. Beaufort, who, within the past few years, has raised this branch of photographic work to a pitch of technical perfection and to an industry of very considerable proportions. The process, which has been worked out by him, has been applied, not only in the making of photographic enamel miniatures, such as still form a profitable branch of a professional photographer's business, but also in the wholesale production of badges of a kind not to be confused with the celluloid or photo-paper button which is still very largely made, but has not, of course, a title of the permanency of the real enamel, which, short of deliberate destruction with a hammer, is imperishable. As we understand it, the "Vitramic" enamel is a photographic equivalent of the genuine painted enamel in which the picture lies imbedded between two enamel layers. The fact that the enamels themselves, as well as the colours, are manufactured by Mr. Beaufort in his establishment allows of the method, in his hands, being most readily adapted to all descriptions of work, and some of the small coloured badges which we have examined, for example, one bearing the familiar legend, "Votes for Women," and another of the John Bull League—of which 100,000 are to be made—are most beautiful examples of this finest of photographic processes.

We have dwelt more upon the wholesale work of the Beaufort firm, for the reason that credit is surely due to it for the creation of this new description of business, but we should not overlook the fact that Mr. Beaufort specially appeals to professional photographers on account of his unique facilities for producing enamel miniatures both in monochrome and colour at most moderate prices and with great punctuality. The prices of miniatures from photographers' own negatives are from 5s. 6d. each, up to one-inch circle; enamelling on silver articles costs about the same as plaques, plus the cost of the silver support.

CATALOGUES AND TRADE NOTICES

THE LUMIERE PRICE-LIST.—The new edition of the general catalogue and price-list of Messrs Lumière is now a book of seventy-four pages, and though primarily a list of prices is much more than this owing to the inclusion of instructions for working the celebrated Lumière products in the way of plates and papers, the Autochrome process and the series of distinctive chemical preparations worked out by MM. Lumière. Thus particular attention may be directed to the formulæ for developers from p. 52 to 60, to the simplification in formulæ produced by the use of formo-sulphite as a single substitute for both sulphite and alkali, and to the directions for the use of the persulphate and cerium reducers, bi-sulphite solution, the permanent and rapid mercuric-iodide intensifier, etc. The list, which is one often found valuable for reference, is sent free on application to the Lumière N. A. Company, 89, Great Russell Street, London, W.C.

PHOTOGRAPHIC PENNY POSTCARDS.—Mr. Philip G. Hunt, 34, Paternoster Row, London, E.C., has just issued a booklet describing the works of which he is proprietor at 332, Balham High Road, London, S.W., where a most complete plant has been laid down to produce postcards on a large commercial scale. Mr. Hunt rightly lays stress on the many directions in which the penny picture postcard can be used with profit to the photographer, and the latter may certainly be advised to make himself acquainted with the excellent "real photographic" toned glossy cards made by Mr. Hunt at most moderate rates from photographers' own negatives.

FLASHLIGHT PHOTOGRAPHY.—Messrs. Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C., have just published a 14-page booklet of "Hints on Flashlight Photography," which, while written in reference to the Agfa flash-powder and the Agfa flash-lamps—on which account there is no occasion for apologies—contains a good many useful hints on making portraits by magnesium flash, on employing the light for copying small originals, and on developing the negatives. Amateur workers of flashlight will find

it quite worth their while to apply for the booklet, which is sent free on receipt of a postcard. Dealers should find it to their advantage to keep the booklet at hand as a ready and efficient means of answering flashlight questions.

"THE PROFESSIONAL PHOTOGRAPHER."—The November issue of this attractive monthly publication, published by Kodak, Ltd., contains notes on photographic chemicals, correcting negatives, in addition to giving particulars of a number of useful novelties for the studio and professional dark-room.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 26.

Bideford Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Lincoln Amateur Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Mill Camera Club. "Autotype Carbon." Demonstration.

SATURDAY, NOVEMBER 27.

Idlers' Camera Club (Bristol) "What Can be Done with a Hand Camera." C. P. Goerz, Ltd.
Edinburgh Photographic Society. "Breton Customs, Coifs and Calvaries." James Oliver.

MONDAY, NOVEMBER 29.

Southampton Camera Club. "Ensyna." F. J. Stedman.
Exeter Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Stafford Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Leek Photographic Society. "Amateur Photographer and Photographic News Prize Slides."
South London Photographic Society. "Preparing the Negative for Pictorial Purposes." E. W. Taylor.
Scarborough and District Photographic Society. "A Sicilian Holiday." R. F. Jameson.

TUESDAY, NOVEMBER 30.

Royal Photographic Society. "Glimpses of Scenery in Ceylon and Burmah." S. E. Tench.
Hackney Photographic Society. "Handwork on Negative and Print." B. C. Wickison.
Leeds Photographic Society. "Walks in the English Lake District." Gilbert Middleton.
Manchester Amateur Photographic Society. Opening of New Rooms.
Worthing Camera Club. "A Trip Round the World." E. C. Patching.
Glasgow Southern Photographic Association. Monthly Lantern Slide Competition. "Photographic Facts and Fallacies."
Birmingham Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Reading Literary Club Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Rotherham Photographic Society. "Peeps at Nature with a Camera." Rev. Bernard Butler.

WEDNESDAY, DECEMBER 1.

Croydon Camera Club. "Some Delightful Walks in Surrey."
Woodford Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Tamworth and District Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Sale Photographic Society. "On the Broads." F. Mahler.
Borough Polytechnic Photographic Society. First Lantern Slide Competition.
Edinburgh Photographic Society. "Mistakes I Have Made." James Baillie.

THURSDAY, DECEMBER 2.

Watford Camera Club. "Photography and Focus Slides, 1909."
L.C.C. School, Bolt Court, E.C. "Press Photography." Fried O. Penberthy.
Hull Photographic Society. "In Central France." J. V. Saunders
Rodley, Faisley, Calverley, and Bramley Photographic Society. Members' Night.
Handsworth Photographic Society. "Modern Photographic Apparatus and Exhibition of T. P. Prize Slides." R. Hesketh.
Southend-on-Sea Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Dundee and East of Scotland Photographic Association. "Some Shetland Impressions." Rev. H. M. Davidson.
Leigh Photographic Society. "Ancient and Modern Methods of Illustration." W. Perry.
Midlothian Photographic Association. "A Midlothian Bazaar." John Reid and R. M. Reddie.
Liverpool Amateur Photographic Association. "Promoil." F. J. Motimer.
Tynemouth Photographic Society. "Ensyna." F. J. Stedman.
London and Provincial Photographic Society. "Ensyna." F. Marshall.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 23, Mr. George E. Brown in the chair. The twelfth Traill-Taylor Memorial Lecture was delivered by Professor A. W. Porter, B.Sc., F.R.A.S., on "The Growth of the Photographic Image." The lecture consisted of two parts. In the first the lecturer dealt with the representation of the action of light on a photographic plate as first adopted by Hurter and Driffield and commonly accepted as a statement of the physico-chemical change which takes place on an emulsion being exposed to a series of light impressions of increasing intensity. He explained the H. and D. curve of the plate, and the measurement of the inertia from which

the speed measurement of a plate was usually taken. Several lantern experiments were made to illustrate the kind of action which exhibited inertia, this phenomenon being marked in the case of the action of an acid on a solution of hyposulphite of soda, the decomposition of which was small at the start and continued with increasing rapidity up to a maximum, after which it fell off again. Professor Porter dissented from the view that the actual physico-chemical action of light on a photographic plate partakes of this same character. If the quantities of light-affected haloid were plotted against the light intensities a curve was obtained which had not this inertia character familiar in every H. and D. curve. The lecturer had worked out a formula for the theoretical rate of growth of the latent image which, he thought, was simpler in its application than that adopted by Hurter and Driffield. It was:—

Rate of growth of latent image = $a I (m_0 - m)$, where I is the intensity of the light, m the mass of latent image formed, m_0 the total mass of silver haloid, and a , a constant. This formula could be given the form

$$m = m_0 (1 - e^{-a I t})$$

The second part of the paper dealt with the resolving power of photographic plates—that is to say, the ability of an emulsion to give an image of extreme fineness. The lecturer's examples and experimental results were drawn from a paper by Dr. C. E. K. Mees, to be published shortly by the Royal Society. From the lantern-slide reproductions of Dr. Mees' experimental results, shown by courtesy of Messrs. Wratten and Wainwright, it was seen that the capability of a plate to give extremely fine images was not proportional to the fineness of grain of the emulsion. A process plate, the size of grain in which was .001 mm., gave considerably greater resolving power than a lantern emulsion of .0004 mm. grain. There was every reason to agree that the explanation given of this phenomenon by Dr. Mees—namely, that the lessened resolving power was the result of diffraction in the film—was the correct one. The lecturer very clearly demonstrated the kind of spreading action which was caused by refracting media, and, further, drew attention to the fact that in the photographic plate, just as in ordinary diffraction phenomenon, the quantity of spreading action varied with the wave-length of the light. Unfortunately, he said, the laws governing the scatter of light by granular media of the fineness of the photographic plate had not been theoretically worked out. In the case of very much finer scattering media, as also in that of much coarser media, laws (quite different in the two cases) had been derived, but the structure corresponding to that of the photographic plate represented a field between the two, of which, as yet, there had not been a theoretical investigation. On the proposition of the Rev. F. C. Lambert, seconded by Mr. W. B. Ferguson, the lecturer was accorded the thanks of the society, and was made the recipient of the medal presented to each Traill-Taylor lecturer.

CROYDON CAMERA CLUB.—Messrs. W. H. Smith and E. A. Salt gave a joint demonstration last week on home-made primary batteries for illuminating small Osram lamps, chiefly for use in the dark-room, with suggestions as to the construction of dark lanterns and safe-lights. The table was literally crowded with various types of batteries running many miniature lights, and a number of different models of dark lanterns constructed by the lecturers. Mr. Salt opened the proceedings with a general sketch of the principles underlying the generation of constant currents, and, assisted by many diagrams, outlined Ohm's law and its important applications to actual work. Both he and Mr. Smith had been in the field when the first Swan lamps saw the light of day, and the former well remembered running several 5 c.p. lamps from gigantic batteries at considerable trouble and expense. The advent of the tungsten filament Osram lamps, requiring, as they do, only about one-fourth the current for a given candle-power, had obviously altered the aspect of things and made lighting on the small scale perfectly feasible at little cost. A small Osram lamp, if run from a good constant-current battery, or, better, an accumulator, formed an extremely convenient, and a very constant source of light for contact printing on bromide papers, as well as for the illumination of dark rooms. Of the many primary batteries described and shown, perhaps a modification of the Leclanché cell, devised by Mr. Salt, aroused most interest. In one example, 2 lb. jam jars (about 5½ in. by 3½ in.) were utilised, each containing one zinc element, 5 in. x 1½ in. x 4 in.,

sandwiched between two carbons, $6\frac{1}{2}$ in. x $1\frac{1}{2}$ in. x $\frac{1}{4}$ in., the cell being tightly packed with about $1\frac{3}{4}$ lb. of crushed carbon, and the same quantity of granular manganese dioxide. The zinc element was kept apart from the carbon and manganese granules by being wrapped round with two thicknesses of ordinary white blotting-paper, followed by two thicknesses of unbleached calico, held in position by a winding of thread, and a final single thickness of blotting-paper. Sealing-wax was useful in securing joints at the top, bottom, and sides. The charge was a 10 per cent. solution of "Selectron," in lieu of the more usual salammoniac solution, so apt to form insoluble deposits. Three such cells (costing approximately 3s. 6d.) brilliantly lit a 1 c.p. 4-volt $\frac{2}{5}$ amp. lamp for over an hour, and it was stated they would probably be good for a year for intermittent lighting. A somewhat larger battery of three cells had been tested for two months' running of lamps from 1 to 3 c.p. for periods of three hours to twenty minutes each day, and showed no signs of exhaustion.

From the varied types of specially designed lanterns shown, each possessing some point of novelty, either in construction or design, a revolving one, due to Mr. Smith, came easily first in point of ingenuity. Four grades of filters, from bright yellow to deep red, at a touch were brought into operation, the light from the filter not required being automatically cut off. A second electric bulb, in an opal globe on top, afforded white light when required on touching a switch. Messrs. A. E. Staley and Co.'s "Geka" filters had been found useful, cheap, and efficient, and, there being practically no heat evolved, no buckling resulted. Messrs. Wratten were also prepared to adjust their well-known safe-lights for use with small electric lights.

During the evening several mysterious little lamps in coloured globes had been steadily displaying a bright circle of light, and were apparently neither electric nor oil. Towards the termination of the lecture Mr. Smith explained their construction. They illustrated another little idea of his own, and an extremely good one. A brass container, holding methylated spirit, supported a fine vertical tube, with a tiny wick running its length. This tube was closed on top, but a minute hole on one side at its upper end permitted the ignition of spirit vapour on the application of a lighted match for a few seconds to the orifice. The almost invisible blue flame jet impinged horizontally on a disc of Welsbach mantle about the size of a sixpence, held in a mica frame contiguous, giving a bright if small light. The lamps had been primarily designed for night lights, but were also applicable to small dark lanterns. By fitting a lever arm the jet could be directed away from the mantle and darkness secured.

In the discussion which followed, Mr. S. H. Wratten described suitable methods for mounting the disc-mantles in the Smith lamp. Mr. Harpur discovered some relevancy of the new lamp to an instrument alluded to by him as a "guillotine," and presumably an improved form of print trimmer. Mr. Geo. E. Brown congratulated both lecturers on a very complete exposition of an interesting subject. He was particularly struck with Mr. Smith's midget methylated spirit lamp, and suggested, by a small modification, it might be made into a highly efficient and portable travelling dark lamp. Mr. C. Welborne Piper, Mr. Raffety, F.R.A.S., and Mr. Oliver Dawson continued the discussion. The President, Mr. J. M. Sellors, in proposing a vote of thanks, alluded to the enormous amount of trouble which must have been occasioned in the preparation of the capital lecture they had heard. It was extremely fortunate that the society could rely so largely on its members for demonstrations of the most varied character. He was also pleased to see so many distinguished visitors present, and, on behalf of the club, most cordially welcomed them.

MIDLOTHIAN PHOTOGRAPHIC ASSOCIATION.—At a meeting of the Midlothian Photographic Association on Thursday, the 18th inst., Dr. Drinkwater delivered a lecture on "Light: Its Nature and Use in Photography." After stating that the knowledge of light was derived from observation of its properties, and explaining the accepted theory that it consisted in wave motions on the ether which are conveyed by the eye to the nerve centres of the human brain, the lecturer proceeded to demonstrate those properties which were of particular interest to photographers. Some simple experiments were made to show that light becomes visible only by reflection—on particles of dust or moisture in the atmosphere—and that the diffusion and degradation of pure light so caused was of advan-

tage to the camera. The nature of refraction was explained, and by means of lantern-slide diagrams, and of a spectrum projected through a simple prism, the varying dispersions of the colours and the refractive powers of prisms of different density were demonstrated. The lecturer then proceeded to show the necessity for the correction of a photographic lens, and the method of doing so. In theory this consisted in placing two series of prisms of different refractive powers together so that by first dispersing and then collecting the rays the visual and chemical foci were brought together.

After a vote of thanks had been conveyed to Dr. Drinkwater, the question-box of the Association was opened, and among the replies given for the information of beginners it was stated that the loss of density of a negative in the fixing-bath varied according to the developer and to the density-giving property of the plate used, and that a worker who did not wish to adhere to one formula required a knowledge of these variations to secure evenness of results. Some discussion on the use of a single solution developer as the most satisfactory for a beginner showed a difference of opinion, but it was pointed out that by using a combined developer at its standard strength, the simplicity of the single developer was obtained and a knowledge was secured of the qualities of the combined solutions, which would be in good stead when the worker had advanced to the stage of desiring control in development. At the same time, the trouble of mastering the peculiarities of a new developer would be avoided when that stage was reached.

A large collection of the pictures of Mr. Cleland, one of the prominent workers in the Association, was on view, and was inspected with great interest at the close of the meeting.

Commercial & Legal Intelligence.

SEQUEL TO BRIGHTON AMENITIES.—At the Brighton Bench last week, a coloured photographer named "D'jornette Plummer," of 56, Western Road, was summoned by a photographer's assistant named Benno Piltin, of 5, Brighton Place, to show cause why he should not forfeit the recognisance of £10 to keep the peace which he entered into on October 29.

Mr. Marx (for complainant) explained that originally his client had to issue a summons against defendant for wages. This was settled out of Court by mutual consent, one of the conditions being that the defendant was to give Piltin employment for six months. While working he was threatened, with the result that a summons was issued, and defendant (as reported in the "B.J." for November 5) was bound over to keep the peace. Subsequent happenings had resulted in this case.

Complainant swore that he resumed work after the last proceedings at two o'clock on October 29, when defendant was bound over in the sum of £10 to keep the peace and to pay a sum of £2 14s. 6d. as costs. He was at once ordered to clean the floor of the dark-room, and he did this work, though he was really engaged as a photographer's assistant. He heard Mr. and Mrs. Plummer having a row together in French about him, though he could not understand what the conversation was. Subsequently Mrs. Plummer made a statement to him, and after she had gone away defendant came to him, and held a "very dark conversation" with him at the back of the premises. After the proceedings he was in a bad temper, and said, "The Court is a play to me, and I will treat you worse than before. I am used to the Court already." He also threatened violence. Taking money from his pocket he showed it him and said, "I am rich, I will do you bad, I will ruin you, and the money will help me in the Court. I buy the Court with money."

Piltin said that after telling the young lady in the shop to keep her place, defendant sent him in the cellar to wash the plates. He went there, it was very dark, and glass came flying down on so him and ringing on to the floor. In consequence of this he could not do his work, and on striking a match he saw that glass was falling around him. Putting away the plates, he ran upstairs, and saw defendant creeping away from the back of the premises to the front. There were a lot of openings in the floor of the studio, and he did not know through which of them the glass came. Witness was frightened, and asked defendant why he threw the glass. He

replied, "Go out, you crazy man, go out to the back and do your duty." At eleven o'clock on the following day he applied to the Court, and had not since been back to defendant's premises, as he was afraid of Plummer.

In cross-examination he said he was of Scandinavian nationality. Part of the conversation he had sworn to was in German and part in English. The studio where it took place was like a stable. There was rubbish there and amongst it some broken glass. He had not brought any of the glass with him. He did not tell the young lady in the shop that he had made Mr. Plummer pay and that he would make him pay still more. He said nothing about advice the solicitor had given him.

A plan of the premises was produced by Mr. John L. Denman, of the firm of Messrs. Denman and Matthews. He denied the statement of the plaintiff that a person standing at the shop door could not see into the studio. There was a lot of rubbish in the dark room, and amongst it was some broken glass, on which a person might have trodden in walking to the sink. There was no position on the ground floor from which glass could be thrown at a person at the sink. He had stood in the shop and could hear part of a conversation in the studio.

In cross-examination he said he was prepared to say that it was absolutely impossible for a person standing either at the sink or at the foot of the stairs to be struck with glass from above.

Complainant was then again put in the box, and in reply to Mr. Grantham, he admitted that when he spoke to the lady assistant about the glass she said it must have been a ghost—"She must have meant Mr. Plummer," the witness added amid loud laughter. That lady, Miss Flint, told him she was afraid to leave him in a room with Mr. Plummer.

Miss Flint (from the back of the Court): I didn't say that, how dare you?

Mr. Grantham: Be quiet, Miss Flint.

In cross-examination the witness said he was quite prepared to carry out his contract with Mr. Plummer had he been allowed to do so.

This concluded the plaintiff's case, and Mr. Grantham at once submitted he had no case to answer as there was no corroboration whatever, while Mr. Denman's evidence had put the complainant out of Court altogether.

The Bench, however, ruled that there was a case to answer.

In his evidence Plummer said that for some years he had carried on business in Brighton, Hastings, and other parts of England. It was untrue that he threatened Piltin on the day in question or that anyone threw glass at him. He denied that he was creeping away when Piltin came up from the dark-room; as a matter of fact, he was standing in the shop talking to the assistant. He went away to Brussels on the Saturday afternoon, and had had to come back specially to answer this case. He suggested that the proceedings were taken with a view to extracting money from him. As a matter of fact after the previous case an offer was made to settle the whole affair for £25, but he refused it.

In reply to Mr. Marx, he denied that he had no further use for complainant's services, as a matter of fact he wanted all the men he was able to take on, and had done so ever since he had been in business. He had not said he had no use for Piltin, as a matter of fact he intended to send him to a shop he was opening at Hastings. He denied telling one of his managers to give Piltin hell and to work him to death. It was quite untrue that he had threatened complainant at any time. It was a concocted story between him and his witness on the last occasion. His wife had never complained to him of his treatment of Piltin.

Bessie Flint, the lady assistant at the West Street branch, said that she remembered the afternoon after the previous proceedings, Piltin then told her it was all right on his side, Mr. Plummer had to pay the costs, £2 14s. and £10. He also said, "I have made Mr. Plummer pay that, and I'll make him pay more. My solicitor said Mr. Plummer's only got to say one word to me and I'm to go to him." He also told her he was to remain for six months and asked her if Mr. Plummer was keeping it on all the winter. She said, "I don't know, I understand so," and he replied, "It'll be cold here, won't it." She advised him to try to settle matters and leave, and after speaking to his wife on the subject he agreed that witness should speak to Mr. Plummer with regard to it. She was in the shop all the afternoon and evening and heard complainant and defendant

talking, but regarded plaintiff's story of glass-throwing as a romance. When he came up from the dark-room he asked Plummer if he had thrown glass at him, and he replied by asking him what he meant. Subsequently Piltin told her the master must have thrown glass at him, but, with a laugh, she replied, "Impossible, it must have been the ghost you were talking about the other night. You know you are frightened to go down after dark because the other night you heard someone walking in the rubbish." When there was some talk about a settlement so that he could leave, Piltin said, "He will have to give me three months' wages."

Addressing the Bench, Mr. Grantham submitted that he had supplied an adequate answer to the charge, and that it was all actuated with an idea of getting money from his client.

The Bench retired to consider the matter, and on returning into Court the Mayor said the summons would be dismissed.

Mr. Grantham applied for costs, pointing out that his client was similarly condemned in the previous case. He argued that costs should follow the event.

The Magistrates refused to make any order.

NEW COMPANIES.

PROVINCIAL CINEMATOGRAPH THEATRES, LTD.—Registered office, Clarence House, 24, St. Martin's Lane, Cannon Street, E.C. This company was registered on November 12, with a capital of £100,000, in £1 shares. Its objects are to carry on any business, or operations, connected with the business of providers of entertainment and cinematograph pictures, etc. The signatories are: R. L. Jupp, 101, Jermyn Street, S.W.; W. W. Cresswell and J. W. Lovett, both of 9, Quality Court, Chancery Lane, W.C.; A. Meares Willows, Whitchurch, Glamorgan; L. Davis, 13, Berners Street, W.; W. H. Cresswell, 80, Station Road, Barnes; and R. J. Norbury, 11, Frobisher Road, Hornsey. Directors: Sir William H. Bass, Bart., Byrkley Lodge, Burton-on-Trent (chairman); J. J. Newbould, Tatenhill, Burton-on-Trent; and R. T. Jupp, 101, Jermyn Street, S.W.

News and Notes.

DECORATIVE PHOTOGRAPHS.—A number of specimens of a process for producing coloured photographs on glass, into which a further local embellishment with mother-of-pearl can be introduced, have been sent to us by the inventor, Herr P. S. Wolff, of Munich. The process is applicable to making highly decorated views, etc., and we understand that the inventor is open to introduce it to firms in this country.

PRESS PHOTOGRAPHY.—Messrs. Gallichan and Gasquoine, established as Press agents in the heart of printers' land at 188, Strand, London, W.C., send us their prospectus of terms for placing photographs, etc., with the illustrated Press. Messrs. Gallichan and Gasquoine are conveniently situated for showing work to the daily and weekly Press, and photographers in the provinces and abroad may be glad to make a note of their address.

R.P.S. MEETINGS.—The Council of the Royal Photographic Society has been requested to hold one meeting in each month at an earlier hour than in the past. Members who desire such a change to be made are requested to send post-cards to the Secretary to that effect, and to state whether they would prefer the meeting to be held at 5.30, or at 7 p.m. Those who prefer that the hour of meeting should be at 8 p.m. are also requested to state their views. So far, very few expressions of opinion on the subject have been received.

GLASGOW PHOTOGRAPHIC ART CIRCLE.—The Circle at its last meeting had a novel subject—viz., a criticism of prints (by well-known workers), belonging to Mr. J. M. Whitehead. The portfolio contained fifty-four prints, including the work of Mrs. Barton, Mrs. Cottam, Miss Warburg, Messrs. S. G. Kimber, C. F. Inston, Arthur Marshall, L. J. Steele, Dan Filshill, Charles Gaitley, W. R. Bland, H. Y. Simmons, Harry Lindoe, W. G. Clark, etc. Mr. Archibald Cochrane was critic, and treated each print individually, pointing out its strong and weak points. He opened his remarks by stating that it might seem somewhat presumptuous to criticise pictures, some with a dozen awards noted down on the back of them, but it was education that was desired, and he would criticise from as broad a standpoint of sympathy as possible. If they were all going out to

seek for pictures they would not all see the same beauty. One might set up his camera at what he considered the best the district afforded, while another would pass on; the first worker might know to leave out the hurtful features, while another worker would try from another standpoint. His aim was to get them to see that any suggestion made was an improvement; that was the most that could be expected.

A NICE HOBBY IF—!—We quote the following paragraph from a provincial paper, for obvious reasons suppressing the name of the gas-employee who finds photography "a nice hobby if you make it pay":—One of the workmen of the gas company (Mr. ———, of ———) has attained such skill in amateur photography that his employers on Wednesday last honoured him with the commission to do all the photographic work in connection with the inauguration of the new purifying plant. Photography has been a profitable hobby with Mr. ——— for several years. He makes most of his apparatus, and he uses a little bedroom as a dark-room. Mr. ———, who has been employed at the gas-works for about fourteen years, has done exceedingly good work, as his large stock of photographs shows. These include wedding groups, flowers, street scenes, flower gardens, etc., one of the photographs being that of a fellow-workman, Mr. ———, in his wonderful chrysanthemum garden at ———. "Photography is a nice hobby so long as you make it pay," said Mr. ——— yesterday. "I could not afford to carry it on unless I made it pay." The fact that he makes it pay is proof of the excellence of his work, in which he receives every encouragement from his employers.

A PHOTOGRAPHIC DETECTOR.—In our issue of November 12, under "Patent News," we mentioned an application by Mrs. Rose Stevens, of 25, Church Stile, Rochdale, for a patent respecting a "Photographic Detector." This lady now sends us the following particulars. The invention is for obtaining the portraits of persons requesting banks and large public buildings so as to provide a clue in case of fraud and burglary. The system is the combination of a balanced mat connected with a camera in such a manner as to be put in operation by a person treading upon the mat.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

POSITIVES DIRECT.

To the Editors.

Gentlemen,—The process to which you refer under the above heading was suggested by Professor Corsi, according to Woodbury's Encyclopædic Dictionary of Photography, 1896, p. 141, and the instructions are to immerse in an acidified bichromate solution till the image turns red, then in three successive baths of chrome alum and boric acid, and dissolve the chromate of silver by potassium bromide and hydrate and then develop. Obviously some one has blundered, and the process hardly possesses even the merits of novelty.

E. J. WALL

November 20, 1909.

CONCENTRATED SINGLE SOLUTION M.Q. DEVELOPER.

To the Editors.

Gentlemen,—In formula for a concentrated No. 2 developer in this week's "B. J.," the water is given as 24 ozs.; it should be only 4 ozs. so, in par giving the strength of developer per oz., it will contain 6 grs. of soda sulphite and not 2 grs. as stated. This second mistake is of course, not yours, as it is a misprint in "The Photographic Manual."—Yours faithfully,

R. L. BOYD.

10, Annesley Park, Rathmines, Dublin,
November 20, 1909.

STEREOSCOPIC PORTRAITURE.

To the Editors.

Gentlemen,—I wish to remark, in reference to the article on this subject in last week's "B. J.," that while the plane portraiture depends largely on tonality, or contrast in obtaining the relief of the subject from the background, stereo work has this effect binocularly, and uses the lighting of the subject or sitter to obtain roundness solely. To make my meaning clear, let me say that most

backgrounds are painted so that in a portrait the lighted side of the head is contrasted against a dark portion, and the shadow side is similarly relieved by a lighter tone in background. This, to emphasise certain important characteristic outlines, but the stereoscopic artist abhors painted backgrounds, as both unsatisfactory and belittling his work, and he, in order to obtain in a more natural manner the relief effect, looks around for materials for backgrounds among common-place articles, of which there are many cheap enough (like the built-up window or panelling) now on the market. For my own part, I wish manufacturers would turn attention to the once popular "Alto Relievo Ground," as I find them excellent for stereoscopic portraiture. Plain ground are no use for this class of work, as the eyes when "seeing round" the sitter must have some pattern, object, or moulded form to mask the spot it covers on the background, otherwise there is no relief effect, and for this reason cloud grounds are scarcely better. A capital background may be constructed by a wood trellis, covered as to taste with entwined artificial flowers, and if the question of cost is great, wall-papers of tasteful design stand forward as eminently suitable—different patterns to be chosen to suit each class of subject. Six would be a complete assortment for any studio. Next in importance to a suitable background, is the placing of accessories midway between sitter and the background. These should be used to show the amount of perspective desired, but should be subordinate to the subject or motif expressed. Chair backs, palms, table tops, pedestals, or, in genre group work, other figures may be thrown out of focus as accessory to the main theme. For example, if the subject is a street flower-girl, what would be more natural and unobtrusive than passers-by shown in less relief between subject and distance. Again, great care must be observed in the disposition of the arrangement of accessories in front of the sitter. They must be usual, and tend to lead the eye to the chief portion of the picture without attracting attention solely to itself. Few appreciate more fully the high standard of Mr. Elwin S. Neame's work in plane photography, and I believe that, after the style of the late Lord Leighton, he values beauty of outline as of primary importance. I would feel gratified to find him give expression to his talents by modern stereoscopy. Now, as to size of picture. I don't see that large work is necessary, as a 3in. picture, 9in. from the eyes, might appear as a 300ft. arena at 100 yards' perspective distance, providing the work is accurately carried out by an educated, up-to-date stereoscopist who possesses some of the spirit of Michael Angelo, who, when his friends asked him why he scraped and examined a rough block of marble, said, "I see an angel in it, and I must release him"—and he did.—Yours faithfully,

9, Mary Street, Dublin.

GILBERT DYAS.

BRITISH TRADE WITH PERSIA.—In competing with Russia for Persian trade Great Britain labours under serious disadvantages. The north of Persia, which contains more than one-half of the entire population of the country, produces such valuable products as cotton, dried fruits, hides, and precious stones, and manufactures such goods as carpets, and cotton and silk tissues, all of which are suitable for export to the protected market of Russia. In other words, the trade is reciprocal. The geographical position, too, is very favourable for Russia. A merchant trading with the United Kingdom or India can only turn over his money once in the year, as against five or six times in the case of merchants dealing with Russia. The fact that British goods are still imported is either due to their great excellence or to the fact that Russia cannot produce the articles. Another factor of Russian success, as Major Sykes. His Majesty's Consul-General for Khorasan points out (No. 4,376 Annual Series), is the transport company, which is ready to book an order on a Russian firm if 10 per cent. of the value be paid on account, although for breakable articles 50 per cent. is required. By the contract, the purchaser agrees to pay the balance in two or three months' time—i.e., upon the arrival of the goods. If, however, he fails to pay, he is charged interest at 8 per cent., and the goods are released as he pays for 55 per cent. of the value of his consignment in cash, on which advance he also pays 8 per cent. interest. All carriage is paid by the consignee, and everything is insured by the purchaser at 1 per cent. Major Sykes considers this system admirably adapted for Persia, where merchants trade on very small capital, and urges that it is worth being carefully studied, and perhaps imitated, by British traders.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- F. Burton, 13, Preston New Road, Blackburn. *Photograph of a Combined Photograph and Drawing of a placed Group of the Blackburn Rovers.*
- Leo. Legge & Co., 12, Grainger Street, Newcastle-on-Tyne. *Three Photographs of Richard Collins, Bishop of Hexham.*
- W. A. Singleton, 23A, Victoria Chambers, Knowsley Street, Bolton. *Photograph, Laying Foundation Stone of Astley Bridge Library, November 3, 1909.*
- R. T. Watson, 70, Anlaby Road, Hull. *Photograph, Group of Sergeants 5th Batt'n East Yorkshire Regiment (Territorials).*

TWO-COLOUR OIL PROCESS.—I should be much obliged to you if you could give me some particulars of the oil pigment process in two colours—for instance, a slightly different colour for the sky in a landscape (sunset) or for the figure in a portrait—what colours to use. Is there any indication in a book on the subject?—C. G.

No book has been published on this special branch. So far, oil-prints in colours have not been successful. The most pleasing have been the portraits done in colour-inks and shown by Mr. F. C. Tilney at the last P.P.S. Exhibition. All these were kept in light tones. Multicolour oils in full dark tones have so far proved very incongruous. The technique is the same as the ordinary (monochrome) process. A considerable range of colour inks are supplied by Jas. A. Sinclair, Ltd, 54, Haymarket, London, S.W.

COMBINED BATH.—I am using a combined toning bath composed of the following ingredients:—

Sulphocyanide of ammonia	7 drs.
Citric acid	2 drs.
Sugar of lead	3 drs.
Alum	2 drs.
Hypo	9 ozs.
Gold chloride	15 grs.
Water	40 ozs.

I should be glad to know if you consider P.O.P. prints toned in that bath are permanent. I might add after toning I fix in hypo bath, 3oz. to one pint, for about ten minutes.—COMBINED (Jersey).

We must say that we prefer, for the sake of more permanent results, a bath of the alkaline type or one, at any rate, without acid—as given on page 760 of the forthcoming "Almanac"—but we recognise that these will not give sufficiently cold tones with all papers. Provided that your formula is not used when exhausted of gold, it should give satisfactory results, particularly with the after-fixing, which is a good plan. We should advise replenishing the bath with gold according to the prints toned—say, 3 to 4 grains of gold for each sheet of paper.

PENNY PHOTOGRAPHS.—I should be obliged if you could tell me the process for taking sitters direct on to paper, as I believe this is the way that the penny photograph game is worked, and I should like to know, if you could possibly tell me.—OLD PRO.

So far as we know no process of taking direct on to the bromide paper is worked. The exposures are made on dry plates, and printed on bromide paper.

TUBE CINEMATOGRAPH.—I was much interested in your note about the Tube Railway, for I had often talked about its possibility as a cinematograph, and been told that it would add a new horror to travelling. My idea was to have enlarged biograph pictures fixed on the wall of the Tube alternately with black spaces of

the same size, and the light from the carriage as it passes would supply the illumination. As all my knowledge of kinematograph projection was gained at shows before the C.C. shut them in fireproof boxes I imagined that the black spaces would serve the same purpose that the string that used to revolve in front of the lantern did, and I am curious to know whether you think any way would not give just as good a result as the elaborate one you describe.—C. B. S.

We quite agree that the idea is likely to add a new terror to travelling if it is ever carried out. We do not think your idea would work, as each picture would be visible for so long that the movement would destroy the effect.

W. BOOTH.—You would find the *f*/6.8 lens better for all-round work. The other is not much used now on account of the care and shading needed when using it against a strong light, in consequence of the many glasses. The *f*/5 lens will not be quite as much more rapid than the *f*/6.8 as would be thought from the respective aperture numbers, owing to this same cause.

COPYRIGHT.—I see by your reply to my query that you have misunderstood me, so I will give you the facts in full. For the last two or three years I have been taking negatives of local buildings and country scenes for picture postcards to sell in my shop, and a printer a few doors below me has bought the best of my views and reproduced them, and is selling them at half price, and it has completely destroyed my sale. What I wish to know is, if there is any way to prevent him reproducing my views? I wish you to understand that my negs. are not copyright.—A READER OF "JOURNAL."

If you wish to stop the infringements you must register the copyrights in your views, or, say, in twenty of them. You can then stop further sales. Your best plan will be to register, and then employ a solicitor to write the printer, asking him what he proposes doing.

J. P. O'HEA, H. M. S., and others.—In our next.

A. GEO. B.—If you cannot obtain sharp focus at *f*/6 it is evident the lens is suffering from spherical aberration. If this is the case, the use of the smaller stop is the only remedy.

RE-SITINGS.—After some years' practice as an amateur, I have started a studio in this town as a professional. I find the sitters are very troublesome, as so many want re-sittings, although the photographs are excellent. When I ask for extra payment for taking again they grumble and say they will not pay for it. I shall be obliged if you will be good enough to tell me what is the general rule amongst professionals with regard to re-sittings when the photograph is really good and it is only the expression or the pose that is not liked by the customer?—PROFESSIONAL BEGINNER.

We see by your memo. heading that "a satisfactory likeness guaranteed." In face of that you cannot expect your sitters to pay for re-sittings if the portrait is not satisfactory. As a rule the better class portraitists are only too pleased to give a re-sitting when a portrait is not liked, their object being to please the sitters under all circumstances and so increase their business. You will do well to do the same. As you say "so many" of your sitters complain of their portraits it would seem that you are not sufficiently experienced in studio work.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Mr. Welborne Piper describes a method of producing positives rect by a process of reversal depending on phosphorescence which as being worked out by the late Mr. Douglas Carnegie at the time of his death. (P. 932.)

We draw attention again to the fallacies involved in suggested methods of obtaining colour effects by combination of the two prints each differently coloured) of a stereoscopic pair. (P. 929.)

One of the most painful tragedies in which photography has played a part occurred at Portsmouth on Tuesday last. (P. 941.)

Colour screen-plates, cameras for full-size focussing, and diaphragm shutters figure under "Patents of the Week." (P. 936.)

A paper read before an American professional photographers' meeting dwells upon a number of the factors in a studio's commercial prosperity. (P. 933.)

"The Selection of Originals for Press Illustrations," "The Reduction of Pencil Drawings, etc.," are topics treated under "Photo-Mechanical Notes." (P. 934.)

An exhibition of oil and bromoil prints is now open at the Sinclair Gallery, Haymarket, S.W. (P. 935.)

Further steps are being taken towards establishing a camera club in London. (P. 941.)

"Dum" photographs. (P. 940.)

Mr. W. Gamble, in a letter on page 942, sends us documents showing that the idea of the production of animated photographs of a tube railway was suggested by a photo-engraver in Rotterdam some months ago.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. Colin N. Bennett contributes an article dealing with the adjustment of the compensating filter to the "Thames" plate. (P. 89.)

Herr E. Valenta has examined a large number of dyes with a view to their suitability for three-colour inks. The results are given in an article on page 92.

M. V. Cremier has published one or two useful notes on the uses of the defects most usually met with by beginners with the autochrome process. (P. 94.)

M. Francis Sforza, in a letter on page 95, criticises the use of the ferric bichromate method for dealing with subjects of extreme contrasts when making Autochromes.

Professor R. Namias has made further experiments in the use of iron compounds in the so-called "Diachrome" process, and has discovered a simplified method of obtaining three-colour transparencies by this means. (P. 91.)

EX CATHEDRA.

The Contents of the 1910 Almanac.

As has been already announced in advertisements of the Almanac, the general arrangement of the volume remains unchanged. It is hoped that the section "Epitome of Progress," which during the past few years has become a highly appreciated feature of the book, is this year still more useful from the fact that each item in it is somewhat more fully dealt with than previously. It has been thought that, particularly to readers in distant parts of the world, an abstract of any paper which has been published during the year should give every necessary detail as far as possible, and in this respect it is believed that the epitome of the progress recorded in 1909 will be found of greater practical usefulness than hitherto. The reviews of new apparatus have run to a somewhat greater length, though it cannot be said that they embody descriptions of many articles which represent radical developments in apparatus. As in last year's issue, the Index to Goods Advertised, which occupies the last seven pages of the book, will, it is hoped, prove an actual shop-window of the photographic trade, inasmuch as it provides a rapid reference to the enormous variety of materials and apparatus offered for sale in the Almanac.

* * *

A Binocular Fallacy.

We have been struck of late by the persistence with which the old myth with regard to the combination of colours by binocular vision holds its ground. Long ago it was demolished by Du Tour and by Wheatstone, but it is now revived and actually made to serve as the basis of methods of producing stereoscopic photographs in natural colours. The ignorance which prevails on the subject is evidenced by the fact that in one projected process the colours are assumed to combine additively, while in another they have to combine on subtractive principles. Both cannot be right, while it is quite clear to anyone who has experimented with the binocular combination of colours that actually both are wrong. The result is not a mixture of the two colours, but confusion. If, for example, one image is red and the other blue in a stereoscopic slide we may intermittently see a violet image, but in between whiles we shall see alternating blue and red images. If, as an alternative experiment, we view a white object through blue and red glasses we get very similarly changing effects, with the difference that the colours are so feeble as to look almost like neutral tints. One explanation of these variable phenomena is that the eyes always see alternately. This was advanced by Du Tour and a few others, but it is hardly a proved fact. Another suggestion is that the changes are due to non-coincident after-images, but this again is hardly feasible. Possibly the simplest and truest explanation is that our eyes are not constructed for the purpose of combining

colours in this fashion. We know that if red and blue together strike one retinal unit in the eye, we get the sensation of violet, but there is no warrant for assuming that when red meets one retinal unit in one eye and blue a corresponding unit in the other, that we shall again get a sensation of violet. Theory has not a scrap of evidence to suggest that we should do so, while practice proves that we only do so occasionally and by a kind of fluke. The neglect of both theory and practice must surely be responsible for these suggested colour processes. It is interesting to note that we meet with a similar visual breakdown when we try to combine two quite dissimilar monochrome images. Even when they are simple regular line patterns we do not see the two combined to form a more complex regular pattern. All we see is sometimes one pattern and sometimes the other, while these appearances alternate with glimpses of what appear to be broken bits of each pattern. Wheatstone attempted an explanation which practically amounts to suggesting that the brain is inattentive to intelligence sent to it through the eyes when the two eyes simultaneously tell quite different tales. When we meet with two witnesses who spin quite different yarns and both talk at the same time, the only thing to be done is to separate them and make each tell his tale by himself, and it is quite reasonable to assume that this is what the brain does when its scouts, the eyes, contradict one another. It then studies the subject through the medium of each eye alternately until some general idea is obtained.

* * *

The Illustrated Press.

Mr. Thorne Baker, in replying to the discussion which arose out of his paper on photo-telegraphy at the Society of Arts last week, made one statement with which we are in hearty agreement. Speaking of the choice between drawings and photographs for the illustrated press, he said, in regard to the latter, that the demand was "extraordinary." It must be, if the British public obtains any satisfaction other than amusement in the reproductions of events which appear in the halfpenny daily press. The other week, in the "Daily Mirror," we saw a photograph alleged to be—and we have no reason to question the correctness of the allegation—of Mr. Snowden Ward opening a bazaar. If it had been described as Rip van Winkle or the Apostle Paul it would have given us less surprise. And this, of course, was not a telegraphed picture, some of which latter, if we may judge from a page of reproductions, which we see in a daily paper, might form the basis for an interesting guessing competition. We were glad to hear that Sir Henry Trueman Wood expressed his scepticism of the practical service of the telegraphic transmission of photographs.

* * *

The Johannesburg Photographic Art Circle.

The above society, which was formed in January of the present year for the furtherance of pictorial photography in South Africa, held its first annual exhibition in the picture gallery of the Transvaal University College from November 1 to 6. The exhibits consisted entirely of South African work, the major portion being contributed by photographers in Johannesburg, though Cape Town, Pretoria, Greytown, and other places were also represented. The labours of the selecting committee resulted in the hanging of seventy-eight pictures, very varied in subject and in methods of treatment, and—in the majority of cases, at any rate—giving evidence of care and artistic feeling on the part of the authors in the selection of the subjects, and skill in the manipulation of the various processes by which each attained his final result. No awards were offered, and the pictures were effectively hung in panels, the whole forming an attractive display

which drew a large attendance of the general public, who testified their appreciation of the pictorial character and artistic display of the photographs submitted for their inspection. The promoters of the exhibition, and Mr. Harold Smith, the secretary, should feel encouraged by the success of their first effort to raise the standard of photographic exhibitions in South Africa, to look forward with confidence to much greater advances in this direction in 1910.

* * *

"Dum" Photographs. When is a photograph not a photograph? The answer is, when it is a "dum," photograph, which word, we would say at once, is not a misprint for another differing from it only by a single vowel. At the Leicester Police Court last week a photographer was charged for receiving sums of money from persons on account of photographs of themselves or their houses of which he is alleged to have promised delivery. According to the report, which we reprint in another column, the entry "dum" made in a notebook was explained in court to refer to the fact that, in these cases, no exposure had been made. Another instance of commercial candour.

* * *

Percentage Solutions. The old question of percentage solutions is revived in a contemporary, and we are surprised to see that a querist is told that he may safely take grains as corresponding with minims, and ounces with fluid ounces. He may perhaps do so with safety so far as most photographic operations are concerned, but it would be just as well to let him know that if he takes grains as corresponding with minims, he gets a stronger solution than when he takes ounces only. In fact, ten ounces of ten per cent. solution made up by the first method will contain 42 grains more of the solid than ten ounces made up by the second method. There is no equivalence between the grain and the minim, and solutions made up with these units should not be styled percentage solutions at all, but be described under the system of so many grains per ounce. This is a highly convenient system in use, but only confusion results when it is mixed up with the percentage system in which the gramme and cubic centimetre or the ounce and fluid ounce are the units employed.

A SUGGESTED METHOD OF MEASURING VARIATIONS IN THE "RAPIDITY" OF LENSES DUE TO REFLECTION FROM THE GLASSES.

MR. THOMAS BOLAS, in one of our contemporaries, calls attention to the importance of not neglecting what he calls the "lens factor" when estimating the relative rapidity of different objectives: that is to say, the fact that light is lost by reflection and by absorption during its passage through a lens is one that should not be forgotten. The writer quotes what he describes as an "unwritten custom" among working opticians to allow 5 per cent. for the loss by reflection from each air surface of the lens. This rule, however, takes no account of the absorption of the glass with which the lens is constructed, and it is also clear that it cannot be correct to make the same allowance for each surface, for a great deal depends on the form of the surface. If, for example, divergent light falls on a convex reflecting surface the loss by reflection must be greater than when a similar pencil of light meets a concave surface. A good deal depends on the arrangement of the lens surfaces, and by bearing this point in mind the designer can sometimes gain a little in rapidity. The absorption of light by the glass is also not a negligible matter, even in new lenses, for this factor varies with

the thickness of the glass used, and to some extent with its composition. Here again we have a variable factor that cannot well be estimated, and it is evident that what is wanted is a system of measurement. It has occurred to us that such a measurement might well be carried out at the same time that the aperture of the lens is measured. Suppose we are measuring the aperture by the well-known method that involves placing a brightly illuminated pinhole at the principal focus of the lens. If we place a dry-plate against the lens-hood and expose for a short time, development gives a circular dark patch, the density of which, measured in a photometer, must record the relative power of the light reaching the plate. If we now assume the lens to neither absorb nor reflect any light, it seems evident that the intensity of the light reaching the plate should be exactly the same as that of the light which reaches the entrance pupil of the lens; therefore, if we remove the lens, place a plate in the position of the entrance pupil, and expose for the same time to the same illuminated pinhole, we should get a patch of equal density, while any difference in density should afford a measure of the loss of light due to reflection and absorption. Such a test would not be difficult to arrange, and the results of a series of tests with different lenses should give some valuable positive information to replace the speculations upon which we now rely so much.

OUTDOOR WINTER EFFECTS IN THE STUDIO.

If weather prophets were to be relied upon, we are to have a long and severe winter. But all of us have heard prophecies with regard to weather, and know full well that they are not to be relied upon, and possibly this may prove to be the case in the present instance. Anyhow, what we have experienced so early in the season, should continue through the next three or four months, will mean a very long winter, and by no means a profitable one with most photographers. We recently gave some practical hints as to how some of the inconveniences sometimes experienced in the practice of photography may be avoided, or, if not entirely avoided, at least reduced to a minimum. Although during the past decade or so this country has not experienced what some call a "good old-fashioned winter," many of us will not at all regret such a season, particularly were it of very long duration. In some countries where winters are long and severe portraitists turn them to a fairly good account by making a feature of producing portraits in the studio depicting wintry aspects out of doors. For this purpose special backgrounds are painted representing snow-clad scenes; the accessories also are covered with apparent snow, and the effect is enhanced by apparent snow falling on and about the figure.

The object of the present article is to point out how a realistic winter scene may be arranged in the studio by the photographer himself, with but little trouble, and at the most trivial outlay. Even though little direct business accrues, specimens taken under extreme wintry conditions would prove attractive in showcases or windows, and thus form a good advertisement. We have more than once felt upon the subject that the specimens exhibited should be always in unison with the season: in winter particularly it is desirable that those shown should be in accord with winter, and under wintry aspects.

There are few portrait photographers who are not in possession of one or more outdoor backgrounds, and one of these, although it may represent a summer scene, can easily be converted into a winter one to serve our present purpose quite well. If it is an old and otherwise useless one, it will answer whether it be in flatted oil or distemper.

In the first place, we take a white pastel or crayon, or even a lump of chalk, and whiten over those parts of the scene upon which falling snow would settle were the scene a natural one—such as on the branches of trees, the tops of buildings, ruins, and the like. A mere more or less broad line only is necessary, as its sharp outline may be softened off by rubbing it over with a piece of rag folded up and used as a stump, or even with the finger. If the background is a very bright and sunny one, it may be advantageous to subdue some of the brightest portions with grey or even black pastel in the same way, so as to destroy some of the brightest effects. The work need only be roughly done, as, the background being out of focus, the roughness will not show in the picture. If the work is done on a flatted oil background it can be cleaned off at any time with a damp sponge, when it will be as good as ever for future use. If, however, it is a distemper one, the case is different, as then the chalk cannot be removed completely.

The background itself being finished, we next turn our attention to the accessories, and here it goes without saying that they must be outdoor ones, such as rustic seats, stiles, balustrades, rockwork, and similar things that are to be seen in most studios. The tops should be whitened to resemble settled snow. Instead of chalking them over, a better and more natural appearance is obtained by covering the tops with cotton wool. At linendrapers' shops is sold sheet wadding, about a yard wide, at a few pence a yard. This material is really better for the purpose than the cotton-wool, and has the further advantage that it is very much cheaper. Added to that, it can be cut to size with scissors and secured in position by drawing-pins or tacks.

This part of the work having been done, we get a very fair representation of an outdoor winter scene. But it will be obvious to everyone that we must not stop here: the arrangements are not yet complete, for it is clear that all this snow-like appearance could not exist unless the ground was also covered with snow. All that has to be further done is to cover over the portion of the floor where the sitter is posed with the sheet wadding. Two kinds of this material are sold at the draper's, the bleached and the unbleached. The latter is to be preferred for the floor, as it has not the glaring whiteness of the former, and for this reason is not so trying to the eyes of sitters, and it is not so likely to interfere with the lighting of the model. In this simple way it is a very easy matter to arrange in the studio a scene that will convey a good idea of an outdoor one under severe winter conditions.

In some portraits we have seen done in Canada, and also in Russia, the wintry effects have been further enhanced by a representation of snow falling on and around the figure, but not before the face of the sitter. This, of course, makes the picture look incongruous in the extreme. This glaring incongruity may, however, be avoided, whilst still preserving the face, by getting the model to hold a small umbrella in a position which would be adopted in shielding the head from falling snow. The umbrella used for the purpose should have some of the sheet wadding stitched upon it. The whole thing would then appear fairly natural.

We will now add a few words to say how the falling snow effect is obtained. It is done by spraying, or splashing, over the negative with an opaque pigment—say flake white. The usual method is to grind up the colour with water and to just touch the tips of the bristles of a tooth-brush on the colour. Then, holding the brush at some little distance from the negative, the back of a knife is passed over the bristles so as to flick the colour over the film. The uneven splashes produced in this way will give a very good idea of the varying size of flakes of falling snow. The colour may be wiped off from the face, which will then be left

unobscured. It is a good plan, it may be mentioned, to varnish the negative before the spraying is done, as then it can more easily be removed, if not satisfactory, than if it were unvarnished. The above is penned to point out how easily what is not an actual new thing may be of service as a novelty in the way of a seasonable attraction in showcases or windows, and may prove a good advertisement to the photographer. Though not in any sense a novelty—the idea and methods may be said to be

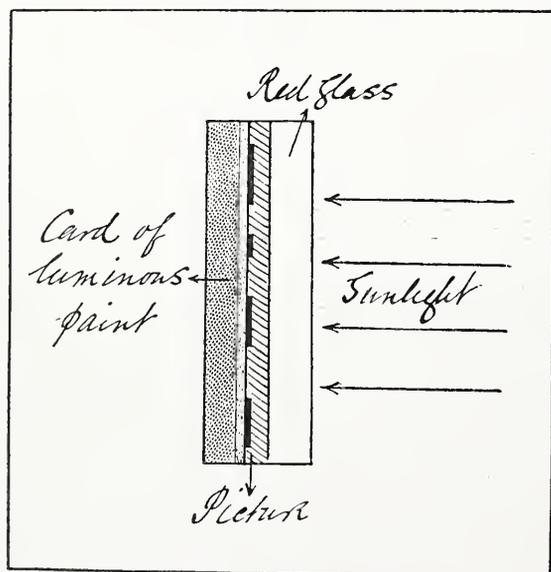

so old as to have become, in the cycles of time, new again—in studios which are engaged chiefly in middle-class business it may be employed with advantage in interesting customers in a photographer's work. The exhibition of specimens of Christmas and New Year's greeting portraits, taken with winter surroundings, would doubtless prove a remunerative line in many places, seeing that they can be produced with so little trouble, and for so trivial an outlay in the first instance.

MR. DOUGLAS CARNEGIE'S LAST PROCESS OF REVERSAL.

SEVERAL methods of producing negatives from negatives or positives from positives have been described in this journal by the late Mr. Douglas Carnegie (see "B.J.," October 23, 1908, and July 9, 1909), all of which methods depended on chemical "reversing" processes. A short time ago, however, Carnegie gave much time to the study of another method of reversal not dependent on chemical processes at all, and he got on so well with it that he anticipated it would be a very useful method when all the details were perfected. Unfortunately, I am not in a position to give exact details of his method as he worked it, and I have not yet come across any written notes on the subject. I have, however, found some of the materials he used experimentally, and have tried the process as I remember it to have been described by him, and the first attempt certainly indicates that it is a very promising one. The following is a brief description of the principles upon which it depends.

Reversal by Phosphorescence.

If we take a slab that has been coated with a variety of luminous paint, keep it in the dark long enough to render it

quite inert, and then expose it to a strong light behind an ordinary negative, the result is, of course, a luminous negative image that can be seen quite distinctly in the dark. If we place this luminous negative image in close contact with an unexposed dry plate or piece of bromide paper, it produces a latent positive image, which we can develop, the result being the same as if we had made a print direct from the original

negative. Obviously such a process of printing has no advantages, but by a very simple modification we can produce a reversed luminous image which will yield a negative instead of a positive result. To do this we vary the procedure as follows:—Take the luminous slab and expose it to strong sunlight or to magnesium until it glows brilliantly when examined in a dark-room. Then place it behind a negative, just as in the previous method, and expose to red light. The red light destroys or reverses the effect of the preliminary exposure, and so the transparent parts of the negative become represented by dark places on the luminous surface, and we have this time a luminous *positive* image instead of a negative. When this is placed in contact with a sensitive film a negative is, of course, produced, and so we obtain the reversed result required.

The Method and its Present Drawbacks.

Mr. Carnegie apparently used a piece of ground ruby glass placed in the printing-frame for making the second exposure. This red glass was inserted first, then the negative, film side up, and finally the excited luminous slab. How long he exposed I do not know, but in my test I exposed to about a foot of magnesium for the second exposure, and finally left the new plate in contact with the slab for one minute. The result was fairly good as regards exposure, but showed a coarse grain that was not visible at all in any of the results that Mr. Carnegie himself had shown me. This coarse grain was evidently due to the fact that I had used the wrong luminous slab. Its surface was rough, and among the several slabs found, there are finer ones, which will no doubt work better. But I have not found a perfect one, and I understood that Carnegie had great difficulty in producing a good surface, and an even greater difficulty in finding a perfectly suitable material for it. If the details of this work are not found, it will be necessary to re-work out the process before results like his can be attained, but, judging from those he possessed, it will be quite worthwhile to undertake this work.

How far the process may be considered new I am uncertain. I was not previously aware of the fact that red light destroys the luminosity, and was surprised to find it act as rapidly and completely as it does. The discovery of this reversing action may or may not be his, but in any case I believe no one else has hitherto taken advantage of the phenomenon for the purpose of producing reversed photographic images.

The diagram is reproduced from one found among the materials, and it illustrates well the method of working the process.

C. WELBORNE PIPER.

ENSIGN COMPETITION.—Mr. Chas. H. Coulton, 111, Oxford Street, London, W., is the winner of the "Ensign" Roll Film Competition for November. Houghtons Limited offer a Three-Guinea Camera

every month for the best negative on "Ensign" Film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" Film.

PROFIT AND LOSS.

(A Paper read before the Nebraska Photographers' Association.)

In treating the subject assigned me by our president, I feel incompetent, indeed, for its vastness covers more than the experience and observation of any one man.

It is a problem in which we are all interested, whether located in the heart of a great commercial centre or in the smallest hamlet of Nebraska. If we cannot realise a profit from our labours, work soon becomes a drudgery, and an unhappy, discontented existence follows. There are, therefore, some fundamental principles which must be applied in every case.

Statistics show that 95 per cent. of all business men meet either partial failure or total loss. I am convinced that this statement is true.

How few men are in business, for instance, in Lincoln to-day who were the bone and sinew of the commercial Lincoln twenty-five, yes, twenty, years ago? There is a reason for this, and no doubt every business man sometimes attempts to solve the problem and stem the tide that is defeating the vast majority.

No man cares to continue long in a business where profit does not exist. I want to repeat what I have said before from this platform, that the accumulation of a competency for old age is of the most vital importance to practical men, and all lines of progress should be founded on practical principles. Men have been and are accumulating profits sufficient to establish homes and provide the luxuries of life for their families out of the photograph business. The man who cannot do this has no right to remain in the profession, for every man is entitled to a competency for his labours. If he fails, in most cases he alone is to blame.

In our profession we find many who merely eke out an existence and live, metaphorically speaking, from hand to mouth. I believe you will agree with me when I say that these are not the men who attend our conventions. Therefore, the conclusion is that attendance at meetings of this kind is profitable financially as well as helpful from the artistic standpoint. The association, one with another, means more to us in the months following than appears during the few days we are together.

Many of us are not successful because we do not possess perseverance and are constantly changing from one location to another. Success does not come in a day, a month, or even a year, and only application and concentration of thought and energy will enable us to possess it. True, a sitting hen never gets fat, but she will have more to show for the sitting than she would if she changed nests every clear day.

Injudicious advertising enters largely into our failures. Advertise, a necessity, of course, but in a way that will dignify the profession and demand the respect of the appreciative public. Too many of us spend money in a way that is not worth the paper on which the contract is written, and wonder why we do not obtain results. A set of rules for advertising cannot be laid down, for conditions vary, and it is up to the individual to choose well the method best adapted to his locality and then study well the matter used.

We little realise how profitable is the proper care of our display medium. Herein the public judge, and judge wisely. Only a suggestion should be needed on this much-discussed subject, and yet look about you and see how shamefully we neglect the words of wisdom offered by every speaker and writer.

We fall far short of the many opportunities of increasing our profits by the failure to grasp the scope of our profession as applied to the desires and, in some measure, the necessities of the common people. I want to call attention to a few that stand out most prominently, and first the duplicate business.

The money lost in this one avenue of trade is appalling if not properly handled. Many men have no system for their negatives, and if able to fill an order it is only after much effort and loss of time. A system should be in vogue in every well-regulated studio which would enable anyone to turn at a moment's notice to the negative. Herein lies the velvet of our earnings and profit.

Reminding customers of the fact that their negative is about to be filed for storage, and a suggestion that it would be well to have additional prints made now, might bring in many a dollar that otherwise would not reach us.

Just a word to sitters who are tardy in ordering does much to hasten the completion of orders. We must not forget our own tendency to procrastinate, as well as our customers', for many of us are very negligent in finishing our orders. Herein is no small item of loss, for the sooner an order is completed the larger the duplicate business, and from this order and its influence many follow. I insist that, were it possible to complete an order the second day after the sitting, our business would be increased to double its capacity. We see this verified in the methods adopted by the postal card and view men who come into our towns and make pictures of school children and of business blocks. The speculative order is ready for delivery the next day, and you know the results. It is through these little things or the lack of them that losses creep in.

I have no doubt that many of us have parts of orders in our cases that should have been called for weeks ago, on which perhaps is a balance due. These delayed deliveries should be looked after as zealously as new business, and no apology is needed for sending them to their owners, with a statement of the balance still unpaid. Many a customer thinks because he has made a payment, and perhaps received one portrait, that he is relieved of any further obligation. I would rather have the entire order in the customer's hands than to hold it for a remittance. It is easier to collect the account.

This work naturally requires systematising, and should be under the direction of the receptionist. This brings to our attention the reception-room and its management. Too much cannot be said concerning the efficiency in this department, for herein lies one of the secrets of success.

The receptionist in a large degree is mediator between profit and loss. To those of us who are not making money enough, who economically are doing a fair business, but still are not laying aside anything for the future, I would say, "Raise our prices." We may say that we cannot get more, and I will answer, "If such is the case, our work is not worth more." We must make our work worth the advance before we can ask it. When we have achieved this the receptionist must be equal to every occasion; with enthusiasm bring the customer to a realisation of the true value of our product.

The first order from a sitting should be only the commencement of a profitable business with a customer. This is especially true in "child portraiture," where speculative enlargements, water-colours, etc., usually meet with lucrative returns.

I believe it would surprise us to learn what we are losing daily by failing to grasp this opportunity of increasing our business.

We all, no doubt, have moods when we vow we will cut down the number of exposures. Apparently, it would seem that here is an item where economy should be instituted, and yet, after all, if we are judicious, does not a number of proofs in the hands of this ideal receptionist really result in profit rather than loss?

The most natural place to look for loss is in the printing department, and there is no question that in the hands of careless workmen this is true. This being the case, it needs only a passing thought at this time, for we all are aware that if there is a department in the studio that requires thought, care, and skill, it is the printing room. Men who possess the qualities so necessary in the management of this important branch of our business are in demand.

"Economy of time." The ability of making our heads save our heels is a virtue we should all strive to possess, for by this means we will find great profit in saving throughout all the branches of our work.

The men who are ambitious for success are not looking the market over for cheap, inferior goods, but rather are searching for the best that money can procure. It does not always mean addition in profits to purchase an article because of its discount. It does, however, amount to a great deal if every legitimate discount is taken advantage of, and herein lies permanency of business success.

We are engaged in a business we should feel proud of, and by careful study along these business lines not only reap personally a financial standing in the community to which we belong, but assist in maintaining its advanced position in the business world.

ALVA C. TOWNSEND.

GOLFERS AND THE CINEMATOGRAPH.

(From the "Times.")

If the cinematograph ever comes to be sold at such a price as to be within the reach of the comparatively humble, there will doubtless be a great demand for it among the more theoretic of golfers, since one of the great difficulties in the curing of golfing diseases is the patient's inability to see himself as others see him. A looking-glass is better than nothing, but the player has to perform unnatural movements which rob his experiment of any great value. He has, in the first place, to stop at the top of his swing to look at himself, and in order to do that he must take his eye completely off the ball and almost inevitably move his head. Then, too, he can only observe himself at the top and at the end of his swing; he cannot stop his swing either half-way up or half-way down to see how its component parts are getting on; or at least he cannot do so with the faintest hope of reproducing his natural attitude. For these reasons a private cinematograph would not only be an engrossing toy but a useful adjunct to study for the golfing theorist. At the same time, while he would derive from it enormous pleasure, he would also suffer one bitter though salutary disappointment.

CHANGES OF "STYLE."

Nearly everyone has been heard to say at one time or another that he is "changing his style," and there are many who have, in their own imaginations, almost as many "styles" as there are days in the week. Yet, if we go out to play with one of these protean golfers, it is most probable that, even although he has explained to us the far-reaching nature of his latest reformation, we shall be utterly unable to detect the very slightest difference. The ball may fly better or worse than usual, but his characteristic appearance in striking it will seem to our unseeing eyes wholly unchanged. The curious part of it is that, though we laugh in our sleeve at the enthusiast's self-deception, we should be quite indignant if it was suggested that there was a similar beam in our own eye. It is the hardest thing in the world for the golfer to realise that he has a style of his own which to the eyes of others is definite and unchanging. It is the same difficulty which besets each one of us in realising that he has a characteristic walk or voice. When the average golfer makes that which he deems to be some improvement in his "style," he cannot but believe that he appears to his most familiar friends as a new and gloriously transformed creature, whereas those friends are, in fact, talking to each other of poor old So-and-So's extraordinary style, which they would know a mile away.

INDIVIDUAL FAULTS.

The cinematograph would show him to his face that which his friends are careful to say only behind his back. He would see that, in his hours of brightest triumph or blackest despair, there is practically no difference to be seen in that which is usually termed "style," except in the one essential of club and ball meeting at the right or wrong time. There would be, no doubt, a horrid shock of disappointment at first, but, if he were a wise man, he would thenceforward cease to agitate himself about his style, and confine his theories simply to his hitting method.

At the same time a minute investigation of "biographic" views of ourselves in the art of striking would, no doubt, reveal differences of method, not style, on different days, and would teach us another valuable lesson—namely, that our faults are less numerous and more persistent than we imagine. The golfer in his very early stages may miss the ball in a particular way from a great variety of causes, but the more mature player has nearly always one or two stereotyped vices into which he periodically relapses. Those who play with him often know these vices quite well; they will say to each other that So-and-So would be quite a good driver if it were not for that fatal habit of jumping in the middle of his swing. The man himself has a more or less hazy idea as to this besetting jump, but he does not properly appreciate it; he feels such an entirely different player in his different moods that he cannot believe that it is, in fact, the same old crime which is responsible for each new breakdown. A comparison of several different records of the cinematograph would let in upon his mind a flood of light. On seeing the presentment of his misfortunes unroll itself with sufficient slowness before him he would suddenly say to himself, "I am looking exactly like I did when I had that horrible fit of topping a year ago last Easter. I

cured that by keeping my head still; let me see if that will do any good this time." After this had happened several times he would begin dimly to understand that his one particular wickedness was the moving of his head, although it might disguise itself under a number of apparently different sensations. Thus, when things began to go wrong he would, instead of groping helplessly for a remedy, be able to attack the old trouble at once with an overwhelming balance of probability that it was also the new one.

Mr. Low has recorded that Mr. Tait, when putting badly, never asked what he was doing wrong, but merely whether he was moving his body, or not taking his club back straight. In the same way most golfers could reduce their sins to their lowest terms, to the great simplification of their cure, if only they could visualise exactly what they were doing. This lack of the power of visualising would be remedied by a series of moving pictures. To be followed round by his own cinematograph, a luxury now only within the reach of millionaires, would be destructive to the golfer's sense of humour, but might be intensely valuable towards the improvement of his game.

Photo-Mechanical Notes.

The Selection of Originals for Illustrated Papers.

On Thursday, November 18, at the L.C.C. School of Photo-Engraving, Mr. Arthur Johnson, the Art Editor of the "Tatler," delivered an address on the above subject, full of good practical points, and all of them copiously illustrated with actual examples.

He stated that the first thing to consider was the journal the work was to appear in. If it were a newspaper printed on a rotary press, such as a daily newspaper, something bolder, with interest concentrated on a central subject, should be offered, rather than the delicate picture full of detail with attractive background that could be accepted by the carefully printed high-class weekly. He said the sort of print preferred was a glossy bromide, but not too glossy, and the negative should be "pin-sharp," as there was certain to be some loss on reproduction. He showed how a flat picture was often much improved by reduction in size, and a contrasted picture improved by enlargement. Dealing with wash drawings, he said that generally the most successful were those made of pure wash alone, though many practised artists could use body colour successfully. Line work should be open, and all lines black on good white ground. Charcoal and chalk was frequently used now, sometimes reproduced as a line block, sometimes very effectively with half-tone screen. Slides were shown of various kinds of work, also many originals, together with their reproductions, which fully bore out the lecturer's remarks.

Duplex Half-tones.

We have recently seen in a little pamphlet, issued as an advertisement by a portrait photographer, some very good blocks in so far as richness of colour and relief were concerned, but the effect was somewhat marred by the pattern caused by the superposition of the two blocks. Why did not the block-maker use a Metzograph screen to make the negative for the tint plate? There would have been just as rich an effect, just as much relief, and no pattern at all to disturb the appreciation of the skilful block-making and printing, and, let us hope, portraiture.

Reproducing Faint Pencil Drawings.

A faint pencil drawing is one of the most troublesome pieces of work to reproduce by any process, by reason of the difficulty of securing a negative which will give a print showing all the detail of the drawing, and at the same time free from unevenness. The most practical way is to give a minimum of exposure, and develop only so as to obtain a negative that will give a print on a gaslight paper, and then work from this. Or a transparency can be made on a process plate and the screen negative made from this, if the reproduction is to be in half-tone. The contrast will probably be much exaggerated in this way, but it is only possible to secure the detail by exaggerating the contrast if printing is done in black ink; but if the printing is done in a grey ink instead of black, then a facsimile effect can be obtained. Some very useful reproduc-

ns of silverpoints, which are even more delicate than pencil drawings, have been made in the manner described above.

The Paynetype Process,

Mr. Arthur Payne has presented the set of stages of his process exhibited at the Royal Photographic Society's Exhibition to the Society, and he has presented the block of the first portrait from the direct on metal (from which we recently printed in these columns), and also an example of his line etching with copper deposited resist the L.C.C. School of Photo-Engraving.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—
PROCESS WORK.—No. 22,776. Process of making pictures. Saalburg.

Exhibitions.

LAND AND BROMOIL PRINTS AT THE SINCLAIR GALLERY.

The prints sent in to the recent competition organised by Messrs. James A. Sinclair and Co., Limited, are now being shown at this artist's establishment, 54, Haymarket, London, S.W., where they will remain on view until Wednesday next, December 8. They may be seen daily from 10 a.m. to 4 p.m., or until 1 p.m. on Saturday, admission being free. The collection runs to 84 prints, about equally divided between the oil and bromoil processes, and in every instance accompanied with the Sinclair permanent inks. With one exception all prints are all in monochrome, the only example (No. 22) in which multi-colour inking has been resorted to being that by John Tucker. "After the Shower, Bruges." We cannot say that this print shows any advance in the technique of multi-colour oil, the application of colour, in our judgment, altogether lacking congruity apart from the addition and degradation which, in the hands of most workers, appears to be inevitable to the multi-colour oil process where the artist is at a full scale of tones. In a number of instances there would seem to have been comparatively little attempt made at obtaining striking effects—that is to say, of using to the full the power which the oil process places in the worker's hands—and we must confess that these prints strike us as among the most pleasing and satisfying on the walls. An example of this reserve type of work is "Landscape" (No. 53), by R. C. Chapman, but other instances could be pointed

As examples of another kind of reserve—the refusal to pile on ink—we may mention one or two quite delightful prints all in light tones. These are "Betsy" (No. 16), by C. David Kay, and "The Shell Gatherers" (No. 28), by R. Lincoln Cocks. A criticism which has been levelled against both the oil and bromoil processes is that while it secures enormous advantages for the worker regarding control, it puts him at something of a disadvantage in the rendering of textures. In many of the prints to be seen at 54, Haymarket, this criticism may quite well be sustained. A few prints may be singled out to disprove it; for example, the flesh tints in "Ariana" (No. 3), by Bertram Park, are remarkably good, but among the prints as a whole we do not find such good rendering of texture as we should get, say, in an exhibition composed of carbon and platinotype prints. Perhaps the subjects in which the oil process shows itself supreme are those in which strong effects of light are still further heightened by the pigmenting brush. A very good example of this, though not of much pictorial interest otherwise, is "A Sunlit Court" (No. 32), by James C. Nunn. Another almost equally good, though perhaps lacking a little of the welcome warmth of No. 32, is "Sunlight" (No. 38), by C. David Kay. The former is by the oil and the latter by the bromoil process.

EDINBURGH MEMBERS' EXHIBITION.

On Saturday, following the precedent of last year, the members of the Edinburgh Photographic Society had an exhibition of their work in the Club Room, Castle Street, when 143 entries were forwarded. Landscape and seascape was the strongest class, the medalled pictures being all seascapes, two of the medals going to a Western member, who also gained the only two awarded in portraiture. Seascape and Seascape.—Medals: A. G. Watson (2), J. G. Angus, and W. J. Hansell; hon. men.: A. G. Watson and Mrs. Watt.

Portraiture, etc.—A. G. Watson (2); hon. men.: T. Drummond and Shiels. Architecture.—D. Lumgair; hon. men.: W. G. Collin. Subjects in Motion.—Medal: C. D. Paton; hon. men.: A. W. McGregor. Colour Photography.—Hon. men.: W. Mitchell. Lantern Slides.—Hon. men.: D. G. Christian, J. A. Angus, and R. A. Malcolm. The judges were Messrs. A. Eddington, R. S. Webster, and J. C. H. Balmain. The absence of the newer printing processes was remarked on.

THE NEW ENGLISH ART CLUB.

This club has felt the levelling effect that time has upon all movements of a revolutionary nature. Starting originally as a band of rabid secessionists, it is now a company of workers doing things but little different from all the rest, and its exhibitions are merely two more a year added to the struggling many with no longer anything out of the way to recommend them. The present show, which is held at the Galleries of the Royal British Artists, is famous for a fine Sargent, "Mrs. Wedgwood" (55), a colour and texture harmony of black silk and silvery-brown fur, out of which the warm-toned flesh tints of the elderly lady beam with much richness of effect. Henry Tonks displays more than usual exaggeration of colour-perception in his study of conflicting lights—outdoor and indoor—entitled "The Baby's Bath" (17), and exhibiting a very posey mother and nurse. It is pleasant to turn to the highly romantic and truly felt landscapes of C. J. Homes, who, by enthusiastically observing and honestly depicting certain effects of storm or light amongst crags and mountains, creates arresting pictures that make a direct appeal to imaginative minds. A. Carruthers Gould is also a good observer, as the cold light of the brilliant sunshine in his "Hawkcombe Valley" (28) clearly shows. William Orpen is represented here by outdoor figure studies, of which his gypsies, bear, and caravan, "In the Dublin Mountains" (34), is the most characteristic. Geo. Lambert's "Portrait Group," where the heads of father, mother and child are arranged at equal distances along a diagonal line, does not show an engaging composition. In fact, composition of traditional kind is not much respected by the New Englishers; the only obvious attempt at it is in Nelson Dawson's "Brigantine" (94), although Alfred Streeton displays highly successful picture-making in his fine "Corfe Castle" (81), in which sun and shadow are employed to the best advantage. The water-colours of Alfred W. Rich dwarf all the others, as usual.

FORTHCOMING EXHIBITIONS.

- December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.
December 15 to 16.—Cowes Camera Club. Entries close December 6. Sec., E. E. Vincent, 4, High Street, Cowes, I.W.
December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.
1910.
January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.
April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

THE HALIFAX PHOTOGRAPHIC Co. advise us that the London depot for their goods is The Tella Co., 68, High Holborn, London, W.C.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—To meet the requirements of its less advanced workers, quite a number of whom have recently joined the ranks of the above society, a course of elementary instruction has been arranged. This includes twenty-four lectures, covering a wide range of subjects, which will be held on Friday evenings, in addition to the usual meetings of the society, which are held on Wednesdays. South London photographers desirous of joining a society of this kind may be glad to know that at the Borough Polytechnic, for the moderate fee of 5s. per annum, they would have at their disposal the use of two fully equipped dark rooms and an enlarging room, in which latter the lantern has recently been brought up to date and fitted with an 11-inch condenser and "Cooke" lens. Full details as to the work of the society may be obtained on application to the hon. secretary, Mr. Alfred G. Buckham, 105, Borough Road, S.E.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for the following patents have been received from November 15 to 20:—

ANIMATED PICTURES.—No. 26,423. Improvements in or connected with the manufacture of ribbons for the production of living or moving pictures. Sherard Osborn Cowper-Coles, 82, Victoria Street, Westminster, London.

BINDING DEVICE.—No. 26,455. Improvements in and relating to binding devices particularly applicable to lantern-slides, passe-partouts, and the like. Harold Waring Atkinson and Ernest Cuthbert Atkinson, 1, Queen Victoria Street, London.

CAMERAS.—No. 26,501. Improvements in or relating to photographic cameras. Auguste Vautier-Dufour, 111, Hatton Garden, London.

COLOUR PHOTOGRAPHY.—No. 26,911. Device for production of three-colour reticules for colour photography. Robert Krayn, 33, Cannon Street, London.

VIEW FINDERS.—No. 27,002. Improvements in photographic view finders. Otto Halbach, 53, Chancery Lane, London.

FILM-PACKS.—No. 27,024. Improvements in film-packs. Johann Georg Schneider, 6, Lord Street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR SCREEN-PLATES.—No. 3,601, 1909 (February 13, 1909). The invention consists in a process of preparing a three-colour screen-plate from a line screen. A plate is sensitised with bichromate, printed under the line screen, and dyed in a mixture of two dyes, one of which attaches to the exposed and the other to the unexposed parts of the gelatine. The excess dye is washed out, the plate re-sensitised with bichromate, and again printed from the line screen, this time at an angle, being finally washed and dyed.

The second stage in the process may also be carried out in such a manner that one of the two dye-stuffs applied in the first step is washed out (after the second exposure to light) from the elements of unaltered gelatine and then the third dye-stuff is fixed only to elements of unaltered gelatine. The process (No. 1) is as follows:—A glass plate, or flat film, is coated with a thin layer of gelatine, sensitised with potassium bichromate. The plate thus prepared is exposed to light under a black-white screen of about 20 lines per millimeter, all of the same width, obtaining thus a set of lines in the gelatine alternately attacked and not attacked by the action of light, after which the excess of the bichromate is washed out. The plate is then immersed in a dyeing solution containing a red and a blue dye-stuff and prepared by mixing equal volumes of a one per cent. solution of Ponceau BO and a one per cent. solution of brilliant azurine, so that the gelatine altered by light fixes only the red colour, whereas the blue colour dyes only the unaltered gelatine. The respective parts of the gelatine being sufficiently coloured the excess of the colouring matters is eliminated by washing with water, a two-colour screen being thus obtained.

This screen is converted into a three-colour screen in the following way:—The plate is sensitised for a second time by bichromate and then exposed to light under the same black-white screen, but so that the lines cross the lines of the first exposure at a suitable angle, such as for instance 45 degrees, whereupon the plate is washed to remove the excess of the bichromate. By this operation the blue lines obtained by the dyeing of the unaltered gelatine in the first step are divided into two series of small quadrangular elements, the one series consisting of altered gelatine and the other of unaltered gelatine.

The excess of bichromate is then washed out by a short treatment with water without essentially altering the intensity of the colours. The plate is then immersed in a solution of a yellow dye-

stuff, for instance into a one per cent. solution of flavazine. In this solution only those quadrangular blue elements which consist of unaltered gelatine fix the yellow colour and become green. The excess of the yellow dye-stuff being removed by washing with water there is produced the three-colour screen showing symmetrically arranged blue and green quadrangular elements between the red lines and not having any spaces between the coloured elements.

One of the characteristics of the second stage in the process is that after the second exposure to light the third dye is applied to the small quadrangular elements consisting of unaltered gelatine without eliminating a part of one of the two dye-stuffs applied in the first step. But this second stage may be carried out in a somewhat varied form in that one of the two dye-stuffs first applied is washed out of the unaltered gelatine after the second exposure to light so that the third dye-stuff is only fixed to these elements of unaltered gelatine. The process is then as follows:—

After having exposed to light the bichromated gelatine under the black-white screen and having washed out the excess of the bichromate as above prescribed, the plate is dyed in a solution containing a red and a green dye-stuff and made by mixing 10 parts of a one per cent. solution of crystal Ponceau and 20 parts of a one per cent. solution of naphthol-green. The plate being immersed in this solution during about 2 to 3 hours, the lines altered by the action of light assume a red colour, whereas the lines of unaltered gelatine have a green colour; the excess of the dyes is now washed out.

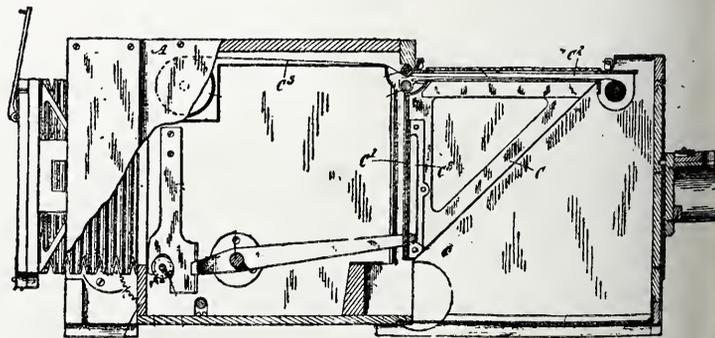

The plate is then brought into a solution of potassium bichromate, whereby the unaltered green lines are chromated; after drying, the plate is exposed to light for a second time under the black-white screen turned through a suitable angle. Now the plate thus prepared is immersed in a bath consisting of 90 parts by volume of water and 10 parts of alcohol, and is allowed to remain therein for about 10 to 15 minutes, the excess of bichromate being removed thereby and the green dye-stuff also being washed out from the small quadrangular elements not altered by the action of light.

Now the plate is dyed in a blue solution containing one per cent. of brilliant azurine. When the respective quadrangular elements have fixed sufficient quantities of the green dye-stuff the plate is washed with water, dried, and then ready for use; thus there is obtained a three-colour screen, showing red, green, and blue elements. Carl Späth, 41, Rheinstrasse, Steglitz, Berlin.

FULL-SIZE FOCUSING CAMERA.—No. 23,415, 1908 (November 3, 1908).

The invention is of a type of camera in which the light-sensitive surface and the focussing screen are carried in a triangular frame and at right angles to one another so that when the focussing screen is in a position transverse to the optical axis of the lens the light-sensitive surface will be parallel thereto and vice versa. The triangular frame is so arranged that it can be swung to bring either a light-sensitive surface or the focussing screen into the required position.

According to this invention there is employed in a camera wherein the focussing screen when in use is transverse to the optical axis of the photographic lens, a device which, while the operator continues to view the picture directly on the screen and

from the side thereof remote from the lens, can by one movement thereof instantaneously and automatically

(a) Swing a shutter and sensitised surface into the line of that optical axis, and swing the focussing screen out of the way.

(b) Operate the shutter.

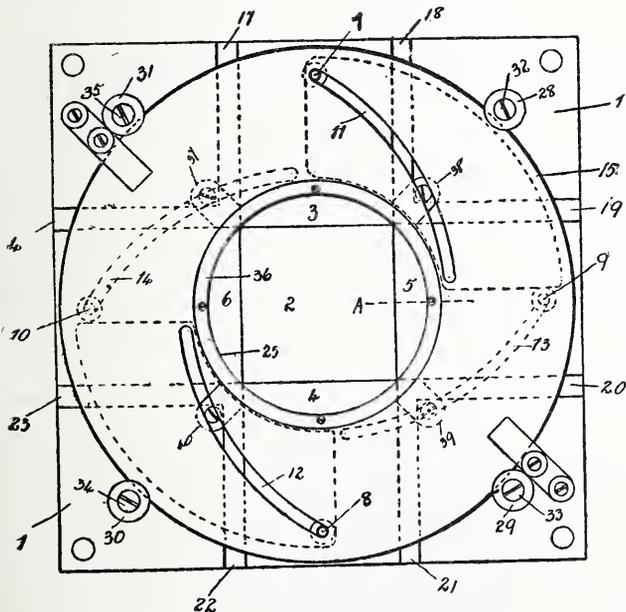

One construction of camera comprises in combination a focussing screen and a carrier for the light-sensitive surface arranged so that

the object is focussed on to the screen, the latter being automatically removed and the carrier brought into the focus of the lens immediately before exposure is made. This interchanging of positions of the focussing screen and the carrier is practically instantaneous so that the object is visible on the screen by the observer up to the moment at which exposure is made.

A shutter is provided which is automatically released after the carrier has arrived in its position in the focus of the lens. The figure shows the camera in the position ready for exposure, the image being viewed (through the bend on the left) in the vertical focussing screen fixed at C1 to the right-angled frame C. On actuating the release the frame C is turned back so that the plate and film at C² is brought into the vertical plane previously occupied by C¹, this latter returning into the horizontal position C³. The focal plane shutter comes into action and exposes the plate. John Appleton, 132, Gwendolen Road, Leicester, and Taylor, Taylor, and Hobson, Limited, Stoughton Street Works, Leicester.

DIAPHRAGM SHUTTER.—No. 27,433, 1908 (December 17, 1908). The invention consists of a diaphragmatic shutter with a rectangular aperture in which the leaves which open or close the aperture work in pairs and each pair independently of the other pair. The object of the invention is to obtain rapidity of the opening and shutting of the leaves of a square aperture shutter. The independent movement of the leaves can be obtained by pins which engage in spiral slots cut in the operating discs, thereby changing the rotating motion of the discs into reciprocating motion of the leaves. The path of motion of each pair of leaves is thus restricted by suitable guides in such a manner that two paths intersect each other at right angles in the centre of the apparatus. The guides also are so constructed as to determine the height of the leaves, one pair in front of the other in order that their surfaces may be covered by any desirable material.

The base may be made of a square plate of metal having a

rectangular hole the same size as, or larger than, the full opening of the shutter. Upon this base may be mounted the guides for the leaves and also the bearing for the operating discs, this latter bearing consisting of a metal ring having two circular steps turned on its outer circumference, the lower step being slightly larger in diameter than the top one, and carrying the lower operating disc, while the top circular step carries the top operating disc, the two discs being separated by either a single washer working on the lower circular step and between the discs, or by a number of washers mounted upon bearing pins arranged around the periphery of the operating discs. The operating discs must move independently of each other, but this movement may be obtained by any desired means. Siemens Brothers and Co., Limited, Caxton House, Tothill Street, Westminster, London, and Harold William Frank Ireland, 79, Church Lane, Old Charlton, Kent.

CINEMATOGRAPH FILM RESIDUES.—No. 14,407, 1909 (June 19, 1909). This invention refers to a process for recovering the material of

the support of the cinematographic films. It consists in depriving used, unsold or other films as well as waste pieces, of their gelatine for the purpose of recovering:—1. The metallic silver of the pictures. 2. The material forming the support without occasioning any alteration of the said material. For this purpose preparations containing soluble ferments (pepsin, trypsin, papain, or the like) or living ferments (liquefying bacteria and the like) are used. When using soluble ferments, the preparations will be obtained either by the direct solution of the ferments or by macerating vegetable or animal parts, or by macerating several different parts some of which may contain strengthening diastases. The materials to be treated will be submitted to the action of the liquids obtained during the time necessary for hydrating, digesting, or liquefying the gelatine; this time will vary according to the products employed, the concentration of the liquids and the temperature.

For the sake of example, the materials to be treated, films, clippings, perforated edges and the like, are plunged into a diluted solution of commercial trypsin, heated to a temperature of about 105 deg. F.; in this case the solution will be effected very rapidly. The solution terminated, the material of the support (in the form of bands, or waste pieces of all kinds) will be washed for the purpose of removing all kinds of impurities and the metallic silver (or in the form of a salt) will be carefully collected. Henry Danzer, 5, rue Richepanse, Paris.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

Simple Brush Treatment for Modification of Bromide Prints.

Mr. Robert Thomson, in "The Amateur Photographer and Photographic News" for November 30, gives the following suggestions for modifying and controlling prints on bromide paper. "A print or enlargement is made in the usual way, and developed up to the required density. The developer is then rinsed thoroughly out of the paper (which is not fixed), and it is ready for modification. Drain the water well off the print, expose the whole of the picture to the full glare of a gaslight burner or any actinic light—say, for the space of fifteen seconds. The exact time, within reasonable limits, need not matter, so long as sufficient exposure has been given to darken it on the application of the developer. This operation should, of course, take place in orange light.

"Take a camel-hair brush, dip it into your developer, and apply it carefully to whatever part you wish subdued, and as each part attains the density required, wash the developer off under the running tap and again apply your charged brush to any other part you wish to darken still further. Lights can thus be stopped out or shadows strengthened. Should the developer be inclined to spread at the edges, care should be taken to hold the picture in such a manner that it will recede from the part you wish left as it is. Glycerine mixed with the developer will also prevent spreading.

"Should a definite line be required, the part of the print can be surface-dried with blotting paper, and the glycerine developer applied in whatever direction required. Cloud effects can be indicated in an otherwise blank sky, and as each worker gets used to the method and improves his brush action with practice, improvements will suggest themselves to suit the individual. After modification is completed, the print is fixed and dried in the usual manner."

New Books.

"Camera Work." No. 28. New York: Alfred Stieglitz.

"With this number 'Camera Work' closes its seventh year. Whether the magazine has remained true to its original ideals and standards must be decided by its readers." These sentences are part of an editorial note at the end of the book. For ourselves, we have no hesitation in saying that "Camera Work" has shown no sign of falling away from its original ideals, and its latest number is, in some ways, its most interesting. It continues those incursions into the domain of painting and poetry which are not the less welcome from the fact that they are extraneous and unimplied in the title. The journal's aims are very high, and its efforts ambitious. What other photographic journal can boast of original parables and sonnets such as we have here from Eugenia Wallace and Leonard van Nappen respectively? True, the first is a little elusive, and the second wickedly spiteful to the great dead, who, after all, have made us what we are; but these "fill-ups" sound a cultured note, at all events. The excellent literature, both sprightly and earnest, contributed by Chas H. Caffin, is at all times the mainstay of the text of "Camera Work." This time his lengthy article upon the Dresden Exhibition is not only entertaining, but absolutely true in its dispassionate review of the present position of photography. His next phrase, the "flip-flops of personal expression" (applied to un-straight methods) ought to become a classic. He recognises, as most people have by now, that the German "professionals" have taken the foremost rank upon the strength of their striving for the best artistic results through technical honesty and conscientious craftsmanship, exhibiting "the characteristically German traits of superior comprehension and thoroughness."

Benjamin De Casseres contributes a vituperation upon the Art "puffer"—by which he indicates the American Art critic—and describes as an eviscerated and castrated descendant (of a less objectionable type now passed away), "Sir Puff, who kills by his silence and immortalises the Vogue and fattens the dugs of the cow that he milks." Fortunately the land which produces this monster also produces "Camera Work," with its photogravures, its parables, and its sonnets. The illustrations in the present part number six first-rate reproductions by J. Craig Annan of D. O. Hill's works, with which goes a biographical note by Mrs. William Sharp. These pictures bear out exactly the contentions of Mr. Caffin, for they are charming *because* they are honestly photographic, not *in spite* of the fact. They show no flip-flops of personal expression. They are realistic in their roundness and fulness. The other plates by modern workers miss something of this convincing naïveté, though they pass muster easily before the standard that modern work has set. George Davison's "Houses Near Aix-les-Bains" has beautiful quality, and Paul B. Haviland's "Miss G. G." is exactly what modern photography has developed as an ideal—an arbitrary lowering and flattening of flesh tones with demonstrative high-lights upon parts of the costume. Such work, however, is, to that of D. O. Hill, what the poetry of Burns is to a latter-day minor poet's "pre-ciosities."

"The 'Wellcome' Exposure Record and Diary, 1910." London: Burroughs, Wellcome, and Co.

The issue for next year of this most convenient photographic pocket-book contains, as before, a vast amount of practical photographic information, which—like Messrs. Burroughs, Wellcome's pure chemicals—is in "tabloid" form. For the past year or two the "Wellcome" diary has shown itself almost incapable of further improvement, but each year the producers manage to supply the photographer with some additional matter which is of direct practical usefulness. This year a supplementary card is included which gives the various ("Rytol") developers necessary when obtaining warm tones on practically every one of the standard lantern-plates. In each case the description of tone obtained is indicated, together with the increase of the exposure over that required for black tones. A most useful card for lantern-slide makers, and issued ready for hanging in the dark-room. In other respects the features of the diary, particularly the exposure calculator, call for a repetition of the commendations we have extended to it in previous years. The

table of comparative plate speeds has been revised up to date, and, as before, is arranged for the use of those wishing to give full exposure, as well as for those who, when having to give a rapid exposure, wish to cut down the time as far as possible. The formulæ for developing, toning, and other solutions prepared with the convenient "tabloid" chemicals are again most clearly and specifically set out, and the mass of other photographic information which the photographer finds it useful to have in his pocket is to be found in the slim volume. The diary is issued in three separate editions, for the northern and southern hemispheres and for the United States, that for European countries being bound in light green, for southern latitudes and the tropics in dark green, and for the United States in red. The diary is now on sale throughout this country, price 1s.

"TRAVEL AND EXPLORATION" (Witherby and Co., 1s.).—Exploration, pure and simple, does not take quite so prominent a place as usual in the December number of "Travel and Exploration" (edited by Mr. Eustace Reynolds-Ball). Room had to be found for reviews of unusually important travel books, such as Sir Ernest Shackleton's "Heart of the Antarctic," Lady Stanley's life of Sir H. M. Stanley, Claude White's "Sikkim," etc. However, we may claim that quality amply compensates for quantity; and Mrs. Bullock Workman's well-written description of her record ascents in the Himalayas is well worthy of the place of honour. Another article, mainly of sporting interest, is one by Captain Dudley Haskard, who gives an account of his experiences of lion-shooting in Somaliland. Mr. P. R. Salmon's graphic description of a tour off the beaten track in Syria, is chiefly noteworthy on account of the singularly good illustrations from his photographs. Dr. Scott Keltie's well-known name prepares us for a very entertaining and instructive article, entitled "Travellers' Tales." Some very diverting experiences, garnered from the professional travels of the well-known guide-book writer, Mr. A. R. Hope Moncrieff, are given in "A Traveller in Travel."

New Materials, &c.

LILYWHITE GREETING POSTCARDS.—The Halifax Photographic Company send us a circular of these sensitive postcards for the Christmas season, issued with the P.O.P. gaslight, bromide, and self-toning emulsions.

"NOCTONA" CHRISTMAS POSTCARDS.—In issuing postcards bearing their new "Noctona" emulsion, Messrs. Griffin, in place of the customary inscription or design on the front of the card, have adopted the somewhat novel and simple plan of issuing a design-mask, which is placed between the negative and the postcard when printing, and, without any registration or any other precaution, imprints upon the

card an ornamental Christmas greeting. The effect obtained is indicated in the illustration. Complete with this mask a packet of 18 "Noctona" postcards costs 1s., the cards being issued in all three grades—pearl-matt, satin, and glossy.

JOHNSON'S PHOTO TINTS.—A most attractive and uncommon window card has just been issued by Messrs. Johnson and Sons,

Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, C., as a means of drawing the attention of a dealer's customers to the very convenient box of nine "photo-tints" supplied for the mounting of postcards, gelatine prints, and lantern slides. The subject of the window bill—a little Dutch boy standing by a canal—picturesque in character, and, delicately coloured as it is with the Johnson tints, forms quite a distinctive piece of advertising literature, which can hardly fail in its object of riveting notice on the maker's products.

CATALOGUES AND TRADE NOTICES.

PLATE-COATING, ETC., MACHINERY.—The well-known firm of K. Oebig, Radebeul, Dresden, sends us its English list of machinery for plate and paper coating, printing plant, film-coating machines, and other installations for the manufacture of photographic materials. Messrs. Koebig have a long experience as constructors, and their list gives a full specification of the various types of plant for the most modern factory equipment.

SECOND-HAND APPARATUS.—Messrs. Sands, Hunter, and Co., who for thirty-six years have made the sale and exchange of high-class photographic apparatus the staple of their business, send us their current 64-page list, conveniently arranged as to (1) class of camera, and (2) size of apparatus. The list thus allows of one's requirements being looked up most readily, and our readers, both at home and abroad, may depend on receiving apparatus in thorough working order. The list is sent free on application to 37, Bedford Street, Strand, W.C.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 30, Mr. John Spiller in the chair. A lecture was given by Mr. S. E. Tench on "Glimpses of Scenery in Ceylon and Burmah," the lantern slide illustrations of which were of a remarkably fine character, forming a valuable addition to the lecturer's remarks.

Commercial & Legal Intelligence.

PENNY PHOTOGRAPHY AND HAIRDRESSING.—In the Clerkenwell County Court last week, before Judge Bray, an action was brought by James McCombie, tailor, 470 and 472, Holloway Road, Islington, against A. Lippavini, photographer, of 42, Tottenham Court Road, W.C., for £70, as damages for an alleged nuisance and breach of agreement.

Mr. Eldridge, counsel for plaintiff, said his client had a lease of the premises, 470 and 472, Holloway Road. The premises were two houses which adjoined each other. The ground floors were used as shops, and the two upper floors, approached by a common entrance and common staircase, were let out. The first floor on one side was let to defendant, and that on the other side was let to a hairdresser, named Osterman. In the covenant was a clause that Osterman should have quiet enjoyment of his occupancy. It was on October 2 last that the first floor on the other side was let to defendant, who entered into a covenant that he would not do anything which would become a nuisance or annoyance to the landlord or his other tenants. Defendant carried on the business of a photographer, and in November Mr. Osterman complained to plaintiff of the way the photography business was being carried on. Plaintiff cautioned defendant, but the nuisance still continued, as the result of the way in which defendant carried on his business. On his handbills defendant announced to the public, "Your photo. taken for a penny. single or group."

The result of taking penny photographs, continued counsel, was that numbers of people, children and young men and women, congregated round the place, and blocked up the staircase. They would sit on the stairs, eating their food, or they would be playing about. The result was that Mr. Osterman's customers had a difficulty in getting to his saloon. Sometimes the boys and girls would open the door of his saloon and call out, "Come and have a shave" or "Get your hair cut." The result of the nuisance was that Mr. Osterman's business practically disappeared, and he sued plaintiff for £115 damages.

Plaintiff gave evidence in support of his case. In cross-examination, he said that before defendant took his premises they were let to a photographer. He had no complaint whatever about that tenant.

Evidence was given by plaintiff's manager at 470, Holloway Road.

He said the photographer who preceded defendant carried on a rather high-class business. Regarding defendant's business, witness used to see a number of people coming there. They were poor-class people. Sometimes he had to turn the gas off at night, because defendant's customers would gather in front of plaintiff's window and block it up in order to look at their photographs.

Mr. Valetta (counsel for defendant): Did you think that people would drive up in motor-cars to have penny photographs taken?—No, but I did not think they would come in egg boxes on wheels, as some did.

Mr. Osterman, in evidence, said the defendant's customers ran up and down stairs shouting and laughing. That caused witness great annoyance. Sometimes the boys and girls coming to defendant's place would come up the stairs in batches of nearly a dozen. They were laughing and shouting, and would sometimes call out, "Get your hair cut." His customers complained. Once he saw some of defendant's customers eating fried fish and potatoes on the stairs.

Replying to counsel, witness said it was because of the difficulty they found in getting to his shop, through people being on the stairs, that his customers stayed away.

Mr. Valetta: You knew that this staircase was only three feet wide when you took these premises?—Yes.

Does not your complaint really come to this: that Mr. Lipparini became a very successful cheap photographer?—He had a great number of customers.

Supposing they had come to your place for a shave before being photographed—would you then object?—They could not afford to pay 2d. for shaving and 4d. for haircutting before going to be photographed. Then there were a lot of girls who went to be photographed. You don't shave girls.

The Judge: Did Mr. Osterman open his shop on Sundays?

Mr. Eldridge: No. But Sunday was a very busy day for defendant, and the consequence of so many people coming on Sundays was that they had to call in the week for their photographs.

Defendant, in evidence, said the business he carried on was that of penny photographs, sixpenny cabinets, and trade enlargements. Before he took the premises a representative from plaintiff called upon him at his place in Tottenham Court Road, so he could have seen the class of business carried on.

Mr. Valetta: What sort of people are your customers?—They are a poor class of people, but they are all right.

When Mr. Osterman complained, added defendant, he engaged a porter and made his light stronger. Sunday was his busiest day. People called for their photographs during the week.

Replying to Mr. Eldridge, defendant said that one Sunday he took 560 midgets and two cabinets, on another Sunday 576 midgets, and on another Sunday 654. In one week, including Sunday, the total was 1,025. The total of 654 midgets would not represent that number of customers, because many would have six, eight, or a dozen photographs. The customers would come downstairs quietly unless the barber insulted them.

Do you say there was no noise?—I don't call it noise.

Defendant's manageress said that Mr. Osterman was often rough towards the customers.

Mr. Eldridge: Why should he be rough towards them?—Because the customers would stop at the top of the stairs to look at their photos. When he was rough, the customers would give him a nasty answer.

To get a correct number of people who called, said another witness, the total number of photographs should be divided by three.

Joseph Plant, defendant's porter, said he had trouble with the barber owing to the way he went on at people as they were leaving the studio.

In cross-examination by Mr. Eldridge, witness said that once he had to "accommodate" one or two of the boys who came there.

What did you accommodate them with—a stick?—No, with my hand.

Mr. Valetta: During the five months you were there you had only to roughly handle two youths?—That is so.

Two customers, in evidence, said the barber abused them on the landing.

At the close his Honour said he would reserve judgment.

"DUM" PHOTOGRAPHS.—At the Leicester Police Court last week it was mentioned that a "dum" photograph is one which does not

exist save only in the vocabulary of its creator. The word was used in the private note-book of a photographer named William James, charged with stealing, at South Croxton, on October 11, 1s. 9d., 1s. 6d., and 7d., belonging respectively to John William Hales, Fred Sreaton, and Harry Wollaston.

Detective-Inspector Taylor said on October 11 prisoner went to South Croxton with a camera, and canvassed several houses. He showed samples of photographs and told people he could supply them at 1s. 9d. per dozen. Mr. Hales consented to have his photograph taken, with his house and two dogs, and he paid 1s. 9d. to prisoner, who said he would deliver the photographs personally the next week. Five weeks went by, and Mr. Hales had heard no more of the matter. He then wrote to the address given by prisoner, and the letter was returned through the Dead Letter Office. The next morning he received four photographs, but not such as he ordered.

The same day prisoner went to Mrs. Sreaton, and photographed her child, for which he received 1s. 6d. Five or six weeks afterwards she received two inferior photographs. A similar procedure was followed in the case of Mr. Wollaston, who ordered half a dozen photographs of himself, his mother, and his shop, and received two of the village street.

Mr. Hewitt: A sort of comprehensive photograph.

The recipients, added the witness, were all dissatisfied with the photographs delivered, which were not the same subjects as ordered. Mr. Hales complained to Superintendent Bowley, and a warrant for prisoner's arrest was issued. In company with Sergeant Freer Detective-Inspector Taylor went to the house of prisoner's father, in Wolverton Road, and told prisoner of the complaints that had been received. He said he had completed the orders and sent them off. The two police officers went through about fifteen hundred negatives but failed to find any resembling those supposed to have been taken at South Croxton. On the counterfoil of the receipt given to Mr. Hales, which was found in the house, was the word "dum." When questioned about this, prisoner said it referred to the number ordered but he afterwards admitted that it meant the photographs had not been taken.

Complaints had been received from all over the county and from other counties, Detective-Inspector Taylor added, respecting similar frauds by prisoner.

On this evidence prisoner was remanded, to enable the police to complete their inquiries, and to get the necessary witnesses.

On Saturday last, November 27, the case again came up, and prisoner was sentenced to six weeks' imprisonment in the second division.

INVENTOR'S BANKRUPTCY.—At Southampton Bankruptcy Court, on November 24, George Simper, 10, West Street, Southampton, the plate worker, whose gross liabilities were put at £601, with assets £170, was publicly examined. He ascribed his failure partly to losses incurred by experiments in connection with a patent rotary washing photographer's machine. He explained that there was a sale for the machine. The examination was closed.

ILFORD, LIMITED.—The report for the year ended October states that after making allowance for depreciation and provision for doubtful debts, the net profit is £33,618 (as compared with £28,810 for the year ending October 31, 1908), which, with the surplus brought forward, gives £37,267. The directors recommend that £12,000 be set aside for writing down goodwill, investments, plant, and for contingencies, and that a dividend of 6 per cent. be paid for the year, leaving £2,467 to be carried forward.

NEW COMPANIES.

THE THAMES COLOUR PLATE, LTD. (registered office, Broad Street, Avenue, E.C.)—This company was registered on November 22, with a capital of £25,000, in £1 shares. Its objects are to acquire a take over as a going concern the business of manufacturers of a dealers in Thames Colour Plates and panchromatic plates, and other photographic plates, films, and accessories, now carried on by O. Dawson and C. L. Finlay, 254A, High Holborn, and 49, Pentonville Road, under the style of The Thames Colour Plate Company; and to enter into an agreement with same. The signatories are O. Dawson and C. L. Finlay, both of 254A, High Holborn, W.C.; J. B. Brooks, 140, Leadenhall Street, E.C.; T. J. Tee, Turnpike Wood Green, Essex; H. W. Gallagher, Silverleigh Road, Thornhill

Heath; H. L. Lomas, 102, Rosebery Square, Rosebery Avenue, E.C.; and H. S. Tee, Ashleigh, Station Road, Loughton, Essex. The first directors are F. H. Glover, F.A.A., Broad Street Avenue, E.C.; Admiral Sir Frederick G. D. Bedford, G.C.B., Swiss Cottage, Weybridge; and O. S. Dawson and C. L. Finlay, both of 254A, High Holborn, W.C.

News and Notes.

AERIAL PHOTOGRAPHY.—According to the daily papers, Captain Sacamney, of the French army, has succeeded in devising a practical system of aerial instantaneous photography for employment in warfare. The plan adopted was to create a double aerial rail by sending up two kites harnessed to each other. When they became poised at an angle of 60 degrees with the horizon he ran up a photographic apparatus with the aid of a pulley, just as one would haul up a flag. In this way some excellent photographs were obtained at an altitude of 200 metres, and it was found possible to determine the positions and works of the enemy at a distance of over four kilometres.

"COUNTRY AND TOWN," one of the latest additions to the list of monthly illustrated magazines, has instituted a photographic competition in which an award—in the form of a silver cup—is offered "for the best set of three photographs of a subject treated in an original manner." These photographs, it is stated, may be of three different (architectural) subjects or of the same subject differently treated, but must have been taken in the United Kingdom. Full conditions of entry, the latest date for which is December 13, will be found, together with the necessary coupon, in every copy of "Country and Town," the offices of which are at 13 and 14, Tothill Street, Westminster, London, S.W. The result of the competition will be announced in the January issue of the same magazine.

WILD SPORT ON THE CINEMATOGRAPH.—The Duke and Duchess of Connaught, accompanied by Princess Patricia, were present on Tuesday last at a private view, given in the Alhambra Theatre, of Mr. Cherry Kearton's cinematograph pictures taken in British East Africa during Mr. Roosevelt's tour. Some excellent still and moving pictures of wild beasts and birds were shown upon the screen. They had been obtained after journeys on foot for hundreds of miles across desert and plain, and in some cases after days of waiting and watching. A lion had been photographed by flashlight near his drinking pool, and there were animated pictures of a young Serval cat skipping about in the jungle, young dikdik, and horned chameleon. Hippopotami and crocodiles were seen at home on the Theka River, and the pictures of bird life included one, taken 8,500ft. above the level, of Jackson's dancing bird. There were several pictures of Mr. Roosevelt's hunting expedition.

THE NEW CAMERA CLUB.—At a meeting held at the Gaiety Restaurant, London, under the chairmanship of the Earl of Crawford, the following resolution was unanimously carried: "That it is desirable that a Camera Club for London should be formed." In proposing this resolution the chairman referred to the success of the old Camera Club. In 1886 it was started in Bedford Street, and continued to flourish there for a number of years. It was only when on removal to other premises in Charing Cross Road an attempt was made by means of a kitchen and dining-room to provide bodily as well as mental pabulum that its financial resources proved unequal to the strain and it had to be wound up in 1904. Since then not only the members of the old club but the increasing number of enthusiastic photographers had greatly felt the need of opportunities for quiet talk, such as photographic societies could not offer. London was the first large town to start a camera club, and now, although very few towns were without one, we had none, and it was thought that the time had come to resuscitate it. (Hear, hear.) Mr. A. Evershed spoke in support, and desired to remove the idea that the proposed new club was to be a "house of call" for a certain body; the organisers had not the slightest wish to confine the membership, and it would be open to all interested in photography. Mr. R. Craigie, who will act as secretary, then outlined the scheme, which

provides for the acquisition of premises in John Street, Adelphi, at a moderate rental. The estimated amount of capital required to fit up and furnish the club was £850, and it was proposed to formulate a small company amongst the members, with a capital of £2,000. Each member would be required to take up at least one ordinary £1 share, and the subscriptions for town, country, and foreign members respectively would be £3 3s., £2 2s., and £1 1s. It was proposed to revive the lectures, which were so popular a feature of the old club. If 375 members could be found the receipts were estimated to cover the expenditure. He had great pleasure in announcing that Lord Crawford had consented to be their first president. After Professor Armstrong, Mr. Ward, Mr. Martin Duncan, and Mr. Lambert had spoken in support, an appeal was made to those present, with the result that it was announced that £670 had been promised, representing 57 members.

PHOTOGRAPHER'S TERRIBLE MISTAKE.—At Portsmouth, on Monday last, the coroner's jury returned a verdict of death from misadventure at an inquest on Mr. Edwin Webb, a local solicitor, who was found dead in the cellar of his house, where he had gone to do some photographic work. Death was stated to be due to a dose of cyanide of potassium, self-administered. The drug was evidently one of the chemicals used for photography, and on the back of a piece of photographic paper found near the body was a note in Mr. Webb's handwriting, addressed to his wife, which read as follows:—"In semi-darkness have made awful mistake. Must have poured cyanide into ale. Only few seconds to live. Cannot call. God help you, my pet! Brain reels. Tell. . . ." Here the writing ended abruptly. The evidence showed that Mr. Webb had a bottle of beer with him, and the medical opinion was that, after taking the poison, he would lose the power of locomotion and be unable to call out, though he would live long enough to be able to write such a note. It was shown that Mr. Webb was of a cheerful temperament, and had no financial or business worry.

Correspondence.

- *• *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- *• *We do not undertake responsibility for the opinions expressed by our correspondents.*

STEREOSCOPIC PORTRAITURE.

To the Editors.

Gentlemen,—At the conclusion of a very interesting letter on the above subject, in your issue of to-day's date, Mr. G. Dyas says:—"I don't see that large work is necessary, as a 5in. picture, 9in. from the eyes, might appear as a 300ft. arena at 100 yards' perspective distance, providing the work is accurately carried out. . . ." etc.

This is, of course, correct, but it may be pointed out that the special advantage of large stereographs is that they give increased scale to the objects represented, and bring them nearer to the observer. With the Pigeon stereoscope, a print 12in. square, for example, can be inspected at practically the same distance from the observer's eyes as the 5in. square old style stereograph. If the subject and the amount included are identical in both cases, it is obvious that the 12in. picture will show the same objects four times as large in diameter, and at apparently only one-quarter the distance of those seen in the 5in. stereogram, with a corresponding gain of detail. The perspective, too, with the longer focus lenses used in taking the larger picture will, for many subjects, and notably for portraiture, be much more pleasing.

Small stereographs can, however, equally well be examined with this stereoscope as large ones, if so desired, provided the left-hand picture is reversed—in fact, there is no reasonable limit to the size or shape of the prints in either direction, beyond those fixed by ordinary convenience.

In addition to these advantages, the Pigeon stereoscope is, without

the slightest adjustment, suited to the eyes of practically every observer.—Yours faithfully,

88, Brook Street, Kennington, S.E.,
November 26, 1909.

A. LOCKETT.

THE TUBE RAILWAY AS A CINEMATOGRAPH.

To the Editors.

Gentlemen,—The paragraph you published in your issue of November 12 quoting from the "Scientific American" a scheme for adorning the walls of the tubes with designs which, when viewed from the train, would appear as moving pictures, illustrates once more the singular coincidence which has so frequently occurred in the history of inventions of two inventors in different parts of the world simultaneously conceiving the same idea. In August last, when I was away on holiday, I had sent on to me from my office a letter, dated August 18, from a business friend, Mr. Louis Delgeur, a well-known photo-engraver in Rotterdam, and I quote from it the following paragraph:—

"I have been thinking of a new kind of advertising, which I would like to submit to your opinion. Here it is. The side walls of the Underground are white, and are illuminated by the light from the carriages. The last 200 yards before each station the train goes somewhat slower. Would it be possible to have painted on the walls a series of silhouette pictures at full length, each in figure a slightly different position, somewhat like a bioscope film? By doing so a

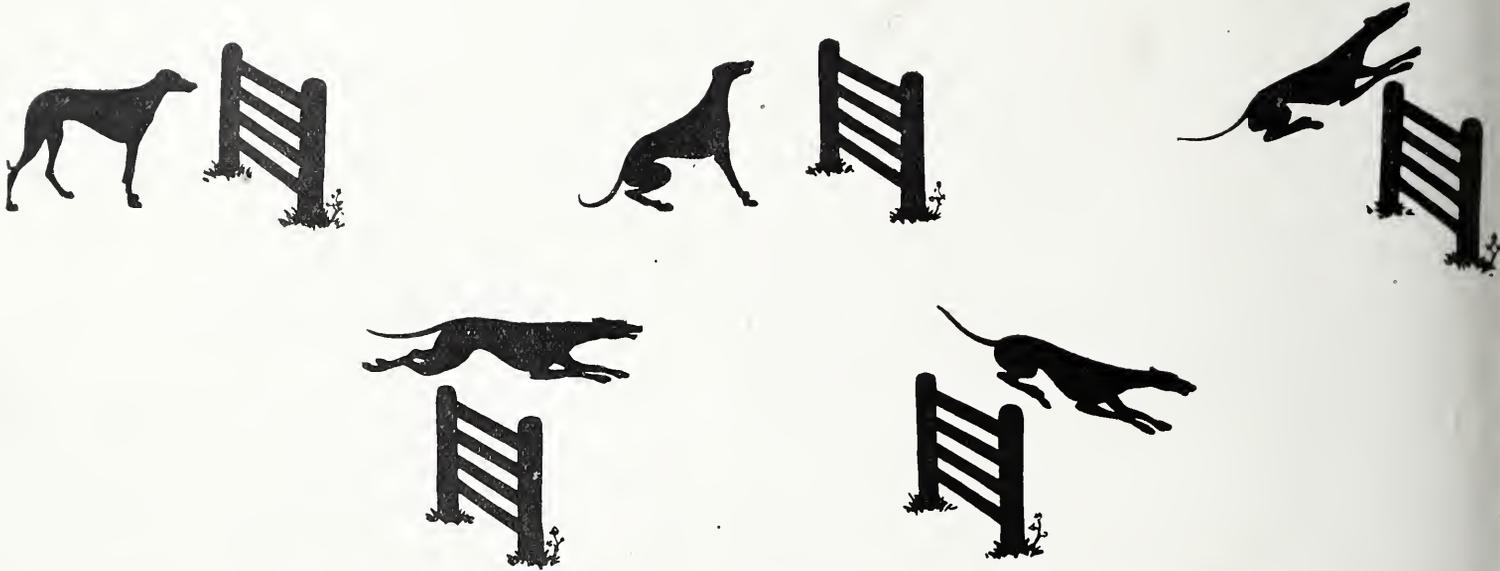

His idea is very complicated. I believe that the tube trains must have lights not only at the inside, but at the outside (the cost of these would be small for a concern which has millions of kilowatts). The pictures must be painted in black and white, with great intervals, not as shown on the print of my unknown brother inventor, and you will see that the pictures become living."

I think it will be admitted that it is a curious coincidence, and the exact similarity of the ideas is remarkable. I send for the perusal of the editor the original letters, and also Mr. Delgeur's drawing suggesting the style of the pictures, which probably it would be interesting to reproduce.

WILLIAM GAMBLE.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

In the band of the above pictures which Mr. Gamble sends us, the space between each phase of the action is greater than here shown: it is about 1½ times the width of each drawing.—EDS. "B.J."

kind of living advertisement would be the result. Thus, it would be just the reverse of the bioscope, where the public rest in their places and the pictures change. You will comprehend my idea from the drawings I send you herewith."

The rest of the letter invited my opinion on the practicability of the idea, and my assistance in getting the idea introduced in the proper quarter. My reply was that I thought the idea a very ingenious one, and if it would work as he anticipated there would be money in it. But my impression was that to operate it successfully it was necessary to view such pictures through a narrow slit, or a series of such slits as in the case of the Praxinoscope, from which the idea must have originated. I could not, however, think of any way in which the scheme could be practically tested.

Since then I have not spoken about the matter to anyone, and, indeed, pressure of work caused the matter to pass entirely out of my mind until I saw the quotation from the "Scientific American." I then wrote to Mr. Delgeur asking if the publication of the idea was due to him, and he replies:—

"Thanks for your interesting letter. I am not the man referred to by the "Scientific American." Only to you I have written about it, and to nobody else. It is very curious that two persons, one in America and one in Holland, have at the same time hit upon the same idea. Now I feel curious to know which of us has the priority.

- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- G. A. Dean, 14, High Street, Rugby, Warwickshire. Two Photographs of John Baird, Esq., C.M.G.
- H. B. Collis, Westgate Studio, Canterbury. Photograph: 12 by 10 Exterior View of Canterbury Cathedral.
- J. H. Anderson and Son, 5, High Street, Welshpool. Two Photographs of Lord Powis's Shooting Party and Ladies (Twenty Figures), including T.R.H. the Prince and Princess of Wales. Taken at Lymore, Montgomery, on November 25, 1909.

LACQUER.—Will you kindly oblige me by giving me a good brass lacquer for covering brass to keep it from tarnishing, the same that the makers of brass work use? I have had two given to me, but they do not do at all.—J. G.

There are many receipts for lacquer, most of which are good in the hands of those who use them. So probably are those you have been given. Do you know the brass should be heated before the lacquer is applied? If it is laid on cold it will not answer. There is, however, a "cold lacquer," sold by most large dealers in

varnishes and polishes that can be applied to the metal without its being heated, and it is the best for novices in the work to employ. It may be had from the Crane Chemical Co., Newhall Hill, Birmingham.

ARTIFICIAL LIGHT.—Being desirous of introducing artificial light into our studio for portraiture, etc., we are communicating with you in the hopes that you may advise us as to the best method of procedure. This being a country place, where there is no system of lighting other than by oil lamps, we are unable to employ the usual methods of gas or electric light. We have thought of two methods, viz., acetylene gas, and the more modern petrolite lamps. Not having a spacious yard in which acetylene generators could be used, we imagine that the smell of carbide on confined premises would probably be objectionable, and also that the using of a large quantity of carbide, necessary to give sufficient candle-power for efficient portrait lighting, would probably be a matter of considerable expense. We have by us a catalogue of petrolite lamps, which, though powerful in themselves, might not be capable of arrangement, as acetylene burners would be.—P. C. AND SON.

We are sorry that we have no experience of petrol lamps. We think you could get a suitable outfit from Messrs. R. J. Moss and Sons, 98 and 99, Snow Hill, Birmingham. The firm's catalogue lists and describes portrait equipments.

PHOTOGRAPHS OF BOXERS.—Will you kindly advise me where to obtain postcards (wholesale) of famous boxers, past and present?—E. SEYMOUR.

Try W. H. Rau, 1,324, Chestnut Street, Philadelphia, U.S.A., for photographs. We do not know of postcards on the market.

NOXURIOUS EFFECTS OF AMIDOL.—I have recently taken to the use of "Amidol" developer for bromides, and the ferricyanide and sulphide method of toning them. I now find that my hands are swelling and becoming very painful, and inflamed places on the fingers somewhat similar to chilblains. As probably this matter has been written about in the "Journal" at some time, possibly you can tell me of some remedy or preventative.—HAYNES WELCH.

The trouble no doubt is due to the amidol. Many persons who use it suffer in the same way. The only preventative is to give up its use and employ another developer, or to prevent the amidol coming into contact with the skin, say, by wearing india-rubber gloves or finger-stalls.

FLASHLIGHT AT SEA.—I wish to take a photograph of hauling a catch of herrings inboard. This must be done at night, and eight to ten miles out at sea, and will, therefore, have to be taken by flashlight. Will you kindly tell me in your next issue how to go about it? I will categorise and number by queries as follows:—

1. What is the best flash powder to get?
2. Can I fire it by a spark from a pocket battery or motor-car accumulator?
3. What is the duration of a flash in fractions of a second?
4. What receptacle could the powder be fired in, and could it be mixed and placed therein before leaving shore, or should we have to mix it when we reached the fishing ground?

In order that you may understand the circumstances I will give you details. The herring "drifters" are boats of about 25 feet in length and 7 feet beam. I propose being in one of them with the camera and photographing a second one when the herrings are being hauled inboard. I should be about 20 to 30 feet away, and should need a flash that would give a good lighting to the boat taken at that distance. It is important that I should be able to fire the flash the moment I am in focus, as the boats are constantly changing position, and I should be out of focus while touch-paper, etc., was burning. I am using a $\frac{1}{2}$ -plate Watson "Argus," and shall set the blind and mirror to "time"; focus in the mirror, and when I have focussed, expose the plate and fire the flash. That is why I am anxious to know about firing electrically. Is there any danger of blowing the side of the boat out, because an accident of that sort, ten miles out at sea, would be unpleasant? I shall be greatly obliged if you will give me any information that occurs to you on the matter.—HERRINGS.

We cannot recollect a more difficult subject for a flashlight photograph having been brought to our notice. We fear that the quantity of powder required will be very great; we should say, two or three ounces per exposure may very likely be insufficient. And the size of the flash in these conditions may be such as to endanger

the sails of the boat you are on. The "Agia," "Scales," or the powders mentioned in the article on page 836 are all reliable. Messrs. Chas. Zimmermann and Co. supply an electrical method of firing. The duration of the flash will not be very short with a heavy charge of powder, say, 1-10 of a second. It is most essential to keep the powder in an air-tight case until the moment of use. Seriously, we see so many difficulties in the way that we should think it would be well to stage-manage a haul by early morning light, from which result it would not be difficult to prepare a print giving the effect of a night-haul.

AMARDOR.—Could you kindly give us information as to where we can purchase some Amardor. It is a kind of felt for working up enlargements in black and white?—N. ENLARGERS.

We are sorry to say we do not know the makers of this material. If the makers or any reader will give us the information we shall be glad to forward it.

J. T.—See the firms mentioned under "Dry Mounting" in the 1910 "B. J." Almanac, p. 1,314.

LIGHT.—(1) We advise you to make a lamp for powder (e.g. Agia) on the lines described in the article on page 836 of the "B.J." for October 29. (2) Apparently you must use incandescent gas, which will serve well for single portraits. The Tress Company supply suitable installations. (3) We should say the introduction by means of a knife and pencil of landscape or indoor backgrounds into negatives taken against a plain ground.

PATENT.—1. So far as we know, it is not patented. (2) £1 for nine months' provisional protection.

BLACK SPOTS ON BROMIDE PRINTS.—Can you give us any explanation of the black specks appearing on this print? We have been troubled with them during the last few months, and cannot make out their nature and origin. Only this particular paper is affected by them, while two other kinds of bromide paper used concurrently with the enclosed show no signs of such metallic (?) deposits. The print we send is not nearly so bad as some others, but we presume that the defect is sufficient to form a reliable judgment of it.—BORUP BROS.

The spots look like dirt of some kind in the emulsion, and we can only suggest that you drop the use of this particular paper.

RAPIDITY OF LENSES.—In your "Answers to Correspondents" of November 26 you state that "the f 5 lens will not be quite as much more rapid than the f 6.8, in comparison with their respective aperture numbers, on account of the many glasses." I have a f 6.8 lens (A), and was intending to get a f 6 lens (B). Would this objection of reflecting surfaces apply to lens B, in comparison with lens A, the former having more components?—HERBERT CLIFFORD.

Possibly it will apply, as there are six surfaces in one lens, as against four in the other, but the difference is not likely to be appreciable in such a case. The biggest differences are to be noted when the surfaces are increased to eight or ten. Your lens A is well known as being extremely rapid for its aperture, and probably no others are quite equal to it in this respect. You will see some notes on this question of rapidity on another page in this issue.

EMMETT'S STONES.—We are sorry we do not know actual makers. We should advise you to try the makers of ebomite or vulcanite, whose names and addresses you can find in a trades' directory.

LENSES.—Could you inform me if the rapidity of lenses would be retarded if kept in a damp room?—J. HITCHING.

The lens will be slower if the glass becomes visibly discoloured or if the surface suffers. Either process will probably take years unless the lens is exposed to quite unreasonable treatment.

WASHING PRINTS.—What do you consider enough washing for prints after a thorough fixing? I give them 20 changes, one by one, fresh water each time. Is this enough?—R. W. BROWN.

Allowing five minutes for each soak, and assuming prints are placed one by one at each change into clean water, we should say the washing is ample.

SPOTTING MEDIUMS.—I use — for blocking out the background of negatives of machinery applied to the film side. It is very satisfactory except the price. Can you tell me if there is a substitute for it which would be cheaper? I should be quite con-

tent to use — on the film side for the actual image, and use the substitute on the glass side from the image to the extreme corners of the plate. If you know of any substitute I shall feel obliged. It must not chip off for many years.—E. E.

We can only refer you to the formulæ for similar preparations in the "Almanac" for 1910, just published, page 748.

TONING BROMIDES.—I should be glad if you could give me the formula for toning glossy bromides to get tone similar to the one enclosed, which I believe to be a toned bromide, and such as are done by the — Company and other similar firms.—TONER.

The usual commercial method is by the hypo-alum process, for which many papers are very suitable. Those of the makers you name are. The formula is given on page 767 of the "Almanac" now published.

POSITIVES ON COPPER.—Will you kindly inform me as to what book (if any) I should be able to get information on how to produce positives on copper direct, as I have had several inquiries for same, and am at sea how to produce them?—CONSTANT READER.

We do not understand what you mean by "positives on copper direct." Do you mean photogravure plates for printing from, or merely positive pictures on the metal, or photo enamels? If you send us an example of what is required, or write fuller particulars, we may possibly help you.

LENS.—Our advice is that you meet your neighbour's competition by competition. The best way of doing that is to produce better and more artistic pictures than he is doing. The public in your district will no doubt appreciate the better work. Unless the man has a private installation the townspeople will know that he has not the electric light, which, of course, discounts his advertisement.

H. LONGNEY.—We find on reference to the catalogues of the four makers of the lenses that three out of the four in your list do not tally with the numbers and series you give, and what they are made to cover by the makers. The exception is that of the portrait aplanat—that is rightly described, and its price is £4 4s. Your best way will be to get the lists of the other makers and see if you can from them identify the lenses you name.

DISPUTED COMMISSION ACCOUNT.—I was canvassing operator on a salary and commission to — and —, and for a time all went well, but owing to them not finishing the work, of course the orders did not come in, and, as a matter of course, no commission. Result, I gave notice and left and accepted another situation, but — and — offered me extra and better terms and made promises, etc., that I gave up my job and went back to them; but after the second week they drifted back to their old ways, and for a second time I left, and even then they wrote me to come back, but, as I refused, they would not pay me any commission that was due, and they refused to give me any statement of business done. They never gave me any statement of business done; they simply gave me a few shillings each week, saying: "That's all the com. this week," and never showed me the books. They used to bring small bits of paper or card with "Com. paid on so and so, week ending, etc.," for me to sign. So I never knew how much work was really done. I know there is a lot of work ordered that I have not been paid on. I was taking out a summons, but was told they are not a registered company. They are a new lot, who paid up the debts and saved the old — and — going through the Court. I don't know how many there are in the company, but there is only one man and one girl who work the business, and he is called managing director. Should I sue him? At the county court they do not know the meaning of — and —, Ltd.—they say it is not "Ltd." Would you give me your valuable advice?—H. MASON.

You were remiss in not having a statement of the business that was got through you when signing a receipt for the commission. However, you can sue in the county court for anything that you know is due, and possibly obtain, through it, a sight of the books. The firm was turned into a limited liability company about a year ago, and was registered as such.

STUDIO QUERY.—I should be much obliged if you would let me know if the proposed alteration to studio (as per enclosed sketch) would be satisfactory? Studio is 28ft. long, with north-east light. Do

you advise a three-quarter span roof for one so narrow, also what length should top and side lights be?—MORE LIGHT WANTED.

The alteration indicated in the sketch will certainly give you much more light, and the design seems good, but the glass need not be continued quite up to the ridge. Eighteen inches or two feet from it will be sufficient. Six feet opaque at either end top and side will be good; then the sitter can be placed at either end as occasion may require.

STUDIO LIGHT.—(1) Will you please advise as to whether my light is sufficient and correct in my studio which I have roughly drawn overleaf? Position is north light. It is lean-to, 18ft. long and 8ft. wide. (2) Will you also kindly say where I can buy the metal-bodied rubber stamps to title negatives?—GOLD LEAF.

(1) The studio is very small if it is required for professional portraiture. The sketch, however, shows that the arrangement of the light is fairly good. But if the glass can be extended at the side about 3ft. it would be an improvement. (2) Messrs. Richford, Snow Hill, London, E.C.

WORKSHOPS AND FACTORY ACTS.—Can you kindly inform me if I come under the Workshop and Factory Act? My business is portrait and landscape photography, postcard publishing, and photographic dealer. The business is conducted by my sister and myself without any outside help. Factory inspectors called, and on my explanation that the business was conducted by my sister and myself, and that she took the same interest in its conduct and well-being as myself, coming in and out when and as she pleased, and receiving remuneration which was satisfactory to her, I considered they had nothing to do with me. With this explanation they were satisfied, but lately a new inspector has come to the district—a man who feels the importance of his position keenly—and he says unless I expose a copy of the Act on my walls and render certain other returns he will take me before the court. I feel that this is "bounce" on his part, and although he has the law on his side, the law, when administered by a civil servant whose mind can only run in a very narrow groove, is really a misapplication of justice, and his action is contrary to the spirit of the act in which all right-minded people recognise a protection for the dissatisfied or overworked. My business and my treatment of my family generally is open to the light of day, and I am too well known here to fear the result of any outside criticism either in my social or business relations with the public generally.—A. M.

The Act certainly applies to photographers, but it, when framed, was not intended to apply to such a case as yours. Still it is the law. If you are summoned, and the facts be as stated, the penalty, if any, will be quite a nominal one. However, it may save you trouble if you comply with the inspector's requirements, which, after all, are but trifling.

WILSON.—If you find that the passing trains cause such a vibration that you cannot get sharp negatives in the studio you have no remedy. You came to the railway, and should have considered the effect that the passing trains would have. If the railway came to you after you had been established for a long time the case might possibly be different.

SUMMARY.

The Southport Photographic Society deserves every congratulation on its really great exhibition, which we review on page 953.

Mr. G. T. Harris, in a letter on page 961, refers to a formula in the "B.J. Almanac" as "the best and most convenient ever published for a pyro-soda developer.

A number of practical points in making screen-plate colour transparencies were brought out by Mr. Essenhigh Corke in a paper before the R.P.S. on Tuesday evening last. (P. 959.)

A lecturer on press photography at the Bolt Court School last week thought that a capable man ought eventually to command £1,000 a year. (P. 952.)

Mr. L. C. Leon, in a short article on page 949, gives the different multiplying factors for use when exposing orthochromatic plates through a series of light-filters prepared with the Hoechst K dye. (P. 949.)

A patent has been taken out for a solid preparation of vanadium suitable for the making of a green toning-bath for bromide and aslight prints. (P. 946.)

Those who may not yet have discerned any profit for themselves in the General Election may possibly do so from the article on page 947.

A lens attachment for producing one continuous panoramic negative from a series of exposures figures amongst "Patents of the Week." (P. 955.)

A German process for photo-engraving direct on metal in the camera, which strongly resembles Paynetype, is said to have been worked out. (P. 953.)

Dr. Hauberrisser has recently given formulæ for tank development with edinol. (P. 948.)

We deprecate two recent suggestions, one for using acid for setting black tones on self-toning paper and another for employing so an acid bath for sepia tones on development papers. (P. 946.)

A rocking table for the dark-room worked by weight of water has been recently described. (P. 950.)

German medical authorities are now making observations and records of the heart-beat by means of X-rays. (P. 945.)

Some recent formulæ for making a plain sensitised paper of sufficient rapidity for enlarging purposes are given on page 950.

A number of the considerations which need to be borne in mind in stereoscopic portraiture are mentioned in an article on page 947.

EX CATHEDRA.

Advertisements by Picture Post-Card.

The picture post-card has for some time been used by hotels and a few commercial houses as a means of gaining publicity through customers who write upon them to their friends. But it has remained for a Yankee real estate dealer to use a regular post-card to exploit his business. According to "System," which mentions the incident, he secured the colour-plates of a number of post-cards showing attractive views along the Hudson, where his property was located. He printed several thousand copies, hired girls to write in ink apparently informal and personal letters on the backs, dilating upon the beauties of the place and signed with an uncompromising initial and mailed them to a select list of names. The postcard had every appearance of a genuine souvenir card from a friend on a vacation, and was presumably read with more than passing interest by each of the puzzled recipients.

Prints in Indigo.

In the course of a recent paper before the German Chemical Society, a Munich chemist named Kalb has described a process in which the sensitiveness of a new compound of indigo is employed to make prints for ordinary photographic negatives. The author first prepares de-hydro-indigo bisulphite from de-hydro-indigo and bisulphite solution, and from this compound (which is a well crystallised salt of canary yellow colour and intensely sweet taste), obtains the tetra-brom derivative by addition of bromine followed by neutralisation with sodium bicarbonate. These result needle-shaped crystals of the tetra-brom sodium salt, which after purification dissolve readily in water. The solution of this very sensitive substance is applied to fabrics as a bath or to paper with a brush, and, after drying, exposure made to sunlight behind a negative. The dye is thus formed in the light-affected parts, and an image thus obtained in tetra-brom-indigo. The chlorine compound may also be used in the same way for the fixation of the prints, and a bath of plain water is used to remove the soluble sensitizer, which consists of the bisulphite compound of the dye.

Viewing the Heart-beat by X-Rays.

There is practically no limit to the usefulness of photography in its application to modern science. Not only has it been associated in some way or other with several of the most important discoveries of recent years, but it has been the sole means of making a few of these possible. Mention need only be made of the photographs made by means of the Röntgen rays and the epoch-making effect this has had in the science of medicine and surgery. What was pronounced the impossible has now

become so common as to be passed without any more notice being paid to it than if it were one of the most commonplace affairs of life. Not only has the camera done much to alleviate human suffering, it has also added very considerably to the scope of our knowledge of the human body and the different organs, and the service it has thus rendered to the human race cannot easily be estimated. To-day every medical institute and every up-to-date hospital has a thoroughly equipped photographic department, and the importance of this establishment yearly increases as new inventions continue to add to the facilities for obtaining truthful records and of obtaining reliable records. The latest addition made to nearly all the most important physical laboratories on the Continent is an ingenious contrivance for making photographic records of the beating of the human heart, virtually throwing light on that most sacred of all organs. This can be done without so much as troubling the patient to take off his clothes. He is merely ushered into a room into which no light of any kind is permitted to enter, asked to sit down on an ordinary chair facing a huge glass bulb. Presently the globe begins to hiss and splutter, electric sparks crackle in it, giving off a peculiar pale greenish light. A plate coated with barium-platinum is held at some distance from the patient near to the region of the heart. On it a well-defined image of the heart is distinctly visible, the various parts being seen so distinctly that the movements of the muscles as the blood rushes through and the valves open and close may be studied in all its minuteness, without the patient feeling the slightest shock or being in any way conscious of what is taking place.

* * *

Photographic Records of the Heart-beat.

Unfortunately photography has not yet made sufficient progress in all branches to keep astride with science. Chemists have not yet been able to prepare a sufficiently sensitive emulsion to record the movements of the heart, thus seen on the prepared plate or screen, and as repeated attempts to make cinematograph film records have only proved so many failures, science has been compelled to resort to other means. What is termed an electrocardiogram is made instead, after the following manner: On either side of the patient of whose heart the chart is to be made, two large jars containing pure water are placed. Into each of these is led the end of an electrically charged copper wire. Attached to this in the centre of the copper wire, midway between the two vessels, is an extremely thin platinum needle. As this needle rests within a highly charged magnetic field the reader can readily understand that it must begin to move immediately contact is made with the copper wire to which it is attached. All that is necessary to accomplish this is for the patient to place his bared arms into the water vessels. Immediately he does so the contact circuit of electricity is complete; the human body being a conductor of electricity causes the needle to begin to move. Experience has proved that the action of the needle follows exactly the action of the muscles of the heart in the performance of their functions. The needle moves from left to right at varied speeds and different intervals, according to the rapidity and the strength of the heart-beat; irregularities in the action or movement of the needle indicate irregularities of the heart's action. A weak heart beat produces a short stroke, a strong beat the reverse, while variations are recorded between. Photographic records of these movements are made by placing a sensitised film under the needle, moved by clockwork from left to right at a registered speed. Immediately over the needle an electric lamp is attached in such a manner that the shadow thrown by the moving needle on the revolving

film gives a clear image on development. The result is a black zig-zag line, for all the world resembling the "her-ringboning" stitching of our grandmothers. By means of these charts doctors have already been able to study more scientifically the heart and its action, and to treat with greater exactness affections of the heart which have never been very clearly understood.

Sulphur Toning of Development Papers.

A subject cognate to the above is touched upon in an American journal, where it is suggested to tone gaslight prints by transferring them direct from a strong hypo bath into weak sulphuric acid. Of course, the result of this is to deposit sulphur in the print, and must lead to yellowing of the high lights. True, the hypo bath contains a little sulphite $\frac{1}{4}$ oz. in 20 oz.; but this is a trifling proportion to the hypo, of which there are 8 oz. to the pint. While we can understand that this procedure leads to active toning, we cannot think that anyone will find it of any practical use. And, in fact, it would almost seem that the writer, Mr. D. H. Cross, does not rely on the method, for he proceeds to give a formula for obtaining sepia tones by direct development which we reproduce, as it looks worthy of a trial:

Eikonogen	20 grs.
Hypo cryst.	20 grs.
Hydroquinone	70 grs.
Soda sulphite anhydrous	240 grs.
Soda carbonate anhydrous	240 grs.
Ammonium bromide	30 drops.
Water	20 ozs.

* * *

Black Tones on Self-toning Papers.

The suggestion is made by a writer in a German contemporary to use a 5 per cent. bath of hydrochloric acid as a means of securing a cold black tone in the subsequent hypo fixing bath, customarily used for self-toning papers. The paper is strongly over-printed, given first a short immersion in distilled water, then placed for ten minutes in the 5 per cent. hydrochloric acid and, after a thorough washing, fixed for ten minutes in 10 per cent. hypo. It is difficult to see why this process should facilitate the production of a black tone actually due to gold, whereas there is every reason to think that traces of acid left in the paper are actually the cause of a species of sulphur toning taking place which would give a result of the kind described. The author declares that prints made by this process have so far withstood a year's keeping but despite that fact we would express the opinion that the safe and proper course of treating self-toning papers where permanency is a consideration, is to preserve—no acidity—but alkalinity of the paper throughout its treatment. A small quantity of carbonate of soda secures this condition in the fixing bath, or bicarbonate of soda may be used to prevent actual development of acidity from the paper. Other things being equal, we should give preference to a self-toning paper which would best give its results in these alkaline solutions.

* * *

A Solid Vanadium Green Toner.

According to the particulars which the "Chemiker Zeitung" gives of a recent German patent (No. 215,071, of January 16, 1909), granted to the Chemisch Fabrik auf Aktien (vorm E. Schering), a dry vanadium compound suitable for marketing in tablet or cartridge form is prepared by adding anhydrous oxalic acid to syrup of vanadium chloride. A solid mass is formed which keeps well and dissolves in water readily. This compound in conjunction with ferric oxalate, oxalic acid, and potassium

ferricyanide, forms a solution which gives fine green tones on gaslight and bromide papers. It is stated that 1.35 gm. of oxalic acid is used for 500 gms. of the liquid vanadium chloride, though the strength or specific gravity of this latter solution is not mentioned. On addition of the oxalic acid the mixture becomes a dry mass with evolution of hydrochloric acid gas. A suitable toning mixture is prepared by dissolving in 1,000 ccs. of water, 3.8 gms. of the dry vanadium compound, 1.5 gms. oxalic acid (anhydrous), 1 gm. ferric oxalate, and 1 gm. potass. ferricyanide.

STEREOSCOPIC PORTRAITURE AND THE DIXIO STEREOSCOPE.

MESSRS. A. LOCKETT AND GILBERT DYAS have recently drawn attention to the advantages of stereoscopic portraiture in our pages, but while we thoroughly agree with them in wishing that more work of this description were produced, yet we cannot at all agree with some of the assumptions that they individually make. One point raised has been the question of large *versus* small pictures. This involves another matter, which has apparently been overlooked both by Mr. Lockett and the French writer from whom he quotes. If large pictures are used and we employ either the Dixio or the Wheatstone stereoscope for viewing purposes, then we are limited in our choice of lenses because our viewing distance is limited. In the case of the Dixio stereoscope, the viewing distance is limited by the height of the centre partition, which is generally about ten inches. The photographs must, therefore, be taken with lenses of about ten inches focal length, otherwise we may obtain distorted and false relief. Probably the lens most suited to the Dixio stereoscope is one of about nine inches focal length, and this is not long enough for pictures much over half-plate in size. If 12 or 14-inch lenses are to be used, the centre partition of the stereoscope should be lengthened, and then only those whose vision is adaptable to that distance will be able to use the apparatus, unless they employ spectacles. Similar conditions apply to the Wheatstone stereoscope, but as in this the viewing distance is adjustable it is more readily adaptable to varying conditions.

In regard to this use of large pictures, a caution is necessary with respect to lens separation. With the ordinary stereoscope we cannot adopt a very wide separation for a near object, because it becomes impossible to mount the pictures. With a moderately wide separation we can mount if we trim the pictures down sufficiently, but then we may get other troubles in the form of either an apparent reduction in size of the object, or confusion and ghost effects. When an extra wide separation is possible it is often inadvisable, and for precisely similar reasons it is often inadvisable even when the Dixio stereoscope is used and mounting difficulties disappear. We must here object to the suggestion that in portrait stereographs a plain background should be avoided. It is even suggested that if there is no pattern on the background to give an effect of parallax between sitter and background there will be no relief visible. This is quite a mistake. The form and modelling of the sitter are fully apparent in the result without any help from the background, and this is all that is wanted in the stereoscopic portrait pure and simple. In some of the best work that we have seen in this line the background is absolutely plain, while no accessories are visible at all. If accessories and visible backgrounds are used they become far more prominent than in an ordinary single photograph, and the sitter is reduced to a mere item in a "view." The introduction of these extras does not render the relief truer, but tends to make it more obvious and more intrusive than it is in

nature. By far the truest effect of portraiture is ensured when we eschew all accessories of any kind and concentrate attention on the sitter alone. The Dixio stereoscope is a very valuable introduction, and surprise has been felt that it has not become more popular. This may, we think, be explained very easily. Many have failed to get a good effect with it simply because they have used it wrongly. The instrument must be held so that the mirror is on the *left* side of the centre partition. It does not matter which picture is on the right or left: a change simply reverses the rights and lefts of the subject, but does not affect the stereoscopic relief. If, however, the mirror is on the right of the partition, nothing but pseudoscopic effect is obtainable, and no shifting of the pictures will cure it. This point has not been so clearly explained by the inventor of the instrument as it might have been, and, as a consequence, probably nine people out of every ten who have tried the apparatus have held it the wrong way up, with very disappointing results. If they had only tried it the other way round they would have been perfectly satisfied at the start.

The reason why pseudoscopy results when the mirror is on the right-hand side is not quite clear at a glance, but there are several other features of this instrument that deserve mention. For example, if the left-hand picture is kept still while the right-hand one is moved in or out horizontally, the image most obviously contracts or expands. If the right-hand picture is kept still while the left is moved, exactly reverse effects take place. Moving the right-hand picture outwards or the left inwards is equivalent to increasing the mounting separation of an ordinary stereoscopic pair, while a reverse movement is equivalent to a reduction of the separation. The former change increases the apparent scale and often introduces distortion, while the latter change corrects distortion and produces the small scale model effect. Such an adjustment is, of course, not very conveniently made, and instead of relying on it to compensate for a wide lens separation, it is best to use a normal lens separation and then keep the two pictures equidistant from the stereoscope partition. By doing this we can avoid both distortion and reduction of scale.

PHOTOGRAPHERS AND THE ELECTION.

THE present political contest, which has perhaps been precipitated upon the country more suddenly than is often the case, has nevertheless found many photographers prepared to take advantage of it, although, like its predecessor of 1905, it comes inconveniently at a time of year when business in other directions is more plentiful than usual. However, the kind of trade which flows from a Parliamentary election is one which photographers who have been at pains to cultivate it can usually work without in any way dislocating their customary arrangements. Probably the present programme of both parties will be more fully aided by pictorial matter than has ever been the case before. In the form both of post-cards and posters, the portraits of candidates will be very largely distributed, and there are already signs that advantage is taken of the better class processes, colotype, or two-colour, or even three-colour printing, to produce the result which will be kept by those to whom it is offered. In fact, a Parliamentary candidate may have reason to fear that the very lavishness of the literature of his party which is scattered through a constituency may innocently bring him within the scope of the Corrupt Practices Act.

Of this business, and particularly that portion of it which takes the form of small advertising stationery, the photographer ought to obtain a reasonable share. In many cases he is well equipped for producing at quite

short notice considerable editions of actual photographic post-cards, but even if he is not, there are plenty of trade firms who can do the work for him; whilst still greater rapidity is obtained by those who turn out a machine-printed edition either in half-tone or collotype. In many instances the photographer will have the best and latest portrait of the candidate, so that his copyright should ensure his being easily in the position of obtaining a proportion of the business. Reproductions of candidates' portraits in the local and London press will be a further, though small, source of profit, whilst there may be also some sale for enlarged portraits of rival candidates. It has been estimated that the amount of money spent through an election in reproduction fees alone amounts to about £2,500, and though one or two of the large firms may be relied upon to have copyright negatives of many of the candidates, yet the opportunity offers for the photographer in the leading town of a constituency to turn portraits of his own taking to good advantage.

As regards the issue of post-cards, a caution may be uttered. These are saleable only during the heat of an election struggle, and will certainly amount to so much

waste-paper the minute the poll has been declared, so that as regards production—whatever the photographer's personal predilection may be as regards politics—a conservative policy in this case is more likely to be the wise one. One further note may be made, and one which is a re-echo of letters addressed to us by readers at the time of previous elections, and that is the grist which may come to the photographer's mill by contracting for illuminated displays in his town of events and scenes of the election, in addition to statements of the results as they are declared in different parts of the country. In many cases the photographer's outfit includes a good projection lantern, and as most local papers of enterprise now make a feature of bringing results pictorially before the townsfolk, there is the opportunity for the photographer to "take care of the job" from first to last, himself supplying the lantern slides of portraits, in addition to preparing the election results by the very simple method of writing the names and figures with a stylus on the plates, now sold by most of the large houses, coated with a soft coloured varnish so that the lettering is produced in bright white lines on a dark coloured ground.

EDINOL AS A TANK DEVELOPER.

[In the following article, which we translate from the current issue of the "Wiener Mitteilungen," the author claims to discover special virtues in edinol as a developer of under-exposed plates. Incidentally he comments upon the preservation of pyro and similar staining developers when used in a tank which protects the developer during use from exposure to the air.—EDS. "B.J."]

Or late development tanks in which the plates occupy a very large proportion of the space, and thus largely exclude air from the apparatus, have come into general use. This has led to certain peculiarities being noticed, an account of which would seem to be desirable. The experiments which follow have been made with a tank known as the "Foco,"¹ which holds six plates, and is provided with a water-tight lid, so that a very small proportion of air is present in the apparatus. In the course of numerous experiments I have found that the advantages of a tank of this type claimed by the makers are quite borne out in practice, and the results are frequently quite remarkable. A series of pyro cartridges are used with the tank. Whilst the pyro developer after a few moments' use in a dish forms a brownish mixture, the same developer runs out of the tank at the end of an hour's development almost as clear as water. In the case of comparative experiments with other developers the results were still more striking. Using edinol in the form of the concentrated single solution diluted with 10 to 12½ parts of water, all details were brought out in the well-known manner, and in comparison with the use of pyro as the developer, the exposure could be cut down to at least half. I therefore compared plates developed with edinol with those which had been treated in the tank. Plates exposed for an equal time and developed with edinol in a dish gave exactly the same negatives, so that the superiority of edinol compared with pyro is noticeable only when both are used in the open dish. This result can only be explained by the fact that the oxygen of the air rapidly weakens the pyro developer, and that the resulting products more or less restrain the developing solution. It was with the idea of using the edinol developer in the tank in order to bring out still more details in the negative than is possible when using edinol in a dish that further experiments were made.

It was found best not to employ the ordinary formula for the

edinol developer diluted with a corresponding quantity of water in the tank, since dichroic fog is readily produced. If, however, the proportion of sodium sulphite is reduced, the tank-developed negatives are of fine clear quality. The first successful results were obtained with the following developer:—

Edinol	1 gm.	9 grs.
Soda sulphite, cryst.....	2 gms.	18 grs.
Potass carbonate	10 gms.	90 grs.
Water	1,000 ccs.	20 ozs.

Comparative experiments with pyro developer in the tank and edinol 1 part concentrated solution diluted with 10 parts of water in the dish gave three quite similar negatives. As I have ascertained by comparative experiments that only the concentrated edinol solution, which contains caustic alkali, gives results which are about the same as the ordinary rapid developers, I attempted to prepare a special edinol developer made up with caustic alkali for use in the tank, and obtained good results with the following formula:—

Edinol	1 gm.	9 grs.
Soda sulphite, cryst.....	2 gms.	18 grs.
Caustic potash	5 gms.	45 grs.
Water	1,000 ccs.	20 ozs.

Three exposures were made under similar conditions, each given about one-quarter the requisite time; one was developed with pyro in the tank, the second with 1 : 10 edinol in a dish, and the third with the foregoing caustic potash formula in the tank. Whilst the first two exposures gave negatives strongly under-exposed, the third was vigorous, and could scarcely be described as under-exposed. Apart from the density of the negative, the detail in the shadows was distinctly better than in the others, and the formula would appear to be an excellent means of treating under-timed exposures in the tank. The complete exclusion of air is readily attained by removing the two stoppers of the tank, pouring the developer until the solution almost fills the tank to the outlet, and then again inserting the stoppers.

(¹) Apparently the tank is one upon the English market under another name, but the construction in which six or twelve plates are placed in very narrow grooves in a rack, which again fits tightly into the tank, applies to many of the development tanks which have been issued of late by British houses.—EDS. "B. J."

A similar and almost better result was obtained with the edinol developing salts MH , dissolving 50 gms. of A powder and 75 gms. of M in 3,000 ccs. of water. This mixture, which is made up by the Bayer Co., originally for the Kodak film-developing machine, on being used for a plate which had received from one-third to one-quarter the correct exposure, gave a perfect

negative in half an hour's development,² whilst, using pyro in the same way, a strongly under-exposed negative was obtained. A further advantage of the edinol preparation is that it can be used several times in succession. **GEORG HAUBERRISSEK.**

(²) The author says, in what is an obvious misprint, half a second.

A COMPARISON OF EXPOSURES ON ORTHOCHROMATIC PLATES SCREENED WITH YELLOW K.

It has often occurred to the writer how very misleading is the statement: "An (x) times screen" or "filter." It obviously means that the correct exposure for a plate behind that screen is to be multiplied by this factor to give the correct exposure with the screen; and many filters are placed on the market with a factor attached. In some cases these filters do increase the exposure by the factor, as stated, but in many others they are far from correct, as practically all the orthochromatic plates on the market are checked in a different manner by the same filter. It is with the intention of simplifying this trouble, so that those who have neither the time nor the inclination to experiment for themselves may be able to judge of the variations which arise in the use of commercial leading makes of orthochromatic plates.

During the last few months the dye known as "Rapid Filter Yellow," or "Filter Yellow K," has made great strides in the favour of both screen experts and photographers for the making of yellow filters, both on account of the slight increase in exposure necessitated by its use, and of the amount of correction obtained. Also because it is one of the very few dyes which, while holding back the violet and blue rays, absorbs the ultra-violet, thus enabling one to obtain with a weak screen and a very slightly increased exposure a colour-rendering equal to some of the older screens needing three and four times as long as the normal exposure to obtain the same correction. This in the case of an exposure running into hours (as in the case of some oil paintings) is a very great boon to the professional man.

In the table given below the screens used were made from white patent plate glass, coated with the stained gelatine, two glasses being coated and cemented together with Canada balsam.

The depth of the screens chosen are the same as recommended by the Farbwerke vorm Meister Lucius and Brüning, in their leaflet issued with the dye, and reprinted in October 1 (page 79) issue of the "B.J." "Colour Photography" Supplement, with the addition of the screen, 1-32 being half the strength of the screen they number 1-16, and the one called 2 being double the strength of their 1.

The exposures were made on a chart representing the principal colours in the spectrum, and five exposures were made, each double the other (as 2, 4, 8, 16, 32), with each plate behind each filter. All the plates were exposed in a constant light, and developed in a tank with the same strength of solution and temperature and for the same time.

Besides numbering the screens in the way that makers recommend, it is much better to mark them with the exact proportion of dye per 100 square centimetres of filter; thus the 1 screen contains .023 and the weakest one .00103 of dye for every 100 square centimetres of glass.

Thus a filter 4 cm. x 4 cm. contains in the (1) screen $.023 \times 100 \div 16 = .00368$ grains.

In the writer's opinion, this is the simplest and best way of marking the filters, as otherwise the strength or depth is only to be determined by experiment.

The amount of correction given by the 1-16 screen (.00206 per cent.) is very decided, particularly in the case of plates bathed with pinacyanol and pinachrome; and this screen is a most useful one when one desires to do away with haze, as in most distant views and for telephoto work, where, as in the latter case, the exposure is desired to be curtailed as much as possible.

One should in no case consider a plate as inferior to another simply on account of the fact that it requires a considerably higher factor compared to another with the same screen, as it may have other features, such as latitude and fine grain, etc., which outweigh its shortcomings in the former respect.

As regards colour-correction, the lower the factor is for a given plate the higher or more perfect this correction seems to be, we find that a plate requiring four times normal exposure behind, say, the $\frac{1}{8}$ screen is better corrected than one requiring eight times its normal exposure.

There is no doubt that the home-bathed plate is most satisfactory, and renders the reds and greens perfectly (if the right dye has been chosen), with a minimum increase of exposure, more so than any ordinary (by ordinary, I mean where the dye is mixed with the emulsion) orthochromatic plate on the market (plates bathed by the maker excepted); nevertheless, the rendering given by most of the commercial orthochromatic plates is very perfect, and, with a suitable screen, will satisfy the requirements of all but very special subjects.

With regard to the correction obtained with the different plates behind the different screens, the writer would prefer to make no comment; but the two deepest screens might well be dispensed with for all but very special work, as there is little difference between the correction of the $\frac{1}{2}$ screen and the 2—in fact, in some cases over-correction had set in.

MULTIPLYING FACTORS WITH FILTER-YELLOW K AND VARIOUS COMMERCIAL PLATES.

Without Filter.	1-32 or .00103 p.c.	1-16 or .00206 p.c.	1-8 or .00412 p.c.	1-4 or .00825 p.c.	1-2 or .0165 p.c.	1 or .023 p.c.	2 or .046 p.c.
3	5	8	10	15	20	25	30
4	8	12	16	18	20	25	30
4	6	8	10	12	15	20	25
4	8	12	18	24	30	36	44
4	6	8	10	15	20	25	30
4	10	15	20	30	40	50	60
6	8	12	16	20	24	28	32

In each case the most rapid orthochromatic plate made by the maker was chosen.

Wherever possible, it is better to use the screen $\frac{1}{2}$, as with this screen the rendering is very good, and with, say, the Wratten Verichrome plate it has only a factor of 4, thus increasing the exposure but four times.

L. C. LEON.

STOLEN GOERZ LENSES.—Messrs. C. P. Goerz advise us that the following lenses have been stolen from them. Any persons who may be offered them are begged to endeavour to detain the parties having them and to communicate with Messrs. Goerz:—Dagor 0/261990 in

sunk mount, Dagor 1/255513 in sunk mount, Dagor 1/262577 in sunk mount, Dagor 2/254604 in sunk mount, Dagor 168/249484 in sunk mount, Celor 1/256826 in sunk mount, Celor 4/242271 in ordinary mount.

SENSITISED PLAIN PAPER FOR ENLARGEMENTS.

[The following formulæ from "American Photography" relate to a type of paper less used nowadays for the making of enlargements, though still employed to some extent commercially, for producing of enlarged portraits.—Eds. "B.J."]

UPON various occasions the writer has received letters from many persons requesting information as to how a photograph can be made upon the centre of a sheet of paper, or upon small pieces of thick paper, such as an ordinary postcard, without going to the expense and labour of making up an emulsion in quantity for the production of a small number of prints that can be made by development.

The formula having been given to several individuals in a private way, and as it has proved to be both successful and beneficial to those who have practised it, a further benefit can be supplied to all those who wish to practise a simple process by making it more generally known by publication in this journal. Two methods of development can be employed, both of which are effective, and will give the operator the choice of colour best suited to his taste, while the material and chemicals can be obtained almost anywhere. As to the choice of paper, ordinary note-paper will answer the purpose very well; many of the drawing papers, as well as the ordinary postcard, Whatman's, and other varieties of drawing papers, can be used, and excellent results obtained; in fact, an excellent base can be obtained of a view or portrait by enlargement suited for after-painting or working up in sepia or black and white.

The process, in fact, is suited particularly for enlargement from small negatives.

Any number of sheets of paper can be salted, and after drying kept in a dry place under pressure, as, for instance, in an ordinary printing frame, until required for use. The salting solution is made up as follows, which can be made up and used in daylight, when if any air bubbles are found they should be dispersed by dipping a quill camel's-hair brush into the salting liquid and lightly rubbing over the spot where the bubble has formed.

SALTING SOLUTION.

Serum (made from milk)	6 ozs.
Iodide of potassium	1 dr.
Bromide of potassium	30 grs.

The iodide and bromide of potassium are best dissolved by grinding them in the serum in a small mortar, or crushed in an eight-ounce glass graduate with a glass rod (do not use wood or metal of any kind for this operation).

When the salts are dissolved mix with the rest of the serum, and filter through a tuft of absorbent cotton pressed lightly into the neck of a glass funnel, after it has been wet with water and wrung nearly dry. This will prevent clogging during filtration. The pieces of paper may be salted either by floating them upon the liquid for three minutes, and then suspended to dry, or they may be brushed over the middle of the paper in a circle or square and dried, always placing a lead-pencil mark upon the back, so as to know which is the side to be sensitised when the time arrives to make the picture.

SENSITISING THE PAPER.

Make up the following sensitising solution:—

Distilled water	10 ozs.
Nitrate of silver (c.p.)	300 grs.
Glacial acetic acid	$\frac{1}{2}$ oz.

Now take the piece of salted paper and float this upon the sensitiser in a clean glass or porcelain tray for three minutes, or, carefully brush over the surface some of the silver solution with a small tuft of absorbent cotton, that will be for the paper that has been salted in the centre; allow the paper to become only slightly dry, so that there is no liquid to run off the surface, then, having the enlarging apparatus ready, place the sensitive sheet of paper in place of the focussing card. After making the exposure, which may require from a few seconds to a minute or more, remove the paper and develop with the following solution:—

DEVELOPING SOLUTION.

Distilled water	6 ozs.
Citric acid	20 grs.
Pyrogalllic acid	12 grs.

The picture will develop in a very short time, when it must be washed in running water in a tray, then fixed in the following bath:—

FIXING SOLUTION.

Water	10 ozs.
Hyposulphite of soda	2 ozs.
Chloride of gold	1 gr.

Place the marked print into this, and allow it to remain for five minutes. It may then be removed and washed well in running water for half an hour, then dried, or pasted up and mounted.

Another developer consists of the following:—

IRON DEVELOPER.

Distilled water	10 ozs.
Glacial acetic acid	$\frac{1}{2}$ oz.
Photosulphate of iron	$\frac{1}{2}$ oz.
Alcohol (photographic)	$\frac{1}{2}$ oz.

This developer will bring out the image rapidly. The development must not be carried too far, or the paper will become grayed; after development wash well and fix as described.

Serum is readily prepared from milk by allowing about a quart of milk to stand until the cream has become well separated, then add one ounce by measure of acetic acid to the remaining skimmed milk, stir the acid well into the milk and allow it to stand for twenty-four hours; the curd will separate from the serum, which is the clear liquid that remains. This must be filtered so as to eliminate any trace of fat produced by the cream. A piece of rennet can also be used in place of the acetic acid, the serum in either case will answer the purpose.

Enlargements from small negatives by the above method are produced without gloss; there being no gelatinous base, the picture is mainly upon the surface of the paper, the natural surface of the paper being retained, so that it lends itself admirably for water-colour work or India ink. The resultant picture when worked up presents no appearance of a photographic base.

A. J. JARMAN.

SOME SUGGESTED MECHANICAL DEVICES.

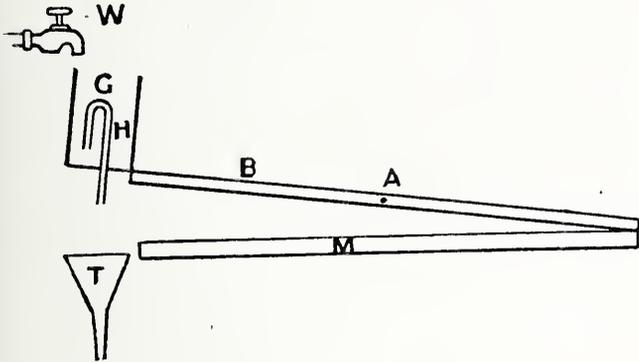

[In the current issue of "Photographische Rundschau" a contributor, Herr H. Steinach, describes one or two designs of apparatus which possess certain elements of novelty, and though we consider it outside of our province to devote space to the making of equipment which, with scarce an exception, can be more cheaply obtained ready made, it may be of service to describe one or two of the pieces of apparatus which the writer in our German contemporary has suggested.—Eds. "B.J."]

A Simple Rocking Table for the Dark-room.

AN arrangement by which the water supply of the dark-room may be readily applied to working a rocking table is as follows. Although the apparatus does not keep the dish in constant motion, it provides intermittent movement of the contents, and, therefore, is particularly suitable for tanks containing developer which is being used on the time system as well as fixing and toning baths

which require to be kept in movement every now and then. It consists of a table A, which is pivoted at a point A, and is provided at the left-hand end with a small vessel G, fitted with syphon H, which will draw off the water in the vessel G into a funnel T, which latter, of course, may be dispensed with if the syphon can be made to deliver directly down a sink. The table is weighted at the right-hand end so that when the vessel G is empty

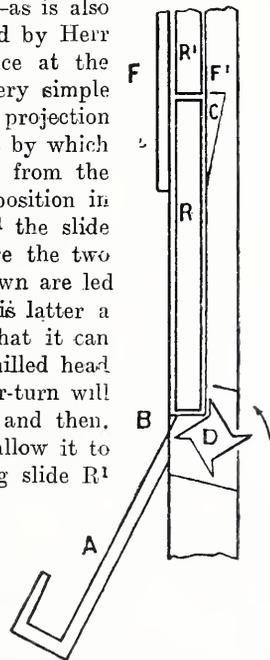

it takes the position shown in the drawing on a somewhat exaggerated scale. Thus, if the water supply W be turned on so that the vessel G—which should hold about 15 oz. of water—becomes full in about one minute, the weight of the water will bring down the left-hand end of the table, but as soon as the syphon works and empties the

vessel G the weighted table will re-assume the position shown in the drawing. The syphon tube should not be of too wide a bore: about 4 mm. (.16 inch) is a convenient internal diameter. If much wider, there is the difficulty of air being sucked in to the syphon tube, and as a result the syphon continuing to work after it should have stopped its action.

An Automatic Lantern-slide Carrier.

Although a number of plans by which a lecturer may himself operate the changing of the slide from the lecture platform have been suggested, none of them, in our experience, have proved to be really effective in use, and most of them—as is also the case with the present device suggested by Herr Steinach—actually call for some assistance at the lantern. The method now suggested is very simple in construction, and is adaptable to any projection lantern having an open stage. The device by which the slide is changed will be understood from the drawing. R is the lantern slide in the position in which it is being shown on the screen, R¹ the slide which is next to be shown. F and F¹ are the two guides between which the slides to be shown are led into the carrier. In the lower part of this latter a wheel D with four teeth is mounted so that it can be given a quarter-turn by means of a milled head on either side of the carrier. One quarter-turn will thus raise the slide R a short distance, and then, on the wheel being further turned, will allow it to fall into the receptacle A, the succeeding slide R¹ automatically dropping into position. The author of this device suggests that it may be actuated by a small electro-motor, put into action by the lecturer himself by means of a flexible connection to the platform.

Frames for Washing Enlargements.

For the use of the amateur worker, who, when making enlargements, is apt to overlook their proper treatment in the washing

water and is liable to leave them to soak together when they should be kept properly apart, the series of frames suggested by Herr Steinach are certainly useful, particularly as each may also be used as a frame on which to spread the enlargements out to dry. The

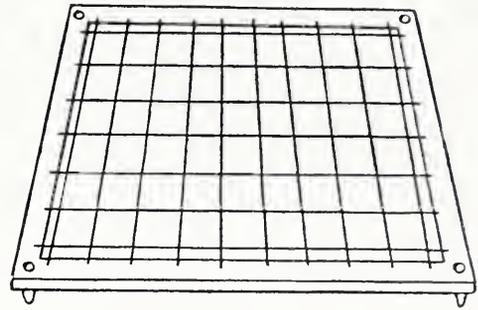

Fig. 1.

arrangement, it will be seen, is similar to a type of washer which Messrs. Marion have had upon the market for some years, whilst, on the other hand, the separate frames might well be made by suitably weighting the drying nets—consisting of a fabric held in a wooden frame—which Messrs. Houghtons have supplied under the

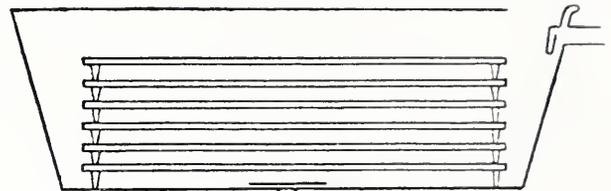

Fig. 2.

name of "Ensign." As the drawing indicates, each frame is provided on its under side with four small knobs or buttons, whilst on the upperside four recesses are made to take the buttons projecting from the frame above (see section drawing, Fig. 3). This allows of a series of half a dozen frames or so being quickly put together and placed in any convenient trough or tank where they can be washed with the assurance that the water is coming freely in

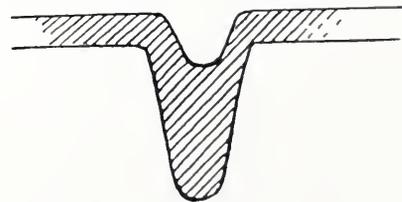

Fig. 3.

contact with each enlargement. Naturally wood, from the fact that it floats in the water, is not a suitable material for the frames. Herr Steinach recommends a metal frame, but for our own part we should think that the best of all would be a frame of heavy wood with some heavy metal rod inset into each to weight down the frame, but yet not to give any metal surface which might come in contact with the prints.

LOOK ON THIS PICTURE—AND ON THIS.—For some unexplained (but not inexplicable) reason a writer in the organ of a Midland photographic society is unable to express approval of some verses (he misquotes them, but never mind) which recently appeared in our pages under the title "Hyperfocal Distance." We regret this, because they were remarkably fine verses and moreover pointed a useful moral. Our friend is all for purism in literature, so we may be pardoned for drawing to his notice one or two phrases in an article which faces his in the periodical in question. And we may suggest that the lines in which Stevenson once dedicated a book to his "Critic on the Hearth" would be profitable reading to those who

apparently resent any sort of criticism. The writer on "the page opposite" gives of his quality as follows:—

"After I have developed my prints I used an acid bath, a few crystals of pot. metaspulphite dropped in the Hypo is good."

"If I have a margin in my prints I always clean them off with a little Farmer's Reducer."

"Now when your prints have been sulphided, wash for a few minutes and dry. Then try this: use a little vaseline—Lanoline is better, and rub thoroughly with the finger tips on a little cotton, then take clear cotton, or a soft piece of muslin and rub all off, and you will be surprised at the richness of tone."

PRESS PHOTOGRAPHY.

ON Thursday, December 2, Mr. Fred O. Penberthy lectured at Bolt Court School on "Press Photography." He said that the fact underlying the success of the Press photograph was that it replaced actual sight of the thing depicted much better, as a rule, than a description in words could do. This was the origin of all pictorial representation, and the photograph came closest to fulfilling this condition. The first condition requisite from a Press photographer was that he should be both journalist and photographer. The drawback with most of those at present engaged in the business was that they were either too much journalist and not enough photographer, or too much photographer and not enough journalist. What he felt sure was evolving was a sort of "super" journalist, who could give the essence of the news in a pictorial manner. He stated that after making a careful computation he came to the conclusion that at least £500,000 was spent every year by proprietors of newspapers and publishers in the purchase of photographs for publication. This was entirely due to the development of the half-tone process. He thought that England was five years ahead of any other country in its Press photography, not even excepting America. Editors here seemed to have a much greater respect for the value of the photograph as a news item, and showed more discretion in selecting a particular portion of any photograph of a telling character. The lecturer said that a photograph was, of course, very much superior if it showed some character in composition, and he illustrated what he considered to be the ideal news photograph by the picture depicting the evacuation of Port Arthur, in which two of the prisoners were placed in the foreground, and the mass of the prisoners were allowed to get so far away that the whole twenty thousand appeared as a long dark mass on the side of the hill in the background. In that photograph the whole story was most impressively and convincingly depicted.

Undoubtedly the most successful photographs were those with human interest, as people are much more interested in looking at other people than at things and places only. An examination of any of the illustrated papers would confirm this remark.

Many people were under the mistaken impression that Press photography was an easy and delightful recreation; and when he had recently advertised, he had received no less than 350 applications, out of which, after interviewing twenty, he had not been able to engage one. Some of the applicants were most amusing. One man thought he would be most suitable, as he was fond of an open-air life; he knew nothing about photography or journalism, but he was fond of being out of doors. Yet, Mr. Penberthy said, Press photography was extremely difficult work, and he described the very uncomfortable straits to which news photographers were occasionally put, giving, as an example, the case of a man who photographed the "Elevation of the Host" outside Westminster Cathedral, and had to be conveyed up a coal shaft to the top of the roof, and when there could only take his photograph by allowing a man to hold on to his heels, while he projected himself over the edge of the roof. This photograph, a particularly successful one, had been carefully thought out days before. He also showed a photograph of some of the incidents in the Spanish war in America, in one case where the photograph had taken three hours to be composed. This was a picture of men in a blockhouse which (after this trouble had been taken) not only told the story, but was in itself of quite pictorial excellence.

The lecturer's remarks were illustrated by a large number of slides of most varied interest, concluding with the famous picture of the bomb explosion on the occasion of the marriage of King Alphonso of Spain. This was taken by an amateur, who had no idea of its value, and did not discover he had taken it until two days after he had done so, and then he only sent along a poor quarter-plate albumen print of the scene. He was exactly opposite the spot, and waiting to snap his shutter, when the explosion of the bomb caused him to do it quite unconsciously. A curious object in the foreground of the picture looks like the bouquet of flowers in which the bomb was concealed, falling through the air.

Speaking of the remuneration for Press photography, Mr. Penberthy thought that any Press photographer worth his salt should not be content to remain a mere messenger sent to do whatever he is told, but he should specialise and make his work individual, so that he could always command good prices for it. He thought a capable

man ought to be able to obtain eventually £1,000 a year. On the other hand, many men now in the business—and more were drifting into it—were not worth as much as 30s. a week.

ELECTRICAL DISCHARGES ON PHOTOGRAPHIC PLATES.

PROFESSOR A. W. PORTER, B.Sc., gave a demonstration at the Röntgen Society's meeting, on December 2, of the effects he has obtained on photographic plates when a discharge of electricity from an induction coil is made to pass over them. A copper plate at the back of the photographic plate forms one of the terminals, and the other terminal is a wire on the opposite—i.e., the sensitive—side of the plate, coming into contact with it near the centre. The originality of Professor Porter's experiments lies, in the first place, in the fact that he has made discharges pass when a partial vacuum has been created around the plate. No investigator, so far as is known, has followed this line of work. He finds that when the pressure is reduced from that of ordinary atmosphere to about 55 centimetres of mercury there is a general tendency, in the negative discharge, for the familiar fan-shaped figures to spread out rather more widely. At 45 centimetres' pressure this is still more noticeable, and at this stage there comes into view a new phenomenon, of which neither Professor Porter nor any of the speakers in the discussion could furnish any explanation. It is a detached, triangular, bright figure, which looks as though the separated effects of the line of discharge had re-aggregated. At about half atmospheric pressure this effect is still more noticeable, and there is also a rosette surrounding the wire terminal on the plate.

Professor Porter has also tried the experiment of changing the nature of the gas surrounding the plate. If, instead of air, nitrogen be taken at atmospheric pressure, quite different figures make their appearance, and there is a tendency towards the formation of the central rosette, which does not begin to form in air until a much lower point has been reached in the scale of pressures. Different appearances are also seen in oxygen, in which the discharge is more curvilinear than in other cases; in carbon dioxide, where moss-like shoots separate from the main lines of discharge; and in ammonia, in which the figure is much more jagged than with the other gases.

He has arrived at another type of effect by sending a blast of air across the plate, and by placing the plate between the poles of an electro-magnet and producing as strong a field as possible. Only one part of the discharge is affected by the magnetic field, and that is the main discharge which passes across to the edge of the plate. This is swept to one side, and the effect in that region is as though the plate had been in a cyclone. Professor Porter believes that this part of the discharge consists of heated air, which is made into a conductor, and the effect of the blast of air on the magnetic field is to sweep it out of its course.

Most interesting of all were some experiments in which the electrode on the sensitive side of the plate consists of a wire brought down to contact with a small triangle of copper or other metal. In the case of a positive discharge under such conditions—that is to say, a discharge in which the triangle was made the positive terminal—there was a tendency for the streamers to come from the corners of the plate, whereas in the case of a negative discharge the streamers come off at right angles. The fact that the negative discharge comes off at right angles, says Professor Porter, seems to indicate that it is governed much more by statical conditions than the discharge of the positive. Replying to a great many suggestions for certain of the phenomena, which were put forward in the course of the discussion, Professor Porter said that he had not tried the use of a plate slightly moistened, nor of a specially desiccated plate. With a reasonably dry plate—though not desiccated in the modern chemical sense—there was no difference in the lines of direction taken by the discharge. In fact, he could trace nothing which depended on the photographic plate. Whatever plate was used, slow process or the fastest and most sensitive, the same effect was produced. But if the air around the plate was varied a different effect was obtained at once. Mr. Campbell Swinton, in a communication sent to the meeting, said that he believed results obtained in this way on photographic plates were really due to the luminosity of the discharge acting photographically in the ordinary manner. The luminosity though faint to the eye, was full of ultra-violet rays, and no doubt very actinic.

Photo-Mechanical Notes.

A Method of Preparing Half-tone Etched Plates Direct on the Metal.

In the current issue of "Photographische Kunst" Professor W. Urban gives an account of a method which has been worked out by an inventor named Fritz Hausleiter, of Nuremberg, the process having for its object the making of half-tone and line blocks direct on the metal plate in the camera. The metal plate, which may be zinc, copper, or brass, is first of all treated in a special solution (Brünierungs-Flüssigkeit), the object of which is first to secure better adherence of the emulsion, and at the same time to isolate the latter from the metallic support. A special gelatine emulsion, containing both silver iodide—in addition to the usual bromide—and a small proportion of colloidal silver, is coated on the plates. According to Hausleiter, the colloidal silver is necessary in order to give a development of the latent image through to the back of the plate. Representing the latent image as *a* in the figure the effect of the development of this latter in presence of colloidal silver may be represented as *bb*. The inventor does not give any explanation of the action of colloidal silver, but, according to Herr Urban, there would appear to be a kind of physical intensification, the electrolyte of the developer precipitating the silver hydrosol of the emulsion film as a silver "gel," which attaches itself to the silver nucleus produced from the silver bromide.

The plates coated with emulsion will keep for a considerable time; their sensitiveness is something between a wet plate and that of a good collodio-bromide emulsion. The plates are laid direct in the dark-slides and exposed behind the ordinary half-tone screen, using one stop only and without giving any "flash" exposure. They are then subjected to the "first development." For this, is used a glycin formula containing plenty of bromide. Development, of course, is to be judged from the appearance of the plate as it lies in the dish, but is readily controlled, and is completed in a few minutes, after which the plate is rinsed in water. It is then ready for, what is termed by the inventor, the "second development," which con-

sists in treatment in a special reducing solution which is kept protected from the action of the air by a layer of heavy paraffin oil and allowed to act for a certain time by daylight or artificial light. In this bath the portions of the silver haloid which have been left unaffected by the "first developer" are completely reduced so that the whole image disappears; at the same time the gelatine part of the plate complementary to the image is very strongly tanned. The composition of this second solution, which constitutes the essential part of the process, is preserved as a secret by the inventor. The plates are next rinsed with warm water, which removes the untanned portion, that is, those darkened in the first developer, so that in these portions the bare metal is exposed, whilst the parts tanned by the second developer exhibit considerable relief. The silver, still present in this latter, is removed by means of Farmer's reducer, and the plate then put in a bath of methyl-violet to make the image visible. The plate is then treated with potassium bichromate solution, the action of which bath on the film and on the underlying layer of oxide gives to the coating the properties of an ordinary fish-glue film, so that it can be burnt in as usual in the enamellene process and etched with iron perchloride of strength 36 deg. Beaumé. In the case of zinc a solution of fish glue, bichromate and formaline is used before treating with Farmer's reducer.

Herr Urban remarks upon the general resemblance of this process to Paynetype, but insists upon its essential difference from the latter in the absence of a collodion substratum. We rather gather that the Hausleiter process has not yet been brought to a fully working condition, but considerable use of it both for line and half-tone work is prophesied in anticipation of this event.

The process, we would say, seems very similar to Paynetype in all respects, except the difficulty of working, for Paynetype is a much simpler process than the one described. Collodion substratum

is not essential to Paynetype, though a substratum is; this can be any substance possessing the requisite qualities of insolubility in developing solutions and solubility in some other solutions. Shellac, for example, would serve instead of collodion.

Paynetype Process.

Mr. Arthur Payne, the inventor of this process, has consented to give a lecture-demonstration of it at the Bolt Court School on Thursday, January 13, at 7.30 p.m. All those interested in recent advances in process work should not neglect this opportunity of hearing details and seeing demonstrated this remarkable invention.

PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—

ETCHING.—No. 27,276. Improvements in apparatus for etching printing plates. William Matteson and Tom Birch Gould, 6, Lord Street, Liverpool.

PROCESS WORK.—No. 27,387. New or improved tools suitable for use in the production of process engraving, process prints, and for other like purposes. Joseph Bell, 115, Cannon Street, London.

SCREEN-PLATES.—No. 27,665. Improvements in screen-plates for half-tone process printing. Henry William Hamblin Palmer, 52, Stephen's Road, Tunbridge Wells.

Exhibitions.

SOUTHPORT PHOTOGRAPHIC SOCIETY.

THE promoters of this exhibition may be heartily congratulated on the collection of photographs they have got together and which is now on view, by permission of the Southport Corporation, at the Atkinson Art Gallery. It is pleasing to record this further instance of municipal recognition of photography. Here it is a well-deserved compliment, in which Dr. E. W. Bradley (chairman of the Exhibition Committee), Mr. J. McLellan (hon. secretary), and the other officials are fully entitled to share. In all 630 pictures are hung. Autochromes and lantern slides represent a further fifty-eight entries. The leading feature of the exhibition is the Dresden collection. It more than fills one large room. Perhaps the one picture which for size and realistic effect stands out is "A Wind Sea," by F. J. Mortimer. The loan collection is very strong, and may be described as a Royal and Salon combined, so many of the best prints at each of those shows being here. Included are works of the Buffalo circle and a Hungarian section. The visitor, on ascending the entrance steps, finds himself amid flowers and shrubs and the exhibits of the open section. As the space at our disposal is limited, we will only say that this section is good, and that we propose to return to it later to expostulate.

It must be understood that where corporations extend hospitality to photography, as in this case, their principal object is to benefit their townsmen. They wish to encourage their own ratepayers. If the local society respond by a satisfactory number of exhibits, a corporation then feels that the end it had in view has been achieved and will look with favour on a future request for similar privileges. The members of the Southport Society, about 100 strong, have responded well. They show 140 pictures and 16 sets of lantern slides. While some of the pictures might have been dispensed with, one must remember that the principal object of a local show is to encourage the local men, and this cannot well be done by rejecting their work. As a whole the members have done well and show a refreshing outlook on nature which is full of promise for the future. Dr. and Mrs. Bradley jointly have thirty-five entries, including slides, and have secured a number of merited awards. These workers have the honour of a panel to themselves. It contains sixteen ozobrome prints of large size, while others are entered in the open class. They have essayed almost every branch of subject. In some they have been quite successful, but a verdict given generally would be that shadows are on the heavy and solid side, and the interiors, of which there are seven in the above-mentioned panel, are mostly similarly affected and lacking in atmosphere. The most successful as regards quality of shadows and atmosphere are Nos. 165, 166, and 172. No. 164 is a suave and dignified composition—indeed, the word dignified may be applied to all Dr. and Mrs.

Bradley's interior work. No. 158, "Cloisters, Salisbury," is ornate. This print is awarded a plaque. E. W. Johnson's, No. 86, "Sandhills," deserves a better place. The sand looks as sand does when seen in sunshine and shadow. The seated figure is in the right place. This little print is as good as any in the class. No. 89, "A Dutch Study" (medal), by J. R. Rawlinson, is technically good. It is pure, straightforward portraiture of a woman who appears to be a Dutch virago. No. 110, "Shades of Evening," by Joseph Meadows, raises the question whether the farmhouse and the two trees on the right would not make a better picture than does the whole. No. 94, "Head Study" (medal), by G. C. Appleyard, is a charming portrait of a girl, and almost suggests a dainty flower. No. 70, "Liverpool—Impression," by William Rees, shows, as well as does any print in the entire exhibition, a capture of real light. Space will not permit of mention of several other meritorious works. Nos. 57, 63, 128, 188, and a few others are below the standard. Nos. 81, 103, 112, 114, 133, and 143 lack treatment of the shadows.

Reverting to the open section, one must at once admit that photography has its fashions. The fashion which appears to be coming in is deadly dull. It is the purely decorative. Dr. Evershed has one, entitled, "Profile," No. 55. There is no facial modelling, the tones are very, very few, and the manhood of the sitter is extinguished for the sake of obtaining decorative line and mass. This is the faith of the pot-hook school. Decorative line and mass—the latter when there is any—are their Alpha and Omega. Nothing else matters. Should the spectator think that something resembling life, light, virility, sea, or land, is more desirable, it is evident he has not found salvation. He is not of the elect who find mundane things unworthy. Another exponent of this weedy gospel is J. C. Warburg, in No. 429, "Out into Evening Mist." This time it takes the shape of an isosceles triangle—a steamer going out of the picture on the left, smoke trailing out on the right, and the wake of the steamer completing the triangle, although very little can be seen of anything. This decorative line, solely for the sake of decoration, is a revival of the soulful times, now almost forgotten, when the elect deemed their life mission fulfilled when they felt themselves worthy to live with feathers out of the tail of a peacock and an old china teapot.

The exhibition was opened on Saturday last by the Mayor of Southport, and will close on January 1. It is emphatically one which should be seen. Mr. A. H. Blake was the judge. Space will not allow of an enumeration of the awards. To-morrow (Saturday) Mr. J. McIntosh will lecture at 8 p.m. on "The Thames from its Source to the Sea."

SOUTHAMPTON CAMERA CLUB.

THE ninth annual exhibition of the Southampton Camera Club was held at the Art Gallery last week, and was voted a great success by members and visitors. The exhibits proved to be a very level lot this year, and Mr. Furley Lewis, F.R.P.S., who judged them, felt compelled to award a very large number of "hon. mentions" in order to show due appreciation of the work he was called upon to consider. The pictures were well displayed; the lighting both by day and night was all that could be desired, and a curtained stand, illuminated within (nicknamed the "Lovers' Retreat"), showed off to perfection a fine collection of colour transparencies and lantern slides. Altogether the exhibition was one of the most enjoyable yet held at Southampton, and it is to be hoped that the committee will not slacken their efforts next year because of the meagre support accorded them by the public.

The space at our disposal will not allow us to give anything like a detailed criticism of the exhibits, but a few of the more outstanding pictures may be noticed. The members' classes, always the most interesting, because they show what advance or otherwise has been made in a particular district, are somewhat disappointing; for, with the exception of the work of three or four, things are just where they were a year ago. Guy Vachell took the premier award again this year with four portrait studies, all showing beautiful quality, but the subjects were—in three instances, at any rate—somewhat stiff and "posed." "Sir Francis Galton" was this worker's best picture, we thought, but the judge evidently preferred "A. P. Wells Sandford, Esq.," and "Dawn." C. D. Kay showed six oil prints, four of which received recognition from the judge, who considered

"Portrait, Miss G.," the best picture in the members' classes. Another, and very popular, award in the premier class went to A. Gibbings for a delicate forest picture, whilst in addition to those mentioned "hon. mentions" were given to work by H. Essex and A. D. R. Bacchus. Some good work was also shown by C. Daw, H. J. S. Quilter, R. E. Parson, F. Watson, O. P. Butler, and G. Long. In the class for those who had not previously won an exhibition award, R. G. Vaughton Dymock scored heavily, his best picture being "Mountains and Mist," an exceptionally pleasing Swiss landscape, whilst two other pictures that caught the judge's eye also hailed from that country. F. S. Albert and W. P. Purvis took awards for good sound work, as did Miss E. Alder a "hon. mention"; and it would be unfair to pass on without mentioning that other prominent exhibitors in a strong junior class were A. Lisle, J. Heath, W. R. Olney, G. Long, Mrs. Alan Francis, E. E. Butler, and Miss H. A. M. Vokes.

The work in the open classes was representative of the best pictorial work in the country. Walter Selfe's "Winter's Morning" and Mrs. Barton's "Boy with Apple" seemed to be the favourites with visitors, but the latter picture was passed over by the judge in favour of the same lady's "Walter Neville, Esq."

The display of colour work was exceptionally fine, including over fifty Autochromes kindly lent by Capt. Stomm; and a trade stall, where Mr. W. Martin had a fine show of "Everything Photographic," completed the attractions in the room.

The award list was as follows:—

OPEN CLASSES.

CLASS A.—Framed prints, any subject.—Awards: 127, "A Winter's Morning," Walter Selfe; 164, "Peonies," Miss M. A. Smart; 172, "Winter's Solitude," E. Alwyn Biscoe; 182, "Still Waters," Mrs. Ambrose Ralli; 201, "Walter Neville, Esq.," Mrs. G. A. Barton. Hon. Mentions: 126, "Playmates," Mrs. Ambrose Ralli; 139, "The Rivals," E. J. Grant; 141, "A Portrait," Miss Vandamm; 145, "A Portrait Study, Lady at Spinnet," A. Keith Dannatt; 146, "The Lord Protector," A. H. Dodman; 147, "The Visitor," Miss B. McFarlane; 149, "His New Socks," H. E. Galloway; 158, "Cloud Capped Towers," W. A. J. Hensler; 166, "An Impression," B. and W. Fisk Moore; 167, "The Old Jetty," Rich. Delf; 168, "Sunshine in Old Whithy," Rich. Delf; 169, "Light and Shade: Norwich Cathedral," Rich. Delf; 176, "Yellowing Woods in the Sun's Waning Light," Rich. Delf; 178, "The Vanity of Youth," Miss C. McFarlane; 183, "Dr. J. F. T.," H. E. Galloway; 191, "Over the Hills and Far Away," E. Alwyn Biscoe; 196, "Grasshopper Warbler," Wm. Farren; 199, "Garden Warbler," Wm. Farren; 201b, "The Cuckoo," Alf. Taylor.

CLASS B.—Framed prints, any subject. Open to those who have never received an exhibition award.—Awards: 214, "Telephoto 10 Dia. Chamonix," C. A. Swan; 222, "Expectation," T. D. Ralli; 238, "Meditation," Miss K. Paget. Hon. Mentions: 202, "Egyptian Columns, Venice," C. A. Swan; 210, "Court of Lions, Alhambra," C. A. Swan; 226, "The Mill," Dr. C. F. Metcalfe; 227, "A Silent Stream," Elliott Peel; 230, "Ancient and Modern," Dr. G. P. Jordan.

CLASS C.—Lantern slides, any subject.—Awards: "Rue Bougherie Caudebec," W. A. Clark; "Spring Landscape," T. H. Franklin. Hon. Mentions: "The Garden's Promise," T. H. Franklin; "The Bishop's Eye," W. A. Clark; "Morning Sunlight," H. Essex; "A Courtyard," W. A. J. Hensler; "A Vista, Rouen," W. A. Clarke; "Gossip," Dr. F. Thompson; "The Watched Pot," Dr. F. Thompson; "Young Wood Owls," Alf. Taylor; "Grasshopper Warbler, No. 1," W. Farren; "Grasshopper Warbler, No. 2," W. Farren; "The Rivals," E. J. Grant; "Harvest Time," T. H. Franklin; "The Realm of the Snow King," Graystone Bird; "Heron," G. A. Booth; "Great Tit," G. A. Booth.

CLASS D.—Colour work.—Award: 286, "A French Laundress," T. D. Ralli. Special Hon. Mentions: 258, "Conservatory Flowers," A. F. Robinson; 260, "Arum Lilies," A. F. Robinson; 287, "A Farm House," T. D. Ralli; 291, "Still Life," H. O. Klein. Hon. Mentions: 247, "The Larder," H. J. Comley; 256, "Frame of Autochromes," Colin N. Bennett; 288, "The Captain," H. O. Klein; 289, "Iris," H. O. Klein; 298, "Madresfield Court," G. E. Saxby Thomas; 294, "In a Chemical Laboratory," H. O. Klein; 302, "The Orang Stall," J. C. Warburg; 309, "The Gleaners," U. W. Jones; 310

"River Wye, Hereford," U. W. Jones; 312, "Peonies," G. E. Saxby Thomas.

MEMBERS' CLASSES.

Champion award for the best four pictures by a member in the club classes: Nos. 7, 13, 24, 41, G. C. Vachell.

CLASS E.—Framed prints, any subject. The "Amateur Photographer" silver medal for the best picture in the members' classes: "Portrait, Miss G.," C. D. Kay. Awards: 1, "A. P. Wells Sandford, Esq.," G. C. Vachell; 32, "Dawn" (debarred), G. C. Vachell; 59, "A. J. Kay, Esq.," C. D. Kay; 68, "The Church in the Vale" (debarred), C. D. Kay; 70, "A Corner of the Common," A. Gibbings. Hon. Mentions: 11, "The Village," H. Essex; 13, "Sir Francis Galton," G. C. Vachell; 23, "After Rain," C. D. Kay; 30, "An Autumn Morning," A. Gibbings; 37, "November," G. C. Vachell; 40, "Chrysanthemums," H. Essex; 51, "Major Dalrymple," G. C. Vachell; 62, "Funnel Web Spider," A. D. R. Bacchus.

CLASS F.—Framed prints, any subject. For those who have not previously received an exhibition award.—Awards: 80, "Low Tide," F. S. Albert; 84, "Mountains and Mist," R. G. Vaughton Dymock; 94, "A Specimen of Swiss Carving" (debarred), R. G. Vaughton Dymock; 108, "Holy Trinity Church, Hull," Dr. W. P. Purvis. Hon. Mentions: 98, "Relics of By-gone Days," Miss E. Alder; 93, "Twas in the Winter Cold," R. G. Vaughton Dymock; 99, "The Falls of the Kander," R. G. Vaughton Dymock.

CLASS G.—Lantern slides.—Awards: "An Alpine Valley," W. R. Kay; "A Corner of Clovelly," H. Essex. Hon. Mentions: "The Awakening of the Fleet," W. R. Kay; "Lucerne," W. R. Kay; "A Hampshire Farmhouse," H. Essex; "Greyfriars Bridge," R. E. Parson.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

BUT a few weeks the junior of the Hackney Society, the North Middlesex comes of age this year also, last Wednesday witnessing its twenty-first exhibition. The high standard of its work, and the enthusiasm evinced by its industrious members, are but another proof that amateur photography is daily growing as a hobby and pastime, and that its results are everywhere attaining to a higher standard. The North Middlesex Society is particularly strong in the oil and bromoil processes, and the prints in this method make up one of the distinguishing features of this year's show. The other feature is a striking display of night photography—the outcome of a nocturnal ramble by a group of the members in and about Leicester Square. The palm in this work is held by the president, Mr. H. W. Fincham, whose fine treatment of the Shakespeare statue seen against the lights "In Theatre Land" (60) has lifted a mere experiment into an excellent pictorial achievement. The picture preserves the breadth and tones natural to the scene under the conditions of artificial lighting. Not a few of the other attempts suffer through over-exposure, in showing too much detail and too great a range of tones. We are pleased with the figure works of Chas. A. Morgan, which show much taste and power of treatment. Louis Dick is also masterly in his treatment of bromoil work. In "The Surrey Docks" (23) it alone saves a rather cumbrous composition. He atones for this in his other subjects, especially in the capital "Auld Stirlin' Brig" (93). S. E. Wall's "Essex Mill" (16) is a first-rate bromoil, and the fine "Impression of Edinboro" (85) will not be forgotten as a triumphant bromide picture. "The Queue" (144) is the kind of picture which we may expect to be the future strength of photographic art. "Loch Duich," by Chas. Beadle (155) and "On the Canal, Ghent" (166), by W. A. Fincham, are two works that we must not omit to recommend. The record work, for which this society is justly famous, is as interesting as ever.

The awards made by Messrs. A. H. Blake and Furley Lewis were as follows:—

PRINTS.—12, "A Haven of Rest," A. G. Lawson; 25, "Devotion," Chas. A. Morgan; 28, "Walberswick," James Allbon; 51, "The Orphanage," Louis Dick; 60, "In Theatre Land," H. W. Fincham; 95, "From the Quayside on a Winter's Morning," Douglas P. Fox; 122, "Interior—St. Mary's, Whitby," A. R. Rollings; 144, "The Queue," M. F. Black.

LANTERN TRANSPARENCIES.—263, "A Portal," E. Burton; 508, "In Finsbury Park," J. F. Nisbett.

COLOUR TRANSPARENCIES.—395, "Cramond Brig," J. F. Nisbett.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between November 22 to 27:—

RELIEF PHOTOGRAPHS.—No. 27,076. Process for the manufacture of relief photographs. Karl Lachner, 19, Southampton Buildings, London.

STEREOSCOPY.—No. 27,284. Optical combination for use in connection with stereoscopic apparatus. Jules Richard, 53, Chancery Lane, London.

PIN-HOLE CAMERAS.—No. 27,306. Improvements in and relating to pin-hole cameras. Wolfgang Otto, 46, Marmion Road, Southsea, Portsmouth.

CINEMATOGRAPHS.—No. 27,520. Improvements in cinematograph films. Oskar Messter, 100, Wellington Street, Glasgow.

BORDER PHOTOGRAPHS.—No. 27,587. Improvements in or relating to the production of border or like photography. George Jobson and William Smith, 111, Hatton Garden, London.

LANTERN PROJECTION.—No. 27,603. Improvements in reflecting screens for cinematographic and lantern projecting. Henry William Hamblin Palmer, 52, Stephen's Road, Tunbridge Wells, Kent.

CINEMATOGRAPHS.—No. 27,642. Improvements in cinematograph films. Oskar Messter, 100, Wellington Street, Glasgow.

STEREOSCOPY.—No. 27,666. Improvements in or relating to stereoscopes and books containing stereoscopic views. Harry Cox, 8, Brems Buildings, London.

REFLEX CAMERAS.—No. 27,667. Improvements in or relating to photographic cameras of the type known as reflecting or reflex cameras. Arthur Lewis Adams and Walter George Roberts, Birkbeck Bank Chambers, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 27,675. Improvements in or relating to cinematographs. Thomas Percy Middleton, 7, Southampton Buildings, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PANORAMIC PHOTOGRAPHS.—No. 10,669, 1909 (May 5, 1909). The ordinary camera is used, and a "blender" arranged to graduate the exposure at each end of the plate.

Each picture or exposure is made to overlap the next preceding one at its ends, and the overlapped portion of one exposure is such that it will compensate for the lack of exposure of the next one,

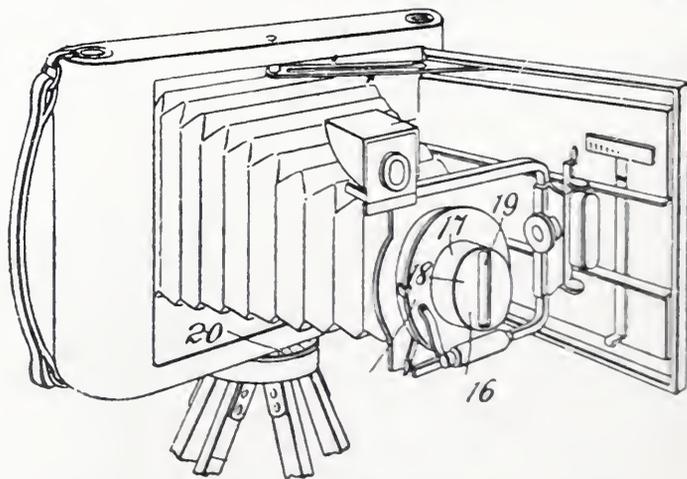

Fig. 1.

so that when two succeeding exposures have been given the successive pictures will make a continuous photograph. The pictures may be made without moving the camera and lens, or the camera may be moved to take a succession of views each different from

the other and in this case means is provided whereby the camera may be moved the proper distance so that the succeeding pictures will overlap the desired extent.

The camera is of the ordinary folding type known as the "Kodak," and has the usual finder, folding casing, and movable lens front, and on the back is the usual red glass, through which the marks may be seen which indicate the proper distance the film should be moved at each exposure. On the lens front is the blender, 16, which may be constructed of any suitable material, and is preferably cap-like in form. It has a cylindrical body 17, provided with a front disc-like face, 18, in which is arranged a slot, 19. This slot 19 extends vertically when the "blender" is in use, and by reason of the slot, the "blender" cuts off gradually the view at both ends of each exposure, or causes the main part of the exposure to exceed that at the ends. If, for example, seven inches of film is used for each exposure the centre of each exposure would be full timed, but about one inch on each end is only partially exposed. The second exposure, which overlaps the preceding one to the extent of one inch, corresponds as to the view to the part to be blended in the preceding exposure, and the second exposure also has its ends gradually cut off, and its inner part between the ends full-timed. Thus the second exposure at the overlapped ends will make the exposure equal to the other part thereby producing a full-timed negative throughout, as well as to blend one exposure into the other where they overlap. By this means the photographs are produced without division lines, and are absolutely continuous.

The size of the opening in the "blender" depends on the dis-

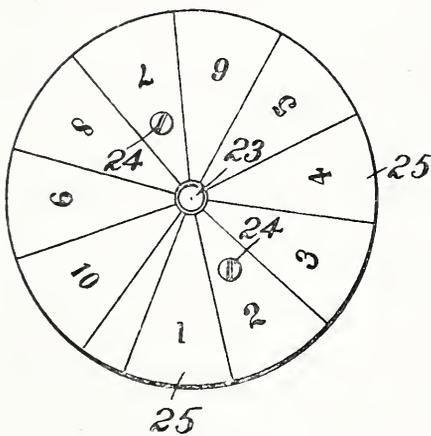

Fig. 2.

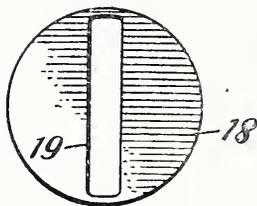

Fig. 3.

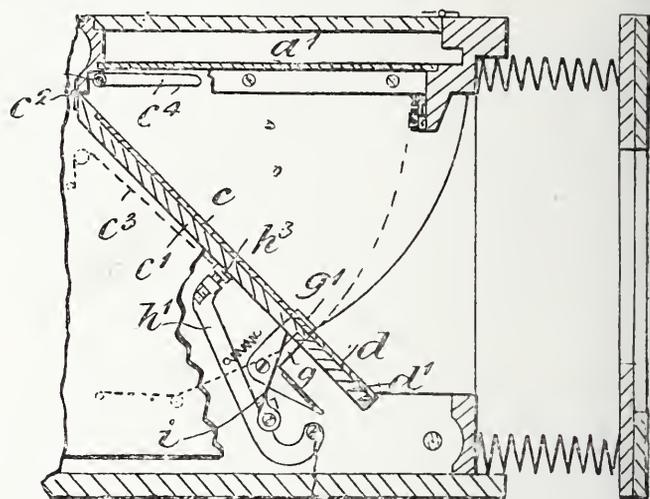

tance of the opening from the lens. If the opening is small, it will be placed nearer the lens, and if larger farther away, for the nearer the opening is to the lens the more it blends the picture taken. It will thus be seen that the exact distance of opening from the lens in any particular "blender" and the size of the opening or slot therein will vary according to the character of the camera, although the opening may be arranged relative to the lens at any point desired within a reasonable distance thereof.

Where a succession of views is to be taken, it is desirable that the camera be arranged so that the same may be moved a fixed distance according to the size of the pictures to be taken. If it is intended to use seven inches of film for each exposure, in that case the camera would be turned a corresponding distance each time. For this purpose a dial, 20, may be arranged on the head of the tripod, this dial being provided with the central opening, 23, which is adapted to fit over the usual tripod screw. This dial is provided with a series of divisions, 25, numbered consecutively and made to correspond with the distance the film is to be moved after each exposure, and the extent of view to be taken at each exposure.

The camera is provided with pointer 26, Fig. 2, and this pointer will indicate the exact distance the camera is moved each time along the dial. As the camera is moved for each exposure the film is correspondingly moved in the camera in the usual manner, and by reason of the blender, the successive photographs or views will have a part thereof overlapping the one next adjacent thereto, and these overlapped portions will be merged into each other as already explained. Edward Nelson, White, Banes, Oriente, Cuba

REFLEX CAMERAS.—No. 338, 1909 (January 6, 1909).—According to this invention the component parts of the mirror are not connected: the retaining mechanism of one portion is actuated by the other when it approaches its terminal position, one part being alternately released by the other when setting the mirror and releasing it.

The mirror is formed in two parts, *c* and *d*, of which the larger part *c* is secured to the plate *c*¹ hinged at *c*² in any convenient manner to a transverse portion of the body of the camera. The upward movement of the plate *c*¹ is effected by means of a spring such as *c*³ indicated by dotted lines in Fig. 1, whilst the movement of the plate *c*¹ against the action of the spring is effected by means of the arm *c*⁴. The opposite or smaller portion of the mirror *d* is attached to the plate *d*¹, which is under the influence of a spring, not shown, the tendency of which is to force the body upwards until its further movement is checked by its ends coming

against the edges *d*³ of projections or cheeks secured to the sides of the interior of the camera body or by the mirror plate *c*. The meeting edges of the parts *c*¹ and *d*¹ are preferably so shaped that they overlap, and thus the mirror presents a practically continuous surface sufficiently large to reflect the whole of the view. In order that the portion of the mirror carried by the part *d*¹ may be prevented from throwing any light into the interior of the camera, a shield *i* is pivotally secured at its ends to the cheeks, which are shown broken away in Fig. 1. The shield *i* has bearing upon it one end of a spring, which, as the part *d*¹ is moved downwards, causes the shield to swing over and lie upon the upper surface of the mirror *d*. The shield otherwise occupies the position shown in the figure. Herbert George Chessher, trading as the Tella Camera Company, of 68, High Holborn, London.

PRINTING FRAMES.—No. 16,093, 1909 (March 15, 1909). The invention consists in forming the pressure-giving surface by leaf springs supported in suitable supports so that the actual surfaces of contact are widely and regularly distributed. The pressure between the frame supporting the springs and the negative-holding frame may then be obtained by a single clamping bolt and nut co-acting with a bracket on the spring frame. In small frames the necessary distributed pressure may be obtained by a row of similar parallel springs extending across the whole width of the pressure frame; in larger frames alternatively with the springs passing from side to side are a series of shorter springs, a support for which is added along the centre of the pressure frame, and these shorter springs have the effect of extending the pressure towards the sides. As it is important that the points of contact should not all be in line, springs of various lengths may be employed so that these points of contact are distributed in two or more parallel lines, by which the useful pressure surface is largely increased as compared with the surface available if the springs are in one row.

The supports for the springs are so placed that when not under pressure they have a small downward curvature, consequently when the pressure is applied the point of contact is extended by the continued compression of the springs. Dr. Eugen Albert, 55, Schwabingerlandstrasse, Munich, Germany.

CINEMATOGRAPH-PHONOGRAPH.—No. 27,766, 1903 (December 21, 1908).

The apparatus devised by the inventor consists of two members arranged to receive reciprocating motion from the cinematograph and sound-production apparatus respectively, and thereby to engage and operate an intermediate member in such a way that the latter is not moved in a linear direction when the movements of the cinematograph and sound-production mechanism are synchronous, but does receive such motion when the movements are out of synchronism. Cecil Milton Hepworth, 17, Cecil Court, Charing Cross, London.

The following complete specification, etc., is open to public inspection before acceptance, under the Patents Act, 1901:—

COLOUR PHOTOGRAPHY.—No. 26,911. Device for production of three-colour reticules for colour photography. Krayn.**New Trade Names.**

RODINAL.—No. 317,271. Chemical substances and chemical preparations used in photography. The Berlin Aniline Co., Ltd., 26, Princess Street, Manchester, Chemists and Druggists. October 15, 1909.

ISOLAR.—No. 317,293. Chemical substances used in photography. The Berlin Aniline Co., Ltd., 26, Princess Street, Manchester, Chemists and Druggists. October 15, 1909.

UNAL.—No. 317,295. Chemical preparations for use in photography. The Berlin Aniline Co., Ltd., 26, Princess Street, Manchester, Chemists and Druggists. October 15, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Printing-out and Toning Gravura Paper.

In the course of an article on the manipulation of Gravura paper in "Photography and Focus" for December 7, a writer says: "The Gravura paper can be placed in the printing-frame in diffused daylight in precisely the same way as the ordinary print-out papers. The prints lose very slightly in toning and fixing, so must not be printed too deeply. Printing should be done in direct sunlight if printing is slow, and each print should be washed for ten minutes in several changes of water before toning.

The following toning bath may be used, toning until no traces of the red image are visible through the backs of the prints by transmitted light:—

Gold chloride (15 grains in 5 drams)	30 minims
Ammonium sulphocyanide (10 per cent. solution)	15 minims
Water to make	7½ oz.

This quantity is sufficient for twelve quarter-plate or six half-plate prints. After toning, the prints are washed for about ten minutes, fixed for ten minutes, in a plain hypo bath of 3oz. to the pint, and washed as usual."

New Books.

"Kompendium der Gerichtlichen Photographie." By Wilhelm Urban. Leipzig: Otto Nemnich. 7 mks. 50.

In this volume of 200 pages the author gives an account of the practical methods employed in using the camera for the purposes of identification of criminals and for the many other departments of criminal investigation. In the preface by Herr Koettig, the chief of the Dresden equivalent of Scotland Yard, reference is made to the great interest aroused by the section of the recent Dresden Exhibition devoted to this subject. Herr Urban's volume has been prepared with a view of placing in the hands, not only of police departments large and small, but also in those of individual officials and experts, the systems and methods which have been adopted by police authorities in the chief European countries. Naturally among these, France, with its elaborate systems worked out by M. Bertillon, occupies a leading place, and considerable space is devoted in the volume to a description of the Bertillon outfit for recording the

physical characteristics of prisoners and also of obtaining measurements of any scene from a single photographic exposure. Herr Urban sticks closely to the practical side of his subject, and commendably refrains from enlarging on the triumphs of judicial photography. Sensational as some of these are. In the latter portion of the book, which is devoted chiefly to the methods for the deciphering of burnt or damaged manuscripts for detecting forgeries and erasures, the practice of Dr. Jeserich of Berlin and Professor Reiss of Lausanne is largely drawn upon, and very effective use is made of illustration in showing the remarkable results obtainable by comparatively simple methods. The volume concludes with a bibliography of its subject arranged as an alphabetical list of the authors; there is also an Index to the text and a short glossary evidently prepared for readers who are unacquainted with photography

"Die Standentwicklung." By Hans Schmidt. Halle: W. Knapp. 2 mks. 40.

In this addition to the very useful series of books on photographic processes—some seventy of which have now been issued by the firm of W. Knapp—the subject is the development of plates and films a number at a time in apparatus specially devised for the purpose and usually supporting the plates in a vertical position. Herr Schmidt's monograph deals strictly with development in this way and does not touch the question of factorial development nor of the compensation for temperature by varying the time of development. It is a pity, perhaps, in a volume in which is brought together a good deal of useful information, that its scope was not enlarged to take in these almost equally important developments of the subject. A good deal of the space devoted to developing formulæ might easily have been spared, for although the author states that many published formulæ are unsuitable for stand development, he does not point out what are the essentials of a suitable formula, and it is difficult to gather, from the five or six pages of prescriptions which he gives, any clear conclusion as to the essentials of a developing solution for stand work. Allusion is made to the discrepancies as regards time of development noticed when a solution is diluted considerably with water. The author gives an example showing the great excess of time over, say, ten times, which must be given when a certain developer is ten times diluted, but he omits to point out that this feature is not shown to anything like the same extent by other developing solutions, nor does he point out that dissolved air in the water is largely the cause of the effect. Possibly the manuscript of the volume was in the printer's hands before the publication of the paper of Messrs. Wratten and Wainwright some months ago.

"Deutscher Camera-Almanach," 1910. Edited by Otto Ewel. Berlin: Gustav Schmidt. 4 mks.

The fifth issue of this German annual appears under a new editorship, Herr Loescher having died whilst the previous issue was passing through the press. The "Almanach" divides its space about equally between articles which provide fairly light technical reading, and illustrations which are selected apparently to show the progress in pictorial work in Germany and other countries. In the present volume we notice the novel and very convenient system of bunching the reproductions together in lots of about half a dozen instead of allowing them to break up almost every page of text. This makes the text easier reading, and has allowed of pictures illustrating a particular subject being all brought together. Thus, "Pictorial London," which is treated by Mr. E. O. Hoppe, goes with six pages of illustrations by Mr. A. H. Blake. Mr. Martin Duncan writes on orthochromatic photography, and Miss A. B. Warburg on portrait photography in England, with illustrations by Edith L. Willis, T. Lee Syms, Will Cadby, F. T. Hollyer, and herself. Among the most interesting reproductions in the volume are the intensely clever photographs of animals by Käthe Hecht. In photo-engraving and printing the volume is altogether admirable, though one may wish that the publishers could do with a less glossy art paper.

"Deutscher Photographen-Kalender," 1910. Pt. I. Edited by K. Schwier. Weimar: Office of the "Deutsche Photographen-Zeitung." 2 mks.

The twenty-ninth volume of this "Kalender" includes, as before, a diary of the year, a large number of tables, and a formulary of

photographic processes from A to Z—that is to say, from wet-collodion through dry-plate, developers, intensifiers, etc., and printing processes to such odds and ends of photographic practice as putting titles on negatives, or cementing paper to glass. This programme is carried out in Part I. of the Kalender, Part II., which forms a separate volume, not yet issued for 1910, being devoted to trade and other photographic information. We note that one item in the volume before us is the text of the German Copyright Act of 1907.

New Materials, &c.

“Hyptona” (self-toning) Collodion Paper. Made by Ilford Limited, Ilford, London, E.

When the Ilford Company, at the commencement of last year’s photographic season, placed a collodion paper on the market, it was naturally to be assumed that there would follow in due course a C.C. paper of the self-toning class which would particularly appeal to the amateur worker. In the new “Hyptona” paper, just issued, we have this natural development of events in a product which surely represents the furthest which a manufacture may be expected to go in enabling prints of beautiful quality being produced with the very minimum of trouble. We learn that the new paper receives its name in reference to the fact that the only “bath” in which it requires to be treated is a solution of hypo of the strength of 2ozs. in a pint of water. But we are, nevertheless, glad to notice that the Ilford Company direct a brief washing of the prints first of all in plain water, a proceeding which removes the toning process from the suspicion of being due to the introduction of acid into the hypo from the paper. We found that when following these instructions we obtained the most excellent cool-brown tones in the hypo bath, and as for the general qualities of the emulsion as regards gradation we can only say that we employed a dozen or so negatives of very different character—some almost flat and others in which the contrasts were quite excessive—and did not obtain a single print which could be called bad. The very best results in our experience are obtained with that type of negative which prints well on ordinary P.O.P., and the degree of over-printing which is necessary for a perfect result on “Hyptona” is exactly that to which users of ordinary P.O.P. are accustomed. The vehicle of the silver salts being collodion, the worker is further relieved of troubles incidental to drying the prints, whilst he has nothing to pay for this in the way of curling of the prints in the bath or their cracking on drying, the prints lying very flat in the dishes and showing a quite flexible coating when finished. For those who prefer a colder tone—that is, one of a more purplish hue—the use of a salt bath, prior to fixing in the hypo, may be recommended, but for ourselves we think the full beauty of the paper is obtained by simply fixing alone.

“Hyptona” paper, we should add, is made in four varieties—glossy-mauve, matt-white, matt cream smooth, and matt cream rough; these varieties, with the exception of the last, being also obtainable in a stouter variety, heavy enough to make a mount unnecessary, but, perhaps, not unduly stiff. All four of these variants of the paper have their special qualities—the Matt White is a very smooth paper, giving the very finest detail; the Matt Cream Smooth has the same quality of surface, but with a very pleasing cream tint, which does every justice to subjects in which a suggestion of warmth is wanted; whilst Matt Cream Rough has a figured surface which particularly suits negatives the excessive hardness of which calls for some ready means of breaking up unsuitable masses of shadow and of producing a more harmonious effect. The prices of the new paper are 2s. 4d. per two sheets, 24½ by 17; or 1s. per packet of twenty-two quarter-plate pieces; or, again, 8s. 6d. per box of one gross 5½ by 4 pieces.

CATALOGUES AND TRADE NOTICES.

POSTCARD PRINTING.—Messrs. Droege and Co., 43, Comeragh Road, West Kensington, London, W., send us their latest list of prices for postcard printing, enlarging, and other departments of trade work for which they are well equipped.

Dew Apparatus, &c.

The “Choroplast” Double Anastigmat $f/3.9$. Made by Dr. Staebble-Werk Optical Company, Munich, Bavaria. English Agents, Sherwood and Seldt, 15, Mount Pleasant, London, E.C.

This anastigmat lens of the very large aperture of $f/3.9$ makes its appearance on the English market along with a number of other photographic objectives from the Munich factory of the firm which was formed about two-years ago under the title of Dr. Staebble-Werk. The firm represents the conjunction of two mechanics—O. Jaeger and A. Neumann—with Dr. F. Staebble, under whose charge is the theoretical and scientific side of the business. Dr. Staebble’s two colleagues have occupied positions in several of the leading German optical factories, so that this young firm of opticians approaches the manufacture of photographic lenses with experience gathered in the best centres of the trade. They have made several innovations in the form and mounting of their manufactures, of some of which we shall be able to write later. In the meantime, we would suggest that those who are interested in the new series of these optical instruments should address their inquiries to the English agents, Messrs. Sherwood and Seldt, 15, Mount Pleasant, London, E.C., who represent the interests of the Staebble firm for the United Kingdom, the British Colonies and Possessions, and other parts of the world. The “Choroplast” is a double anastigmat of an aperture that

renders it of the greatest possible service in high-speed focal-plane work, while the corrections are extremely good. At the full aperture it is intended for use on a quarter-plate, and it covers this excellently and without more falling off in illumination that is to be expected. Indeed, a feature of the lens is the relatively large area of plate over which the full aperture is effective. As a general rule, with lenses of $f/4$ or thereabouts, the cutting off of the aperture by the mount begins almost immediately one leaves the centre of the plate, but in this case the full aperture is effective over an appreciably large circle. The definition is very fine, indeed, and a test with a point source of light shows hardly a trace of astigmatism. The correction for this aberration is, in fact, far better than we are accustomed to see even with lenses of much smaller aperture. The 6-inch lens submitted to us covers a half-plate well at $f/5.6$, and as the angle of illumination is a wide one, a much larger plate can be covered with $f/8$ and smaller apertures. The price is certainly moderate, as a 4¾-inch lens only costs £5, and the 6-inch that we have tried only £6 15s.; a 7¼-inch lens costs £8 5s., and either this or the 6-inch lens would be a most valuable instrument in a reflex camera. We can recommend the “Choroplast” as a really high-class large-aperture lens at a moderate price.

PRICES OF BUSCH OMNAR ANASTIGMATS.—Messrs. Emil Busch Optical Co., 35, Charles Street, Hatton Garden, London, write to point out that an error appears in their advertisement on page 367 of the “Almanac,” 1910, relating to the prices of the Omnar lenses, $f/4.5$. This portion of the advertisement should read as follows:—

BUSCH ANASTIGMAT “OMNAR,” SERIES I. F 4.5.

No.	Diameter of Lenses.	Equivalent Focus.	Covers Plate.		Covering Circle.	Prices with Iris Diaphragm.			
			F. 4.5	F. 8		Ordinary Mount. Model A.	With Helical Focussing Mount. Model B.	In “Unicum” Shutter Model U.	With “Kohlos” Shutter.
2	1½	5½	4½ × 3½	5 × 4	7½	£ 4 10	£ 5 5	£ 5 10	£ 6 10

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 7, the president, Mr. J. C. S. Mummery, in the chair.

A donation was made to the society by Messrs. Newman and Guardia, Ltd., in the shape of an Atkin-Swan tilting table. Mr. and Mrs. Ernest Marriage also presented a recent work by themselves to the library. The thanks of the society were tendered to these donors. Mr. A. B. Hitchins exhibited several bromide prints which had been locally toned with a set of uranium and iron toning solutions. Mr. E. H. Atkinson showed a piece of apparatus for attaching binding paper to lantern slides. It consisted of a pair of rubber rollers which pressed the gummed binder firmly to the edges and sides of the lantern slides; on the latter being removed from the apparatus, this automatically fell back from the slide so that there was no tendency for the gummed strip to come away from the

glass. Mr. Atkinson also exhibited a focussing screen of greater transparency and finer grain than ground glass. He stated that the screen was more liable to damage than that of ground glass, but that it allowed of much greater fineness and ease of focussing. It was being placed upon the market.

Mr. H. Essenhigh Corke then gave a lecture on "Screen-Plate Colour Work," which he illustrated with a large number of lantern slides, made chiefly on the Autochrome and Thames plates, with also one or two on the Omnicolore. He also exhibited a specimen and a photo-micrograph of the Aurora screen-plate. Admitting, with quite refreshing candour, that his discourse on this branch of photography should be accepted as coming from one who claimed no scientific knowledge of the subject, but did claim a considerable practical experience of at least two methods, he contributed a good deal of very useful information on the making both of Autochrome and Thames colour transparencies. He commenced by showing a few slides illustrating the failures to be met with in the Autochrome process, such as over- and under-exposure, over- and under-development, green spots, etc. In the case of outdoor work, he said he had found the exposure indicator of Burroughs Wellcome a most useful guide. He ignored the division of subjects, and treated all outdoor alike as "strong foregrounds." He still used the pyro ammonia developer of Lumière, but found also that the quinomet formula worked excellently, and where it was necessary to deal with great extremes of light and shade he used 1:12 rodinal, developing for six minutes, or 1:40 azol, developing in four minutes. In the case of these subjects he preferred to wait until the sky was somewhat obscured by light clouds in order to lighten up the shadows of the subject. For development he found Dr. Drake-Brockman's suggestion of the use of a solution of potassium metabisulphite applied to the plate a minute or so before pouring on the developer of the greatest service in allowing development to be done by a quite bright yellow light. In redeveloping when daylight was not at hand to which to expose the plate, he used incandescent gas, or better, burnt one foot of magnesium ribbon fairly close to the plate. Unless ample exposure to light was given, and also the full time of re-development, the plate would lose very greatly in the fixing bath. He had tried the glycerine method of preserving plates from the action of heat, but he found that in those particular instances where he had used the glycerine bath the Autochromes, on keeping, developed a bright red in the skies, whilst spots also appeared in other parts. In common with speakers who took part in the after-discussion, he attributed these spots to bacterial growths in the moist gelatine. So far as concerned the duplication of Autochromes, he had made many experiments, but had never been able to prepare a duplicate equal to the original. This he considered a great drawback to the Autochrome from the commercial point of view, since the photographer could not obtain a high enough price for one transparency to make the job worth his while, whereas if a dozen could be prepared from a single exposure the process became commercial. On this account, and also because of the much shorter exposure which could be given, he had turned his attention to the Thames plate. He had not got on well with the first form in which the plate had been sent out, where a separate panchromatic plate had to be reversed and then bound up with the original separate screen. He found he could not reverse the plate so as to get a good clear positive, and, therefore, in ignorance of what Joly and others had previously done, he had prepared from the negative made through the screen a positive transparency, binding this up in register with the original taking screen. He still thought that this method, on account of the ease of preparing a number of duplicates, was the best form of screen-plate colour work, though he exhibited one or two results made on the Thames combined plate—that is, with the emulsion coated on the filter-screen. He thought it was due to the Thames Company to emphasise the very great improvement which they had made in the screen of later manufacture. Those first issued were not really fit for the market, but in regularity and colour great strides had been made by the makers, and he found that for studio portraiture he could take the plate as having the rapidity of 40 H. and D., which allowed of portraits in the studio being made with an exposure of 4 or 5 seconds at f/4.5. He exhibited several excellent colour portraits made in this way on the Thames plate by the separate system, and pointed out the great opportunity which this form of the process offered in

controlling or improving the result attained in the negative when printing the positive transparency. He had not found any difficulty in registration, and had, in fact, registered one transparency whilst travelling to the lecture that evening in a South-Eastern train.

In the discussion which followed Mr. Atkinson drew attention to the value of the yellow dye—such as tartrazine—for correcting the blueness of Autochromes which had received too much exposure or for which an inadequate compensating filter had been used.

Mr. E. J. Wall said he found it difficult to find in his own mind a reason for the better colour values of the Thames plate as compared with the Autochrome.

Mr. F. C. Tilney asked whether there was any reason to suppose that the tonal colour values of the Thames plates which had been shown were better than those of the Autochrome. He had no doubt in his own mind that the Autochromes were immeasurably superior to the Thames, and, speaking as a non-technical person, he would like to hear Mr. Wall's opinion of the two.

Mr. Wall replied that Mr. Tilney was an artist, and he (Mr. Wall) never argued with artists.

Mr. Oliver Dawson on this point said that possibly the answer was to be found in the fact that exposures made in daylight were exhibited by artificial light. He went on to say that the great want in screen-plate photography was a means of determining the exposure which went further than the ordinary exposure meters.

Mr. W. A. Casson referred to the very long exposures required in making Autochromes of interiors: for these subjects he found it best to use a diluted developer.

With Mr. Corke's replies to these and several points which were raised by other members the meeting closed.

LONDON AND COMMERCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held on December 2, Mr. Haddon in the chair. Mr. W. F. Marshall demonstrated "Ensyna," and in the course of his remarks said that if a colder tone was required, all that need be done was to add a few drops of a weak solution of potass bichromate to the soaking water prior to development, until the water was faintly tinged yellow. Development was done as usual. Over-developed prints should be bleached in potass ferricyanide and potass bromide and re-developed. For bright red tones in place of plain water it was well to use a saturated solution of plain alum for the soaking water, and give plenty of exposure; the longer the exposure the redder the tone, the resulting image was in all cases pure metallic silver.

MIDLOTHIAN PHOTOGRAPHIC ASSOCIATION.—At a meeting held on the 2nd inst an illustrated lecture, entitled "A Midlothian Burn," was given by two of the members, Mr. John Reid and Mr. R. M. Readdie. By word and picture the course of the Gogas Burn was traced from its source in the moorland of the hills down the open slopes and through the tree-clad dells to the pasture lands and the noble estates of Midlothian, till it met the Almond Water. The illustrations gave evidence of careful selection, both with regard to pictorial effect and the varied character of the scenery through which the charm of the stream has carried these two devotees of the camera. To those were added notes on the historic associations of the neighbourhood, and on the more fleeting beauties of the flowers and birds in their haunts by the stream which showed how the labours of photography could be lightened. Every season had afforded opportunity for the work, and there was accordingly a delightful variety of spring sunshine and autumn haze, the strong lights of summer and the whiteness of winter. In conveying to the lecturers the thanks of the appreciated audience, the president, Mr. J. B. Johnston, recommended the members to adopt such a plan for their photographic work, and in his acknowledgment Mr. Readdie dwelt on the pleasure and value to his friend and himself of the work they had undertaken.

WELLCOME PHOTOGRAPHIC CLUB.

An excellent little exhibition of photographs by members of the Wellcome Photographic Club was opened at the Wellcome Club and Institute, Dartford, on Saturday, the 4th inst., by Mr. G. E. Pearson, general manager of the firm of Burroughs Wellcome and Co. The chairman of the club opened the proceedings by extending on behalf of the club a cordial welcome to Mr. Pearson and their

visitors. He further expressed his appreciation of the favour which Mr. Mortimer, the editor of the "Amateur Photographer," conferred upon the club by coming down to act as judge. Mr. Mortimer said that as a members' exhibition it was excellent, and it was very encouraging to see so many members of the staff taking an active interest in photography as a hobby, particularly when there was such a variety of other enjoyments and recreations available for the members of the Wellcome Club and Institute.

Mr. Pearson, in opening the exhibition, referred to the origin of the club in 1900, which, he explained, was entirely due to the kindness of Mr. Wellcome, who provided the dark-rooms and equipment for the use of members. From a membership of twenty-two it had now increased to fifty. The present was the eighth exhibition which had been held, and, in the opinion of visitors and the Press, these exhibitions had been marked by steady improvement in the work shown. Dr. Jowett proposed a vote of thanks to Mr. Pearson for his kindness in coming down to open the exhibition. This was carried with applause.

AWARDS.

CLASS A (open to all members).—Bronze casket (presented by Mr. G. E. Pearson), "Portrait," by H. W. Lane. Second award: "The New Bailey," by G. T. Gale. Hon. Mention: "Trafalgar Square," by E. G. Price; "Ebb Tide," by W. H. Fowkes; "The Mermaid," by F. H. Carr; "Evening," by F. S. Clarke; "Winter," by W. H. Fowkes; "View from Lyme," by F. C. Starnes.

CLASS B (open only to members who have not previously won awards).—1st, bronze plaque (presented by Dr. H. A. D. Jowett), "Homeward," by R. G. R. Swainston. 2nd, bronze plaque, "Taking the Air," by F. H. Carr. Hon. Mention: "San Mamette, Lake Lugano," by H. C. Sayer; "Gathering Wild Flowers," by C. I. Pearsall; "Dartford Heath," by R. E. Jackson; "To the Golden Sands," by F. H. Carr; "Santa Maria dell Salute," by H. C. Sayer; "Sunrise, Brent," by C. I. Pearsall.

TECHNICAL SECTION.—Award: H. G. Sayer. Hon. Mention: G. G. Watt.

News and Notes.

THE LATE MR. WM. WARRINGTON.—We regret to record the death, at the comparatively early age of 37, of Mr. Wm. Warrington, who carried on a business at 38, Church Street, Liverpool.

A DEALER'S ADVERTISEMENT.—A very effective scheme for advertising a newly installed photographic department (writes "System") was employed by the Raboteau Drug Company, St. Louis. With every film purchased on a certain Saturday the firm gave a ticket entitling the holder to have a roll of films developed and one print made from each negative, provided the film was presented within a week from the date of purchase. This offer brought crowds of amateur photographers to the store and the new department was thoroughly advertised. The free service cost the company very little, as it employed a photographer regularly, and the plan simply kept the developing department busy.

THE HOUGHTON SMOKER.—Messrs. Houghtons Ltd. announce their annual "Ensign" smoking concert, to take place on Saturday, December 18, in the Prince's Hall, Hotel Cecil. A fine programme has been arranged under the direction of Mr. Phil Payne, and several star artistes will appear, including Mr. Charles Pond, Miss Clarice Mayne, Miss Mabel Green, Miss Ruby Wilson, Mr. Will Edwards, Mr. John Vincent, Mr. Clifford Morgan, Mr. Harry Hall, Mr. George Blackmore, and Mr. Frederick Arthur. Applications for tickets (2s.) should be made to the Secretary, 88/89, High Holborn, W.C.

ROYAL INSTITUTION LECTURES.—The following are the lecture arrangements at the Royal Institution, before Easter:—Mr. W. Duddell, a Christmas course of six illustrated lectures on "Modern Electricity," adapted to a juvenile auditory:—1, First Principles; 2, Electrical Instruments; 3, Röntgen Rays; 4, The Generation of Electricity; 5, Electric Oscillations; 6, Electric Lighting; Professor W. A. Herdman, three lectures on "The Cultivation of the Sea"; Rev. C. H. W. Johns two lectures on "Assyriology"; Professor F. W. Mott, Fullerian Professor of Physiology, R.I., six lectures on "The Emotions and their Expression"; Major Martin Hume, two lectures on "Europe's Debt to Mediæval Spain"; Professor Silvanus

P. Thompson, three lectures on "Illumination, Natural and Artificial"; Mr. A. J. Finberg, two lectures on "Turner"; Dr. H. Walford Davies, three lectures on "Music in Relation to other Arts"; Professor Sir J. J. Thomson, Professor of Natural Philosophy, R.I., six lectures on "Electric Waves and the Electromagnetic Theory of Light." The Friday evening meetings will commence on January 21, when Professor Sir James Dewar will deliver a discourse on "Light Reactions at Low Temperatures."

THE CROWN PHOTOGRAPHIC MANUFACTORY of Rotherham ask us to state that they have received two applications from a Mr. H. Culliford—dated November 18 and December 3, respectively—asking for a copy of the firm's price list of Christmas mounts, but in neither case has any address been given. If Mr. Culliford will rectify this omission and send his address to the Crown Photographic Company the required list will be forwarded to him by return of post.

THE members of the Tunbridge Wells Amateur Photographic Society recently presented Mr. Joseph Chamberlain, the late secretary, with a handsome clock, as a mark of their appreciation of the valuable work he had done for the society during the twenty-one years of its existence.

FORTHCOMING EXHIBITIONS.

December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.

December 15 to 16.—Cowes Camera Club. Sec., E. E. Vincent, 4, High Street, Cowes, I.W.

December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1910.

January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.

April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

MEASURING VARIATIONS IN THE "RAPIDITY" OF LENSES.

To the Editors.

Gentlemen,—I am much pleased to see your suggestion on p. 930 "The British Journal of Photography" for December 3, 1909. As regards the desirability of measurement rather than an all-round estimate there can be no two opinions, especially as the measurement should include all those disturbing factors to which you refer. I cannot think of any method of testing better than that which you suggest ("B.J.," December 3, 1909, p. 930-1), and the method at I have experimented with involves a somewhat similar principle, but my radiant was a large surface, rather than one so small that in theory it should be a point. The lens was directed towards an evenly illuminated surface, and an exposure was made; a second exposure being made after the removal of the glass or glasses. According to circumstances, one or both of the following readjustments may be necessary after removing the glass or glasses. Alteration of the diaphragm from its actual size to its virtual size. Approximation of the illuminated surface, and the sensitive surface to a distance equal to the separation of the principal planes of the lens. Further, when lenses of different type are compared, considerable corrections or readjustments may be required. This method of testing did not prove by any means satisfactory in practice as a means of record, the only real success being when comparative experiments were made in immediate succession, with a constant source of light, and when all exposures were on different parts of the same plate, so that development conditions were identical.

Complications and sources of error arising from the chemical or physical conditions incident to the production of density, and from

the measurement of density, are by no means trifling; but the variations which may arise from more or less of the highly actinic elements in the light are of much more moment, and the colour-sensitiveness of the recording surface has a considerable influence. All ordinary glasses in their absorption discriminate unfavourably against the more actinic rays, and as the method of testing that is now under consideration allows of no distinction between loss by absorption and loss by reflection, widely different readings are obtained with the same lens by standard-candle light, on the one hand, and mid-day light on the other hand.

A quite extreme difference might be expected between a measurement made by the light of an ultraviolet (quartz mercurial) electric lamp and a determination by standard-candle light.

Should we ever arrive at fluor spar-quartz-rock salt lenses for ordinary use the issues may be somewhat simpler; but alas! such lenses as at present made lack stability sadly; still it has sometimes occurred to me that the City process worker might with advantage use such lenses in conjunction with the quartz mercurial lamp, and special plates for ultra-violet—such plates as were suggested some seventeen years ago by Dr. Schumann. Possibly a system of this kind might make it quite easy to cinematograph at night.

The subject of testing lenses for rapidity bristles with difficulties and complications, and there is much merit in the simple test mentioned by the late J. Traill Taylor in his chapter on "The Deterioration of Lenses by Light" (Optics of Photography, 1892 edition, pp. 158 to 164). In a good light the lens is placed on white paper and inspected. If a random assortment of lenses be thus examined, the difference in colour and brilliancy may surprise the observer.

Yours faithfully,

THOMAS BOLAS

Chiswick,

December 4, 1909.

THE "B.J." PYRO-SODA FORMULA

To the Editors.

Gentlemen,—The Almanac has appeared (as probably you are aware), and I send you my congratulations on it. On looking through its pages I was particularly glad to notice that you had included in the Selected Formulae the pyro-soda formula you first published in the "Colonial Number" of this Journal last April. As I have always been very keen on this form of developer, and have never lost an opportunity of trying any formula that appeared distinctive, I made yours up the day the "Journal" came to hand, and after using it for six or seven months I have no hesitation in saying that it is the best and most convenient formula ever published for a pyro-soda developer, and I have tried them all.

For landscape and architectural work I use one part of mixed developer with two parts of water; for reproduction of negatives, one part of mixed developer and one part of water; for black and white copies, equal parts of the stock solutions. The freedom from staining is really quite remarkable, and its keeping qualities are excellent, as you will see from the sample sent, which is part of the pyrogallol solution made up last April. Those who, like myself, have a predilection for pyro-soda as a developer must certainly feel indebted to you for originating a most satisfactory formula, and I suggest that it be called the "B.J." formula, or, as Imperialism is now so much in the air, "The Colonial."—I am, yours faithfully,

Sidmouth, S. Devon.

G. T. HARRIS.

REVERSAL BY PHOSPHORESCENCE.

To the Editors.

Gentlemen,—Mr. Welborne Piper's interesting note on the late Mr. Douglas Carnegie's experiments on the above subject winds up with a question as to its novelty, and also as to the extinction of phosphorescence by red light. In the face of this, possibly the following notes abstracted from Eder's Photochemie, chap. 30, pp. 447-455, may be of interest.

Seebeck, in 1810, discovered the extinction effect of the less refrangible rays, which include the yellow and orange, besides the red. This was also pointed out as regards yellow glass in Polytechn. Notizblatt, 1881, p. 305. Becquerel (compl. rend., 1884, vol. 94, p. 374) used this property for obtaining spectrograms of the infrared. This action was also pointed out by Dahms (Chem. Zentralbl., 1905, I., p. 1,054).

With regard to the obtaining of reversed negatives, Warnerke described a process in a letter to the Photographic Society of Great

Britain, April meeting, 1880. No doubt this is printed in the Journal, and quite possibly in the "B.J.," but I have not at the moment the opportunity of referring to either. It appeared in the "Photo. News," 1880, p. 257. Lieutenant Darwin also reports on similar experiments ("Photo. News," 1880, p. 262), as did also Vincent ("P.N.," 1881), and Zenger ("Annal. d. Physik," 1887, p. 94).

Warnerke suspended calcium sulphide in albumen, and coated glass therewith, exposed it for one minute in the camera, and obtained a reversed negative by placing in contact with a dry plate. He points out that heat increases the luminescence, and that red and green light destroyed it. The phosphorescent plate is to be exposed also to light so as to excite the whole of its surface, then placed in contact with a negative and a plate of glass of the extinguishing colour and exposed to light; there is thus obtained a luminous positive image.

Ives ("Philadelphia Phot.," 1887, p. 180) obtained positive pictures by extinguishing the luminescence of a phosphorescent plate by the heat rays alone, such as would be passed by black glass and printing from the luminous tablet by contact. Lime-light was used as the source of heat.

According to Abney (Colour Measurement and Mixture, 1891, pp. 32-34) it has been asserted that, if a luminous tablet be excited generally, and a spectrum allowed to fall on the same, and then cut off so as only to act for a short time, the red and infra-red rays increase the brightness of the luminescence, although if allowed to act longer there is extinction. This he explains by the familiar experiment of placing a hot iron on the back of a luminous tablet, with consequent increase of radiation, so that the image of the iron appears brighter than the general surface. As the luminescence is merely the giving out again of energy, which has been imparted by light, it is obvious that the more rapidly that energy is given out the shorter the duration of the radiation, hence the image of the iron eventually appears darker than the general surface. Obviously, on the face of this explanation, any terms such as "extinction" or "destruction" of the primary light action are not quite correct.—Yours faithfully,
E. J. WALL.
Ealing, W.

THE MAKING OF A PHOTO-BUTTON.

To the Editors.

Gentlemen,—As "photo-buttons" will be much in evidence at the approaching General Election, perhaps the following details of production might be of interest to the uninitiated. As we make our own parts, it takes twenty-four distinct operations to produce a "photo-button" as follows:—

1. Cutting of steel sheets into strips for shells.
2. Stamping out blanks for shells.
3. Shaping blanks into shells.
4. Rumbling off rough edges of shells.
5. Cutting tin sheets into strips for backs.
6. Stamping out blanks for backs.
7. Shaping blanks into backs.
8. Stamping out centres of backs.
9. Titling and preparing original for copying.
10. Exposing plate for making negative.
11. Developing exposed plate.
12. Fixing plate.
13. Washing plate.
14. Printing from negative.
15. Toning print.
16. Fixing print.
17. Washing print.
18. Uniting print to celluloid.
19. Stamping out to correct gauge
20. Stretching over shell in press.
21. Closing shell over back in press.
22. Inserting advertisement at back.
23. Inserting pin.
24. Counting, carding, packing, and despatching,

thus completing an article which sells to the trade for ½d. and under, yet we are invariably asked whether we cannot do them cheaper.—
Yours truly,
DORRETT AND MARTIN.
16, Belle Vue Road, Upper Tooting, S.W.

A HANDY FORM OF FOCUSING SCREEN.

To the Editors.

Gentlemen,—The demand for critical focussing in connection with the use of lenses of large aperture, coupled with the necessity of carrying a screen separate from the camera of a none too portable

and fragile nature, prompted the writer to adopt the form described later, which may prove welcome to the many users of the "A" pattern Mackenzie-Wishart slide.

First, cut a piece of finely ground glass to the size of the plate in use, and insert it as one would a dry plate, cut through the linen envelope and celluloid back, leaving a margin sufficient to stick the edges down with any form of glue; remove the strip of wood attached to cover. This will form a screen of the exact register as the dry plate, and easily carried and protected with the envelopes in the same case.—Yours truly,
R. C. RYAN.
Bream's Buildings, London, E.C

AMADOU.

To the Editors.

Gentlemen,—In the "Answers to Correspondents," in this week's "B.J.," I notice "N. Enlargers" ask where they can purchase some "Amardor."

I fancy they mean "Amadou," which I understand is a dried fungus. It is probably obtainable from most large dealers in artists' materials, and is certainly listed by the Army and Navy Stores at 11d. an ounce.—Yours faithfully,
L. SAVORY.

51, Horsford Road, Brixton, S.W.

December 3, 1909.

To the Editors.

Gentlemen,—What your correspondents want is probably "Amadou," or German tinder, a prepared velvety surface fungus, sometimes used as a "stump" in pastel and charcoal drawing. Try Winsor and Newton's.
W. B. FERGUSON.

Answers to Correspondents.

** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co. 24, Wellington Street, Strand, London, W.C.

** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C. undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form etc. Two unmounted copies of each photograph must be sent with the fee.

LAMP.—The arc lamps you mention were made from 15 to 20 years ago, and it is very improbable that you would find them at a suitable for instantaneous portraiture. Most probably the lamp would not be in a very good condition, and the advances made since they were placed on the market are so great that you would be seriously handicapping yourself by using lamps of an obsolete type. We should have no hesitation in saying that the actinic power—as we understand actinic power to-day—would be distinct low.

GOVERNMENT PHOTOGRAPHER.—Could you please let me know in your next issue how to become a Government photographer, and what qualifications are necessary? Trusting you can give me the required information, and oblige—A YOUNG READER.

What do you mean? So far as we know, appointments of photographers are not filled from those outside the Civil Service. Your query is too general for us to say more than this.

PRESS PHOTOGRAPHY.—1. What is the quickest method of developing plates and getting glazed gaslight prints from same? 2. Is it possible to take photographs here in the afternoon and get printed in London in time for publishing in the papers next morning? What is the best way of glazing prints so that they dry quickly?

—C. E. B.

1 and 2. By adopting the ordinary methods of printing from a wet negative and drying prints with spirit, you could usually have

photographs ready for despatch within an hour of getting into the dark-room; but, as a general rule, your results could not get to London in time for use in the next day's morning papers. 3. Squeegee on to glass and put to dry in a warm place. If prints are hardened with alum or formaline before putting on the glasses a degree of warmth can be used such that they will dry and strip off in half an hour.

L. SAVORY.—We are much obliged to you for your letter, and for your correction, which latter is deserved.

RIGHT TO NAME.—I should be glad if you would kindly give me some advice regarding the following particulars:—I am going into partnership, and we desire to have the name of the studio as, viz., "The Globe Photo Co." Is it a registered name, and can we use it without any action being taken against us?—**J. P. JEFFERSON.**

So far as we are aware there is no registered company under that title. There will be no objection to the use of the name supposing there is not a similar title to a studio in your town.

STOPPING OUT SUN.—I should be glad if you could tell me a way of stopping out direct sunlight on a west sidelight. A room which I am thinking to convert into a studio must have the light that side. There are no buildings which might shade it; all on that side is a large open space. Could I so arrange screens inside to prevent, or would to stipple the glass with starch (as mentioned in "B.J.," March 21) be best?—**LYNDO.**

With a west light you are not likely to be very much troubled with the sun. When troublesome, it may be stopped out with a large movable screen, covered with thin muslin, or permanently by stippling over the glass in the way given in the article referred to. The former way will be the preferable, as the screen need only be used as occasion may require.

PRINT CLEANING.—Some little time ago you published in the B.J. some very useful instructions for cleaning old and stained engravings. Presumably the treatment prescribed might be detrimental to coloured prints. If you could give further instructions for the proper method of cleaning valuable old coloured prints the information would be much appreciated.—**WALTER BOURKE.**

The method given would certainly disturb the colour, supposing the prints are coloured with water colours, and if the engravings are printed in colours it is possible that the bleaching action of the chlorine might have some influence on them. The best advice we can give you, as the engravings are valuable, is to put them in the hands of a professional print-restorer to do the work for you. It is not advisable to tamper with valuable pictures.

BIG ENLARGEMENTS.—1. It is not absolutely necessary. If washing is omitted we advise you to add $\frac{1}{2}$ oz. of potass metabisulphite to each pint of fixing bath, as a remedy against stains. 2. In the case of a few enlargements we suggested a pair of boards, each about 30 by 40, placed supporting each other like a roof of a house and with a water-supply pipe (perforated) on each side running along the ridge. A stream of water running over the prints for half an hour will be ample washing. If the number is greater than this method will allow, we can only suggest the use of a large wooden dish, with glass bottom. 3 and 4. Hang up in the usual way, but do not let them become bone-dry; whilst still a little damp they can be easily put under pressure and will then dry flat easily. 5. The best solution for removal of stain is very weak solution of iodine and potass cyanide. This is a reducer, will clear the white parts perfectly, but must be used with care, and not until it has been tried on a spoilt print. 6. Yes; a diluted developer applied with a good big scrap of cotton wool or a soft Turkey sponge would answer. For this purpose we should prefer a metol developer to one containing hydroquinone, as density is not reached so quickly, and the work is under better control.

E. F. RICKARDS.—No doubt any of the photographers who have negatives of marine subjects can supply you. Try a firm such as West, of Southsea, explaining your wants.

PRINTING IN SIGNATURE.—I should be very much obliged to you if you will give me a few hints as regards titling and initialling, or signing prints. If ink is used it looks so very black and prominent; on glossy paper it looks hideous, and on a lightly-printed bromide most obtrusive. Then on some mounts—certainly on the majority

of those I use—ink runs, and looks very bad. I am not clever enough to paint anything on with a brush, as I believe is done by artists, and I should be very glad to know if there is anything else I could use, more artistic than ink, and that would lend itself to harmonise better with the colour of the mount or of the print.—**H. M. S.**

We should advise you to write to the Autotype Co., who prepare film signature negatives, which can be obtained to print of depth suitable for any given class of print.

JOURNAL, ETC.—1. Is there any journal or periodical giving information to artists like the "British Journal" does for photographers? 2. I would like to colour enlargements in oil or water. Am I obliged to join some society before I can work in the trade?—(Miss) **L. BALL.**

1. The art publications rarely deal with technical matters of interest to artists. The best source of such information is the series of text books such as those issued by Geo. Rowney and Co. 2. No; certainly not. 3. Certainly; we will gladly give you our opinion on work for the trade in the way of working up colouring.

METOL DEVELOPER.—Please inform me, through the "B.J.," how I could make a metol developer up without it precipitating when I add the sulphite, etc. I generally dissolve metol first, then add sulphite, and it curdles to a grey curdle and does not keep. The formula is:—Metol, 75grs.; soda sulphite, 1 $\frac{1}{2}$ ozs.; soda carbonate, 1 $\frac{3}{4}$ ozs.; potass bromide, 8grs.; and water 4ozs. I use everything pure and clean. Could you give me a remedy?—**METOL OAKHAM.**

You are apparently using too little water, 4ozs. is not enough to keep all the ingredients in solution. Your formula is generally made up to a quantity of 10ozs.

VARIOUS.—1. Please tell me the percentage composition of "bisulphite solution" referred to in the "Almanac." Is this the same as "bisulphite lye"? 2. Please give a formula for coating paper with gum and pigments to be sensitised at some future date, similar to the commercial papers.—**J. P. O'HEA.**

1. Yes; it is equivalent to a 40 per cent. solution of sodium bisulphite. 2. We cannot give you the commercial formulæ, and can only suggest that you use the ordinary formulæ, omitting the bichromate. You can then sensitise at a later date by applying the bichromate solution.

FIXED FOCUS ENLARGER.—I am desirous of making a fixed focus enlarger, $\frac{1}{4}$ to $\frac{1}{2}$ -plate, and should like to know if a Lancaster lens ($\frac{1}{4}$ -plate) will serve the purpose; also what length the box should be, and how to find out the distance between negative and lens.—**A. J. B.**

Quite impossible for us to answer your query in the form you state it. If (as we can only guess from what you say) you wish to enlarge from $\frac{1}{4}$ to $\frac{1}{2}$ -plate, and if your lens has a focal length of 5 inches, then the distances either side of the stop of the lens will be about 12 $\frac{1}{2}$ and 8 $\frac{1}{4}$ inches respectively. But until you have verified the focal length of your lens you must not take these figures, since the focal length may be 4 $\frac{1}{2}$ or 5 $\frac{1}{2}$ inches. The rule for finding the above distances is as follows:—Distance from lens to paper = focal length \times degree of enlargement (1 $\frac{1}{2}$ in case of $\frac{1}{4}$ to $\frac{1}{2}$ -plate) plus the focal length. Distance from lens to negative = focal length divided by 1 $\frac{1}{2}$, plus again one focal length.

STRIPPING NEGATIVES.—Some time ago a very good formula appeared in the "B.J." for stripping negatives from glass for storing purposes without the use of hydrofluoric acid. Will you kindly reprint it, and oblige?—**L. A. GORDON.**

We think you must refer to an article which appeared in "Photography," February 4, 1908, p. 100, and an abridgement of which was given in the "B.J. Almanac," 1909, p. 588. A later article appeared in our pages for September 10 last, but is too long for quotation here.

COPYRIGHT.—We have two registered photographs, which a trade paper (copy sent herewith) has reproduced without any permission or pay for same, the prints being bought in the shop in the ordinary way of sale. We, on learning they had reproduced them, placed the matter in the hands of a local solicitor, and, after a few letters had passed between them, the firm offered £5 in full settlement. But we do not think this amount meets the case, as we had anticipated advertising these photographs, and thought we should have a great sale for them, but as they appeared in this paper

we did not go on with it, as we consider the interest gone. Now our solicitor tells us to take it into court; we must prove what we have lost in sales, which we consider a difficult point to prove, for by doing the way we had intended might have been a very large one, or the opposite, so that to prove a loss this way is, as we say, difficult. So before moving further in the matter we thought we would ask your advice. We may say in conclusion the prints were sold at 2s. each, and by buying this paper they got the lot for 3d., as you will see.—X. Y. Z.

Certainly, if you claim damages, you must be prepared to prove them. You will most likely be asked to produce evidence of having in previous instances made profits by publication of similar photographs. In this particular instance we imagine you will not find it easy to prove great damage, as from the journal it is evident that several other photographs of the event were taken. Yours was not the only one. We should feel inclined to accept the offer, which for a case of ordinary infringement is reasonable.

POSTCARD JOURNAL.—I remember about twelve months ago getting a monthly or quarterly trade paper dealing with postcards. It is mentioned in 1s. book on "Postcards" by H. Snowden Ward. I have mislaid the book. Will you kindly let me know where I can get it, and its title?—D. J. DAVIES.

"The Postcard Collector," as it was formerly called, is no longer issued separately. We believe it appears as a supplement to "Stationery Trades' Journal," published at 11, Warwick Lane, E.C.

STUDIO QUERY.—Nearly eighteen years ago I started business in this town, and some few years after I built a new studio here, on a fifteen years' lease, which is now almost at a close, and as the proprietor now proposes to take re-possession of the premises I occupy, to safeguard my position I have purchased a property in an adjoining town in the main street, to which I propose removing, after building a new studio there. My difficulty is that nearly all the feus in this particular street are only 25ft. wide, although extending back for upwards of 162ft. in the case of my own particular property; but the exposure necessitates building on the width of the feu to obtain a N.E. light. Would you advise me to obtain lenses of short focus, to use on a working length of only 24ft., which will be the absolute maximum working length, or would you suggest the building of a tunnel studio, which would enable me to use longer focus lenses? My present studio was built fourteen years ago, and cost me almost £300, and is 36ft. by 15½ft. floor space, and, as you can understand, I fear I shall feel very much cramped in working in a room only 24ft. long. Undoubtedly there are very many studios of no greater length than 24ft., but I feel rather undecided as to the best course to pursue.

Here I have had my studio entirely glazed with obscured glass, and I think that by glazing with clear glass the exposures might be much more rapid, but there is the disadvantage of being overlooked by the tenant in the house above the shop on the street frontage. No doubt you may think it is a curious request on the part of a practical photographer to put such a series of questions, but I am anxious to have a technical opinion from a reliable source, and to consider it in conjunction with my own before going on with the building and alterations.—W. J. S.

In all the circumstances we think you will do well to put up with the 25ft. studio. You will require lenses of shorter focus than you employed in the studio you are relinquishing, but use the longest that circumstances will allow, so as to get as far away from the sitter as possible. If the place is glazed with fluted glass instead of plain, neighbours cannot see through, and but little light will be obstructed.

COPY OF PAINTING.—Some time ago I received permission to copy an oil painting from an original by a living artist, which was exhibited in a public art gallery. A friend of mine is anxious to purchase the copy which I painted. Can I do so without being liable to a penalty legally? The Curator of the gallery gave me permission to copy the original only for study purposes, but hinted that no business was to be made with the same. I should be very thankful if you would please inform me whether I can sell the copy as such with safety.—A. A. GITTLESON.

We should say that if there is still copyright in the painting—and there probably is, as the artist is alive—you have no right to

issue copies. It is a moot point, but we expect the rights of the matter are based on the law of contract, not of copyright. Apparently you were granted permission to make one copy for your own use, nothing more than that.

ELECTRIC LIGHT IN STUDIO.—I have taken a shop with premises at the back, which I hope to turn into a studio, and would be glad of your advice as to the lighting of same. The premises are 25ft. by 11ft., and I want 18ft. by 11ft. for studio. I have a light in the roof 5ft. by 4ft., also windows in end of building. The ceiling is about 14ft. high, and the room seems very light, but I wish to put in electric light. I have two good arc lamps, and would like to know the best position for them. I enclose a rough sketch of the room, so will you please state if one lamp is required or two, and the distance from sitter, also height from the floor for fixing lamps?—H. C.

We should advise the use of the two lamps, the one to soften the shadows cast by the other. The one for the dominant light may be placed at the side and a little before the sitter, so that the light falls upon him at about the angle of 45 degrees. One lamp, the chief one, may be, for a sitting figure, about 8ft. 6in. or 9ft. from the floor. The other lamp may be placed on the opposite side, and at a greater distance from, and more in front of, the sitter. A few experiments will show you the best position of the lights to get different effects in the lighting.

LENSIST.—The orthoscopic lens by Voigtländer is a very good lens for the time it was introduced—now more than fifty years ago. It was eclipsed by the triplet, afterwards by the R.R., and later by the anastigmats. It has practically, at the present time, no market value. If you advertise it at the price you mention it is very unlikely that you will get a purchaser of it. Indeed, we should doubt if it would sell at a tenth of the sum you name, for it is quite an obsolete form of lens.

A. P.—Glucose may be had from any operative chemist, and when obtained from such a source it may be relied upon for the powder process. Glucose in the form of syrup is much used by confectioners, and is an important commercial article, but it is not to be recommended for photographic purposes.

THOS. WAKELEY.—1. Undoubtedly a good R.R. lens to cover the half-plate size may be had for fifty shillings, but you will have to make your own selection, as it is strictly against our rule to recommend any particular maker or dealer's goods. If you get the instrument from a good house you may rely upon getting value for your money. 2. Tank development can certainly be recommended to amateur photographers. 3. We have not used the apparatus ourselves, but we have heard it well spoken of by those who have.

R. A. C.—A village druggist is not the best source from which to obtain photographic chemicals, particularly those which deteriorate by keeping, such as sulphite of soda, liver of sulphur, etc. The village druggist naturally has but a slow sale, and the goods often remain a long time in stock. It will be better for you in future to draw your supplies from a regular photographic dealer in some large town. We have little doubt that your stained negatives arise from the use of an unsuitable sulphite of soda—one that has suffered from long keeping and exposure to the air.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

SUMMARY.

Mr. D. Berlin, in experiments on flash powders, has found that the shape of the tray exerts more effect on the flash than so-called "spreaders." (P. 967.)

Stereoscopic Portraiture, Colour in the Stereoscope, Reversal by Phosphorescence, Carbon Printing in Winter, Production of Photo-Buttons are among the topics discussed under "Correspondence." (P. 980.)

In some notes on page 966 photographers are reminded of a few of the regulations as to the carriage of parcels, attention to which is more necessary than usual at this time of year.

A species of heartless fraud, which apparently has been going on for many years, would appear to have been brought to an end at the London Sheriff's Court last week. (P. 973.)

A practical point in trimming a number of prints from one negative, so as to include the same amount of subject in each, is mentioned on page 966.

Some simple geometrical rules of occasional service are given on page 971.

Still another film-pack patent, and the use of a tube railway as a cinematograph, appear under "Patents of the Week." (P. 975.)

At the annual general meeting of Ilford Limited, the chairman addressed the shareholders on the improved condition of the company, and the directors' recommendation of a 6 per cent. dividend was adopted. (P. 973.)

There seems a call for definiteness in describing enlarger movements. (P. 966.)

The inaugural address recently delivered by Professor Sylvanus Thompson, before the Society of Illuminating Engineers dwelt upon a number of points likely to become of photographic importance. An abridgment of the address appears on page 969.

Under "Photo-Mechanical Notes" we review Messrs. Penrose's "Year-Book," just published, and refer to several other process matters. (P. 974.)

In some notes on the economics of preserving sulphite solution, attention is called to the advantageous use of hydroquinone for this purpose. The cost of preserving one pennyworth of sulphite by a method which has been recommended is sixpence. (P. 965.)

EX CATHEDRA.

The Chemistry of Sulphite.

The mere fact that hydroquinone and other developers act as preservatives of soda sulphite is sufficient to disprove the old theory that sulphite preserves a developer by using up the oxygen that would otherwise attack it. This theory dies hard, for it still often appears in modern textbooks and articles, even though it is some time since its fallacious nature was made clear. Evidently the action is not so simple, and we have yet to understand why two readily oxidisable substances when brought together seem to preserve each other from oxidation. The whole subject is very obscure, for, in spite of the amount of research that has been devoted to the subject of sulphites, we do not as yet comprehend how they deteriorate. It is repeatedly stated in textbooks, photographic ones especially, that sodium sulphite oxidises to sulphate, but this is not strictly correct. The sulphite eventually reaches the state of sulphate, it is true, but it does not do so directly, excepting under very special conditions. It appears that the precise series of changes that it undergoes depends to some extent on the rate of oxidation, and upon the amount of oxygen present. Apparently before the state of sulphate is reached dithionates, trithionates, and various other thio compounds may be formed, while sulphur, sulphides or thiosulphates, and oxides are possibilities. Careful titrations of a sample of sulphite made at frequent intervals during its slow decomposition show various anomalies that can only be accounted for by assuming the formation of various temporary decomposition products that affect the titration. For one thing, the formation of an acid is always strongly suggested. In these circumstances, it is very difficult to prophesy what will happen when other substances are added. We cannot say whether they will assist or retard any of the unknown intermediate reactions, and therefore cannot say what their effect will be on the general progress of decomposition. There is a fine field of research here for anyone with the time and inclination to enter it, but it will not be an easy one to explore.

* * *

The Preservation of Sulphite.

We see that Dr. J. H. Wigner, in one of our contemporaries, in dealing with the matter of the preservation of soda sulphite, describes some experiments of his own upon the action of mannite, and comes to the same conclusion as we did some time ago, namely, that it is practically useless as a preservative. He found that it reached oxidation but did not prevent it. One per cent. of mannite in a five per cent. solution of sulphite had only a slight effect, and it is evident that with sulphite at sixpence per pound, and mannite at something like nine shillings per pound, the game is not worth the candle. His experiments with hydroquinone as the preservative gave, however, very dif-

ferent results, and he appears to have found, as others have also done, that this is a most excellent preservative. A five per cent. solution of sulphite kept well with the addition of one-twentieth per cent. of hydroquinone, so that one part of the latter compound sufficed for 100 parts of sulphite. The cost of preservation in this case is very different, for, in round figures, we may say that one pennyworth of hydroquinone will preserve six pennyworth of sulphite, whereas in some old experiments of our own we found that about six pennyworth of mannite was required to preserve only one pennyworth of sulphite, and even then the advantage was not very substantial. It would seem that before adding the hydroquinone it would be just as well to dispose of any carbonate existing in the sulphite by adding an acid, sulphuric, for example, until the solution is neutral to phenolphthalein. The carbonate can do no good, and it is quite possible that the hydroquinone will be even more efficient in the absence of any alkaline salt.

* * *

Description of Enlarger Movements.

The movements of enlargers now almost rivalling those of a field camera, it seems a pity that some short and descriptive phrase cannot be uniformly adopted for each of them with a view to shortening catalogue and other specifications. The part of the apparatus to which different, and in some cases contradictory, terms are applied is the negative stage in which, at the present time, three distinct movements are usually embodied, namely, one straight up and down of the negative, a rotating movement of the negative, and again a swing movement by which the negative is placed at an angle, other than a right-angle, with the optical axis of the lens. We think much confusion would be saved if the usual terms applied to the back and front of a camera were used in describing these movements of an enlarger, since everybody would know what they mean. Hence we might speak of a negative stage with "rise and fall," "rotating," and "swing" movements. In a recent admirable article on enlargers in the "Times," the writer uses the word "tilt" to describe the rotating movement of the negative in an enlarger stage, a phrase which we are afraid most people would take to mean the swing movement above referred to.

* * *

Trimming Prints,

Where a number of prints from a single negative are all required to be trimmed down as closely identical with each other as possible, the use of a trimming shape and a knife calls for the separate adjustment of each edge of each print when making the cuts. A ready means of getting over this difficulty is to make use of the ingenious "Maitland" trimming gauge of Messrs. Butcher. This, we may remind some of our readers, is a piece of translucent paper accurately ruled into squares. It is laid over the face of the print—or in our present case over the pile of prints—and through each of the four corners of the rectangle, which corresponds with the size the print is required when trimmed, a fine pin is driven, the prints being afterwards cut down by any suitable means through each of the pin holes thus made, these being most easily seen from the back of the print. So long as means are taken to push each printing paper up to the corner of the printing frame when taking off the prints the use of the gauge will give a ready means of securing a whole lot of prints, each including exactly the same amount of subject. We are writing now for those who have not a fairly strong guillotine trimmer with which the whole batch of prints can be cut at one stroke for each side while the prints are clipped together in register with the outside edges.

PHOTOGRAPHERS' PARCELS AND THEIR TRANSIT.

COMPLAINTS have been pretty frequent of late of parcels dispatched or received by photographers being damaged or lost in transit. In many instances which have come under our notice this has been due to the sender's carelessness in the packing; indeed, in not a few cases it was not at all surprising that the contents of the parcel came to grief: it would have been more surprising if they had not. When such carelessly packed parcels reach their destination intact they seem to show with what care they have been handled by those through whose hands they have passed. It may reasonably be supposed that just at this season photographers will be dispatching more packages than usual, and that also there will be more than a usual amount of parcel traffic through the different channels than at other times of the year. Under these circumstances it can readily be conceived that in the press of business parcels may not meet with the same care that is usually given to them by carriers, and it therefore behoves the senders to take extra care with regard to the packing and labelling.

Carriers and railway companies are responsible, and have to pay compensation in the case of loss or damage which may result while any parcel is in their hands, and the object of this article is to give prominence to a few points in connection with this subject. In the first place, carriers—railway companies come within the same category—are protected by an old Act of Parliament to a limit of ten pounds only. Beyond that sum no compensation can be claimed, even if the value of the goods were a hundred pounds or more. But it must not be imagined that, should a parcel, we will say, of the value of fifty or a hundred pounds, be lost or destroyed, the owner will recover even the ten pounds; he would, in fact, get nothing at all, as the value of the parcel should have been declared at the time it was handed to the carrier, and a small insurance fee paid on it. The railway company thus becomes responsible, and that to the amount of the declared value. But even then it must not be assumed that when the contents of a parcel are declared of a certain value that, therefore, that sum will be paid. The owner will have to prove that it was of that actual value, and, further, if the contents of a parcel are insufficiently protected by the packing, that fact will exonerate the carriers from liability, as it would be through the fault of the sender that the damage was sustained.

All parcels containing fragile articles, such as negatives, framed pictures, etc., should be distinctly labelled as "glass," pictures, etc. For such things an extra charge for carriage is made, and in the event of the parcel not being so labelled nothing will be recoverable if the contents include glass or such things as would be charged at the higher rate.

When a parcel is delivered to the consignee it should be examined before it is signed for, and if it is seen from its outside appearance that the contents may be damaged it should be opened in the presence of the one who delivers it, and then signed for as received damaged. If broken glass or anything else can be detected in it by shaking, the parcel should be refused, and it will then be returned to the sender, who can then fight the matter out with the railway company. It should be borne in mind that when a parcel is received and the carman's sheet signed, the signature implies that it has been delivered in good condition, and therefore a rule should be made to sign "unexamined." If it is found when opened that the contents have been damaged in transit, no time should be lost in apprising the company of it by letter, so that it can forthwith investigate the matter. Sometimes photographer

are negligent, and do not do this until some days afterwards, when difficulties frequently arise that might have been avoided if more immediate action had been taken.

After the full compensation for the loss or damage has been paid, the parcel becomes the property of the railway company, unless an arrangement to the contrary is made at the time. Goods paid for are usually consigned to the lost luggage department, to be sold at the succeeding periodical clearance sale for what they will fetch. Some little while back a correspondent wrote us with reference to an enlargement he had sent by rail. The portrait, which was that of a lady, got injured on the way, and the husband claimed for its value. This the railway company paid in full and sent the picture on to the lost property office. Our correspondent wanted to know if the company could legally sell the enlargement, as her husband would, naturally, not like his wife's portrait to be put up to public auction. Of course, as the company had paid the full amount claimed, the picture was their property to do as they thought fit with. We mention this case to show that in arranging terms of compensation, facts such as these should be kept in mind.

In all business establishments a "parcels book" is kept, in which the names and addresses (as on the packages), with the date of dispatch, are entered. This book is always taken with the parcel to the receiving office and is signed by the clerk or agent who receives it. This is a receipt that the parcel was received for transit, and no after-dispute on that point can arise. It is not uncommon to find that parcels are merely handed in at carriers' receiving offices and no receipts for them taken. That should never be done. If a regular parcels book is not kept, the name and address of the consignee, with the date, should be written on a slip of paper, to be signed by the agent. The signature in either case will be a proof that the parcel was placed in the agent's hands.

As parcels up to eleven pounds in weight can be sent through the post, and photographers probably do more with the Post Office than with carriers or railway companies, and it may be of service to some to say a few words with regard to carriage by the Post Office, inasmuch as some instances have come under our notice which show that senders are not fully cognizant with the rules. It may not be generally known to everybody that no legal liability rests on the Post Office for loss or damage to parcels. That is to say, it would be useless to sue in a court of law for compensation. However, the Postmaster General will, as *an act of grace*, give compensation up to two pounds, but not more, unless the parcel was registered. The fee for this—in addition to the ordinary postage—is but trifling. Thus a fee of twopence covers up to £5, threepence up to £10, and so on up to £400, for which the fee is only one shilling and tenpence. Photographers who send parcels of negatives, framed pictures, etc., through the post should not neglect to register them, as the extra cost is a mere bagatelle. The parcels, however, must be marked "registered" and sealed with wax; and, in the event of their containing glass, or easily breakable articles, must be labelled "fragile, with care." The mere word "fragile," or "with care," are not sufficient; they must bear the words "*fragile, with care*" to secure compensation. When the parcel is posted a certificate for it must be obtained for it to ensure recompense. Certificate forms can be had at all post offices, and no charge is made for them. Photographers will do well to keep a small supply of them always in stock, and then all that has to be done is to fill in the name and address of the party to whom the parcel is sent and hand it in with the packet. The clerk will sign it and append the official date stamp—two points of importance, as no compensation will be paid unless the certificate of posting is forthcoming in the case of loss or damage.

SOME FLASHLIGHT TESTS.

THE area of flame given by a stated quantity of flash-powder seems to deserve some consideration both with regard to the effect of lighting and also from the point of view of safety, as when working among inflammable surroundings. The following experiments were made with the idea of finding whether any definite size of flame might be expected under similar circumstances. At the same time, it was thought a suitable opportunity to test a device advertised in one of the American journals as a "flame-spreader," much being made of the large area of flame supposed to be given, with the natural result of more even lighting. This lamp was apparently similar to Houghtons' "Ideal," viz., a trough of semi-circular section of about 1½ in. diameter and about 9 in. long, with mechanism in the centre for exploding a percussion cap by a pneumatic release; the "flame-spreader" being a sheet of metal forming, as it were, a roof curving upwards a couple of inches above the trough.

Having an "Ideal" lamp (with an attachment, of my own device, for rapidly placing and holding the cap in position), a "spreader" was made of a piece of tin, so that it could be placed on or lifted off the lamp as desired. The lamp was set up a couple of feet from a black screen, and with the trough lying parallel with the background. The camera was pointed at the screen, so that the image of the trough would be near to and parallel with the top edge of the focussing screen.

A few preliminary exposures showed that the flame spread somewhat over the lamp itself, and so obscured it in the photographs, even with the smallest quantity of powder; so a wooden

bar was supported about six inches in front of the lamp, so that the top edges of the wood and of the lamp-trough coincided on the focussing screen.

Perpendicular and central with this bar an upright was fixed, having wire nails driven in at intervals of one inch apart as a scale which would automatically register the size of the flames.

The flame in Fig. 1 was one gramme of flash-powder (Agfa powder was used throughout), in a heap over the cap. It will be noticed on reference to the photographs that the combustion is so rapid that no image of the ascending column of smoke is obtained, the lens being open for some seconds both before and after the flash.

Fig. 1A is a repetition of No. 1, but with the "spreader" fixed in position. In order to obtain the greatest possible accuracy, Nos. 1 and 1A were developed simultaneously, as were each of the other pairs.

The size of the flame is easily measured by means of the scale, and it should be noticed that the flame in every case goes below the lamp, but the so-called "spreader" in neither 1A, 2A, or 3A has altered to any extent the practical area of the flame. In Nos. 2A and 3A it has driven the flame forward and downward, so that it may be of some use when working near a ceiling.

Nos. 2 and 2A were each 3 grammes of powder in a central heap, Nos. 3 and 3A being 6 grammes each, laid in a train about six inches long.

A larger quantity should be laid in a longer train in the

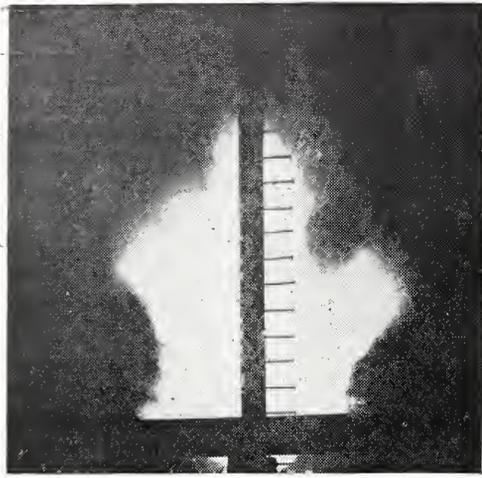

Fig. 1.

Fig. 1A.

SCALE 1/2 INCHES.

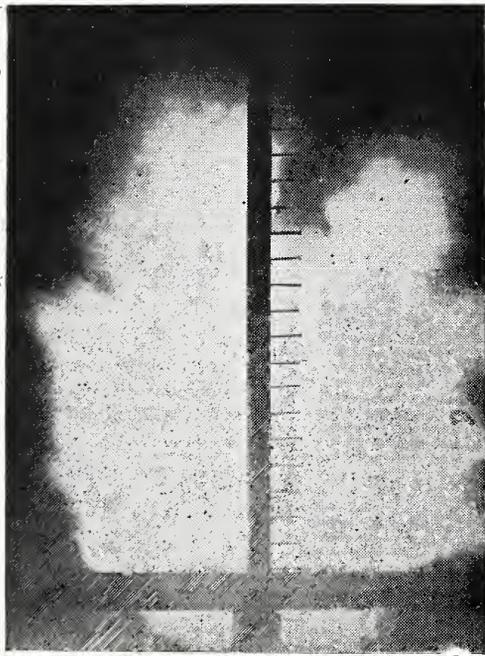

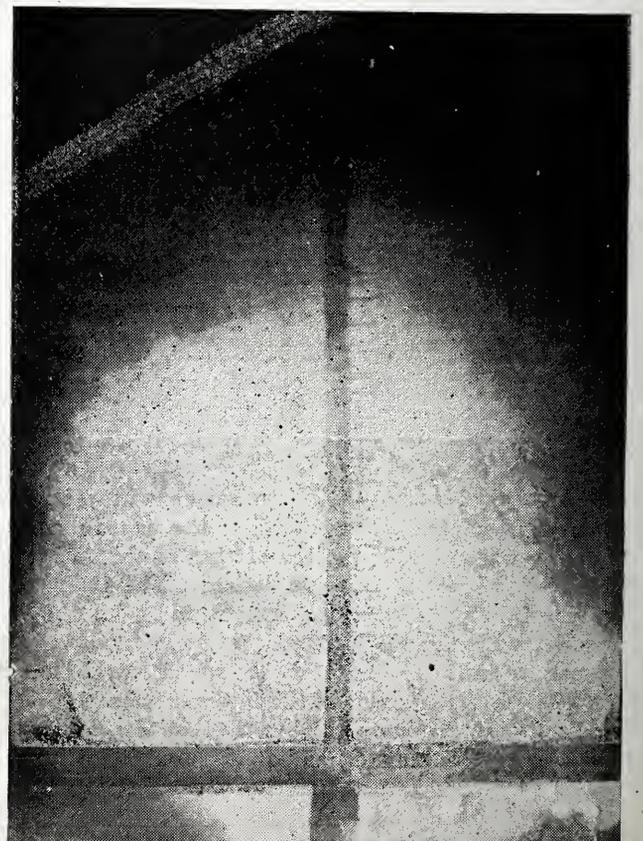

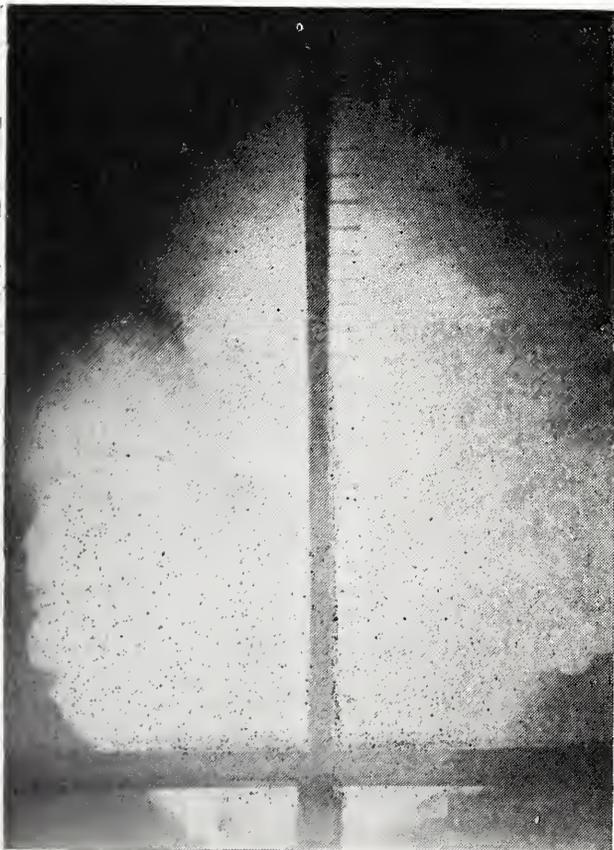

Fig. 2.

Fig. 2A.

same proportion, so that the flame need never exceed twenty-four inches in height from the lamp; it is sure to vary according to circumstances, such as currents of air, but the duplicate exposures made in the course of these experiments differed only in a negligible degree, both as to size and shape of the flame.

It would appear that the shape of the tray has more effect on the flame than any device over the top, the gutter-shaped trough apparently making the flame spread fan-shape, whereas

on a flat surface one would expect a pear-shaped flame. This is, of course, a point in favour of the trough.

The quantities of powder were measured, as they would be in practical work, with a small spoon which holds three grammes, while the handle end, which is bent up slightly, holds one gramme.

The plates used were Ilford "Process." The positions of camera, lamp, etc., were kept the same throughout.

D. BERLIN.

THE ART AND SCIENCE OF ILLUMINATION.

[The subjects with which the newly formed Society of Illuminating Engineers is to occupy itself are naturally of prime importance, both to those who employ daylight or artificial means for the illumination of photographic studios, exhibition galleries, factories, and work-rooms. Professor Sylvanus P. Thompson, in delivering his address as President at the inaugural meeting of the Society, showed the great advances which have been made of late in lighting, and drew attention to the more scientific methods which are now available for the measurement of illumination. The following is an abridgment of his address.]

This society has been founded to bring together all those who are interested in the problems, practical and theoretical, of the art of directing and adapting light, that prime necessity of civilised, as well as of uncivilised, existence, to the use and convenience of man. To advance the subject of illuminating engineering, to investigate through all its lengthened breadth the facts within its domain, to increase and diffuse knowledge respecting them, and to unite those who are devoting their energies to these things, is the object of the society. The ascertained facts are few—all too few; their significance is immense; their economic and social value is great; but the ignorance respecting them generally is colossal.

For practically a century only have there been any systematic means of illumination in use in any civilised country. Before the year 1800 there were, as means of illumination, daylight, oil lamps, rush lights, tallow dips, and wax candles. Monarch and peasant, merchant-prince and workman, had alike to depend on individual sources of light at night. Only in the larger towns and cities was there any organised attempt to light the streets by oil lamps. In 1819 the authorities of the day stoutly resisted the proposal to light the then House of Commons by gas—nothing but wax candles could be admitted; but gas lighting was coming in, and Argand and colza lamps were the sole competitors until after 1850. Everything else dates since then—practically during the last half century. For paraffin lamps were not widely spread until the 'sixties. Arc lighting, though tried for spectacular and lighthouse purposes from the 'fifties, did not come into public question until about 1879. Glow-lamps followed three or four years later. Still later came incandescent gas mantles and acetylene gas lights, while the newest things in both gas lighting and electric lighting are affairs of only a year or two ago. Many persons now realise the immense stride made in the introduction of the Auer (Welsbach) mantle for incandescent gas; far fewer people realise the significance of the corresponding step forward that has been begun by the introduction of the metallic filament glow-lamp. We are, on both sides, in the very middle of an immense evolution in the art of illumination.

But whilst the means of illumination have thus been developing with amazing strides during a single generation, and the organised systems of distribution by municipal and urban and rural authorities, and by private corporations, have ramified throughout the community and brought supplies of gas and of electricity—shall I also say of oil?—to our doors, there has been another and very different development going on. I refer to the growth of that branch of the science of optics which deals with the measurement of luminous values. Photometry has been growing into an exact science by the explanation of its laws and the improvement of the instruments of measurement. It was not until 1760 that the first real discussion of photometric principles was made known. In that year Lambert, in his "Photometria," laid down the fundamental laws, and likewise in the same year Bonguer gave to the world his "Traité d'Optique," wherein a primitive photometer was described. Rumford's shadow photometer was invented in 1794, and Ritchie's in 1824. Then comes a long gap. Save for Bunsen's over-rated grease-spot instrument, there was no important advance in photometry until the

'eighties, when there were produced many novel forms, some of them, including the now well-known forms of L. Weber, Lummer-Brodhun, and Rood, capable of yielding results of much higher precision in the comparison of different sources of light; also in the 'eighties we meet for the first time with special forms of photometer of the kind destined to play a very important part in the work of our society, many photometers measuring the values, not of the brilliancy of a source of light, but the illumination of a surface.

Our primary concern is the adequate and proper illumination of things; and as we have to reduce the present chaos to an exact science, our first business is to secure some common agreement as to the measurement of illumination and the establishment of reasonable rules as to the amounts of illumination required in different cases.

Foremost, then, in the programme of work for our society we put the question of the units of measurements and the promulgation of the proper definitions of them. We must secure agreement—national, and, if possible, international—as to what shall be taken as the unit of light and what as the unit of illumination at a surface.

Happily, the long-standing controversy as to the former appears to be settling itself by at least a preliminary agreement between the standardising laboratories of the great nations. One "candle" is no longer to be a vague and indefinite thing. The new definition provisionally agreed upon is an ideal unit, in terms of which one can describe the several standards in use in different countries. If this provisional *entente* can but be ratified by a little international common sense we shall have henceforward an international "candle," such that it is the same in England as in America, equal to the *bougie décimale* accepted in France, and related to the Hefner-candle of Germany in the precise proportion of ten to nine.

But we have still to find agreement on the standard of illumination. Here in England, and in the United States, we have already grown accustomed to describe amounts of illumination of surfaces in terms of a British unit—the "candle-foot"—not perhaps a very happy term—one that we would readily exchange for a better—meaning, thereby, the intensity of the illumination at a surface situated at the distance of one foot from a light of one "candle." The source being assumed here to be concentrated at a point, the law of inverse squares holds good.

Adopting the candle-foot as the unit of illumination, one may readily state certain facts with definiteness. All competent authorities are agreed that at night, for the purpose of reading, an illumination is required not less than one candle-foot, some authorities saying $1\frac{1}{2}$ candle-foot. The facts appear to be that reading is impossible with an illumination of one-tenth candle-foot, difficult and fatiguing with one of one-fifth candle-foot, comfortable with from $1\frac{1}{2}$ to 3 or 4 candle-foot, but that if the illumination exceeds 6 or 8 candle-foot, the glare of the page is again fatiguing and dazzling. The page should neither be under-illuminated nor over-illuminated. Something depends, it is true, on the size of the print. Under a feeble illumination of, say, $\frac{1}{2}$ candle-foot, a type of pica size printed in a fount of bold face properly inked is legible, when one of long primer size, printed in a weak way, would be practically illegible.

Something also depends on the state of the eye as affected by the general illumination of the surroundings. Very seldom does one find in any ordinary room an artificial illumination exceeding 3 candle-foot. By day, on a writing-table placed near a north window—or near any window not receiving direct sunlight—the illumination may exceed 3, and may even attain 4 or 5 candle-foot.

Until a unit of illumination was thus agreed upon, it was impossible to render any reasonable certainty to estimates of the amount of illumination in any case of dispute. What is the meaning of the term well-lit as applied to any room, building, factory, workshop, or studio? Formerly the term was entirely vague. To-day the answer can be given in numerical terms. Formerly judgment had to be made by the unaided eye, and the eye is notoriously a bad judge. As between two different illuminations, the powers of discrimination of the eye are very limited. The eye can equate, but it cannot appraise. It can tell with fair accuracy whether two adjacent patches are equally bright; if they are not equally bright it cannot say with any kind of proportionality what their relative brightnesses are. All photometry depends on the perception of an equality.

Photometers for the measurement of illumination have been mentioned earlier as coming first into notice in the 'eighties. One of the earliest in this country was that constructed by Sir William Preece, with the assistance of Mr. A. P. Trotter, for measurement of the illumination of side-walks and pavements of streets. It has been subsequently developed by Mr. Trotter, and, as constructed by Mr. Edcombe, is a most useful and handy instrument, telling the amount of illumination directly in terms of the candle-foot. Another, by Mr. Haydn Harrison, measures the illumination, not on the horizontal, but at 45 degrees. Almost equally early with the Preece-Trotter illumination photometer was the school photometer of Petruschewsky, apparently little known in this country. Most recent of this sort is the form due to Martens.

The principles and construction of photometers are matters that have interested me for nearly thirty years. About 1880 I brought out a form of wedge-photometer (modified from Ritchie's form), in conjunction with Mr. C. C. Starling, for electric light measurements. Later I gave to the Physical Society an investigation of the errors arising in photometry from the almost universal assumption that the law of inverse squares is fulfilled. In 1882, when lecturing at the Crystal Palace Exhibition, I gave diagrams to show the effect of the superposition of illumination from two or more lamps, and discussed the variations of illumination in a street between the places of maximum and the places of minimum illumination. Twelve years ago I described a tangent photometer, which has remained a mere optical curiosity.

No one can have worked at the photometry of modern lamps, or of the illumination of surfaces lit by lamps, without becoming conscious how much misunderstanding there is of the elementary laws of illumination. There is Lambert's cosine law, admirable and simple, if only it were not in so many cases vitiated by the presence of organised—that is, specular—reflection. There is the law of inverse squares, itself a universal geometrical law of action radiating from a point, so fatally and absolutely misleading if applied to any other case than that of action from a point.

One subject on which more information is badly needed is the specific brightness of surfaces of different kinds when subjected to a standard illumination. For instance, how much light is reflected, per square inch, when illuminated with an intensity of 1 candle-foot, from such materials as oak panelling, whitewash, brown paper, or the surface of a red brick wall? Here in this theatre the walls are tinted of a dark Pompeian red or maroon, which reflects but little light. The extra annual expense on lighting that might be saved had a lighter tint been used is surely worth considering.

The subject of diffuse reflection which here comes into play has indeed been investigated partially by several persons. There are Dr. Sumpner's researches of 1894 and those of Mr. Trotter on white cardboard and other white matt surfaces, but how few others! Again, there is the subject of diffuse refraction, which occurs in ground glass shades, ribbed and corrugated glass panes, and other devices for diffusing the concentrated light of lamps. Yet how little does any optical book tell us on the subject of diffuse refraction. Reflection and refraction as they occur at dull or irregular surfaces appear to be of no importance to the academic writer of text-books of optics, but they are of vital interest to the illuminating engineer.

Again, there are a number of semi-physiological problems that demand investigation and settlement. We all know that our eyes have an automatic diaphragm which stops down the entering light to protect our eyes from glare, rendering us relatively insensitive to bright lights. Does anyone know whether the contraction of the pupil depends on the total amount of light entering the eye or on the intensity of the image on local patches of the retina?

Again, we all know how an unshaded arc-lamp, or even glow-lamp, "cuts" the eyes by the very concentration of its beams, even when it may be many feet away, while the same actual amount of light, if diffused over a greater apparent surface, as by a surrounding globe of ground glass, is quite readily endured, and does not produce the same painful sensation. Does anyone know how great is the specific brightness of surface that the eye will tolerate without experiencing this discomfort? We can look at a white cloud or at the blue sky without pain. Can we endure a specific brightness of so much as one-tenth of a candle per square inch?

Our eyes are provided by nature with a most exquisite and automatic iris diaphragm, which opens in the dark and closes in the light, thereby shielding us partially against the evil effects of glare. Putting it in the language which the photographer uses to describe the stopping-down of a camera-lens, the automatic iris of our eye can close the pupil so that while in a comparative darkness the aperture opens to $f/2$ or $f/2.5$, it closes amid a brilliant surrounding illumination to about $f/20$. Suppose we are looking out in relative darkness, and are confronted with a brilliant patch shining with a specific brightness of one-tenth of a candle per square inch, we shall feel a certain amount of discomfort from its glare, and if we regard it steadily for a second or two will, on closing our eyes or turning away, see those persistent coloured images that trouble us after looking at any very bright light; but now let the same brilliant patch be placed against a bright background. Far more light will enter the eye; the automatic iris of the eye will in a few moments have contracted, stopping down the lens of the eye so that it will be far less sensitive. In these circumstances, will the patch that has a specific brightness of one-tenth candle per square inch pain or dazzle the eye? I ask the question, but I do not know the answer. Does anyone know what the answer ought to be? It is a simple question, and a few experiments would soon settle it. Of course, one must admit that the automatic action of the iris diaphragm, important as it is, does not by any means account for the whole of the facts about the want of proportion between the intensity of a stimulation and the intensity of the resulting sensation. Fechner's logarithmic law of psychophysics gives a clue, but even this does not seem capable of expressing, much less of explaining, the facts about the observed want of proportionality. Why should a light of ten-fold brilliancy not produce a sensation ten times as intense? And why should a greater brightness of the general surroundings relieve us of the annoyance of those coloured after-images? After-images can be seen even under extremely feeble illumination, as I have again and again found. Has anyone discovered any exact law governing their occurrence?

All these queries show that there is plenty of work awaiting us, even in the mere collection and completion of such scattered information as is already available; but there are even more important questions before us, more important, not in science, but in their relation to the public welfare and the economics of the community.

Now that we have a standard of illumination and simple portable instruments that will measure it, there can be no excuse for inaction or ignorance in applying that knowledge to securing proper illumination for public and private buildings.

Let me begin with school buildings. They are the most important; for whatever bad results flow from bad lighting of churches, factories, or railway stations, those which result from the bad illumination of schools are far more to be deplored—they imperil the eyesight of the next generation.

All ophthalmic surgeons agree that the cause which forces the children into increasing shortsightedness is protracted poring over books under an insufficient illumination. Even in what an inspector might call a well-lit school the illumination at the surface of the desk may be quite insufficient if the desks are badly placed, or the windows insufficiently high, or the lamps badly distributed.

All educational authorities ought henceforth to insist on rational requirements as to lighting. Hitherto they have had nothing definite

to specify; now that illumination photometers are available, they ought to require a minimum of $1\frac{1}{2}$ candle-foot at the worst-lighted seat in the schoolroom, and not depend on purely architectural rules about heights of windows or areas of window space. In England the Board of Education, in its Building Regulation (1907), Rule 6, clause c, has laid down a foolish rule: "Skylights are objectionable. They cannot be approved in school-rooms or class-rooms." That perfectly monstrous provision ought to be at once repealed. The universal experience of the textile industries, where adequate lighting of spinning and weaving machinery is a prime necessity, is that no method of lighting is so satisfactory as skylights in roofs specially constructed to receive light from the northern sky.

Hitherto little attention has been paid by either local or central authorities to conditions affecting the lighting of factories and workshops. It is true that the factory inspectors require periodic white-washing of factories, but that is for sanitary reasons, not primarily to secure better illumination. The Home Office has its regulations as to temperature and degree of moisture required or permissible in the different classes of factories and workshops. Then why not also similar regulations as to the proper amount of illumination? Surely the eyesight of the workers is as well worth protecting from injury as their lungs and their limbs. So far as I am aware, Holland is the only country in which legislation has fixed a statutory amount of illumination in factories, the figure there being from 10 to 15 candle-metre, equivalent, therefore, broadly to the value of 0.9 to 1.35 candle-foot.

Architects are often blamed for deficiencies in the lighting of the buildings they design, perhaps more often for the deficiencies found

at night by artificial lighting than for those of the lighting by day. For this the fault rests no doubt largely with the persons who have installed the lighting arrangements, and one must not blame the architect too severely for having been as ignorant as all the rest of the world about the principles of illumination; but henceforward, when once it is known that much illumination is required in the rooms of different kinds, the architect ought in his specification to set down, with appropriate numerical values, what degree of illumination is required in the various parts of the building.

I venture to suggest that it would be a good thing if, in the public interest, our society, or some committee appointed by it, could draw up a model specification, or model clauses for architects to insert in their specifications, in which the proper way of prescribing the requisite amounts of illumination in different classes of cases should be set forth.

Outside all these matters of more public interest, there are topics enough to occupy our society for many months to come. We shall have discussions on several interesting subjects during next spring, and there are many problems awaiting solution. When all else fails us, we can turn to the eternal question of the measurement of colour. We have also the long outstanding problem of the production of light without heat, accomplished in nature by the fire-fly, but unrealised by any artificial lamp. We might turn to discuss special cases, such as the flashing lights of lighthouses, or the special lights needed in the hospital for the detection of rashes or the treatment of disease. Amid such endless ramifications of our subject there is no fear of coming to a premature end of our programme. There is, indeed, abundance of work before us. SYLVANUS P. THOMPSON.

SOME USEFUL GEOMETRY FOR PHOTOGRAPHERS.

[Some simple methods of geometrical construction, which are as the author remarks, by no means new, yet are probably unfamiliar to many photographers who, in cutting vignetting masks, trimming glasses, etc., to various "fancy" shapes, will at times find the simple use of a drawing board, T-square, and set-square of the geometrical method as regards tools is in favour of the latter. and a straight rule are the only instruments required.—Eds.]

1. To halve a distance. From each end of the distance ab strike a portion of a circle on either side of the line, the line forming the two points of intersection—i.e., the line cd bisects the line ab . (Fig. 1.)

2. To draw, from a point in a given line, a perpendicular to the line. From the point c in the line an equal distance ca and cb on either side is marked off with the compass. From each of these

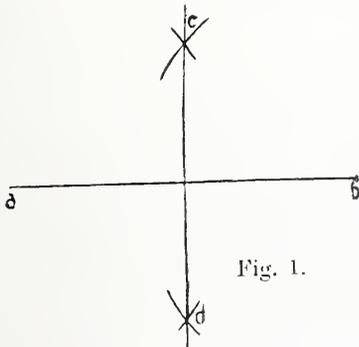

Fig. 1.

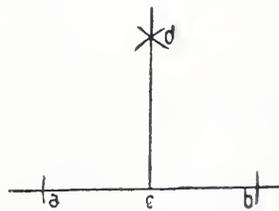

Fig. 2.

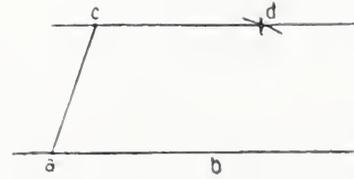

Fig. 3.

points a and b a piece of a circle is marked off with the same stretch of the compass, the two portions crossing in d . On joining d and c the line formed is the perpendicular to the line ab . (Fig. 2.)

3. To draw a parallel line at a given distance. A perpendicular from any point in the line to which the parallel is to be drawn is erected as just described in 2. The distance which the parallel is to be from the given line is marked off on the perpendicular, and then a second perpendicular drawn forming the parallel.

4. To draw through a given point c a line parallel with a given line. Joint the point c with any point in the line, say a , then from any second point in the line, say b , describe a circle with ac as

radius, and from the point c , a second circle with ab as radius, these two circles intersecting in d . On joining the points c and d by a straight line this latter is the parallel required. (Fig. 3.)

5. To halve an angle. The construction in fig. 2 divides the angle adb into two parts by the perpendicular dc . In a similar way any other angle may be divided into two.

6. To construct a triangle with three equal sides. Drawing the

line ab to form one side of the triangle a circle is struck off both from a and from b , the two portions intersecting at c . On joining c to a and b the complete triangle is formed. (Fig. 4.)

7. To draw a regular hexagon. Draw a circle with a radius of length equal to the desired length of each side of the hexagon. Starting from any point of the circle set off successively with the compass straight lines each equal to the radius of the circle. On joining the points thus marked on the circumference the result is a regular hexagon. (Fig. 5.)

8. To draw a square. A straight line ab to form one side of the square is drawn, and a perpendicular drawn from a and from b by

line ab to form one side of the triangle a circle is struck off both from a and from b , the two portions intersecting at c . On joining c to a and b the complete triangle is formed. (Fig. 4.)

7. To draw a regular hexagon. Draw a circle with a radius of length equal to the desired length of each side of the hexagon. Starting from any point of the circle set off successively with the compass straight lines each equal to the radius of the circle. On joining the points thus marked on the circumference the result is a regular hexagon. (Fig. 5.)

8. To draw a square. A straight line ab to form one side of the square is drawn, and a perpendicular drawn from a and from b by

line ab to form one side of the triangle a circle is struck off both from a and from b , the two portions intersecting at c . On joining c to a and b the complete triangle is formed. (Fig. 4.)

the method given in 2. Along each perpendicular the distance $a b$ is marked off, giving the points c and d , on joining which the complete square is formed. (Fig. 6.)

Another method is to draw a circle and one diameter of it. A second diameter perpendicular to the first is then drawn, and the

The point d is then connected to a and b by straight lines, and e is likewise connected with these two points. From b with radius $b a$ the arc of a circle is drawn, $h a i$, and from a with the same radius the arc $f b g$. Finally, with radius $d f$ and from the points d and e further arcs $h k f$ and $i l g$ are drawn completing the oval. (Fig. 9.)

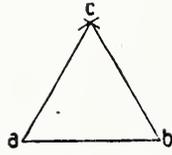

Fig. 4.

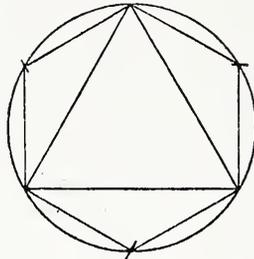

Fig. 5.

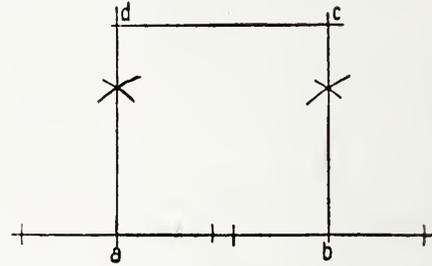

Fig. 6.

four points at which the two diameters intersect the circumference of the circle on being joined together form a square. (Fig. 7.)

9. To draw a regular pentagon. A circle is drawn and the diameter $a b$ drawn through the centre c . The radius $c b$ is then halved at d , and from c a perpendicular drawn $c e$. Then from d as centre and with $d e$ as radius the arc of a circle is drawn which meets the

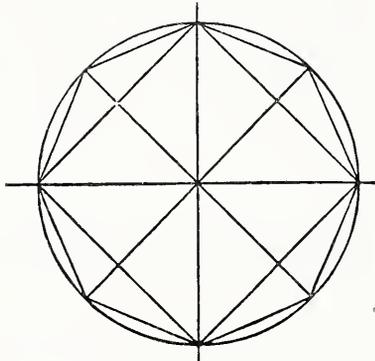

Fig. 7.

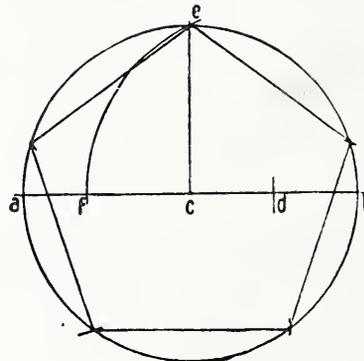

Fig. 8.

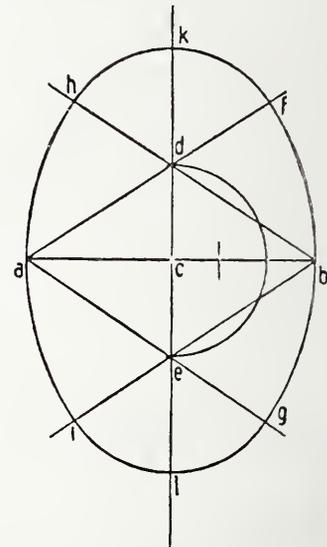

Fig. 9.

diameter $a b$ in f . This distance $e f$ is then set off five times inside the circle forming the pentagon. (Fig. 8.)

10. To draw an oval of given width. A line $a b$, the desired width of the oval, is halved at c and a perpendicular drawn each way. The distance $c b$ is then divided into three equal parts, and from the centre c , with radius two-thirds of the distance $c b$, a semicircle is described which meets the perpendicular to $a b$ in the points d and e .

If, instead of proceeding as directed above, the first semicircle drawn from centre c is made with a less radius than two-thirds of the distance $c b$ and the remainder of the process carried out as before the oval obtained is rounder, whilst if a longer diameter, that is more than two-thirds of $c b$ be taken a longer oval is obtained; but the most pleasing dimensions are those when two-thirds of the diameter is adopted.

ILFORD, LIMITED.

INCREASED REVENUE AND A DIVIDEND OF 6 PER CENT.

THE thirteenth ordinary general meeting of shareholders in Ilford, Ltd., was held last week at Winchester House, Old Broad Street, E.C., Colonel Ivor Philipps, D.S.O., M.P. (Chairman of the company), presiding.

The Secretary (Mr. F. J. Jenks) having read the notice convening the meeting and also the auditors' report,

The Chairman said: Gentlemen,—Taking the debtor side of the account first, the reserve for bad and doubtful debts is exactly the same as last year. The item of sundry creditors shows an increase of £4,000; that is because last year we had purchased a lot of silver and paid for it in advance, while this year we had, at the time the books were closed, a debt of £2,000 for silver and of £2,000 due to the builders for the new buildings at Ilford. The item of goodwill is reduced by the sum of £6,000, and it stands at £216,000, but the Board look forward to reducing it steadily as opportunity occurs. The item of freehold land and buildings shows an increase of a little over £7,000 since last year, caused by improving and enlarging our factories, etc. Then we have written off for depreciation £3,147, which makes the net increase on freehold land and buildings £3,900. Your buildings and plant have never been in such good order as they are this year. I have personally taken great trouble to see that your buildings and property generally should be put in good order

and kept in good condition, and I can say, without any question that your buildings are in perfect order. As to the item of "investments at cost or under," they stand in your books at £100,267, which is an increase of £12,690 since last year. Here I would draw your attention to the note appearing in the balance-sheet which says that the actual market value of these investments was £86,617 on October 31 last. All these investments are in easily realisable securities, and if you should, for any reason, wish to develop your business in any line you have at your call at any moment a sum of between £80,000 and £90,000. Sundry debtor are the same as last year, which is satisfactory, considering the increased business done. The office furniture is a little reduced in amount, as we have liberally depreciated that small item.

Turning to the profit and loss account, the item of salaries, advertising, rates, taxes, and sundry trade expenses is £2,300 more than it was last year, but it is still £1,000 less than it was in the preceding year. The item of income-tax is less. There is an increase in the item of repairs and depreciations of £881, and we have written off more for depreciation, as we wished to place the company in as satisfactory a position as possible in this respect. The item of directors' and auditors' fees is the same as last year. The net profit on trading shows an increase of £8,064. This increase is satisfactory, but it is not quite as satisfactory as we could wish in comparison with the increased turnover. The item of "interest on investments" is about the same as last year.

The result of it all is that we carry to the balance-sheet a balance of £33,618, as compared with £28,810 last year, an increase of £4,808. We brought into the account £3,649, which leaves available for us to dispose of £37,267. We have already paid the Preference dividend of 6 per cent., which absorbs £11,400, and leaves £25,867 to be dealt with to-day. Your Board has considered this matter very carefully, and they recommend that we should set aside £12,000 to writing down goodwill and investments and also to writing off plant and for general contingencies. That leaves £13,867, and out of that we recommend an Ordinary dividend of 6 per cent., which absorbs a further £11,400, and leaves £2,467 to be carried forward, as against £3,600 last year. The comparatively small attendance here to-day shows, I hope, not that their interest in Ilford, Ltd., is less to the shareholders, but that they are satisfied with the steps which the Board have taken to carry on your property during the last twelve months. I should look upon it as a misfortune if it indicated that the shareholders were taking less interest in their property. The market value of their shares is, I am glad to say, returning to somewhat like the proper value, and I hope—and indeed I know—that not many of our shareholders have been so foolish as to part with their shares in that time of depression which overtook us. I hope you will agree that the progress we have made during the past year is satisfactory, but it is not quite so satisfactory as we desire or consider that it should be, in view of the manner in which the turnover has developed.

The constant cutting of prices, and the severe competition to which this business is exposed, prevent us getting the full benefit from the superiority of our productions, and the large sales thereof which take place. I have referred on previous occasions to this cutting of prices, and I can only say now that it continues, and is even more violent than before, much to the damage of your property. I believe that it is a very foolish policy; I do not know who benefits by it, but we certainly do not. It is our intention, of course, to maintain the high quality of our goods and to push their sales in every way possible, and we hope to continue to show a good profit. Still, I cannot hold out very great hopes of increasing profits in proportion to this increasing output. It is to the economies which we have effected, as foreshadowed at the last meeting, that the present improvement in the gross profits is mainly due. The expectation held out at the last meeting has been amply realised, and I look forward to still further economies in that direction, economies not in any way affecting the quality of your goods, but mainly economies in manufacture. It affords me very great pleasure again to express our indebtedness to those shareholders who bring their complaints and suggestions directly to the Board. We received a great number during the year from shareholders interested in the business, and every letter that is received has my personal attention. Suggestions that are put forward are always adopted whenever we believe that they will in any way benefit your business, and the Board fully appreciates the benefit to your business resulting from shareholders taking a personal interest therein. We have a large body of shareholders, many of them personally interested in the retail trade and the pushing of your goods; therefore, it is to them that we must look to spread about the country the fact that your goods are not only as good in quality as they ever have been, but that they are a great deal better. (Applause.) The steady increase in your business shows that quite clearly. We stand, as regards our business, in a different position to any other photographic business in the country. We are the only photographic business whose accounts are published, and in these days of severe competition that is, undoubtedly, a very great disadvantage. It is on this account that I am compelled, in your own interest, to give you as little information as I can on many subjects which I know would be of the greatest interest to you, but I am always pleased to give shareholders any information which I possibly can. The company is going ahead, and the Board are working harmoniously together in your interest. The staff, as on all occasions since the company was started, have been most loyal to the Board and to your interests. The balance sheet we have put before you is more satisfactory than you have had for many years, and I can assure you that we are working wholeheartedly to put your business in a still better position than it occupies at present. I now beg to move: "That the annual statement of accounts and balance-sheet, together with the reports of the directors and auditors, be and are hereby adopted, and that a dividend be declared in accordance therewith."

Mr. J. Kemp-Welch seconded the motion, and after a short discussion, it was unanimously adopted.

On the motion of the Chairman, seconded by Mr. W. Ashmole, the retiring director, Mr. R. D. Lewis, was re-elected. The auditors were reappointed, and the proceedings terminated with a vote of thanks to the Chairman, directors, and staff.

THE P.O.P. FORMULA FRAUD.

IN the London Sheriff's Court, on December 8, before Mr. Under-Sheriff Burchell and a jury, the case of Brandes v. Macfarlane, which had been remitted from the High Court for the assessment of damages, came on for hearing. There was no appearance for the defendant.

Mr. W. Allen, counsel for the plaintiff, said his client, Mr. Wilfred Brandes, was a young German gentleman who, in the autumn of 1907, was prepared to go into business. In December of that year he saw the following advertisement. —

Gentleman with £150 wanted as partner or otherwise, to assist in working an exceptionally nice business selling for cash only at very large profits, and with small expenses. Advertiser has special facilities for commanding a large sale and can furnish absolute proofs and best references. Can rely on £200 a year. —Apply H. M., etc.

Plaintiff got into correspondence with the defendant, who resided in Avenue Road, Isleworth, and Macfarlane wrote him a letter giving him particulars of a new photographic printing-paper which he had invented, and which he said would be the best "P.O.P." on the market. It would, he added, cost about 6s. 3d. a quire to produce, and could be sold for 15s. a quire, and seeing that there were 40,000 professional photographers and 2,000,000 amateurs, he calculated that there would be no difficulty in disposing of fifty quires a week. In his letter Macfarlane also said that he could not work the business himself, being in a situation.

As a result of the correspondence, counsel said, the parties entered into a contract, whereby the plaintiff paid him £60 down for the formula, the names of firms, and the necessary apparatus. In a verbal conversation Macfarlane said he had got reports from the best experts in England that his paper was better than any other. The plaintiff made the paper according to the defendant's instructions, but instead of selling fifty quires a week he sold only half a quire in four and a-half months. The plaintiff issued a writ alleging misrepresentation and fraud, but the defendant put in no defence, and he also failed to comply with an order to deliver up the documents. The defence was accordingly struck out, and the plaintiff signed judgment.

Wilfred Brandes, formerly of Lime Grove, Uxbridge, but now of Amsterdam, bore out his counsel's statement, and said the defendant told him that a child could make the paper. Beside the £60 which he paid the defendant, he spent £31 15s. 10d. in raw paper and chemicals, and £20 15s. 10d. in rent, circulars, and the wages of an assistant, etc. He devoted his whole time to the business from January to June. One photographer who purchased some paper wrote saying it was useless. He showed the letter to the defendant, who kept it. When he asked the defendant to show him the expert reports, he replied that they would be no use to him.

Frederick Weidhoff, called to give expert evidence, said that commercially the paper was absolutely useless.

In summing up, the Under-Sheriff said it might strike the jury, as business men, that the plaintiff was badly advised in not ascertaining the commercial value of the paper before launching into the business.

The jury awarded the plaintiff £100 damages, and judgment was given accordingly.

MINIATURE PAINTING FOR PHOTOGRAPHERS.—An evening class in miniature painting, tinted-pencil drawing, and water colour from the costume model will probably be arranged at the L.C.C. Central School of Arts and Crafts, Southampton Row, W.C., on Tuesdays and Thursdays, from 6 to 8.30. The class is intended primarily for the assistance of retouchers and others professionally engaged in photography. The fees are quite nominal. Full particulars and forms of application can be obtained from the secretary at the school.

Photo-Mechanical Notes.

A New Process of Reproduction.

The "American Photographer" has a supplement this month, of reproductions by a new process, in which they profess great pride, and of which they state that "as a matter of fact, they are probably the most faithful reproductions of photographic originals we have ever presented to our readers." All we can say is that either the former reproductions offered by the "American Photographer" must have been atrociously bad, or else these originals are such as should never have been reproduced. It is true the illustrations are printed on rough paper, and while no one has pleaded more persistently than the "British Journal" for experiments in this direction, yet to put forward results such as these with a flourish of trumpets is far more likely to retard progress in abolishing the glossy clay surface than to hasten it. Some of the results remind us of the early attempts of the newspapers to print half-tones. Although details regarding the process of production of these illustrations are kept back, it seems pretty certain that they are cross-line and irregular screen work printed from the offset press. Great things are hoped from the alliance of process with lithographic methods of printing, particularly in offset work, but if the conjunction cannot improve upon these results, the letterpress printer will not have much to fear.

A New Tex-book.

"Metallithography." By Charles Harrap. Published by Raithby, Lawrence, and Co., Limited. 3s. net.

With the advent of the offset press and the many applications of lithography to process, this new text-book ought to be very welcome to process engravers, as well as lithographers. Besides pure lithography, it deals with many branches of photo-lithography, showing in what directions photography has already been applied. It gives full recipes, and references to patents, and it ought to be suggestive as to further progress in this direction. Although dealing mainly with printing lithographically from metal surfaces, it nevertheless gives a good deal of attention to stone, especially with regard to the chemical reactions concerned. The book is compact, well illustrated, and especially authoritative wherever proprietary articles are mentioned, as these references have all been checked by the readers themselves. We should say that no lithographer can afford to be without this book, and, in view of recent advances, the process engraver will be foolish to neglect it.

A New Process School.

THE Leeds Technical Institute has just added a photo-process and printing section in a separate building to its photographic department. The equipment for the photo-mechanical work has been provided by Hunters, Ltd., and comprises all the necessary apparatus of the most up-to-date pattern. In addition to the camera and "Westminster" arcs, there is a full line of mounting machinery, including straight-line router, beveller, and circular saw. The Institute is also to be congratulated on having secured a first-class instructor in the person of Mr. Guy Symmons, head of the photo-mechanical department of Alf Cooke, Ltd., whose former teaching experience at the Regent Street Polytechnic will serve him in good stead. The printing department is equally well equipped by Messrs. John Haddon and Co. In addition to a most complete outfit in the case-room, sufficient to accommodate eighteen students at one time, there is provided a Babcock flat-bed machine, a Caxton platen, an art platen, a cropper, and an Albion press. Altogether very complete provision is made for teaching the crafts concerned, and there is every prospect of a most useful future for the department, considering that the school has already secured the hearty support of the trade in Leeds. The large entries have very agreeably surprised everyone concerned. The principal of the institute, Mr. R. E. Barnett, B.Sc., has been exceptionally successful in organising trade classes in Leeds. This is one more laurel for him. He has been ably assisted in this instance by the energetic Mr. S. E. Bottomley, head of the department, who has worked extremely hard for long past to extend his photographic department in this direction.

The Process Year Book, 1909-10.

THE fifteenth volume of Penrose's pictorial annual is just to hand, and is a more tasteful production than ever before. The cover of green cloth, with quiet lettering in white and black, is a welcome change from many of the garish covers of previous years, and this restraint is carried further with regard to the inks used in printing the plates, as there are very few departures from a sepia or a black and none of the hideous "double tones" with which we have formerly been depressed. Although there are no examples of unrelated plates interpolated in the middle of articles, still the practice is maintained of sandwiching the pictures between the articles without any sort of order or classification. We once again reiterate our belief that the book would be more useful without any detriment to its appearance if the text were kept at one end of the book, interspersed only by such illustrations as had reference to it, and all the supplements at the other end. There is a very good precedent for this in the examples of "Eder's Jahrbuch," and we should like to see Mr. Gamble make the experiment.

With regard to the matter of the book, it is perhaps better than ever. Most of the well-known personalities in the process world contribute. Major-General Waterhouse on "Sensitive Asphaltum," Dr. C. E. K. Mees on "Orthochromatic Filters," Dr. Reginald Clay on "Determining the Constants of a Thick Lens," A. J. Newton on "Newspaper Half-Tones." Prof. Namias, N. S. Amstutz, Arthur Payne, E. W. Foxlee, H. L. Shawcross, and Chas. E. Dawson also have articles on various subjects. In short, no one engaged in the illustration crafts can afford to do without the volume. The supplements are about the usual level. They comprise examples of almost all the current processes and one notable novelty in the shape of a five-colour print, produced on the offset machine of Messrs. Mann and Co. The work is photo-mechanical, having been put on to the metal direct from screen negatives. The rough paper on which this example is printed and the generally soft effect is a startling example of what this process offers for reproductions in coloured half-tone. The frontispiece is a mechanically produced photogravure, and for the rest there are examples by practically all the reputable firms in the trade, several from abroad, though not so many as last year. Mr. Gamble, in his editorial survey, is rather gloomy, and speaks as though no one, either workman or proprietor, was deriving any benefit from the reproductive industries to-day. All we can say is that it would be hard to persuade any one not in such business to believe it, and the evidence of his own volume affords him no support whatever for his pessimism.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

SCREEN-PLATES.—No. 27,906. Improvements in screen-plates for half-tone process printing. Henry William Hamblin Palmer, 52, Stephen's Road, Tunbridge Wells.

FORTHCOMING EXHIBITIONS.

- December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.
- 1910.
- January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.
- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.
- February 1 to 5.—Norwich and District Photographic Society. Entries close January 18. Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

MESSRS. RAINES AND Co., Ealing, write: "During the last week we have received three parcels of negatives for enlarging, with order forms that have not been signed, and upon which the postmarks have not been sufficiently plain to enable us to trace the senders. May we beg the kindness of a note in your columns to this effect. It may help the senders to obtain enlargements that are doubtless wanted for Christmas."

Analecta.

Extracts from our weekly and monthly contemporaries.

Reducing Contrasts in Pigmenting Bromoils.

From an architectural negative with strong contrasts (writes Mr. Charles F. Gare in "The Amateur Photographer and Photographic News" for December 14), a 12 by 10 enlargement was made, yielding, naturally, an abnormally harsh result, with entire loss of detail in the shadows.

After bleaching, etc., pigmenting was proceeded with in the usual manner, producing, as expected, an image very similar in effect to the original bromide. At this stage a method was adopted for removing the excess of colour from the shadows, without vigorous "hopping." The dabber was thoroughly cleaned in the customary way, by drawing it over muslin moistened with petrol; when practically, *but not absolutely*, dry, the brush was applied gently to the heavy portions of the subject. By such means the shadows were immediately and evenly reduced, becoming beautifully transparent, while the adjoining lights remained unaffected, this almost magic action of the brush being maintained by frequent recourse to the petrol rag.

The finished picture displayed qualities unlooked for from the unsuitable class of negative—perfectly harmonious in gradations, and excellent rendering of sunshine and reflections. Another pleasing feature was that the entire print dried with a uniform matt surface.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between November 29 and December 4:—

COLOUR PHOTOGRAPHY.—No. 27,818. Improved process of photography in colours. Auguste Jean-Baptiste Tauleigne and Elie Mazo, 11, Southampton Buildings, London.

CINEMATOGRAPH-PHONOGRAPH.—No. 28,161. Improvements in apparatus for indicating the movements of gramophones and cinematographs. William Fenn, 1, Beverley Cottage, Kingston Vale, Putney, London.

TRIPODS.—No. 28,162. Improvements in and relating to tripod and like stands. William Alfred Deane, 70, Chancery Lane, London.

LENSES.—No. 28,287. Lenses for cameras, cinematographs and the like. Harry Ashton Wolff, 33, Cannon Street, London.

CINEMATOGRAPHS.—No. 28,311. Improvements in and connected with cinematographs. Robert Stewart, 154, St. Vincent Street, Glasgow.

REFLECTORS.—No. 28,358. Improvements in or relating to reflectors for artificial light for photographic purposes. George Jobson, 111, Hatton Garden, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

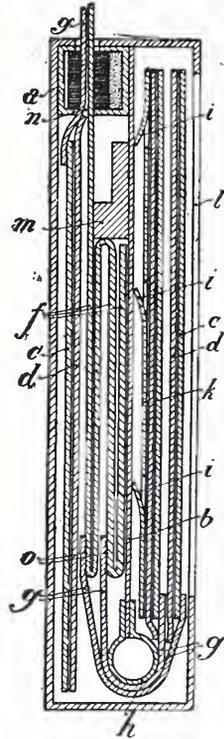

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FILM PACKS.—No. 18,266, 1909 (August 7, 1909). The invention has for its object to enable films to be more easily changed than in film packs, where the alternately folded film-carrying band also serves for covering the film. Whilst in these film packs the carrying band must be drawn out to about twice the length of the film when changing the latter, in the film pack according to the invention it only requires to be moved to about half that amount. This is rendered possible by the film, which is covered by a separate sheet and lies in the front chamber of the film changing box, being connected by intermediate bands with the carrying

band which lies in the rear chamber of the box and the separate folds of which (each consisting of two parts) are about equal to half the length of the film. Semicircular cut-out parts are formed in the intermediate bands, in order to enable the carrying band to be easily taken hold of beneath the ends of the intermediate bands, which adhere to the already exposed films and project from the extraction aperture, which ends have to be torn off each time a film is changed.

A film box with the improved pack is shown in vertical section on an enlarged scale in the figure.

The film box *a* is divided in the ordinary manner by means of a vertical partition *b*, into two chambers, the front one containing the films *c* to be exposed and the covering sheets *d* lying between them, and the rear one intended on the one hand for receiving the alternately folded carrying band *f*, and on the other hand acting

as a chamber for the already exposed films. The films in the front chamber and their cover sheets are connected with the lower edges of the folds of the carrying band *f* by intermediate bands or strips *g* which are carried round a cylindrical shoulder *h* formed on the lower edge of the partition *b*. The films are pressed forward towards the exposure aperture *l* by means of a plate *k* bearing by springs *i* against the partition *b*. In the rear chamber a cross-bar *m*, arranged on the partition *b*, serves as an abutment for the folded carrying band *f*, and is somewhat narrower than it. Consequently the films drawn into the collecting chamber do not encounter the cross-bar, as it is covered over by the carrying band which is drawn out in known manner through the outlet aperture *n*.

Somewhat beneath the point *o* at which the intermediate bands *g* are attached to the carrying band *f* the former are perforated, so that they may be easily separated. At the edge of the still adhering part of the intermediate band a semicircular cut-away part *p* is formed, and on the part of the carrying band which is to be separated is stuck a paper strip *q*, of such a width that it covers the cut-out part *p*. The object of this is that the corners of the cut-out

part may not catch in the outlet aperture and disarrange the film pack. When the intermediate band and the carrying band are torn through, the paper strip remains hanging on the severed part of the carrying band and uncovers the cut-out part *p*, so that now the carrying band *f* below the intermediate band *g* may be easily gripped and drawn out farther. The gripping of the carrying band is further facilitated by its being formed of white paper, and thus being strikingly different from the intermediate bands, which are made of black paper. Johann Georg Schneider, 2, Meiersgasse, Würzburg, Germany.

CINEMATOGRAPH MECHANISM.—No. 5,048, 1909 (February 8, 1909).

The object of the invention is to provide a combined spool and casing adapted to be slipped on and off the machine so that when the receiving spool has received the film from the machine it can be taken off the machine with its casing and laid to one side, thus preventing the films rolled upon the spools which may be out of use lying near the machine coming into contact with any fire, either from the machine, or any other outside source. The spool casing is not fixed to the machine, but is held stationary by the film as it passes through the casing from or to the spool enclosed within it. Frank Ernest Butcher and Francis William Baker, Camera House, Farrington Avenue.

CINEMATOGRAPH IN TUBE RAILWAY.—No. 21,491, 1909 (September 20, 1909).

The essential claim is for an animated picture apparatus wherein a vehicle moving relatively to another part of the apparatus causes images in an illuminated condition to be momentarily and successively brought into the line of vision of the observer, moving each picture in the direction of travel of the vehicle to maintain the picture stationary in relation to the vehicle.

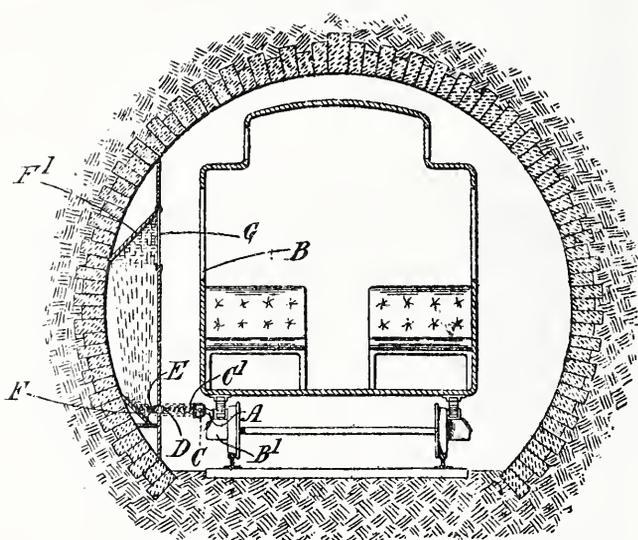

Preferably an arm projecting from the vehicle engages a proje-

tion from a support carrying the picture to move it in the direction of the travel of the vehicle.

According to one modification, the movable support carrying a picture has working in conjunction with it a restoring device whereby after the picture has been moved to a predetermined position the support carrying the picture will be returned to its initial position. Waclaw Czerniewski, 30, Palace Road, Crouch End, London, N.

CINEMATOGGRAPH IN TUBE RAILWAY.—No. 27,583, 1908 (December 18, 1908).—In this specification, applied for nine months earlier than No. 21,491 just mentioned, protection is claimed for the same idea somewhat differently worked out.

A bracket A is fixed to a part of the vehicle B, as for example on the axle box B¹. The bracket carries an electric lamp C that is situated at such a level that it can be brought to register with each of a series of progressive miniature pictures D carried on the wall of the tube. The lamp C carries lens C¹ and the picture on the slide is enlarged by means of a lens E of any well-known form and projected on to a mirror F disposed at an angle to the slide.

From the mirror F the picture is reflected on to another mirror F¹ disposed at an angle to the other mirror and at an angle to a ground glass screen G. By this means the picture is reflected on to the ground glass screen, which is so disposed at the side of the track that the picture on it can be clearly viewed by an occupant in the vehicle B.

The operation of this apparatus is as follows:—The picture on each slide is in turn illuminated by the rays of light from the lamp C as this is carried past by the vehicle. The image on the picture is enlarged and projected by the lens E on to the mirror F. From there it is reflected on to the mirror F¹ and thence on to the screen G, where it can be seen by an occupant of the vehicle. When the light has passed the slide momentary darkness ensues before the next slide is reached, and the result to an occupant carried by the vehicle is the same as that obtained with the well-known form of animated picture apparatus.

The details in this invention may be variously modified. Instead of the picture being projected upon a ground glass screen supported from the track or wall of the tunnel, it may be projected on to a ground glass or other screen carried by the vehicle itself.

Again, instead of a momentary illumination being provided for each picture a light may be constantly maintained before each, but intercepted by a shield or shutter operated by the vehicle as it passes, so that each picture is momentarily thrown on to its screen.

Also, instead of the vehicle carrying the source of light, as already stated, it can be so arranged that some part of the vehicle or the wheel operates a series of electrical switches so that the miniature pictures are in turn projected on to the screen as the vehicle arrives opposite each. Waclaw Czerniewski, 30, Palace Road, Crouch End, London, N., Witold Prus Szczepanowski, 65, Elsenham Street, Southfields, London, S.W., and Jozef Czerniewski, 30, Palace Road, Crouch End, London, N.

New Trade Names

FILEXTRA.—No. 317,853. Chemical substances used in manufactures photography, or philosophical research and anti-corrosives. Pinchin, Johnson and Co., Ltd., Minerva House, 26 and 27, Bevis Marks, London, E.C., varnish, colour, and paint manufacturers. November 3, 1909.

VELOX.—No. 311,795. Sensitised photographic paper. Kodak, Ltd., 43, Clerkenwell Road, London, E.C., manufacturers. March 29, 1909.

LILYWHITE (DESIGN).—No. 316,775. Sensitised photographic papers. Arthur Frederick Sergeant, trading as the Halifax Photographic Co., Lilywhite Works, New Brunswick Street, Halifax, photographic paper maker. October 1, 1909

New Books.

WATKINS' EXPOSURE NOTES.—The pocket-book of exposure data, published by the Watkins' Meter Co., Hereford, has appeared in a seventh edition, and is issued either at 3d. in a limp cloth cover, or at 2s. 3d. in stout pig-skin leather case, provided with two envelopes serving to accommodate the speed list, a spare light-filter or actinometer paper. The entries for exposure provide for notes as to the subject, plate, stop, light, and time of exposure, whilst underneath each set of six spaces for these particulars, lines are provided for entering the developing factor or total time of development adopted. The "Notes," though not in any sense claiming to be a substitute for the Watkins' "Manual," give useful tables and memoranda on exposure, copying, pin-hole photography, development, etc., and, particularly in their new form, should be appreciated by users of the Watkins' meters.

TRIMMING, MOUNTING, AND FRAMING.—No. 102 of the "Photographic Miniature" of our contemporary (the November issue) is a re-edition of No. 20 of the "Miniature," short books on photographic subjects, but is almost entirely a new monograph of these operations. No. 102 deals with trimming prints square with ruled cutting shape, T-square or guillotine, with mounting prints in numbers, with centring prints on large mounts, with dry mounting, with multiple mounting, with passe-partout framing, and with making cloth covered frames. The number is illustrated with several half-tone reproductions and line drawings.

New Apparatus, &c.

The "Sandco" Dark-Room Heater. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

This is a little device which will be appreciated by those who wish to provide moderate heating of the dark-room without the trouble of installing a gas stove, for which frequently there is not sufficient

space, and the fumes of which cannot always find an escape. The "Sandco" heater consists of a fireclay vessel of almost spherical shape, and about 3½ in. diameter. This is mounted on a fitting about the size of one carrying an ordinary incandescent mantle and chimney, the whole adjustment screwing on to any standard gas

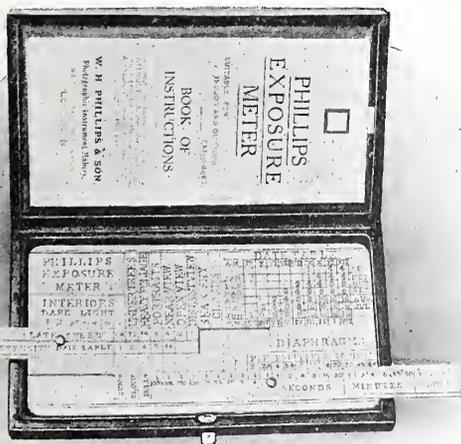

connection. On the burner being lighted the blue flame can be adjusted to heat the fireclay sphere, which then gives out a very considerable amount of heat. So long as the flames are not allowed to spread above the disc, but are adjusted to keep it at a red glow, the heater can be used with safety in the dark-room when handling sensitive plates and papers. The price is 3s. 6d.

The Dallmeyer Enlarging Calculator. Made by J. H. Dallmeyer, Ltd., 83, Denzil Road, Neasden, London, N.W.

Messrs. Dallmeyer have now brought out a spring tape measure to serve as a useful means of calculating enlargement distances when working with a lens of any given focal length, the little device being made up closely on the lines of the telephoto calculator which we recently reviewed. It consists of a circular case of nickelled metal of 1½ in. diameter and about ⅜ in. thick, containing a tape 38 in. in length. The free end of the tape is attached to the enlarging easel and the tape drawn out until the number indicating the required degree of enlargement or reduction appears. The distance between the negative and the easel is then adjusted until the negative is exactly opposite this number, when racking-out of the projection lens to get an image in sharp focus will give an enlargement of the required size, or—as there are always two positions for the lens in the space between the object and the image—will give also on further racking-out the position of the lens when reducing, as for making lantern slides by reduction. The reverse side of the tape bears a scale of inches divided into eighths, and when ordering this useful device it is only necessary to give the focal length of the lens which is being used. The price of the calculator for distances up to 3ft. is 2s., up to 5ft. 3s.

The Phillips Exposure Meter. Made by W. H. Phillips and Son, 98, Truro Road, Wood Green, London, N.

A most convenient form of exposure calculator is made under this name. It provides the means of ascertaining the exposure for the widest range of subjects, from cloud and sky to dark interiors, in all cases without any kind of mental calculation, and at the same time taking account of all the necessary factors, such as light-intensity, plate-speed, and lens-aperture. Not only this: the calculator is so arranged that the most variable element in the case, the condition of the sky, whether "sun" or "cloud," is adjusted last, so that the worker can keep his meter set to a given subject and plate, and make the final adjustment in an instant, according to the time of day and state of the light. This shows him the exposure for each of the series of eleven diaphragms from $f/2$ to $f/64$. We think

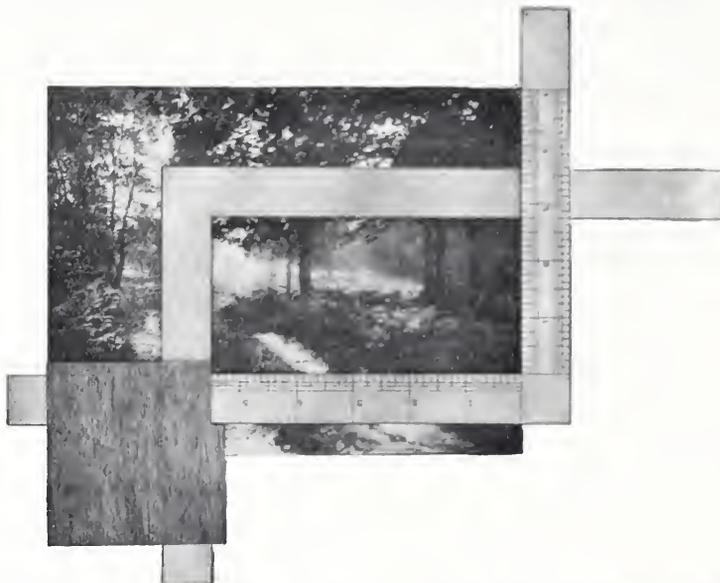

the designers of the meter have taken a very sensible course in dividing plates, as regards speed, into seven classes, denoting the most rapid by 64, and taking the numbers 32, 16, 8, 4, 2, and 1 as the denominators of slower plates. In the instructions it is stated that these Phillips numbers are about 1-10 of the H. and D. number, but it is probable that every worker would fix on the Phillips number which he finds most advisable by one or two preliminary exposures. The meter is made in polished boxwood, contained in a cardboard case, at the price of 5s. 3d., post free; a No. 2 pattern, in box-

wood, stained black, with white lettering and white ivory sliding scales, price 10s. 3d.; a No. 3, in white ivory with black lettering, in wooden case, price 15s. 3d.; whilst an "edition de luxe," made in aluminium, is also supplied, price 20s. 6d. The instructions for use with the meter give a good deal of useful information, including the means of using the meter in conjunction with the Steadman "Solio" method of actually measuring the value of the light.

The "Ensign" Print Proportioner. Made by Houghtons Limited, 88 and 89, High Holborn, London, W.C.

In this piece of apparatus, which Messrs. Houghtons have just issued, we have the old device (of two L-shaped pieces of card) for picking out the best part of a print put into still another, and, we must say, a very convenient, shape. The illustration is almost self-explanatory: the two L-shaped pieces are mounted to clip in a

wooden block, which can be held down firmly with one hand, while each piece is separately adjusted on the print. One piece is graduated into inches and eighths, and the user thus sees at once the exact size which the section he thinks of selecting will have. A pencil run round the inside of the gange then gives him a useful mark when trimming the print. The apparatus takes prints up to 7 x 5, and, rather, we should say, provides for selecting sections of a print up to this size, and costs 4s. 6d.

CATALOGUES AND TRADE NOTICES.

SPENCER'S SECOND-HAND LIST.—A new list from the well-known firm of Arthur Spencer, 41, Harrow Road, W., has just been published, and is particularly worth the attention of professional photographers on account of the large selection of portrait and other lenses, studio and field cameras, and studio stands. Mr. Spencer offers only goods (chiefly standard makes) which are in thorough working condition, and his prices are remarkably moderate.

COOKE LENSES FOR PORTRAITURE.—Messrs. Taylor, Taylor, and Hobson have just issued a 12-page illustrated booklet containing a set of illustrations of the work of the new Cooke $f/3.5$, $f/4.5$, and $f/5.6$ portrait lenses. The negatives are by Mr. Y. Burns, Victoria Studio, Blackpool, and that on page 11 is particularly interesting for its slight and pleasing degree of diffused definition. The booklet, which gives the focal lengths, covering powers, and prices of the lenses, is sent free on application to Stoughton Street Works, Leicester.

PRINT-ON BACKGROUNDS.—The Print-on Ground Co., 171, Jay Street, Schenectady, N.Y., U.S.A., send us their list of "print on grounds," which latter are supplied as stamps, serving to impress a given design of background on the back of the negative. The application of the ground to the negative is evidently an easy matter, but it is difficult to see how the same drawing of, say, a window seat, can be suitable for portraits taken from different standpoints. The price of an outfit, including seven patterns of background, is 12 dollars (£2 10s.).

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, DECEMBER 20.

Shettleston and District Camera Club. "Large Prints from Small Negatives." W. F. Slater.

ROYAL PHOTOGRAPHIC SOCIETY.

At a meeting held on Tuesday, December 14, the President, Mr. J. C. S. Mummary in the chair, Dr. F. W. Edridge-Green gave a lecture on "The Relation of Photography to Vision."

CROYDON CAMERA CLUB.

On Wednesday, December 8, 1909, Mr. H. P. C. Harpur demonstrated the printing in of skies on lantern plates and transparencies in his usual inimitable style, the result being an evening abounding in practical instruction, blended with amusement. Mr. Harpur's usual method is to print the sky on a separate plate, to be afterwards bound up with the landscape transparency, and for this purpose he has devised and made several pieces of apparatus which would be quite beyond the mechanical skill of the average worker. The construction and use of these he explained at considerable length. He always makes warm tone slides, and said he never experienced any difficulty in getting his skies the same colour as his landscapes, because he was precise and methodical in his work. Mr. Harpur's Ex Cathedra style of exposition and his robust belief in the perfection of his own methods inevitably arouse controversy, which, in this case, was mainly sustained by Mr. W. E. Dunmore, who received a severe mauling at the hands of the lecturer.

Commercial & Legal Intelligence.

BANKRUPTCY OF AN INVENTOR.—The first meeting of creditors in John Berryman, 186, Sutherland Avenue, W., was held at the London Bankruptcy Court on December 8. Debtor, who did not appear, having written to the effect that he was ill, had filed no complete statement of affairs, but the Official Receiver said the liabilities were about £800, and there were no available assets. Debtor was described in the receiving order as a patentee, but in his preliminary examination he says that he was for fifteen years a photographer. Five years ago he invented a patent match-box, and gave the sole agency for the manufacture to a firm against whom he subsequently brought an action for infringement. He lost the case, and the firm was now one of his largest creditors. In the spring of 1907 he placed an order with another firm for the manufacture of match-boxes, and subsequently claimed £1,000 damages from them for infringement, but he failed to prove his case, and judgment was given against him for £205 costs in July last. He attributed his position to this litigation, and to speculations on the

Stock Exchange. He claimed to be entitled to about £200 under the will of a relative, but this was disputed. In the result Mr. Child was appointed trustee of the estate, with a Committee of Inspection.

BRIGHTON BANKRUPTCY.—The first meeting of the creditors of Richard William Wicks, photographer, carrying on business at 90, Preston Road, Brighton, was held in Brighton on December 8, when accounts were submitted showing liabilities £460 and assets £67. The matter was left in the hands of the Official Receiver. At a public examination at Brighton on the following day, debtor said that two years and nine months ago he took over the business from his father, for whom he had previously worked. He had a capital of £100—money borrowed without security. There was no profit on the first year's trading, and he believed there was a loss throughout. He added that probably there was no business in which profits had been so cut down as in photography. The examination was adjourned.

PHOTOGRAPHER'S AFRICAN TOUR.—His Honour Judge Woodfall heard an interesting case at Westminster on December 8, when Mr. Frederick Paget, a photographer, sued Mr. Newman, a lecturer in the United States, for arrears of salary and expenses incurred during an expedition through Africa.

Plaintiff's case was that he was engaged at a salary of £5 a week to accompany Mr. and Mrs. Newman on a journey from London to Mombassa, British East Africa, and other places, for the purpose of taking photographs to illustrate a series of lectures that the defendant proposed to deliver in the United States. All plaintiff's expenses were to be paid.

Mr. Paget left London on June 2 of this year, and arrived at Mombassa on June 23, and from there went to Nairobi, Lake Victoria Zanzibar, and then south to Johannesburg and Cape Town. In all the journey lasted 122 days, of which 69 days were spent in train and steamer travelling, leaving only 53 days on which he was able to take photographs. He arrived back in London on October 2, and three weeks' salary was still due to him.

In giving his evidence Mr. Paget said that for sixteen days they were camping out. He exposed over 500 plates and several thousand feet of cinematograph film, and he got 457 perfect negative suitable for lantern slides. Sometimes they crossed sandy desert when it was absolutely useless to take photographs. Developing the plates was also difficult, as it had to be done at night, and frequently in the morning the plates were not dry, and witness had to stay behind when the caravan went on and catch them up as best he could. The water where they camped was generally very muddy, and often contaminated, and this was bad for developing. With regard to the claim for extras, when they were on Lake Victoria the water was so bad as to be undrinkable, and plaintiff drank beer and mineral waters, which were respectively 2s. and 9s. a bottle, the total cost being £3 7s. 6d.

Photographs were taken as Mr. Newman directed, and plaintiff considered that the results were above the average. Mr. Cherry Kearton, whom he met in Nairobi, assisted him for three nights in developing cinematograph films, witness turning his bedroom into a dark-room, with water flooding the place, and the water from the drying films dripping all over the bed. In Zanzibar, plaintiff added that he took seventy-four photographs in two days and exposed 800ft. of film, and, as the result of the hard work in the hot sun, he caught fever, and was ill for a week.

In cross-examination, plaintiff said that for the most part they travelled by train and steamer, with the exception of sixteen days camping near Nairobi. Travelling was very expensive. He denied that Mr. Newman ever said he wanted 500 perfect negatives from him. He wanted 100 for each of five lectures, but he obtained a number of negatives from other sources. With regard to the cinematograph films, Mr. Paget said he took two of the "war dances of the chiefs."

Mr. Cherry Kearton explained that he met Mr. Paget, whom he knew as an expert photographer, in Nairobi, and helped him for three nights until 3 a.m. developing the film, which was better than his (witness's) own. "And the defendant never even had the decency to thank me," added Mr. Kearton.

Asked as to whether it was possible to take twenty-five photographs a day, witness, who had had experience of photography in all parts of the world, said that it was absolute nonsense.

photographs were required for a lecture, and there was a great difference between photographs wanted for that purpose and ordinary amateur snapshots for a penny reading.

Witness had often waited seven days for one photograph. Mr. Paget was working very hard, and Mr. Newman had expressed himself as being very pleased and satisfied with his work. Mr. Newman was rushing through the country like a madcap, and Mr. Paget was doing all he possibly could in the time at his disposal.

Other witnesses were called to show that Mr. Paget was not only an expert photographer, but that Mr. Newman had expressed himself as highly satisfied with his work.

Defendant's evidence, taken on commission, was read by Mr. A. M. Bullock, his counsel. Mr. Newman said that he was the president of the Newman Lecture Company, Chicago, and, having made arrangements for lectures on British East Africa and other places, he found that he must come to London to purchase the necessary apparatus for taking the photographs. He advertised in the "Daily Telegraph" for a photographer to accompany him, and plaintiff was engaged, and assisted defendant in purchasing the apparatus. The agreement was that Mr. Paget was to take 500 perfect negatives, and at his suggestion 3,000 plates were provided.

From the time that Mr. Paget arrived in Africa, Mr. Newman said, he was taking him to task daily about not having enough photographs, and he was always "going to do better next day." While his competitors were taking fifty photographs a day plaintiff was only taking seven, although there was always plenty of material.

His Honour found that defendant was entitled to set off certain items against plaintiff's claim, but he had entirely failed to make out his counter-claim. That being so, plaintiff would have judgment on the claim for £12 10s., with costs, and on the counter-claim with costs.

THE SERVICE COMPANY.—The report is to hand, and shows a gross profit of £7,234 7s., and a net amount available for distribution of £1,751 5s. 7d. Out of this the directors propose to pay a dividend amounting to 9 per cent. in all on the Preference shares, to pay 10 per cent. on the Preferred Ordinary, and 6 per cent. on the Ordinary shares. £196 4s. 6d. has been carried to reserve, increasing that account to £2,000, and the balance, £391 7s. 3d., is carried forward.

DISSOLUTION OF PARTNERSHIP.—The partnership between Esther Mary Robinson and Emma Chambers, carrying on business as photographers at Newark-upon-Trent, under the name of Hunt and Company, has been dissolved. All debts due to and owing by the late firm will be received and paid by Emma Chambers, who will continue to carry on the business.

NEW COMPANIES.

BARKER MOTION PHOTOGRAPHY, LTD.—Registered December 8, with a capital of £5,000, in £1 shares. Formed to enter into an agreement with W. G. Barker, and to carry on the business of cinematograph manufacturers, etc. Signatories: W. G. Barker, Westmorland Lodge, Ealing Common, W., cinematographer, and Raymond, 3, Town Hall Mansions, Fulham Road, S.W., stage manager. First director, W. G. Barker; qualification of other directors, fifty shares. Registered office, 1, Soho Square, W. Private company.

FRANCIS, BYRNE, AND COMPANY, LTD.—Registered December 10, with a capital of £5,000 in £1 shares. Formed to carry on the business of photographic artists, photographers, makers of, and dealers in, photographs and photographic materials, dealers in cameras, etc. Signatories, J. R. Francis and L. Francis, both of High Road, Chiswick, S.W. First director, J. R. Francis. Qualification, 400 shares. Registered office, 19, Hill Street, Richmond. Private company.

PHOTOGRAPHIC EXHIBITION.—At Moscow in March-April next there will be held an International Photographic Exhibition, under the direction of the Russian Photographic Society, of Moscow.

AMADOU.—In reference to the recent queries as to this material, J. Dunning, Chemist, Ventnor, writes:—"I can forward some Amadou. It is 1s. per ounce, and about twelve inches square to the ounce."

News and Notes.

"THE PICTURE POSTCARD."—We find we were in error last week in giving the name of the journal, with which has been incorporated "The Picture Postcard." This should have been the "British Empire Paper Journal," published at 57-59, Ludgate Hill, E.C.

LONDON CAMERA CLUB.—We learn that the minimum amount of capital necessary to launch the project had been subscribed, that steps will be taken forthwith to secure the premises, and that the new club will be ready for the first meeting by March next. Members of the old Camera Club and others interested are requested to write to Reginald Craigie, Esq., 32, Windsor Court, Bayswater, W.

AMERICAN FOOTBALL ON THE CINEMATOGRAF.—The prohibition of football in most of the public schools of America, consequent upon a casualty list of thirty deaths and more than two hundred serious injuries, has raised so great an outcry against the reckless and often brutal manner in which the game is played in the U.S.A., that Mr. Charles Urban (being in New York for the permanent installation of "Kinemacolor," at Madison Square Gardens), promptly bioscoped a typical "Rugger" match, as Americans play it to-day. It took place between the military cadets of West Point and the students of Yale University; the negatives were forwarded by express to this country, and Mr. Alfred Butt is now presenting them nightly in the "Urbanora" number at the Palace Theatre.

DEATH OF MR. MUDIE THOMSON.—We regret to record the unexpected death of Mr. J. Mudie Thomson, the late editor of the "South African Photographic Journal" and hon. secretary of the Cape Town Photographic Society, which occurred on Monday, October 1. The deceased, who was nearly 50 years of age, was educated at Glasgow, and after leaving the University joined the staff of the "Glasgow Herald." Subsequently he was attached to the "Yorkshire Post" and to the Paris edition of the "New York Herald."

Mr. Thomson went to South Africa about twenty years ago, and, in addition to a wide journalistic experience there, saw service in three campaigns—the Matabele Rebellion, the operations in German South-West Africa, when he was attached to General von Trotha's staff, and in the Anglo-Boer war as a non-commissioned officer in Damant's Horse.

LEEDS TECHNICAL INSTITUTE.—On Saturday last the annual re-union dinner of the past and present students of the photographic and printing departments of the Leeds Technical Institute took place at the Great Northern Hotel, Leeds. As the institute has only just added a process and printing section, it was thought appropriate to invite Mr. A. J. Newton, of Bolt Court School, to be the guest of the evening. A very enjoyable evening was spent, inasmuch as the dinner was excellent, the speeches short and enlivened with a good deal of humour, and the musical programme provided a very pleasant entertainment. Among others present were Mr. R. E. Barnett, B.Sc., principal of the institute, Mr. R. B. Fishenden, Mr. Guy Symmons, Mr. John H. Gash, and Mr. Herbert Bairstow.

PHOTOGRAPHS BY ELLIS AND WALERY.—In reference to the illustrations which accompany the inset of Messrs. Fordham and Co., Ltd., on pages 567-70 of the "British Journal Almanac," 1910, Messrs. Fordham write us as follows:—"We shall be glad if you will allow us to intimate to your readers that in our 'Almanac' advertisement of our specialities in mounts we have unwittingly infringed copyrights in three photographs, the property of Messrs. Ellis and Walery, Ltd. The photographs were attached to commercial mounts of our manufacture bearing the name of other photographers, and as these appear in the reproductions we shall be glad of this hospitality of your columns in order to make it known that the portraits in question are actually the work of Messrs. Ellis and Walery."

PHOTOGRAPHIC EXHIBITION AT ST. MORITZ.—Amateur photographers in the Engadine are invited to take part in an exhibition which will be held in the rooms of the Sergantini Museum, St. Moritz, from January 28 to 30, 1910. Three prizes will be offered in each of the following five classes: (1) Landscapes, (2) Sport Scenes, (3) Portraits, etc., (4) Autochromes, (5) Stereoscopic Pictures, and, with

the exception of class 3, preference will be given to photographs taken in the Engadine. Several painters and professional photographers have offered their services in judging the exhibits, which latter must be received at the Museum not later than noon on January 24. All pictures must be mounted, and transparencies provided with means for hanging, but apparatus will be provided for showing stereoscopic pictures. The prizes, which will be exhibited early in January in the windows of Mr. Küpfer's establishment, will be distributed on January 28.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.—The annual members' exhibition, held at the rooms of the association, 180, West Regent Street, Glasgow, has created a record in the annals of the society both with regard to the quantity and quality of the work submitted to the judges, Messrs. Archibald Cochrane and W. A. Gibson. The majority of the entries show that due consideration had been given, not only to the selection and composition of the subjects, but also to their technical qualities, whilst the greater portion also display an equal consideration in the method of framing, and the judges found it no easy task to select the best where so much was first class. The following is the list of awards:—Class I.—Bronze plaques: Messrs. John McClure, Alex. G. Watson, John W. Downs, W. R. Baxter, and Harry Thomson. Hon. mention: Messrs. Thomas Carlyle, Robert Ure, Peter Mitchell, and Thomas Calder. Class II.—Bronze plaques: Messrs. Robert Crerar and John Sawers. Hon. mention: Messrs. William Baird and John Weir. Class III.—Bronze plaque: Mr. John Martin. Class IV.—Bronze plaques: Messrs. Harry Thomson and John Sawers. Hon. mention: Mr. Robert Ure. Class V.—Bronze plaque: Mr. John Sawers. Hon. mention: Mr. V. L. Alexander. Class VI.—Bronze plaques: Messrs. James McKissack (2) and A. J. Gaswood. Hon. mention: Mr. Thomas Carlyle. In the non-competitive class Mr. James McKissack exhibits twenty-three of his characteristic studies, which form an attractive feature of the exhibition.

The association announce that they will hold an open exhibition in February of next year, particulars of which we hope to publish shortly.

Correspondence.

THE MAKING OF A PHOTO-BUTTON.

To the Editors.

Gentlemen,—I fear that the letter in the present issue on making "photo-buttons" will frighten many photographers; but if Messrs. Dorrett and Martin will only save themselves ten out of the twenty-four distinct operations by using my own London-made button parts, they could doubtless afford to sell the finished photographic buttons at a much lower figure. I have during the last few weeks supplied many photographers with "photo-button" outfits, and the only necessary operations they will find are as follows:—

1. Taking or copying photograph.
2. Printing from negative.
3. Cutting print and celluloid.
4. Covering shell.
5. Fixing back and pin to shell.
6. Despatching.

I have at present a repeat order from one of my customers for 25,000 button parts, and photographers who are energetic and wish to make a profit out of the coming general election cannot do better than take up "photo-button" work. I supply the complete apparatus, all London-made, for £5.—Yours faithfully,

JONATHAN FALLOWFIELD.

146, Charing Cross Road, London, W.

REVERSAL BY PHOSPHORESCENCE.

To the Editors.

Gentlemen,—Mr. Wall's letter (p. 961) gives some very interesting particulars with regard to the method of reversal by phosphorescence, and since writing my article on Mr. Carnegie's experiments

I have come across some of his notes, which may serve to confirm, as well as add, to some of the information collated by Mr. Wall.

With reference to the action of heat on the phosphorescence, it appears that Mr. Carnegie finally took advantage of this. The following is a note relating to the production of a positive transparency from a picture cut out of "Punch":—

"Exposed card to sun, then with ground ruby gave three-quarter minutes' exposure to bright sun [of course through the picture]. The card not quite black. Put process plate in contact and heated for four minutes over escape from dark lamp. A splendid strong positive, with whites quite clear. There was certainly some spreading of lines, but this probably due to over-exposure of plate. This evidently is best method of attacking the problem."

A later note says:—

"Subsequent experiment seemed to indicate that spreading of lines is a result of halation, and cannot be avoided by altering exposure." It appears, therefore, that the trouble of mottled appearances over the plate, or granularity, was got over by the heating process. The spreading of lines was not got over, but it was not a very obvious defect in the examples he showed me some time ago. For my own part, I think a perfectly smooth luminous surface will get rid of this trouble, but such a surface is hard to produce.

With regard to Warnerke's experiment of exposing luminous paint surfaces in the camera, Mr. Wall's note mentions an exposure of one minute, but Mr. Carnegie records a similar experiment in bright July sun in which seventy-nine minutes' exposure, followed by heating on a copper plate, was necessary to give a distinct luminous image.

Another item in the notebook refers to the effect of the spectrum when thrown for ten minutes on a sheet coated with luminous paint that had been kept in the dark for two days. The note says: "A sharp band in the red was dark. There was evidence of another darkish band further up the spectrum. The intensest phosphorescence was in the violet and ultra-violet."

Another experiment—this time made with an artificial spectrum—led to the following results, the same sheet being used:—

"On throwing artificial spectrum on it and examining at interval found—

"(1) About as much, if not as much, phosphorescence at less refrangible end of spectrum (red and yellow) as at more refrangible end.

"(2) The phosphorescence increased most rapidly at more refrangible end—in the violet, for the most part. The green and blue green remained darkest. The red end lost in intensity relative to the violet."

This seems to bear on Abney's statement referred to in Mr. Wall's letter.

Some other experiments recorded by Carnegie seem to show that the phosphorescence of one luminous card does not cause phosphorescence in a second card. He also makes several notes recording the fact that good images can be produced easily on bromide paper by placing it in contact with a luminous image produced directly, yet he seems to have failed to produce equally good results by using reversed luminous image produced by a second exposure through red glass. The first method is, of course, of no use, as the result is only equivalent to an ordinary print from the original.

Though hardly connected with the same subject, it may be well to draw attention to some further notes from the same book on Niepce de St. Victor's process of copying prints by first exposing them to sunlight and then laying them in contact with sensitive surfaces. A series of experiments with modern plates and papers recorded, but in every case the finish is "no result." Another set of notes, headed "Niewenglowski's Experiment," records complete failure to find any evidence of phosphorescent light acting similar to X-rays. Traces of fog are noted, but in each case it appears that pressure was the most probable explanation of it.

I think it fairly certain that Mr. Carnegie was not acquainted with Warnerke's experiments, but Abney's, Seebeck's, and Becquerel's work he was pretty sure to know. His own experiments that I have referred to formed only a part of the preliminary stage of what he hoped to make an exhaustive research into the phenomena of phosphorescence and fluorescence—subjects in which there is, of course, a vast amount of work to be done.—Yours faithfully,

C. WELBORNE PIPEF

CARBON-PRINTING IN WINTER.

To the Editors.

Gentlemen,—As the result of your article on carbon precautions in cold weather, I have been reminded of some very simple dodges that practical carbon-printers resort to for testing the condition of the issue. A slip of tissue is cut off and pinned to the workroom wall by its upper end. This forms a very effective little hygrometer. If it lies flat against the wall the atmosphere is moist and the tissue is considered to be damp. If, on the other hand, the slip curls outwards from the wall, it denotes dryness of both atmosphere and tissue. I have been told of one ingenious individual worker who has made a rough paper protractor or scale, which he fixes alongside his slip. As the slip moves it passes over the scale, upon which is indicated the modified procedure desirable for different degrees of humidity.—Yours very truly,
December 12, 1909.

TRANSFER-MAN.

STEREOSCOPIC PORTRAITURE AND THE "DIXIO" STEREOSCOPE.

To the Editors.

Gentlemen,—In the very able editorial dealing with the above subject, in your issue of December 10, some interesting and important points are raised. One of these, the pseudoscopic effect which results when the mirror of the "Dixio" stereoscope is placed at the right-hand side instead of the left, whether the stereograms themselves are transposed or not, is extremely perplexing and hard to explain. The fact, also, that the transposition or non-transposition of the pictures does not interfere with the stereoscopic effect, provided only that the mirror is on the left, adds to the perplexity, and almost seems at first sight to upset some of the usually received theories of binocular vision.

But, after all, this would not be surprising. Optical and physiological authorities are about as unanimous in their explanations of stereoscopic phenomena as chemists are with regard to the nature of the latent image. Brewster disagrees with Wheatstone, while Brücke and Le Conte differ from both.

Theoretically, as your editorial says, the ideal viewing distance should correspond with the focal length of the lens used in taking the stereoscopic negatives, or, strictly speaking, with the actual focus of the objective at the time of exposure. This, however, is a rule which, to a certain extent, may be violated without any very grievous detriment to the relief or perspective observed in the stereogram. One has only to consider the case of anaglyphic stereograms, seen through bi-coloured spectacles and with no fixed viewing distance, to perceive the truth of this statement. Stereoscopic projection, also, is another instance where the rule is broken, as far as most of the spectators are concerned, without very objectionable results. In the case of the "Dixio" stereoscope, prints larger than 2 in. by 10 in. are hardly likely to be examined, and with these there is no exaggeration of relief nor perceptible distortion with a 10 in. or 10 in. viewing distance, though, as far as portraiture is concerned, such conditions are not recommended. This size would be exceptional; for ordinary purposes the average dimensions probably would not exceed whole-plate.

It would certainly be an improvement if the partition were provided with a sliding panel holding the mirror, having a scale of inches attached and actuated by rack and pinion. Then, if the stereograms were marked with the focal length of the lens, the exact viewing distance could readily be obtained for any subject or size. In default of this, if very large pictures are to be examined, the partition with the mirror is easily raised in the hand.—Yours faithfully,
A. LOCKETT.

COLOURS IN THE STEREOSCOPE.

To the Editors.

Gentlemen,—In reference to Mr. Lockett's comparison of stereoscopic methods, I must say that, considering the advance in modern apparatus, I consider the double prism the most efficient and, when one takes into account its applications, the more commercial. As to the question of grain, the manufacturers may be complimented, for both plates and papers are so finely grained that even when magnified the grain does not assert itself so as to cause inconvenience; if it did, the effect would be eliminated by the exact grain

not coinciding in both pictures. Again, as to the amount of detail, let us consider the amount in a microscopic negative, and then we may readily obtain all that is desirable (and more, if necessary) on the stereogram, which is hundreds of times larger.

In reference to the paragraph in "Ex Cathedra," you say it is not possible to combine colours binocularly, and you state that when the effect is produced of combining blue and red the result is feeble or weak. Whatever did you expect? If you had gone further and added the complementary colour, say, by viewing in a yellow or greenish light, you would have made all trace of colour disappear. Why? Because one colour, when blended optically with another, dilutes it towards white. The result of the suggested experiment (that of viewing a white object by red and blue) I fail to imagine, but can inform you that the intermittent effect occurs from several causes, the chief being that the blue and red (or whatever colours are used) are not balanced, or are held at an angle to cause reflections from extraneous sources. This is obviated by screening out cross lights by "hooding" the prisms. I am led by the result of years of practice with the ophthalmoscope to ascribe this effect to the abhorrence that the brain has for confusion. This causes a sudden flow of blood to various parts of the system. For example, take the sudden flush of blood that immediately saturates the brain on the occasion of (may I say chaotic?) fright, and, similarly, the retina of each eye receives the same when the eye strain signals the brain for help. The more finite colour spores or minuter nerves are brought to a state of high efficiency, and then, choked with blood, it devolves upon the other eye to try to grapple with the confusion when, in the interval of rest, the blood recedes. Incorrect pupillary distance or badly centred prisms are, perhaps, another cause. The eyes will only combine colour when the result makes proper sense. The ears are similar. This can be proved by attaching two phonographs, mutually synchronised, one to each ear, and each playing part of the same music—one might represent the voice and the other the accompaniment—but make the pieces dissimilar so as not to harmonise, and the result is maddening. And, indeed, why not? Otherwise, if we could not expect one eye or ear to do the usual work of the two (except for difference of position), many a one-eyed or one-eared man would be worthless. Yes, we can obtain combined colour impressions in the brain when those colours are the assembling of parts to form a whole, but not otherwise. I enclose postcard to illustrate my meaning, and should be pleased to hear if you succeed in forming a yellow effect (in the centre of petal) from a red and green source.—Yours faithfully,
GILBERT DEAS.

9, Mary Street, Dublin.

December 7, 1909.

[We gather from the above letter (which reached us before the appearance of last week's article on "Stereoscopic Portraiture and the Dixio Stereoscope") that our correspondent is largely in agreement with our views as to the difficulty of combining colours on the stereoscope. But from the above letter we cannot be quite sure of this. It is quite true that a degraded yellow is to be seen in the stereoscopic combination of the prints which our correspondent sends, but other hues, saving a dirty plum colour, are absent, except in the background, which is disturbed by blue and bluish-green tints. Our point was that stereoscopic combination is most unsatisfactory for obtaining effects in natural colours, and this our correspondent's result abundantly proves. In reference to his theory, we are sorry we are unable to discuss "colour spores," and we have never known "chaotic fright." Has our correspondent studied Wheatstone's original writings on this subject in the "Philosophical Transactions," and now obtainable in "Wheatstone's Scientific Papers"?—Eds. "B.J."]

GOVERNMENT PHOTOGRAPHIC POSTS

To the Editors.

Gentlemen.—To become a Government photographer! The easiest and perhaps the best way is to enlist in the R.E., stating you desire to enter the Photographic School of Engineers. You will first be sent to the Institute School at Chatham and be taught process work, photo-litho transfers, and wet plate collodion for printing on zinc, also to produce dry-plate negatives of maps sufficiently dense by development, and this without blocking up the fine lines—tri-colour work, also enlarging and lantern-slide making, printing in albumen, carbon, platinum, bromide, gaslight, P.O.P.

and doubtless some of the newer processes. After this you may be sent to the survey at Southampton. Judging from Colonel Grant's lecture at Bolt Court, they employ about 50 retouchers and about 500 others as photographers, lithographers, engravers, electrotypers, accountants, typists, etc., in fact all the staff for a large commercial concern. Foreign posts are generally advertised. A man was recently required for Cairo at £300 a year, two months' holidays.

The British Museum, South Kensington Museum, the Royal Geographical Society, and the Law Courts all employ a man and a youth each. The Admiralty employ one man, whilst the Foreign Office, the Home Office, the Colonial, and the War Office and the India Office have to be satisfied with a man and a youth among the five offices. At Aldershot and other camps the work is generally performed by a local man, who can turn his hand to any process. Gale and Polden have the work from the Aldershot command. In the London offices preference is always given to an old army man who has been through Chatham and Southampton. The pay in London is not very grand, but the hours are from 10 to 5.—Yours, etc.,
X. Y. Z.

Answers to Correspondents.

- *.* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- *.* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- *.* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- *.* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

WEIGHTS AND MEASURES.—Chemicals are sold, so the table tells us, by avoirdupois weight, which gives 16 drms. or 437½ grs. per oz., or 16 ozs. or 7,000 grs. per lb. Side by side with this is apothecaries' weight, by which formulæ are made up. 1. When I buy 1 oz. of pyro or bromide from a chemist, what do I receive—the avoird. oz. of 437½ grs. or the apoth. oz. of 480 grns.? The photographers' book of scales containing the weights from grains to a 1 drm.-weight are, I presume, apoth. weights, since formulæ are made up by apoth. measure; therefore, I understand that when I buy an ounce of any chemical from a chemist I get 16 drms. or 437½ grs., yet the table for making up a formulæ, the apoth., requires 480 grns. to its oz., and the lb. is 12 ozs. or 5,760 grns., while the avoird. lb. is 16 ozs., or 7,000 grns. I shall be glad to be satisfied on this matter once for all in the same simple way that you explained in last year's "B. J." Almanac what a 10 per cent. sol. was, and why.—C. W.

Chemicals such as you mention are sold by the avoirdupois oz. of 437½ grns. This oz. corresponds with the oz. of water, so that a 10 per cent. solution (to be measured out in ounces) is produced by dissolving 1 oz. in water and making up to a total volume of 10 ozs.

BLEACHING PHOTOGRAPHS.—In making line drawings from photographs, I have difficulty in getting the image to bleach entirely

away. The enclosed specimen is developed with amidol, fixed and washed, both very thoroughly, and then bleached in bichloride mercury, 1 oz.; water, 20 ozs. When the card is wet there is absolutely no trace of the image, but when dried it is as you see. I notice two other formulæ for bleaching in the "Almanac," but as I know it can be done with mercury, I am puzzled to know where I have gone wrong. Will you be so kind as to tell me in this week's "Journal," as I want to make some Christmas cards?—PUZZEL.

For the purposes for which the process is usually employed—viz., preparation of drawings for reproduction in the Press—the faint residual image is negligible. Still, we think you should get the image to disappear completely. Try adding 1 drm. of strong hydrochloric acid to the 20 ozs. mercury solution, and use a matt instead of a glossy paper. You must recollect, however, that the mercury-bleached image is very susceptible to chemical change, and that sulphur compounds in the air, such as those from gas, will revive it quite sufficiently to account for your difficulty. For your purpose it would be better to use, say, the iodine-cyanide formula (in the "Almanac," page 769) which removes the image completely.

COPYRIGHT.—I have been asked to copy an illustration from a book—the portrait of a gentleman—by a cousin of the person represented. The gentleman was killed in the Indian Mutiny, and his brother (who, I understand, wrote the book), has been dead thirty years or so. Will it be safe for me to undertake the work?—COPY.

All things considered we should say it will be safe. No doubt copyright in the original drawing has expired, and unless the subject is a person of great importance, it is hardly likely that copyright has been subsequently created in copies of the original.

EMULSIONS.—Please recommend me a good practical up-to-date work on emulsions.—BROMIDE.

There is none which represents the present practice. Abney's "Photography with Emulsions" (from second-hand booksellers), or his "Instruction in Photography" (Iliffe and Son) will tell you how to make a good but slow emulsion. Next to that you may get Eder's "Photographie mit Bromsilber Emulsionen" (Knapp Halle, a.S.).

ENGAGING AN OPERATOR.—Will you kindly advise me respecting the following, and what I had best do? Being out of a berth, answered an advt. appearing in "B. J." about three weeks since for operator and canvasser. I replied, submitted my references which proved satisfactory, and was engaged at a salary of 15s. and 10 per cent. on results. As I had no money to pay my fare from Liverpool, where I was living, to Sheffield, where the firm had their offices, I wrote and told them I was not in a position to pay the fare. They then wrote back, offering the fare, which was to be paid back out of my salary and commission in instalments, according to amount earned weekly. To this I agreed. They stated, when engaging me, the berth was permanent; so I, of course, accepted same. I was sent from Sheffield to address above, and started work on the Monday, and, as far as I have learned, my operating was satisfactory; at any rate no complaint was made by the gentlemen in charge here. But to my surprise this morning I was told that the firm did not require me further, and was paid up to the amount of 15s. only, and the money advanced for my fare from Liverpool to Sheffield was deducted, leaving me with the large sum of 8s. 6d. to pay my digs. and expenses for the week. It is practically leaving me stranded, about 150 miles from my town and the sum of 8s. 6d. to pay digs. and expenses and to get back. What do you advise me to do in the matter? They give no reason for not requiring me further. My work is all right, so they say; my references are of good character also. The only reason given is they do not require me further. Cannot a stop be put to these methods of dealing with employees? It is hard on a man to be placed in such a position. Is there no way of exposing firms who carry on these methods towards operators and canvassers, and is there no remedy for the employee so treated? Can you not make some warning of my case to the readers of the "B. J." and so prevent others from being caught in the same manner by advts. appearing in the "Vacant" column?—FETCHED.

Your case, as you put it, may seem somewhat hard to you,

we cannot see that you have in any way been duped. The firm sent you the money to pay your fare, to be repaid by instalments. It is not improbable that your work as an operator, or your methods as a canvasser, were found not satisfactory to the firm after the first few days' work. Possibly the statement that you were no longer required was a polite way of saying that. As the firm had advanced you the money to pay your railway fare, of course they would deduct it from the amount due to you. All things considered, we do not see that you have been so ill-used as you seem to think.

MERCURY INTENSIFIED PAPER NEGATIVES.—We have made some large paper negatives intensified with mercury. We find now that after some exposure to light the paper that is the back of the neg. turned brown, though the whites on the film were pure enough. To test it we took a freshly intensified paper neg. and exposed the back to an arc light, covering up half, and in less than thirty seconds it had turned brown. How can we avoid this?—FINCHLEY STUDIO.

This is due, no doubt, to the mercury retained in the paper. In the case of ordinary negatives, several acid baths are necessary to remove the mercury retained in the gelatine, and in the case of paper negatives no doubt the paper absorbs a quantity of the mercury, which is not easily got rid of. We suggest that you try the application of three or four baths of dilute hydrochloric acid after bleaching, and test the effect. If the trouble recurs it seems that your best course will be to abandon the use of mercury for paper prints. For the simple purpose of increasing printing contrast you would probably find chromium intensification quite as efficient.

COPYRIGHT.—About a month ago one of our firm, when out operating, had business in a certain country public-house. The landlady remarked that she would like to have her two children photographed on a large rocking-horse. Our representative offered to, and did, expose a half-plate on same, but did not trouble to take a definite order at the time, as he had other pressing business on hand, and knew he would be there again the next day. He called next day with proof, and showed same to the landlady, who asked the price of one only, but she was told that it would not pay us to take an order for less than half a dozen (half-plate p.B.711). Our representative, however, afterwards offered to print her three for 3s. She left him, saying, "Wait a minute," taking proof with her. He waited nearly half an hour, but she was not again to be seen. This also occurred again the next day. About four days afterwards our representative saw her husband, and asked him about it, and was told there would be no order, as we were *too dear*. He then asked for return of proof, but could not get it, but was told it had been sent away. We afterwards learned that it had been handed to a travelling firm of oil photo painters for a copy of it to be taken in oils (which we have since seen) at about double the price we should have charged for the same thing. What we wish to know is: (1) Have we any claim (if we copyright our photograph) against the publican or the Empire Art Company for infringement (we may say both were cautioned and told that we claimed the copyright by our representative, who happened to call when their proof arrived)? (2) If not, can we make a claim for our trouble and expense in taking negative and proof?—DOMINOE.

Apparently the landlady gave you some sort of an order in the first instance. You did your work in the expectation of being paid for it. You did not regard the job as one which you did with the idea of obtaining an interesting subject of which you, as the owner of the copyright, might make use. This being so, it is immaterial whether the landlady has or has not paid for the work; the copyright is hers. You can sue her in the county court for work done. The case, it seems to us, is almost on all fours with that of a person who comes to a studio to be photographed, and when he gets the proofs does not order from them, but gets them copied elsewhere. The fact that the landlady has had the photograph copied in an expensive way is proof that she considers it good work; she should be made to pay for it.

METOL-HYDROQUINONE DEVELOPER.—As we have several times seen normal formulæ for developers, etc., given in the "Journal," we should be very much obliged if you would give the formula

for metol-hydroquinone which you think to be the most profitable. We use the formula given below:

A. Metol	5 gms.
Hydroquinone	75 gms.
Sulphite of soda	100 gms.
Water to	1,000 gms.
B. Carbonate of potash	100 gms.
Water to	1,000 gms.

For plates equal parts A and B. For over-exposure two parts of A and 1 part of B. For bromide under-exposure 1 part of A and 2 parts of B. For lantern, gaslight, and bromide paper as for over-exposure. We get very good results indeed, but we should like to know your opinion about the following matters:—1. Which quantity of sulphite is necessary to make the developer most keeping? We find quantities from 14 up to 150 gms. in developers as given above, in other formulæ. 2. Do you think it profitable to work with different alkalis for different exposures? 3. Would it be better to use carbonate of soda or caustic soda for under-exposure? Which would be the proportion between these three alkalis? 4. Has the carbonate of soda any advantage over the carbonate of potash? Proportion for above developer? 5. Do you agree with Mr. Watkins that all developing agents are capable of giving throughout same result? 6. Is there any special reason why bromide is included in the different formulæ, wherein it is a general opinion that the best result (by normal exposure) are obtained without bromide (except, perhaps, by hydroquinone alone)? 7. Has the bromide influence on the keeping quality of the developer? We should be very much obliged if you would put this in a short form and answer the questions in the journal.—H. and P. (Copenhagen).

1. You can do with less sulphite if the developer is used for negatives only; you require more if for bromide and (particularly) gaslight papers. Thus we should say that for 1,000 ccs. of mixed developer as applied to the plate, 15 gms. of sulphite is sufficient. This equals 30 gms. of sulphite in your A solution. For developing papers the sulphite per 1,000 ccs. mixed developer may be 50 to 60 gms. = 100 to 120 gms. per 1,000 ccs. A solution. 2. There is no distinct advantage in using different carbonated alkalis for the B solution. The difference, if any, is insignificant. 3. Caustic alkali may be of advantage for under-exposures, though our experience is that the gain does not amount to much. 2. A suitable proportion of caustic potash for 1,000 ccs. B solution is 21 gms., using sodium carbonate cryst., 60 gms., is about right, whilst in the case of potash carbonate about 50 gms., equal to 25 gms. in 1,000 ccs. mixed developer. Caustic alkali is less suited for paper prints, owing to its softening action on the gelatine. We prefer soda carbonate cryst. as the alkali. 4. It has the advantage of being more regular in composition if purchased in pure crystals. There is always some doubt about the proportion of water of crystallisation in the potash carbonate cryst., or, in the case of the dry or anhydrous potash carbonate, how much water has been absorbed. 5. We cannot, nor do we believe that the statement is made in this way by Mr. Watkins. 6. We think a little bromide, say $\frac{1}{2}$ gm. per litre of mixed developer, should be used. It does no harm, and does actually improve the cleanness with which the developer works. 7. None at all.

DRYING PRINTS.—(1) Which is the best way to dry prints so that they will not cockle and curl? (2) Which is the best way to dry mount photographs, cabinets and others, so that they will be perfectly flat when dry? My method of mounting is as follows: I soak prints, blot off the surplus water, put my mountant on with a stiff brush, starch paste, then lay on the mount, and then squeegee in contact with a roller. After wiping with a sponge I put to dry on their backs on clean paper. Can you give me a better way than this? Hoping you can.—F. WALL.

(1) Lay prints face down on thin open-mesh nets, remove before they are quite bone dry, and place under pressure. Messrs. Houghtons supply these nets, mounted in wooden frames. (2) If you use a penetrating mountant like starch you must expect to get a certain amount of curl in the mounts. You will get less if you use a stiffer mountant like dextrine, and none at all if you dry-mount. However, we advise you to arrange some parallel strips of wood about $\frac{1}{4}$ in. square section, and at such distance apart that the mounts when placed between a pair of strips are

bent outwards into a slight bow. If left to dry in this condition they will be easily reduced to flatness under slight pressure.

STUDIO.—In the business of house-painter and decorator, with paintings in oil and water-colour added, it is intended to embrace a branch of artistic portraiture. Can you give any information and advice as to the erection of studio, the most suitable lens for the purpose, as well as a few accessories necessary to complete the outfit? The position of the present premises used is one in which there is a clear space facing to the south of 30ft. by 15ft.; there is no possibility of buildings obstructing this south view, as the ground in front is a churchyard, with an old and historic abbey, some 75 yards or 100 yards from the site of proposed studio. On the other side is drawn a small plan of the present buildings, with their surroundings, as well as the position of the proposed studio. Any information will be most gratefully welcomed.—R. M.

The sketch shows the best that can be done under the conditions. If the plan is drawn approximately to scale we should suggest that the light be somewhat increased, say, to 12 ft. We should also advise that it be glazed with ground glass, which will materially soften the light when the sun is shining. With regard to the lenses, we can give no opinion, as we have no idea of the size pictures it is intended to produce. However, those of the portrait type will be the most suitable, and, in the production of high-class work, the focus should be double in length that of the longest dimension of the picture. As regards accessories, you had better get the catalogues of two or three of the large dealers and see what will best suit your ideas.

CATTLE SHOW PHOTOGRAPHS.—Kindly help me to procure photographs of the different exhibits at the Cattle and Agricultural Show at Islington. I visited the show, and inquired if photographs of the cattle and certain other exhibits were being sold, and was told they were not. If you would kindly let me know to whom to apply I should feel much obliged.—HOPE KAVANAGH, 10, Alexandra Road, Bedford.

We have not heard that there was an official photographer for the show. A number of photographs have appeared in the weekly papers, and the photographers or agencies will doubtless supply prints.

REDUCING SULPHIDE-TONED PRINTS.—Will you kindly tell me if it is possible to reduce a sulphide-toned bromide print, and, if so, the method of procedure?—EN AVANT.

Prepare a stock solution of:—

Copper bromide	260 grs.
Sodium bromide	5 ozs.
Water	20 ozs.

and mix with two to three times its bulk of water to form the reducing bath.

THREE-COLOUR BLOCKS.—Could you inform me whether there is any method (in practice) by which three-colour process blocks can be made without fine-etching, that is—simply rough-etched? At the present time I am using pinachrome bathed dry plates, with Meister Lucius and Brunings' filter dyes. Have also used Dr. Albert's emulsion. Both these methods are good, but still there is a considerable amount of work for the fine-etcher. If you could tell me of a perfect method (practical), I should be greatly obliged.—COLOUR OPERATOR.

Whether three-colour blocks can be produced without fine etching depends very largely upon the original, the materials used, especially the inks, and the care with which the operations are carried out. In the report of the Bolt Court School the year before last, we remember seeing a lithograph and a three-colour reproduction (which was practically a facsimile) shown side by side, without any fine etching at all. On inquiry we find that they always use Wratten's Panchromatic plates, and their own, or Wratten's filters, which have similar absorption regions. On the other hand, they state that, to procure the best results, inks which are not quite permanent have been used. The best commercial inks on the market now are the three-colour complementary inks issued by Mander Bros. Unless, however, the greatest care is taken in all the manipulations, and the original is quite suitable, the inks especially, some fine etching is almost inevitable, whatever process is used.

JAP.—There are two monthly journals: "Shashin-Shimpo" (T. Tato, 4, 10 ch st., Kobikicho, Tokyo), and "Shashin Shava" (Y. Isawa, 18, Neihome, Minami Sullumacho, Sheba, Tokyo). We may refer you to a short article on photography in Japan, which appeared in our issue of March 26, p. 236.

DEPTH OF FIELD.—I have worked out the depth of focus of a 7in. lens according to the table on p. 894 of the "British Journal Almanac," and cannot make the theory agree with practice. In practice the infinity is not sharp in the following example, whereas according to theory it should be. Will you tell me where the fallacy is? I should be very much obliged. Example: Lens, 7in.; value, $f/16$; object focussed 10 yards. Result: Nearest object in focus, 4yds. 2ft. 2in.; farthest object in focus, infinity.—W. DE F. COLLENETTE.

Your figures seem to be correct for a circle of confusion of .01in., but this does not, of course, involve critical sharpness, a confusion of that amount being quite visible. If you want the distance to be critically sharp you must reduce the circle of confusion, as stated in the rules quoted. Probably you would personally consider a confusion of .005in. sharp, and if you calculate on this basis you will find that depth extends from 18ft. 9in. to 75ft. All depends on your own definition of sharpness.

MASTER.—If the young fellow has served two out of his three years' apprenticeship we are not at all surprised that his friends demur to his having to deliver parcels of photographs to customers after the day's work is finished. They paid you the premium to teach the young man his business as a photographer and not for you to employ him as an errand boy. We should certainly say that he is quite justified in refusing to act as such after serving so long a time.

WARNING TO COMMERCIAL PHOTOGRAPHERS.—"I don't take much stock nowadays in these mouth-watering pictures of salads and desserts that are so thick in all the magazines," said a young New York photographer who has lately added a writer of ordinary topics to his list of patrons. "The first time I was asked to take such a picture the subject was just about the most appetising collection of sandwiches I'd ever seen. They were arranged on a dainty d'oyles and placed in a beautiful silver dish. I was told where to deliver the photograph and return the dish, but to never mind about the sandwiches. As I saw in these a much better lunch than I could get anywhere else, I took the picture at once and then sent out for a pot of coffee to go with the sandwiches. I hardly knew which one to begin on, but finally decided in favour of an artistic combination of brown bread and cream cheese. The filling which I'd supposed was cream cheese proved to be a stiff paste, and rancid at that. It coated my mouth and stuck to my teeth. I did so inquiring after that and found that many a photographer has tried to eat similar stuff. Croquettes made of soap, then covered with glue and rolled in bread crumbs, was one appetising subject brought in to a friend of mine to be photographed, and another in the business told of little blocks of wood dipped in frosting to represent fancy cakes. Most of the whipped cream is in reality cotton wool and so it goes."

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Committee appointed by the Board of Trade to enquire into the Revised Convention of International Copyright, signed at Berlin last year, has presented its report, and has indicated the respects in which the suggestions of the Convention are in agreement or at variance with British copyright law. Photography and particularly cinematography figure prominently in the report. We give the paragraphs in the latter concerned with photography (p. 995), and in an article on page 987 draw attention to the possible effect of the Committee's report.

In an article on page 986 an explanation is given of the somewhat puzzling effects which are obtained in the Pigeon or Dixio stereoscope according to the way in which that instrument is used. It is shown that the pseudoscopic and other effects correspond to those which are obtained when viewing glass stereoscopic transparencies under different conditions.

A recent paper by Dr. C. E. K. Mees, read before the Royal Society, has provided the first scientific investigation of the properties of dry plates in respect to "resolving power," that is to say, rendering minute detail. It is shown that resolving power depends both on reflection and diffraction by the grains of the emulsion film, and that it is not the finest grain plate which gives the best rendering of detail. The full text of the paper and reproductions of the results obtained are given on page 989.

Time-thermometers, developing tanks, etc., figure under "Patents of the Week." (P. 996.)

Engagements of operators, and a business point as to the despatch of goods, and the processes concerned in making a photo-button figure with other matters under "Correspondence." (P. 1,002.)

The few practical precautions which are necessary in using the carbon process for making lantern slides are the subject of some notes on page 988.

A notable instance of the capability of a platinotype print to withstand severe conditions is given on page 995.

Under "Photo-Mechanical Notes" reference is made to the production of half-tone blocks direct from transparencies. (P. 995.)

EX CATHEDRA.

A Centre Pointer for the Enlarging Easel.

Makers of the most recent patterns of enlargers have so pampered the worker as regards providing all manner of movements of the negative stage that perhaps there is less occasion for drawing attention to a little device mentioned by Mr. H. Hands in Penrose's "Year-book." It is the provision of a pointer pivoted to one corner of the easel and brought by a touch of the hand against a stop so that the free end of the pointer touched the exact centre of the easel. Such a pointer will, however, be of service when using an enlarger which does not allow of nice adjustment of the negative.

* * *

Photometry and the Law of Inverse Squares.

In our last issue we published an abridgment of Professor Sylvanus P. Thompson's address before the Society of Illuminating Engineers. It contains much matter of moment to photographers, even though at first sight that fact may not be very apparent. Photometry was a prominent feature in the address, and this is the special matter to which we now wish to draw attention. Many of those who have had experience in reading densities must have felt a sympathetic thrill when they noted the reference to "Bunsen's over-rated grease-spot instrument," but possibly they hardly appreciated the full force of the reference to "the errors arising in photometry from the almost universal assumption that the law of inverse squares is fulfilled," which law is, as Professor S. P. Thompson remarks, "so fatally and absolutely misleading if applied to any other case than that of action from a point." In at least one form of photometer that has been put on the market for the use of photographers the source of light is very much larger than the area that is illuminated by it, while in most instruments a fairly large source is of necessity employed in order to obtain a sufficient amount of light. In the type known as the H. and D. photometer the source of light is a disc 6mm. in diameter, and even this may be looked upon as too large in certain circumstances. The late Mr. Douglas Carnegie made some experimental observations on the effect of the size of the light source in this instrument, and we remember he told us that he found that an appreciable error was introduced when the photometer head was brought close to the light for the purpose of reading high densities. He therefore abandoned the usual method of using the instrument, and instead of working as long as possible from one zero observation, he took a new zero for every second or third density, and so kept the photometer head always near the centre of the scale. As, in this instrument, only the right-hand source of light can be reduced in size, and as the error due to size is less as the distance is increased, it

would seem advisable to work always with a zero that is as far to the right as possible. This diminishes the light for all readings, but the diminution is not felt so much as it is when we change from a strong light to a weak one.

* * *

A Bactericide for Photographic Papers.

We constantly receive from correspondents specimens of prints in which are spots and markings, the only apparent explanation of which is the presence of bacteria or the attacks of minute insects. The former trouble, of course, will prevail chiefly when the gelatine is in a moist condition, and on that account photographers in tropical countries are chiefly exposed to it. It is, therefore, interesting to find that a photographer, Mr. F. K. Lawton, in Ceylon, writing to Penrose's "Year-book," recommends a preparation which is without deleterious action on the silver image and yet renders prints immune to the attacks of insects. The active principle is said to be a decoction of the root of the aquatic plant "sweet flag," met with in Ceylon, and called in Tamil "Vasambu." We have no knowledge of the chemical constituent of this extract to which its alleged activity is due, but perhaps some of our medical or botanist readers may be able to supply the information.

* * *

Weights and Measures.

A correspondent last week once more raised the old queries with regard to avoirdupois and apothecaries' weights and measures, and asked whether it was a fact that chemicals were sold in avoirdupois ounces, while formulæ prescribe the apothecary's ounce. This point so often puzzles photographers that it seems necessary to state once more that the word "ounce," when applied to weights, always means the ounce avoirdupois, and never the apothecary's ounce, which does not exist outside books of weights and measures. If a formula in which the ounce is mentioned is to be translated into grains, the ounce should be transposed to $437\frac{1}{2}$ grains, or into 440 grains, which is quite sufficiently accurate for all practical purposes. Our correspondent also refers to another weight that does not exist outside the tables—that is, the avoirdupois dram or drachm. At one time the avoirdupois ounce was divided into eight drams, just as the fluid ounce is still divided into eight drams. If this weight existed to-day it would be a very useful one to photographers, for the two different drams had the same relationship to each other as the solid and fluid ounces, or the more modern gramme and cubic centimetre. However, interfering "reformers," who evidently knew little about the practical requirements of weights and measures, changed the avoirdupois dram. They halved its weight; made sixteen drams to every ounce, and so created a useless weight which dropped out of existence simply because nobody wanted it. It will be noticed that many photographic formulæ give such quantities as 22, 44, or 88 grains per ounce. These arise from the decimal division of the ounce of 440 grains, while quantities of 55 or 110 grains per ounce, which are also met with, show that the writer of the formula has been working on the basis of the old avoirdupois dram. All such formulæ are really in avoirdupois weights, as the avoirdupois ounce is the unit. Where, however, we see such quantities as 60 or 120 or 160 grains, we should look upon the formula as in apothecary's weight, with the dram as the unit, and the ounce should not be mentioned at all except as the unit of the fluid constituents. Unfortunately, some formulæ show that the writers have confused the weights, and the quantities change from avoirdupois to apothecary's units in the most erratic fashion. Carelessness

such as this is responsible for much of the confusion that exists. If people would only remember that there is no such thing as an apothecary's ounce of 480 grains, all confusion would be avoided. The only 480-grain ounce now in existence is the troy ounce, which is used for metals only.

THE DIXIO STEREOSCOPE AND PSEUDOSCOPIIC EFFECTS.

OUR article of December 10 on stereoscopic portraiture and the Dixio stereoscope drew attention to some curious effects produced in this instrument, which effects were described as not quite clear at a glance. From Mr. Lockett's letter of last week we gather that he has also been puzzled by these phenomena, and has apparently failed to find an explanation. It is, however, not a very difficult problem to solve, once we have grasped clearly the state of affairs that exists in the Dixio stereoscope.

It must be remembered that the left-hand picture of the pair used is a reversed picture. This is seen in a mirror which re-reverses it so as to counteract the original reversal; therefore, in the ordinary way the left eye sees an unreversed picture just as it does in the more usual form of stereoscope. Suppose we interchange the two pictures in the Dixio instrument. The reversed left-hand picture is now on the right, and is seen directly by the right eye without the intervention of a mirror, and it therefore appears reversed. The original right-hand picture which was unreversed is now on the left and is seen in the mirror which reverses it. The left eye, as well as the right eye, therefore sees a reversed picture, and the final effect is precisely the same as that of viewing an ordinary stereoscopic transparency from the wrong side. As is well known, such a transparency may be viewed from either side without disturbing the stereoscopic effect. The rights and lefts of the subject are changed, but the relief is just as true in the one case as the other. It is therefore apparent that the interchange of the two pictures in the Dixio stereoscope is simply equivalent to reversing an ordinary stereoscopic transparency, so that proper relief is obtained however we place the pictures.

Now let us consider the case in which the Dixio stereoscope is turned, so that the mirror comes on the right side of the central partition. Let the left-hand picture be on the left side and the right-hand one on the right. The former, which is reversed, is seen direct, while the latter, which is itself unreversed, is seen reversed in the mirror. The effect in the stereoscope is then pseudoscopic instead of stereoscopic.

An exactly parallel case to this can be produced as follows:—Take an ordinary stereoscopic uncut negative, and from it make a transparency without any cutting or transposition of pictures. On reviewing this transparency from the back and through the glass we have exactly the same condition of affairs in the case we are considering, for while each picture occupies its correct relative position, each is reversed as regards right and left. If viewed in the stereoscope a pseudoscopic effect is produced just like that seen in the Dixio instrument.

If we transpose the pictures in the Dixio instrument then the reversed left-hand picture comes on the right, and being re-reversed by the mirror becomes non-reversed to the eye. The unreversed right-hand picture is seen directly by the left eye, and the whole arrangement is therefore similar to that of an uncut print made from a stereoscopic negative, with which, as is well known, a pseudoscopic effect is always produced.

If we invert each of the two pictures so that the subject

is seen upside, the effect produced with the pictures when the right way up are, of course, reversed, just as it is with an ordinary stereoscopic print. The conditions that ordinarily give pseudoscopic relief therefore give stereoscopic relief when the pictures are inverted.

All these varying effects are most easily studied by using a Dixio stereoscope fitted with two mirrors, one on either side of the centre partition, so that the two can be used alternately. We can then get all the effects in rapid succession without the trouble of reversing the instrument.

Possibly the preceding explanation will be clearer if we state briefly the conditions that produce pseudoscopy. In the ordinary stereoscopic slide we see the left-hand view of the subject on the left and the right-hand view on the right, each picture being also correct as regards the rights and lefts of the subject. We can effect two kinds of changes in this arrangement. We can either transpose the pictures so that the left-hand picture is on the right, or we can simply reverse each of the two pictures as regards its own rights and lefts. Either of these changes made alone produces pseudoscopic relief, but if we make both changes together we still have stereoscopic relief, though the rights and lefts of the subject are reversed.

THE REPORT ON THE INTERNATIONAL COPYRIGHT CONVENTION.

THE report of the committee appointed by the Board of Trade to inquire into the recommendations made by the International Copyright Convention at Berlin last year has just been published, and we give on another page the extracts from it specially dealing with photography and allied processes. Our readers will perhaps remember that we published in our issue of November 27 last year the anticipation of the conclusions arrived at by the Berlin conference, and embodied in their Revised Convention, and that we followed these with a further article on December 18, that is to say, on the semi-official publication of the proceedings of the conference.

It will be understood the "Berne Convention" of 1885 represented the result of a conference held at Berne in that year by several of the Great Powers. In 1886 the British Government passed the International Copyright Act, the object of which was to enable the Crown to pass Orders in Council embodying the chief features of the new convention. The subsequent revisions in the Berne Convention made at Paris in 1896 were similarly endorsed in part by Great Britain in 1898, and presumably it is with a view to the issue of still a third order authorising the "Revised Convention" of Berlin that the present inquiry has been instituted by the Board of Trade. Certain passages in the report, however, seem to foreshadow a more thorough revision of the law relating to copyright.

The report of the English committee makes interesting reading. The committee represented the literary, artistic, and dramatic professions, in addition to having within its membership at least two representatives of the publishing trade and several authorities on copyright law. Moreover, the witnesses called numbered forty-five and represented practically all the interests affected by the amendment embodied in the Revised Convention." The first conclusion of the committee will be received with interest, in view of the efforts which are being made to introduce reform into British copyright law. As the result of epitomising the many acts still in force with regard to copyright, the committee refers to the "confusion which prevails," and proceeds to emphasise the advantage which could result if the law could be placed "on a plain and

uniform basis." At present, as the committee's epitome shows, the law relating to literary works, dramatic works, prints and engravings, sculpture, and to fine arts, are dealt with in a large number of Acts, in reference to which the committee quotes the report of the Royal Commissioners on copyright of 1878 to the effect that "the law is wholly destitute of any sort of arrangement, incomplete, often obscure, and even when it is intelligible upon long study it is in many parts so ill-expressed that no one who does not give such study to it can expect to understand it." The whole tenor of this portion of the report is to strengthen the hands of those who would wish to see the consolidation of copyright law. As our readers know, a draft bill for the alteration of the law of artistic copyright is in existence, but it would seem that if the recommendations of the present committee are heeded any new bill will include within its provisions copyright not only in artistic works but in the many other forms of original composition, literary, musical, etc.

One of the notable recommendations of the committee is that architecture be accepted as matter to be protected, an innovation in British legislation which it is thought should be undertaken for the sake of uniformity and because such legislation presents no difference in principle from that applicable to the sister arts. The committee, however, are not unanimous in this matter, and one member, Mr. T. E. Scrutton, whose wide experience of copyright procedure cannot be questioned, strongly dissents from the decision on the ground that it would be very difficult to say what are new and original houses or features of houses, and equally difficult to prescribe remedies for infringement. Nevertheless, in view of the fact that architecture is granted protection in France—possibly also in other countries—it would apparently seem that it is legislatively possible. The matter is only a side issue from the photographic standpoint, but if copyright protection was given to architectural work the result *might* be that photographs representing public buildings, in which there was copyright, would be held to be infringements.

The committee draws attention to the anomalies which exist in copyright law as to registration, and its general conclusion is that it is unfair to authors to enforce compliance with a technicality before granting them the facility to enforce their rights. They are led to recommend the adoption of the clause of article 2 of the Revised Convention, namely, "the enjoyment and the exercise of these rights shall not be subject to the performance of any formality; such enjoyment and such exercise are independent of the existence of protection in the country of origin of the work. Consequently, apart from the express stipulations of the present Convention, the extent of protection, as well as the means of redress secured to the author to safeguard his rights, shall be governed exclusively by the laws of the country where protection is claimed."

A good deal of discussion centred round the period for which copyright shall last, article 7 of the Revised Convention recommending a period equal to the life of the author and fifty years after his death for works of fine art, but for photographic works a period regulated by the law of the country where protection is claimed, provided that this term shall not exceed the term fixed in the country of origin of the work. In regard to this matter, Mr. E. C. Elliott, on behalf of the Artistic Copyright Society, advocated a term of fifty years for photographs, whilst Mr. George Davison advocated the same term as that given to drawings, whatever the latter might be. We may take these two opinions as expressing the commercial and amateur, or pictorial, branches of photography respectively. It will be remembered that the draft bill prepared by the Artistic Copyright Society named thirty years as the period during which copyright endured, and we believe

that that time was decided upon after consultation with leading professional and commercial photographers in whose judgment it was thought to give ample protection and to be more efficient than the present regulation of a term for the life of an author and seven years after his death. The committee, however, in reference to photographic works, recommend a period of protection of the life of the author and fifty years after his death, and in doing this they suggest that when a photograph is produced by an individual author who takes it himself or personally superintends and directs its production on his own account, he should receive the same protection as the actual producer of any other work of fine art, viz., life and fifty years, but that where a person is employed by another, whether the employer be an individual, a firm, or a company, the employer should receive protection for the term of fifty years from publication. They suggest that works produced by processes analogous to photography should be dealt with in a similar manner.

In regard to copyright in cinematographic productions, the committee is quite in accordance with the recommendations of the Revised Convention, namely, that authors of literary or artistic works should hold the exclusive right in the reproduction of these latter in animated photography, whilst original productions intended for representation by cinematograph should receive protection as literary or artistic works provided that the "arrangement of the acting form" or "the combinations of the incidents" can be regarded as the creation, by the author, of work of a personal and original character.

It will thus be seen that the report of the committee, although limited by the matters brought up in the Revised Convention, nevertheless touches a number of points of importance to photographers, and there is every reason to think that the document will be of importance in influencing any proposed alterations in copyright law in this country. Although the draft bill prepared by the Artistic Copyright Society aims to deal only with copyright in this country, yet the great complexity of International Copyright makes it very desirable that any changes in the copyright law of a country should be in the direction of bringing it more closely into line with that in other countries. This view appears to have been kept before the committee.

LANTERN SLIDES BY THE CARBON PROCESS.

THERE was a time when the carbon process was looked upon by amateur photographers as being a difficult one to work. That idea, however, has to a great extent been dispelled, and it is now a favourite process with many amateur workers, partly on account of its simplicity, but largely because of the varied effects which can be obtained with the least possible trouble and with great uniformity in the results. Notwithstanding its large employment for paper pictures, it is at present not very extensively worked for lantern-slides, yet for this purpose it is most admirably suited. This neglect is no doubt due in some measure to the excellence of the special lantern-plates now on the market, the ease with which they can be manipulated, and not least, perhaps, their cheapness. Most persons know that with them, by modification in the exposure and development, a great variety of tones from red-brown to black may be obtained; also, that by different methods of after-toning the colours first obtained can be greatly modified. But in these processes there is difficulty in getting a series of slides all of the same uniform tone, and some methods of after-toning cause the deepest shadows of the picture to lack transparency and the high-lights to be veiled, hence the picture looks more or less muddy

when projected on the screen. These drawbacks to toned gelatine lantern-plates do not obtain in the case of carbon slides.

Tissues may now be had of almost every conceivable colour or tint, and with them we have the assurance that any number of slides may be produced with the certainty that they will all be of exactly the same tint while the shadows are transparent and the lights free from veiling. There seems to be an impression with some few that for making transparencies the special transparency tissue must be employed. That is quite a fallacy, as any other answers the purpose quite as well. There is thus a great choice of colours—various tints of browns, reds, greens, blues, purples, blacks, etc., are all at command.

Here we propose to give some practical hints on working the carbon process for lantern transparencies which may even be useful to those who may be familiar with the process as applied to paper pictures. In the first place, the glass plates must be thoroughly cleaned. This may be done if they are new by rubbing them over with whiting moistened with water and a pledget of flannel. The whiting is then washed off under the tap, and the plates placed in a rack to dry. The plates should then receive a substratum. This will make the after-manipulation easy, as well as ensure that the film will not split off with the heat of the lantern, which it is somewhat liable to do when bare glass is used.

There are several formulæ for the substratum that may be employed. An excellent one, published by the late William Bedford, stands as follows:—

Hard gelatine	270 grs.
Water	3½ ozs.
Chromic alum solution 5 per cent.	g.s.
Glacial acetic acid	7 drs.
Methylated spirit	17 ozs.

The mode of preparation is as follows: The gelatine is softened in the water and then dissolved by heat. The chrome alum solution is added by degrees with vigorous stirring, until the gelatine is all precipitated. It is then well drained and redissolved, with the aid of heat, by the acetic acid. The spirit is then added slowly with constant stirring. Finally, the solution is filtered through fine muslin or swansdown for use.

Another substratum that is probably more generally employed than the above, as it is more easily prepared is:—

Photographic gelatine	1 oz.
Water	25 ozs.

When softened in the water, the gelatine is dissolved by heat; sufficient solution of bichromate of potash is then added to give the solution a golden sherry colour. It is then filtered as above: The glasses, having been warmed are coated with this and dried in daylight. The light renders the substratum insoluble in warm water, and the coating will then hold the image film firmly to the plate during the development, as well as when subjected to the heat of the lantern.

Now a word on the sensitising of the tissue. This may be done in the usual way, say, by three minutes' immersion in a 3 per cent. solution of bichromate of potash, to which a few drops per ounce of liquor ammonia has been added. After taking the tissue from the solution, it is well to squeegee it lightly on a glass plate to remove the superfluous solution, and then hang it up to dry in the dark. Or it may be left to dry on the glass, if that has been previously waxed or treated with French chalk. When that is done the surface of the tissue is protected from dust, and also from injurious vapours while drying. When stripped from the glass the tissue will be quite flat, and will have a highly glossy surface.

As the drying takes place somewhat slowly at this time

of year, unless it is done in a warm and dry place, it may be greatly accelerated by, after the squeezing, immersing it for a few minutes in a dish of industrial alcohol, which will abstract a large proportion of the water. If the tissue is sensitised with a spirit sensitiser—such as that sold by the Autotype Company—all drying troubles are avoided, as it dries in a quarter of an hour. This sensitiser is very economical when small quantities of tissue are required. Spirit sensitiser also has the advantage that, as the fingers do not come into contact with it, they do not get stained, as they may do when the tissue is sensitised by immersion. The negative, or such portion of it that is to be printed from, must be provided with a "safe edge." A lantern-slide mask will do, and for convenience in working it may temporarily be attached in position with a touch of cycle tyre cement at each of its corners. As a further convenience in working, the tissue should be cut a trifle smaller than the glass plate—say, the eighth of an inch each way—then, when it is soaked (by its expansion) it will be just about the size of the glass.

In printing, the exposure should be kept to a minimum, and not be nearly so prolonged as is necessary when the transparency is for enlarging from; about one-third of that time is enough. It should be kept in mind that for lantern-slides the highest lights must be quite bare glass, and not slightly tinted as is desirable when the transparency is required for making enlarged negatives.

Before the exposed tissue is squeegeed on the glass for development, it is well to soak the plate in cold water for a few minutes, so that the substratum is slightly softened. The text-books tell us to soak the exposed tissue in water until it begins to curl film outward. For transparencies on glass it should be removed before this stage is reached—say a little before it gets quite flat. When this is done a slightly greater crispness in the image is obtained, and the carbon film holds more firmly to the glass while being developed. In the development it is well to keep the temperature of the water as low as possible, as too hot water, with a minimum exposure, has a tendency for the delicate tones in the lights to wash away and so leave them bald and hard. After the picture has been developed it should be washed under the tap and then put into the alum solution, as in the case of paper prints, for a few minutes. After that the slide should be well washed to free it from alum, for should any be left in the film it might crystallise out, and thus somewhat impair the transparency of the picture. A slight trace of alum in the film does not have such a marked effect on a paper print as it would do on a lantern-slide when seen on the screen.

The transparency of the shadows may sometimes be increased by varnishing the slide or coating it with plain collodium, but this is seldom necessary, as with most tissues the slides will be as transparent as can well be desired.

ON THE RESOLVING POWER OF PHOTOGRAPHIC PLATES.

[A paper by Dr. C. E. K. Mees, communicated to the Royal Society by Sir William Ramsay, K.C.B., F.R.S., and reprinted by permission of the Council from the Proceedings of the Society.]

Introduction.—The convenience of the photographic plate as a recording instrument, in that it not only makes a record, but also integrates impressions which are individually too faint to be observed, is so manifest that to a continually greater extent physicists are designing instruments for use solely or chiefly by photographic methods.

It is curious to note that while the resolving power of physical instruments generally has been completely investigated, very little indeed has been published upon the resolving power of the plates used as recording instruments.

In considering the resolving power of a photographic plate it is, of course, necessary to deal with the linear resolving power, so that we may define the resolving power to be the distance which must separate two lines of light falling upon the plate in order that the developed image may be recognised to be that of two separate lines.

This resolving power will then give the distance by which, *g.*, the images of two spectral lines must be separated in order that they may be recorded as separate lines, or the images of a double star in order that it may appear double. It is clearly of no use to obtain a higher resolving power in an instrument than the plate used in that instrument will possess.

The only attempt to state this resolving power appears to be that of Wadsworth.¹ Wadsworth states that two lines can be separated if between the particles in the maxima of the lines there are one silver particle and two spaces—that is to say, the linear distance between the two maxima or centres of the lines is equal to four times the diameter of a particle. If the diameter of a particle be called *e*, then we may assume that for photographic resolution it is necessary that the linear distance between the centres of the lines be equal to $4e$.

E. C. C. Baly² states that *e* may be taken as lying between 0.005 to 0.025 mm. This statement is not confirmed, however, by other workers. Sheppard and Mees³ give grain as varying from 0.0011 to 0.0034 mm., which figures agree with those given by Schaum and Bellach.⁴ It is not difficult to make slow plates in which the grain does not exceed a diameter of 0.0005 mm. According to Wadsworth, these plates should therefore resolve lines which are not more than 2,000 of a millimetre apart.

As rough experiments showed at once that the resolving power of such plates did not exceed about 1/20 to 1/40 of a millimetre, the subject was thoroughly investigated in the manner to be described.

Apparatus.—A box was constructed of 16 cm. square section and 330 cm. length. This was screwed to a platform fastened to two heavy beams set edgewise, and the whole was suspended by ropes from the roof, thus eliminating vibration. At one end were arranged an illuminating Nernst lamp and condenser, together with the holder where the slit and gratings shortly to be described were placed. At the other end was screwed a camera built of heavy brass tube, and containing a spectroscopic objective of 15 cm. focal length actuated for focussing by a very slow motion screw. The camera and objective were specially made by Messrs. Adam Hilger, Limited, for the work, and the latter has proved perfectly satisfactory, the images formed by it showing no degradation when examined by a microscope with an enlargement of 100 diameters. The images used in this work were always axial, and did not exceed 3 mm. in diameter. Microscopic examination justified me in assuming that the definition of the image was perfect. At the back

of the camera tube was a brass face-plate against which the brass front of the dark slide fitted. The plates were forced up into a constant plane by springs at the back of the dark slide. The whole apparatus consisted in essence, therefore, of a reducing camera arranged to give a reduction of about 22 diameters, and to maintain a very exact focal plane.

The Slit.—In order to discover what happens to a narrow line of light falling upon a plate, a spectroscopic slit was arranged at the end of the apparatus, and in front of the slit was placed a wedge of neutral black glass giving a variation of intensity in the length of the slit of about 1 to 60. The slit was 9 mm. long and 1 mm. in breadth, and the image was there-

Photomicrographs of the "tadpoles" obtained on various plates are shown below (Fig. 1).

Now the grains of these plates are of the following orders of magnitude:—

An "Extra Rapid" plate	0.0015 to 0.004 mm.
A medium-speed "Process" plate	0.0010 to 0.0015mm.
Homogeneous Grain (a special plate having all its grains of the same size)	0.0015 mm.
Chlorobromide plate	0.0008 mm.
A "Lantern" plate of silver bromide only	0.0004 mm.

It would therefore be expected that the amount of the irradiation would diminish steadily as the grain became smaller,

fore 0.5 mm. high and 0.055 mm. wide. Since the top of the slit was transmitting 60 times as much light as the bottom, the spreading of light by the film of the plate (which is usually known as irradiation) caused the developed image to appear of a "tadpole"-like shape.

Plates backed and unbacked were used; the backing makes no difference, the effects measured being of a different order from those produced by reflection from the back of the glass.

All the plates used were of the same thickness. In the case of fast plates the results are not affected, within considerable limits, by the thickness of the film. In the case of slow plates it is explained later that the thinner the film the greater the resolving power.

vanishing in the very fine-grained plates. This is seen not to be the case at all: the irradiation is at a minimum in the medium-grained "Process," and "Homogeneous Grain" plates, being greatest in the chlorobromide plate.

It would therefore appear that irradiation is not due to one simple cause, but in all probability to at least two causes. These two forms of irradiation might be:—

(1) Irradiation due to reflection, operating in the plates of coarser grain, and to a much less extent in the plates of fine grain. This is the only form of irradiation which appears to have been recognised hitherto.

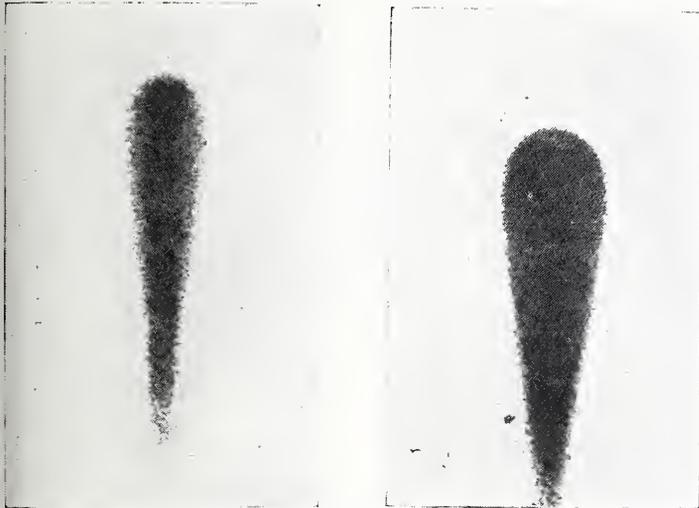

(2) Irradiation due to *diffraction*, operating in plates of fine-grain, and only to a small extent in those of coarse grain.

These two separate causes of irradiation would produce the effects observed, since, as the reflection scatter disappeared, the diffraction scatter would grow, probably producing a minimum of scatter where the reflection scatter was small and the diffraction scatter was also small; and the scatter finally becomes small again as the grain of the plate falls below the wave-length of light.

The effects produced by these two causes will differ:—

(1) Diffraction scatter will become less as the wave-length of the incident light increases. Reflection scatter will be unchanged by an alteration of wave-length.

LANTERN PLATE.

With α screen.

With θ screen.

Fig. 2.

tween the results on the "Process" plate, but that on the "Lantern" plate the scatter is normal with the θ screen, but is greatly diminished by the use of the α screen.

In order to examine the second possibility, a photomicrographic apparatus was arranged behind the small camera, so that by opening the back of the dark slide the appearance of the image as scattered by the film of the plate could be photographed. This appearance, as scattered by the "Process" plate, is shown in Fig. 3. No difference was observed in the image whether the front or the back of the film was photographed. But with a chlorobromide plate (Fig. 4) the scatter

With α screen.

With θ screen.

Fig. 3.

Fig. 4 (a).

Fig. 4 (b).

(2) Diffraction scatter will be small upon the surface of the film, and will grow as the film is penetrated. Reflection scatter will be nearly constant throughout the film.

In order to investigate the first possibility, "Process" plates which were expected to show "reflection" scatter, and "Lantern" plates which were expected to show "diffraction" scatter were made sensitive to red light by bathing them in a solution of pinacyanol. Two screens were then taken, the one, α , transmitting red light of from 660 to 720 $\mu\mu$; the other, θ , letting light of from 400 to 450 $\mu\mu$; and the slit was photographed on the two plates through the two screens. The result (Fig. 2) shows that there is a very small difference, if any, be-

was small on the face of the film (4a) and great on the back of the film (4b).

We may therefore conclude:—

(1) That the resolution of a photographic plate is dependent on the amount of irradiation displayed by that plate.

(2) That irradiation is not directly proportional to the size of grain, but is caused by two different forms of scatter arising from (a) reflection and (b) diffraction.

(3) That the resolving power is likely to be much smaller than that indicated by the theory of Wadsworth.

In order to experimentally determine the resolving power, a series of black and white line gratings were constructed

having alternate black and clear lines of equal width, the width of the clear glass being as in second column of table.

Grating.	Width of clear line in millimetres.	Distance apart of lines on plate in millimetres.
1	0.88	0.049
2	0.64	0.036
3	0.47	0.026
4	0.36	0.020
5	0.32	0.018
6	0.29	0.016
7	0.14	0.0078

place of the slit), these produced images in which the width of the black space (the distance between two lines) was as in third column.

These gratings were then photographed upon the various plates and the effect observed. Some of the actual results obtained are shown as photomicrographs in Fig. 5:—

I. Grating I was resolved by all the plates. Fig. 5—(a)

So that the limit of resolution possessed by dry plates chemically developed may be stated to be as follows:—For an ordinary fine-grained plate, lines will be just resolved if they are separated by 0.018 mm. (For a coarser grain, as in all fast plates, about 0.030 mm. is necessary.)

For very fine-grained plates for violet light, 0.018 mm. will be resolved; with red light, 0.008 mm. may be discerned.

The resolution on the surface of a fine-grained plate will obviously be much greater than this, as is shown by the very high resolving power possessed by the fine-grained "albumen" plates which are developed by the deposition of silver from an acid silver solution.

In order to discover whether or not a similar advantage would be shown by gelatine plates when developed in the same manner, the experiments on the resolving power of "Lantern" plates were repeated, the plates being developed in a solution suggested by Lüppo-Cramer, namely:—

Metol	2 grammes.
Citric acid	10 grammes.
Water	100 ccs.

To which is added, just before use, 10 ccs. of 10-per-cent. solution of silver nitrate.

Although plates so developed show no trace of grain under 1/10-inch objective, yet the resolving power is not greater than in plates developed in the ordinary way.

This method of development enables us, however, to utilise gelatine plates having a very much thinner film than would otherwise be possible, and there was prepared on these lines a special plate, having the fine-grained lantern emulsion coated very thinly, and made panchromatic by bathing in pinacyanol. These plates are more sensitive to red than to blue, and seem to be suitable for photographic use in spectrographs of small dispersion.

With violet light it just resolves grating No. 7, corresponding to lines of 0.008 mm. separation; with red light, lines of

0.004 mm. separation can be resolved. Fig. 8 shows grating No. 7 with red light on the special plate.

Application of these Results to Spectroscopy.—We have seen that in order to be resolved by an ordinary plate, lines need to be separated by 0.03 mm. Now, in the first order of a 6.5-metre focus Rowland grating of 14,438 lines per inch, 0.37 mm. length of the plate corresponds to 1 A.U.⁵

The plate will therefore just resolve lines separated by 1/10 of an A.U. Now, for a 5-inch grating the resolving power will be 75,000, or (at 5000 A.U.) 1/15 of an A.U. So that the limit of resolving power is fixed, even for spectroscopes of great dispersion, by the plate and not by the resolving power of the instrument. In the case of small spectroscopes having a dispersion of about 500 A.U. to 10 mm. on the plate, the resolving power is limited to about 2 A.U. With the special plate, this can be increased to 0.5 A.U., corresponding approximately with the resolving power of such small instruments.

The work on the effect of irradiation upon the diameter and position of spectral lines, star images, etc., is being continued.

My best thanks are due to Mr. E. J. Denney and Mr. Kenneth Hunter, who have made a great number of the measurements and photographs required, and also to Mr. S. H. Wratten, who has made many experimental plates. I am indebted also to Dr. L. N. G. Filon for his interest and advice.

My thanks are due to Messrs. Wratten and Wainwright, Limited, for permission to publish this work, which was done in their Research Laboratory. C. E. KENNETH MEES.

RECOMMENDATIONS AS TO COPYRIGHT LAW.

THE report of the committee appointed by the President of the Board of Trade to consider the revised International Copyright Convention, signed at Berlin in November, 1908, has been holding its meetings during the past summer, and its report has now been presented, and was published on Saturday last by H.M. Stationery Office at the price of 5d. It is obtainable from any bookseller, or from Wyman and Sons, Ltd., Fetter Lane, E.C.; Oliver and Boyd, Tweeddale Court, Edinburgh; and E. Ponsonby, 116, Grafton Street, Dublin. The committee was presided over by Lord Gorell, its other members being the following:—Sir Lawrence Alma-Tadema, Mr. G. R. Askwith, K.C., Mr. E. Cutler, K.C., Mr. T. E. Scrutton, K.C., Messrs. H. Granville Barker, William Boosey, C. W. Bowerman, Henry R. Clayton, Henry Cust, Anthony Hope Hawkins, W. Joynson-Hicks, Algernon Law, Frederick Macmillan, Walter Raleigh, and E. Trevor Ll. Williams.

The duty of the committee was to examine the various points in which the revised International Copyright Convention, above referred to, was in any accordance with the law of the United Kingdom, and to consider in each case whether that law should be altered so as to enable His Majesty's Government to give effect to the revised Convention. General considerations of literary, musical, and artistic copyright occupied the committee, and one of the most debated subjects was the reproduction of musical works by devices such as gramophones and mechanical pianos.

Photography figures perhaps next in order of prominence among the matters which were specially raised. Among the witnesses called were Mr. E. C. Elliott, of Messrs. Elliott and Fry, who, with Mr. George W. Agnew, Mr. Edwin Bale, Mr. D. Croal Thomson, Mr. V. Reynolds-Stephens, and Mr. H. A. Voysey, represented the Artistic Copyright Society. Mr. A. L. Coburn and Mr. G. Davison were called in reference to certain views as to copyright in photographs.

We refer, in an article on another page, to the recommendations made as regards photographic copyright by the committee, and we give here the extracts from the report which deal particularly with these items. The complete report, it may be mentioned, contains a very useful summary of previous copyright legislation, and also an appendix which shows the revisions carried out in the Convention

last year, as compared with the Berne Convention of September 9, 1886. (In setting out the articles of the Revised Convention, the provisions of the Revised Convention which differ from those of the Berne Convention and the Additional Act of Paris, to which alone Great Britain was a party, are shown in thick type.)

Art. 3.—The present Convention shall apply to photographic works and to works produced by a process analogous to photography. The contracting countries shall be bound to make provision for their protection.

It will be noticed from a perusal of this article, compared with the corresponding provisions of the Additional Act of Paris, that an alteration is made in the present article to the effect that it will be obligatory on the contracting countries to make provision for the protection of photographic works. Photographs are protected in the United Kingdom under the provisions of the Fine Arts Copyright Act, 1862, but there is no reference therein to processes analogous to photography, if there are any such. The Act also requires registration, see section 4. The 4th section of the International Copyright Act, 1886, dispenses with registration in the case of foreigners to whom an Order in Council applies. It therefore appears to the Committee that, except so far as required to give protection to works produced by processes analogous to photography, no change in the present state of the British law is necessary to give effect to this article, but it is quite obvious that an amendment of the British law would be required in order to place the law of this country as related to its own inhabitants on the same footing as that which would apply to the position of foreigners.

The Committee accordingly recommend that this article should be adopted, and that the British law should be altered with a view to bringing about general uniformity.

In this connection it may be noticed that a question may arise as to who is the author of a photograph or to whom the copyright belongs in the case of a company. So far as these matters affect the duration of the copyright, they may more properly be dealt with under Art. 7. We may, however, point out that it would be advisable in dealing with the protection of photographs to provide for the copyright remaining with the author unless it is agreed in writing to the contrary, except in the case of a person who orders a

photograph to be produced for him, and that in that case the copyright should, on completion of the terms of the order, become the property of the person giving the order, unless there is an agreement in writing to the contrary. If this view be adopted it would be necessary to alter the provision contained in the Fine Arts Copyright Act, 1862, section 1. Similar observations may be made with regard to dealing with the protection of works produced by processes analogous to photography.

Art. 4.—Authors who are subjects or citizens of any of the countries of the Union shall enjoy in countries, other than the country of origin of the work, for their works, whether unpublished or first published in a country of the Union, the rights which the respective laws do now or may hereafter grant to natives as well as the rights specially granted by the present Convention.

The enjoyment and the exercise of these rights shall not be subject to the performance of any formality; such enjoyment and such exercise are independent of the existence of protection in the country of origin of the work. Consequently, apart from the express stipulations of the present Convention, the extent of protection, as well as the means of redress secured to the author to safeguard his rights, shall be governed exclusively by the laws of the country where protection is claimed.

The country of origin of the work shall be considered to be, in the case of unpublished works, the country to which the author belongs; in the case of published works, the country of first publication; and in the case of works published simultaneously in several countries of the Union, the country the laws of which grant the shortest period of protection. In the case of works published simultaneously in a country outside the Union and in a country of the Union, the latter country shall be considered exclusively as the country of origin.

By "published works" must be understood, for the purposes of the present Convention, works copies of which are issued by a publisher. The representation of a dramatic or dramatico-musical work, the performance of a musical work, the exhibition of a work of art, and the construction of a work of architecture shall not constitute a publication.

Par. 2 of the Article makes considerable alteration in the provisions of the Berne Convention, Art. 2, par. 2, under which compliance with the formalities (if any) imposed by the country of origin is a condition of protection in other countries, and it is a question for consideration whether all formalities should be done away with in accordance with the new provisions introduced by Art. 4, par. 2 of the Revised Convention.

On general principles there seems to be no reason why owners of copyright should be required to comply with formalities which are not imposed in most other cases of ownership of personal property. Anyone who copies the products of an author's genius ought to be taken to be doing so at his own risk.

The present requirements of British law as to registration are anomalous, uncertain, and productive of great disadvantage and annoyance to authors, with little or no advantage to the public. In some cases registration is required as a condition of suing, in others it is not; in some cases proceedings can be taken for infringements committed prior to registration, in others they cannot. Special reference may be made to the requirements of registration in the Musical Copyright Act, 1906, which appear to extend to foreign authors claiming by virtue of the Berne Convention, as well as to British authors. It would seem to be a question whether, although registration is necessary before proceedings can be taken under this Act, infringements committed prior to registration are not liable to its penalties.

The Committee fail to see what advantage to the public can be expected from systems of registration which are particularly onerous in the case of foreign authors, and if abolished for them should equally be abolished for authors of our own country.

One of the witnesses laid stress on the importance which he attached to the requirement of registration (in regard to photographs) as a means of ousting frivolous claims for damages if it should not have been effected. But it seems to the Committee that this example serves rather to illustrate the unfairness to authors of making their ability to enforce their rights depend on compliance with a technicality.

The present requirements of the law under section 1 of the Fine

Arts Copyright Act, 1862, with regard to the first assignment of copyright in artistic works, amount to a formality which presses hardly both on British and on foreign authors.

Art. 7.—The term of protection granted by the present Convention shall include the life of the author and fifty years after his death.

Nevertheless, in case such term of protection should not be uniformly adopted by all the countries of the Union, the term shall be regulated by the law of the country where protection is claimed, and must not exceed the term fixed in the country of origin of the work. Consequently the contracting countries shall only be bound to apply the provisions of the preceding paragraph in so far as such provisions are consistent with their domestic laws.

For photographic works and works produced by a process analogous to photography, for posthumous works, for anonymous or pseudonymous works, the term of protection shall be regulated by the law of the country where protection is claimed, provided that the said term shall not exceed the term fixed in the country of origin of the work.

The proposal in the first par. of Art. 7 is new to British law, and considerable discussion has arisen before the Committee as to the advisability of acceding to the grant of a lengthy protection such as is contemplated by this paragraph. On the one hand it has been contended that, without such an extended term, authors do not in all cases receive adequate protection, especially for the more important class of works, and instances of these have been given in evidence before the Committee. On the other hand, it has been contended that such a period of protection as that suggested is detrimental to the public interests and possibly to some trades, but after very careful consideration of the matter, the Committee have come to the conclusion that it is desirable to accede to this proposal. In the case of works of a short term of popularity, practically no difference would in effect be made by adopting this proposal, and in the case of more important works which should receive a lengthy protection it seems desirable that such protection should be afforded.

Par. 3 leaves the law of the country where protection is claimed to provide for the duration of protection for photographic works and works produced by processes analogous to photography, for posthumous works, and for anonymous or pseudonymous works, provided that the said term shall not exceed the term fixed in the country of origin of the work; and therefore it will be open to the British Legislature to make special provisions for the term of protection for such works although par. 1 may have been adopted. The considerations to which we have referred under par. 2 would seem to apply here, and it appears that Great Britain may, in carrying out the Revised Convention, give for protection the lesser of two periods (if there be any difference), i.e., the period given by the domestic law of the United Kingdom and by the country of origin, but may give a longer period than that of the country of origin.

The Committee make the following recommendations with regard to the works mentioned in para. 3:—

Photographic works and works produced by processes analogous to photography are specially dealt with, because, while certain countries—England, for instance—recognise no difference between photographs and other works of fine art, other countries, notably Germany, treat them exceptionally.

In the United Kingdom photographs have always been regarded as works of fine art, and when copyright protection was given to the latter in 1862, photographs were placed on precisely the same footing.

Evidence was given by certain witnesses in favour of giving to photographs a fixed term of 50 years from publication rather than a term of life and 50 years, owing to the alleged difficulty of determining the author, but the Committee, on the whole, see no reason for making this suggested distinction, and accordingly recommend that a term of life and 50 years shall be given to photographs and works produced by processes analogous to photography generally.

In order, however, to meet the practical difficulty of determining the author in the case of photographs produced by a company or a firm, we suggest that when a photograph is produced by an individual author who takes it himself or personally superintends and directs its production on his own account, he should receive the same protection as the actual producer of any other work of fine art.

...t, viz., life and 50 years, but that where a person is employed by another, whether the employer be an individual, a firm, or a company, the employer should receive protection for the term of 50 years from publication. We suggest that works produced by processes analogous to photography should be dealt with in a similar manner.

Art. 14.—Authors of literary, scientific, or artistic works shall have the exclusive right of authorising the reproduction and public representation of their works by cinematography.

Cinematograph productions shall be protected as literary or artistic works if, by the arrangement of the acting form or the combinations of the incidents represented, the author has given the work a personal and original character.

Without prejudice to the rights of the author of the original work, the reproduction by cinematography of a literary, scientific, or artistic work, shall be protected as an original work.

The above provisions apply to reproduction or production effected by any other process analogous to cinematography.

The Committee consider that this Article is reasonable, and therefore recommend its adoption, although it introduces new matter into the area of protection, and that the necessary legislation for that purpose and for domestic purposes should be included in any enactment necessary to carry out the suggestions in this report.

A CRUCIAL TEST OF PLATINOTYPE PERMANENCY.
The permanency of a platinotype print has long been a truism. The test of time and the action of chemical reagents have combined to show that the image of a platinotype makes the latter the most permanent form of photographic impression, or, to use a phrase which

photograph—considerable differences exist between the paper or raw stock which forms the support of photographic impressions. And therefore there seems good reason for drawing attention to a most interesting case of photographic permanency, the examples of which, lying before us, show, not only the remarkable permanency of the picture produced on a platinotype print, but also the ability of the paper print itself to retain its qualities under the most trying conditions. The prints in question were made on ordinary cold-bath black platinotype paper, and were supplied by Mr. Thomas E. Howe, a professional photographer, of High Street, Chatham, to a member of the staff of the ill-fated cruiser, H.M.S. *Gladiator*, during the submergence of which vessel, from April 25 to October 4, they were exposed, with other property of the officers, to the action of seawater. The photographs had been originally mounted on fairly stout boards, but when recovered from the ship the whole of the mounts were disintegrated and separated from the surface paper, to which alone the prints still adhered. In the half-tone reproduction which we have had made of one of the examples, it is seen that, whilst the mounting paper has been totally ruined, the photograph is unaltered; as regards its quality and permanency (to which a half-tone copy cannot do justice), our readers must take it from us that they are, to all intents and purposes, those of a freshly made print. Such a record as this will perhaps not surprise those who have had other opportunities of noting the high degree of permanency of platinotype prints, but we have thought it well to refer to it at this length, as it is a case the particulars of which are fully authenticated by the owner of the photographs.

Photo-Mechanical Notes.

Half-tone Blocks from Transparencies.

In the early days of block-making it was quite the usual thing to make screen negatives from transparencies, and most establishments had a special transparency camera fitted with a large condenser, for this work. That was before the bad practice of "flashing" had become so prevalent, so that if any original of too strong contrast was sent, it was doubly photographed, an ordinary negative first made in order to compress the scale of contrasts within the limits of the screen process, from this a transparency was made and from that the screen negative. The advantage is obvious, as all the gradation and detail is secured, the only thing altered being the scale of contrast. To-day, with "flashing," the contrasts are reduced, but at the expense of detail and truthful gradation. Also the transparency camera is extremely useful when negatives themselves were sent or could be secured, because it so often happens that a better glass positive could be obtained from a negative than any form of paper print. This is particularly true of very thin negatives or films. Also, of course, positives themselves, such as lantern slides, could be reproduced direct, provided their scale of contrast was not too exaggerated. Nowadays we fear that if a positive is sent to an engraving house it is often the practice to make first a negative, and then a paper print, which means that a large amount of trouble is taken only to secure in the end an inferior result.

Even if no special transparency camera with a condenser is installed, it is easy enough to so arrange matters that glass positives can be worked from. A sheet of clean white blotting paper is pinned on the copy-board, the two lamps arranged, one at each side, to illuminate this as powerfully as possible, and then some sort of frame rigged up about 6 to 12 inches in front of the white blotting paper to hold the transparency. A nest of rabbetted frames to take all the usual size plates are a stock article with the material dealers. The outside one can be fitted to a home-made frame constructed even out of a packing-case. The negative is made without a prism or mirror, or putting the camera at right angles to the copy, because the reversal can be secured by turning the positive glass side to the lens instead of film side. There is no need to have any covering from the positive to the lens, as long as no direct light from the lamps enters the lens. In fact, the whole arrangement is of the simplest possible description, and one that must be adopted (or something similar) when an indirect three-light job has to be done. In this case it is impossible to ensure register from paper prints, so that glass positives have to be made. Any one habitually using glass positives for originals would soon come to the

...s often been employed to describe this high degree of permanency, as permanent as the paper on which it is made." We are afraid, however, that, eloquent as this last tribute is meant to be to the properties of platinotype photographs, it does not emphasize the fact that—quite apart from the chemical permanency of a

conclusion that it is much more easily possible to secure exactly what is wanted than from any form of paper print.

Modern Processes.

On Thursday last, at the Bolt Court School, the principal, Mr. A. J. Newton, lectured on "The Usual Processes of Reproduction," and dealt with the very great extent to which all these processes were now indebted to photography. Even the plates given away with the Christmas numbers of the illustrated papers, which were formerly entirely the work of the lithographic artist, now had some of the printings photo-mechanically produced.

He described the new Albert process as being extremely ingenious, and while allowing that it was capable of producing very fine work, of which he showed specimens, he did not see any theoretical justification for the claims made that it was superior to the processes now in vogue. The lecturer then went on to deal with the recent advances in rubber off-set printing, and showed numerous examples of the truly marvellous work now turned out by this type of machine, which he was sure would open new fields for photography allied to lithography.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for the following patents have been received from December 6 to 11:—

BROMIDE PRINTING.—No. 28,440. Apparatus for the rapid production of bromide prints. Alexander Good and Richard Lang Sims, 45, Thornton Avenue, Chiswick, London.

COPYBOARDS.—No. 28,448. Improvements in copyboards or easels, and in copy-holding appliances therefor, for photographic reproduction apparatus. Albert Nixon, 8, Quality Court, Chancery Lane, London.

DETACHABLE MOUNTING.—No. 28,449. Improvements in means for detachably securing paper, card, and other light objects to smooth impervious surfaces. Albert Nixon, 8, Quality Court, Chancery Lane, London.

CINEMATOGRAPHS.—No. 28,563. Optical lanterns and cinematographs. George Calvert, 100, Evering Road, London.

MAGIC LANTERNS.—No. 28,586. Improvements in magic lanterns. Henry Thomas Culliford, 110, St. Martin's Lane, London.

CINEMATOGRAPHS.—No. 28,714. Improvements in cinematograph apparatus. Reginald William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes Cinematographes et Appareils de Précision, France.

PRINTING DEVICE.—No. 28,786. New or improved device for use in printing from negatives on to photographic printing papers, postcards, or the like. John Grossart, 96, Buchanan Street, Glasgow.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TIME-DEVELOPMENT THERMOMETER.—No. 12,120, 1909 (May 22, 1909).

The invention consists of a thermometer provided with a logarithmic scale, such that the time of development (at various temperatures of the developing solution) is directly indicated on the stem of the thermometer. The invention is supplementary to that of specification No. 22,456, 1907 ("B.J.," August 21, 1908, p. 646), in which is described apparatus for determining the relative times of development of photographic plates for different temperatures. This consists of two movable slides, one bearing a temperature scale and the other a logarithmic scale, which scales are adjustable to each other. But it is not essential that the thermometer should bear a temperature scale, and the present invention relates to a method of directly indicating the relative times of development of any photographic plates for different temperature, by means of the expansion of a fluid, by modifying the apparatus described in the preceding specification in either of two ways. In the first form the thermometer bears a single mark

thereon, which mark is set to the known time of development on the relatively movable logarithmic scale at the given temperature indicated by such mark on the thermometer.

The operator is thereupon guided not by the scale of the thermometer, but by the height of the fluid in the thermometer in reading off the time of development to be used. Figure 1 of the accompanying drawing shows a thermometer according to this part of my invention. As shown in this drawing the mark of the thermometer, for instance, is assumed to be fixed at 60 degrees, the fixed logarithmic scale for a medium plate is set to read 6½ minutes for development. Should the temperature increase so that the fluid rises in the tube say to 80 degrees, the reading on the logarithmic scale opposite the height of the fluid would be 3¼ minutes for the same class of plate. The logarithmic scale is made adjustable by making it as an endless band *a* passing over rollers *b* mounted in a skeleton frame *b*¹ suspended in the tube, the thermometer being provided with a cap *c*, which can be removed to operate this band by the fingers so that for other classes of plate, the setting of the scale can be adjusted and the readings varied accordingly.

The second form of construction, illustrated in fig. 2, relates to an application of the same principle for use with the logarithmic scale

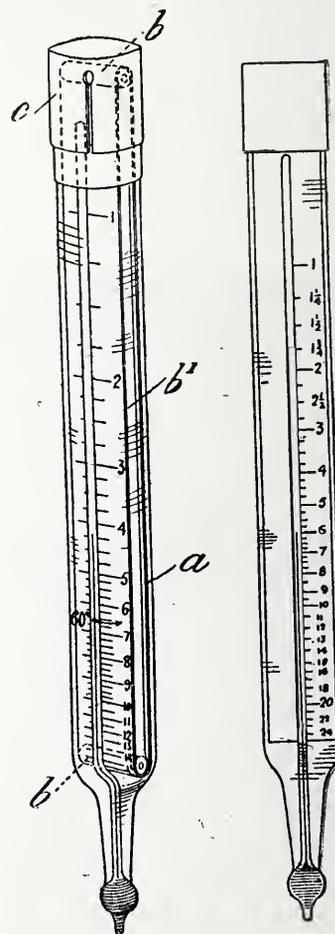

Fig. 1.

Fig. 2.

fixed in relation to the thermometer and not movable. In this case a certain time of development correct for a plate and a fixed dilution of a stated developer is fixed in relation to the height of the fluid at a standard temperature. As the temperature increases or decreases, the fluid in the tube rises or descends, and the operator then reads off the time of development opposite the height of the fluid and uses that particular time.

For example, as shown in fig. 2, assume that the thermometer so constructed that at a temperature of 60 degrees the height of the mercury in the tube is set opposite 6½ minutes development on the fixed logarithmic scale for a medium plate, and that the temperature rises to 80 degrees, the time on the logarithmic scale would be 3¼ minutes for the same class of plate and developer. The time of development will also be correct for certain other plates with other specific dilutions of the same developer, and these particular combinations can be indicated in the instructions issued

with the instrument and be printed on the back of the logarithmic scale or any other part of the thermometer.

When a scale is constructed entirely from experimental data, it may be found to depart somewhat from the logarithmic form, but it could still be used as part of this invention with sufficiently accurate results.

The logarithmic scale used in the above two constructions is prepared or calculated according to the instructions contained in the specification of previous Patent No. 22,456 of 1907. Alfred Watkins, Imperial Mills, Hereford.

DEVELOPING TANK.—No. 5,025, 1909 (March 2, 1909). The invention relates to a developing tank in which means are provided for the removal of the escape of the liquid contents from below, so that the tank may be used for washing negatives, etc.

The tank by which this is accomplished consists of two portions which may be telescopic, and each nearly of the full length of the whole box when closed. One—the outer—end of each of these portions is closed and provided with a mouth and stopper, say a screwed stopper, whilst within is a light-trap.

One part, *i.e.*, that having the lower end closed and fitted with a stopper, is preferably adapted to slide into the other, its exterior surface being adapted to slide on the interior surface of the other part, which is closed at the top, and provided there with a mouth and stopper and open at the lower end. In some cases, this outer box part is made to project at its open end beyond the smaller and inner box part, and the lower edge of this part will be the base of the box when complete, upon which it can stand; the stopper of the inner part lying within this projecting part. William Laurence Parkinson, 5, Commutation Row, Liverpool.

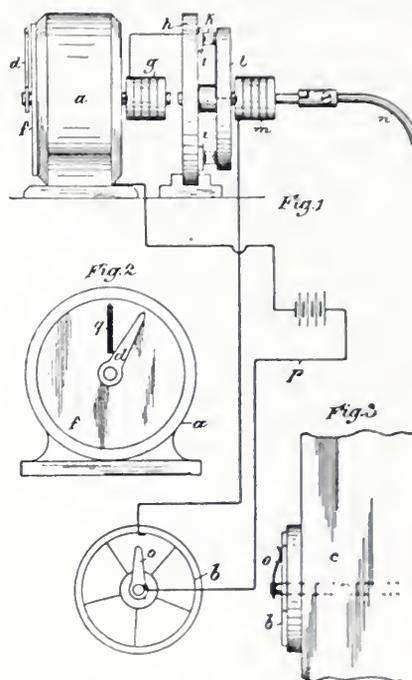

STEREOSCOPIC SHUTTERS.—No. 25,513, 1908 (November 26, 1908). In the newly invented shutter (intended chiefly for stereoscopic cameras), the movement of the shutter-leaves in one direction or in both, is operated by percussion by means of a percussion member which acts only with the shutter mechanism during the latter part of its stroke, with the result that it comes into action only when it has attained its maximum speed. By these means the inertia of the actuating mechanism cannot retard the action of the shutter mechanism.

The leaves are not subjected to any strain and may therefore be made exceedingly thin and of very light material, for instance they may be constituted of a thin plate of ebonite. Hence these leaves possess a very low inertia. Moreover, the displacement of these shutter leaves being effected by percussion, the inertia of the operating mechanism cannot cause any delay in this displacement since the operating organ does not act on the leaves until the moment when it has attained its maximum velocity. In these conditions the opening and closing of the leaves can be effected in a very short space of time, and in such a manner as to allow in all cases the leaves to remain at rest for a time when they are fully open whatever the speed of the instantaneous exposure. Jules Richard, 25, Rue Mélingue, Paris.

CINEMATOGRAPH-PHONOGRAPH.—No. 21,675, 1909 (September, 22, 1909). According to this invention the supervision of the synchronous running of cinematographs and photographs working together is obtained with the aid of an electric motor influenced by the phonograph, the shaft of the motor being provided with an indicating device. On the other hand, however, the motor is so influenced by the cinematograph that the latter opposes the rotation produced by the phonograph so that when the cinematograph and phonograph are actuated simultaneously, the motor must stand still. Consequently the indicating device also stands still, which is the indication of synchronous running. The standing still of the indicating device is obtained by the conductors from the phonograph collector to the motor passing a current which is turned by the cinematograph in the direction opposite to that of the rotation of the phonograph collector.

The axle of the electric motor *a*, the armature of which has five segments in correspondence with the five-part collector *b* of the phonograph *c*, carries a pointer *d*. This moves in front of a disc *f*. This motor is also provided with a five-part collector *g*. On a fixed disc *h* there are arranged in a circle five segments *i*, of which only two are shown in the drawing for the sake of clearness. On these segments slide contact rings *k*, which are mounted on a rotating disc *l*. With the latter

a five-part collector is connected which rotates together with the disc *l* and is connected by means of a rigid or flexible shaft *n* with the cinematograph. Each of the slip-rings of the collector *m* is connected with one of the contact springs *k* on the disc *l*, and likewise each of the segments *i* is connected with one of the slip-rings of the collector *g* of the motor. Finally, each of the rings of the collector *m* is connected with a segment of the phonograph collector *b*. In the drawing only one connection is represented. In the same manner the other corresponding parts are connected together. The contact-spring *o* of the collector *b*, which spring is rotated by the phonograph, is also connected with the motor by

means of a conductor *μ*, in the course of which a source of current is inserted and which forms the general return wire.

If the phonograph is started while the cinematograph is out of action the motor will start and the pointer *d* rotate. If now the cinematograph is also set running, then in consequence of the opposite rotation of the collector *l* the rotation of the motor armature is opposed and the rotation ceases, so that the pointer *d* remains at rest. On the disc *f* a mark *g* is provided which must be opposite the pointer when the machines run synchronously. It is the duty of the person attending to the cinematograph to rotate the machines at such a velocity that the pointer remains at rest opposite the mark *g*. A deflection of the pointer to the right or to the left indicates a disturbance in the synchronous running of the machines in the one or other sense. Jules Greenbaum, 22, Friedrichstrasse, Berlin.

COPIES OF BOOK ILLUSTRATIONS.—No. 14,502, 1909 (June 21, 1909).

The invention relates to the use of sensitive papers for making of copies by contact of illustrations, etc., in books, magazines, etc., where there is matter on both sides of the printed page. The method appears to be that of Payer, in which exposure is made through the sensitive paper and an image obtained, as the result of the different reflective power of parts of the original. The claim is for the use of a printing-out (chloride or cyanide) paper for this purpose, or for a platinum paper, the sensitive films being made to strip from their supports if so required. Gustav Kögel, Wessobrunn, Bavaria, Germany.

New Trade Names

AGEA.—No. 517,272. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. The Berlin Anilin Co., Ltd., 26, Princess Street, Manchester, chemists and druggists. October 15, 1909.

LEKOS.—No. 517,425. Photographic apparatus included in class B. W. Butler and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C., photographic apparatus manufacturers. October 19, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Testing the Flatness of a Light-Filter.

THERE is one point in connection with the examination of a filter (writes Dr. C. E. Kenneth Mees in "Penrose's Pictorial Annual" for 1909-10) which is of considerable importance. It is necessary not only that a filter should be right in colour, but that the glass of which it is made shall be of such satisfactory optical quality that the definition will not suffer by the placing of the filter on the lens.

In order to test a filter for any defect in this respect, a piece of cardboard, from which white cross lines have been cut out, is placed so that it is well illuminated, and the image of the cross reflected in the filter is observed by holding the filter down and looking into it at the illuminated cross. When you examine, *e.g.*, a yellow filter in this way, you will see two images of the cross, one coming from the front surface, which will be white, and another coming from the back surface, quite yellow. If, as you move the filter about so that the cross falls on different portions of the filter, these two images remain constant with regard to each other, then the filter is only wedge-shaped and the double image does not matter, but if they vary with regard to each other, then the filter is not satisfactory and will produce distortion to some extent. Commercial filters at low prices cannot be made of the accuracy of lenses, but all filters should fulfil this test to this degree.

New Books.

"Harmonic Vibrations and Vibration Figures." By Joseph Goold, Charles E. Benham, Richard Kerr, and Professor L. R. Wilberforce. Edited by Herbert C. Newton. London: Newton and Co., 3, Fleet Street, E.C. 6s. net.

Though this book is credited to four authors, the bulk of the matter is by Messrs. Benham and Goold, both of whom are well known for the clever varieties of pendulum apparatus they have devised, while Mr. Benham is known also in the photographic world for his stereoscopic work, and especially for the application of stereoscopy to the harmonograph curves, several examples of which application are given in this book. There is, so far as we know, no other book published dealing with the subject of the harmonograph, and though the latter is one of the most fascinating instruments in existence, few people have ever seen it in action. Both Mr. Benham and Mr. Goold have devoted a very great deal of time to the perfection of the apparatus and the study of its effects, and there is little doubt that the strange and beautiful figures it produces contain a great deal of information with regard to the mysteries of the natural wave motion and vibrations which play such an important part, not only in photography, but in every phenomenon of nature. Vortex plates, the geometric pen, the Wilberforce spring, and synchronous springs all receive attention from the several authors; while one chapter is devoted to the optical projection of vibration figures on a screen. In this chapter, one method of projection devised by Mr. Lewis Wright and described in his "Optical Projection," is fully dealt with. There are, however, other rather simpler methods, such as the two described by Mr. Cecil M. Hepworth, in the "Lantern Record" Supplements to the "B.J." for June 5 and July 3, 1896, under the slightly doubtful title of "Sound Curves with a Lantern." We often wonder why these curves are not more frequently shown on the lantern screen at photographic societies. They are not difficult to produce, and are most fascinating to watch. Mr. Newton's preface contains the remarkable statement that two of the most famous scientific publishing firms in London declined the book on the ground that it could not be produced profitably. We are inclined to think that both these eminent firms have made a grievous blunder. This book was wanted badly, for there is no other like it, and it is of far more real value than many of the scientific text books which are presumably published at a profit. Messrs.

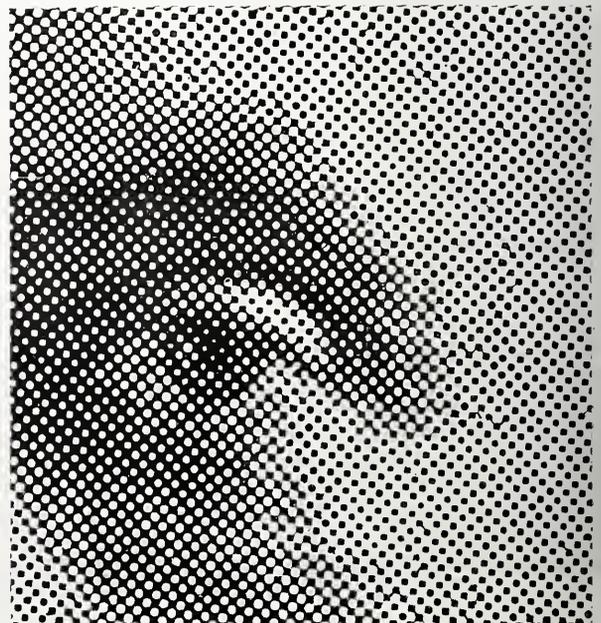

Newton are to be highly commended for the scientific spirit that induced them to ignore such discouraging advice, and we both hope and believe that they will find this book by no means unprofitable. It is very unfortunate that the publication of scientific books should be generally governed, not by the needs of students, but by the prospective profits of the publishers, and we are inclined to think that publishers who give so much consideration to the matter of profits are, after all, not proceeding on very sound business principles.

New Materials, &c.

BARNET "COLD TONE" LANTERN PLATES.—Messrs. Elliott and Sons, Ltd., have just issued a new brand of lantern plate specially for use in slide-making by reduction and giving transparencies of cold black tone. The plate is more rapid than the Barnet lantern plate hitherto issued either for cold- or warm-toned slides, and with a developer such as hydroquinone and caustic potash, which is one very suitable for making slides of cold tone, gives very bright and brilliant lantern slides of this character. The new brand is issued at the standard prices for lantern plates, and ought to find favour with slide-makers during the dull days of winter, when the exposures, in the case of negatives which are above the average in density are apt to run into inconveniently long times.

EDWARDS' MATT TRANSPARENCY PLATES.—Messrs. The Leto Photo-Materials Company, Ltd., send us samples of the new form in which they are putting out the well-known Edwards transparency plate. The "matt" plate, as it is named, contains the diffusing medium applied to the glass, so that in making transparencies for exhibition in windows, etc., no ground-glass is necessary. The plates can be bound up with ordinary glass from spoilt negatives, and the transparencies thus made are ready for exhibition. The emulsion is that of the Edwards special transparency plate, and, particularly for pyro-ammonia development, gives excellent results.

ELECTION POSTERS.—Messrs. Hood and Co., Ltd., St. Bride Works, Middlesbrough, send us several specimens of the large poster portraits which they are prepared to execute at the shortest notice from ordinary photographs. They are ready to send a specimen of this work to any photographer who may have the opportunity of securing an order for election posters, a piece of

business which, as Messrs. Hood rightly point out, may frequently be secured by him by virtue of his ownership of the copyright in a candidate's portrait. These specimens, it should be mentioned, are printed without Messrs. Hood's name upon them, so that they may be displayed in the window or shown to intending customers.

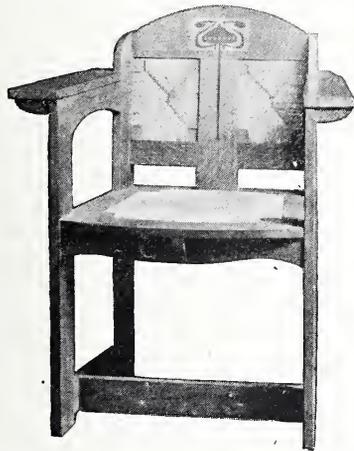

The section from one of these large half-tones gives an idea of the scale on which the portraits are produced.

"PHOTOGRAPHIC PROGRESS."—From No. 7 of this publication, which has just reached us, we observe that the editorial staff (of which Mr. Thomas Bedding was a member) formerly responsible for its production, appear to have relinquished their duties. The size of the magazine has been reduced, the editor is now Mr. A. K. Boursault, and the publishers the A. M. Collins Manufacturing Co., of world-wide mount fame. Our contemporary has not lost in interest from these changes, and in its current issue well sustains its claim to cater exclusively for the professional photographer.

New Apparatus, &c.

Studio Furniture, Etc. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

Messrs. Griffin have recently shown us some selections from their large variety of studio furniture, which are pleasing, because free from any taint of sham. The day is largely gone by when a photo-

grapher can afford to place in his studio the imitation rock-work seat and like accessories which have done service in the past. The fact that many photographers will go even to the expense of genuine old furniture for the studio shows that there is a sense of what is likely to attract a certain class of sitter. Fortunately, models of old furniture and designs in modern style are plentiful at a moderate price,

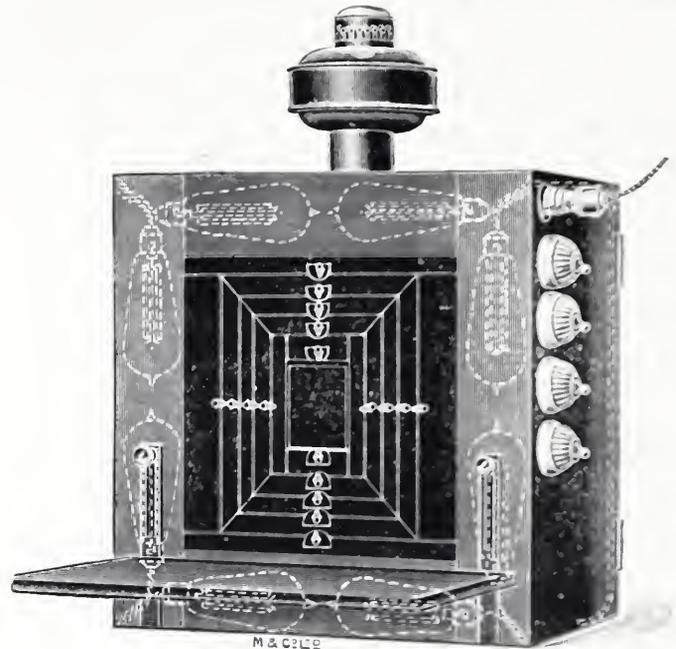

and therefore attention may be drawn to one particular article of Messrs. Griffin's, which satisfies the requirements of modern furnishing. This is the "Unique" chair, made in fumed oak, with broad arm-rests and panelled upholstery. The price is £2 10s. Messrs. Griffin have also introduced several seats and pieces of furniture specially for children's portraits, one of which, the "Doris,"

we illustrate. The finish is white enamel, with silk upholstery, and the set of two chairs and table at £1 17s. 6d. provides a useful means of posing small groups of children.

The "Robinson" Enlarging and Copying Apparatus. Made by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

In this piece of apparatus the photographer secures the means of illuminating negatives from 4-plate up to 12 by 10. for both enlarge-

ment and reduction, whilst the apparatus also serves with great efficiency for copying originals, such as drawings, documents, etc., or even small objects which have to be photographed for catalogue illustration. This double purpose is fulfilled by providing the illumination by reflection, the light being that of eight of the new metal-filament lamps. These are contained around the front of the enlarging chamber in the position shown in the white dotted lines in the drawing, and are controlled by the four switches seen on the right, so that the light may be produced either from top or bottom or from either side separately, whilst with all eight lamps in action a remarkably powerful and even illumination is produced. In this respect the cabinet may be said to provide the facilities of daylight, but with much less trouble of control.

For enlarging or reducing, that is to say for copying a negative or transparency by transmitted light, a white-surfaced metal reflector is used of size 20 inches square, sufficient to give even illumination over the full 12 by 10 plates. This reflector can be removed from the back door of the apparatus, and the latter, on being closed, then provides a perfectly black copy-board on which prints, etc., may be placed and thus strongly illuminated without the reflected light from the margins in any way prejudicing the brilliancy of the results.

As will be seen, the front of the apparatus carries a shelf which can be raised to a level with the negative, be the latter large or small—and thus support an ordinary camera which makes, with the illuminating chamber, a very efficient artificial light enlarger. It will be understood that the up-and-down movement of this shelf fulfils the purpose of the moving stage of the ordinary enlarging lantern, whilst the focussing cloth, thrown over to form a junction between the back of the camera and the apparatus, serves quite efficiently to exclude stray light from the enlarging room.

After having had the apparatus in use, and having seen for ourselves the really strong illumination which it gives we have every confidence in recommending it, particularly to the professional photographer, on grounds both of efficiency and economy. Many professionals shirk the trouble of rigging up a daylight apparatus when enlarging from negatives of whole-plate and larger sizes, but with the "Robinson" apparatus they have only to make use of the camera with which the negative itself was taken, and can thus do such enlarging work at any time and without incurring the expense of condensers of the large size necessary to cover a 12 by 10 negative.

The whole apparatus—with the photographer's camera dismantled

from it—occupies comparatively little space, the body measuring only 22 inches square and 13 inches deep. Above this is a light-trapped cowl (removable and packing inside the case), 8 inches in height. Complete with the eight 50-candle-power metal filament lamps and 17 ft. of flexible connection, the price of the apparatus is £6 10s. This includes the shelf for support of the camera, and the set of carriers seen in the drawing to accommodate quarter, half, whole-plate, 10 by 8, and 12 by 10.

CATALOGUES AND TRADE NOTICES.

THE PROFESSIONAL PHOTOGRAPHER.—The December issue of our contemporary, issued by the Kodak Company, contains articles on the practice (and profit) of advertisement photography, on the use of Velox paper, and on a number of Messrs. Kodak, Ltd.'s seasonable introductions for professional workers.

CAMERAS AND LENSES.—Messrs. A. E. Staley and Co., 19, Thavies' Inn, Holborn Circus, London, E.C., have just issued a new edition of their list of Euryplan, Phaos, and other anastigmats, the artistic "soft" lenses for portraiture, reflex hand-cameras, shutters, Nettel focal-plane cameras, and the various Staley-Wheeler telephoto lenses and accessories. Every item in the list is a specialty of Messrs. Staley's, and therefore the catalogue which is sent for the asking, is worth getting.

PICTURE FRAMING.—Readers who make or take orders for picture frames should write to Mr. C. G. Engert, 17, Eton Street, London, N.W., for particulars of four most helpful charts published by him. These are: "The Actual Making of Frames at the Bench" (1s. 3d.), "What to Charge—How to Take Orders" (2s. 1d.), "Square Feet Indicating Chart" (1s. 7d.), for checking measurement of glass, etc., and "Gilding or Re-gilding," showing how to do it (3s. 1d.).

SUTER LENSES.—Messrs. A. E. Staley and Co., 19, Thavies' Inn, Holborn Circus, London, E.C., have now issued the first English list of the well-known lenses of Suter of Basle, the English agency of which they have taken over. Messrs. Staley are taking steps to bring before English workers the excellent properties of this series of anastigmats, of aperture from $f/5$ to $f/7.2$. The list also gives particulars of the Suter portrait lenses, telephoto attachments, and the very convenient casket set of anastigmats.

FORTHCOMING EXHIBITIONS.

December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.

December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1910.

January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.

February 1 to 5.—Norwich and District Photographic Society. Entries close January 18. Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

February 1 to 16.—Glasgow and West of Scotland Amateur Photographic Association. Entries close January 20. Sec., J. McKisack, 68, West Regent Street, Glasgow.

February 26 to March 12.—Edinburgh Photographic Society. Entries close February 12. Sec., J. C. M'Kechnie, 31a, Castle Street, Edinburgh.

April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

April 9 to 16.—Photographic Arts and Crafts. Sec., Arthur C. Brookes, 15, Harp Alley, Farringdon Street, London, E.C.

FATAL ACCIDENT TO MR. COLVILLE STEWART.—Those who have perused with interest and profit the contributions to a contemporary by Mr. Colville Stewart will regret to hear that, in consequence of a slight accident, it is unlikely that articles under this signature will appear with the same regularity as hitherto. At the foot of some notes by Mr. Colville Stewart on Lantern Experiments we read:—"Readers will be glad to know that Messrs. Butcher and Sons, of Camera House, Farringdon Avenue, E.C., supply a complete cabinet of chemicals and apparatus for experiments in the optical lantern similar to those described above by—Mr. Thorne Baker!"

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, DECEMBER 28.

Royal Photographic Society. No meeting.
Blackpool and Fylde Photographic Society. "What can be Done with a Hand-Camera." C. P. Goerz, Ltd.
Glasgow Southern Photographic Association. Monthly Lantern Slide Competition.

WEDNESDAY, DECEMBER 29.

Balham Camera Club. "Large Prints from Small Negatives." W. F. Slater.
Croydon Camera Club. Conversational Evening.
Sale Photographic Society. Social Evening.
North Middlesex Photographic Society. Nomination of officers.

THURSDAY, DECEMBER 30.

Watford Camera Club. "Clouds in Landscape," by J. Linley.
Loughton and District Photographic Society. "Photographic Facts and Fallacies." Burroughs, Wellcome and Co.
Liverpool Amateur Photographic Association. Prize Slides of the 1909 Competition of the Affiliated Societies.
Leek Photographic Society. Nomination of Officers and Committee.
Rodley, Farsley, Calverley, and Bramley Photographic Society. "Pinhole Photography." J. R. Coulson.
The London and Provincial Photographic Association. "Screen Plate Colour Photography." H. Essenhigh Corke.
Weybridge and District Photographic Association. "Large Prints from Small Negatives." W. F. Slater.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, December 21, Mr. Chapman Jones in the chair. Dr. Francis Ward delivered his lecture on "Photography as an Aid to Marine Biological Research," in the course of which he gave many valuable hints and suggestions to workers in this branch of science, illustrating his remarks by a number of very fine lantern slides. The lecturer laid great stress on the fact that any photographer, with ordinary care and intelligence, could obtain far more valuable records by means of his camera than an expert biologist could do by means of his pencil drawings, as the necessary handling of the delicate organisms, in the latter case, often led to injury and death, which rendered them useless as specimens owing to the change which immediately took place in their general characteristics. In the course of his own work, Dr. Ward stated that he frequently had recourse to anasthetics, putting a few drops in the water with the specimens, thus rendering them quiet long enough to enable him to give a short exposure showing full detail.

A hearty vote of thanks to the lecturer brought the proceedings to a close.

Commercial & Legal Intelligence.

THE SALE OF FLASH POWDERS.—The story of how "a Wesleyan Congress" was "scattered" in the Central Hall on Easter Monday by the explosion of a photographic flashlight apparatus was told in the Manchester County Court last week. Edgar Levin, 18 years of age, who, it was said, is an outside operator to Messrs. Lafayette photographers, of Deansgate, claimed damages through his father the Rev. H. Levin, of Elizabeth Street, Cheetham, for personal injuries sustained through the alleged negligence of F. Foxall, proprietor of the Rothwell Photographic Materials Company, of St. Mary Street, Deansgate. Mr. Acton was counsel for the plaintiff and Mr. Burgis for the defendant.

Mr. Acton said the plaintiff had occasionally to take flashlight groups of people at dinners and meetings. For some years he had purchased from the defendant for this purpose a certain flashlight powder, sold by the ounce and used by him for flash-lamp. On April 10 he called for an ounce of the powder, having to take a flashlight photograph of a Wesleyan Congress in the Central Hall. Mr. Foxall said he had none of the loose powder previously supplied but handed him instead a packet containing a bottle and a tin, each of which had a powder in it, saying it was much better and more successful, as it produced a whiter light. Mixing the powders according to the directions, the plaintiff went to the Wesleyan Congress put it in the usual way into the lamp, and applied the contrivance for blowing the powder into contact with the flame. There was a tremendous explosion, and the plaintiff was much injured. It occurred

tered the Wesleyan Congress, burned the clothing of some of them, and caused a great deal of alarm and confusion.

The plaintiff confirmed Mr. Acton's statements. For five days after the accident, he added, he had to remain in a dark room for fear of his eyesight being lost.

The defendant asserted that he certainly told the plaintiff explicitly to fire the powder on an open tray, and well above his head, by means of the "touch" paper enclosed in the packet. He gave these directions to all his customers, because he had been burned himself by the same powder at a Unionist demonstration. That, however, was not the fault of the powder. He had to place it on the balcony of the Free Trade Hall, and could not get far enough away, because of the pressure of people, and to shelter others he opened his coat and took the risk. It was, he added, a most elementary rule among photographers not to use compound flashlight powders in enclosed lamps, and that the plaintiff ought to have known better than to do what he had done.

Half a dozen expert press photographers gave evidence on the use of flashlight compounds.

Mr. Burgis said he agreed that in law a seller of such an article was bound to disclose the fact that it was dangerous, but he contended that this had been done both verbally and by the printed directions in the packet.

The Judge said it was quite clear that the powder sold to the plaintiff on this occasion was not similar to that sold previously, and used safely with the Todd-Foret lamp, and it was equally clear that the plaintiff was not an expert, and had relied upon the defendant giving him something similar to what he had used before. The only real defence lay in a piece of yellow paper, said to have been enclosed in the packet, and containing in big type a direction not to fire the powder "in any description of magazine or blow-through lamp." If it had been proved that this was actually in this packet the plaintiff could not have succeeded. The defendant had not only made no effort to prove it, but had even omitted to rely upon it when first called upon to answer the claim by the plaintiff. This accident might do good, the Judge added, if only in calling the attention of the public and the large number of young people purchasing these things to the need for being very careful in using them.

Judgment was entered for the plaintiff for £25, with costs on the scale of the £50 claimed.

NEW COMPANIES.

FRANK A. CHATWIN, LTD.—Capital, £2,000 in £1 shares. Formed to carry on the general business of photographers, etc. Signatories, R. W. Parker, 41, Church Street, Birmingham, and W. H. Newell, 20, Temple Row, Birmingham. First directors, H. Furze, Fore Street, London, and R. W. Parker, 41, Church Street, Birmingham. Remuneration, £50. Registered office: Forward Works, 30, Leopold Street, Birmingham. Private company.

News and Notes.

MESSRS. SANDERS AND CO., of 71, Shaftesbury Avenue, London, W., have issued a list of their charges for developing, printing, enlarging, etc., which may be obtained on application to the firm at the above address.

THE TELLIA CAMERA COMPANY advise us that they have fitted up at their premises, 68, High Holborn, London, W.C., a special show-room for the demonstration of enlarging apparatus, so that customers may see the actual working of any enlarger they wish to purchase.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY is organising a competition, in which are offered a silver plaque, a bronze plaque, and a certificate respectively for the three best photographic records connected with the county. Mr. R. Child Bayley will adjudicate, and all prints should be sent to 20, Tudor Street, E.C., on or before January 31, 1910, the envelopes being marked "Survey and Record Competition."

THE EDINBURGH PHOTOGRAPHIC SOCIETY announce that the annual open exhibition will be held from February 26 to March 12, 1910, the latest date for entries being February 12. Messrs. W. D. McKay,

H. W. Kerr, and F. P. Moffat have undertaken to act as judges, and pictures entered also for the exhibition of the Glasgow and West of Scotland Amateur Photographic Association will, if desired, be transferred to Edinburgh free of cost to exhibitors. Further particulars and entry forms (which will be ready shortly) may be obtained from Mr. J. C. M'Kechnie, 31A, Castle Street, Edinburgh.

FLASHLIGHT MISHAP.—At the end of Mr. Wyndham's meeting in the Drill Hall, Wolverhampton, last week, Mr. Harold Gordon Peat, photographer on the staff of a Manchester paper, was engaged in taking a magnesium flashlight photograph of the great gathering, when an explosion occurred, and the operator, with his face blackened, staggered back into the arms of a gentleman standing near. Colonel Waterhouse's motor-car quickly took him to hospital, where it was found that his eyes were seriously injured, part of his hair and eyebrows burned away, and his clothing scorched. Subsequently Mr. Peat was conveyed to Wolverhampton Infirmary for treatment.

CITY OF LONDON AND CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—The eleventh annual exhibition will be held from February 21 to 25 inclusive, in the large hall of the Cripplegate Institute, Golden Lane, E.C., the latest date for receiving entries being February 4. Special attention is called to two of the open classes, namely, Class F, which is for straight prints from straight negatives, and Class G, for pictures in the oil, bromoil, ozobrome, or gum processes only. Silver and bronze plaques will be placed at the disposal of the judges, Messrs. Furley Lewis, F. J. Mortimer, and J. B. B. Wellington, for award, and the society's medal will be awarded to the best trade exhibit. Pictures will be sent to the South London Exhibition if so desired. Full particulars and entry forms may be obtained from the secretary, Mr. H. S. Cuming, Cripplegate Institute, Golden Lane, London, E.C.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.—This society will hold an open exhibition at 180, West Regent Street, Glasgow, from February 1 to 16, 1910, one of the four classes being set apart for photographs in colour by any process. All pictures submitted will first go before a selection committee, those selected and hung being judged by Mr. A. H. Blake, at whose disposal the Association plaque will be placed for award. Entries close on January 20, on or before which date entry forms, duly filled up and accompanied by the necessary fees, must reach the secretary, Mr. James M'Kissack, 68, West Regent Street, Glasgow. In the case of those pictures not accepted for exhibition the entry fees will be returned. All pictures sent to Glasgow which are also entered for the exhibition of the Edinburgh Photographic Society will, if desired, be sent from Glasgow to Edinburgh free of charge. Entry forms and further particulars may be obtained from Mr. M'Kissack at the above address.

ENSIGN SMOKING CONCERT.—Messrs. Houghtons Ltd. held their fourth annual smoking concert on Saturday evening last when the Prince's Hall of the Hotel Cecil was crowded by a company which included a number of leading members of the photographic trade:—Messrs. J. B. B. Wellington and H. W. Hall (of Wellington and Ward), Hubert Elliott and F. E. Greenwood (of Elliott and Sons, Ltd.), Thomas K. Grant (The Lumière N.A. Co.), Thos. Illingworth, R. J. Kinson (Chas. Zimmermann and Co., Ltd.), Leslie Clift (Hare and Co.). Mr. Edgar Houghton presided, and Mr. Phil Payne proved himself once again an impresario of the most accomplished order. From a programme, which entertained the company until a late hour, we must name the finished performance of Miss Clarice Mayne, the singing of Mr. Philip Ritte, and the delightful character sketches of Mr. Chas. Pond. During the interval a collection amounting to £9 10s. was taken in aid of the "Referee" Children's Dinner Fund.

At a later interval Mr. G. E. Brown, on behalf of the guests, thanked Messrs. Houghtons for their hospitality, and took the occasion to congratulate the firm of Houghtons Ltd. on their maintenance of a reputation which dated back to a period earlier than photography, to the year 1834, and to the foundation in the Strand, on the site of the present Gatti Restaurant, of the first photographic studio. He congratulated those in the firm on their association with a business which for so many years had upheld the best traditions of English trading, and he hoped that they might see Mr.

George Houghton with them on many succeeding anniversaries of that occasion.

Mr. George Houghton, in a short speech, referred to the early days of the business when he was with his father. He was pleased to be with them that evening, and to see the continued growth of the business, and both for himself and the directors of the company he expressed his thanks for the reception given to them. Mr. Edgar Houghton also responded, and subsequently moved a vote of thanks to Mr. Phil Payne and the artists, a vote which was assuredly well deserved.

NATURE PHOTOGRAPHIC SOCIETY.—On Saturday, December 11, at the Institute of Science, Art, and Literature, Leeds, Mr. John J. Ward, the well-known author, nature-photographer, and lecturer, presided at the inaugural meeting of the Nature Photographic Society, a society whose primary object is to form a fellowship amongst the growing band of nature-photographers in all parts of the world. Since the moment of its inception the society has proved an immense success, and already there are some thirty Fellows and Associates elected, including many distinguished men of letters, and some of the élite amongst nature-photographers. The president is Mr. Richard Kearton, F.Z.S.; vice-presidents, John J. Ward, F. Martin-Duncan, F.R.P.S., Henry Irving, and Oliver G. Pike, F.Z.S., F.R.P.S. The Council elected are as follows:—Ben Hanley, Stanley Crook, J. Digby Firth, F.L.S., F.E.S., Wm. W. Gaunt, Herbert Lazenby, H. Armytage Sanders, F.R.P.S., Bertram A. W. Stone, B.A. (Oxon.), M.R.C.S., L.R.C.P., Charles Kirk, G. H. Carter, and Miss M. A. Haviland. The secretary is Mr. Carl Edwards, Woodlesford, Leeds, who will be pleased to supply particulars to all who are interested.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

ENGAGING AN OPERATOR.

To the Editors.

Gentlemen.—Under the heading, "Engaging an Operator," in the "Answers to Correspondents" column of this week's "B.J.," we note you deal with a letter from "Fetched." We should not have troubled you regarding this, but being practically the only, or, at any rate, the principal, firm in Sheffield in this line of business, we are likely to suffer damage through publication of the same, notwithstanding your admirable comments. It has already occasioned remark. The facts are as follows, the most material having been withheld:—

The man was engaged by us from Birkenhead, as a canvassing operator, on a week's trial, at salary only, as you will see at the very commencement of the letter enclosed, this course having been forced on us by sad experience. If thought fit, a second week on the same terms to be served, before final engagement, if satisfactory, at 15s. and 10 per cent., terms which enable our men to average 35s. weekly during the summer by a clean and straightforward method of business.

A week's trial we take to mean a week's trial. He claimed to be a smart man, and one of his references described him as a first-class outdoor operator. We found he was neither the one nor the other, being, in fact, worse than useless, was disreputable in appearance, untidy in habits and work, and our charge hand complained of association with a man with so foul a tongue. Naturally, nothing of this was communicated to him on his dismissal, for obvious reasons, as you surmise.

15s. 6d. had been advanced to him up to Wednesday, and on Saturday morning first thing a further 6s. 6d., being his fare back to Sheffield, where he was engaged, as per receipt enclosed, was paid to him.

This he did not use, as he immediately obtained a situation in the same town with a rival firm, in somewhat the same line of business. Our disbursements on his account have totalled between 30s. and 40s., for which we have received no return whatever.

There seems to be no way to guard against loss through this floating army of duffers, rotters, and unemployables.—Yours truly,

AUSTRALIAN PHOTO COMPANY,

Arthur J. Martin, Proprietor.

Corner of Norfolk Street and St. Paul's Parade, Sheffield.

December 20, 1909.

[We quote side by side the statements made by our correspondent to (1) us; (2) the Australian Photo Company.

1.

They stated, when engaging me, the berth was permanent; so, of course, I accepted same.

2.

Should be pleased to come on week's trial, and would accept terms as quoted for same week.

We are willing to publish the above from the Australian Photo Company, but we must refuse to publish certain passages which follow, the substance of which is not relevant to the query addressed to us by "Fetched," though doubtless it is prompted by circumstances annoying to our present correspondents.—Eds. "B.J."]

THE MAKING OF A PHOTO-BUTTON.

To the Editors.

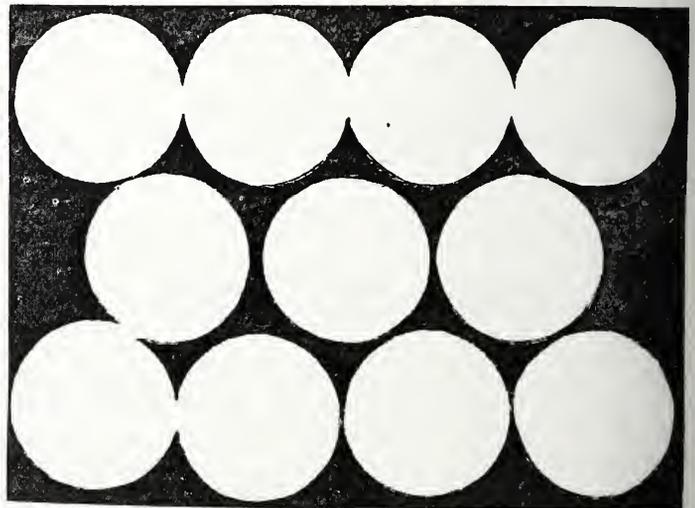

Gentlemen.—The reply to our letter re "The Making of a Photo-Button," by Messrs. Fallowfield, is interesting, as showing the shop-keeper's point of view as opposed to the manufacturer's. Whether exposing the plate, developing, fixing, etc., constitutes one or several operations (the same applies to printing, toning, fixing, etc.) does not matter much, as each reader will decide that for himself, and will be able to judge of the work required to produce a "button" at the small price which prevails. We are surprised that they did not reduce the operations to two:—

1. Making a print from copy.

2. Making button from print.

Simplicity itself, and a "liberal profit," as their advertisement says.

We can only look upon the statement that, if we used their parts, we could doubtless afford to sell the finished button "at a much lower figure," as damaging to our reputation, especially at the present time in a line which we worked long before Messrs. Fallowfield entered the market. We should like, therefore, with your kind permission, to give a few particulars of the art of making a photo-button.

Plan drawing arrangement of 11 buttons in half-plate. It will be evident that making 12 per sheet is cutting it too fine for all practical purposes.

We will take 1,000 as a unit of the popular penny button, 1½ in. in diameter, known as "50-lign size." In the first place, a multiple negative will have to be made, either 11 on a half-plate (12 is cutting it too fine for practical purposes), or 42 on a 12 x 10. The remainder is simple arithmetic. Supposing we decide to cut it fine, we shall then require 84 half-plate prints, leaving only a narrow margin of 8 spoilt buttons per 1,000. To turn out a decent button, the prints will have to be united to celluloid. This is omitted in the "abridged" operations, and we enclose samples to show the difference (which is very marked; the uncemented buttons look poor in comparison with the others.—Eds. "B.J."). This will take 84

sheets of celluloid, 7 x 5in. Now, if we take the cost, as per their list, we shall see how we can "doubtless afford to sell at a much lower figure," bearing in mind that they sell at 37s. 6d. to 45s. per 1,000, according to quantity and time.

7 gross 50-lign parts, at 3s.	£1 1 0
4 1-5 sheets celluloid, 36 x 20	0 7 0

Total for the button parts only £1 8 0

Leaving 17s., taking the highest figure, or 9s. 6d., taking the lowest, for the making of the multiple negative, cost of material and labour for making 84 half-plate prints, uniting same to celluloid, stamping out singly to size, and making into the 1,000 buttons, not forgetting waste, packing, booking, wear and tear of machinery, allowance for bad debts, rent, etc., the residue constitutes the "liberal profit," and we fail to see where it comes in, unless there is at least a 50 per cent. discount off their prices in the list. The reason we do not buy our parts from your correspondent will be obvious to anyone who compares the two lists, and we shall doubtless continue to make our own on the premises.—Faithfully yours,

DORRETT AND MARTIN.

16, Belle Vue Road, Upper Tooting, London, S.W.
December 20, 1909.

To the Editors.

Gentlemen,—Might I ask Messrs. Fallowfield, through your columns, what use there is for a roller and plate in photo-button making? I notice that they advertise one in their price list, but omit to mention it in the list of six operations. I have made a few buttons, and between operations Nos. 2 and 4, there seems to me to be others not mentioned. For instance, cutting the celluloid, sticking the print to same, punching it out, and placing a shell and back in the machine, all before covering the shell.

As I am fond of labour-saving, and find the number of necessary operations rather large for less than ½d., I should be glad if any of your readers can tell me how to do this in the one operation. Enclosed is my card.—Yours faithfully,

ANXIOUS ENQUIRER.

December 20, 1909.

ADVICES AS TO ROUTE ON INVOICES.

To the Editors.

Gentlemen,—I have read your interesting article, "Parcels and Their Transit" in current issue of the "B.J.," and would like to suggest an improvement which ought easily to be effected in the despatch of parcels and cases of goods.

It is an exceedingly common occurrence to receive invoices which give no clue as to which route goods have been sent. I have three instances myself this last week where goods on order were urgently wanted. I received one parcel by post two days after receipt of invoice, which proved conclusively that invoice had been sent before goods were ready. This obviously led me to think carriers were at fault. Further, I expected said parcel by passenger train on account of its weight, and, of course, I troubled the railway company unnecessarily. The other two cases are instances where the goods have now been invoiced five days, are no use as I could not wait any longer, but had to substitute something else. All this trouble would have been obviated if invoices had been marked "Per — Railway Co., Goods," or "Per L. and N.W. Railway Co., Passenger," or "Per Sutton." It would then enable one to apply for delivery without waste of valuable time, especially at Christmas. The extra amount of trouble is infinitesimal, and would not necessitate employing an extra staff of clerks at the warehouse. The idea could be worked by means of a series of rubber stamps at the hand of the invoice clerks. It is certainly time something was done.

It is worth an extra 5 per cent. to consignee, especially in out-of-way places like ours, to help him to waken up the right railway company, who go to sleep nine-tenths of their time. In fact, here one cannot have goods delivered unless one makes repeated applications for them, and then only as your writer says, "As an act of grace"—and a pint.—Yours truly,

G. TURNER.

Crown Studio, Esplanade, Scarborough.

Answers to Correspondents.

** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:

- A. H. Pain, 140, Manningham Lane, Bradford. Two Photographs of Mr. Wm. A. Hewins.
G. Denney, the Promenade Studio, Teignmouth. Photograph of Charles R. Buxton.
A. V. Ranford, 136, High Road, Lee, S.E. Two Photographs of Charles William Gardiner.
W. A. Thomas, 45a, George Street, Hastings. Two Photographs of R. Tweedy Smith, Esq.
Molly Forgan, 70, Tay Street, Perth. Two Photographs of Lord Provost McNab, Perth, in robes.

CHARBONELLE.—1. In an enclosed arc about 1,000 but visual measurements of candle-power are not much good. 2. We do not know. It is not a form in common use. If you can tell us more about it, perhaps we can say. 3. Address the Aerograph Co., 45, Holborn Viaduct, London, E.C., or the Airostyle Syndicate, 35, St. Bride Street, Ludgate Circus, E.C.

IRON CARBON PROCESS.—I have a recollection of having read, some years ago, of a carbon process in which the sensitiser rendered the gelatine insoluble and the light action produced solubility. In fact, the reverse of action of bichromate. I have searched high and low and can find no trace of such a process, and should value any help you could give me in the matter. To the best of my recollection, the article I have in mind appeared in the "B.J. Almanac" some twelve, fourteen, or more years ago.—E. B. E.

The process referred to appeared in the "Almanac" for 1889, page 365. It is also described in "Ferric and Heliographic Processes" (Dawbarn and Ward, Farringdon Avenue, E.C.). The process is that of Poitevin, and he obtained a patent (586, 1863), or rather a provisional protection for it. The specification can be seen at the Patent Office, or may be purchased for 8d. The process has not proved of much commercial value up to the present time.

FLASHLIGHT.—I have to take a flashlight group of about sixty or more in a large schoolroom, and I have a Busch Rapid Aplanat (12in.) working at F. 8. What quantity of "Agfa" powder will be necessary?—FLASH.

Impossible to say with accuracy, as much depends on the colour of the walls, but we should say about half an ounce of powder placed in a trail of, say, 18 inches or two feet in length.

COPYRIGHT.—Some months ago there appeared in the "Journal" a short agreement "re copyright" between photographer and sitter. I am wanting this now, and cannot find the number that it was in. Would it be any trouble to you to repeat this in next Friday's issue? I know it is against your rules to repeat, but if you can possibly favour me I will be obliged.—SNOW-STORM.

You probably refer to the form of assignment drawn up by the Professional Photographers' Association. This runs as follows:—"To Mr. Photographer,—In consideration of your allowing me a reduction from your usual terms for taking photographs of me or on my behalf this day, I hereby agree that the copyright in such photographs shall be reserved to you, and that I will not deal in any way with the photographs to prejudice

your interest in the copyright. Dated the — day of —, 190 .
Signed —. Witness —."

GELATINE RELIEFS.—If you could assist us with your kind advice in regard to the following difficulty we should esteem it a great favour. We are making trials for the production of relief, by means of photography, by the bichromated gelatine process, and can get a good relief ($\frac{1}{8}$ inch or more) by this means; but it is not nearly so sharp and well-defined as we could wish. We expose the prepared gelatine under a suitable negative to the light of the sky, but, naturally, it spreads in all directions under the negative, instead of acting at right angles to it, and so we get a relief that is pretty sharp where thin, and softer and softer the thicker it gets. We know that if it could be exposed to the direct rays of the sun this defect would be got over, but this is a most uncertain factor. We have thought that you may be able to assist us in advising how best to get over this trouble; perhaps by some form of lens that will divert the rays into a parallel direction, or by other means. We may mention that we have tried printing in the bottom of a deepish box, but this, in consequence of the diminished light, takes a very long time—more than a week at this time of year. We have overcome all other technical difficulties. Any assistance in advice you can give us will be very much appreciated.—G. H. and Co.

No form of lens would be of use to you with diffused daylight. Your best way, in the absence of sunlight, is to employ the arc electric light. You must bear in mind, however, that it is impossible by the swelled gelatine process to obtain the same crisp image as one gets in a dried washed-out one, such as that of a Woodbury relief. Also, the higher the relief you get the less crisp it will be.

MOISTURE ON LENSES.—(1) I am troubled with a mist, which covers my lenses on the outer surface (I use several makes) when ready for exposure. I first of all thought it might have been the damp air of my studio, but after having made a number of experiments I find it only happens when the lens is capped and the slide put in ready for exposure. I have also taken particular care not to breathe upon the lens while capping same. Of course, this defect does not occur when using a behind-lens shutter; but why it should occur when using the cap I do not understand, as I have been in the habit of using the cap for a number of years in another studio, and without this trouble. (2) My studio is constructed as per diagram. What is the best method of lighting the floor without removing the wall?—J. H. J.

(1) The cause of the mist is the warm, damp atmosphere in the studio condensing on the lenses when they are colder than that. The way to avoid the trouble is to always keep the lenses at the same temperature as that of the studio, then there will be no condensation when the cap is removed. Moisture will not condense on glass that is warmer than, or as warm as, the atmosphere. (2) If the wall cannot be removed, the best way will be to colour the opaque side and top of the studio of a pale grey tint. Then it will reflect some light towards the floor.

A. L.—It is quite possible that you might, by a legal quibble, be able to shuffle out of your obligation. We, however, decline to give you any assistance or advice as to how to carry out what is—well, a rather discreditable piece of work on your part.

R. J.—In buying the business and the copyright negatives with it you should have had the copyright in each one properly assigned to you. This not having been done, the copyright in them has lapsed, and your neighbouring stationer is quite at liberty to reproduce them. It would be of no use your proceeding against him for infringement, as you would certainly lose your case.

ILL-USED.—Had you taken our advice in the first instance you would have been money in pocket. The whole sum was not worth fighting for, and now that you have been awarded a part of it you are worse off than you were before. Even if you had recovered the whole of it, we expect (considering loss of time) you would have gained nothing.

COPYRIGHT.—In this small town I do a good few lantern slides of local scenery, local functions when they occur, and subjects to be shown at Sunday school treats, church and chapel gatherings. Yesterday a Dissenting minister brought me a dozen and half photos of pictures in the National Gallery for me to make slides

from, to be shown at a forthcoming evening meeting of his congregation. I asked him if the photographs were likely to be copyright, and he assured me they were not, as the pictures were the property of the nation, and were in the National Gallery. Before executing the order I shall be glad if you will tell me in next week's "B.J." if I shall be running any risk in doing the work.—
J. BLIZZARD.

It is true, as the clergyman told you, that there is no copyright in the paintings by the old masters in the National Gallery. But there may be, and probably is, in the copies of them that he has brought to you. The copyright will be in the photographs, though there is none in the paintings themselves. We should advise you to decline the order and thus avoid all risk.

MOULDY MOUNTS.—(1) Herewith please find half a dozen mounts. They have been in stock for about nine months, and you will see that they have mouldy spots upon them. Can you account for it? They are —'s make. (2) Would it be safe to mount P.O.P. prints upon them?—M. F.

(1) There may be more than one cause of the mildew. The mounts may have been stored in a damp place, in which case they may well be expected to become mildewed, or they may not have been thoroughly dry when received from the maker; then, if they were kept in a warm place, it would not be surprising that they became mouldy. (2) It would certainly be unwise to mount silver prints upon them if permanency is a consideration.

BORNEO.—If the gas bags you have been given are in the state you describe, we imagine they are quite useless. If they are placed before the fire they will become softened, no doubt, but we very much doubt if they will then be serviceable. With age, rubber perishes, and there is no way of restoring it.

THE BOLT COURT SUPPER.—Under the chairmanship of Sir George Frampton, R.A., a jubilant evening was spent by the students and staff of the L.C.C. School of Photo-Engraving on Monday evening last. A number of distinguished guests were present, including Mr. Pomeroy, R.A., Mr. William Strang, A.R.A., Mr. Selwyn Image, Mr. Claude Shepperson, Mr. Lenfesty, Mr. Niels Lund, Mr. R. Anning Bell, Mr. W. A. Casson, L.C.C., Mr. Emery Walker, Dr. Wm. Garnett, Mr. Strange, Mr. Wm. Gamble, Mr. J. Corey, Mr. F. Colebrook, Mr. E. M. Rich, Mr. F. Gaywood, Mr. S. H. Wratten, and Mr. W. H. Amery. A supper at 7 preceded a smoking concert, the "pièce de resistance" of which was a "new drama," by F. E. Butler, entitled "The Sapience of Cynicus," or "From Sole to Suicide." This farcical tragedy proved to be a play of art, commerce, and love, though we are bound to express reprobation of its moral tone. The entire cast falls dead upon the stage at the curtain, saving only a professional murderer, of the Murderers' Agency, Ltd., who goes scot free. During the evening the prizes were distributed by Sir George Frampton, and the toasts of the London County Council, the Principal and Staff of the School, and the Chairman were received with much enthusiasm. Mr. A. J. Newton and his colleague, Mr. Cecil Rea received quite an ovation. At a late hour the corners of Bolt Court re-echoed with the last toast (not on the programme) of "The Old Building." No. 6 will be vacated at the end of the present session for the erection of a new block to provide sufficient accommodation for the School.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The index to the 1909 volume of the "B.J." and of the "Colour Photography" Supplement is presented with this issue.

Messrs. Henry Greenwood and Co. beg to announce that the edition of the "British Journal Almanac," 1910, is completely exhausted; they cannot supply further copies.

An exhibition of appliances for the rapid printing on development papers from negatives, for postcard and lantern-slide printing and of printing frames for use in the ordinary way, will be held at the house of the "B.J." from February 10 to 26. Further announcements as to this exhibition will be made later.

The long story of a lady who had put money into a photographic canvassing business was related before the Brighton Borough Bench on December 20, when Harry Marks and Lena Chorley were charged with obtaining money on false pretences. (P. 1016.)

A comparison of some recent formulæ for acid diamidophenol developer is given in an article on page 1006 in reference to the use of metabisulphite in place of acid sulphite.

MM. Lumière have just published revised formulæ for the metoquinone developer, the substance which may be used amidol fashion without an alkali or with a small proportion of a carbonate when extra energy is required. (P. 1008.)

Professor A. W. Porter, in the Twelfth Traill-Taylor Memorial Lecture, which we reprint on page 1010, took for his subject the representation of the action of light on a photographic plate as rendered visible by development. He explained the conventional H and D curve, and gave a formula which he thought was simpler than that of Hurter and Driffield. He laid stress on the distinction necessary in the use of the word inertia for indicating (1) the deviation of the plate from a perfect one, and (2) a true inertia of the process of image formation. He also described the phenomena underlying the theory of plate-grain set forth by Dr. C. E. K. Mees in the paper which appeared in the "B.J." last week.

A note on page 1006 draws attention to the means which can be taken to avoid apparent exaggeration of the size of objects in lantern-slides projected on the screen.

The practical methods which may be used in combination printing by carbon or other process which does not give a visible image are the subject of an article on page 1007.

MM. Lumière and Seyewetz have recently estimated the amount of gold which is actually utilisable in a combined bath. They find that the most economical use of the combined toning and fixing bath is obtained if the prints are given a preliminary fixation in hypone. (P. 1009.)

EX CATHEDRA.

An Exhibition of Printing Appliances.

We propose holding at the house of the "B. J.," from February 10 to 26, an exhibition of modern apparatus, such as bromide printing machines, postcard and lantern-slide printing frames, as well as printing frames of the various patterns employed for negatives in the usual way. This apparatus will be explained to visitors, and the special features pointed out by an attendant engaged by Messrs. Henry Greenwood and Co. By the time these lines appear every firm which within our knowledge markets specialties of this kind will have received an invitation to show their goods, but if any should have been overlooked we trust that they will place themselves in communication with us, when we shall be glad to write them as to the exhibition of their apparatus. It should be understood that the exhibits are confined to devices for holding *negatives*: we have not the space in which to show cabinets, etc., for holding *printing frames*. We should also like to announce that inventors or patentees of apparatus coming within the foregoing classes are also invited to show working models. These will be catalogued and reviewed, as will other apparatus in the exhibition. Hence those who take advantage of this offer should bear in mind that we cannot keep any exhibit or form of construction secret, or to be shown to a particular class of visitor. At the same time, we hope that this offer may be of service to some who may have new designs in apparatus which they are anxious to bring before users and manufacturers.

* * *

The Index to the "B.J."

With this issue we present as a supplement the index to the 1909 volume of the "B.J.," and to that of the "Colour Photography" supplement for the past twelve months. As in previous indexes, we have endeavoured, as far as possible, to make each item self-explanatory, so that in using the index as a guide to the contents of the volume the reader is spared unnecessary reference to pages. Again, as in previous years, subjects are classified as far as possible under general headings. Thus, all kinds of cameras—with the exception of reflexes—are indexed under "Camera." Information regarding developers and developing apparatus appears either under "Developers," "Developing," or "Development," and so on. This course has rendered it possible to provide an index which, within a moderate space, is nevertheless an almost complete key to the contents of the thousand pages of the volume. The compilers have also aimed at avoiding the "howlers" which beset the path even of the most painstaking indexer. Readers of one of the book-trade journals may perhaps have seen the volume "Chats with the Chicks" placed under the heading "Poultry and Farm," an aberration of

the indexer which led "Punch" to hope that we might have a succeeding volume, "Half-Hours with the Hens." Photography, fortunately, does not expose the indexer so much to accidents of this kind, but nevertheless, in the case of the "B.J." index, it has been found necessary to make it clear in a number of cases that the same word refers to totally different things.

* * *

The "B.J." Almanac.

Our publishers desire us to announce that the whole edition of the 1910 "British Journal Almanac" is now exhausted, and those requiring further supply should make application to the larger wholesale houses, who may still have a few copies, or, if unable to obtain from them, to retail dealers. The issue of the "Almanac" this year appears to have been better distributed than ever before, so that on the day of publication the publishers had still a few copies—about 300—in hand, applications for which have come in steadily during the past few weeks, with the result that the last were disposed of immediately before the Christmas holidays.

* * *

The Characteristic Curve.

In the Traill-Taylor Memorial lecture Professor A. W. Porter raised some points with regard to the "characteristic curve" that seems to afford matter for an interesting discussion. He challenges the assumed evidence of so-called "inertia" in the photographic plate, pointing out that the assumption depends almost entirely on the peculiar method adopted for plotting the curve. If the method of plotting density against exposure is employed in place of that which involves the logarithm of the exposure, a convex curve, rising fastest at the beginning and then more slowly, results, instead of the concave curve which indicates lag or inertia. He also throws doubt on the method of measuring sensitiveness by the position of a point which is not on the representative curve of the plate at all. We believe, however, that this has never been claimed to be an accurate method of measuring sensitiveness, only a useful approximation that gives a rough idea of the relative speeds of different plates. His other point is more subtle, for it is certainly a fact that the form of a curve varies with the mode of plotting, and it is therefore necessary to be cautious in drawing inferences from form. Many have been confused by the evident fact that the characteristic curve, as usually drawn, is not a correct graphic representation of the state of affairs that actually exists in the plate, and possibly another method of plotting would be useful for purely demonstration purposes.

* * *

Scale in Lantern Slides.

The suggestion has recently been made by a well-known writer that lantern-slide makers should always bear in mind the size of the projected image and avoid producing slides that will afterwards appear too gigantic on the screen. The advice is good, but it is a little difficult to follow it, seeing that the size of the projected image varies so greatly. At one time the slides may be shown on a 6-foot disc with a linear magnification of 24, and at another time on a 12-foot disc with a magnification of 48. A figure $1\frac{1}{2}$ inches high on the slide will then be 3 feet high on the screen in the one case and 6 feet in the other, and while the one may look too tall, the other may look too short. The lantern-slide maker cannot control the absolute size of the projected images that will afterwards appear on the screen, but he can control the apparent scale, for this depends not on linear measurements, but upon the

relative proportions of the various parts of the subject. We may, for example, consider the cases of children and adults. In a natural scene the former occupy less of the total subject area than do the latter, but in the process of masking slides it is easy to ignore this fact. A small child in a small, closely masked picture will be given the same importance as an adult in a larger picture and then, if the two pictures are seen after each other, either the child will look too big or the adult too small, even though the relative sizes of the figures are the same. Though the actual figure shown on the lantern screen may be either very gigantic or much under life-size, yet neither fact will be unpleasantly noticeable if due care be taken in arranging the picture as a whole. A great deal, therefore, depends on masking, and much more consideration should be given to this matter than it usually receives. Photographers who spend a great deal of time and trouble in trimming large size prints often give little or no attention to the masking of their slides, though these really require equal care.

—•—

ACID SULPHITE, METABISULPHITE, AND DIAMIDOPHENOL (AMIDOL) DEVELOPING FORMULÆ.

WE are continually receiving queries as to the substitution of potassium metabisulphite for the solution of acid sulphite, or bisulphite lye, so frequently recommended by Continental writers, but not always obtainable here. The question is not an easy one to answer accurately, for the equivalent of the various chemicals used in photography is a matter not very well understood. Probably, however, the following method of estimation will give results that are near enough for practical purposes. The first difficulty that we meet with is the fact that the precise difference between an acid sulphite (or bisulphite) and a metabisulphite is rather obscure. It has been stated that a solution of metabisulphite in water is the same thing as a solution of acid sulphite, because by chemical equations it can be shown that one molecule of metabisulphite added to one molecule of water is equal to two molecules of bisulphite. This argument is faulty, for it is evident that the solutions are not the same, seeing that on crystallisation each deposits its own peculiar crystals. Apparently the one solution is more stable than the other, and parts with its sulphurous acid less readily, but the difference in effect on development is quite uncertain, and therefore, in considering the question of equivalents, we are obliged to take as a basis the discredited equation, and to assume that metabisulphite is practically twice the strength of bisulphite. The acid sulphite lye sold in solution is said to be a 40 per cent. solution of sodium bisulphite, and we may therefore take it as roughly equivalent to a 20 per cent. solution of sodium metabisulphite, which in its turn may be considered to be nearly equivalent to a 24 per cent. solution of potassium metabisulphite. This is a stronger solution than can be made, as potassium metabisulphite is not very soluble; we can, however, make a 6 per cent. solution and take four times as much of it as we are told to take of the acid sulphite solution. On a cubic centimetre of the acid solution may then be considered to be equal to 6 ccs. of 4 per cent. potassium metabisulphite, or .24 (one-quarter) of a gramme.

It has been suggested that the amidol formula given in our last "Colonial Number," which formula has been highly appreciated by many workers, might be modified to combat the effects of over- and under-exposure of similar lines to those advised by MM. Balagny and Underberg. On looking up the matter, however, we find many serious differences of opinion on the conditions th

tend to increase or diminish contrast that it does not seem worth while to elaborate the formula. Lumière and Seyewetz found that contrast is not materially increased by the addition of acid sulphite, and that the addition of bromide does all that is necessary. On the other hand, Underberg adds both bisulphite and bromide, and also reduces the sulphite, to effect the same purpose. In view of this difference of opinion, we do not see that we can do more than advise the addition of bromide to our formula to increase contrast. To diminish contrast, Lumière simply dilutes with sulphite solution, Underberg with water, at the same time reducing the bisulphite and the bromide. Our own method is to simply dilute. In our experience, amidol or diamidophenol is not at all well suited to the development of wrongly exposed plates, but for the simple purpose of increasing contrast we use a more concentrated solution, with more bromide, and for reducing contrast a well-diluted solution. Compared with Underberg's "normal" formula, ours contains less of all the ingredients—that is, it is more dilute. The proportion of sulphite to diamidophenol is the same, but we use only half the amount of acid salt and only one-fifth the amount of bromide. We recommend $\frac{1}{4}$ gr. of bromide per ounce of developer, while he has $1\frac{1}{3}$ gr., and as this can be increased to $2\frac{1}{2}$ gr. per ounce to give contrast, it is obvious that there is plenty of scope for variation. If our formula is diluted with an equal part of water it becomes approximately equal to Underberg's formula for soft results, with the exception that it contains more acid salt and less bromide.

The following comparison of Underberg's formulæ with the "B.J." formula may be of interest, as it shows at a glance the relative strengths of the solutions. All the formulæ are expressed in grains and ounces, and potassium metabisulphite is substituted for the acid bisulphite, the equivalent quantity being estimated in the way described in our previous note:—

	Underberg's Formulae.			B. J. Formula.
	Hard.	Normal.	Soft.	
Diamidophenol	25 grs.	25 grs.	10 grs.	20 grs.
Sodium sulphite	160 ,,	300 ,,	120 ,,	240 ,,
Potassium metabisulphite	117 ,,	62 ,,	2 ,,	30 ,,
Potassium bromide	25 ,,	$13\frac{1}{2}$,,	4 ,,	$2\frac{1}{2}$,,
Water to	10 ozs.	10 ozs.	10 ozs.	10 ozs.

It is interesting to note that Underberg's normal formula agrees as regards proportions almost exactly with the first "B.J." formula, in which we used double the quantity of metabisulphite now recommended. The bromide is, of course, much greater in quantity, but this is the only variation.

DOUBLE PRINTING IN DEVELOPMENT PROCESSES.

DOUBLE printing, or, as it is more generally termed, combination printing, is not a difficult thing when we have a visible image to deal with as we have in all printing-out processes, but even with them but comparatively few printers do it so well as it might be done, for often the junctions between the two printings are painfully manifest. In the early day of our art, combination printing was looked upon as one of the qualifications of a photographic printer. Nowadays, however, very little is done in that way, and the skill of a printer in this direction is seldom called for. Different methods of doing

this class of work have frequently been described in past volumes of the "Journal," and need not be referred to here.

What we propose to describe now is a method of double printing in cases where there is no visible image to guide us, as, for example, in the carbon or bromide process.

Many of our older readers can call to mind the excellent large pictures, printed from two or more negatives, which were produced by M. Leon Lambert about the middle seventies. Although they were made from two or more enlarged negatives, no trace of a join could be detected in them. These pictures were all by the carbon process. Lambert's method was treated at the time somewhat as a secret process, and was only taught or demonstrated to the inventor's licensees. Although Lambert employed only the carbon process, it will be seen that his method is equally applicable to any other where there is no image to be seen in the printing.

By way of a simple illustration of the process, we will assume that we have an enlarged negative of a portrait subject, and that for some reason or other it is desirable to take out the background and substitute another. In the first place, a piece of thin non-actinic paper of lemon or orange colour, an inch or two larger than the picture, is taken and laid on the negative, and the outline of the figure roughly traced upon it with a pencil. This is then laid aside for the time being. The back of the negative is then covered with thin mineral paper. In order to get the paper flat and even, it is placed for a few minutes between sheets of slightly damp blotting-paper to cause it to expand slightly. While it is there the edges of the back of the negative are touched round with gum solution. The paper is then laid on and the edges pressed in contact with the gum. The paper then dries flat and as even as the glass itself. The next step is to put the negative on the retouching desk and trace, neatly, round the figure using a blacklead pencil lightly, when it will be ready for the printing frame.

It is important that the glass of the frame fit tightly in the rabbet; if it does not it must be wedged tightly in, so that it cannot shift. The reason for this precaution will be seen later on. The printing frame should be somewhat larger than the negative, and the glass of it should not be so thick as is usually the case—say only three-sixteenths of an inch or so. In placing the negative in the frame it must be pressed closely in one corner of it; the top left-hand will, on the whole, be found the most convenient in working. The tissue, which must be cut at right-angles at one corner, is then placed on the negative and pressed accurately in the angle of the frame. It is well to mark this corner, as then there need be no mistake when it is removed and replaced for the subsequent printing from the second negative.

Next, on the glass of the printing frame the figure is painted round for half an inch or more, on the background portion, with oil colour; Indian red, as sold in tubes, is a suitable one to use when thinned with a non-drying oil, such as olive oil. Tube water colour, mixed with glycerine, will do as well. In doing this part of the work, the tracing on the back of the negative serves as a guide, but the precaution must be taken to keep a trifle outside the line, as it must not at all overlap the figure. The yellow paper with the previously traced outline upon it is then taken and roughly cut out about a quarter of an inch inside the line, and then about the same distance outside it. This will give us a couple of masks each a quarter of an inch or so less than where the junction is to be. In this way we get masks with openings about half an inch larger than the figure. The background mask is now put into position on the paint and kept in place by a few

pieces of lead or glass. It may as well be mentioned that the object of the paper mask is merely to avoid having to cover the whole of the background, or in the second printing the figure, with the paint.

All is now ready for the printing. This should be done in diffused light, and it is well to alter the position of the frame occasionally, so as to avoid a sharp edge in the print. When the exposure is finished, the frame is taken in, the paper removed, and the paint cleaned off. Next, without anything being disturbed, the figure is painted over round the edges as before, but this time keeping just within the guide line on the negative—about the same distance as it was previously outside it. The tissue and the negative are now taken out of the frame. If the tissue were developed at this stage we should, of course, get the figure on a plain white background, with the outline of it slightly vignetted, owing to the light creeping under the paint. Supposing a plain background is required, the exposed tissue is replaced in the now empty frame, registration being secured simply by pressing it close in the corner of the frame, as in the first printing. In printing

in the plain background it can, as a matter of course, be graduated by shading.

Should the second printing be from a second negative, the plan is as follows:—This negative, like the previous one, is coated on the back with mineral paper. The first negative is placed on the retouching desk, and the second placed on it and adjusted to the position the two images are to occupy in the finished picture. The outline of the figure in the first negative is then traced on the paper of the second one, after the first printing has been done and the second mask prepared. The first negative is then taken away and the second put in its place, the tracing on the back being a guide to its position.

It will be seen from the above that the principle of this method is really that of vignetting the one picture into the other, so that no sharp joins show. This is the principle on which the late Mr. O. G. Rejlander produced all his large pictures, some of which were built up from sometimes a dozen or more negatives, though he carried out his work somewhat differently, as he employed a printing-out process—albumen paper.

NEW METOQUINONE DEVELOPING FORMULÆ FOR PLATES AND PAPER.

THE special suitability of metoquinone for the development of Autochrome plates, to which we have recently drawn attention, has led us to experiment further with this developing reagent for ordinary plates and papers. It will perhaps be remembered that metoquinone possesses certain distinct properties as a developer. It combines within itself the properties both of those developers which work without alkali (sulphite only) and of those which—like metol and hydroquinone—can be used with alkalis. Thus the developer can be made up simply with sulphite of soda, or may be composed of the metoquinone plus sulphite and a carbonated alkali, or substitute for it.

Metoquinone developers retain their properties exceedingly well, and this fact renders the developer a very suitable one for use in a tank in very weak solution (stand development). With bromide papers the developer gives very vigorous blacks and pure high-lights. In the case of papers, the fact that metoquinone may be employed with a very small proportion of alkali is an advantage as regards freedom of action of the alkali upon the gelatine. Moreover, metoquinone is an economical developer, since a large number of negatives may be treated in succession in the same solution. The latter may be used as long as it lasts without fear of its losing its activity. Lastly, the metoquinone developers do not stain the fingers.

In spite of these properties, metoquinone has not been very extensively used, probably on account of its somewhat high price. It has now been found possible to issue it at a much cheaper rate, and the following formulæ have recently been worked out.

We will first give the formulæ most suited for the development of negatives on plates and films in the ordinary way—that is to say, developing for the usual time in a dish.

For time exposures the following solution is used, the metoquinone being first dissolved, and then the anhydrous soda sulphite:—

Water	1,000 ccs.	20 ozs.
Metoquinone	5 gms.	44 grs.
Soda sulphite anhydrous ¹ ...	30 gms.	130 grs.

For snapshots the above formula may be used, but it is better to prepare a somewhat more energetic developer by the addition

of a small proportion of alkali, or of a substitute for an alkali, in accordance with one or other of the following formulæ:—

1.—Water	1,000 ccs.	20 ozs.
Metoquinone	5 gms.	44 grs.
Soda sulphite anhydrous ...	30 gms.	130 grs.
Soda carbonate, anhydrous	5 gms.	44 grs.
Potass. bromide, 10 per cent. solution	10 ccs.	1½ drs.
2.—Water	1,000 ccs.	20 ozs.
Metoquinone	5 gms.	44 grs.
Soda sulphite anhydrous ...	30 gms.	130 grs.
Potass. bromide, 10 per cent. solution	10 ccs.	1½ drs.
Acetone	10 ccs.	1½ drs.
3.—Water	1,000 ccs.	20 ozs.
Metoquinone	5 gms.	44 grs.
Formosulphite, Lumière.....	30 gms.	130 grs.

The three formulæ give practically the same results. No. 1 is the least expensive, Nos. 2 and 3 are not quite so advantageous in this respect as No. 1, but they avoid the use of an alkaline carbonate, and are therefore particularly recommended for use in hot countries or during hot weather in Europe.

For under-exposed negatives one or other of the above formulæ given for snapshots is used, diluting 1 part of developer with 2 parts of a solution of carbonate of soda containing 5 gms. per litre.

For over-exposed plates the single solution developer given for time exposures is employed, but with the addition of 10 per cent. bromide solution to the amount of from 2 to 20 ccs. per litre of developer (= 20 minims to 3 drams per 20 ozs.). As a developer for lantern-plates, where a black tone is required, the first formula given above, namely, that for time exposures, may be used, or No. 1 and No. 2 of the formulæ for snapshots. Of these No. 1 gives somewhat softer results than No. 2.

The great solubility of metoquinone in acetone allows of a very concentrated solution being prepared by taking advantage of this fact. This is as follows:—

Water	700 ccs.	25 ozs.
Soda sulphite anhydrous ...	120 gms.	4 ozs. 102 grs.
Acetone	160 ccs.	5½ ozs.
Metoquinone	32 gms.	1 oz. 55 grs.

The metoquinone is dissolved in the water at 105 deg. F. after

¹ Or, crystal, 60 gms. (26½ grs.).

having added the sulphite and acetone. This developer is mixed with nine times its bulk of water to form the working solution.

Stand Development.

The facts that metoquinone may be used with an alkali and that the solution keeps excellently render it a most ideal substance for stand development. The following is a very suitable formula, due to M. F. Dillaye:—

Water	4,000 ccs.	140 ozs.
Metoquinone	5 gms.	80 grs.
Soda sulphite anhydrous ...	50 gms.	1 $\frac{3}{4}$ ozs.
Potass. bromide, 10 per cent. solution	5 ccs.	85 minims.

The negatives should be turned over in this solution at the end of every quarter of an hour, and well washed between developing and fixing; the total time of development will be about an hour, and the fixing bath is preferably one of "acid" formula.

Three-Dish Development.

In developing a large number of negatives, the correct exposure of which in many cases is uncertain, metoquinone may be usefully employed by making up three separate developers, each of a different degree of activity. A great number of formulæ might be given for working upon this system, but the following is as simple as any:—

For dish No. 1 developer for over-exposed negatives.

For dish No. 2 developer for snapshots.

For dish No. 3 developer for under-exposures.

Commence development in dish No. 1, and if there are no signs of over-exposure, withdraw the plate, and continue development in No. 2; or, if it shows signs of under-exposure, remove it to No. 3.

Development of Bromide and Gaslight Papers.

The following two formulæ differ considerably. No. 1 is intended for bromide papers, whilst No. 2 is used for chlorobromide papers of gaslight rapidity, such as "Radios."

No. 1, Bromide.

Water	1,000 ccs.	20 ozs.
Metoquinone	3 gms.	27 grs.
Soda sulphite anhydrous ...	30 gms.	130 grs.
Soda carbonate anhydrous...	5 gms.	44 grs.
Potassium bromide, 10 per cent. solution	10 ccs.	1 $\frac{1}{2}$ drs.

No. 2, Gaslight.

Water	1,000 ccs.	20 ozs.
Metoquinone	12 gms.	106 grs.
Soda sulphite anhydrous ...	40 gms.	$\frac{3}{4}$ oz.
Soda carbonate anhydrous...	20 gms.	180 grs.
Potassium bromide solution, 10 per cent.	20 ccs.	3 drs.

During hot weather it is a good plan to use acetone instead of carbonate of soda. In formula No. 1 the 5 gms. of carbonate can be replaced by 10 ccs. of acetone, and in formula No. 2 the 20 gms. of carbonate also by 10 ccs. of acetone.

A. AND L. LUMIERE.

EXPERIMENTS ON TONING P.O.P. IN THE COMBINED BATH.

It is well known that the gold in combined toning and fixing baths is utilised only partially when toning prints on P.O.P. After having done about a hundred 7 x 5 prints in a combined bath containing .12 gm. (1 $\frac{3}{4}$ grs. of gold chloride, toning takes place very slowly, details are eaten out, and the final tone of the print is reddish, although there is still a considerable proportion of gold in the bath. The usual method is to strengthen the bath by further addition of new toning bath, but this plan does not allow of the gold, which has become inactive in the bath, being utilised; the further toning action which is obtained corresponds fairly closely with the quantity of new bath added. Not only is there no advantage in this method, but there are certain serious objections to it, in that it causes the accumulation in the combined bath of double hyposulphites of silver, and that it also involves the solution in the bath of substances, such as citric acid, etc., contained in the paper, all of which products, more or less quickly, decompose the bath. We have made experiments to find what method of using the combined bath allows of the most complete utilisation of the gold without prejudicing the toning action. For this purpose we have ascertained the quantity of gold which is left in the bath after the toning action of the latter has been effected in different ways upon the number of prints sufficient for the exhaustion of the gold in the bath. The formula adopted for the bath is that which is customarily recommended for the Lumière papers.

Bath.

Water	1,000 ccs.	20 ozs.
Hypo	250 gms.	5 ozs.
Alum	15 gms.	130 grs.
Lead acetate	2 gms.	18 grs.
Gold chloride (1 per cent. solution)	60 ccs.	1 $\frac{1}{4}$ oz.

This bath was used in the following ways:—

1. By toning prints in it in succession.
2. By toning together a number of prints equal to those which were previously toned in succession.

Further, each of these methods was employed in a different way:—

(a) Toning and fixing in the combined bath in the ordinary way after having given the prints a preliminary washing in water.

(b) By removing the silver salts from the prints by preliminary fixing before immersion in the combined bath.

This last method of toning naturally prevents the accumulation of double hyposulphites of silver in the bath, and, as we have previously shown,¹ and as Namias has confirmed,² removes one of the causes for the falling-off in tone when treating a large number of prints.

The results of our experiments are contained in the following table:—

Method of using Combined Bath.	No. of 7 x 5 prints toned in 100 ccs. toning bath containing .0264 gm. gold.	Time of Toning of—		Proportion of gold used in toning compared with that put into bath.
		First print.	Last print.	
Prints toned and fixed in combined bath without previous fixing ...	a. Prints toned in succession	24	4 minutes	60
	b. Prints toned together ...	24	Twenty-fourth print... 25 minutes	52
Prints first fixed in hypo and then toned in combined bath	a. Prints toned in succession	30	First print	70
	b. Prints toned together.....	30	Thirtieth print	63

¹ "Revue Trimestrielle," Feb., 1908.

² "B.J.," Nov. 20, 1908, p. 886.

These results show:—

1. That the most economical method of working the "combined" bath for print-out papers consists in fixing the prints before toning.
2. That the quantity of unused gold remaining in the exhausted bath is an important factor, since, even under the

best conditions, one can only make use of two-thirds of the gold.

3. That the quantity of gold used in toning one 7 x 5 print is one-half milligramme = .008 of a grain.

A. SEYEWETZ.

THE GROWTH OF THE PHOTOGRAPHIC IMAGE.

[The following is the text of the twelfth Traill-Taylor Memorial Lecture, delivered by Professor A. W. Porter, B.Sc., F.R.A.S., on November 23, at the house of the Royal Photographic Society.]

WHEN I was first offered the privilege of delivering this lecture, my first notion was to choose as the subject one connected with optics, which is the branch of science with which I am most familiar. My intention was strengthened by an appreciation of the fact that Mr. Traill-Taylor, whom this lecture commemorates, was widely known for his labours on photographic optics. However, in consultation with one of your members, I learned that several lectures in this series had already been given on the subject of optics, and it was suggested to me that it might be as well to steer away from it. I intend carrying out, to some extent at any rate, that suggestion by selecting as my subject "the growth of the photographic image." It is not my intention to go with detail into the history of the complicated and numerous theories that have been put forward from time to time, many of which are still held—for the matter is one of great dispute—but my intention is simply to consider one or two points in connection with the subject, and state what to many of you will seem, I am afraid, *obiter dicta*, because I am not myself a professional photographer—I am merely a physicist.

PART I.

It is a matter of common knowledge that in order to obtain a correct negative the exposure must at least reach a certain minimum value. Below this value the density of the deposit fails to increase

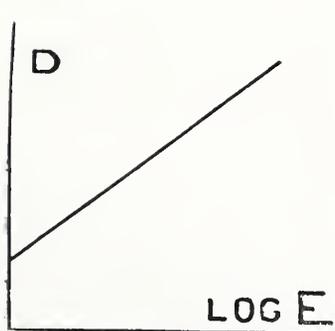

Fig. 1.

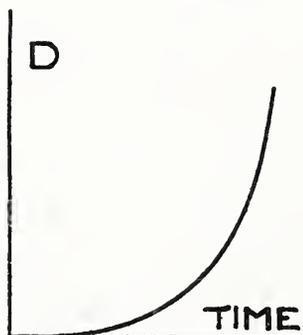

Fig. 3.

with the exposure, according to the law which is necessary in order that the positive finally obtained should have the correct gradation. It is easy to show that to obtain a true positive the product of the transparency of the developed negative into the exposures to which it corresponds must be a constant—that is, that $T E$ must be constant. It is more usual to state the law in terms of the so-called "density of deposit" D , which is defined as being equal to the logarithm of the reciprocal of T . The law then becomes that the density must increase in arithmetic progression as the exposure increases in geometrical progression if correct results are to be obtained. That is to say, that if I increase the exposure 3 times, then 9 times, then 27 times, the density ought to increase as the numbers 0, 1, 2, 3. Now, real plates fail to comply with this law except for a certain range of exposure; and unless you give such an exposure that the law can approximately come into play your picture will not be correct. These statements can be illustrated by means of diagrams.

If I draw a diagram on which vertically I represent the densities produced, and horizontally I place numbers in geometrical progression at equal distances to specify different exposures; or, what comes to the same thing, if I represent on the horizontal line equal distances

as being equal to equal changes in the *logarithm* of the exposure, then the diagram representing the character of a perfect plate would be a sloping straight line as in Fig. 1. I do not want to introduce any more mathematical conceptions than are needful in order to make the subject clear; and I want, at any rate, to explain as I go along any particular mathematical ideas that one does introduce. So for fear some of you are not familiar with logarithms, I want you to realise, to start with, that if you take the logarithms of numbers which are in geometrical progression, for example, 1, 10, 100, 1,000, 10,000, thus increasing ten times at each step, they will be found to be 0, 1, 2, 3, 4, and so on; that is, they increase in an arithmetic series. Take the exposure by which for light of too small intensity you mean the product of the intensity of the light which is producing the images multiplied into the time during which it acts, and instead of letting equal distances along the horizontal represent equal changes in the exposure, let them represent equal changes in the logarithm of it; then I say that on a perfect plate, which would give you the correct

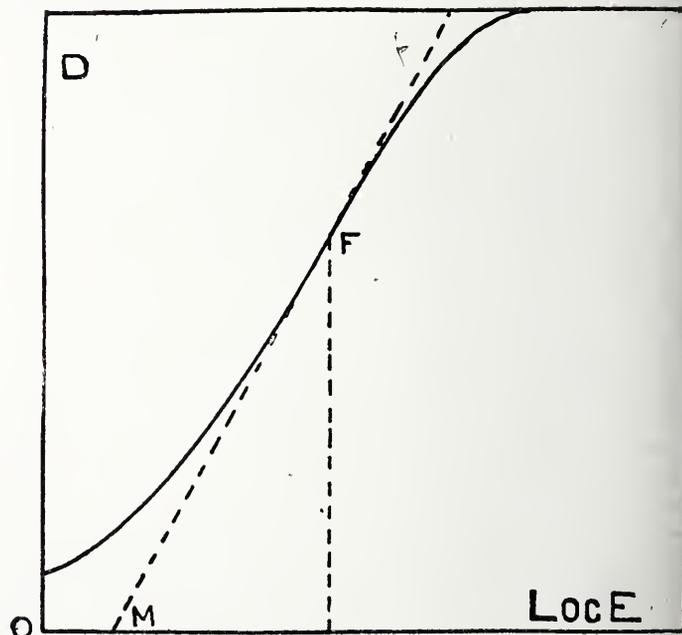

Fig. 2.

gradation no matter how small the exposure, the density would have to be simply proportional to the increase in the horizontal distance—that is to say, the plate would be depicted by a straight line on the diagram. No plate satisfies that simple law, and in consequence you get a region of under-exposure, and also a region of possible over-exposure. If you give less than a certain exposure, you will not get the correct gradation. If you give more than a certain exposure you will not get the correct gradation in your image, and the deviation of any actual plate is represented by the fact that you obtain instead of the straight line on the diagram, a curved line, more or less like the curved line in Fig. 2. This means that if the plate is under-exposed you obtain a greater density for very weak images than what the law would require; and, so again, in the case of over-exposure you obtain a flat picture, all intensities giving you nearly the same density. Mathematically, the theory of this was worked out on certain assumptions in 1890, by Messrs. Hurter and Driffeld, and I think

will not be the first time that you have had lectures here on the work of Messrs. Hurter and Driffield. They found you could represent this peculiar law of behaviour of a real photographic plate, by means of a certain mathematical equation. There is no doubt that the equation that they obtained is a more or less useful one for representing the actual behaviour of the plate. There is considerable doubt, however, with respect to the theoretical foundations upon which that law was based. The importance of Hurter and Driffield's work is indicated, however, by the rule adopted to-day, nominally at any rate, I believe, by all photographers in England, in specifying the sensitiveness of plates. And they do it in this way.

The region where you will get a correct gradation is represented by the part of the curve on Fig. 2 which most nearly corresponds to the theoretical law which I expressed as necessary for a perfect plate; and the deviation of the curve from the straight line FM represents the deviation from that law. The exposure corresponding to the distance OM is called "the inertia of the plate," a number which is intended to measure the reluctance of the plate to correspond to the law necessary for the producing of a perfect image. Those who try to build up physico-chemical theories as to how the image is produced must carefully distinguish between the use of this term "inertia" for indicating the deviation of the plate from the perfect law, and a true inertia of the process of image formation. The misleading character of the curve, I think it is, which may give rise to the misconception. Because when you plot the curve in this way it either seems to indicate that at first the density does not grow with exposure as fast as it does later. This result altogether comes about on the particular mode in which the curve is plotted; and you must not suppose that the curve indicates anything whatever corresponding to inertia in the actual physical or chemical process, by which the latent image is first formed. If, in other words, I were to plot the density against the exposure, which would seem the most natural thing to do, I would find that the density in this initial stage actually increases faster than it does anywhere else; in other words, when the light first begins to act on the plate, the action per second is greater than what it is at any later stage. You would then find the curve as steepest near the origin, getting less steep as time went on. I am not denying, what is certainly true, that there is a real inertia in the physico-chemical process, but at any rate as far as considerations such as Hurter and Driffield brought into play, there is nothing absolutely similar to inertia in the behaviour of a plate. I want to try to elucidate this question of inertia by means of one or two experiments, one in which I have a physical (or perhaps a chemical) process setting in, for which a quasi inertia does come into play, and one in which there is no evidence of it. There are a great number of physical and also of chemical phenomena whose growth may be followed and in some of these there is a sort of lag, which corresponds to inertia in the initial stages, while in others there is not.

Let me first explain what one means scientifically by the term "inertia." Take a heavy ball and suspend it by a long string; then by means of a thin elastic cord try to make it move quickly in a horizontal direction. The first effect is that the hand moves, the elastic stretches, the ball remains nearly at rest. It slowly gains speed, however, and follows in the direction of the pull. This reluctance to change its velocity is said to be due to inertia. If I try to raise it very suddenly by the string it will not respond immediately; the string may even break if the jerk be sharp enough.

I will now show a chemical process in which an analogous lag occurs at first. I have an apparatus here by which I can throw two images on the screen. The light of one of them comes through a solution of hyposulphite of soda and of the other comes through a simple aperture, which I can gradually close by means of an iris diaphragm. A pointer attached to the handle which actuates the iris diaphragm moves over a scale graduated into divisions representing changes in the logarithm of the reciprocal of the area of the diaphragm. The diaphragm is first adjusted so that the image formed through it is as bright as that through the "hypo." I will now add a little hydrochloric acid to the hyposulphite at a given moment and then follow the change which takes place by means of this adjustable diaphragm. The effect of adding the hydrochloric acid is to free the sulphur; and it sets it free according to a definite law. Every half-minute the two images are adjusted to equality and the position of the pointer, which is a measure of the density, is read. You shall find that in the initial stages the density increases very slowly indeed. As time goes on, the rate of deposition of the sulphur

increases up to a maximum, and then after that it gets slower again, until finally no more deposition takes place.

After making rough measurements of the opacity produced by the depositing sulphur from time to time we plot a curve of density against time. The curve obtained is shown in Fig. 3.

Thus there is a true lag at the beginning, and it would be justifiable to treat this as a process exhibiting marked quasi-inertia. If I had done the same thing with the growth of the latent photographic image, for a plate following the Hurter and Driffield law, I should have had a curve which rose fastest at the beginning, and then more slowly. And the peculiarity which comes out in the plotting which looks like inertia is merely a peculiarity of the mode of plotting itself. You plot against log E, not against the exposure itself. I shall not say a word against Hurter and Driffield's mode of representing the property of the plate, as long as this is clearly understood. What I am rather warning you is against supposing that there is a true inertia or lag connected with the photographic change of the duration which their language seems to imply. I have another change here, which exhibits no detectable lag. I have here a thermopile, consisting of two wires of different kinds connected with a galvanometer. I push one of these into a potato, and the other into another potato, then wait for things to become steady. I do not know whether to call what I am going to show you a physical or chemical change, or something different from both; but the final result is physical. The stimulus this time will be given by a pen-knife with which I prod the potato. As I stab with the knife, the whole potato will warm up, and since the wire dipping into it will get warm too, the spot of light on the graduated scale which indicates the position of the galvanometer mirror will alter its position. You see the change follows very quickly the application of the stimulus;

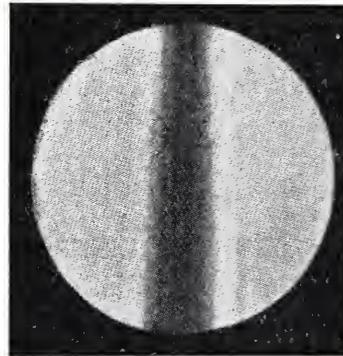

Fig. 4.

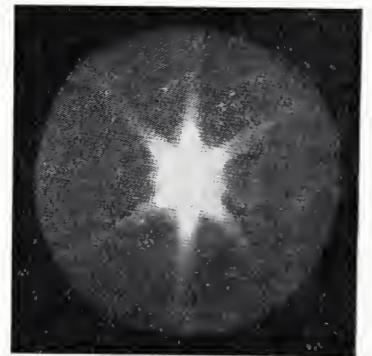

Fig. 5.

so there is very little inertia. What I wish to emphasize is that this change is much more like the change produced by light on a photographic plate than the change produced in hypo by hydrochloric acid is.*

I do not know whether you are interested in merely algebraical things; no doubt some of you are. Messrs. Hurter and Driffield founded their equation on certain assumptions, which are somewhat doubtful, perhaps; but a suggestive theory can be framed on a much simpler basis than theirs. You have to explain the formation of the latent image, and how it grows; what will determine the rate at which it grows? Let us write down the two circumstances upon which we may suppose it to depend. We are concerned with the rate of growth of the latent image, by which I mean the rate of deposit or production of the changed material formed by the action of the light—I do not want to commit myself as to what this material may be. It is natural to take it as proportional to the intensity, I, of the light that is producing it, so that will be one factor. It is natural also to take it as proportional to the amount of unaltered bromide of silver, or whatever the sensitive salt is which remains. Let m_0 be the amount of sensitive material to begin with, and let m be the amount transformed by light; then $m_0 - m$ will be the surviving unaltered material. The assumptions I have made can be written in the form of an equation thus:—

$$\text{Rate of growth of } m = a (m_0 - m) I.$$

That is an equation which the mathematician can deal with, and

* The Nernst lamp used in the demonstration provides an example of a true physical lag in the period while the filament is warming up.

if it is satisfied he can tell you at once how much transformed material there will be at any instant. He would state the result in the form of another equation:—

$$m = m_0 (1 - e^{-at}) = m_0 (1 - e^{-aE})$$

where e is the constant which is taken as the base of natural logarithms and is equal to 2.7183 nearly. Joining this result with the usual assumption for which there is good experimental evidence that the density, D , of the ultimate image is proportional to m and to a factor depending on the time of development we may write

$$D = K (1 - e^{-aE})$$

as the equation connecting D and E^* . This equation does not possess as great a flexibility as Hurter and Driffield's more complicated one; that is, in mathematical language, it does not contain as many constants which can be adjusted so as to represent the peculiarities of different kinds of sensitive plate. But it possesses the same general characteristics as theirs; and it is suggested as a possibly useful one in those cases in which it may be desired to represent the behaviour of a plate by means of an equation which rests on very simple assumptions and has simple properties. If we plot D against $\log E$, the curve obtained is similar to Fig 2. The point of inflection, F , occurs when $E = \frac{1}{a}$; and the density there is .632 K . The point

M is given by $OM = \log_e \frac{1}{a} + -e = \log_e \frac{1}{a} - 1.718$. This distance

may still be taken as the logarithm of the "inertia"; but I am a little in doubt as to whether the customary measure of the sensitiveness of a plate is the most plausible or useful one to employ. It specifies the most important property of a plate by the position of a point which is *not on the representative curve of the plate at all*.

An exposure equal to the "inertia" gives under-exposure, for M lies markedly below the curve. In practice this does not lead to ill results because exposures are accommodated to the requirements of specified values of sensitiveness by experience. But a much more scientific specification would be that of the exposure corresponding to the middle of the flattest part of the curve, viz., the point F ; for this would name a mean exposure which could be deviated from either in excess or defect without risking a false gradation. The exposure would then be adjusted (as in practice it probably is now) by letting the predominant lights correspond to the exposure F (to be quoted on the box) and leaving the insignificant details and highest lights to look after themselves. The determination of the point F is not in general use so easy as that of M , which is found from a few exposures in the "correct" region, and drawing a straight line as nearly as possible through the points obtained on the diagram. But if the above simplified equation be accepted as a working guide the point F will be found to correspond to an exposure whose natural logarithm is greater than OM by the amount e , or 1.7183. Thus a determination of M would simultaneously determine F at least as far as the simple equation is sufficiently accurate.

PART II.

I want now to pass to a subject which is more nearly related to optics, and connected to a property of the finished plate. My object is to introduce you to a subject upon which Dr. C. E. K. Mees has been working, and by means of some simple demonstrations to show you upon what principles his explanations depend. The property in question is the scattering of the light incident upon a photographic plate. The importance of this arises from the influence which this scatter has in broadening the image of a warmer object so that if two very near bright line objects be photographed, their images on the plate overlap and prevent them being seen as two. That such scatter is very important is, of course, quite well known, and it is usually attempted to diminish it by selecting plates in which the grain of silver halide is as fine as possible. But now Dr. Mees finds† that it is not the finest-grained plates which produce the least scatter; in a series of experiments it was a minimum in a medium-grained "Process" plate with grains of .001 to .0015 mm. diameter, and in a special plate with very uniformly sized particles of about .0015 mm.

diameter; and it was greatest in a chloro-bromide plate in which the particles were .0008 mm. diameter. To prove this Dr. Mees merely photographed a very narrow slit upon the various plates, the illumination of the slit being of decreasing intensity from top to bottom of it so as to simultaneously obtain images corresponding to various bright sources. The images were naturally broader at the more illuminated end, and consequently present somewhat the appearance of tadpoles. Photomicrographs were then taken of these, and the above statements summarise the conclusions to be drawn from them (Lantern slides of these "tadpoles" were shown, having been courteously lent by Messrs. Wratten and Wainwright.) The phenomenon of scatter is therefore not so simple as has always been taken for granted.

To explain the complication, Dr. Mees recognises that it is necessary to bring into account the effects of "diffraction" as well as reflection, the latter alone having previously been considered in this connection. I wish to demonstrate what this phenomenon of diffraction is. I focus a narrow slit (illuminated by a lantern) upon the screen, by means of a lens. If I place a piece of plain glass in the path of the beam near the lens no perceptible disturbance is introduced. I now place a piece of glass containing about 500 parallel lines scratched on every inch of it. The result is that I see, instead of one uncoloured image, about ten slightly coloured images on each side of a central uncoloured one; these extend over about 2ft. of the screen. This is a case of diffraction scatter. Taking a similar glass "grating" with about 14,000 lines to the inch (about .002 mm. from centre to centre), the scatter is much increased. In this case there is a central image, and on each side of it, spreading out to an angle of nearly 20 deg. on each side a bright spectrum, succeeded (also on each side) by another making double this angle with the central image. Now these gratings have a structure which is comparable in size with the diameter of the grains in a photographic plate, and we may therefore conclude that diffraction phenomena will be prominent in connection with the behaviour of a photographic film. Figs. 4 and 5 show diffraction effects for a needle and for a small triangular opening respectively, these being placed in turn in the position of the grating in the experiment shown.

Dr. Mees found an easy way of distinguishing between a mere reflection scatter and one due to diffraction. The amount due to ordinary reflection (such as from mirrors) would be independent of the colour of the light; but the amount due to diffraction depends markedly upon colour, hence the spectra which you saw on the screen. Repeating some of his tadpole experiments, using light of different colours, he found that the scatter showed little difference (if any) in the case of the process plate, but is very different for the red and blue in the case of a lantern plate. In the former plate, the effect of ordinary diffuse reflection was sufficiently great to overpower any diffraction effects present; in the case of the latter plate diffraction had become the predominant factor.

The full elucidation of the behaviour of plates in this respect would be a matter of very considerable interest, both theoretically and practically. Unfortunately, the size of grain in a photographic plate is of such a magnitude as to introduce the greatest possible difficulty in working out a theory. If the grains had been very large so much success could probably be obtained by treating them as reflecting spheres. For such spheres the amount of light diffused would be roughly proportionate to the total area of the grains. On the other hand, if their diameter were exceedingly small so that many of them would be contained in a single wave-length of light, the question of the amount of scattered light is again a soluble one. It has been discussed by Lord Rayleigh, and it turns out that for such particles (such as the particles in blue tobacco smoke, or the particles of sulphur deposited in the earlier stages of the experiment shown in this lecture) the amount of light scattered is proportional to the number of particles per unit volume, multiplied into the *square* of the volume of each, and that it is inversely proportional to the *fourth* power of the wave-length of light employed. But it is not justifiable to assume that a blend between these two laws will hold in the case of the grains of intermediate sizes with which we are now concerned. Moreover, a knowledge of the relative numbers of grains in the different plates is required before a complete comparison can be made between them. It can be shown that the breadth of the scatter will be small, both when this number is very small and when it is very large; and that there is a certain intermediate number for which the breadth will be greatest, other things being the same. When the number of grains

* In reality a and K in this formula only represent a kind of mean value of each of these quantities, their values varying from layer to layer through the thickness of the plate. This equation should be taken as applying to any very thin layer of the film and then a summation effected for all the layers. This leads once more to the complication which the equation is intended to avoid.

† "Roy. Soc. Proc.," Vol. 83, No. A 559.

small the amount of scattered light is insignificant; on the other hand when the number is great, although the amount scattered by any element is great, yet it can penetrate little distance because it is topped by the grains in adjacent elements.

The question is of so much importance, however, that it is bound to be more fully discussed, and I thought that the few things I have shown you to-night might enable you to know something about the phenomenon of diffraction, which will be referred to throughout the future discussion.

A. W. PORTER.

Photo-Mechanical Notes.

A New French Textbook.

Reproductions Photomécaniques Monochromes par L. P. Clerc. O. Doin et Fils. Paris. 5 francs.

The last volume of the "Encyclopédie Scientifique" is devoted to photo-mechanical processes and is written by Monsieur L. P. Clerc, one of the editors of "Le Procédé." The name of the author is a sufficient guarantee that the book is quite up-to-date, and replete with the latest scientific investigations concerning process work. Separate sections deal with photography, both by wet and dry plate, with line, zinc etching, half-tone, collotype, photolithography, and photogravure. There is an historical introduction, and two appendices deal with the prices charged for the work, and a bibliography of the literature connected with it.

Altogether, an admirable compilation, compact and complete, in which the theory of the work goes hand in hand with the practice; we wish there were a similar book in English.

Lithography v. Letterpress Illustration.

The introduction of the new off-set presses has given a fillip to lithography, and if photo-process is applied to plates for printing in this manner, as is certain to be the case, the letterpress printer will have more severe competition to meet than he has had for many years past. Already we have seen admirable half-tones and three-colour work in both cases done with the added advantage of being printed on pleasant and durable paper, at probably a lower cost than is possible by letterpress methods.

We suggest that the letterpress printer should see if a rubber off-set press could not be made to work from type and blocks in relief. This would offer many advantages, as it would enable such blocks to be "fine etched" if necessary, which is difficult to the point of impossibility in the case of half-tones printed lithographically. Advantage could be taken of skill now available, and the machines ought to be considerably cheaper as they would need no damping arrangements, as they do for surface printing. It is true the rubber blankets might not last so long, but, after all, the cost of the blanket is not a very serious item, especially if the job ran into large editions.

Improving Half-Tones.

Patent No. 25,968, 1909, of J. Bell, describes at great length the deficiencies of ordinary half-tone blocks, as, for example, "the absolutely black and darker parts of the picture are rendered smoky, dull, and ashy in appearance, in consequence of being broken up by the said screen," and claims the following methods for improving matters:—

First. The improvements in the production of "half-tone" process engraving, line process engraving, process prints, and the like, which consist in the introduction thereto of the relative pure blacks, and the artistic gradations thereof of the original subject or object, by removing portions of the superimposed photographic film from the negative, or "half-tone" screen negative, by drawing or engraving thereupon before being printed from on to metal.

Second. The improvements in the production of "half-tone" process engraving, line process engraving, process prints, and the like, which consist in the introduction thereto of the relative pure whites and the artistic gradations thereof of the original subject or object by removing portions of the superimposed photographic etching resist film from the positive print upon the metal plate by drawing or engraving thereupon before the same is etched.

Third. In combination with the process claimed in the first and

second claiming clauses hereof, the improvements which consist in the introduction of the relative pure whites and the artistic gradations thereof of the original subject or object by drawing, in varied and artistic lines, in combination or not with masses, upon the sensitised "half-tone" screen-negative image with a fine brush and waterproof Indian ink or the like to obtain a corresponding but superior result to that heretofore only attainable by engraving down in artistic lines and masses the relief surface of the already etched block.

Fourth. The improvements in the production of "half-tone" process engraving, line process engraving, process prints, and the like, which consist in the introduction thereto of the combined correlative pure blacks and the correlative pure whites, and the artistic gradations thereof of the original subject or object, by the means respectively referred to in the three preceding claiming clauses hereof.

Fifth. In the process forming the subject of the first, second, and fourth claiming clauses hereof, the employment of a tool having a curved acting longitudinal edge, preferably situated below the central line of the stem of the said tool when in use.

Sixth. In the process forming the subject of the first, second, and fourth claiming clauses hereof, the employment of a tool having a curved acting edge, situated at right angles to the direction of movement of the tool, and preferably situated above the central line of the stem of the said tool.

Seventh. The improvements in process line engraving, which consist in printing an ordinary photographic negative or transfer on to the superimposed photographic etching resist film upon a metal or other plate, and drawing or engraving upon the same in lines, dots, or masses, as in wood-engraving, previous to the etching process, in order to obtain the relief image of the original object or subject for printing.

With regard to the first four claims, it has been the practice, as long as half-tone has been used, to "fake" both negative and print in the manner described, generally with more or less disastrous effect. The special tools proposed may make matters easier, though in the absence of great skill and artistic feeling we should expect results to be worse rather than better. This is probably the process employed in the illustrations in the advertisement columns of the "Daily News" some time ago, when we suggested, without any idea of this patent, the method was similar to the one now described. Patent No. 27,387 of 1909 claims further protection for the tools used.

PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—

HALF-TONE BLOCKS.—No. 29,431. Improved method and apparatus for making half-tone blocks. William Gerrard Rennie, 28, Forth Street, Edinburgh.

PRINTING PLATES.—No. 29,507. Process for etching flat-iron printing plates. Herbert Sefton-Jones, 285, High Holborn, London, for C. G. Roeder G.m.b.H., Germany.

ETCHING MACHINES.—No. 29,660. Improvements in etching machines. Henry Williams, trading as Leeds Electro and Stereo Company, 8, Quality Court, Chancery Lane, London.

"ENSIGN" COMPETITION.—O.R. Colour-Sergeant Arthur Burns, Scots Guards, Guards' Depot, Caterham, Surrey, is the winner of the "Ensign" Roll Film Competition for December. Houghtons Ltd. offer a three-guinea camera every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

NEW FELLOWS OF THE R.P.S.—Thirteen applications for Fellowship were made to the Council of the Royal Photographic Society. The following eight candidates were elected:—E. T. Holding, F. R. Fraprie, Adolphe Abrahams, S. L. Coulthurst, Captain Owen Wheeler, Thomas Wright, Professor G. H. Emmerich, and B. Ward-Thompson.

FORTHCOMING EXHIBITIONS.

December 4, 1909, to January 1, 1910.—Southport Photographic Society. Sec., J. McLellan, 2, Pilkington Road, Southport.
 December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1910.

January 26 to 29.—Bolton Camera Club. Entries close January 12. Sec., H. Mills, Higher Bank, Southills, Bolton.
 February 1 to 5.—Norwich and District Photographic Society. Entries close January 18. Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.
 February 1 to 16.—Glasgow and West of Scotland Amateur Photographic Association. Entries close January 20. Sec., J. M'Kis-sack, 68, West Regent Street, Glasgow.
 February 21 to 25.—City of London and Cripplegate Photographic Society. Entries close February 4. Sec., H. S. Cuming, Cripplegate Institute, Golden Lane, London, E.C.
 February 26 to March 12.—Edinburgh Photographic Society. Entries close February 12. Sec., J. C. M'Kechnie, 31a, Castle Street, Edinburgh.
 April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.
 April 9 to 16.—Photographic Arts and Crafts. Sec., Arthur C. Brookes, 15, Harp Alley, Farringdon Street, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been made between December 13 and December 18:—

- CINEMATOGRAPHS.—No. 29,117. Improvements relating to cinematographs or like apparatus. Albert Harrison Moorhouse, 57, Lincoln's Inn Fields, London.
- COLOUR PHOTOGRAPHY.—No. 29,273. Improved process for the manufacture of polychrome surfaces for colour photography. Société Anonyme des Plaques et Papiers Photographiques A. Lumière et ses Fils, 31, Bedford Street, Strand, London
- LENS DEVICE.—No. 29,282. Improved device for use with, and also as a substitute for, objectives. Jean Marcel Mascart, 57, Lincoln's Inn Fields, London.
- SHUTTERS.—No. 29,285. Improvements in and relating to apparatus for ascertaining the duration of photographic shutter exposures. Frank Philip Whitehead, c/o F. Whitehead and Co., Pickets Street Works, Balham, London.
- CAMERAS.—No. 29,296. Improvements in connection with roll film cameras, whereby a series of exposures can be readily separated from the rest of the film for subsequent development. William Wade, 6, Finkle Street, Stockton-on-Tees.
- PHOTOPLANOGRAPHS.—No. 29,323. Improvements in photoplanographs. Calvia John Ellis, Birkbeck Bank Chambers, Southampton Buildings, London.
- CINEMATOGRAPHS.—No. 29,594. Improvements in apparatus for feeding cinematograph films. William Cecil Jeapes, 55, Chancery Lane, London.
- CINEMATOGRAPHS.—No. 29,684. Improvements relating to moving-picture machines and apparatus for winding cinematograph films. George W. Bingham, 31, Bedford Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

REFLEX CAMERA FOCUSING SCREENS.—No. 27,667, 1909 (November 30, 1909). The invention has for its object to provide a method of showing, at one time on the screen of a reflex camera, only one

version or the other of the two versions of the picture corresponding to the "upright" and "horizontal" position of the rotating back. It comprises a pair of pivoted masking blades, which can be operated either separately by the operator, or in the case of cameras provided with a revolving carrier for the sensitive surface, the latter may be so connected to the masking blades that they will be automatically changed from one position to the

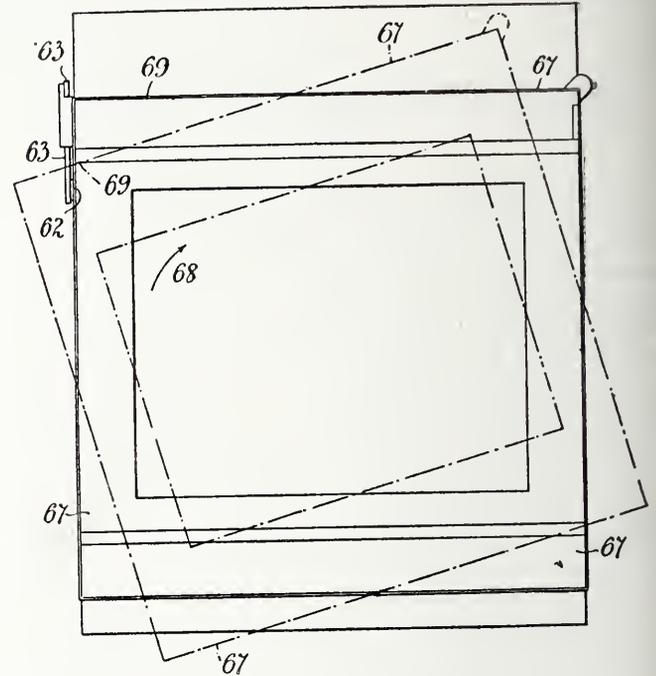

Fig. 1.

other, and thereby ensure that the screen will always show correctly either the vertical or the horizontal position only, so as to coincide with the position which the sensitised surface occupies in the camera.

A frame (such as a metal frame 50) is provided, over or under which the ground glass or other focussing screen 51 is mounted or arranged, and means are provided to block out the corners and

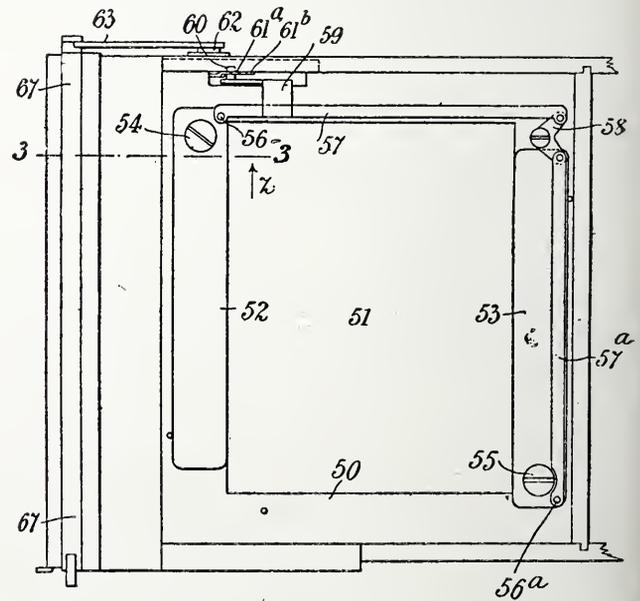

Fig. 2.

opposite side parts on the screen, as, for example, the metal frame may have inwardly projecting corner pieces suitable for blocking out the corners on the screen.

On each of two opposite corners (i.e., diagonally opposite) of the frame a leaf or blade, such as a flat metal strip 52, 53 is arranged and mounted so as to be adapted to be moved into position to occupy the space between either of the adjoining corners. For example,

each such blade may be pivoted at 54 and 55 respectively to the aforesaid corner diagonally opposite to one another, and means are provided to turn the blades around the pivot to an angle of 90 degrees, and to retain each blade in position at the limit of its movement—for example, by means of a crank pin 56 and 56a on each blade, and a connecting rod 57 and 57a respectively attached thereto, and such rods, 57, 57a, are connected through the medium of a bell crank 58, so as to be operated by any suitable means, such, for example, as the fixed angle piece or sliding bracket 59, which latter has fixed thereon the laterally extending pin 60, which pin 60 is engaged between the two forked arms 61a and 61b of the forked rocket lever 61, pivoted at 62 to the inside of the camera case 1, and on the pivot or shaft 62 of the forked lever 61 there is rigidly fixed the lever arm 63.

64 is an extension piece or arm, fixed or formed on the forked lever 61, to which extension arm there is attached one end of a spring 65, the other end of the spring being fixed at 66 to the inside of the case 1.

One of the forked arms—viz., the forked arm 61a—is pivotally mounted on the lever 61, e.g., may be pivoted on the same centre 62, as the lever 61, 64, is pivoted; and the spring 61c is attached

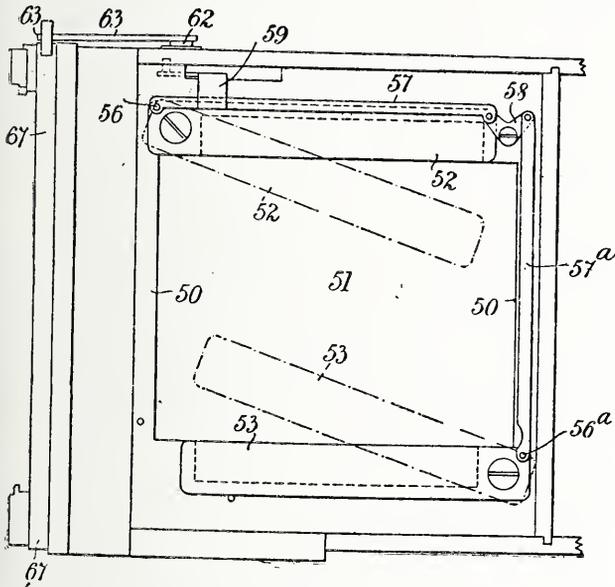

Fig. 3.

at one end to the lever 61, and is attached at the other end to the pivoted fork 61a, so as to thus normally keep the latter pressed towards the other forked arm 61b (this spring 61c being sufficiently strong for this purpose), but enabling the former to be moved apart from the latter when necessary.

The lever arm 63 is of such length as to be adapted to extend to the rear of the camera case, and so that the free end of the lever 63 is interposed in the path of rotation of the revolving back or reversible back 67, which latter may be of any known or suitable form, and arranged and mounted to turn or revolve on the back of the camera in any known or suitable manner. Thus it will readily be seen, when the revolving back 67 is turned from the reverse position into the position shown in full lines in Figure 1, as the back is being swung from the reverse position in the direction of the arrow 68 (Figure 1), when the revolving back reaches about the position shown in dotted lines in Fig. 1, the top edge of the revolving frame at or about the point 69 (see Fig. 1), will ride against the free end of the lever arm 63 (which is caused to project in the path of rotation of the revolving back 67 by the action of the spring 65 and its intermediate connections), and the revolving back will force the end of the lever 63 upwardly out of its path, and thereby will (through the mechanism aforesaid) cause the blades 52, 53, to be swung into the position shown in full lines in Figure 2; while, when the revolving back is moved back into the reverse position, same will consequently release the lever arm 63, and thereupon the spring 65 (acting as before described), will swing the blades 52, 53, from the position shown in Fig. 2 into the position shown in full lines in Fig. 3.

Thus, as the revolving back is turned from one position into the

other, the blades 52, 53, will be automatically moved from one position into the other, and thereby will mask the screen so as to automatically correspond with the position of the revolving back. Arthur Lewis Adams, 24, Charing Cross Road, London; and Walter George Roberts, 5, Nelson Terrace, Islington, London.

New Grade Names:

SUPER SPEED ORTHO (DESIGN).—No. 315,679. Photographic plates. Elliott and Sons, Ltd., Talbot House, Park Road, Barnet, Herts., manufacturers of photographic dry plates, films, and papers. August 19, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Enlarging in One Direction Only.

To the photographer who wishes to record his impressions (writes Mr. H. Wild in "Photography and Focus" for December 28) rather than to make accurate diagrams of the details, the lens image is often very disappointing. Places that impress by their height do not seem high enough, and big things, though they may take up a good part of the negative, do not give the idea of bigness. Much may be done by a careful choice of point of view and by suitable atmospheric conditions, but even then we often wish we had the power to stretch the negative (or rather the resulting print) higher or wider. I have tried several ways of getting this effect, but without much success until quite lately, but I think I have at last found a method that promises well. I have not had time to experiment much as yet, but the results obtained show that the method is at any rate workable.

The apparatus for "stretching" prints in this way only requires one article not usually found in the photographer's outfit, and that is a convex mirror with a cylindrical curvature. Mine is a very old one, and measures about 9in. by 7in., with a curvature of about $\frac{3}{4}$ in. in the 9in. For the rest, an enlarging lantern and a printing frame as large as, or larger than, the required print complete the equipment.

The negative is inserted in the carrier of the lantern, and all arranged as if for ordinary enlarging, except that the convex mirror is placed in the path of the rays at an angle of about 45 degrees, and the printing frame at an angle of 45 degrees with the mirror, and at 90 degrees with the condenser. I find it best to keep the mirror and frame as close as possible at one end. It will be found necessary to stop down to about $f/22$ or $f/32$ to get good definition, but with incandescent gas for the illuminant the exposures are not excessive.

The best way of working is to arrange the mirror and the printing frame (which should have a piece of clear glass, backed with a piece of white paper, in it, on which to focus) at about their respective angles on a piece of board—i.e., a small drawing-board. This is then moved backward and forward in the path of the rays from the lantern until the image is the desired size. It is then focussed as sharply as possible at full aperture, and the lens stopped down until the definition is even all over. The lens is capped, a piece of bromide paper put in the frame in place of the white paper used for focussing, and the exposure made.

R.P.S. AFFILIATION PRINT COMPETITION.—The judges made the following awards in the recent competition: Plaques to W. C. Pettigrew (Bromley C.C.), G. B. Clifton (Ealing P.S.), Harry Lindoe (Wearside C.C.), and P. Martin (Woodford P.S.). Certificates were awarded to the following societies: Wearside Camera Club (1st), Woodford Photographic Society (2nd), and Borough Polytechnic Photographic Society (3rd). The whole of the selected prints will be hung at the house of the Royal Photographic Society, 35, Russell Square, W.C., and will be on view to the public, admission free, from January 11 to February 15, 1910, 11 a.m. to 4 p.m. daily, 11 a.m. to 2 p.m. on Saturdays. At the close of the exhibition the whole collection, together with numerous sketches by Mr. W. J. Morgan, R.B.A., will be circulated among the affiliated societies.

New Books.

"TRAVEL AND EXPLORATION."—The January number of "Travel and Exploration" begins the second year of its fairly successful career. Though, naturally, the demand for a comparatively expensive and emphatically class magazine is not large, compared with that for the popular monthlies; yet this demand shows signs of increasing, and consequently the proprietors have decided to enlarge the magazine permanently, beginning with this number. This will allow of adequate reviews of important travel-books—and "Travel and Exploration" is the only non-technical magazine which confines its reviews strictly to travel literature. The most important article in the January number is, perhaps, Dr. W. Hunter Workman's description of his explorations in the Nun Kun range of the Himalayas. Mr. C. N. Williamson, the well-known motoring novelist, gives a very readable account of the popular motor run from Paris to the Riviera. These constitute the purely exploration and travel side of this number. A very valuable series of articles on "Outfit and Equipment for the Traveller, Explorer, and Sportsman," to which Sir Harry Johnston, Mr. Harry de Windt, Mr. Ralph Durand, and other well-known authorities in this field of exploration have contributed, is begun in this number, chiefly from the pen of Mr. Ralph Durand.

THE "TELEPHOTO QUARTERLY."—No. 8 of "T.Q.," closing the second year of publication, discovers Captain Wheeler offering a liberal programme of articles and illustrations, helpfully emphasising the practical side of telephoto work. We doubt if our contemporary would make a warmer welcome for itself by publishing, as it thinks it should do, more scientific contributions. So far, the stamp of practice has been upon everything which has appeared in it, and on that account we are sure that no one interested in telephoto work will willingly let slip the opportunity of obtaining its four issues per annum at the cost of 2s. The December issue, just about to be published, contains articles of notable interest on "The Tele-lens in Architecture," and on "Mountain Telephotography," with many notes in the editor's always delightful vein of humour. Our readers in the United States should note that "T.Q." is sold by Tennant and Ward, 122, East Twenty-fifth Street, New York. In England, the publishers are Messrs. Gale and Polden, 2, Amen Corner, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 3.

- Nether Edge Camera Club. "Ensyna." F. J. Stedman.
Bradford Photographic Society. "Printing, Developing, and Toning Velox Paper." W. F. Slater.
Southampton Camera Club. The Annual General Meeting.
Leek Photographic Society. Monthly Lantern Night.
Catford and Forest Hill Photographic Society. "Affiliation Print Competition." W. J. Morgan, R.B.A.
South London Photographic Society. "The Amateur Photographer" Prize Slides.
Scarborough and District Photographic Society. Y.P.U. Portfolio of Prints.

TUESDAY, JANUARY 4.

- Royal Photographic Society. No meeting.
Halifax Camera Club. "Ensyna." F. J. Stedman.
Nelson Photographic Society. "Autotype Carbon." Demonstration.
Harwich Photographic Society. "Large Prints from Small Negatives." W. F. Slater.

WEDNESDAY, JANUARY 5.

- Dukinfield Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Croydon Camera Club. "Flashlight Photography." F. C. Hart.
Borough Polytechnic Photographic Society. "Bromide Toning." W. F. Harrap.
Edinburgh Photographic Society. Debate, "That Photography Achieves its Greatest Success in Portraiture." Aff.—T. Drummond Shields. Neg.—J. Robertson Christie.

THURSDAY, JANUARY 6.

- Armley and Wortley Photographic Society. "Autotype Carbon." Demonstration.
Chelmsford Photographic Society. "Ensyna." F. J. Stedman.
Oldham Photographic Society. "Large Prints from Small Negatives." W. F. Slater.
Midlothian Photographic Association. Lantern Slide Night.
Liverpool Amateur Photographic Association. "Process Block Making for Illustration." Frank Vaughan.
Hull Photographic Society. New Year Revels. Smoking Concert.
Handsworth Photographic Society. Annual Meeting.
Watford Camera Club. Lantern Evening, &c. E. H. Jackson.

CATALOGUES AND TRADE NOTICES.

A NEW ZEALAND LIST.—Messrs. Walter Suckling, Ltd., 204, Cashel Street, Christchurch, New Zealand, send us their full catalogue of photographic requisites, which we are interested to see form a volume of over 220 pages, excellently arranged and well printed. It lists every variety of photographic apparatus and material, chiefly of British manufacture. Evidently our readers in New Zealand and the Islands can obtain from Messrs. Suckling the standard articles for all branches of photography.

Commercial & Legal Intelligence.

PROFITS ON PHOTOGRAPHIC ENLARGEMENTS.—At the Brighton Borough Bench on December 20, Harry Marks and Lena Chorley, alias Oswald, were charged on remand that they did unlawfully conspire by false pretences to obtain money from Constance Elsie McLewee.

Mr. Graham Hooper prosecuted, and Mr. Huntley Jenkins (instructed by Messrs. S. Myers and Son, London), defended.

Prosecutrix, who lives at 52, Church Street, and is a young woman of twenty-two years of age, said that on the death of her father in 1906 she was left £300. She saw an advertisement in a local paper:—

"Wanted, a smart young lady, to travel with another. Experience unnecessary. One who can invest small capital preferred. State age."

In consequence, she wrote a letter on September 25, and received a letter signed Lena Oswald, asking for an interview. In consequence she went to a house in Tichborne Street on September 28, and there saw both prisoners. Marks then told her he wanted someone to learn his business of photographic enlargement, and to travel about with him and the other young lady, meaning Miss Oswald. It was, he said, a very profitable business, and he would want a security of some kind. Witness asked him how much he expected. Marks said, "What can you give?" Witness said, "Will £20 do?" And he replied, "Yes." Then he told her that, according to what she invested as security, he would pay her interest on it, that he would give her 2s. 6d. per week interest on the £20, and £1 a week wages besides. He also said she could have her interest paid when she liked, and she told him she would prefer to have it monthly. Further, he said she could try the business, and if she did not like it, and gave him twenty-four hours' notice, he would refund the money. The reason why he wanted security was, he said, because some time previously a man who was working for him went away with some of his money and frames. Witness said she would try the business, and agreed to start on the following Monday. Marks said they were leaving there on Monday, and going into fresh apartments. He said the other young ladies had always lived with them, and that they preferred them to, but that witness could do as she liked. Witness decided to live with them. The female prisoner said ever since she had been with Mr. Marks she had been very happy, that she liked the business very much, and would not give it up for anything. She also said she had been with Mr. Marks three years, and previous to that with his brother George, two years. She further said that since she had been with Mr. Marks she had opened a banking account, and that every year she was adding to it. She also said that when she joined Mr. Marks she invested £40, and that her brother was very much annoyed, and would not let her have it a first. She had never regretted it, and was sure witness would be as happy as she had been. At a further interview on the following Sunday she was told prisoners were moving to Centurion Road. The next day witness went to start in the business, and in the afternoon the removal to Centurion Road took place. Then, in the absence of Marks, the other prisoner asked her if she had settled with Marks. Witness told her no, and that she intended to do so when she unpacked. Oswald said it was only right to settle where one started anything. Witness went upstairs and undid her trunk and brought her cheque-book downstairs. Marks had then returned and witness drew a cheque (produced) for £20 in his favour. She was going to cross it, but he asked her not to as he wanted to get out and cash it. He went out again, and then Oswald told her to

would be going to London next day. He was away a week, returning on October 12. While he was away Miss Oswald took witness round two or three days to teach her canvassing, and the orders she got she sent to Marks at an address in Highbury Grove, London. Witness asked why they did not go out canvassing oftener, and Oswald said it did not matter, and that Marks didn't mind as long as she got so many orders a week. One day witness told Miss Oswald she was going to run down to the bank. Oswald said, "Oh, you have some more money, have you? I thought the £20 was all you had." Witness said, "No, I have a little more." While Marks was away there was trouble with the landlady, who wanted her bill when they had been there a week. Prisoner then asked witness if she had any money on her, so that they could settle up and pay the bill, and she said if witness would pay it, Mr. Marks would let her have it back when he came home. Witness advanced a sovereign. On his return on October 12, Marks asked her how she was getting on, and whether she liked the business. Witness told him she did not like canvassing much. He said she would not always have canvassing; when she got in the business she would have canvassers of her own. During that week witness went out canvassing two or three times, and Oswald made the bad weather an excuse for not going oftener. After Marks had been back a few days he said his brother in London had got a new idea from a foreigner, and that at any time he might write to say that he would have to start with him in this new business, which was a kind of advertising paper. If it came off all right, he said his brother and he would make their fortunes at it. A few days after she saw Marks with a telegram, and he said it was from his brother Alfred, and that it said "everything is all right, come." Afterwards he said if he went with his brother he would not have time for the two businesses, but he did not want to give up his business in Brighton, because he had had it so long, and it was so profitable. Oswald was present, and Marks went on to say he would make it worth their while if they would manage the business for him. He suggested that Oswald should go out canvassing and that witness could finish off the pictures, send up the orders in the evening, and do the housekeeping. Oswald said, "That won't satisfy me; I'm going to manage your business for you. I've been with you five years, and it's time I had a business of my own. I should have started on my own long ago if I had only known the secret of the business. I won't be content with managing your business. I think you ought to sell it to me." Marks said, "You can't buy my business; it's worth £1,000." Oswald replied that she had not £1,000, but that she knew she had enough money to buy the business. She also said Marks was going to make a fortune out of the other business, and that after all the time she had worked for him, and all the money she had earned for him, he ought to do something for her.

After further conversation, Oswald said, "You know there is a secret," and Marks said, "Yes, but it isn't likely I'm going to tell you everything." Miss Oswald appeared to want to buy the business very much, and was apparently very much annoyed because Marks would not sell. After they had gone to bed Oswald said she had made up her mind to get the business, and she was sure Marks would give in in the end. She also said, "You know there's tons of money in this business, and if he'll only sell it to us we'll make an end of money out of it." She asked witness if she would go into partnership with her if she found out the secret. Witness replied, "I don't know; we may not be able to make the thing pay like he does." Oswald said they would be all right if she could learn the secret because she knew everything else in connection with the business. Next morning there was further conversation about the sale of the business, and Marks said, "I suppose I had better sell it to you two girls for £50 each." Upon this Oswald said, "Oh, that is kind of you; I thought I should have to pay at least £100 for my half." To witness she said, "That is kind of him. Fancy his letting us have it so cheap—£50 each." Marks said, "That's all right; of course, I shall have to explain the business to you." Witness asked if he would let them have the secret, and he said he would, and that he would take witness round and teach her his style of canvassing. He asked if they would pay for the business then, and Oswald said, "You know I can't pay for my share now as my cheque-book is at your mother's home in London. Our're going to send me down my cheque-book directly you get to

London, aren't you?" Marks said he would, and that he supposed witness would pay for her. Witness said, "I might as well," and drew a cheque for £35, out of which Marks returned her £5, the £20 she had previously paid being taken into account.

During the next few days Marks took her round Buckingham-road canvassing, and when they called at a house Marks would say, "I have called from Marks and Co. We are opening new premises round her, and are giving pictures free to advertise themselves. Would you like to accept one?" If this offer were accepted he would ask for a small photograph for enlargement, and suggest that if when it was done they would like it framed, they should give his firm the preference. These photographs were sent to a firm in London for enlargement at a cost of 5d. each, and the frames were purchased of a Hackney firm at a cost of 10d., 1s., or 1s. 2½d. The glass cost 4d. for each picture 20in. long by 16in. when witness bought it, but Marks used to buy glass in large quantities and cut it himself. With the photograph in the frame and a few nails put on it and the back pasted with brown paper, the work was complete, and the pictures would be sold at from 5s. 6d. to 12s. 6d. each. The average was 8s. 6d. If persons would not have a frame they did not get the picture, and in some cases they did not get the photograph back. Marks told her she should always say they were opening round there, and should not tell them they were in apartments. Afterwards Marks said there were the book debts, and Oswald said, "Yes, of course, we must pay for those." He made out a list, and Oswald said she should also like to sell jewellery, as there was a great profit on it. Marks brought down a lot of it from London, and they agreed to take £1 worth each. He put the book debts at £23, and Oswald said she should like to pay her share, but as she had not her cheque-book, would witness oblige her by paying her half as well as her own, adding, "Of course, I'll pay you all back when Mr. Marks sends me down my cheque-book." Witness had not any forms left in her cheque-book, but she told Marks she would go to the bank in the morning. One night Oswald told witness she had about £300 in the bank, and asked witness how much she had. Witness told her about £100. Next morning, after witness had packed her small trunk, Marks sent her out to get some paper for the business, and on her return she found Oswald had packed up all her things because she said they wanted to get out quick. On unpacking her things at Church Street witness missed some of them, and subsequently saw them among the prisoners' luggage in the possession of the police. On the way to the bank on the morning of October 25, Oswald said that as she was starting in business with witness she was going to transfer her account to witness's bank. Witness asked her where she banked, and Oswald replied, "In London, near the Bank." Witness asked which one, as there were several there, and Oswald said she did not remember, as Marks managed her money affairs for her. "When," she said, "I want any money I draw a cheque and give it to him, and he draws a cheque for me." Witness described how she got £25 in notes from the bank and paid Marks for the book debts and jewellery, and said Oswald promised to pay her all she owed her when her cheque-book came. It was estimated that Oswald then owed her £50, and she said she would draw a cheque for £60, which would allow witness for stock and other expenses. Marks gave her no receipt for the money, but sent her away from Centurion Road first, because he said the landlady would be annoyed at their leaving, and he and Oswald would settle the matter with her. They afterwards arrived at Church Street with the luggage. Here Marks said that now the time had come for him to leave he did not want to go, but they would get on all right, and if they did not make at least £8 a week each it would be their own fault. Oswald said, "Yes, I am sure it will." After he had left Oswald said she was miserable, and began to cry, and suggested they should go out to lunch, and go to the theatre to cheer themselves up. They did, Oswald asking her to pay the expenses as she had not her cheque-book, and promising to pay all back when it came. Witness paid 5s. 6d. for the lunch, and 4s. for the theatre tickets. Next morning a letter came from Marks stating that he could not find Miss Oswald's cheque-book. It was addressed to "My dear girls," from Highbury Grove, London. Oswald borrowed 10s. on October 26 to get some things from the cleaners, and suggested that witness should write Marks, saying they were very comfortable, and thanking him for being so good to them.

Witness complied. Prosecutrix said Oswald had often told her that she had dreamed her sister was ill, and one evening she received a telegram, and said it was to say her sister was ill. She said she must go at once. Witness was going over to comfort Oswald, when the latter deliberately screwed the telegram up and threw it in the fire. She said she would go in the morning, and arranged to send a telegram to "Horne, 11, Mill Road, Liverpool. If in great danger, wire at once. Will come." Next morning, Oswald said she would have to go after all, as she had got a telegram saying she must go at once if she wished to see Alice alive. She packed up her things and left by an afternoon train to London Bridge. She said she would write to witness when she arrived, but witness was not to write to her, as she would be busy looking after her sister. She did not write witness, who saw her again on October 29. During the time they had been at Church Street they had collected about £1 off the book debts, and this she had shared with Oswald. On her return from Liverpool, Oswald said she had been travelling all day, and had been thinking so much about witness and wondering how she had been getting on. In reply to witness she said her sister was very ill with brain trouble, and that she would have to go away again on Sunday. Prisoner was wearing a new set of furs, which she said her brother had given her for her birthday. She also said another set just like it was coming in the morning for witness, and that the cost was £15 15s. a set. It was to be a present from her to witness for her birthday in November. Witness said she need not have gone to that expense. Next morning she said her brother had given her the money for the furs, and expected her to pay it back. She hoped her cheque-book would have been returned before then, but it had not, so would witness let her have the money for the furs. She also said her sister was wanting extra things in connection with the illness, and that there was a trained nurse to be paid for, so that in all she would want a good deal. Witness said, "How much money do you want in all?" and Oswald replied, "About £35." At first, witness said she did not like to let her have such a large sum, and to this prisoner said, "You know I would always let you have £100 if you wanted it." Witness told her she was not in the habit of borrowing money, but prisoner said she was unkind, and that in a day or two she would let her have a cheque for £60. Witness then drew a cheque for £35, and gave it to her, and she went out, saying she was going to the bank to cash it. A set of furs arrived later. During the day witness collected £2 or £3 and shared it with prisoner. Oswald left Brighton next day, saying she was going back to her sister at Liverpool, and would write to witness. During the next week witness tried to carry on the business, and went round to collect money. She had a great deal of difficulty, and had only been able to collect something over £5 out of the £23 said to be due. Witness heard nothing of Oswald, and on November 6 she wrote Marks, asking if he had seen or heard anything of her. The same evening she got a telegram purporting to come from Oswald, and saying she would arrive at 9.20. Oswald walked in at 8.30, and said her sister was awfully ill and believed to be dying, and that she was afraid she would have to go home for good. She asked witness how she was getting on, and she replied not very well, and that she had had difficulty in getting the money in. Oswald said she must send them a blue paper. As she was going away for good she wanted witness to buy her share of the business for £50, but witness said she could not afford it for one thing, and that for another she did not know much about the business. Prisoner said someone in Liverpool was prepared to give her £100 for her share, and witness said that if her share was worth that, so was hers. She asked prisoner for the money she had borrowed, and prisoner said she had not brought her cheque-book with her, but that she would go to Highbury next day and get it. Afterwards she said she could not let witness have it back at once because she had lent all her money (£300) that week. Then witness told her she believed she had been telling a lot of untruths and planning it all with Marks to get her money out of her. Prisoner indignantly denied this. There was talk about selling the business, and witness suggested that they should get Marks to sell it for them, but Oswald said he was nothing to do with them now. On November 15 she obtained a warrant for the arrest of both prisoners. In further correspondence, Marks suggested she should come to London to see him. She went with a detective, but did not see either of the prisoners. Witness believed the business and the

transactions were genuine, or she would not have parted with her money, no part of which had been repaid.

In reply to the Bench, Witness said she received one week's wages while she was with prisoners. She believed they sent out between fifty and sixty pictures a week, but she did not know how much money was taken during the three weeks she was with prisoners. She only sent up a few orders as the result of her own canvassing.

Cross-examined by Mr. Huntley Jenkins, Witness said when she met prisoners she had about £150 left of the £300 she came into in 1906. Some she had lost in business, some she had given away, and some she had spent on herself. From the time she paid the first £20 until after she parted with the last £35 she had never asked for her money back, because she was content to try the business.

Counsel put it to witness that Marks was doing a very good business in the photographic line, and Witness replied that he appeared to be.

Witness had tried to carry on the business by herself, but found she could not manage it, and she had only sent up a few orders to town.

Was it not because you were not successful that you went to the police and made a complaint?—No.

Supposing this had turned out a tom tiddler's ground, and you had found it was a gold mine, would you have made a complaint?—No.

Is not the real reason because you have lost your money and the thing has turned out a failure?—No.

In answer to other questions by counsel, Witness said she expected Miss Oswald to stay, and if she had stayed witness would have been satisfied with the business. When she wrote at Oswald's suggestion, thanking Marks for all his kindness, she did think he had been kind.

At this stage the case was adjourned until December 29.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

MOISTURE AND LENSES.

To the Editors.

Gentlemen,—The condensation of moisture on the lenses described by your correspondent, J. H. J., as occurring only when using a cap can probably be avoided by refraining from handling the cap.

In a cold and damp place I have often found that if the cap is held in the hand or accidentally breathed on, or even put in one's pocket for a minute while focussing, it becomes warmed and causes the front of the lens to steam.—Yours faithfully,

D. BERLIN.

Newcastle-on-Tyne.

THE ENGLISHMAN IN CANADA.

To the Editors.

Gentlemen,—
WANTED—Photographer, good finisher, not necessarily retoucher; young man preferred; no foreigners or English need apply
Box 756 Province.

It will come as a shock to the average Englishman that in Canada there exists a section of the trading public which can, or thinks it can, dispense with his services.

In other walks of Canadian life—chiefly agricultural—we have become unpleasantly familiar with the class of advertisement which the enclosed is a specimen. It was cut from the "Province" of December 10, and it is a sign of the times that respectable newspapers can still be found in the Dominion to publish such like.

The reasons for the dislike of the Englishman in Canada are good, bad, and indifferent. It is, to say the least, natural that the English farm-hand finds himself somewhat at a discount in the face of conditions which he has never had to face in the Old Country, and therefore in the first flush of his initiative on a strange soil cannot—indeed, cannot be expected to—accomplish the tasks with the same facility of those familiar with local conditions from the

youth up. But the prejudice—and it is a genuine one—which has gripped the land of the maple in connection with a certain class of English manual labour is new to find among brethren of the photographic craft. The good English photographer can hardly fail of his craft in any portion of the Empire upon which the sun never sets. The Englishman who cannot make good could not possibly be less of a craftsman than the untutored Canadian.

Who, then, is this miserable Protectionist, who doubtless claims British protection, British justice, British fair play, and British credit as his due in a British colony—who is he who debases the British language to insult not only the lone British photographer out of a job, but the whole of right-thinking, English-speaking Canada?

I have not made the smallest endeavour to discover. Fortunately the despicable temper which incites such a blood-and-language reservation is not likely largely to affect international complications, neither will it widely appeal to the gaiety of nations—with Great Britain left out.

Such a declaration is merely nauseating.—Yours faithfully,
Vancouver, B.C.

L. HAWES.

FLASHLIGHT ACCIDENTS.

To the Editors.

Gentlemen,—A large amount of interest has been raised by the reports in the photographic press and newspapers during the last week re two explosions which have taken place, caused by the use of flashlight powders. This should be a warning to many workers inclined to be lax in their handling of these dangerous compounds. It is all very well for people making and selling these compounds to urge upon their customers the ease of working, and although they certainly give warning as to the dangerous nature of the powder, they perhaps do not sufficiently impress upon the users that there is a deal of real danger in working them.

Not very long ago, having a meeting to photograph, I had occasion to use several ounces of very rapid flash powder, and although I was fired by touch-paper and I was two yards away from the train, which was laid in a special troughing, the flame on this occasion came within six inches of my face, and particles of flying powder affected one of my hands as a gunpowder explosion would do.

In many cases I attribute faulty combustion to foreign mineral matter being mixed with the magnesium powder. Photographers wishing to use flashlight powder should see that the room in which this is to take place is large enough, that all the hangings are quite clear, and then by spreading the powder lightly on a plate and in not too large quantities, and firing by means of a piece of string soaked in paraffin, which will allow the operator to remove himself a distance of two or three yards, there will be little danger. We are surprised that some firms of photographers send out assistants who have not been thoroughly grounded in the principles and working of a flashlight, and it would be far better if the masters could undertake this work personally, and not delegate to assistants this branch of work, as an accident once caused may cost them dearly, and spoil their reputation for a good many years.—Yours faithfully,

A. F. SERGEANT.

Gibbet House, Halifax,
December 28, 1909.

PLATINOTYPE PRINTS IN SALT WATER.—In reference to the note p. 995 of last week's issue as to the resistance to sea-water of the actual paper of a platinotype print, we find, on a re-reading of the article, that we omitted to name the precise brand of paper. The word "platinotype" will have made it clear that the paper was made by the Platinotype Company, and we may now add that the actual brand was the standard A.A. cold bath.

THE NEW CHELTENHAM STUDIO.—We note with interest in the "Cheltenham Looker On" an illustrated description of the new studios which Messrs. Debenhams, Longman and Co. have opened at 33, The Promenade, Cheltenham. The new premises are furnished throughout in excellent taste, and it is interesting to note the extensive use which Messrs. Debenhams make of electric light in their portraiture.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:

J. H. S. Roberts, 12, Market Street, Carnarvon. Five Photographs of F. J. Lloyd Priestley.

J. T. MEDCALF (Nelson, B.C.).—We have not. On the Pacific Slope, as you doubtless know, softness is a trouble in many places, and calls for alum baths or harder emulsions. Great hardness of the water is not usually a drawback. We think you might apply to local health authorities, who could doubtless tell you the nature of the salts in the water and their possible effect in washing photographic prints. For ourselves, we think it unlikely that a natural water will be so bad as to be unfitted for washing prints.

GELATINE LIGHT FILTERS.—Through the "B.J." will you please tell me how to make gelatine film for use in light-filter experiments? If the description be too lengthy for reply in the "Journal," please give me particulars of any book you know of from which I can obtain the information.—CALIFORNIA (Los Angeles, California).

We have not made these filters, but we should think the best way would be to coat glass, previously waxed, with the dyed gelatine, and, when partially dry, immerse in formaline, and, when dry, strip off.

"AT HOME" PORTRAITS.—Having had to give up indoor work on account of my health I should be very grateful to you if you will kindly give me the following information through your columns. I have frequently read of (1) "at home portraits." I wish to know are there travelling photographers who make a living by "at home portraits"? (I mean taken in the homes, not backyard portraits). If so (2), do they rely entirely on the window light and on the natural surroundings of the room for backgrounds? (3) My apparatus only consists of a half-plate taper bellows camera and one Dallmeyer R.R. 6 x 5 lens (an old one), and a Busch half-plate R. symmetrical $f/8$ lens, and a Ross No. 4 R. symmetrical (an old one). Ought I to be able to do satisfactory work with these? For any other advice and information you can give on this subject I shall be very much obliged.—TRAVELLER.

(1) So far as we know, the "at home" portrait is not being relied upon as the sole basis of a photographer's business. We are afraid that it is looked upon with suspicion, unless offered by a firm having an established studio business. This, in consequence of the many frauds which the public have been made the victims of by mountebanks, representing themselves to be photographers.

(2) In cases where the aim is to supply a high-class result, it is not usual to depend solely on daylight. In some cases a portable arc-lamp is used, whilst those who do at home portraits for the press make much use of flashlight, in conjunction with daylight—not with great success, however, so far as a pleasing likeness is concerned.

(3) We think you should have a lens of about 8 or 9 inches focal length, and $f/4.5$ aperture for cabinet work. This rather short focus will often be necessary owing to exigencies of space in "at home" surroundings.

VIEW-ALBUM.—I am thinking of publishing a view-book of this district, containing about 150 views, size about 12 x 10, to be sold at 1s., and could you oblige me with any information to the following questions? (1) Is there any book dealing with the subject? (2) What charges would be made to those who advertise in same for

whole, half, or quarter page? (3) When would advertisers pay? (4) The best way to introduce book to advertisers; would it be necessary to have all views printed and bound to show them, or one similar? (5) Which would be the cheapest, collotype or half-tone, in producing the views? (6) In writing to ask a gentleman permission to publish his portrait in same, would you enclose stamps (as I wish to include M.P.s, magistrates, chairmen, etc.)? (7) Could you recommend a publisher for above?—M. P.

(1) None that we know of. (2) It depends on the edition. Your best guide would be to obtain tariff for advertisements in similar albums of other places. (3) Usual to invoice with voucher copy on publication and collect account as for any other order. There is no custom as to payment unless order is accepted on basis such as "cash on publication." (4) Sufficient to get a dummy volume made up to show size and positions available for advertisements and to fill in a few pages with blocks or letterpress. (5) Half-tone. (6) Certainly you will do well to enclose a stamped envelope for reply. You should also bear in mind the fact that if the portrait is the copyright of a photographer, the person himself has no right to permit its reproduction. Neglect of this may land you in difficulties. (7) You, of course, know local firms better than we do. We should doubt if a London house would take it up. You might approach the Health Resorts' Association, 29, John Street, Bedford Row, London, W.C.

CAMBRIAN.—We can only advise you to address an inquiry to the headquarters of the regiment at Chatham.

D. P., or A.S.—Through our own advertisement pages and in those of some few of our contemporaries—e.g., "Wilson's Photographic Magazine" (U.S.A.), "Photo-Revue" (France), "Photo Chronik" (Germany), and the Australian and New Zealand papers. See list and addresses in the "Almanac," p. 620.

W. E. B.—A theoretical knowledge alone will be of no service whatever to you. You require practical training in a school such as the L.C.C. School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., or the Regent Street Polytechnic, Regent Street, W. Write them for prospectus. The demand is greatest for half-tone operators, printers, and fine etchers; but lithography is now coming in in connection with process work.

FERROTYPES.—Would you be so kind as to inform me of the emulsion and developing formulæ of the old-fashioned ferrotypes? If you could inform me I shall be greatly obliged.—E. SAVEALL.

The "old-fashioned" ferrotypes were not done by an emulsion process, but by the wet collodion process, as used for glass positives. You will find formulæ for the collodion, bath, and developer on pages 751 and 752 of the "Almanac" recently issued. Messrs. Fallowfield publish a small work on the working of the process, price sixpence. This is for emulsion plates.

MOUNTING PRINTS ON GLASS.—Will you kindly answer the following question through the columns of your paper? We want to fix some photographic prints on glass. Do you know of any transparent glue with which we can do this?—TRANSPARENT.

Make a thin solution of white transparent gelatine—say one ounce to 25 ounces of water. Place the solution in a dish kept at a temperature of about 125 degrees or 130 degrees Fahr. Immerse the prints with the glass, bring them in contact in the solution, and then squeegee together.

FOCUSING.—Please say (1) whether I can get sharp pictures by using the scale only of my focussing camera as I do by a "fixed focus" instrument—the former has a 5½ in. lens? (2) Supposing I set the scale at 15 feet and take a snapshot of a dog at 12 feet will the picture be as sharp as with a fixed focus instrument? (3) Would such pictures be sharp enough for press work? (4) Can I fix a supplementary to my focussing camera so as to bring "infinity" to about 12 feet? (5) Is it possible to buy a lens (F. 6) with "infinity" at 6 feet away?—OPTIC.

(1) Certainly, if the distance is actually that to which the scale is set, the results should be quite as sharp as when using a "fixed focus" camera. (2) At full aperture of the lens, say F. 6 or F. 8, it will not. Stopping down will give you as much sharpness as your "fixed focus." (3) The great majority of press photographs are taken in scale-focussing hand-cameras. (4) Yes, if you shorten the focal length you reduce the "distance beyond which everything is in focus." You will need to reduce focal length to about

four inches and use a stop giving F. 11 with this reduced focus—that is, one of about $\frac{3}{8}$ diameter. (5) Practically no. It would have to be of such short focus. With a 4-inch lens at F. 6 the distance beyond which all is in focus when sharp focus is obtained on infinity is 22 feet.

C. J.—Send us a few examples of your failures, then we shall probably be able to assist you.

RELATIVE COST OF GAS AND ELECTRIC LIGHT.—Can you tell us which would be the cheapest light to employ for night portraiture—incandescent gas or the electric light? We want it principally for midgets and stickybacks, and sometimes for larger pictures. We have the gas laid on and the electric main is in the road close to our front. As we are going to do a cheap line cost is an object.—J. H. H. and Co.

We can give no opinion, as we do not know the price of electricity or that of gas in your district. If gas is dear with you and electricity is cheap the latter will probably be the more economical in use. *Vice versa* the former will have the advantage in cost, but the arc light is the more effective light. Gas is suited only to single heads and figures.

AGREEMENT.—Two years ago I made an agreement with an operator for three years at £2 15s. a week. The agreement, I find, he afterwards got stamped at Somerset House. I now find business so bad that I cannot afford to keep him on. I gave him a week's notice, and explained the circumstances fully to him, but he refuses the notice, and says that he must hold me to the agreement for three years' services. I have offered to give him an excellent reference and let him take any specimens of his work that he likes, but to no purpose. He says he will hold to the agreement. Will you kindly inform me how I can terminate this agreement, trade being so bad?—J. R. J.

The agreement having been legally made for three years, it is binding on both parties for that time. At the end of that it terminates by effluxion of time. Business being bad does not liberate you from the agreement you made. We are not surprised that the operator refuses to release you from it, particularly at this time of the year. The only thing we can suggest to you is that you compromise the matter by paying the man a lump sum down, which he may possibly accept.

DISPUTE ABOUT PLATES.—About two months ago, at the solicitation of a traveller for the ——— Dry Plate Company, whose plates we had never used before, we gave him an order for a gross of half-plates. On trying them we found that they were not at all equal to those we were using. We complained to the company, and, of course, they said they were all right. We offered to return them but they said "No"; they could not take them back. They are now demanding the money for them. By separate post we are sending you half a dozen of the plates, and would beg of you to try them as we feel sure you will say that we are justified in refusing payment.——— AND Co.

We shall certainly not try the plates as requested. It is quite without our province to settle disputes between makers or dealers and their customers. We may tell you, however, that the maker of plates you find such fault with are in excellent repute among professional photographers. Possibly your operator does not know how to use them.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE OLDEST PHOTOGRAPHIC JOURNAL IN THE WORLD.

PUBLISHED EVERY FRIDAY.

ESTABLISHED 1854.

PRICE TWOPENCE.

.. THE ..

British Journal of Photography.

Charge for PREPAID ADVERTISEMENTS of Four Lines (each Line containing about Seven Words) of the following Classes ONLY:

<p>Photographers Requiring Assistants Assistants Wanting Situations Photographic Businesses and Premises to be Let or Sold, Partnerships Second-hand Photo. Apparatus for Sale and Wanted Miscellaneous Announcements Miscellaneous Trade Announcements</p>	1/	<p>Per Insertion, Net Prepaid. No reduction for a Series. Each Additional Line, Sixpence.</p>
--	----	---

Those wishing to have their Advertisements addressed to initial letters, c/o **BRITISH JOURNAL OFFICE**, may do so by remitting 6d. extra per insertion, each advertisement, for receiving and forwarding replies; but no charge is made if letters are called for.

DEPOSIT.—When dealing with strangers our Deposit System renders the transaction safe, and the commission is trifling compared with the protection thus afforded. The purchase-money must be deposited with the publishers, **HENRY GREENWOOD & Co.**, 24, Wellington Street, Strand, W.C., and all Cheques, Money Orders, &c., made payable to them. Acknowledgment is sent to both parties, and deposit is held until receipt of advice that goods have been received and found satisfactory, in which case the amount deposited is forwarded to the seller, less a commission of 2½ per cent (minimum, one shilling). If goods are not approved the publishers wait original owner's acknowledgment of their safe return before refunding the deposit, the usual commission being deducted. All disputes or questions arising must be settled between the contracting parties.

NOTICE.—THE LATEST TIME FOR RECEIVING SMALL LINE ADVERTISEMENTS IS 2 O'CLOCK P.M. ON WEDNESDAYS for insertion in the current week's issue. DISPLAYED ADVERTISEMENTS should reach the Publishing Office not later than TUESDAY.

* * To prevent delay communications relating to Advertisements and general business affairs should be addressed to the publishers, and all advertisements are received subject to their approval or revision, and the right is reserved to refuse any advertisement without giving a reason for so doing.

HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

RETOUCHING. — T. S. Bruce. (Established 1886.) Cab. vig., 1s.; ¾, 9d.; full, 6d.; C.D.V. vig., 9d. Cash and postage with order. Very quick returns. For lessons, etc., see "Sit. column" and page v.—4, Villas-on-Heath, Vale, Hampstead, London.

General Election

Thousands of Photo Buttons will be required by both sides to enable their representatives to retain or win seats in Parliament, and at a

Conservative

estimate, over a million of such Buttons will be worn. It is necessary, therefore, that every photographer in the country should understand how easy large profits are obtained, and those who have machines should keep a

Liberal

stock of Button Parts, as at any moment orders for thousands may arrive. I shall be pleased to send free of charge my booklet, "How to Make Photo Buttons and Stamp Photos," if trade card is sent.

We Want You

to try KENTMERE "Art" Bromide Paper.

We want YOU to be one of its appreciators.

KENTMERE "Art" is made in two grades—Rough Matt for Enlarging upon and Smooth Matt for Contact Printing, or for Enlarging when a smoother surface is required.

There is no other paper at the same time so good and so cheap.

It is easy to use—easy to work up—and has a delightful artistic appearance when finished.

Let us send you our Price List.

KENTMERE, Ltd.,

. . . Staveley . . .

Westmorland.

THE GENERAL ELECTION

The rush for Photo-Buttons of the Candidates is now in full swing, and we would remind intending customers not to delay their orders, as same are executed in rotation unless they are at EXPRESS RATE (15 per cent. extra). Customers will save time by enclosing remittance with orders, as same will not be put in hand without.

Net Prices of Popular Sizes:—

	1,000	5,000	10,000	20,000
1½ in. dia.	45/-	42/-	40/-	37/6 per 1,000.
9/10 in. ,,	37/6	35/-	33/-	30/6

We can insert advertisement at the back of Button at 3/- per 1,000 extra. This is an important feature, as it lowers the initial cost, and we beg to call customers' attention to this fact.

Orders are executed in Bromide unless extra time can be allowed for P.O.P. The latter we would point out are considerably superior, and the cost only 10 per cent. extra. Orders will be returned within a week to ten days.

Samples and full particulars on application.

GENERAL ELECTION.

BESIDES the Enlargements of the Candidates themselves, there is a good deal of business to be done in connection with the Elections, especially by the Photographer who has an Outdoor Operator.

But—as we have already said—speed is the first necessity no matter what the order be, Enlargements, Lantern Slides, or contact prints, you can rely upon getting the work at the earliest possible moment when you entrust it to the RAINES SERVICE.

That's one of the many reasons why ours is called "The Service that helps."

Photographic Shutters.

The Bausch & Lomb Optical Co.'s New Models.

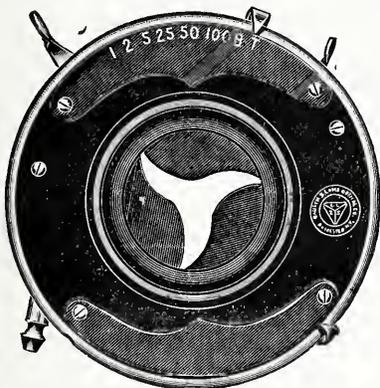

In order to compete with the many imitations of our goods, we have produced for the coming season two new models, entirely reconstructed.

They will be the most rapid and accurate "cheap" shutters on the market, giving, according to test, an effective exposure of 1/100th second, owing to the improved form of segmental opening, the actual speed being between 1/50th and 1/60th second.

The valves and all moving parts are now enclosed in the aluminium case, making the shutter dust and light-tight. A safety locking or security lever has been added, to prevent accidental opening or shutting by pressure on ball when closing camera or by careless handling.

Shutters can be operated by ball and tube, or by antinous release.

New 5 x 4 1909 Model Shutter.

Camera makers should fit this improved model to all new cameras.

Please write for particulars and trade terms.

21/- each.

ELECTION WORK.

¶ The wonderful covering power of the Dallmeyer Stigmatic needs to be seen to be appreciated. A Group of several hundreds of people can be tackled with this lens without fear of failure. The definition all over will be crisp and clear as well in the centre as at the edges.

¶ The No 6 of 10.7" focal length covers an 8½ x 6½ at full aperture and a 15 x 12 stopped down. It is good also for full lengths and busts, cabinets and for all-round work. The front and back give large different sized pictures. No other f/6 lens has this wonderful quality of

FOUR LENSES IN ONE.

Why not try one ?

J. H. DALLMEYER, LIMITED,
