COLOURING FILMS.—No. 14,743. Improvements in processes for colouring cinematographic films. Reginald William James, 1 Queen Victoria Street, London, for Compagnie Générale de Phonographes, etc., France.

COLOURING PRINTS.—No. 14,824. Improvements in processes for colouring photographic prints by previously toning. Reginald

William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes, etc., France.

ANIMATED STEREOSCOPY.—No. 14,834. Improved process and apparatus for obtaining and observing animated stereoscopic views. Louis Joseph Emmanuel Colardeau and Jules Richard, 11, Southampton Buildings, London.

CAMERAS.—No. 14,883. Improvements in photographic cameras. Otto Halbach, 53, Chancery Lane, London.

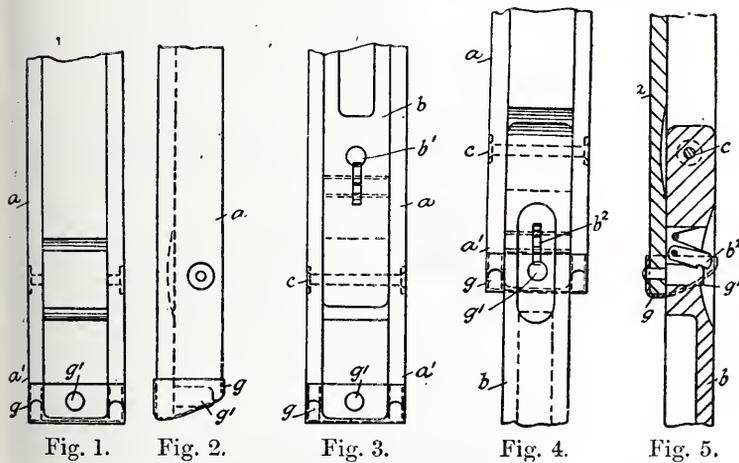

CINEMATOGRAPHS.—No. 14,950. Process for neutralising the band supports of cinematographic films. Reginald William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes, etc., France.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRIPOD LEGS.—No. 5,159. 1909 (March 3, 1909). The invention is an improvement of that described in Patent No. 19,198, 1908 ("B.J.," January 8, 1909, p. 29). The sections of the tripod leg are now made of channel or U shape. The end *a'* of the lower end of section *a* of a tripod of channel form, within which another section *b* is folded, is inserted in a metal shoe *g*, the shoe extending along the bottom and clipping the sides of the section, which are thereby rigidly retained and are not forced out by any lateral pressure. A stud *g'* is fitted in the centre of the shoe *g*, which when an extension as *b* is turned over will enter the hole *b'* in

the extension as shown in figs. 4 and 5, and retain it in position, a spring catch *b²* or an equivalent preventing it being withdrawn until the catch is pressed back when the leg is required to be closed. We may if preferred place the spring catch *b²* on the opposite side of the stud *g'*. By these means the several sections of the legs can be opened and closed instantly, and perfect steadiness of the tripod when the legs are extended and in use is ensured. John Wilkinson and Alfred Wilkinson, of St. Oswald Street, Rochdale Road, Manchester.

PORTABLE DEVELOPING CHAMBERS.—No. 668. 1909 (January 11, 1909). The invention is a box having an open top, an inner cover of coloured transparent celluloid closing the top, an opaque cover hinged enclosing the inner cover, the outer cover being so arranged that it may be closed while handling the dry plates and open while printing. There is a combined lens, shutter and focussing apparatus in one of the walls of the box, and an adjustable plate holder arranged in the box and behind the lens. John Bunyan Willyerd, 3726, South Jefferson Avenue, Saint Louis, U.S.A.

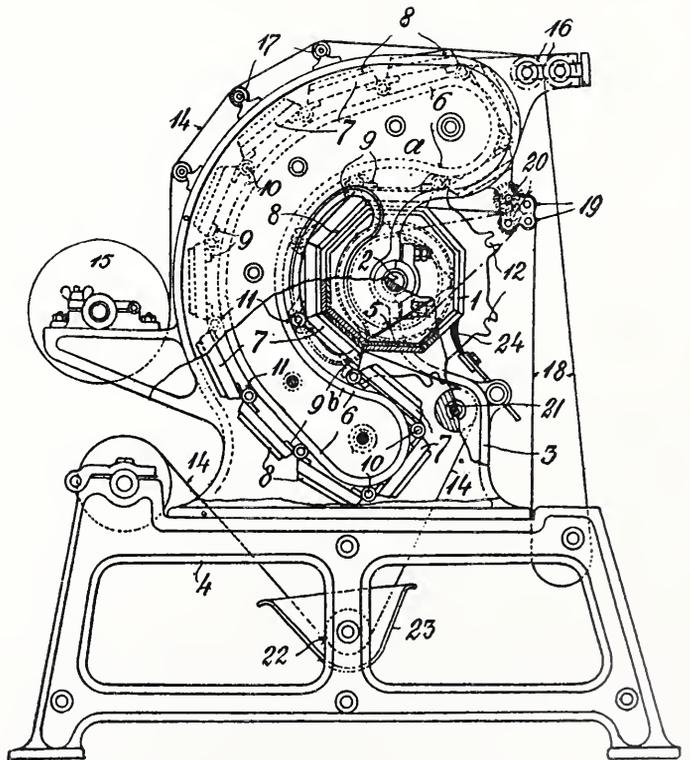

FILM CAMERAS.—No. 14,828. 1908 (July 13, 1908). The invention relates to a removable back for roll-film cameras provided with yielding pieces adapted to engage the film and flatten its edges against bearing surfaces on the camera. The whole surface of each film is thus maintained in the focal plane of the lens. A further object is to provide a simple device for supporting a photo-

graphic plate within the camera when it is desired to use a plate instead of films.

Yielding pressure pieces, preferably in the form of parallel strips of resilient material, are supported on the inner side of the back. These strips project inwards to an equal extent and are normally in contact with the bearing surface for the edges of the film. They are curved slightly in cross-section and are so mounted that a brushing contact is maintained between the rear surface of the film (or its backing) and the faces of the strips. When it is desired to use a plate instead of a roll-film, the plate, instead of being carried in a plate-holder or dark-slide, may be mounted directly on the inner side of the removable back, brackets being provided in the rear or underside of one yielding strip to support one edge of the plate, the opposite edge of the latter being held in place by the other yielding strip, the arms on which the strips are preferably mounted preventing any transverse displacement.

The inspection opening in the back, in addition to having the usual transparent coloured window is provided with a slide or shutter whereby the entrance of even non-actinic rays is prevented. Kodak, Limited, 57-61, Clerkenwell Road, London, E.C., for Robert Kroedel, Rochester, U.S.A.

ROTARY PRINTING MACHINE.—No. 5,801. 1909 (March 10, 1909). The invention consists of a machine for the rotary printing of lengths of papers in such a way as to avoid the use of rubber cloth and the uneven stretching to which the latter is liable. This is done by means of a pressure device which is composed in the manner of a chain or links of individual pressure blocks corresponding exactly in size to the side faces of the drum, which

device is automatically moved forward by the drum by means of a suitable feeding device. The tension effort necessary to produce the forward movement is always applied directly to the connecting bolts of the individual links whereby stretching in any manner is prevented.

The improved machine consists of the polygonal drum 1 made of transparent material, the shaft 2 of which rests in bearing brackets 3 which are secured to a suitable sole plate 4. The drum may be actuated by hand or by any suitable mechanism. In the interior of the drum is located a source of light and a screen 5 cutting off a part of the drum surface corresponding to the field of illumination. The pressure device co-operates with the drum 1 and is moved forward by the drum itself. On the sides of the standards 3 facing each other a guide-way is formed by means of projecting ribs 6 of which the part *a-b* corresponding to the field of illumination limited by the screen is concentric with the axis of the drum while the remaining part represents a return

path suitably connecting the two end points *a*—*b*. This guide-way 6 serves to guide the pressure device proper. This pressure device consists of a number of frames or plates which at the side coming in contact with the sides of the drum is covered with an elastically resilient coating, preferably of sponge rubber, or with an air cushion of a size corresponding exactly to the size of one side of the drum. These frames or links are assembled to form an endless chain, by means of eyes 9 and bolt 10. Each bolt carries a roller at each end, the rollers running on the outer surface of the ribs 6, forming the guide-way when the pressure device is being fed forward. The drum 1 carries at the corners of the end faces blocks 12, which in the rotation of the drum successively embrace the bolts 10 of the links 7, and so move the link of the chain located between two bolts, and thereby move the pressure device.

In this way regular movement of the pressure device is obtained, and as during that time when the covering 8 of the links bears on the side of the drum, the corresponding rollers 11 are running on the concentric part of the guide-way 6, the pressure must be entirely uniform and continuous.

The machine further provides for the automatic pull off of the web from the supply roll. Heretofore the web was pulled off the supply roll directly by the tension between the drum and the pressure device. This has the drawback that the material forming the web is often subjected to irregular or excessive strain and may accordingly be stretched.

According to the present arrangement the web 14 is pulled off the supply roll 15 over guide-rollers 17 by means of a pair of rolls 16 driven from the shaft 2, so that there is always a loop 18 ready to be supplied taken off the roll, from which the machine takes its supply according to requirements. The web 14 runs then between two guide rolls 19 and two brush rolls 20 to the drum 1, is then guided by the latter through the field of illumination limited by the screen, and passes finally over guide-rolls 21 to a winding-roll 22 or directly into the developer for further treatment. Paul Hamburg, 96, Reinickendorfer Strasse, Berlin.

The following complete specification is open to public inspection, before acceptance, under the Patents Act, 1901:—

CINEMATOGRAPHS.—No. 14,343. Manufacture of cinematograph films. Dupuis.

New Trade Names.

DREADNOUGHT.—No. 312,529. Sensitised photographic plates. Arnott Halliday and Co., Marshall's Mills, Marshall Street, Holbeck, Leeds, photographic mount manufacturers and printers. April 24, 1909.

Acta.

Extracts from our weekly and monthly contemporaries.

Judging Distances Correctly when Using the Hand Camera.

Learning to judge distances accurately and quickly (writes Mr. F. J. Mortimer, in "The Amateur Photographer and Photographic News" for July 6) is easily learnt by some, but with others it is a matter of difficulty. The following method can therefore be recommended for training the eye, and when once the lesson has been thoroughly learnt it is difficult to go wrong. The procedure is as follows:—When out walking choose a number of yards, say ten, and as each street-corner, pillar box, lamp-post, etc., is approached, a guess is made as to when you have arrived at a distance of ten yards from the object. It is then measured with full strides—each stride being approximately one yard. This is repeated with the next convenient object, and on all possible occasions for one or two days, until the eye has got a good grip of a ten-yard distance with all sorts of objects and under different conditions.

Follow this with another distance, say six yards, and continue the exercise until this is well drilled into the eye. Several distances—e.g., six, eight, ten, twelve, fifteen, twenty yards—can be thoroughly learnt in this manner with absolutely no trouble, but only a little

thought every time you go for a walk in town or country. The next course is to stop at all sorts of irregular distances during your walk—e.g., eight, twelve, ten, six, fifteen yards—guess the distances at once, and then verify by long strides. Then the new power thus obtained can be applied to the hand camera, and, provided the scale is correctly marked, very few spoilt plates or films will result through being out of focus. The best—i.e., most useful—of all distances to get well fixed in one's eye is ten yards, as this is in many cases the nearest distance one can have foreground figures (on a quarter-plate with five-inch lens) without the near figures looking out of proportion in comparison with others at, say twenty yards' distance.

The Fading of the Autochrome Colour Screen.

In the issue of "Photography and Focus" for July 6, the editor says: "A number of Autochromes which were shown to us the other day were all quite wrong in their colour rendering, having a bluish-violet tinge all over them. When the cause of this defect was sought it was found in the colour screen with which they had been taken. Last year this screen gave perfectly satisfactory results, but having been left lying casually about since then it was now found to be visibly several shades less deep in colour than a similar screen of the same age that had been protected from light when the two were put side by side for comparison. The moral of this, of course, is to keep the screen in its box whenever it is not actually in use. But one may go further and say that not merely the Autochrome but no other colour screen should be exposed to light more than is necessary, as few, if any, are made without the employment of more or less fugitive dyes."

New Books.

"Optisches Hilfsbuch für Photographierende." By Dr. H. Harting. Berlin: Gustav Schmidt. Price Mks. 4.50.

In this volume Dr. Harting has provided a text-book of the modern optics of the photographic lens. Within the space at his disposal he has not attempted a lengthy exposition of the more theoretical parts of this subject, but, nevertheless, he has produced a very readable account of the principles of the construction of the modern photographic lens, and a description of the properties of the chief objectives. When we say readable, we do not suggest that the "Hilfsbuch" is a volume for a railway journey, but the mathematics in it are only such that any one with a nodding acquaintance with algebra may readily digest without having to indulge in surmises as to the precise meaning.

After a brief consideration of the principles of reflection and refraction of light, the author introduces the reader to the formation of images by way of the pinhole, and then passes to the single and double lenses. The next section explains the chief aberrations to which a lens system is liable, and is followed by short chapters on the regulation of the rays in photographic lenses, orthoscopy, depth of field, and achromatism.

The chief section is in the later part of the volume and is that in which the modern types of astigmatic and anastigmatic lens are classified and their relations to each other shown. The consideration of the telephoto lens and an appendix on the optical calculations which require to most frequently made in photographic work bring the volume to an end.

"Das Arbeiten mit farbenempfindlichen Platen." By Dr. E. König. Berlin: Gustav Schmidt. Price, Mks. 2.25.

In this volume (which forms No. 25 of the "Photographic Encyclopædia," issued by Herr Schmidt) Dr. König gives a most useful précis of the present technics of orthochromatic photography. He first describes the properties of the chief sensitising dyes and gives formulæ for their use both as baths or as additions to the emulsion. The functions of the different classes of light-filter are dealt with at length, and formulæ given for compensating and contrast filters suitable for plates of given types of sensitiveness. In these matters the practical points which the worker must observe receive a full share of notice, and the same may be said of the chapters on development and dark-room illumination for plates. The later portion of the book deals with the photographic uses of orthochromatic plates and filters in portraiture, landscape, copying, and flashlight work,

and is well illustrated by a series of plate illustrations which appropriately emphasise the differences producible. The volume is not a large one, but it is certainly the best-selected formulary of colour-photography which has come before us.

"Leerboek der algemeene Fotografie. Part I.: General Principles." By W. H. Idzerda. Amsterdam: S. L. van Looy.

This is the first part of a treatise on photography which is evidently planned upon a comprehensive scale. The present volume aims at giving a general review of the principles of photography and of the many applications of the camera, such as cinematography, astronomy, photo-micrography. It also contains a brief history of the early days of photography from the time of Schulze to the conclusion of the work of Fox Talbot.

CATALOGUES AND TRADE NOTICES.

MESSRS. FALLOWFIELD have just issued a new edition of Nos. 2, 3, and 4 of their small price lists, which deal respectively with the plates, papers, and sundries, mounts and albums, and chemicals and preparations obtainable from this firm. Those who do not care for the trouble of consulting a large comprehensive catalogue when they are in need of some particular description of chemical or material should procure these lists, which are arranged in a manner very easy for reference, and may be obtained on application to the above firm at 146, Charing Cross Road, London, W.C.

USES OF THE AIR-BRUSH.—There is now a journal issued under the title "Die Spritmalerei," devoted to air-brush work, which gives particulars of the many ways in which this well-known and fascinating process may be employed. From a perusal of some early numbers of the paper, shown to us by the firm of The Airostyle and Lithos, Ltd., makers of the noted "Airostyle" air-brush, we should say that the new journal will find a ready welcome by users of the process, as well as by manufacturers of the apparatus. The publisher is Otto Dietrich, Albrechtstrasse 102, Steglitz-Berlin, Germany.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 10.

Glasgow Co-operative Camera Club (Govan). Outing to Uplawmoor.
South London Photographic Society. Rambles round Rickmansworth.
Southampton Camera Club. Ramble to Fawley.
Worthing Camera Club. Outing to Angmering.

TUESDAY, JULY 13.

Birmingham Photographic Society. Ramble to Solihull.
Hackney Photographic Society. Members' Sale (Council Meeting).

THURSDAY, JULY 15.

Leamington Photographic Society. Exhibition of Home Made Apparatus.

Commercial & Legal Intelligence

LEGAL NOTICES.—The first meeting of the creditors of Chas. Hamilton Walker (carrying on business at 120A, High Street, Marate, with a limited partner, under the style of the High Street Photographic Company) is fixed for the 10th inst. at Canterbury. The public examination of the debtor will be held on the 15th inst.

PICTORIAL POSTCARD FAILURE.—The first meeting of the creditors of E. Alexander, pictorial postcard dealer, etc., of 71, Southampton Row, W.C., was held on July 5. The liabilities are £2,393, with assets estimated at £1,905 and classed as uncertain, consisting mainly of shares of E. Alexander, Ltd. According to his statement, debtor in 1903 entered into a partnership arrangement with Messrs. G. and W. Knight to carry on the business of fine art publishers under the name of Knight Bros., in Southampton Row. Shortly afterwards the debtor became seriously ill, and remaining so for nine months, the partnership was dissolved by mutual consent. In the latter part of 1904 debtor became the English agent for the Leipzig Photographic Printing Co., at 71, Southampton Row, W.C., and so continued until March, 1908. Subsequently E. Alexander, Ltd., a limited liability company, was formed, with a capital of £6,000—£3,000 in shares and £3,000 in debentures. Of these were allotted £1,107 in shares and £1,893 in debentures. Under this arrangement debtor became

managing director of the company, receiving a salary of £6 a week and a weekly allowance of £4 for expenses. In February, 1909, the company went into voluntary liquidation. It was resolved by the creditors, with the concurrence of the Official Receiver, to appoint Mr. F. S. Salaman to wind up debtor's affairs, and also to appoint a committee of inspection.

NEW COMPANIES.

RECORD FILM TRADING COMPANY, LTD.—Capital £500, in £1 shares (150 Preference). Objects: To adopt an agreement with P. Rittener, and to carry on the business of photographers, cinematographers, manufacturers, and exhibitors of, and dealers in, pictures, photographs, cinematographs, etc. Private company. The first directors are P. Rittener and L. Shrapnel. Qualification, one share. Remuneration, £6 per week, divisible. Registered office, 31, Norfolk House, Laurence Pountney Hill, E.C.

J.P. INFORMATION REGISTER, LTD.—Capital £500, in £1 shares. Objects: To carry on the business of advertising agents, printers, publishers, newsagents, merchants, displayers of advertisements, photographers, etc. Private company. The first directors are not named. Registered office, 15, St. Andrew's Square, Glasgow.

DAILY EVENTS, COMPANY, LTD.—Capital £50,000, in £1 shares (40,000 Cumulative Participating Preference). Objects: To take over the business of advertising apparatus, pictorial advertisements, photographs, contracts for placing of cabinets and frames in hotels, clubs, public-houses, theatres, mess-rooms, and other places, and contracts for the display of advertisements in the said cabinets and frames, and other assets belonging to the Daily Events Syndicate, Ltd., of 105-106, Moorgate Station Chambers, E.C., and to adopt an agreement with the said syndicate and its liquidator. The signatories are: O. G. Browne, The Pines, Kelling Heath, Holt, Norfolk, 75 shares; E. N. Trappo-Lomax, Clayton Hall, Accrington, 1 share; C. E. Constable, 21, Carlyle Mansions, Cheyne Walk, S.W., 1 share; W. D. Smith, 73, Denbigh Street, S.W., 1 share; T. E. J. Fitzgeralds, 75, Jermyn Street, S.W., 1 share; J. H. M. Roberts, 31, Acre Lane, Brixton, S.W., 750 shares; H. W. Brown, 1, Bishopsgate Churchyard, E.C., 750 shares. Minimum cash subscription, £8,000. The number of directors is not to be less than three nor more than nine. The first are O. G. Browne, J. H. M. Roberts, and H. W. Brown. Qualification, 750 shares. Remuneration, £100 each per annum (chairman £150), free of income tax. Registered office, 236, Dashwood House, New Broad Street, E.C.

News and Notes.

THE PHOTOGRAPHIC STUDIO of Albert Wilkes, the well-known International football player, who carries on business as a photographer at West Bromwich, was completely gutted by fire last week. Cameras and fittings were either destroyed or damaged.

ROYAL INSTITUTION.—At a meeting of the members of the Royal Institution, held on the 5th inst., the Duke of Northumberland, K.G., President, in the chair, the Duchess of Northumberland, Lady Victoria A. Percy, Mr. H. E. Edmunds, Colonel Sir Charles Euan-Smith, K.C.B., and Mr. Alfred Rowe were elected members.

FIRE IN GLASGOW.—A fire broke out one morning last week on the premises of Messrs. Lafayette, Ltd., photographers, at 15, Gordon Street, Glasgow. The scene of the fire was the studio on the top flat, and the flames spread to the roof. Before they were extinguished the studio was destroyed, along with a large number of valuable negatives and thirty square feet of the roof. The damage is estimated at £500.

"EAST COAST HOLIDAYS" is the title of the Great Eastern Company's latest handbook, and those intending to spend their holiday in this part of England should not fail to provide themselves with a copy. Whilst dealing with all the holiday resorts on the East Coast, special prominence has been given to some of the less known districts, also to the districts around Cromer and to the Norfolk Broads. The information is of an eminently practical character, including such items as the railway service, cost of journey, names of hotels, boarding houses, etc., excursions by road or rail, a list of golf links, and particulars of the facilities for fishing and yachting. The book contains a number of illustrations in colour, together with maps of the various districts dealt with, these latter being clearly printed.

with the routes of the railway, motor omnibus service, and the carriage roads distinctly indicated. Copies may be obtained free from the Superintendent of the Line, Liverpool Street Station, London.

EASTMAN'S NON-INFLAMMABLE FILM.—The "Kinematograph Weekly" publishes the following report, on the new Kodak "non-flam" film, from the chemical laboratory of the Bureau for the Safe Transportation of Explosives and Other Dangerous Articles, of South Amboy, N.J. :—

"Two samples of picture films, one plain and the other printed, were received from the manufacturer, the Eastman Kodak Company, of Rochester, N.Y. Material has the same appearance as the ordinary celluloid film, but has an odour resembling carbon tetrachloride.

"Material when held directly in flame ignites with difficulty and burns much more slowly than the ordinary film. It was found by holding film in path of sparks from an induction coil that it was a much better insulator than the regular celluloid film. With apparatus here, it was impossible to make sparks penetrate the film without starting spark on edge of film and letting it work into the centre of the sheet gradually. In this way a series of holes would be melted or burned into the film, but no flame or ignition of body of film occurred. With regular film from the same maker sparks will penetrate the film at any place, and a succession of sparks in same place invariably ignites the film.

"When gradually heated the film swells up, melts, and finally turns black, but does not ignite, even at a temperature of 400 degrees C. This film is evidently practically free from fire risks."

HOLIDAYS IN IRELAND.—The latest additions to the popular series of holiday booklets published by the Health Resorts Development Association, 29, John Street, Bedford Row, London, W.C., are devoted to some of the beauty spots of Ireland, and deal with the towns and surrounding districts of Cork, Enniskillen, Kingstown, Londonderry, Portrush, and Youghal. These little guide books, like those previously issued by the association, are abundantly illustrated and contain much useful information, both topographical and historical in character. Copies may be obtained post free by addressing a postcard application to the respective Town Clerks.

THE SCOTTISH SALON.—It is a custom of the Scottish Salon, initiated at the opening exhibition, to ask one or two "foreigners" to send representative collections of their work. The workers invited for the 1910 Salon, to be opened at Dundee in January next, are Charles Job, who is sending a collection of twenty-four of his pictures, and the Brothers Hofmeister, who will be represented by six of their large "canvases."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday, July 22, has been set apart by the above association for the showing of lantern slides made upon the various colour-screen plates that are now obtainable, and visitors will upon this evening find a hearty welcome awaiting them at the meeting rooms at the Apple Tree and Mitre, 50, Cursitor Street, Chancery Lane, E.C., at 7.30 p.m., and are invited to bring any slides that they may have made upon the plates mentioned, as the association wish the evening to be not only a show of this class of work but also an instructive one.

PHOTOGRAPHS BY THE "REGINA" ARC LAMP.—A competition has recently been held by the Regina Arc Lamp Works, Sülz, Cologne, Germany, the awards taking the shape of apparatus and cash prizes. The awards were made by Dr. G. H. Emmerich, of Munich, Ernst Ohle, of Cologne, Herr Lichtenberg, of Osnabruck, and J. Rosemeyer, of Cologne. The following is the list of awards, the judges being guided in their decisions by technical quality, in which there were the least signs of the fact of artificial illumination having been employed:—First prize—Julius Thomson, Sonderburg, 2 Regina Studio Lamps; second prize—Eugène Coubilliers, Cologne. Hohenstaufenring 36, 1 Regina Studio Lamp or Printing Table and 100 marks cash; third prize—E. O. Hoppé, London, W., 8, Mar gravine Gardens, Baron's Court, 1 Regina Printing Table; fourth prize—Messrs. Spalte and Kluge, Augsburg, £5 cash; fifth prize—Felix Korb, Crimitschau, £3 cash; sixth prize—Arthur Schneider, München, Thorwaldenstr., £1 10s. Although the number of exhibits sent in was not great, the Regina Works has been fortunate in having submitted to it a considerable quantity of excellent photographic portraiture, considering the short time during which the

studio lamp has been available. The Regina lamp, it may be mentioned, is an enclosed arc of special pattern and portability, and the makers claim that the apparatus allows of photographs being made with effect quite equal to daylight; the lamp, too, is extremely simple in manipulation. We understand that further competitions are to be arranged by the Regina Works, while the prints which have been entered for the present competition are being exhibited at the stall of the Regina Company in the International Exhibition at Dresden.

GEVAERT PAPERS.—An error crept into the paragraph in our issue of the 25th ult. in reference to the Dresden Exhibition, in which it was stated that the Gevaert factory is solely supplied with raw paper by the factory of Schoeller. Messrs. Gevaert and Co. advise us that this is not the case, and that their arrangements allow of them purchasing raw stock from other sources, both in France and Germany.

Correspondence.

* We do not undertake responsibility for the opinions expressed by our correspondents.

* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE SPEED NUMBERS OF PLATES.

To the Editors.

Gentlemen,—The various discrepancies which Mr. Biermann alludes to will not cease even if a standardised speed test is agreed upon by all makers. Accuracy can only be attained if each batch of plates is marked from an actual test of that particular batch. This is not likely to be adopted by makers who follow the nonsensical plan of advertising that their plates are the most rapid on the market, for in actual practice it would be sometimes one maker and sometimes another who would have the highest markings on their boxes if the tests were actually made on a uniform system.

The firms who sell exposure meters obviously cannot attempt to test every batch turned out by a maker, and can do no more than test them at reasonable intervals and give approximate information.

At present, while there are a few makers who mark actual batch tests on the boxes, the great majority simply put an approximate number on the box, which stands unaltered through the variations of different batches and changes of emulsion makers.

I have had two different boxes of the same brand bearing the same speed numbers, one of which, on careful H. and D. test, proved to be double the speed of the other. I have known a firm change their emulsion maker, and one of their brands becomes suddenly quite different in speed and in character, without there being any indication on the box of any change. It is obvious that the speed cards of different meter makers cannot possibly agree under such conditions.

Even suppose they are dealing with a plate accurately marked by a standardised speed test which the meter makers have also adopted: the average speed number of the particular brand is 300. The one meter firm gets hold of a batch marked 280, and as this comes within the 250 group, he quotes it at that speed. The other meter firm gets hold of a batch marked 320, and as this comes within the 350 group he quotes it as such, and at once some one shows up by comparison the supposed inaccuracy of their quotations.

Hereford, July 3.

ALFRED WATKINS.

INTENSIFICATION MARKINGS.

To the Editors.

Gentlemen,—Allow me to say, in reply to "Kent," that his remarks seem to apply to negatives intensified after developing before drying. For the most part mine are intensified afterwards, as after intensification with me is rather the exception than the rule. I am disposed to think that my trouble partly arises from the water off chalky soil; it certainly is not caused through such carelessness as "A. F." suggests, and the marks are not removable by hypo. I have tried after a long soak in plain water and shorter one in acid water with a little improvement, but success is not yet attained.

PROF.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- I. Ramsden, 63, Granby Street, Leicester.** Six Photographs of Miss Nellie Wilson; Photograph of Miss Olive Carson; Two Photographs of Miss J. Fletcher; Photograph of Miss Ethel Shipley.
- V. Rochard, 3, Honey Street, Bodmin, Cornwall.** Photograph, a Group consisting of the Prince and Princess of Wales with Mayor and Town Clerk reading Address on steps of Assizes Court, Mountjolly, Bodmin, June 8, 1909.
- B. Hughes, 28, Patrick Street, Cork, Ireland.** Photograph of the Most Rev. Dr. O'Callaghan, Bishop of Cork.
- H. Webster, 141A, Stockport Road, Levenshulme, Manchester.** Three Photographs: New Mills Town Hall; St. Mary's Road and Church, New Mills; and New Mills Wesleyan Chapel.

PAIRING LENSES.—I have two Taylor, Taylor, and Hobson $\frac{1}{2}$ -plate R.R. lenses. The focus of one is 7.32 inches, that of the other 7.35 inches. Will you kindly tell me in your Answers to Correspondents' Column what foci supplementary lenses I must add to the two R.R.'s to make them both 5 inches focus so as to use them for stereoscopic work?—W. H. R.

The 7.32 inches lens would require a supplementary lens of about 13.62 inches focus and the other one of about 13.57 inches focus, but it is impossible to calculate the right foci with absolute accuracy, and you will probably have difficulty in obtaining supplementary lenses that will exactly suit. If each of your lenses is exactly symmetrical, as an R.R. should be, your best plan will be to change the glasses. Use those now belonging to one objective as the two back lenses and those belonging to the other as the two front lenses. You should then have a pair sufficiently alike. Of course, only two lenses need be changed, the front lens of one objective changing places with the back lens of the other. You can then add a 14-inch (or 2.75 D) supplementary lens to each objective to reduce the focal length to about 5 inches.

PHOTOGRAPH ON WATCH CASE.—Having seen some time ago a photograph printed on the inside of a watch-case, I should be much obliged if you could give me any idea how the process is done. It was on a gold ground, without any paper support, being the same colour as the gold, and looking more like a toned bromide. Whether it was burnt in or not I cannot say; it would not wash off with hot water. Does this work need special apparatus? If so, where can it be obtained?—E. H. HIGGIN.

First prepare the following:—

- | | |
|---|-----------|
| No. 1. Plain collodion, of a tough character... | 1 oz. |
| Venice turpentine..... | 20 drops. |
| Castor oil | 10 drops. |
| Spirit of camphor | 2 drops. |

The above will require thinning with ether and alcohol—about a quarter of an ounce of each, according to the viscosity of the collodion.

No. 2.—Take the white of one egg, remove the germ, and put into a bottle with 2 ozs. of water and 3 drops of liquor ammonia and shake well for a few minutes.

No. 3.—A bottle of Zapon enamel, "No. 103." This may be obtained from the Frederick Crane Chemical Co., 22, Newhall Street, Birmingham, at 1s. the bottle.

Having made a glossy vignettted C.C. print of the subject, this is toned, fixed, washed, and dried as usual. It is then flowed over with No. 1, just as in varnishing a negative. This strengthens the film for the next stages. The face of the print is then well gone

over with Higgins or other thick mountant, laid face down on clean glass and well squeegeed down, being then allowed to dry. To transfer to the watch-case or other article, the glass plate bearing the print is dipped into warm (not hot) water, and when the paper softens the latter is removed by rubbing, re-dipping in the water two or three times as necessary. The paper is rubbed away only from those parts of the print which are to appear on the article, this leaves a margin of paper which supports the delicate collodion film. When the area has thus been cleared of paper the plate is put in very hot water when the film separates. It is dried and then cut off from the paper frame on which it finds itself, and trimmed to size. The surface of the article is now flowed over with No. 2, the picture immediately pressed down on it, and, without further delay, flowed over with No. 3 and allowed to dry.

PAINTING BACKGROUNDS.—Can you give me some information respecting the painting of backgrounds for studio? I have been using vegetable black and white lead, with gold size and turps, upon unbleached calico previously sized. My difficulties are: (1) That the colour sets too quickly, not allowing sufficient time to blend the various shades together. (2) The colour dries several shades lighter than when in the wet state, and also rubs off a little when dry. Can you inform me how to mix a paint (giving quantities) that will dry a matt surface without the above difficulties?—SMUDGER.

You are evidently using too much turps or not enough gold size. Add more black until the colour dries to the right shade and then add gold size or reduce the turps until the colour remains fast. We cannot give exact proportions. The only way is to try the mixture and vary it until it gives the effect you want. You would probably find it easier to manipulate a water paint, mixed with ordinary size alone, in place of the gold size and turps.

MOUNTANT.—Can you please give me some information upon making up a dextrine mountant that will keep well. We make it according to the "Almanac" formulæ, but when left in the pots the surface gets quite hard and dry, almost brittle and horny, whereas a jar of patent mountant, evidently much the same, is not affected by air like this. What can we put in ours to keep it usable, but, at the same time, fairly stiff and thick?—S. E.

We have found that the commercial pastes also get very hard as the water evaporates. Most probably you are using too little water in the first instance and so producing too stiff a paste. Overheating or boiling will also account for a considerable loss of water and cause the paste to dry very rapidly. We cannot suggest any better addition than a little more water.

WORRIED.—(1) We do not think fading is due to keeping the gold and acetate in the one stock solution, nevertheless it is best not to keep in this way, as the gold is more likely to be thrown down. It is preferable to keep in separate stock solutions, which should be mixed 24 hours before use. (2) Imperfect fixation it is the most likely of the causes you name. Your procedure is quite correct. Do you use plenty of fixer and keep prints constantly on the move in this bath? (3) We can hardly believe that any atmosphere which you would tolerate in your reception room would be sulphurous enough to affect prints. Gold and sulphocyanide will keep in single solution for some time—not indefinitely—but it is best to keep separate and mix two hours before use.

F. G. CHRISTOPHER.—We can only advise you to go to a dealer in old furniture and curios, such as is to be found in most towns. You could possibly dispose to some other photographer by an advertisement in our columns.

W. J. B. T. (Calcutta).—The paragraph you refer to appeared in our issue for April 2 last, page 261.

MAKING BACKGROUNDS.—Would you please give me the information required for repainting photographic backgrounds in distemper and flatted oil? (1) Where I can get the canvas or linen? (2) The strength and material used for distemper? (3) Ditto for flatted oil? (4) Which is preferable and the easiest to work? (5) The tools usually required? I do a good deal of picture drawing and painting, and would like to do my own grounds.—COLOUR ARTIST.

(1) At any large drapers, under the name of unbleached sheeting. (2, 3, 5) We cannot spare space in this column to give full working

details, but if you refer to our issues of February 1 and March 1, 1907, you will find full working details of both methods. (4) Flatted oil is the most durable, though not perhaps the most easy, for a novice to work. The Vanguard Manufacturing Company, Maidenhead, supply colours ready for use of different tints, and they are very good.

BURNISHER.—I should be much obliged if you could inform me where I can get the bar of my burnisher ground and polished. The bar is hollow, and this causes the photographs to stop halfway through, which results in a mark across them.—W. RUDLAND.

The best way will be to send the bar to the makers of the burnisher, or to those who supplied it to you; either will do the needful.

LENS QUERY.—Would you kindly inform me on the following subjects? (1) I sent to a second-hand dealer's for a 6in. focus cabinet portrait lens, and they sent me one on approval. It bears the name G. Fleming, 198, New Oxford Street, London, and the diameter is 2½in. There are no stops; it takes 13ft. from the sitter to get a full length. Can you tell me what focus it is, and can I have stops made for it? If so, where? as I find it does not give head and shoulders so sharp as I should like, also particulars as to price and quality of lens, and what it is most suitable for? (2) Where can I get an iron stamp made to stamp plate-sunk mounts?—ANXIOUS.

Fleming was not a maker of lenses, but a photographic dealer in New Oxford Street some forty or more years ago. You must not expect a portrait lens of 6in. focus, made forty or fifty years ago, to cover cabinet size to the edges. As you have the instrument on approval you can see, by trial, if it answers your purpose, and if not return it to the dealer. (2) Such houses as Fallowfield's, Houghtons, or the like, will supply the stamp, or any die-sinker will make you one.

VARIOUS QUERIES.—Will you kindly inform me (1) whether there is a temporary studio made up of canvas and glass to be had anywhere? Does anybody sell such a thing, and what is about the price of same in small size? (2) I have a large lens in my studio camera, with Waterhouse stops; there is a screw to separate one lens from the other. What is the use or effect of moving same further or nearer to one another? (3) How to vignette a cabinet bust direct on plate. (4) How to get a distant part of a street view clear and print even with near part of the camera. I get the sides of negative very dark, printing quickly, the middle part rather diffused, and printing slowly, although I use good lens (Goerz), $f/4.8$, I stop it down to $f/11$ or $f/16$. (5) Will sulphocyanide bath keep long, or does it require to me made fresh every time?—POROYSON.

(1) We do not know of anyone who makes studios of canvas and glass. You will find the addresses of some who make ordinary studios in our advertisement columns. (2) To diffuse the focus, the greater the separation the softer will be the definition. (3) This may be done by interposing a white screen, with a serrated opening, between the sitter and the camera. The size of the opening and its distances from the sitter is a matter for experiment. (4) Probably you are using a lens of too short focus to cover the plate. Try using smaller stops. (5) It is best to make up a fresh bath an hour or two before use. This is no trouble if you keep the sulphocyanide as a stock solution.

RETOUCHING (Reply to "A. R. B. K.")—Your retouching tells that experience is defective; the touch is much too minute and mean for the nature of the study. This head should be boldly treated and the likeness fully respected. Note how you have filled in the wrinkles of brow—much too radical an alteration and unjustifiable. You have the making of a good retoucher in you, but need careful guidance at this stage of your progress.

STUDIO QUERY.—(1) I am enclosing a plan of a bungalow I have taken. By its help could you advise me as to the best method of utilising it for portraiture studio—viz., what method of curtaining to employ and what source of light to use and which to block out? The whole of the roof is glass except the alcove, and one of the ends has also a glass side to within 6ft. of the floor. I should also like to know what focus lens on a half-plate camera should be employed for portraiture. I want to approximate as near professional results as possible. (2) Can you tell me what paper is used

for enlargements by the newspaper press illustration agencies? I cannot secure the same contrasting results that they do—pure blacks and whites. What developer should I use, and is there a special bromide paper made for this work? I presume the prints are burnished to secure the high glaze.—A. THORBURN.

(1) We are afraid that we are not quite clear with regard to the sketch. It seems to us that you will have little but a top light. However, we should think that the best way will be to place the sitter at the S.W. end of the room and stop off the light there for about 6ft. of the roof, and then use curtains and screens, in order to convert the top light as much as possible into a side one. We are unable to advise you further from the sketch. A suitable lens, as you have a good length, would be a portrait one of about 12 in. focus. (2) A glossy bromide paper is what is generally used for the purpose, and that will be glossy enough. Better employ the developer recommended by the makers, but avoid over-exposure if you require great vigour.

C. JAMES.—We cannot trace having received your query until now. We will reply next week, but such formulæ are naturally kept secret, as far as possible.

FERROTYPE CAMERA.—I want to take one-inch circular as well as quarter-plates by means of one ferrotype camera. Do you know of such an instrument at home or abroad to suit this double purpose? I have tried Billcliff (Manchester) and Fallowfield (London).—FERROTYPE.

We do not know of such an article being obtainable, if not from these two sources.

A. NICOLSON.—We have looked back two months, but cannot find the advertisement you mention.

REGISTERED PHOTOGRAPHS.—1. Where can we get a list of all photographs registered during last month? 2. Re the list given week by week in JOURNAL, is this a full and complete list of all registered photos, or only photographs registered by your publishers, Henry Greenwood and Co.?—DOUBTFUL.

Only at Stationers' Hall. For a fee of one shilling the registers may be examined. 2. Only those sent to our publishers for registration.

B. R.—They are made by W. Butcher and Sons, Ltd., Camera House Farringdon Avenue, E.C.

ANXIOUS.—Usually the higher the better up to 15ft. or so. In your case you should try and average 10ft. It is placed to one side and a little to the front of the sitter. The usual diffusing screen of muslin is placed a few feet in front of the lamp.

TEACHER OF RETOUCHING.—Could you, through the medium of your columns, give me the address of the secretary or headmaster of the London School of Photography, or refer me to the best means of finding out where to apply for a post as teacher of retouching?—QUERY.

Mr. Howard Farmer, Photographic School, Regent Street Polytechnic, W., is the most likely person to be able to make use of your services.

PHOTOGRAVURE.—Messrs. Penrose and Co., Farringdon Road, E.C. supply copper plates for the process of photogravure. Zinc plates are no good for the process, since the softness of the metal prevents more than a very few impressions being taken.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Photographic Convention. We publish this week the papers on stereoscopic photography by Mr. C. Welborne Piper, and on "High Power Telephotography," by Captain Owen Wheeler, read before the Convention on the 8th inst. (P. 549.)

The key to the group presented as a supplement with last week's "B.J." is given on page 554.

Mr. Godfrey Bingley has been elected president of the Convention for next year's meeting to be held at Scarborough. (P. 545.)

That art is inborn and that the life work of the artist lies in perfecting his technique are two opinions on this much-discussed question which apparently we do not share with Mr. Snowden Ward, whose recent address before the Convention is the subject of an article on page 547.

The really pressing need of photographic record work lies, we think, in the housing and arrangement of the photographs which have been and will be made. (P. 548.)

A last reminder of the invitation being made through our columns by Messrs. Speaight for photographers to visit the exhibition now being held at 157, New Bond Street, appears on this page. A note on some new photographs recently added to this exhibition of "Fair Children" appears on page 558.

The whole secret of regularity in sulphide toning is contained, according to Mr. S. H. Fry, the well-known enlarger, in making a perfect bromide in the first instance. (P. 546.)

We draw attention to the dicastrous effects upon P.O.P. prints of an impure sample of alum. (P. 545.)

A very interesting example of the commercial utility of the telephoto lens is to be found in the current issue of "T. Q." (P. 546.)

A contributor, Mr. D. Berlin, offers some practical hints on the repair of printing frames. (P. 556.)

One of the advertising papers has recently commented upon the absence of even occasional advertising by photographers in the daily press. (P. 546.)

Rush work in photo-engraving, lithographic processes for poster work and sensitisers for collodion emulsion are topics dealt with under "Photo-Mechanical Notes." (P. 557.)

A German chemist has patented the use of an acid bath for destroying the red-sensitiveness of panchromatic plates prior to development. (P. 546.)

EX CATHEDRA.

Next Year's Convention. As decided at the annual general meeting of the Photographic Convention, held on Monday in last week, the place for the 1910 meeting will be Scarborough. At a subsequent meeting of the Council Mr. Godfrey Bingley was unanimously elected president. Mr. Bingley, who is a Yorkshireman by birth and residence, has been one of the most staunch supporters of the Convention, and his sustained and unostentatious work in record and architectural photography has been steadily carried on for many years past. "A conventioner for the Convention" has been a P.C.U.K. watchword, and in electing Mr. Bingley to the presidency for the Scarborough meeting the members have the gratification of knowing that no one perhaps has a more intimate knowledge of the district and of its photographic possibilities than their president.

* * *

The Speaight Exhibition. In reference to the visit which Messrs. Speaight are asking photographers to pay to their gallery on July 21, from 6 to 8 p.m., we learn that the president and officers of the Professional Photographers' Association have signified their intention of being present, and it is expected that other prominent photographers in the West End of London and in the provinces will take this opportunity of forgathering with their colleagues. Messrs. Speaight have issued no invitations except a general one through our own columns, so that we may be allowed to say again that admission is simply by presentation of visiting card, or, in the case of photographers' assistants, by presentation of the employer's card. The invitation is extended to photographers and their assistants of both sexes, and it is hoped that a gathering which will not be without its importance for professional photographers will be brought together at 157, New Bond Street. Any foreign photographers who may now be in London are also invited to be present.

* * *

Impure Alum and P.O.P. Prints. Alum is one of the numerous chemicals used by photographers that is seldom under suspicion of producing evil effects, and therefore one the purity of which is seldom considered. We have, however, recently come across a sample of alum that proves this confidence to be misplaced. A correspondent sent us a sample taken from a hundredweight of powdered alum recently purchased by him, and also a specimen of a P.O.P. print submitted in the usual way to a hardening bath prepared from this alum. The result was a very strong reduction of the image, all detail in the high-lights having been destroyed. We tried the sample with similar results. It served as a reducer, and also altered the colour of a P.O.P. print

toned in the gold and sulphocyanide bath, while it almost destroyed another print that had been toned in a combined bath. No such effects are, of course, produced by pure alum, whether that be ammonia or potash. Ammonia iron alum does, however, have this effect, and testing showed that this bad sample was simply loaded with iron compounds. It contains both potassium and ammonia alum, while the presence of the iron no doubt shows that it had never been properly purified. Evidently, therefore, it is advisable to be cautious in the selection of alum samples. There may not be many as bad as this one, but any sample that has not been properly purified by the manufacturers may be expected to produce a similar effect to a certain extent. The iron exists in both the ferrous and ferric state, and no doubt it is to the latter that the reducing effect is due. Pure alum gives no indication of iron, but in the early stages of manufacture large quantities of iron salts are present, and have to be removed. Their presence in the commercial article shows that the alum is of exceptionally bad quality, and quite unfit for photographic purposes.

* * *

Snapshotting "in Camera." Like a boy with a new watch, as the saying goes, a Paddington Councillor, in the pride of possession of a hand-camera, must needs take it with him to the meeting, and commence to mark down his fellow-members. What is the strange passion that impels the hand-camera worker? We believe it to be the combination of two factors: the first, that fatal ease in pressing the button, which makes the fingers itch for action, and second, the fanatical enthusiasm which cries, "I must have that" to everything. In the Councillor's case it rose to such a height that the Mayor was cheeked, a solicitor sought and consulted, excitement and disorder involved, an hour and a half of public time wasted, the police called in, and finally the camera man forcibly removed by two beadles and the mayor's marshal, before the police arrived. The last episode would have made a capital subject. Of course, we do not hear the photographic martyr's side of the case. It may be that the Paddington Councillors are in fact irresistible as subject matter, in which case we can understand their efforts to fend off the fusillade, while we sympathise with the operator in the fruitlessness of his valiant attempts and deeply laid plots.

* * *

Developing Panchromatic Plates. A recent German patent granted to R. Krayn describes the use of an acid bath or acid developer for the treatment of red-sensitive plates prepared with dyes, such as panchromes, which are decolourised by acids. This has for its purpose the destruction of the red-sensitiveness of the plate after exposure, and is on the lines of the acid diamidophenol developer which has been stated to be effective for the same result, although some experimenters have failed to find that it does behave in this way. If the process recommended by Krayn be that mentioned in the patent specification, namely the use of a $\frac{1}{2}$ per cent. bath of sulphuric acid before development with ferrous oxalate, or the addition of acid to the developer itself, it is possible that the stronger sulphuric acid may be able to effect a more complete action than that of sulphurous acid.

* * *

Photographers' Advertisements Under the title of "The Sun Artist's Opportunity," a recent issue of "Printers' Ink," the little journal of advertising issued by Messrs. S. H. Benson, Limited, of Kingsway Hall, London, W.C., remarks upon the almost complete absence of por-

trait photographers' advertisements in the daily press. Our contemporary's comments are suggested by a recent illustrated article in the "Chronicle" on a lady photographer's work, and it is led to suggest the forms which advertisements of a firm of popular photographers might take—such as notes on the kind of clothes to wear, the necessity of avoiding the ultra-fashionable attire now existing—for example, the present combination of Directoire clothes and beehive hats—which give a date to the photograph and appear grotesque in a year or two's time, if not a good deal sooner. While it is realised that a photographer cannot make lavish use of such advertisement in the daily press, the suggestion is made that an expenditure once a year on a series of, say, quarter-page advertisements in a London daily paper would prove remunerative, particularly as the photographer's business lends itself excellently to the making of very satisfactory advertisements by means of half-tone blocks. And we are glad to note our contemporary's last words, namely, that if such a business is "to achieve success through advertisement, it must deserve success."

* * *

Commercial Telephoto Work.

There is one article in the current issue of Captain Owen Wheeler's "Telephoto Quarterly" which runs to only a score or two of words, but points a practical lesson which may be learnt with profit by photographers making a business of outdoor work. The writer, Mr. E. A. Biermann, shows the advantage of a telephoto lens, working at nine magnifications in the particular instance, in making a series of photographs of houses on a certain estate which was being offered for sale. Owing to the undulating nature of the ground the natural picturesque surroundings of the houses could not be shown when a near standpoint was taken, as required by a lens of the normal focal length, but by taking a more distant view-point a greatly improved aspect was obtained, and the two illustrations reproduced make the strongest possible case for the inclusion of a telephoto lens in the equipment of the photographer who would go out prepared to make the very best of a commission of this kind.

* * *

Regularity in Sulphide Toning.

So much discussion takes place as to the causes of trouble in the sulphide toning of bromide prints that one might almost suppose that the method was incompatible with the regular output of work on a commercial scale. But as a matter of fact the commercial enlarger or printer, even if he is not prepared to discuss the formation of the sulphates or dithionates in the toning-bath, nevertheless has a practical science of his own which is commercially sufficient. Being the other day at the Frisian House establishment whereat Mr. S. H. Fry carries on his business of enlarging and printing for photographers and the trade we happened to mention the question of sulphide toning and were interested to hear Mr. Fry's declaration that in their experience the sole secret of regularity in working lay in the making of a perfect bromide print in the first instance. Errors of exposure, development, or incomplete fixing or washing would upset the toning process, and the print was found to tone irregularly or to give an unsatisfactory colour in the sulphide bath, the only necessary course was to send it back to the enlarging-room to be repeated. An ocular proof of the soundness of the principle happened to be forthcoming at the time of our visit in the shape of seven or eight enlargements, each measuring 60 x 24 inches, and all toned by the sulphide method. The evenness of the tone over the whole surface of each of these large prints, and at the same time the

regularity of the tone throughout the series, showed that the principle adopted worked out most satisfactorily in practice, for the enlargements were of remarkably fine colour and quality.

ART AND PHOTOGRAPHY AGAIN.

SINCE an art status is undoubtedly the acme of the hopes of pictorial photographers, and the only footing by which the amateur can stand up to the professional portraitist, it is not surprising that Mr. Snowden Ward should elect the vital topic for his presidential address at the Photographic Convention at Canterbury. He has always been a staunch supporter of art interests in camera work. It is to be doubted, however, whether he really contributed to the gaiety or the illumination of the conventioners by stamping down, so to speak, the already hard-trodden ground of that dry and sterile question: "Is Photography Art?" Presidential addresses usually take the form of a retrospection, followed by a prophetic outlook; but they may do this without disinterring old bones of contention, and without uttering wild and sanguine forecasts that are lacking in due justification.

Mr. Ward led off with his question, "Is Photography Art?" answering it with an unhesitating "No." But this proved a mere quibble, for in the same breath he paraphrased the question, and gave it as unhesitating a "Yes." It would seem that, as a class, photographers feel inwardly the "No," but assert the "Yes" in mere loyalty to their craft, and hope in themselves. When the president crystallised his observations into aphorisms, it was not always possible to agree with him entirely. For example: "A picture does not mean a beautiful thing photographed, but a thing beautifully photographed." One can approach such an ambiguous statement from several opposite points of view and make it either wrong or right. It has, therefore, little in it beyond sententiousness. Possibly Mr. Ward's real meaning is one that we could readily endorse; but, on the face of it, the epigram is open to dispute. In elaborating the point he betrays that his mind was running upon the fact that matters of sentiment and romance form a part of the make-up of the artist, for he talks of beauty in a noble head of a fine old man who has done and triumphed greatly; or of a gentle lady who has suffered and been strong. Further, he alludes to a "greater art" which sees the marks of struggle and high aspiration in the degraded faces of those who have failed. Our contention is that all this is not art at all, but something else. Though it smacks of the Parish Church Magazine, it may, indeed, afford that "literary" help to a picture which many seek and enjoy; but, nevertheless, it is no part of the picture's art in the strictest connotation of the term. To refer to a view of Harlech Castle as called up in a Welshman's mind by the strains of the famous march is just as much beside the point. Who is to say that the man who takes the *pretty* "local view" is less imbued with Welsh patriotism than Mr. Geo. Davison? Association of ideas is one thing, and art, or even an innate feeling of romance, is another. The precise and commonplace view is really the more likely one to cause association of ideas. But though sentiment and romance may, to some extent, prompt the work of the artist, they are not the qualities which make him either great or feeble in art. Moreover, they are possessed by many more people who have no touch of the graphic artist in their composition. These qualities have as much, and no more, to do with the equipment of the artist, as "the history of music" and "the depths of sorrow and disaster," or of "art, literature, poetry, music, history, architecture,

anatomy, religion, politics, even engineering and manufacture." "Ars longa; vita brevis." If a man put himself to any pains to get more of these things than he could get reading as he ran, he would be stultifying instead of brightening his chances in art. Admirable Crichtons do not make good painters. Depth, not width, is what is wanted in the studies that pertain to art, and dilettanteism results in superficiality. Mr. Ward's contention is only true in the limited sense that "no knowledge is useless," as he puts it. We are prepared to say all knowledge is useful; but the man who takes the proffered advice, and deliberately studies upon the modest curriculum suggested, will find that, before he has more than begun his "prep.," the great head-master is beckoning with bony finger.

As a matter of fact, the great artist is often the uncultured and boorish man; but however much he may fail in the Crichton accomplishments, he has that in his temperament which makes him know what he wants in a picture, and that is the undefinable and inexchangeable gift that all but a very few photographers do *not* possess.

This gift is only too rare, and thousands of painters are without it, namely, the daubers who commercialise and live upon the shame of their handiwork. The gift is born in the painter, and is developed by practice. Mr. Ward says art is a matter of education. Here we believe him to be wrong. "Execution" alone is a matter of education, and the art student is concerned with that, and that alone. He may become a perfect virtuoso in paint, but he will not be an artist without the natural gift. Yet this execution is a lifelong thing to come by. Sargent once (perhaps often, for that matter) employed a model four days a week for nine months consecutively, and painted a head every one of those days, scraping it all out at night, to do another at the next sitting. The model grew weary first. In such singleness of purpose has he arrived at his ease and dexterity of execution. If mere technicality demands so much there is little time for book-learning or sight-seeing. Fortunately, the gift, the artistic talent, grows by what it feeds on, making no demand upon the outer world. Or, rather, we should say that, whilst the outer world can teach nothing of art to a person wanting the proper receptivity, the talented one gathers sustenance everywhere unconsciously. As to the president's view that to-day some leading painters might learn good lessons from leading photographers, we should regard it as a sop-in-the-pan for his audience had he not put forward the claim "quite seriously." "Our exhibitions of paintings show mastery quite inferior to that of Annan, Crooke, Hollyer, Furley Lewis, Hoppé," says Mr. Ward. The picture of Sargent sitting at the feet of Mr. Hoppé learning good lessons is too exquisitely delightful.

The closing words of the address referred to the future position of photography among the arts. Needless to say, they were highly sanguine. Loath though we should be to place a deterrent in the way of enthusiasm such as Mr. Ward's upon a matter wherein our own sympathies and interests are so much involved, we cannot but question whether the apostles of free methods in pictorial photography are not living in a fool's paradise. The greatest pictorial advances are being made upon lines which do but react against photography as a means of artistic expression, and the question, "Is Photography Art?" becomes less difficult to answer day by day. It is an undignified spectacle, that of photography struggling and panting up the slopes of Parnassus, only to slip back again and again. If its apostles would not claim so much, but contentedly employ it for what it is, there would be less room for faction among its votaries and for the amused smiles of those who look on.

PHOTOGRAPHIC RECORD.

It is a pity that Mr. Bothamley, in his paper before the Convention last week, did not say less on the methods of photographic record and more on the measures to be taken to render the results of photographers' work accessible to those to whom it is of particular value. There would appear to be a general impression among those who advocate photographic record work that the making of a photographic print of any building or scene of interest to the antiquarian or historian is necessarily a valuable piece of work. In the circumstances under which record work is carried on at the present time the chances are largely against such indiscriminate photography by detached workers being of the slightest use to anybody. From the point of view of service to antiquarians or archæologists, what is now wanted is not so much the stimulation of photographers to take up record work, but the provision of means whereby such work is rendered accessible, and particularly means whereby duplicates of the photographs made are readily obtainable. We think the example which has been set by the Sussex photographic survey, namely, placing the prints in the charge of a public librarian, deserves to be largely followed. After all, the proper place for record photographs, because the easiest and most accessible place, is the home of some educational or literary body in the immediate neighbourhood. That is obviously the best course so far as inspection or consultation of the prints is concerned, but it does not solve the difficulty of obtaining copies of any photographs of special interest. The suggestion that those who took the negatives

will be prepared to supply prints is one which can hardly be considered as practicable. Though it may suffice for a few years, yet in time to come the owners of the negatives, if not the negatives themselves, will have disappeared, and the only means of obtaining duplicates of the prints will be by copying. If those who spend their labour in the advocacy of record work would turn their attention to awakening municipal interest, they would, we think, be touching the weak spot in this very desirable branch of work. Really, what is needed is not a great amount of work by separate workers, much of which overlaps, but a planned and concerted scheme whereby within a few miles of any historical building, and most properly in a public library, there shall be collected photographic prints, and also the negatives from which they were made. Such a scheme will give plenty of opportunity to those who are interested in this branch of work, and it will supply all that the archæological students require. We think that many of our professional readers, who take an interest in the affairs of their town, might do worse than concern themselves with the question from this standpoint. The cost to the municipality of the storage of prints and negatives should be trifling, and the work of indexing and cataloguing one which could be done without laying any appreciable extra labour upon the staff employed in a public library, and the fact that the archæological student will usually require prints to take away with him would mean that a certain amount of business should come the way of the professional photographer in districts where such collections of negatives as well as of prints exist.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

II.

THE weather conditions continued mixed during the Convention week, but were never so serious as to interfere appreciably with the excursions and other fixtures. At the garden party, given by the Mayor of Canterbury, on Wednesday afternoon, the group reproduced last week had just been taken when the rain descended heavily, and the party had to take advantage of the shelter offered to them by Mr. Bennett-Goldney, whose many acts of kindness and hospitality to the Convention remain one of the most pleasant memories of the meeting.

Among the many pleasant functions held during Convention week, the dinner at the County Hotel was one of the most successful. To begin with, the dinner was good, and well served. The toasts were "The King," "The Queen and the rest of the Royal Family," "The Photographic Convention," "The Dean and Chapter of Canterbury," "The Mayor and Corporation," "The President," and "The Ladies."

Among the guests were The Mayor, The Rev. Dr. Moore (Canon in residence), and Mr. B. Twyman (Secretary of the Canterbury Chamber of Commerce). Sir Cecil Hertslet proposed "The P.C.U.K." in his usual felicitous manner, and highly eulogised the Hon. Sec., who replied reminding Sir Cecil of the time when they were together on the Council of the "Parent Society," and, in conjunction with other gentlemen, prevented the absorption of that body by the Polytechnic.

Canon Moore spoke of the pleasure it gave the Dean and Chapter to offer facilities to the members visiting the Cathedral. Mr. E. J. Humphery made an excellent speech in proposing "The Mayor and Corporation," and the Mayor not only responded, but gave a very fine recital of one of Kipling's poems. Mr. Bothamley, who was entrusted with "The President," spoke

with the weight and deliberation due to such an important toast, and Mr. Snowden Ward, who during the evening had kept up a running commentary on the proceedings, "and so on and so forth," responded in his usual genial and cheery way. Mr. Alfred Watkins submitted "The Ladies," and a suitable response was made by Mr. A. H. Dodman. In fact, everyone endeavoured to say as many nice things as possible about everyone else, and the majority succeeded admirably.

The proceedings were interspersed with some excellent music by members of the St. Lawrence Amateur Musical Society, who gave a selection of orchestral pieces, songs, instrumental solos etc., the concert being under the auspices of the Canterbury Chamber of Commerce.

Among the many absent members who desired to be present "in spirit" at the dinner, and expressed their regret at being unable to be present "in the flesh," were Mr. and Mrs. Alfred Werner, Mr. and Mrs. Alfred Ellis, Mr. Andrew Pringle, Mr. J. H. Walker, Mr. T. C. Turner, Mr. Geo. Davison, Mr. and Mrs. G. W. Atkins, Mr. Harold Baker, Mr. and Miss Brand, Mr. and Mrs. F. P. Cembrano, Mr. and Miss Seaman, and Mr. W. J. Croall.

On the Rochester excursion the President proved a tower of strength in pointing out the many literary and historical associations of the castle, cathedral, and other ancient buildings of Rochester. At the evening meeting Mr. C. H. Bothamley delivered a very lengthy address, which was further prolonged by an exhibition of a set of lantern slides dealing with "Some Aspects of Photographic Record Work." The paper dealt with the general desirability of record work, and of the lines upon which it might be most advisably done; but it cannot be said

that the lecturer touched any new ground in his treatment of the question, his dicta as to the taking and printing of photographs intended for record purposes repeating the methods which are generally found suitable for this purpose.

The excursion of Friday to the ancient towns of Rye and Winchelsea was attended by a large party, most of whom spent the day amid the picturesque surroundings of Rye, a small proportion journeying to Winchelsea, and exploring the quaint nooks of this ancient place.

The two papers at the Friday evening meeting proved full of interest. Captain Owen Wheeler described his practice of high-power telephotography in the concisest form, and illustrated the results attainable by a number of comparative examples, the remarkable sharpness of definition in the case of the high-power work proving the most convincing demonstration of the possibilities of this branch of work. Mr. Martin Duncan, in a lecture on "Colour Photography Applied to Natural Science," showed a number of examples on the Autochrome plates of the processes of fertilisation in plants by means of bees, and proceeded then to show also some cinematograph pictures, which illustrated the use of this method in the investigation of physi-

cal phenomena—namely, in recording the forms of vortex rings, and, further, in natural history, in reference to the prevention of yellow fever by covering the surfaces of pools containing the germs of fever with some oily layer which prevented the organisms, existing near the surface of the liquid, from obtaining the necessary supply of air. The formal part of the proceedings of the Convention came to an end with this meeting, and the occasion was taken to offer to the Mayor of Canterbury a framed photograph of the group of members as a mark of the great help and hospitality received by the Convention from Mr. Bennett-Goldney. The Mayor, in acknowledging the gift, expressed the pleasure the visit had been to him, then somebody said "Why is there no vote of thanks to the President for all he has done?" and, on the motion of Mr. Bridge, the meeting showed by acclamation its great appreciation of the President's interest and help.

Saturday's outing was taken by a few conventioners who, under the guidance of Mr. Snowden Ward and several members of the Maidstone Camera Club, visited the assize town of Kent and some of the surrounding objects of interest, chief among which was the ancient Allington Castle.

WHY WE SEE RELIEF IN THE STEREOSCOPE.

(A paper by Mr. C. Welborne Piper, read before the Photographic Convention, July 8.)

THE complete theory of stereoscopy should include an explanation of why the objects represented in a stereoscopic slide appear to be "in relief" when we view the slide through a stereoscope. As a rule, however, we hear very little of this part of the theory, and a great deal with regard to that which concerns the proper method of making the slide. I therefore propose in this paper to deal only with the more neglected part of the theory, and to describe some of my own experiments made in the endeavour to elucidate the true cause of the effect produced.

The first of my experiments was devised to test an assumption that seems to have been almost universally accepted without question and without test. It is generally assumed that the stereoscope reproduces by artificial means the conditions that prevail when we look at the original object with our two eyes, and that the cause of relief is in both cases the same.

It is, of course, clear that the conditions are not, and cannot be, exactly alike. In the stereoscope we look at prints on a plane sur-

face by the apparent diminution of size due to distance, and by atmospheric effects that alter tones at different distances. This factor of perspective must therefore be eliminated in any experiment such as that I attempted, and, consequently, the only satisfactory test subject will be two simple points situated in space and at different distances from the eye.

The slide shows the apparatus used.

An oblong rectangular box is shown in Fig. 1 in thick lines. This box is 13in. long, 6in. wide, and 4½in. deep, while 2½in. from one end and it is divided by a vertical partition, *a, b, c, d*. In this partition there is a narrow horizontal slit *s*¹; in the nearest end a corresponding slit *s*², and at the other end another slit *s*³, this last slit being covered with tissue paper. All three slits are on the same level, and if the box is dead-blackened inside and covered with a light-tight blackened lid nothing but slit *s*³ is visible when we look through the box lengthwise with the eyes at *s*². Two thin black rods, *r*¹ and *r*², are fixed in the positions shown, so that both are easily within the limit of clear vision from *s*². The more distant rod, *r*², is slightly thicker than the other, so that each subtends the same angle and looks the same width when seen from *s*². On looking through slit *s*² we can see only such portions of the rods

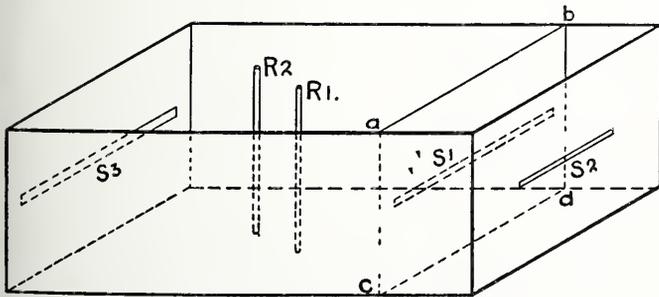

Fig. 1.

Fig. 2.

as are opposite slit *s*³, the effect of a single rod being something like Fig. 2. All perspective is thus eliminated. We cannot see the tops or bottoms of the rods. We can see no apparent difference in thickness and no apparent difference in tint or lighting; therefore the effect is very much that of viewing two points in space.

Whatever differing effects may be visible when looking with both eyes through slit *s*² at either of the two rods must therefore be due only to the change of convergence of the eyes and the accompanying change of accommodation.

The effect actually produced is, however, somewhat surprising, in view of preconceived ideas, for the difference that actually exists in the distances of the two rods becomes altogether unrecognisable. Instead of two points at different distances we see three all at the same distance.

The next slide shows in plan the effect produced.

*E*¹ and *e*² are the two eyes, and the black dots *r*¹ and *r*² the two rods. If we converge the two eyes on to *r*¹ we see three rods in a row apparently equidistant from the eyes, as indicated by *r*¹, *a*, and *b*. If we converge both eyes on to *r*² we again see three rods, *r*², *c*, and *d*, all equidistant from the eyes, but apparently more widely separated from each other than the first three observed.

To see these effects the rods should be placed so that *r*² is about

face and our eyes are accommodated, or focussed, always on that plane, even when their axes converge to points beyond it. But in viewing the natural object the accommodation is always varying with the convergence and with the distances of the different parts of the object. This may seem to be a small matter that cannot affect the truth of the proposition that the stereoscope reproduces the conditions that prevail when we view the actual object, but it is never safe to neglect small matters in scientific work, so I tried a practical experiment.

Perhaps the problem involved may be expressed more clearly in this form. Is the effect of varying distance, relief, or solidity that we see in the stereoscope due to the same causes as the similar effect produced when observing the actual object? Of course we know that one condition conducive to an effect of relief exists in both cases, that is perspective. No argument is needed to show that our ideas of solidity or of shape or of distance must be governed to some extent by perspective—that is, by the direction of lines,

2in. farther away than r^1 , while each rod is about $\frac{1}{4}$ in. away from a central line $e f$. If placed farther away from this line there will be some difficulty in seeing all three points distinctly.

A variety of other effects, including curious movements of the points, can be observed in this vision box, which is a very useful instrument for testing various phenomena of vision, but for our present purposes we need only consider the two effects described.

The existence of three images is, of course, in all cases, due to the fact that the point at which we are not directly looking appears to be doubled. When looking at r^1 , then r^2 appears in duplicate at a and b , and when looking at r^2 , r^1 is doubled at c and d .

Now the line r^1 , a , and b is not straight, but forms part of a circle (shown dotted) which is known as the horopteric circle, the property of which is that all points lying upon it are seen as single points when the eyes are converged upon any one of them. Thus if a and b were actual points we could look at any one of the three points r^1 , a , or b without seeing either of the others doubled. But any point not on the circle, such as r^2 , is seen double, and in the conditions of the experiment the doubled images are so realistic that we take them for two real points, a and b , situated on the circle.

The same conditions apply exactly to the points d and c , which are situated on another horopteric circle which is not shown.

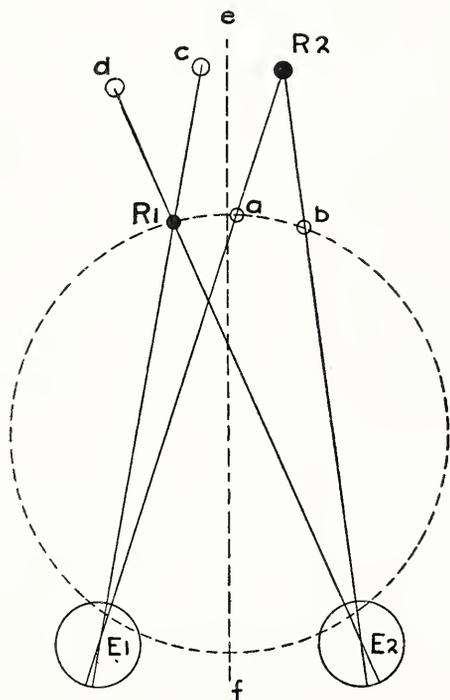

Fig. 3.

If we take away rod r^2 and substitute two others at a and b , we see precisely the same effect as when we have the two rods alone and converge both eyes on to r^1 . Further than this, when using the two rods only, we can with a little practice turn both eyes on to either of the apparent points at a and b without disturbing the illusion. I mention this last effect as an interesting fact which adds to the realism of the result, but at present there are difficulties in the way of understanding why we are able to do this, and it is just possible that the sensation is deceptive and that the two eyes do not move in the manner they appear to do. In any case, however, the impression that three rods really exist at r^1 , a , and b is very convincing, while there is no effect tending to suggest that the real subject we are looking at is simply two rods in the positions of r^1 and r^2 .

If we increase the number of rods the points visible, of course, increase, but however we arrange the rods and whichever one we look at, all the points appear to be at an equal distance from the eyes. This is a very interesting fact, as it confirms what is known as the law of Aguilonius (or Francis Aguillon), a Jesuit who published a book on optics in 1613. This law has been disputed and generally considered to be erroneous, but those who have denied its truth evidently failed to test it under conditions in which per-

spective effects were eliminated. Aguilonius made one mistake in his law. He stated that all objects seen at a glance with both eyes appear to be situated in the plane of the horopter; but the horopter, or surface upon which all points that exist appear to be single, is not a plane. It is a complex surface that can be represented in plan by a circle just as I have shown in the slide. If this mistake is corrected and the effects of perspective are eliminated, we see that his law holds good.

From the result of this experiment we see that in ordinary vision the convergence of the eyes and the act of accommodation have no effect in enabling us to see the difference in the distance of two points. We can only tell that r^2 is really farther away than r^1 by a complex process of reasoning. To do this we must understand the meaning of the various effects produced when we change the directions of our eyes from one rod to the other. That is, we must know what is indicated when the three points appear to separate or when they appear to draw nearer together, and beyond this we must understand the meaning of the appearance of three points and be able to distinguish the real points from the doubled false ones. If the arrangement of the rods is previously unknown it is a very difficult thing to exactly determine their relative positions. Even when they are known, and the experimenter has had a great deal of experience, it is very easy to become confused.

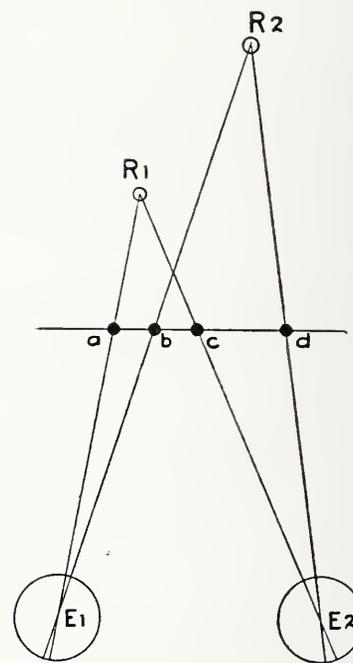

Fig. 4.

I may point out that some practice is necessary before the effect I have described can be exactly repeated. Not only are they confusing, but at first it is difficult to control the eyes in such a way as to direct both on to either r^1 or r^2 . One of the first discoveries made with the box is that our eyes are very much out of control when no perspective effects exist to guide them, and that the sensations aroused are then very deceptive and difficult to interpret.

The next experiment is made on similar lines, but with the view of testing stereoscopic vision.

In Fig. 4 the circles r^1 and r^2 show the positions of the rods previously used, but we now replace these rods by four others, a , b , c , d , arranged in a plane nearer the eyes, but still beyond the second slit in the box. The four points in space that these rods represent can now be combined stereoscopically by the eyes (e^1 and e^2) without any difficulty whatever, and the result is the representation of two apparent points, r^1 and r^2 , at unmistakably different distances from the eyes. When our attention is directed more especially to one of these apparent points the other may appear doubled, but the double images do not by any means seem to be in the same plane as the point we are looking directly at. We can see distinctly at all times and in all circumstances that the image produced by the combination of points a and c is nearer to us

han that formed by *b* and *d*. This effect can be confirmed in the ordinary stereoscope if we take a stereoscopic mount, mark our dots upon it, as in Fig. 5, and examine it in the stereoscope.

From these experiments it is, I think, evident that the stereoscope does not exactly reproduce the conditions of ordinary vision. On the contrary, it gives us a power of appreciating differences in distance that we do not ordinarily possess.

The reason for this cannot well be ascertained by direct experiment, but it appears quite logical to attribute it to the different conditions of stereoscopic and ordinary vision referred to before.

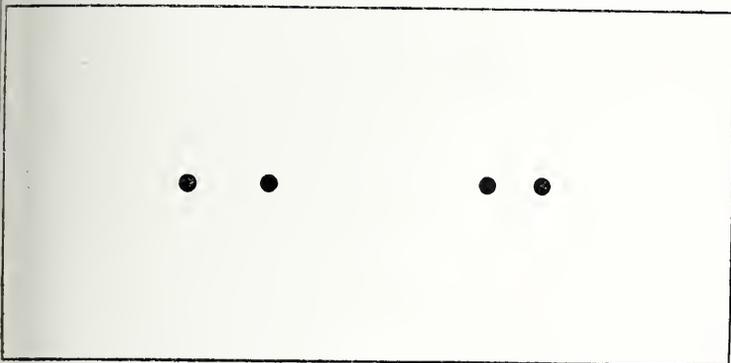

Fig. 5.

That is, to the fact that in stereoscopic vision the accommodation of the eye does not alter with the convergency, while in ordinary binocular vision it does so.

It has been generally assumed that we distinguish variations in distances because we appreciate changes in the angle to which the two eyes converge, and that the information is conveyed to us by the varying muscular sensations aroused, the most familiar sensation being that of the rotation of the eye-ball in its socket. It has, however, seemingly been forgotten that muscular sensations are practically obliterated in time as the result of much exercise. The only muscular sensations that we are really forced to appreciate are new ones aroused when we begin to exert the muscles in an unusual fashion or when we put a strain on muscles that are ordinarily little used. The eye muscles are certainly among the most freely exercised muscles in the body, and therefore it would appear quite natural for us in time to fail to appreciate any sensations aroused by their ordinary use. Possibly the sensations aroused in the case of a young child, who is just learning to use its eyes, are of great importance as guides to the meaning of what is seen, but the experiment with the vision-box proves, I think, that in the adult these sensations are no longer appreciated. In the stereoscope, however, a quite new sensation is aroused, for the muscles controlling the accommodation have to work independently of those controlling the convergence, while in ordinary vision the two sets work in unison. This new sensation enables the observer to appreciate relief independently of the aid of perspective.

We can now consider another matter rendered clear by the use of the vision-box. When I devised this experiment I was under the impression that it was a new one, which impression was confirmed when the facts observed also appeared to be new.

You will perhaps not be surprised to hear that this assumption proved to be quite wrong, and that the experiment in question is really a very old one. It is, in fact, described by Joseph Harris in his "Treatise of Optics," published in 1775 (Book II., sec. ii., article 169), but in his experiment he employed rods of different colours, which materially assist the observer, and he also fails to exclude all effects of perspective. His apparatus appears to have been quite open, therefore the differing lighting of the rods is sufficient to enable one to tell which is the nearest. This is so, even with black rods, when the lighting is not properly arranged, and the effect produced by the introduction of such an insignificant effect of perspective is an important thing to note. The moment perspective comes in then the differing distances of the rods are immediately observable. This shows the important part that perspective plays in vision. Some old writers have claimed perspective to be the important factor by which we appreciate distance, and while more modern writers have disputed this claim, I am inclined to think the old ones were correct. In any case, I feel certain that it is the

factor that the adult observer relies upon in ordinary binocular vision.

It may be argued that this theory cannot be correct because only a few specialists understand perspective at all; but, as a matter of fact, a person who does not even know the meaning of the word is absolutely familiar with all the important facts of perspective. Every one knows that an object seems to become smaller as it is removed farther away, and even though it has never occurred to him that, as a necessary consequence, parallel receding lines must appear to converge on to a single point, yet he will at once appreciate the fact that receding lines that do not converge cannot be parallel. Dimness and mist, lack of detail, and softness of colour he also appreciates as evidences of distance. Indeed, he is perfectly familiar with all the facts, though quite incapable of formulating or describing the theory. This instinctive knowledge is, of course, only obtained by experience, and while the child with no such experience is probably quite dependent on the sensations aroused by eye movements, the adult relies on experience and neglects the muscular sensations which it is no longer necessary for him to note or interpret. In the stereoscope perspective plays the same part as in ordinary vision, for a good photograph must show perfect perspective, but the perspective effects are supplemented by one due to the unusual muscular sensations aroused, so that in the final result relief and solidity may be even more obvious than in the original object. That these qualities are actually more apparent soon becomes evident if we inspect a number of slides.

We may now conclude that the appreciation of relief in the stereoscope depends on two things—on perspective and on the sensations aroused by the unusual manner in which the acts of convergence and of accommodation are accomplished. It must, however, be understood that these unusual sensations would not exist at all but for the fact that the two pictures which make up the slide present slightly different views of the object. The right-hand view shows a little more of the right-hand side of the object than is visible in the left-hand view, while the left view shows a little more of the left side than is visible in the right-hand view. In these circumstances what is known as "parallax" exists, and we may therefore describe the relief as due partly to perspective and partly to parallax.

Here again we are led to another inquiry. We can not only appreciate form or relief in the stereoscope, but also distance. That is, we can distinguish that one point is close at hand and another a very long way off. Suppose we have a slide in which a distant church spire and a near tree are both shown. Put a spot of ink on the same point of the spire in each image and another spot on the same part of the tree in each image. Then bleach out, or in some way destroy, the photographic image so that only the four spots remain. Examine the result in the stereoscope, and we see two spots at slightly different distances, but both apparently within a foot or so of the eyes. The destruction of the image has also destroyed all perspective effects, and with it the perception of distance has vanished. The parallax which remains enables us to perceive relief, but it is evident that our conception of distance must depend entirely on perspective. In other words, we must have perspective to show us what the objects are, and what their distances are likely to be, before we can estimate distance at all. In the absence of perspective we simply refer all points to the nearest possible positions.

The importance of parallax in stereoscopy has always been realised, but that of perspective has generally been under-estimated in the cases of both stereoscopic and ordinary binocular vision. In the latter the mistake has also been made of attributing to parallax an importance which it does not possess. It exists, of course, but I think my experiments show that the change of convergency, which is brought about as the result of the parallax, is not the factor by which we appreciate relief in ordinary vision, though it is a very important one in stereoscopic vision, owing to the peculiar conditions that prevail in viewing the slide. This idea is confirmed by the fact that a one-eyed man can see solidity and form in natural objects and also appreciate distance with practically the same accuracy as a two-eyed man, though parallax is a factor that does not exist for him.

I do not, however, mean to suggest that the possession of two eyes is no advantage to us. On the contrary, it permits us to see more of a near object in one glance—an obvious and very material advantage which we also possess in stereoscopic vision. In binocular vision we can judge form by the aid of two different perspective

views from two different view-points. In stereoscopic vision we can do the same, but we have the additional advantage of the special sensations aroused by the change of convergency.

The rest of the theory of stereoscopy is mainly concerned with

the methods of obtaining correct parallax and of avoiding distortion in the mounted prints; but, as stated before, I do not propose to touch on this matter, which is fairly well understood by all practical stereoscopic workers and of little interest to anyone else.

HIGH-POWER TELEPHOTOGRAPHY.

(A paper read by Capt. Owen Wheeler before the Photographic Convention, July 9.)

Ladies and Gentlemen,—Before I touch even the fringe of my subject I want to put myself right with this highly representative audience as to my personal attitude towards high-power telephotography. I have given, I confess, a good deal of time and thought to the employment of the telephoto lens at comparatively high magnifications, and some of my friends seem to think that because I have done so I look upon high-power work as the be-all and end-all of telephotographic practice. Now this is really quite a mistake. As a matter of fact the great bulk of my own work, such as it is, is done at comparatively low magnifications, and it is only occasionally that I use very high-power lenses to secure some special effect, or for purposes of technical demonstration. I fully agree with the majority of those experts who hold that the future popularity of telephotography depends upon the general and successful use of lenses of moderate power. And I admit that there is a great deal to be said for the proposition that a telephotograph at six magnifications which can be comfortably enlarged four diameters is more to the point in nine cases out of ten than a direct telephotograph at twenty-four magnifications which will stand no enlargement at all.

But there is another side to the question, and it is with reference to this other side that I seek to explain my own predilection for an occasional attempt at magnifications somewhat beyond the average. In the first place it is surely pardonable on the part of any enthusiast to familiarise himself with the utmost limits to which he can ride his hobby, provided that in so doing he does no harm to anyone else. The telephotographer at, say, thirty magnifications may be a crank, but he is, at least, a harmless crank, whose high-power negative is not in the same category as, say, the eighty horse-power car of the racing motorist. Secondly, it does sometimes happen that you must either use a very high-power telephoto lens, or do without the result you want to secure. Lastly, high-power telephotography is really—if you go the proper way about it—by no means difficult, and it is immensely instructive, besides being rather fascinating. I do not suggest that it is a good policy to obtain a grip of the differential calculus in order to enable you to solve simple equations with facility. But I do say that, looking at the small extra trouble involved in learning how to take high-power telephotographs, it is worth while, at any rate, making a few cheap experiments, if only for the reason that a little success in these higher flights will make ordinary telephotography seem almost ridiculously easy.

High, Low, and Moderate Power.

After this preface let us now get to facts. First, we have to consider what high-power telephotography is. As far as I can make out most writers on the subject have slightly different opinions on this point, but I daresay none of them would quarrel seriously with the proposition that, when you fix a telephoto attachment to an ordinary lens, and use the system thus obtained in such a way that an image is produced showing an enlargement from two to four diameters of the image obtainable by the ordinary lens when used alone, this is low-power telephotography. When the magnification is from five to eight or nine diameters the result may surely be called a moderate-power telephotograph. Anything above nine magnifications may, I think, fairly be classed as a "high-power," and, indeed, since in telephotography all magnification is linear, I think the majority of those who see a photograph

enlarged in area even sixty-four times are inclined to regard the "power" used as considerable.

Placing our lowest high-power at nine magnifications, let us see what in the ordinary way is necessary in order to produce even this enlargement. As most of you are probably aware, a telephoto lens consists of two elements, a positive and a negative, the former being usually an ordinary photographic lens, and magnification in telephotography depends upon three conditions, the separation of the positive and negative elements, the camera extension, and the focal length of the negative lens. It has nothing to do with the focal length of the positive, so we can leave that out of account. We also need not trouble ourselves now about the separation of the two elements. But the other two conditions, the camera extension and the focal length of the negative, have seriously to be reckoned with in high-power telephotography. They are inter-related, and the connection between them is expressed by two important rules, which lie at the root of all telephoto work. These rules are as follows: (1) To find the camera extension which is needed for any particular magnification you must multiply the focal length of the negative by the number of magnifications less one. (2) To find the magnification at any given camera extension you must divide the camera extension by the number of magnifications, and add one to the result.

Camera Extension versus Short-focus Negative Lens.

Now, if you ordinarily use a 7-inch lens, and want to convert this into a telephoto system, an optician will probably advise you to have a 2½-inch or 3-inch negative, because he will assume that you want to work at the lower magnifications, and at these the plate will not be properly covered by a system in which the negative is of short focal length and small diameter. But, suppose you take his advice and procure a 3-inch negative, you very soon reach the limit of your capacity. Your camera may have an extension of as much as 23 inches. From this you will probably have to deduct two inches for the projection of the tele-mount inside the camera, leaving 21 inches clear. Taking the second of the two rules given above, and dividing 21 inches by 3 (the focus of your negative lens), and adding one to the result, you find that the utmost magnification you can obtain is eight diameters.

It is obvious, then, that high-power telephotography means either very long camera extension or the use of very short focus negatives. Theoretically, the former has some advantages, and it certainly makes it possible to cover a large plate with good marginal definition. But the disadvantages are very great, especially in working at very high powers. In Boissonnas' famous telephotograph of M. Blanc, where the magnification is thirty-six diameters, I believe that a 2-inch negative was used, and, even with this, the clear camera extension would have to be nearly six feet. Well, a camera with a six-foot extension is hardly a portable instrument. Moreover, at their full extensions, most cameras, other than the good old square-form type, are not rigid enough for high-power work, in which the slightest tremor renders focussing extremely difficult. That means added weight and complication in the matter of a support, a very simple form of which is sufficient when even a portable camera is used, at a moderate extension.

Commercial Tele-Negatives.

Turning to the alternative method of obtaining high-power by the use of very short focus negatives, I feel certain that the majority of workers do not appreciate the wonderful facilities which lie ready to their hands in this connection, provided always that they are not unreasonable in their expectations. It may be stated at the outset that the possessor of a 7-inch positive who expects by the use of a very short focus negative to be able to cover large plates with fine definition will be disappointed. But, if he confines himself to the half-plate which his positive lens is intended to cover if used alone, he will be amazed at the extra power which is placed in his hands by the possession of a tiny circle of glass about $\frac{1}{2}$ -inch in diameter, and costing at most not more than a couple of pounds.

There are at present three very short focus single tele-negative lenses listed by leading opticians who have establishments in this country, the $1\frac{1}{8}$ -inch Ross, the 1 1-16 Zeiss, and the 30-mm. Goerz, and, as they are all splendid lenses, you have only to pick and choose the one which you think will best suit your positive. The difference in power is, of course hardly worth mentioning. Assuming that you have an available clear extension of 21 inches, the Ross gives 19 2-3 magnifications, the Zeiss a fraction over 20, and the Goerz very nearly 19.

Surely these figures will appeal to anyone interested in tele-photography. Even granting that the occasions are few when you want to take a telephotograph at eighteen or twenty magnifications, it is interesting to be able to do it with such very little trouble, and at such small expense. For it must be remembered that no separate tele-mount is necessary. All that is required is an extension tube of from about one to two inches, according to the focal length of the low or moderate power tele-negative in ordinary use, and a simple adapter for the high-power lens. The change can be effected in a few moments, and in that time you can alter the equivalent focal length of your telephoto system without touching your camera—from 56 inch to 140 inch.

The Staley-Wheeler Tele-lens.

Nor is this the limit to which you can go by using a high-power negative with even a half-plate camera. There is on the market a tele-attachment of peculiar construction, called the Staley-Wheeler Tele-lens, the special function of which is to provide the possessor of small cameras with the means of obtaining telephotographs on special occasions, up to thirty or even forty magnifications. I hesitate even to allude to this instrument, in which I am personally interested, but, as it is the only lens of its kind in existence, and embodies a principle which has a direct relation with the subject under discussion, I may be permitted to make a brief reference to it and its capabilities. The tele-attachment in question is a compound one, consisting of three ordinary negative lenses of different foci which can be used separately or in any combination. The focal lengths of the three negatives which are lettered A, B, and C are respectively about 67, 50, and 27 mm. The two highest power combinations are, of course, BC and ABC, the former having a focal length of about 5-7 inch, while the focal length of the latter is about $\frac{1}{2}$ inch. Looking back at our rules we find that, using the Staley-Wheeler at its full power, we can obtain thirty magnifications with a clear camera extension of only about $14\frac{1}{2}$ inches.

Now, of course, the results at this great power are not equal in definition and in quality generally to those taken at a low magnification with a single specially calculated tele-negative of the first class. All telephoto lenses, except those which, like the Bis-Telars and the Zeiss special combinations, work only at one unalterable focal length, are necessarily to some extent compromises. When it comes to constructing a compound convertible set of three negatives, one has to com-

promise pretty freely in order to get lenses which will both work satisfactorily as single lenses and in any combination. But, taken all round, I think it may be claimed that the Staley-Wheeler attachment, behind a good positive, will make a good showing under all ordinary circumstances, and, if required, will do what simply cannot be done by any other lens at present available. Personally, I seldom use it at its full capacity, though I have worked it up to forty-one magnifications, using 20-inch camera extension, with very fair success. But I often employ the BC combination, even with a 6-inch positive and a portable 5 by 4 camera, at about seventeen magnifications. The definition falls off at the margins, it is true, and better results are obtainable with a 7-inch positive, for which the attachment was primarily designed. But it is interesting to be able to obtain even good central definition at seventeen magnifications with such an extremely portable kit.

A Limit of Useful Magnification.

Personally speaking, I put the limit of useful magnification at about thirty diameters. One can go a good deal further, but at anything over thirty so little light is passed, even when the positive is of large aperture, that accurate focussing becomes very difficult, and is only possible with specially rigid apparatus, and on a very fine day.

It is well to bear in mind, in dealing with these very high powers, the working aperture and the equivalent focus of the system which you are using. In regard to the former the rule is that you multiply the aperture of the positive lens by the number of magnifications, and, in regard to the latter, you apply the same multiple to the equivalent focus of the positive. Thus, a telephoto system in which the positive has an aperture of $f/6$, and an equivalent focus of 7 inches, has, at thirty magnifications, an aperture of $f/180$, and an equivalent focal length of nearly eighteen feet. At other than full apertures the aperture rule is not, I think, to be depended on, for reasons which are outside the scope of this little discourse.

Telephotographs of the Sun.

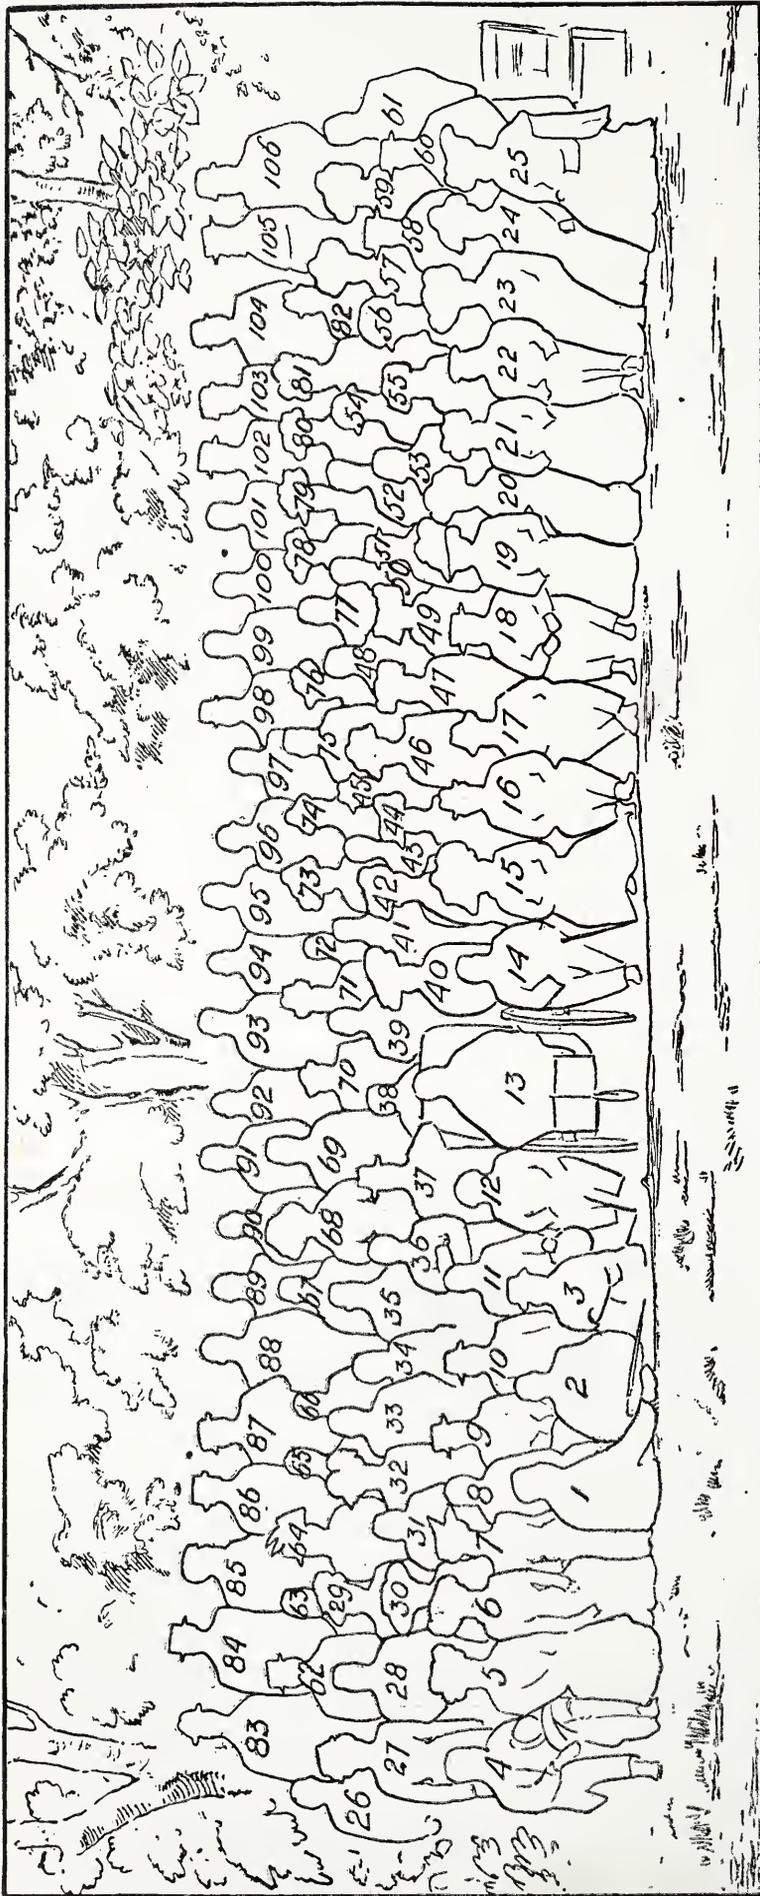

The matter of equivalent focus has a bearing upon the possibilities of the telephoto lens as applied to solar photography. I have myself only made a very few experiments in this direction, but they have been both interesting and encouraging. I think the calculation is that for every ten inches of equivalent focal length you can get an image of the sun 1-10 inch in diameter. Well, by using a compound negative lens of very short focus you can get 200 inches equivalent focus without much difficulty, which gives you an image two inches in diameter. In the case of the sun one can make an exposure which shows a clean margin, but, of course, in dealing with the moon, an equatorial movement with driving clock would be necessary.

And now a few concluding words as to working methods. My own are very simple, and I attribute such little success as I have attained to the fact that they are so. As I have explained elsewhere, I almost invariably work at one camera extension, and vary my powers by using different negatives or combinations of negatives. The proud possessor of a Staley-Wheeler can do this with peculiar ease, as at about 15-inch clear extension he can get from six to thirty magnifications without doing much more than shuffle his negatives as required. I generally use a tripod two or three sizes larger than the one which an amateur keen on having everything ultra-portable would use with my camera for ordinary photography; also a simple uniped lens support. For the rest, my principal stock-in-trade for high-power telephotography is a pretty close adherence to the old exposure rule of multiplying the exposure required with the positive lens only by the square of the magnifications (having regard to the portion of the picture to be telephotographed), a long telescopic lens hood, an opaque focussing

KEY TO THE GROUP OF MEMBERS OF THE 24th ANNUAL MEETING OF THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM,

HELD AT

CANTERBURY, JULY 5th to 10th, 1909.

cloth of generous size, a focussing screen smeared with lanoline which has been well rubbed in and off, a really good focussing magnifier, and a fair amount of patience. If I want to take a telephotograph at thirty magnifications with a half-plate camera, I simply set up the latter, extend to about $16\frac{1}{2}$ inches to allow for the projection of the tele-mount into the interior of the camera, affix the lens with an A B C Staley-Wheeler

combination in position, form the focussing cloth into a sort of tube, and wait. In a minute or two my eyes have got accustomed to the semi-darkness, and, as the separation of the two elements is slowly adjusted by the use of the rack and pinion, some part or other of the picture begins to take shape. The focussing magnifier is then brought into use, and the rest follows as a matter of course.

OWEN WHEELER.

DEVELOPMENT WITHOUT ROCKING.

[The method of applying to a plate which is placed level a certain quantity of weak developer has found occasional advocates during the past few years, particularly in Germany, where the method has been named "flat development," or "horizontal development," in reference to the fact that the essential point in the method is to preserve the developer perfectly quiescent on the plate, so that any products which are formed during the process are not removed to other parts of the film by agitation of the solution. In the current issue of "Photographische Rundschau" some notes appear on this method.—Eds. "B.J."]

THE recommendation to develop plates without rocking in a very weak developer has been made in the past, and experiments have shown that when a plate is thus placed perfectly horizontal, and the developer kept still, there is a notable improvement in the rendering of subjects in which there are very strong contrasts of light and shade, the result giving a more harmonious negative than would otherwise be obtained. In explanation of this phenomenon it is to be assumed that the products of the action in the portions which have been most strongly exposed to light remain in these parts of the film and prevent the further action of the developer, whilst the less exposed portions further develop. In order to comprehend the nature of this process it is necessary to understand the alterations which a freshly prepared developer undergoes during use. In the first place the developer loses strength by the reduction of the silver and by oxidation. In the second place it gains in bromide and in the oxidation products of the developing substances, and therefore, owing to the presence of these substances, the developing process is retarded. The author cannot believe that the reduction is solely due to the bromide which is formed, as the products of the re-action, as shown from the following experiments, do not hold back and render clearly the shadows as does bromide added to the developer, but lead to a flat image such as is obtained by great dilution of the developer. In the third place it is possible that the salts produced exert an action upon the gelatine which hinders diffusion in the latter, and in this way lead to a softer result. In order to exclude the influence of oxidation by the air and to be able to follow the action of the reduction products as closely as possible, properly exposed plates (the "Agfa" extra rapid) were developed in very small quantities of solution with complete exclusion of air. Previous experiments had shown that the minimum quantities of developer which could be used for proper development in weak solution represented a depth of solution of about 3 m.m., that is to say, in the case of a 9 x 12 c.m. plate a total volume of $9 \times 12 \times .3 = 32.4$ c.c.s. In the case of a normal developer a height of .75 m.m. was sufficient = $9 \times 12 \times .075$, or 8.1 c.c.s. With such small proportions of solution the time of development must be about half as much again as when using a normal amount, and the solution is then practically exhausted as regards obtaining density. The removal of oxygen from the air makes it possible to reduce the proportion of sulphite, and therewith the danger of reduction of unexposed silver bromide, so that on this account no ill-effects are to be feared from prolonging the time of development. The vessels used for the experiments are small glass receptacles in which the plate can be so placed that it lies with the glass side on one surface and its edges on the four low walls of the receptacle, whilst between the film side and the opposite wall a space of from 5 to .5 m.m. is left for the developer. In such a vessel, allowing a depth of developer of 5 m.m., a qualitative examination was first made of the formation of the production products, using the commercial glycin developer of Hauff in the dilution of 1:20, the normally exposed plate being placed vertical during development and remaining untouched during the whole period of the pro-

cess—three-quarters of an hour. The temperature was kept constant at 15 deg. C., and it was seen after fixing that the density of the plate gradually fell off from top to bottom. This experiment was therefore varied by employing a horizontal thin glass wall G in the figure placed 1 c.m. from the lower point of the developing vessel, but leaving a space of 1 m.m. both towards the plate and the glass wall of the receptacle. Above this separating wall the plate gave the same result as before, whilst at the height of the partition there was a dark band and underneath it a light band. The explanation of this would appear to be as follows:—As soon as the developer penetrates the film and reduces the exposed silver bromide the resulting products diffuse back again into the developer. There they endeavour to mix uniformly with the solution, that is to say, in general moving at right angles to the plate. As, however, their specific gravity is usually greater than that of the solution, they sink along the plate to the bottom of the vessel. There thus results a slow circulation of the developer to the plate downwards and to the above glass wall upwards, which, however, by repulsion by the walls and circulation currents, is so much disturbed that it only transfers a small fraction of the salts into the upper part of the vessel. The mixture of the products, therefore, accumulates in the lower portion of the solution, and thus retards the development. The formation of the streaks in the second experiment would appear to be due to the fact that the partition G produces more active circulation, and thus leads to an intensified action of the film across its width, thereby accelerating the development.

A second experiment with a plate carefully exposed under the same conditions, with the difference only that the glass receptacle during the whole three-quarters of an hour's development was placed successively on all six of its sides, gave an absolutely uniformly developed negative, which, however, was not of such density nor so clear as the upper portion of the plate in the first experiment, but more nearly corresponded with the middle portion of this plate. The experiment thus shows that the reduction products diminish the strength of the developer if they do not also harden the gelatine. The third experiment was made under the same conditions as before, the plate during the whole time of development (three-quarters of an hour) being fixed so that it was film downwards. The result was a brilliant negative, and the explanation is forthcoming from the two first experiments. The products of reduction are removed from the film, pass downwards by gravity, and diffuse, and thus allow of fresh developer gaining access most rapidly to the plate.

Next a series of experiments were made with thirteen plates. The first plate was developed in a quite horizontal position film upwards, the second was placed at an angle of 15deg., the third at an angle of 30deg., and so on, the seventh plate being vertical, the eighth at an angle of 15deg., and the thirteenth again occupying the horizontal position. This series of plates thus represented the gradual departure from the method of flat or horizontal development recommended by Walther to the ordinary tank process. It was found that plate No. 1 was uniformly flat; plates Nos. 2 to 4 were similar, but showed streaks; plates Nos. 5 and 6 were uniform in character, but not quite so flat; plate No. 7 resembled No. 1, as did also plate No. 8; whilst Nos. 9 to 13 were uniformly clear.

It may now be asked whether the method of development with the film downwards possesses any advantage over ordinary stand development when the vessel containing the plates is reversed once or twice during development. The density of the negatives is actually somewhat influenced thereby, although this defect can be avoided without involving other drawbacks simply by somewhat increasing the proportion of alkali in the developing solution. The worker is therefore in the position to get a brilliant negative of a plate either by inverting the receptacle once or twice or by allowing the plate to lie for some time film up to obtain distinctly softer negatives.

When using the non-rocking method in ordinary dishes the developing solution should be used to the depth of 2cm. ($\frac{3}{4}$ in.), a suitable formula being that given by Schering in the Satrap handbook, namely:—

Glycin9 gm.
Sodium sulphite	2.7 gm.
Potass carbonate	4.6 gm.
Water	1,000 ccs.

The plate is fastened in two metallic holders, the construction of which holds the plate 1cm. from the bottom of the dish, the plate being slid into the solution holding one edge at an angle. This procedure avoids the risk of air-bubbles. At least five times the usual quantity of developer is necessary, but against this may be placed the lesser space and apparatus required when, as is most usual, only one or two plates are to be developed compared with the tank or stand methods.

The virtues of this non-rocking method of development suggested the possibility of reducing the time of development without sacrificing any of the advantages of the method, and it was found possible to devise a method serving excellently for obtaining soft and still stronger developed negatives in the case of under-exposed plates. In order best to emphasise the essential features of this method, the following experiments may be alluded to: A normally exposed plate was developed in one of the above-described tanks, allowing of a free space for the developer of only $\frac{1}{2}$ mm. The normal concentrated glycin developer was used with frequent shaking. It gave a soft negative, with ample density in the high-lights. A similar plate exposed for only one-half the time gave an equally satisfactory result as regards gradation with somewhat longer development—twenty minutes; stronger negatives were obtained by this method of development by increasing the alkali or the developer proper, using, say, a solution containing 4gm. glycin, 10gm. potass. carbonate, in 100 ccs. of water, or in place of this a 1:10 solution of rodinal. The reason for the softness of the prints is the same as that in the second experiment. If the plate with the film downwards was allowed to remain in the horizontal position for ten to fifteen minutes with this particular glycin developer a strong negative was the result, but the expanses of high-light, the sky, etc., were somewhat mottled, and had lost fine details.

A similar phenomenon is noted when developing by the Walther "levelled" method. It has been explained as the result of the sideway running of the reduction products of the developer due to shaking or to a not perfectly horizontal position. In the present case the cause was to be sought in minute local circulation of the developer, this taking place most strongly in the parts which have received the greatest exposure. It would thus appear as if the density of the salts which sink down from the plate should not be too great if this local action is to be avoided—in other words, a certain minimum time of development should not be exceeded. I have found that when using a normal glycin developer in a film of 1mm. to $\frac{3}{4}$ mm. thickness for normally exposed plates, twenty to twenty-five minutes were necessary. These conditions were obtained not only in the case of normally exposed plates, but in the case of under-exposures and in negatives having great contrasts, with excellent results. Over-exposure requires to be corrected by addition of bromide.

It would thus be seen from the three first experiments above mentioned that the mode of action of the non-rocking method of development with solution of normal composition is to be explained by the fact that the strongly exposed portions of the negative quickly exhaust the developer lying beneath them, and do not develop further density after they have reached a certain point, whilst the less exposed portions do develop further. The result is that the

contrasts are softened and a negative of good density obtained. Comparison of the method, using both dilute and normal developer, with that usually adopted shows that in both modes of the non-rocking method better results are obtained. In a comparison with stand development it is seen that the non-rocking method, in conjunction with a dilute developer, is better for all kinds of exposures as regards brilliancy and strength, while it is superior to the non-rocking method using a normal developer only in the case of under-exposure.

HUGO SEEMANN.

REPAIRING PRINTING FRAMES.

DURING the year's work printing frames are often put aside as worn out and useless, and when spring cleaning comes they are put in the firewood box. This is quite a mistake, as a spare afternoon's work will make some of them at least into quite efficient frames once more. All the materials and tools required are some half-inch wire nails, three-quarter-inch round-head screws, some glue, a hammer, bradawl, screw-driver, and a file. Of course, one should discard any frames and backs that are beyond recovery, but as one back will fit another frame and spare springs may be obtained quite cheaply from dealers, out of a dozen old frames one can usually make eight or nine satisfactory ones.

It is best to commence by taking out and placing on one side all the backs and removing all such springs and screws as have perished or become loose. The screw-holes should be plugged before putting in fresh screws, by dipping a little peg of wood into hot glue and hammering tightly into the hole. A smart tap with the hammer on one side of the peg will snap it off close to the frame.

Any parts of the frame that have split or come apart should be closed with glue and have nails driven through. After the glue has set thoroughly hard the projecting ends of the nails, if any, can be filed away. It is advisable, before inserting the nails, to make holes with a small bradawl, as the wood of which many frames are made is liable to split easily. When the hinges of the backs have gone, it is hardly worth while on small frames to get new hinges, as a strip of thin leather or strong cloth glued on and further secured by a few tiny tacks or gimp pins will answer the purpose equally well. Where the cloth on the backs requires renewal the old material should be soaked off with hot water and a scraper. Having cut pieces of baize or similar cloth into pieces slightly larger than each half of the backs, and with one edge quite straight, thin hot glue should be applied evenly over the wood and frothed up by working the brush over it with a rapid circular motion. The pieces of baize can then be placed on with the straight edge along the hinge line and rolled down with a roller-squeegee. When they are quite dry and the glue has set hard, the cloth can be trimmed round with sharp scissors or knife.

A cover-glass in a printing frame serves several purposes; it helps to prevent breakage of the negative, not only by being a protection from outward shocks and concussions, but also from any unevenness in the frame itself. Besides this, if frames get accidentally left in the rain for a few minutes the water will find its way between the two glasses instead of to the film and print. To fulfil these properties to the utmost, a cleaned negative glass of the same size is hardly sufficient, for the reason that the printing frames are usually slightly larger and the negatives slightly smaller than the standard size. Glasses should be cut from cleaned off negatives of a larger size to fit the frames accurately. This can easily be done in the absence of a diamond with a wheel-cutter, sold at ironmongers' for about sixpence.

D. BERLIN.

THE "BLUE BOOK."—From an inspection of the 1909 edition of the "Blue Book," the organ of the Scottish Photographic Federation, which has just reached us, it would appear that the energetic secretary, Mr. J. B. MacLachlan, is still adding recruits to his ranks, the number of "federated" societies being decidedly larger than last year. The portion of the book which will doubtless appeal most strongly to members of the federation is the list of gentlemen who have expressed their willingness to give expert advice in the various branches of photographic work to members who are in need of it. A large portion of the book is devoted to a "gazeteer," the chief interest of which would seem to be the information as to dark-rooms in various localities, where plates may be changed free of charge.

Photo-Mechanical Notes.

Rush Work and the Engraver.

THE BRITISH JOURNAL boasted last week that the reproduction they were able to show of the group photographed at the Convention was in the hands of their printer within a few hours of the photograph being taken. Of course it is essential in all block-making for newspapers that the utmost speed is shown, but it must not be forgotten that rush jobs, nearly always cost the engraver much more to execute, as other work has to be put on one side and special attention devoted to that one job, whereas frequently the same amount of attention and effort could have been seen through several jobs if events had been allowed to take their normal course. The worst of it is, that all customers are now anxious to have their work done in the shortest possible time since so much advertisement has made it plain how quickly it is possible to produce a block. Very often blocks are not required so hastily, and in any case it is frequently possible to wait a reasonable time for the work, which would enable the engraver to turn out his work at a more economical cost.

This difficulty is being met by some of those engravers who clearly recognise the extra costliness of rush work, in one of two ways—either by charging extra for specially quick work, or pricing all their work at a figure which allows of it being done at a rush pace, and then allowing a scale of discounts according to the delay the customer will permit, gradually increasing in amount from that allowed for a few hours until the maximum discount is reached if the customer will allow a week for delivery of his work. The customer finds this pays him, and so does the engraver, as it enables him to sort the work out and take it in batches which go together, thus economising in every direction.

Machine Etching in 1760.

Mr. S. H. Horgan has unearthed in "Diderot's Encyclopædia," published in 1767, a drawing and description of an etching machine, in which a clockwork mechanism is used to keep the etching-tub in movement. A reproduction of this ancient device is given in the current issue of the "Inland Printer."

A pendulum-rod goes through a slit in the table to the weight below. The latter has a set-screw for fixing it at any portion of the rod so as to regulate the speed of the machine.

A cross-section of the glass-covered etching-box calls attention to the bevelled corners on the inside of the box, much as we have them to-day.

Panchromatic Collodion Emulsion.

A reader of the "Inland Printer" writes to the "Photo-engraving" department of that publication, conducted by Mr. S. H. Horgan, to communicate the method he has found best for the colour-sensitising of collodion emulsion. He uses pinaverdol and ethyl violet.

"I first make up separate stock solutions of the two dyes in absolute alcohol; this keeps well in the dark-room. The alcohol is heated before adding twelve grains of the dye to 25oz. of the alcohol. Then I sensitise 10oz. of collodion by adding to it 176 minims of the pinaverdol stock solution and 42 minims of the ethyl-violet stock solution. The glass plate is coated in a faint red light and the excess of dye washed away; then the plate is dipped in a two-grain-to-the-ounce silver bath for two or three minutes. The plate is then drained and exposed while wet. With good strong filters this plate is panchromatic—that is, it is, with sufficient exposure, as sensitive to red as it is to yellow and blue."

Process and Lithography.

The application of photography as an aid to lithography is certainly extending, and it is possible that a majority of the new posters are partially produced by photography. The commonest method at present is to use the half-tone screen. The original sketch or photograph is pinned up and photographed, an ordinary continuous-tone negative being made. This can now be retouched, if necessary. From this negative a dot positive is made, using a fine cross-line screen if there is subsequently to be a big enlargement, as is often the case. This dot positive is then placed in an enlarging apparatus, and an enlargement made on to a wet-collodion plate, giving a dot

negative of the correct size. This plan has two advantages—first, a very large screen is not required; secondly, the negative can be retouched and the positive may be reduced easily so as to get clear high-lights quite free from dots if necessary. The lens is generally placed in the wall, and the camera is formed by the dark-room itself, in which the wet plates are sensitised and placed upon an easel, which traverses runners so that correct focus is quickly attained.

The negative is then printed on to the stone, or more usually zinc or aluminium metal plate, just as an ordinary line print is made by means of bichromated albumen, and after development the work is treated for lithographic printing as usual. Of course, in certain cases a screen and negative may be made direct, and if the job is not to be enlarged a coarser screen may be used. The method of printing grained negatives on to stone is being exploited as a secret process, but this is so simple that no one should be induced to pay any high figure for it, though it may be worth while paying a little for a demonstration from a competent man if it is inconvenient to get instruction at a school.

What we should like to impress upon lithographers is the necessity for meeting the prejudices against the screen-dot, and not to give up the use of photography on this account. We know that some advertisers will not look at a lithograph, however good it may be, if they can detect the screen dot in the print. In such a case an irregular-grain screen should be employed, such as the Metzograph. It can be used exactly in the same way as the cross-line screen, and it has the advantage that lithographic artists' work can be added without the additions being so obvious as in the case of the cross-line screen. Certainly to make as satisfactory negatives may require some practice, but it can be done. Further, there may be some little loss of detail as compared with the cross-line screen, but this is usually not of importance in large work. It will be possible to cure a customer of his prejudice against the cross-line screen by doing his subject first with the irregular grain, then with the cross-line, and letting him compare. For most subjects the greater detail and smoothness of the latter will make an appeal which is irresistible in spite of prejudice. The same process can be applied to two and three-colour printing, and more printings can be added of artists' work.

Some of the finest photolithography now being done is a combination of collotype and lithography, the collotype supplying the form and modelling of the subject and the colours being worked from stones drawn by hand. The photography in this case must be as perfect as possible, and the method is not applicable to large poster work.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

PRINTING BLOCKS.—No. 13957. Process and apparatus for the production of printing blocks by etching. Axel Holmstrom, 40, Chancery Lane, London.

Exhibitions.

CANTERBURY CAMERA CLUB.

It was a happy idea of the Canterbury Camera Club to hold their seventh annual exhibition during the Convention week, and, like many other happy ideas, it had the result of giving the executive of the society an immense amount of work, of providing an interesting half-hour for members of the Convention, and of putting, it is hoped, into the pockets of the club enough money to pay for the enterprise. Moreover, it had the further happy issue of securing the first award of a silver plaque in the open classes to Mr. A. H. Dodman, a member, and a very dogged and Kimber-like member, of the Canterbury Camera Club. The Foresters' Hall, where the exhibition was held, is not an ideal building for the purpose, being both dark and hot, nevertheless the committee had done their best in displaying nearly 300 pictures and a goodly number of lantern slides and Autochrome transparencies, all of which the good people of Canterbury might see for the humble sum of threepence, a charge which, in our opinion, any self-respecting photographic society should at least double.

The best tribute we can pay to the success of the organisation is

that a number of photographs are shown by workers outside the ranks of the small number who regularly send round to every exhibition. The Canterbury Committee may pat itself on the back that they have done more than make use of the photographic pictures which are to be seen at every exhibition outside London. And in thus opening their doors to those who are at present not prominently known in the world of pictorial photography they have admitted very little that is stupid or silly. With the exception of one or two things, such as the "Silver Grey" (No. 60) of F. W. Memory, there is but little that one would wish excluded. C. H. Hewitt shows some striking effects in oil or bromoil, of which we like No. 13, "On the Arun," better than the more dramatic Nos. 11 and 12. A very big and powerful effect is secured in No. 23 by J. Cawood, whilst an equally ambitious but less successful attempt is made by S. A. Chappell in No. 44, which is entitled:—

"He brought streams also
out of the rock, and caused
waters to run down like
rivers."

This production is a curious mixture of idealism and realism. The upper part consists of a series of masses and outlines producing a quite fantastic effect and suggesting mystery and confusion, but at the centre of the picture the subject totally changes its character and the lower part consists of the photograph of half a waterfall, quite effectively rendered, but striking a note of utter incongruity with the part of the picture above it. B. Ward-Thompson exhibits several examples of his characteristic work, of which we like best No. 48, "Since Clouds Dispersed," which excellently renders the space and calm of the scene in a more cheerful key than is to be found in many others of Mr. Thompson's clever renderings of brooding or incipient storms.

Among the exhibits in the members' classes the first place is easily taken by A. H. Dodman, who is equally fortunate in his models as in his method of treating them. No. 219, "Portrait of a Violinist," is a fine piece of dignified work; whilst No. 217, "Sisters," is an excellent portrait of two quaint children. B. and W. Fisk-Moore, who are professional photographers in Canterbury, show quite a variety of work both in landscape and portraiture, No. 264, "The Dance of Spring," being a very dainty figure study of a girl. Another notable exhibitor in the members' class is F. C. Snell, whose "Early Morning" (No. 227), with its rendering of mist, we like best. The exhibition is also strengthened by a collection of twenty prints lent by Mr. S. G. Kimber, and including many of the strong and striking effects of lighting in architecture by which the energetic secretary of the Southampton Camera Club is so widely known. It only remains to congratulate the executive of the Canterbury Camera Club, and especially the exhibition secretary, Mr. B. J. Fisk-Moore, and the honorary secretary, Mr. S. T. Hobbs, upon a most successful exhibition, and particularly upon the plaque embodying a drawing of the Cathedral and the Arms of Canterbury, which—in silver or bronze—forms the award of merit.

PHOTOGRAPHS BY COLONIAL PHOTOGRAPHERS.

At the house of "The Amateur Photographer and Photographic News" there is an interesting collection of colonial work. Naturally it challenges comparison with the work of the Mother Country, and if it really represents the best from all parts, we at home may plume ourselves upon the fact that whatever our prowess in cricket and tinned provisions, in camera work we still hold the palm. Many of the exhibitors are well known, as are also the pictures they show. Mrs. Minna Keene has a good display, mostly old favourites. The work of H. Mortimer Lamb (Canada) is another mainstay of the show. His "Portrait of Lady Drummond" (45) is in our opinion his best work here, in spite of the fact that it is hung in the worst possible place. There seems to be an intentional resemblance to the manner of Rossetti in the head he calls "Portrait" (7). Mrs. M. Eardley Wilmot (India) has secured a strong and fine effect in "Storm Clouds on the Dal" (13). "The Return of the Temple Elephant" (16) is a capital subject and fresh to English eyes. It is the work of J. H. de Saram, of Ceylon. From New Zealand Reginald Passay sends a fine study of light and shade called "The Forest Clearing" (27), and another good work of the same class is "Sunshine and Shadow" (36), by A. W. Hunt, of Trinidad. A

well-arranged scene makes the success of John Quail's (South Africa) "Exiled" (48). Of South African talent is also Arthur Elliott's "Brer Tarrypin" (51)—two naked youngsters on the sand watching a tortoise. "A Maori Wedding" (57) is highly diverting in its go and character. This is by H. Winkelman (New Zealand), whence comes also Nelson Stedman's pathetic "Hard Labour" (60), an over-worked, "used-up" looking horse, which is treated decoratively by being in profile and having all the background blocked in. Arthur Elliott's pictures are all good, and among the best are "The Lanternist" (61), "The Wreck" (62), and "Amidst the Mermaids" (63). He hails from South Africa. When we have further mentioned R. D. Storil's "Canal" (Canada) and "The Village Blacksmith" (77A), by George Bell (Australia), we have dealt with practically the cream of the show. There are, besides, two portfolios of prints which do not appear to have been worth framing and hanging, but are placed at the tender mercies of any who care to handle them.

FAIR CHILDREN.

Since we reviewed the exhibition of "Fair Children," which Messrs. Speaight have been holding at their galleries, 157, New Bond Street, for the past two months, a number of new portraits have been added, and the receipt of a revised edition of the catalogue, in which the additions were italicised, led us to pay a second visit to the beautiful gallery in which Messrs. Speaight have arranged the photographs. Perhaps from the point of view of the subject the most interesting of the new portraits are those of the Earl of Arundel and Surrey, the future Duke of Norfolk, but from the purely photographic standpoint we like best No. 89, the children of the Lady Margaret Duckworth, No. 36, the children of Viscountess Emlyn, and No. 44, the portrait of the little girl of the Lady Hastings. In these, as in many other examples upon the walls, Mr. Richard Speaight shows his skill in securing spontaneity in his portraiture of children, whilst the composition and photographic quality of the portraits are in every instance exceptional. As we again mention in another column, photographers themselves will have the opportunity of inspecting these photographs by accepting Messrs. Speaight's invitation to visit the gallery on the evening of Wednesday next, July 21.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between June 28 and July 3.

CAMERAS.—No. 15,058. Improvements in and relating to photographic cameras. George Arthur Hale, 70, Chancery Lane, London.

DAYLIGHT LOADING.—No. 15,152. Improvements in direct positive print daylight loading flat packages. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

DAYLIGHT LOADING.—No. 15,153. Improvements in direct positive print daylight loading spools. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

FILM PACKS.—No. 15,154. Improvements in photographic film packs. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

FILMS.—No. 15,190. Improvements in or relating to the manufacture of cellulose films. Edwin Brandenberger, 111, Hatton Garden, London.

WASHER.—No. 15,277. Collapsible plate, print, and cut-film washer. George Gamblin, 9, Deynsford Road, Camberwell, London.

FILMS.—No. 15,281. Improvements in or relating to the manufacture of cellulose films. Edwin Brandenberger, 111, Hatton Garden, London.

CAMERAS.—No. 15,416. Improvements in cameras. Otto Halbach, 55, Chancery Lane, London.

Analecta.

Extracts from our weekly and monthly contemporaries.

Oil and Bromoil at One Operation.

In the course of an article describing the above method in the July issue of "Photo Notes," Mr. Ernest Marriage gives the following working instructions. The bromide print should have a smooth, but not glossy, surface. Rotograph half-matt bromide paper takes the ink well, and shows no symptoms of blistering under the brush. The transfer paper can be a piece of smooth final support for the carbon double transfer process.

The ozobrome solution is used at the ordinary strength, that is, one part is added to four of water. The double transfer paper is soaked in the above bath until it is limp. The bromide print meanwhile is soaked in plain water. When the transfer paper is limp it is placed for ten seconds in—

Hydrochloric acid	1 dr.
Common salt	550 grs.
Water to	25 ozs.

After this immersion the transfer paper is drained, holding it up by the corner, for half a minute, and then brought into contact under water with the bromide print and squeegeed in the usual way. It is important that the transfer paper be larger than the bromide print. The transfer paper and the print now in contact should be left to dry a little (say two or three minutes), the print uppermost. The transfer paper, still squeegeed to the print and the print uppermost, is now floated upon the ozobrome solution. In this way all the active solution must go through the transfer paper to reach the silver image, and it is more likely to take effect than if part of the bleaching is done through the back of the bromide print. The time required is about fifty minutes, but this would vary no doubt with temperature and different types of paper. It is easy to see when the bleaching process has been thoroughly carried out by holding the papers against a strong light; a faint image will be still visible, but all black should have disappeared. If this is not the case, the prints should be again floated on the ozobrome solution. The print should be held by opposite corners and lowered gradually on to the surface of the liquid, beginning at the middle. In this way the paper can be floated without getting any of the solution on to the bromide print lying uppermost.

When the bleaching of the silver image has been thoroughly effected the print is separated from the transfer paper by pulling from one corner, and both print and transfer are placed for about a minute in the acid bath. After washing until both papers are free from stain, the transfer paper is dried. The bromide print is fixed in a bath of plain hypo if it is to be treated as a bromoil, and dried after washing, or it may be re-developed, dried, and used again for making further transfers.

New Books.

"A Handbook of Photography for Amateurs in India." By Dr. Geo. Ewing, F.R.P.S. (Calcutta: Thacker, Spink, and Co. London: W. Thacker and Co.). 2nd Edition. 1909.

If, as Dr. Ewing says, the amateur photographers of India have, as a rule, neither the time nor the energy for a great amount of photographic reading, they have, at any rate, in this substantial volume of 769 pages, an excellent source of information that they can make use of as required. The first edition of this book is well known as a very reliable text-book, written for the use of amateurs in India, who have to work under somewhat abnormal conditions. This new edition embodies the good points of the old and is brought very fairly up to date, no easy task for a writer who lives more or less out of intimate touch with what is being done in this country and in Europe. A postscript represents the result of a trip "Home," in the course of which the author industriously endeavoured to obtain all the latest information, and as a result we note that very little

is omitted. Two exceptions are intensification with chromium and also the process of bromoil, the latter of which was probably not in existence when Dr. Ewing completed his book. The book is divided into sections or parts dealing with optics, chemistry, photographic practice, printing, etc., and most of the subjects seem to be particularly well treated. The optical portion is exceptionally good. The more practical part of the book seems equally sound, and the whole should be as valuable to English as to Indian workers. The book has a copious index, which should be an important feature in all works of this class. This particular handbook should be better known in England than it is at present, for it is far superior to the majority of the general text-books available.

"THE TELEPHOTO QUARTERLY."—No. 6 of Captain Owen Wheeler's ever-welcome "T.Q." makes the announcement that the publishing of our interesting contemporary will for the future be in the hands of Messrs. Gale and Polden, 2, Amen Corner, London, E.C., and Aldershot. "T.Q." may therefore be obtained for the year by sending the publishers a postal order for 2s., or may be purchased from Messrs. Smith and Son's bookstalls. The current issue contains some excellent illustrations of snap-shot telephotography by the editor, some notes on the diaphragm values of telephoto lenses, on convertible negative attachments, and on a commercial use of the telephoto lens, to which we make allusion under "Ex Cathedra." In addition to this our little contemporary contains the announcement of practically all the firms offering telephoto apparatus, and it further reviews certain new introductions of service to the telephotographer.

LONDON BY NIGHT.—A recent article by Mr. H. Wild from "Photography and Focus" has been reprinted, with an additional illustration, by Messrs. Iliffe and Sons, Ltd. The remarkable results obtained with a slow instantaneous exposure on Wratten panchromatic plates with a 2B Dallmeyer lens should give an impetus to this description of night photography. Mr. Wild's account of his methods is commendably explicit, and the illustrations offer an incentive to prosecute this interesting branch of work.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 17.

- Manchester Amateur Photographic Society. Ramble to Great Budworth and Arley Hall and Grounds.
- South Suburban Photographic Society. Excursion to Dartford and the Darent Valley.
- Handsworth Photographic Society. Excursion to Bearley for Aston Cantlow.
- Birmingham Photographic Society. Excursion to Broadway.
- Hackney Photographic Society. Outing to Zoological Gardens.

SUNDAY, JULY 18.

- United Stereoscopic Society. Outing to Latton and Netteswell.

MONDAY, JULY 19.

- South London Photographic Society. Monthly Competition—(Prints.)
- Southampton Camera Club. Discussion: "What Makes a Picture?" F. Ryder.

TUESDAY, JULY 20.

- Hackney Photographic Society. "Should we Specialise?" F. W. Gosling.

WEDNESDAY, JULY 21.

- Worthing Camera Club. Outing to Burgham.
- South Suburban Photographic Society. "From Negative to Block." W. Wilkinson.

THURSDAY, JULY 22.

- Handsworth Photographic Society "The Use of Exposure Meters."

CROYDON CAMERA CLUB.—Owing to a contemplated tour abroad for an indefinite period Mr. H. M. Bennett has been compelled to resign the post of honorary secretary, held by him with conspicuous success for the last six years. The club thus loses a skilful pilot and each individual member a valued friend. The keenest regret was expressed by all last week when the not unexpected announcement was made. Mr. W. H. Claypole, of 63, Elmswood Road, West Croydon, was unanimously, and with much acclamation, elected to fill the position vacated.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—At the eleventh annual general meeting of this society, held recently at the Cripplegate Institute, E.C., it was resolved that in future the society shall be known

as the City of London and Cripplegate Photographic Society. We are asked to make this announcement to our readers and point out that the old society is not being absorbed by another, but that the incorporation of "City of London" in the title will very materially assist the desire of extending its sphere of usefulness. The syllabus for the 1910-1911 season is well in hand, and special arrangements are being made with a view to assisting the beginner as well as the more advanced members. The new session commences in October, and the hon. secretary, Mr. H. S. Cuming, of 234, North End Road, West Kensington, W., will be pleased to forward full particulars of membership on application. The annual subscription is 7s. 6d., with-out entrance fee.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Mr. J. A. Lovegrove, lecturing before the South London Photographic Society, on "Trimming and Multiple Mounting," advocated the use of this home-made mountant: Take half a pound of best white dextrine, mix to a thick cream by rubbing up small quantities at a time in cold water, then stir in a further five ounces of cold water, and bring to a boil (stirring all the time) in a water-jacket boiler. It should then form a clear thick syrup. Add 15 minims of oil of cloves and turn into pots to set. It is then ready for use.

Commercial & Legal Intelligence.

AN INVENTOR'S BANKRUPTCY.—At Chelmsford Bankruptcy Court last week the Official Receiver (Mr. Cecil Mercer) mentioned the case of Mr. Birt Acres, Southend, described as managing director of the Seriken Company, Limited, film manufacturers, and stated that he had no questions to ask, but he thought it only fair to Mr. Acres to say that since the last Court he had had an opportunity of examining Mr. R. A. McQuitty on his sworn proof as secretary of the Seriken Company that debtor owed the company £1,482 17s. 5d., and he found that not only was there no ground for this claim, but he had in his possession a large number of vouchers and receipts, handed to him by Mr. Acres, which showed that the company was heavily in the debtor's debt, and he (the Official Receiver) intended to take the necessary steps to recover this amount from the company.

Debtor made an application in person that an order should be made against Mr. McQuitty for payment of costs.

The Registrar replied that he had no power to make such an order. The examination was then closed.

A SOUTHSEA BANKRUPTCY.—George Richard Knight, 63, Castle Road, Southsea, dealer in photographic apparatus, applied at Portsmouth Bankruptcy Court, on July 8, for his discharge. The receiving order was made on the debtor's own petition in February, 1904; the liabilities being put at £804 and the assets at £210. A dividend of 3s. 1d. in the £1 was paid on proofs for £765. The debtor ascribed his failure to having got into difficulties through paying the debts of near relatives, also to inexperience in the photographic business. The solicitor, on behalf of the debtor, said that he was trying to retrieve his position, and the application for the discharge was granted subject to judgment being entered for £20, to be paid within six months.

A BRIXTON BANKRUPTCY.—At the London Bankruptcy Court on June 9, Walter William Powell, photographer, recently carrying on business at 414, Brixton Road, applied for his discharge. The liabilities amounted to £354 13s. 6d., and the assets, which were put at £27 9s. 8d., only realised £5 1s. 10d. Debtor states that for several years prior to 1890 he was employed in the provision trade, and he afterwards became a jeweller's assistant. He also earned £200 a year as a professional singer and dancer, and dealer in curios. In March, 1897, with £30 of his own money and £50 borrowed from his father, he started business as a photographer at 414, Brixton Road, carrying it on under management, while still continuing in employment as a jeweller's assistant. The business, however, was a failure throughout. In November, 1905, he gave up his employment as a jeweller's assistant in order to devote himself entirely to the photographic business, which nevertheless continued to decline, and early in 1907, realising the hopelessness of his position, he closed the business and has since had no occupation. The Official

Receiver reported that the assets were not equal to 10s. in the £, and that the debtor had not kept proper books, but only a rough cash book. Debtor further states that he was aware that he was insolvent in 1905, and with the exception of £7 9s., he contracted the whole of his liabilities since that date. On this the Official Receiver reported that debtor had traded knowing himself to be insolvent. Debtor, who was present, had no remark to offer, and his discharge was suspended for two years.

LEGAL NOTICES.—The voluntary liquidation of Paris Films, Ltd., 5, Cook Street, Liverpool, is gazetted. Mr. F. H. Thornton, chartered accountant, is to act as liquidator, and he has called a meeting of the creditors for to-day (16th inst.).

Thomas Bromwich, photographer, Bridgnorth, Salop, has been adjudicated bankrupt on his own petition. The first meeting of creditors is to be held at Shrewsbury on the 24th inst, and the public examination is fixed for the 3rd prox.

A first and final dividend of 4s. 10d. in the £1 is to be paid in the bankruptcy of James Harriott, photographer, 10, Chapel Street, and 15, High Street, Warwick.

News and Notes.

MESSRS. HALFTONES, LIMITED, whose photographs and those of photographers whose agents they are frequently appear in the press, have been awarded the Gran Premio, the highest award for "newspaper illustration by photography," at the International Exhibition at Milan.

EASTMAN KODAK COMPANY.—The directors of the Eastman Kodak Company of New Jersey have declared an extra dividend of 5 per cent. upon the Common Stock of the company, payable September 1, 1909, to stockholders of record at the close of business on July 31. The usual quarterly dividends will be paid on October 1.

THE PRELIMINARY PROSPECTUS of the international exhibition of optics, cinematography, photography, and talking machines has just reached us from the organisers, Messrs. Brown and Bernard, Ltd., Westinghouse Buildings, Norfolk Street, Strand, London, W.C. The exhibition is to be divided into sections dealing with cinematography and optics and photography, in which latter classes 3, 4, and 5 are to include photographic apparatus, plates, papers and prints and transparencies, for which latter a series of awards are to be made to professional and amateur workers. Silver cups are also to be offered for the best examples of pictorial photography in landscape and figure study respectively. The entry form gives the particulars for prices for space, lighting, and power, and also the general regulations upon which space is allotted. The exhibition is to open on August 9 and to close on September 4.

HOLIDAYS IN SCOTLAND.—Further additions to the well-known official guides published by the Health Resorts Development Association, 29, John Street, Bedford Row, London, W.C., deal with some of the most interesting places north of the Tweed, namely the towns and surrounding districts of Berwick-on-Tweed, Carnoustie, Duffries, North Berwick, Pitlochry, St. Andrews, and Stirling. These little guides are of convenient size, well illustrated, and contain information useful to the tourist who having but a limited time to spend in any one place wishes to utilise it to the best advantage, and also to the visitor who is making a longer stay. These booklets, like others of the series, may be obtained post free by sending a post-card request to the respective Town Clerks, and a complete list of the guides already published may be obtained on application to the Health Resorts Association at the above address.

"KINEMACOLOR" BEFORE THE KING.—At Knowsley, Lord Derby's historic seat, on Tuesday evening, following the Royal review of the Lancashire Territorials, Mr. Charles Urban had the honour of submitting to the inspection of their Majesties the King and Queen, the Princess Victoria, and the distinguished company constituting the house party, "Kinemacolor," the Urban-Smith animated pictures in the actual tints of nature, the exhibition being identical with that given in London at the Palace Theatre. There was also shown to their Majesties a complete pictorial record of the inspection of the

Territorial troops, the presentation to them of colours, the march-past of the whole force in quarter column with the King and Queen standing to receive the salute. The pictures were taken by a special staff of Urban operators at the express direction of the Earl of Derby, and they will be forthwith included in the "Urbanora" section of the Palace Theatre programme.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—The committee of the above association announce that August the 16th has been fixed as the last date for the receiving of papers in the Henderson award competition, for the year ending June, 1909. Papers submitted must have been read either before another society during the twelve months ending as above or published in one of the various photographic journals, and be of the nature as stated below. The award is one of the value of £5, and is given for the best paper read or published during the year, of a photo-chemical or kindred subject, and at the will of the recipient may take either the form of £5 cash, or a gold medal, or a silver or bronze medal and cash, or apparatus to value. It is the wish of the committee to remove the somewhat prevalent idea that this award is only open to the members of the L. and P. It is open to the world, and is given for the best paper no matter from what source it comes. All papers for competition should be in the hands of the Hon. Secretary, 43, Whitta Road, Manor Park, E., on or before the above-named date, and full particulars will be freely sent to all who write enclosing a stamped envelope for reply.

THE GENIUS OF THE STUDIO.—A Boston photographer (writes the "Photo Era") has recently fitted up his studio and reception-room in Oriental style, a unique Japanese portière, with its long beaded strands, being a particularly beautiful feature. One gloomy day he was gladdened by the unexpected arrival of his favourite little five-year-old niece, who was left in his care by her mamma while she did several errands. His fondness for the child was very marked; for, in amusing her, he quite forgot the work he had planned to do that morning. Suddenly remembering, he tore himself away from the small siren, telling her, at the same time, that he loved her very much. Poking her curly head through the Japanese portière she called after him in her own roguish way, "I don't believe you do, uncle!" He had been in the dark-room for only a short time, and was engrossed in the development of a plate, when he heard the voice of the tiny maid, soliloquising in regular, measured cadences, the words accompanied by a rattling sound as of objects falling on the hardwood floor. As this continued for some little time, his curiosity was aroused; he listened and finally became alarmed. He hastily covered the developing-tray, and hurried out of the dark-room towards the scene of disturbance. To his great amazement he saw his small niece standing with her back towards him saying, "He loves me, he loves me not," and then, with a joyous, triumphant cry, she pulled down the last remaining strand of his precious portière with a jubilant "HE LOVES ME!"

BRITISH PHOTOGRAPHIC TRADE ON THE CONTINENT.—A small impromptu meeting of those persons interested in photographic manufacture and trade who happened to be at the Photographic Convention was called by Sir E. Cecil Hertslet, H.B.M. Consul-General for Belgium, and was attended by Messrs. E. J. Humphery (the Platino-type Co.), A. W. Green (J. J. Griffin and Sons, Ltd.), R. R. Beard, P. R. Salmon, Godfrey Bingley (President-elect of the Convention), F. J. Mortimer ("The Amateur Photographer"), Thomas Manly (the Ozotype Co.), J. B. B. Wellington (Wellington and Ward), F. W. Hindley (Jonathan Fallowfield), W. S. Hobson (Taylor, Taylor, and Hobson), Alfred Watkins (Watkins Meter Co.), F. A. Bridge (Hon. Sec. of the Convention), H. Snowden Ward (President of the Convention), and Charles Winter (Imperial Dry Plate Co.).

After discussion of the details put forward by Sir E. Cecil Hertslet, it was proposed by Mr. F. J. Mortimer, and seconded by Mr. J. B. B. Wellington, that "in the opinion of this meeting it is desirable that the British photographic industries be worthily represented at the International Exhibition to be held in Belgium in 1910, and that Mr. H. Snowden Ward be asked to convene a meeting of the photographic trade at an early date."

A meeting of those manufacturers and dealers interested in the matter will be held on Thursday, July 22, at 4 p.m., at 22, Bloomsbury Street, London, by kind permission of Mr. E. J. Humphery. Those who intend to be present are requested to write for parti-

culars of the Belgian Exhibition to Mr. W. F. Wintour, Exhibitions Branch of the Board of Trade, Queen Anne's Chambers, London, S.W., and to come prepared to make suggestions.

Correspondence.

THIOCARBAMIDE TONING BATHS FOR P.O.P.

To the Editors.

Gentlemen,—With reference to the use of a toning bath for P.O.P. prints containing thiocarbamide and "hypo," I should like to point out that it is quite safe to wash prints toned therein directly in water, provided that the "hypo" is greatly in excess of the thiocarbamide. It is also not necessary for such a bath to contain an acid of any kind. We get silver-sulphide stains, as I was the first to point out, when we wash a print containing either in the gelatine film or the paper any silver-thiocarbamide compound. This is due to the fact that such a compound is only stable in the presence of sufficient acid.

In the case of the solution mentioned in your article of last week, we do not get any silver-thiocarbamide compounds formed at all under normal circumstances. When, however, the bath has taken up much silver the case may be different—I have not tested this. I experimented with a solution very similar to Dr. Arnold's about five or six years ago, and published my results in "Photography." I did not, however, think much of the tones obtained, and I should never recommend such a toning bath. I have never been successful with any thiocarbamide formulæ, except those I have hit on myself. I certainly consider that the want of popularity of thiocarbamide for toning P.O.P. prints is due to the fact that the formulæ generally given will not, as a rule, give satisfactory tones. I have published formulæ which I can strongly recommend in the "B.J." and "Photography." I cannot help thinking that any who have reason to feel dissatisfied with the results they obtain when using P.O.P. will do well to give some of my formulæ a trial.—Yours truly,

R. E. BLAKE SMITH.

31, St. John's Road, Putney, S.W.

July 9, 1909.

INTENSIFICATION MARKINGS.

To the Editors.

Gentlemen,—In reply to "Prof." *re* above, which seems to him a real trouble, not imaginary, as some replies seem to point out, I can make no boast of having intensified hundreds of negatives, but I have had no failures by the following methods, which may be of use.

Thoroughly wash the negatives, whether new or old, and then give them a few minutes in an acid-alum bath:—

Alum	1 ounce.
Hydrochloric acid	50 to 100 drops.
Water	20 to 25 ounces.

Then wash free from above and bleach in

Mercury bichloride	10 grains.
Hydrochloric acid	10 drops.
Water	1 ounce.

Wash again and give a bath of dilute hydrochloric acid before complete washing, and darken in ammonia solution, which should not be stronger than 1 in 30 and thoroughly well mixed before applying. The use of only one acid is apparent, and each step is a check on any previous cause of failure.

For the removal of stains already experienced, re-fix in strong hypo, wash, and apply Schlippe's salt, 10 grains; ammonia (fort), 10 drops; water, 1 ounce. On intensify in uranium till shadows appear green, wash till greasy appearance disappears, and clear off in weak ammonia. This can be repeated if necessary.

Wishaw.

WM. M.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

C. Wilken, Photographer, South Street, Elgin. Photograph of Colour Party, 11th Batt. Queen's Own Cameron Highlanders; Photograph of Colour Party and Escort.

A. Stelling, 60, Peckham Road, London, S.E. Two Photographs of the Rev. J. W. Ewing, and Photograph of the Rev. and Mrs. Ewing.

S. Peace, Inganess Cottage, by Kirkwall, County Orkney. Photograph: Ships of H.M. Navy in Scapa Flow, Orkney, Dressed with Flags and Firing a Royal Salute in Honour of the King's Birthday, June 25, 1909.

P. Cameron, 1, Eyre Place, Edinburgh. Photograph: Caledonian Hotel, Princes Street, Edinburgh.

A. Dean, 14, High Street, Rugby, Warwickshire. Five Photographs: His Majesty Planting Tree in School Close, Rugby; His Majesty leaving New Speech Room, Rugby School; His Majesty leaving New Speech Room accompanied by Mr. Arthur James; His Majesty and Rev. Dr. James walking on School Close, and House Party at Coton House, Rugby.

DRAWING REGISTERED:—

A. Dean, 14, High Street, Rugby, Warwickshire. Drawing Depicting His Majesty Opening the New Speech Room, Rugby.

UTOCHROME PROCESS.—Will you be good enough to tell me the most up-to-date books or articles, etc., on colour photography? I want a work dealing with the Lumière process and which describes that fully.—KAZE.

Messrs. Houghtons Ltd. publish a booklet (price 3d.) on the process.

INSTANTANEOUS.—We should select 2 or 3. The former is much used for press work.

A. ARNOLD.—The best answer we can give you is that you purchase "Photography for the Press," advertised in our pages last week.

ITAL.—We believe the book is not sold here, but you might apply to Messrs. Dawbarn and Ward, Ltd., 6, Farringdon Avenue, E.C.

COLLODION EMULSION.—I will deem it a great favour if you can give me an easy and reliable formula for ferrotype dry plate work, similar in speed and character to — brand. I have made up Beechey's unwashed formula, but find it too slow with me, requiring two seconds in bright light, $f/4$. Have already made a rapid wash emulsion, given in the "Almanac." I would be much obliged if the formula given could be developed with hydroquinone, as I find pyro-ammonia so waxy.—C. JAMES.

The makers of the brand of plates named do not publish the formula by which they are made, so we cannot give it. On pages 795-6 of the "Almanac" you will find formula for collodion emulsions and developers suitable for them. You must not expect collodio-bromide plates to be anything like so rapid as gelatine ones.

ENLARGEMENTS, ETC.—(1) In the production of cheap bromide enlargements I have heard that no negative is taken of the subject sent, the enlargement being made direct from the copy by a method of reflection. If so, how is it possible to produce a positive from a positive without a negative intervening, or is the reversal brought about in the developing? Will you please give me the method of doing this, if such a method exists? (2) As a constant user of a hand-spraying device, I inhale a considerable quantity of lamp-black. Have you heard of this being detrimental to the health? Is there any method of carrying the spray away other than the

fan draught? (3) Is it possible to fully protect a patent in this country for £1? (4) In working up B. and W. prints, where black spots and patches occur, is it possible to take these out chemically without using the knife?—ARTIST.

(1) We are not aware that this method is commercially used. It is usual to make a "copy" negative and enlarge that, but the process given by Mr. Carnegie last week may be used with bromide paper. (2) It certainly would be. None that we know of. (3) Yes, provisional protection for nine months is obtained for this sum. (4) The print can be reduced with a mixture of iodine and cyanide, as given in the "Almanac" on page 787, but such reducer requires to be used before the working-up is taken in hand.

ARTICLES IN "B.J."—Would you kindly let me know if I could obtain in book form a series of articles which appeared some weeks ago in your journal, entitled "How to Build a Photographic Studio Business?"—C. V.

The articles in our pages are not re-published in book form except in cases where the author makes special arrangements to this end. Your only course is to purchase the back issues.

W. SULLIVAN.—There is no fault whatever with the cards, as shown by some portions being as good as could be desired. The fault is due to the manipulation, and that alone. The prints have not been kept moving while they were in the fixing bath, and as a consequence they have stuck together, so that the hypo has not had equal action all over the pictures. Where it has had free action those portions are as could be desired. More care in the fixing and after washing will avoid the trouble—more particularly in the fixing.

STUDIO QUERY.—I have recently taken over a studio, in which I find it extremely difficult to obtain satisfactory results, I should therefore be greatly obliged if you could suggest any alteration that would improve matters. I place the background at the north end, about the spot marked in red, for single figure, and at the south end for subjects that there is not enough room to take at the north. The lighting is, of course, not at all good at the south end, particularly when the sun is shining. I usually use a lens of 11.5in. focus. I am prepared to spend up to about £20 on alterations, but of course the less the cost the better. Enclosed is a rough plan of the studio, which I trust you will be able to understand.—J. W. WATSON.

So far as one can judge from the sketches, the studio is too small for general professional work. The only suggestion we can make is to extend the glass at the north end, so that the sitter can be placed further back than at present; that will give you greater length between sitter and camera than you get at present. This is the best suggestion we can make from the sketches.

ARRESTING TONING.—Kindly inform me the most sure way of stopping prints, etc., from further toning immediately after being removed from the toning bath, especially with reference to a combined toning and fixing bath.—TONING TROUBLES.

Plenty of water, or immerse in a weak solution (five grains per ounce) of soda sulphite.

COMBINED BATH FOR ALBUMEN.—Can you give me a formula for combined toning and fixing bath for albumenised paper that you can recommend? And if so, please state if prints require washing previously.—EN AVANT.

Such a formula was given in our last issue (see page 528). If the prints are made on ready sensitised paper which contains an acid as a preservative, they should certainly be washed before they are put into the bath. This is necessary more to get rid of the acid in the paper than the free nitrate of silver. If any of the former remained in the prints it would be liable to set up a sulphurating action, which would jeopardise the stability of the pictures.

CELLULOID VARNISH.—I am making celluloid varnish. I got some celluloid shavings and put in amyl acetate, well covering. The celluloid will not dissolve (after a week), but remains a gelatinous mass at bottom of bottle, with some of the amyl above. I added more amyl acetate, but the mass remains the same. What must I do? At present it is, of course, too thick for use in flowing over a plate, and it doesn't seem to thin out in the amyl acetate. I cannot use spirit, as it is intended for Autochromes.—S. H. C.

Most samples of celluloid dissolve freely in amyl acetate. Pos-

sibly if the chippings you have got are from photographic films from which the gelatine has not been completely removed, we should advise you to try the addition of acetone to the amyl acetate, as that may bring about a perfect solution.

ENLARGEMENTS DIRECT.—I wish to make enlargements from small P.O.P. untuned prints by photographing them. My camera has an extension of 36in., and I wish to make 15 x 12 negatives from $\frac{1}{2}$ -plate prints. What would be the cheapest form of lens to use? The exposure is to be made by means of magnesium ribbon.—A. M.

Your lens should not exceed 7in. focus. A good R.R. of 5in. focal length would answer well.

REGISTERING TRADE MARK.—I have sketched a very good device which will make an excellent trade mark, and which I should like to submit to my employers, feeling confident that they will use same, but would like to previously protect myself in respect to this, giving me the best idea how to proceed without incurring much expense, also stating if same can be sold to the firm and under what conditions.—B. E.

If the device is unmistakably an original drawing we should say it will be sufficient protection to register it at Stationers' Hall as an artistic work. This would cost you only 1s., whereas to register it as a trade mark will cost you £1. In the latter case you should apply to the Registrar of Trade Marks and Designs, 25, Southampton Buildings, Chancery Lane, London, E.C.

VARIOUS.—"B.J." for June 11, page 456, article by G. Watmough Webster, F.C.S., on "Cementium," kindly say who are the makers, and where can it be obtained? 2. "B.J." for July 2, page 510, short par. by yourselves re drying negatives. I have no stove, could I dry mine on the top of a small paraffin stove like you do, with the sheet of asbestos and a wire plate-rack?—OLD KROW.

1. Cementium is now sold by nearly all stationers and ironmongers and you should be able to obtain it quite easily. It is made by The Cementium (Patent) Company, Ltd., Tanner Street, Bermondsey, S.E. 2. Certainly, if you do not let the asbestos get too hot. Put it at such a height from the flame that it never gets too hot to touch.

T. E. CAWTHORN.—If you are quite certain your procedure is not at fault, while the makers are certain the plates are all right, it is a little difficult for us to offer any advice. The spots, however, certainly look to us as if due to partly dissolved developer. If this is not the cause we cannot suggest anything else. Solutions that are not quite clear are very common causes of spots.

LANTERN SLIDES.—We enclose for your inspection some lantern slides, upon which you will notice peculiar spots, etc., which our lantern-slide maker seems quite unable to account for. They occur both on varnished and unvarnished slides. We should be greatly obliged if you would kindly tell us, if possible, what the cause may be, as we cannot account for it in any way, our operator being a skilled man and a conscientious worker, who would be unlikely to curtail the washing of slides, etc.—R.I.P.

The slides sent to us appear all to be varnished, and in some of them dust seems to be imbedded in the varnish. In one the varnish has crackled, owing, no doubt, to its having been applied to a film that was not quite dry. In another it has run into streaks, which show stains. These effects we attribute to heat in the lantern, though you do not say if the slides have been used or not. We are inclined to think that in all cases the fault is in the varnishing, and would suggest that the slides should be more perfectly dried before varnishing, and that celluloid should be used instead of lac. Apparently you have not sent any unvarnished slides, so we cannot say anything with regard to those.

PORTRAIT LENS FOR FOCAL-PLANE WORK.—(1) I have a cabinet portrait lens ("Optimus"), which I wish to use for high-speed focal-plane work. I am told that I shall greatly improve the power of the lens in covering the plate by inserting a spectacle lens between the glasses of the back combination. Is this so? And if so, will you kindly say what focus the spectacle lens should be. The "Optimus" is about 8ins. (2) Would such a lens, with addition as suggested, be suitable for sporting and football subjects used on a reflector camera?—ADDER.

(1) An 8in. portrait lens should cover a $\frac{1}{2}$ -plate well enough without the addition of any supplementary lens, which will be likely

to disturb the focus. If you think of adding such a lens you might try a very weak negative lens, but we doubt if it is worth while. (2) We doubt if you could fit the lens to a $\frac{1}{2}$ -plate reflex, but you might be able to utilise it on a 5 x 4 camera. It should serve fairly well, though an anastigmat would be preferable.

INSOLUBLE GELATINE FILM.—I want to get a very hard and thick film of gelatine on paper. I have tried mixing with the gelatine both alun and formalin before coating the paper, but still the film softens when soaked for a time in water. It still seems to absorb the water, and that is the thing that I want especially to avoid. Can you tell me of anything that will answer better than what I have tried.—C. CONNELLEY.

We should advise your trying a hard sample of gelatine, such as Coignet's Gold Label, to a strong solution of which some bichromate of potash has been added. When the coating is dry, expose to a strong light, preferably sunlight, for a day or two.

LENS QUERY.—I have two rapid rectilinear lenses which I use for outdoor work. I can use either the back or the front combination of them as a single lens by employing a small stop. I have recently bought a portrait lens, whole plate size, the front combination of which, when stopped down, works admirably as a single lens for large work. But the back one I can do nothing with in this direction. It will not give a sharp image, however much it is stopped down. It seems to be of longer focus than the front, and if I could get a sharp picture it would be of great use to me. Can you enlighten me in the matter?—T. BORNER.

You will not succeed in getting a sharp picture with the back combination of a portrait lens. The function of the back combination of a Petzval lens is to correct aberrations of the front one, and that alone. It is only the front combination of a portrait lens that can be employed as a single one.

MOUNTING LARGE CARBON PICTURES.—Will you be good enough to tell us the best thing to mount large (12 x 10) carbon pictures with that will have no injurious action on the print so as to cause it to fade in after years? The prints are mostly on thick rough paper. W. AND Co.

Almost any adhesive may be used for mounting carbon prints with as, unlike silver ones, the mountant will not affect them, even if it contains substances that would act deleteriously on a silver image. Dextrine, flour, or starch paste, are quite suitable. The last-named is what is usually employed. It is made very thick and is best applied with a piece of sponge. In applying, it should be well rubbed into the paper so as to break up all clots. If the paper is very thick, and the prints large, it is well to coat the back twice before putting it on the mount.

TINTING MATT BROMIDES.—Can you kindly tell me of an aniline dye that I could use for matt bromides and platinotypes to give them the appearance of old engravings—I mean something that I could soak the prints in after drying to stain the paper the same pale yellow brown tone that old engravings have. I know there is something that will do it, because many photographers produce such pictures.—T. N. SELL.

We do not know of any aniline dye that will give the tint you desire. A weak infusion of coffee, however, will, and that is what is very generally used for the purpose.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

An exhibition of the results obtainable by the latest method in the mounting of photographic prints will open at the house of the "B.J." on Tuesday, August 3.

A French worker, M. G. Underberg, has recently given formulæ for the use of diamidophenol in the development of negative plates the exposure of which may or may not have been correct. He employs a minute quantity of hydroquinone as a preservative of the sodium sulphite solution. (P. 570.)

In an article on page 567 on the relation between the exposure when copying, the extension of the camera, and the distance of the source of light, some calculations are given with a view to systematising such work.

A new description of printing paper, just placed upon the market, is reviewed on page 578.

The opportunities for photographic trade in Turkey are the subject of an article on page 568 by Mr. Richard Thirsk.

A correspondent, Mr. H. Nolan, of Cairo, writes on page 583 outlining the various methods which may be adopted in the photography of finger-prints.

In "Wilson's Magazine" a writer describes a variation of the sulphide toning process, using a mixture of ammonium sulphocyanide and sodium sulphide as a toning-bath for developed bromide and gas-light prints. (P. 571.)

The first portion of a paper describing experiments on colour-sensitising gelatine emulsions with mixtures of dyes appears on page 572.

The use of the Metzograph screen, scum in the enameline process, non-warping mounting wood, and the rubbing-off of ink from proofs are topics dealt with under "Photo-Mechanical Notes." (P. 575.)

The old-established business of Shew and Co. has been taken over by Mr. W. J. Ramsey. (P. 569.)

Developing tanks for plates and roll-films figure under patents of the week. (P. 576.)

Some further notes on the practice of the albumen process are given in an editorial article on page 566.

EX CATHEDRA.

An Exhibition at the "B.J." House. Professional photographers in the neighbourhood of London, and those visiting the metropolis early in August, will, we

hope, make a note of the fact that from Tuesday, August 3, to Saturday, August 14, an exhibition will be held at the house of the "British Journal" of the results obtainable by the new method of mounting, embossing, and blocking in one operation, recently worked out by the late Mr. G. W. Morgan, of Aberdeen, and described on two occasions recently in our pages. Mr. John Morgan, a son of the deceased inventor, will also have a complete equipment for the process in working, and will demonstrate the manipulation and the methods of obtaining the great variety of results to visitors. The Morgan process representing the latest facility placed at the disposal of photographers in the way of mounting, it is thought that this convenient opportunity of examining the results and seeing the actual working will be taken by many of our professional readers, who will thus be able to secure full technical information at first hand. In addition, there will be on view during the fortnight an outfit of the mercury-vapour lamp for studio use, and those who may be interested in this form of studio light, and care to bring their own plates with them, may make and develop an exposure with the lamp.

* * *

Trade Journal Advertising. The current issue of "Printers' Ink," the journal of advertising issued by

Messrs. S. H. Benson, Limited, devotes much space to the use of trade journals by advertising firms. To it, Mr. W. J. Casey, the manager of the well-known enlarging and printing firm of Raines and Co., contributes an article recording the satisfactory results achieved by constantly changing announcements in the "British Journal of Photography." The optimistic terms in which the attraction of business by this means is described may be said to justify the heading to the article—"Raines and Co.'s trade-paper advertising brought results through painstaking and distinctiveness." We ought to say, in justice to Messrs. Raines, that these qualities in their advertising are quite part and parcel of their technical work for their customers. Were this not the case, we are sure that their weekly address to photographers from the pages of the "B.J." would not have led them to eulogise the results of their advertising in the way in which they have done.

* * *

Paris Hats in the Studio. In a recent article in the "Daily Chronicle" Mr. Elwin Neame has

declared that the tonic which he administers to a feminine sitter who "feels a fright" is not the illustrated papers, nor even a cup of tea, but the suggestion that she might care to try on one or two of the latest creations in hats. The pure joy of observing the latest Paris fashions crown-

ing her own figure is found to dispel the self-consciousness of the sitter as nothing else could do, and the photographer, according to the newspaper article, sees "a depressed and 'wooden' sitter rapidly transfigured into a radiant vision of ecstatic happiness."

* * *

Marking the Focussing Screen.

When a camera is used for a variety of work the advantage of changing the focussing screen is often very great. If, for example, we are making negatives from which lantern slides are to be made by contact, it is of very great service to use a screen upon which the exact size of a lantern plate is marked. Or, again, if we are reducing on a particular scale, it is very convenient to have a scale of inches marked on the screen. When a half-plate camera is used for stereo work a specially marked screen is practically essential, and we find it best for this purpose to block out all parts of the screen beyond the margins of a stereoscopic size plate. Such a screen is, of course, useless for ordinary half-plate work, and therefore it is essential to be able to change it readily. For general work, perhaps, the best kind of ruling is the simple division of the screen into squares of about one-quarter or three-eighths of an inch side. For copying purposes we can also mark on the screen in bolder lines the size of a lantern plate, but in practice we find this method rather unsatisfactory if the camera is over the quarter-plate size. We find it far better to mark out the area of the lantern plate with lantern binding strips stuck on the glass, and to keep this special screen for the purpose of lantern-slide making only. In general it is best to rule all screens in squares to facilitate the squaring up of the image on the plate, and to avoid any specially complicated ruling that is liable to be mistaken when focussing. If a whole plate screen is ruled so as to show various smaller standard sizes, it is extremely difficult at times to tell which are the right boundaries for the image, and any mistake is not detected until the plate is developed. In all such cases we prefer to mark the boundaries with broad lines of black paper blocking out the corners and sides, and to keep a separate screen for such sizes as are required.

* * *

Focussing Screens.

When using an anastigmat of an aperture under $f/7$ focussing is by no means as easy a proceeding as it is generally assumed to be, and, if tests are made on objects that will reveal lack of perfect focus, most people will be surprised at the poorness of the result. One cause of the trouble is the use of coarse ground glass focussing screens, many substitutes for which have been recommended from time to time in our pages. A very common cause is, however, want of register between screen and plate, and this is sometimes due, not to incorrect building of the camera and dark slides, but to the loose fitting of the ground glass. We have often been surprised to find new cameras fitted with screens that were so loose as to actually rattle when the camera was moved. In some cases the glass is kept up to the rebates by rubber pads inserted under the brass plates which hold it in place. This makes a rigid setting, but, unfortunately, a permanent one, and, as it may be necessary to remove the screen and reverse it for Autochrome work, or to change it for a fine grain screen, anything in the way of a permanent fixing is objectionable. It is rather curious that no camera makers seem to have yet realised the desirability of making the ground glass removable, nor the possibility of so fixing it by spring clips as to render it both removable and also rigidly in register. All our own cameras have had to be altered in this respect,

as we frequently require them for Autochrome work, and also very often want to change the screen, either for one with a different surface or one with a different ruling.

* * *

Photography and Libel. This week's Australian mail brings particulars of a novel action for libel which was heard at Melbourne recently. In March of the present year a fireman of the Melbourne Fire Brigade, and a labourer, were charged at the Police Court with having stolen goods from a place where a fire had been. The proceedings were reported at some length in the "Herald," an evening paper, and in addition the portraits of the two men were published in the midst of the report. They objected to this, and each claimed damages to the amount of £500, upon the ground that, although the "Herald" was within its rights in reporting the case, it was not protected by law when it went so far as to publish the photographs. The plaintiffs further claimed that they had a copyright in the photographs, inasmuch as they had paid a professional photographer for same, and nobody had a right to reproduce them without their permission. For the defence it was contended that the photographs were not defamatory—they were, in fact, excellent likenesses of the men. In regard to the copyright, the newspaper had obtained the photographs from the photographer, and it was argued that the plaintiffs had no copyright in them, even although they had paid for them. In the result the Judge held that the portraits were good ones, and that it was not libellous to publish same. With regard to the question of copyright, that claim would also fail, as the photographs had not been registered. The jury accordingly by direction found the verdict for the defendant newspaper as regards both men.

PRACTICAL NOTES ON ALBUMEN PAPER PRINTING.—III.

In the last article special attention was directed to the hygroscopic conditions of the paper at the time of printing, and the effect which this sometimes has on the resulting prints. We will add another note on this point, as it may be useful to those who have to work the albumen process in hot and dry climates. In America, where the atmosphere, as a rule, is much drier than here, most printers make it a practice to expose the paper, after sensitising and drying, to the fumes of ammonia before printing, as it is found that, thus treated, the paper tones better and with less tendency to mealiness. This method was tried by many workers in this country when it was first published now many years ago, and the general opinion was that no advantage was gained, and the results did not repay the extra trouble involved. It is quite conceivable that the fuming really has the effect of introducing a certain amount of moisture in the albumen, and in this way brings it more into the condition which would be the normal if it were dried in our more moist atmosphere. The fuming however, may be a distinct advantage when working in exceptionally hot and dry climates. It is a simple operation, and involves but little trouble. A cupboard with a well-fitting door, or a box large enough to allow of the sheets of paper to be suspended some distance apart so as to permit the fumes of ammonia to act uniformly on all answers the purpose quite well. When the sheets are all hung up, a dish or saucer containing three or four ounces of liquor ammonia is placed at the bottom. About a quarter of an hour suffices for the fuming. Under any circumstances, paper containing an acid as a preservative will be benefited by the fuming, as then there will be less difficulty in obtaining the deeper tones.

In the previous article formulæ were given for some of the more generally used toning baths. We will, however, repeat one that was given a few months back, as it is one

that will yield purple or black tones, and is very convenient in use. It stands thus:—

Chloride of gold	15 grs.
Water, distilled	15 oz.
Lime water	q.s.
Chloride of calcium (pure)	120 grs.

The solution is prepared as follows:—The chloride of gold is dissolved in three or four ounces of the water. A strip of blue litmus paper is then dropped in, and is reddened by the acid in the gold. Lime water is then added by degrees until the blue colour of the paper is just restored. The chloride of calcium is next added, and the bulk made up to 15 oz. Each ounce of this stock solution contains one grain of chloride of gold. For use, one ounce is taken and diluted with eight or ten ounces of water. This will be sufficient to tone a full sheet of paper (22 in. by 17 in.) to a good purple. One of the advantages of this bath is that it can be kept as a stock solution, if preserved from light, for many weeks. Another is that more stock solution may, if required, be added direct to the bath while in use, without fear of mealiness, as in the case of the acetate bath.

We shall now proceed with the work of toning. The best light for the purpose is subdued daylight, but it must be very subdued at this time of year, otherwise the lights of the pictures may be degraded. A professional of our acquaintance who daily produces large numbers of albumen prints always tones by the light of a large paraffin lamp with an Argand burner, since he finds that after practice he can get more uniform tones than by daylight. The free nitrate of silver having been washed out of the prints, the toning solution is poured into a chemically clean dish, which, by the way, should be kept exclusively for toning purposes. If a large number of prints have to be toned it is well to use a bath a little more dilute than is given in the formulæ, as then uniform tones throughout the batch will the more easily be secured. The prints should be introduced into the bath one by one, keeping them in motion by continually turning them over and over. It is well not to put in more than ten or a dozen at the commencement, as with them the toning will proceed rapidly. As soon as, or a little before, the desired tone is obtained, the prints are transferred one by one to a dish of water under a running tap, in order to stop the toning. As just remarked, the first lot of prints will tone quickly, and the one must be judged by looking down on the print, and not through it. The prints, particularly the earlier ones, should be removed a little before they have got to the required tone, for it must be borne in mind that they dry up somewhat darker than they appear in the toning solution; also, that the toning goes on, more or less, in the washing water, so long as any trace of the bath remains in the paper. This continuing action may be arrested by first rinsing and then putting the prints into a dilute solution of salt and water, in which they may remain until they are transferred to the fixing solution.

As the bath becomes reduced in gold its action becomes slower, consequently more prints may be dealt with at a time—say, a couple of dozen or more in experienced hands. Should a variety of tones be required to suit different customers, the prints should be sorted out, and those that are required to be the most purple should be the first toned, for the reason that with a bath rich in gold the purples are more easily obtained. A long immersion in a weakened toning bath does not give the same results as those produced by a short time in a bath containing the full strength of gold. Hence when warm browns are necessary those prints are the last that should be dealt with. Such tones will then be the more satisfactorily ob-

tained than if the prints were the first to be put into the solution.

Something should be said with reference to the temperature of the toning bath; the best is from 60 deg. to 70 deg. F. If it is much below the former, the toning will be slow, and if much above the latter it will be more or less rapid, but the results in the end will not be the same. A print that is toned in a bath at high temperature will quickly colour on the surface, but when the picture is finished it is often found to be of a warmer tint than was expected, whereas one that has been toned at a low temperature will take a longer time in the bath, but when it is finished it will probably be of a darker tone than was anticipated.

In the foregoing articles various formulæ have been given for toning baths which, within certain limits, will yield different tones. But we may here reiterate what has frequently been said in these columns, namely, that the tone and character of the print depend more upon the negative from which it is made than upon the formula by which the toning bath is compounded. With negatives of a feeble character it is impossible to obtain rich purple or black tones, whatever toning bath we may employ; but with those of the opposite type it is easy to obtain such tones with almost any of the baths of the formulæ given in this and previous articles, while at the same time any of them will give warm or reddish browns, whatever be the character of the negative, provided that it is not an exceptionally feeble one. Therefore, when rich and strong tones are not obtained, the negative is most probably the reason. In connection with the colours obtainable on albumen paper, it may further be said that with most of the highly glossy ones—such as the double albuminised—it is next to impossible to obtain the same deep purple or black tones as are to be got on less glossy varieties, no matter what may be the formula used for the toning solution.

EXPOSURE IN COPYING.

A LETTER by Mr. Douglas Carnegie in this issue, while correcting a statement in his article on "The Preparation of Lantern Slides Direct in the Camera," also draws attention to some points concerning exposure in copying that are certainly worth further consideration. It is customary always to consider the illumination of the copy to be a constant quantity, but when working by artificial light it is, of course, not so unless the distance between copy and light is always the same. If we focus by adjusting camera only, leaving the copy and easel stationary, then the illumination is constant, in which case exposure is always proportional to the square of the distance between plate and lens. In these circumstances the smaller the scale of reduction the shorter is the exposure. Therefore if we move the light farther back from the copy, and so reduce the illumination upon it, we can arrange matters so that the exposure required for one scale is precisely the same as that required for another. It is fairly obvious that if with constant illumination exposure is always proportional to the square of the distance between plate and lens, then exposure must become constant if we vary the distance between light and copy in inverse proportion. This, of course, means that the distance between light and copy must be varied for every change of scale. The problem of how the apparatus should be adjusted so as to preserve constant exposure is interesting, but the solution adopted by Mr. Carnegie does not strike us as sufficiently exact to be generally useful, excepting, perhaps, in the preparation of negatives of black and white diagrams.

The figures that he gives show that the plate is over-

exposed for scales of half and one-third full size, and slightly under-exposed for a scale of one-fifth full size, the nearest approach to accuracy being obtained with the scale of one-quarter full size. His figures show the relative degrees of over- and under-exposure, but perhaps the facts involved will become clearer if we note the true exposures required in each case to produce equivalent results in all when the light is arranged by his method. These are given in the following table, where 10 seconds is assumed to be the correct exposure for a scale of full size:—

Scale.	Exposure required.
Full size	10 seconds.
$\frac{1}{2}$	7.1 "
$\frac{1}{3}$	7.7 "
$\frac{1}{4}$	9.53 "
1-5	11.65 "

The inequality of these exposures is due to the fact that the light is only at the right distance (as determined by the rule given) in the one case when the scale is $\frac{1}{4}$. In the two preceding cases the light is too near, and in the last it is too far away. The following table shows the actual distances of light from copy, and also the distances at which it should be to secure constant exposure, assuming a 10in. lens to be used:—

Scale.	Light from copy		Percentage error.
	(actual distance). Inches.	(proper distance). Inches.	
full size	40	40	—
$\frac{1}{2}$	45	$53\frac{1}{3}$	—15
$\frac{1}{3}$	53	60	—11.6
$\frac{1}{4}$	$62\frac{1}{2}$	64	— 2.34
1-5	72	$66\frac{2}{3}$	+ 8

The last column gives an idea of the amount of the error

in each case from the true distance that will give equivalence of exposure.

If we bear in mind the fundamental rule that exposure is constant so long as the distance of the light from copy varies in inverse proportion to the distance of plate from lens, it is easy to draw up a table of the adjustments required to always preserve constant exposure for a given lens and stop. In general it will be convenient to consider the position of the light to be fixed, and the extra adjustment for any particular scale will then only involve a shift of the easel carrying the copy.

Suppose, for example, our standard exposure is ascertained for a full-size reproduction, with light 5ft. from the subject. To copy on any smaller scale we must first run the easel back for the distance given in the following table, and then adjust camera to give the right-size image:—

Scale.	Movement of easel. Inches.
Full size	—
$\frac{1}{2}$	20
$\frac{1}{3}$	30
$\frac{1}{4}$	36
1-5	40

It will be noticed that as the reduction becomes greater the alteration in position of screen becomes less. A range of 49in. will just be enough to enable us to preserve constant exposure for a series of scales from full size down to one-tenth full size. The calculations are very simple. The distance of the light is in all cases inversely proportional to distance of lens from screen, the latter distance being two focal lengths when copying full size. To copy, say, one-eighth full size the distance from lens to screen must be $1\frac{1}{8}$ focal lengths, which is 9-16ths of two focal lengths. Therefore, the distance of the light from copy must be increased by multiplying it by 1 7-9. Assuming the original distance to be 5ft., then the easel must be moved back 7-9ths of 60in., or 47in.

BETTER PROSPECTS FOR PHOTOGRAPHIC GOODS IN TURKEY.

THERE are various signs and indications that Turkey is at last beginning to settle down after the troublous experiences through which it has passed during the last few months. In the course of this time it has passed through a revolution in more senses than one. Its business methods, influenced most probably by the forward action in Government circles, have undergone a radical change. This has been accomplished silently, yet none the less effectively. The commercial men of the country have been roused out of their proverbial lethargy, and are beginning to realise more keenly than ever before the prospects which lie before them. They now see that even in the Levant the old conditions are no longer possible, and the various influences that are being brought to bear upon them on all sides make it no longer possible for them to exist, if they persist in adhering to their old custom of doing business in a half-hearted manner, as though it made no difference to them whether or not they bought and sold. The importation of Western methods has taught them a valuable lesson, so that they are now taking a leaf out of the book of their more successful neighbours, and are introducing more up-to-date and progressive methods. The various changes taking place in the life of the waking Near East have also their accompanying good influence on the trade of the various countries, and it is just possible that the recent boycott of Austrian goods has not been without its good effect for the other nations.

One of the most hopeful signs of this awakening is the spirit of enterprise which is increasingly shown among the native agents and dealers. Many of them have the ambition to make themselves more independent, and are desirous of extending their capacities and energies. They are much more liberal than formerly, being more willing to listen to the foreigner who brings to them what they want; and what is of infinitely more importance is that they are showing a growing tendency to invest their money in such articles. That this struggle for independence, and with it the courage to launch out upon new enterprises, is becoming general, is proved by the fact that many genuinely Oriental houses, which were at one time in the habit of conducting all their transactions with European markets exclusively through the large European houses already established in the Orient, are now departing from this rule, and are finding it much more to their advantage to deal with the manufacturers or exporters direct. Those who are best acquainted with the situation are of opinion that Turkey is now on the threshold of a period of progress and of commercial activity, to which it will settle down in earnest as soon as the Powers have agreed among themselves to clear up the political situation in the Near East, settling for the time being the rumours of war.

There can be little doubt that the imports of photographic goods into Turkey will enjoy a fair share of this increasing

prosperity, and manufacturers desirous of extending their trade to that country would be well advised to take advantage of the present opportunity, and lose no time in getting into the field. Foreign manufacturers, especially Germans, are anxiously watching the situation, and are already making preparations to carry on an extensive propaganda, from which they expect to reap rich rewards. America is also well represented, and the competition promises to be so keen that British manufacturers cannot afford to be idle if they are to hold their own. Happily British goods are already widely known, and have always enjoyed a good reputation in Turkey. Manufacturers should not fail to take every advantage of this circumstance, sparing no pains to improve on the lead which they have thus secured for themselves. The fact that Turkey is not likely to undertake the manufacture of her own photographic goods for many years to come should prove a still greater incentive to the immediate opening up of business relations with her agents and dealers. There is every probability that those who succeed in getting a hold of the markets now will contrive to keep them for a considerable time to come.

Another happy augury for business with Turkey is the promise that in the near future something is to be done towards simplifying the customs arrangements of the country, and to place these on a more reasonable footing. It is almost certain that before long the stupid conditions will be abolished which made possible the comic-opera incident to which we gave publicity in these columns some time ago, when the Customs officials, disregarding instructions, ruined a whole consignment of plates and films by examining them in the sunlight!

While encouraging British manufacturers and exporters to take full advantage of the more favourable conditions obtaining in Turkey, it may be as well at the same time to warn them of the danger of neglecting the customary business precautions before opening new accounts. In a land where the import trade is conducted mostly by Armenians, Syrians, Arabs, and Greeks, as well as by the native Turks, it is probable that some unscrupulous dealers may not be strictly honest in their transactions, and at any rate, little harm can be done by practising the old proverb and take every man for a rogue until you find him out to be otherwise. It is this feeling of uncertainty that has caused most manufacturers and exporters to limit their business relations with the Orient to dealings with the European houses already established there. But this is a mistake, since most of these houses have their old-established sources of supply, and are generally so conservative that it is no easy matter to persuade them to change these. Besides, it is the object of this article to show that the Turkish trade is now flowing into other channels, and that exporters are likely to gain more by avoiding these middle-men and dealing direct with the smaller traders.

In order to accomplish this it is necessary to study the markets, and to master their peculiarities. This presents few difficulties, for the importer is assisted and advised by the well-arranged and splendidly organised Consular Service. Importers do not always take advantage of the information which may be had on application to the Consul, who is generally so well instructed concerning the financial position of the traders that he can at once tell whether or not the latter is safe, so that importers need not run any undue risks. In no other country does the Consul exercise so much power as in Turkey, and

because of this it is certainly the safest country in the Orient with which to do business. The Consul's help is invaluable, especially as he acts on occasion as a sort of intermediary between the exporter and the importer. If the latter has any doubt concerning the honesty of a firm ordering goods from him he need only put this to the test by making it a condition of delivery that the goods must be first paid for, the money being handed over to the nearest British Consul. At the same time the Consul should be advised of this condition so that he may know how to act in the circumstances. Most honest firms are glad to take advantage of this easy method of settling their accounts, while the firms which may not be altogether straightforward find themselves in an extremely awkward position, since, because of the extraordinary power which the Government of the country permits him to exercise, the Consul is greatly feared because of the damage he can do such firms.

It is the duty of Consuls to collect such information as may lead to advantageous trading relations between their respective countries, and the home authorities are yearly bringing more pressure to bear upon British Consuls to do their utmost in this respect. Because of the difficulties arising out of the difference between Western and Oriental business methods, and because of the changing financial condition, the Consuls are instructed to keep a sharp eye on all the business done within their districts. It is also one of their duties to investigate the condition of all importing houses, work in which they not only have great experience, but also have at their command invaluable sources of trustworthy information from which private persons and even the information offices are excluded. Consequently one is always safe in applying to the Consul for addresses of reliable houses, and as it lies in his interest to assist and increase the commerce between Turkey and his own country he may be trusted to do his best to prevent losses or swindles. It is of the greatest importance when making application to the Consul to state clearly to him that what is wanted is the addresses of reliable native traders, and not those of British firms, which latter may be found in any trustworthy commercial directory. Those manufacturers intending to do business with Turkey, and it is hoped that many will be encouraged to do so, may gather from these addresses some idea of possibilities of doing business. The next step is to visit prospective customers. Trade with the Orient by means of correspondence is now practically impossible since so many commercial travellers have come into the field, and the sending of catalogues or samples merely represents so much wasted money, as even if these do bring in replies, they seldom lead to business. Most trade is done by personal representation, and the representative need not necessarily be a man who speaks the language of the country, though that is a decided advantage, and has a magic effect in encouraging confidence in him. As a rule, the Consul has the names of suitable interpreters whom he can recommend for the special work they are required to do. Another thing of the very greatest importance is to quote the prices in Turkish money, as the Oriental does not care to worry himself over equivalent values. Any drawback there may be in this is more than compensated for by the fact that in the end it generally works out to the advantage of the exporter. Bill-headings should be printed in Turkish as well as in English, and it is strongly advisable to follow the same rule in regard to price-lists.

RICHARD THIRSK.

SHEW AND Co.—This old-established business, which for many years past has made a specialty of the manufacture of reflex and other hand cameras, has just been taken over by Mr. W. J. Ramsey, known no doubt to many of our readers as a former manager of the photographic department of the Army and Navy Stores. A recent call paid by a representative of the "B.J." to

88, Newman Street showed us that those requiring any photographic apparatus, and particularly advice and assistance as to the choice of a hand camera, will receive every attention and courtesy from Mr. Ramsey, whose intimate knowledge of the photographic trade is willingly placed at the disposal of his customers.

FURTHER NOTES ON ACID DIAMIDOPHENOL DEVELOPER.

[In a series of articles appearing in the "Photo-Revue," the diamidophenol developer, attention to which has been drawn chiefly in France by M. G. Balagny. We give below a translation of portions of M. Underberg's communication, and would refer those who would compare the present formulæ with those previously given to the abstract of M. Balagny's paper given in the current "B.J. Almanac," page 573.—Eds. "B.J."]

THE chief ways in which contrast may be obtained with the acid diamidophenol developer are by addition of sodium bisulphite; by increase of the diamidophenol, or, which comes to the same thing, by decrease of the proportion of sodium sulphite; by the addition of potass. bromide, and by employing a stronger developing solution. The normal formula for diamidophenol developer is as follows:—

Diamidophenol5 gm.
Sodium sulphite, anhydrous	3 gms.
Water to make	100 ccs.

The action of bisulphite is a restraining one; it increases the time of development, and, moreover, destroys part of the colour-sensitiveness of orthochromatic plates, so that a more comfortable light may be used towards the end of development: it also has a beneficial action on the gelatine of the plate. Those who are unable to obtain bisulphite conveniently may use in place of it a mixture of sulphite and sulphuric acid, adding 5 drops of strong acid to 1 gm. of anhydrous sulphite of soda dissolved in water. This will be approximately equal to 2 ccs. of 40 per cent. commercial bisulphite solution.

Reduction of the quantity of sulphite of soda reduces the energy of the developer. Potass. bromide only makes its influence felt when used in comparatively large quantities; when used in small doses it acts simply as a preventive of fog.

Developers for Contrast and Softness.

Upon these facts may be based the formulæ for two-solution development. In order to simplify this latter I have taken as the standard quantity of diamidophenol a $\frac{1}{2}$ gm. ($7\frac{1}{2}$ grs.), corresponding to a mustardspoonful of the compound, and sufficing for the development of a dozen quarter-plates. A series of trials has resulted in a bath which gives the maximum of contrast. For $\frac{1}{2}$ gm. of diamidophenol a maximum quantity of bromide, which has no injurious effect, is $\frac{1}{2}$ gm.: the minimum quantity of sulphite which, according to MM. Lumière, does not give rise to dichroic fog, is 2 gms. I have found that when using bisulphite this quantity can be further reduced to 1.6 gm. Lastly, the quantity of bisulphite liquor which may be introduced to restrain the action of the developer and to avoid dichroic fog is 10 ccs. The maximum concentration of developer is 100 ccs., and we thus get the following formula when contrast is required or when dealing with over-exposed plates:—

Soda sulphite	1.6 gm.
Diamidophenol5 gm.
Bisulphite liquor	10 ccs.
Potass. bromide5 gm.
Water	1,000 ccs.

In compounding a bath to give the maximum of softness, one is wanted containing a full proportion of sulphite, no bromide (or enough only to avoid veil), no bisulphite (or very little, enough only to restrain the action of the bath), and, finally, a greater degree of dilution. On this basis the following formula may be used for obtaining very soft results:—

Soda sulphite, anhydrous	6 gms.
Diamidophenol	$\frac{1}{2}$ gm.
Bisulphite liquor	16 drops.
Potass. bromide, 10 per cent. solution	8 drops.
Water	250 ccs.

Moreover, in the normal formula, which answers very well for bromide and chloro-bromide papers, enough bisulphite is

given to restrain the speed of development, but the small proportion of bromide necessary for avoiding veil is not enough to lead to hardness of the results. Thus the normal acid formula is:—

Sodium sulphite, anhydrous	3 gms.
Diamidophenol	$\frac{1}{2}$ gm.
Potass. bromide, 10 per cent. solution	2.7 ccs.
Bisulphite liquor	5.3 ccs.
Water	100 ccs.

Preserving Stock Solutions.

Having worked out these formulæ, means were taken to obtain solutions which remain in good working condition for a long time. M. Papazoglou, in a recent issue of the "Photo-Revue," has already recommended sugar and alcohol in addition to bisulphite; but I have found that sugar is of no use for this purpose. Acid diamidophenol keeps very well in normal solution; the more concentrated baths do not keep as well, as will be seen from the following experiment with bottles of developer numbered 1 to 4.

Solution.	Kept in corked bottle partly filled.	Kept in full corked bottle.
Normal solution of acid diamidophenol	1	2
Normal diamidophenol solution to which was added 10 ccs. of 90 p.c. alcohol	3	4

At the end of fifteen days' exposure to light and sun bath No. 1 had a strong yellow colour, but could still be used. Bath No. 2 was yellow, but of less depth. Bath No. 3 was almost colourless, and No. 4 absolutely so. The baths were made up with the greatest care, water freed from air by boiling being employed. From this it will be seen that if it is wished to prepare the solutions a considerable time in advance it is sufficient to add 10 ccs. of 90 per cent. alcohol to each 100 ccs. of the bath. But since the working solutions themselves may be so readily made up by the method given below, there would seem to be no great reason for going to the expense of the alcohol. Still, any method of securing the good keeping qualities of the bath deserves to be mentioned—namely, that discovered by MM. Lumière, and consisting in the addition to the sulphite solution of a small quantity of hydroquinone. This latter mixture forms a practically permanent solution.

The following are the stock solutions to be made up:—

B.—Boiled water	100 ccs.
Potass. bromide	10 gms.

This 10 per cent. solution of bromide keeps indefinitely without spécial precautions.

BB.—Solution B	50 ccs.
Bisulphite liquor	100 ccs.

This keeps well for several months in closed bottles, but there is no object in preparing more than 150 ccs. at a time.

S.—Soda sulphite, pure, anhydrous	20 gms.
Hydroquinone1 gm.
Water, boiled, hot	100 ccs.

Add the sulphite to the freshly boiled water, stirring well; then add the hydroquinone, filter, and keep in stoppered bottles of 100 ccs. capacity. I find it convenient to make up 300 ccs. altogether (3 bottles), which quantity will keep for, at any rate, three months in regular use without appreciable alteration.

Development of Plates and Films.

Diamidophenol made up with acid sulphite is a perfect developer of all brands of plates, both extra rapid and orthochro-

natic. It is a developer which never gives fog nor stain, and possesses great latitude in use as regards the degree of contrast or softness which may be obtained with it, always assuming that development is thorough. This latter is an absolute essential in the use of the developer; and those who have not obtained satisfaction in the use of diamidophenol may be pretty certain that their failure has arisen from negligence in this matter. With almost all the brands of plates the image should appear quite distinctly on the back of the plate. Developing in this thorough way, up to the point when the image commences to veil over, there are obtained excellent negatives, the slight veil which appears towards the latter part of development completely disappearing in the fixing bath. The tendency when commencing the use of the developer is to stop development too soon. In the case of those who employ the two-solution method given below, over-development will not do any harm, whilst curtailed development leaves the negative without its full detail and brilliancy. The following is the method of working the two-solution system. Two developing baths are prepared as follows:—

- A.—For over-exposure: gives hardness.
- | | |
|---------------------|----------|
| Solution S | 8 ccs. |
| Diamidophenol | .5 gm. |
| Solution BB | 15 ccs. |
| Water | 100 ccs. |
- B.—For under-exposure: gives softness.
- | | |
|---------------------|-----------|
| Solution S | 30 ccs. |
| Diamidophenol | .5 gm. |
| Solution BB | 24 drops. |
| Water | 250 ccs. |

The negative is first placed in A. If at the end of 3 to 5 minutes no image has appeared, it is placed in bath B, and carefully watched. If the image on its first appearance shows a tendency to flatness and insufficient contrast, it is at once placed in bath A. If, on the other hand, it appears vigorous without detail, it should be left in B until it has acquired the necessary

softness. The plate is thus transferred from A to B, and inversely, according to the result desired, in either case being developed through to the back. Care is necessary to work in a perfectly safe light, and to avoid removing the plate too frequently from the developer: with some practice it is quite easy to judge of the thoroughness of development by reflected light whilst the plate is lying in the dish. After development the plate is given a good rinse and fixed in a bath of hypo made up as follows:—

Hypo	250 gms.
Bisulphite liquor	30 ccs.
Salt	20 gms.
Water	1,000 ccs.

It is well to keep two baths going, allowing the plate to remain in the first until all the white silver bromide has disappeared, and then to give a further five minutes in the second solution.

Stand Development.

Although the present writer is not particularly in favour of stand development with the plates in a vertical tank, for the reason that a developer which acts too slowly is inferior in its results, stand development in which the time does not exceed from twenty-five to fifty minutes gives the best results, and though the two-solution method given above is recommended in preference to any other, the following procedure may be of advantage when a large number of plates are to be developed. The bath A given above is made up, and water added to make a litre altogether. The negatives are placed in this weak bath, and at the end of five minutes one or two plates taken out and developed by the two-solution method already given. By the time these two plates are developed others will commence to appear in the stand solution. A second two, those which have come up the most, are then taken and developed in the two solutions, this method being followed until the whole batch has been got through.

G. UNDERBERG.

TONING DEVELOPED PRINTS.

[In a recent issue of "Wilson's Magazine," the following modifications of the familiar method of sulphide toning are recommended by an anonymous writer.—Eds. "B.J."]

THE desire to obtain colours other than those given by developing *per se* has led the manufacturers and users of bromide and so-called gaslight papers to resort to different methods. Of the many methods used, the one that has found the greatest application is the so-called sulphide method, of which the Velox developer may be taken as a good example. Sulphide tones properly made are permanent. Sufficient time has elapsed since their introduction to thoroughly prove this. Facility of production is also in their favour. The tones are, however, not very varied, nearly always being some shade of sepia. Experiments to obtain some other permanent sulphide tone were made by the writer with what appeared to him to be a fair degree of success. It was found when finished prints made on Velox and Lepera bromide paper (I mention these papers because my experiments were confined to them) were immersed in a solution of ammonium sulphocyanide and sodium sulphide a good purplish tone, very often equal to a gold tone on printing-out paper, was obtained.

The following formula has proved the most satisfactory of any tried:—

- A.—Ammonium sulphocyanide
- | | |
|---------------------|---------------|
| | 8 ozs. |
| Water to make | 16 fluid ozs. |
- B.—Sodium sulphide (crystals)
- | | |
|-------------|-------------------|
| | $\frac{1}{2}$ oz. |
| Water | 3 ozs. |

Following are condensed instructions for its use:—

BATH No. 1.

Solution A	1 oz.
Water	3 ozs.
Solution B	1 dr.

Mix just before toning.

Immerse the fixed and washed (and perfectly dried) print. The toning action begins almost immediately, ranging through the purple tones first and then into the sepias.

Allow the print to remain in the toner until the desired colour is reached, then wash fifteen minutes in running water and dry as usual. With the bath at 70 deg. to 80 deg. F., prints will tone in from fifteen to forty minutes; at 90 deg. to 100 deg. F., five to fifteen minutes will suffice; but it is not advisable to use the bath at a higher temperature than 100 deg. F., owing to its softening action on the film. Prints developed with Velox N. A. developer tone quicker than prints developed with ordinary developer.

The rapidity of the toning may also be increased by adding more of solution B, but not more than 1 drachm should be added to the original solution at one time, as this would render the bath too alkaline, and soften the film. It works best when freshly mixed, and after forty minutes or so more B solution may be added. The old bath may be kept for future toning, but before use it should be filtered or decanted to remove the

white precipitate formed, and fresh B solution added, but it should be discarded when it becomes so alkaline as to affect the film.

It will be found that the toning is influenced somewhat by the character of the negative used, different degrees of density in the negative affecting the silver deposit on the print and the subsequent action of the toning solution. It will also appear that matt papers tone more readily than the glossy, and that purple tones are easiest secured on glossy papers. It must be confessed that the laws governing the action of this bath are not as thoroughly known as could be desired. Sometimes it will work quite rapidly, and again, under apparently the same conditions, it works much slower.

An Alternative Formula.

Further experiments have shown that its certainty of action could be greatly improved by mixing with it hypo alum toning solution, made according to the following formula:—

C.—Hypo	10 ozs.
Water	50 ozs.

Heat to boiling, and add

Powdered common alum	2 ozs.
----------------------------	--------

Allow to stand until cold. It improves by standing.

BATH No. 2.

A	$\frac{1}{2}$ oz.
C	$\frac{1}{2}$ oz.
Water	3 ozs.
B	1 dr.

When B is added the solution is clouded by the precipitate aluminium hydroxide. This precipitate does not interfere with the toning action.

This latter bath (No. 2) yields tones equal to, and quite often superior to, the former bath (No. 1).

It also smells more strongly of hydrogen sulphide, and it is not advisable to use it where the ventilation is poor. As its action ceases more of B can be added. The latter bath has also better lasting qualities. I have known it to tone without adding an additional quantity of B after it has stood over-night.

An Improvement to Sulphide Tones.

Prints from some negatives when bleached and redeveloped with sulphide solution sometimes incline more to the yellow

than is desirable. Having ascertained this fact, colder tones can be obtained on subsequent prints to be toned by using bath No. 1 as a preliminary bath. How long the print should remain in bath No. 1 cannot be stated with exactness, as there are several factors to be taken into consideration; chief among these are (1) how much the colour given by the bleach and redeveloping method differs from the desired colour; (2) how fresh bath No. 1 is. The fresher the bath the quicker it works. Other things being equal, the longer the print remains in bath No. 1 the colder the tone. In a freshly prepared bath at the ordinary temperature even fifteen seconds is enough to effect a change in colour in the finished print.

As a general thing, any immersion—even one falling far short of the time necessary to produce a visible effect—is quickly made apparent by the print refusing to bleach as much as it would have done were it untreated when placed in the bleaching solution. Prints should be well washed before placing in bleaching solution, and should remain in it from five to ten minutes, or until it is certain that the bleaching is completed. After bleaching, prints should be rinsed free from bleaching solution, and redeveloped as recommended in the Velox developer instructions.

What chemical reactions take place in what I would call the sulphide sulphocyanide method of toning I have not investigated far enough to state.

However, hydrogen sulphide is released, and this in its nascent condition no doubt has power enough to attack the silver of the image. It is also certain that other reactions have an effect, for if the ammonium sulphocyanide is replaced by an equal weight of the potassium salt the toning action is very much slower.

To the question, Why does this method give a different colour from that obtained by simple bleaching and redeveloping with sulphide solution? it might be answered: Because the conversion of the silver is not so complete as in the latter process. In reply I would say that it would be hard to imagine the colours obtained on some prints as resulting from a combination of sepia and black.

As they are, the processes described are practical, but there is room for improvement.

MIXTURES OF DYES AS SENSITISERS OF GELATINE PLATES.

[The following is an abridged translation of a thesis by Guido Daur, presented for the degree of Doctor of Philosophy at the Münster University. The experimental work was done on the suggestion of Professor Miethe, to whose colleague, Dr. E. Stenger, the author of the papers renders his thanks for much advice and assistance. The full text of the paper occupies a book of 105 pages, published by E. Grieser, Frankfurt a/M.—Eds. "B.J."]

In making the following experiments as to the mutual action of dyes when used in admixture for the colour sensitising of gelatine plates or emulsion, it was suggested by Professor Miethe that the experiments should be made with a view of deciding the following points:—

1. The mutual influence upon each other of two dyes when used in solution as a sensitising bath for gelatine dry plates.
2. Is this influence completely regular or does a given dye, when in combination with another of the same class, follow a distinct rule?
3. If so, can this rule be held to apply for mixtures of dyes of different classes?
4. Or do variations occur which are not observable when dyes of the same class are being used?

The following dyes were selected for the experiments:—

- Group I., Eosines.—(a) Aureosin = Dichlorfluoresceïn.
 (b) Eosine = Tetrabromfluoresceïn (Eosine A).
 (c) Erythrosine = Tetraiodofluoresceïn.
 (d) Rose Bengale = Dichlortetraiodofluoresceïn.
- Group II., Isocyanines.—(a) Ethyl red nitrate = Chinolinlepidin-ethylcyaninenitrate.
 (b) Pinaverdol = *p*-Toluchinaldinchinolinmethylcyaninebromide.
 (c) Pinachrome = *p*-Ethoxychinaldin - *p* - methoxychinolinaethylcyaninebromide.

(d) Isocol, a mixture of different isocyanines, the composition of which has not been published.

(e) Pinacyanol is not a genuine isocyanine, but, according to the patent specification of the Hoechst Dye Works, results from the action of alkali on a solution of chinaldinium salts to which formaldehyde has been added.

Group III.—Cyanines.—Dicyanine obtained by the action of caustic alkalies on an alcoholic solution of dimethylchinolinium.

Finally, three further representatives of the dyes hitherto regarded as of service only for very weak sensitising were examined in admixture with a dye possessed of normal sensitising powers. The cyanines are:—

1. Isochinoline-red.
2. Glycin-red, sodium salt of benzidindisazo, α naphthylglycin-*i*-naphthylamin-4-sulfonic acid.
3. Formyl-violet, sodium salt of tetraethyl-dibenzyl-*p*-rosanilindisulfonic acid.

Method of Working.

The spectrographs were taken with a Thorpe replica of a Rowland grating of 15,000 lines per inch, provided with an opening of 50 mm. The first order spectrum had a length of 29 mm. for 100 $\mu\mu$ —that is to say, 3.5 $\mu\mu$ occupying 1 mm., or 1 $\mu\mu$ = .29 mm. The apparatus

as so arranged that the whole visible spectrum from 350 to 750 would act on the plate. The width of the slit was .06 mm., and the distance from the light to the slit 10 cm.

The apparatus was prepared for the plotting of the spectrum by taking photographs on a panchromatic plate of the spectra of mercury (with a mercury-vapour lamp), of magnesium (by burning magnesium ribbon), and of sodium (by means of a Bunsen flame, coloured with lit). The following lines were thus registered on the plate:—

Na	Hg	Hg	Mg	Mg	Hg	Hg	Mg.
589	579	546	518	500	436	408	405

The positive transparency having been made, the divisions corresponding to wave-lengths, from 10 to 10 μμ, were ruled on one side of the plate, and those from 25 to 25 μμ on the other side by means of a dividing engine.

Densities were measured with the Marten's polarisation photometer, in using which a small piece from the edge of each plate to be measured was cut off and introduced into the direct beam of light. This plan thus gave a means of reading the absolute densities.

The light-source used was a Nernst lamp, placed on a circuit of 110 volts, with the filaments parallel to the slit of the spectrograph, and at a constant distance of 10 cm. therefrom. Plates 9 x 12 in. were used, 16 spectra being taken on the one plate. Of these sixteen were of the same spectrum, produced with different times of exposure. The top and bottom spaces were used for recording the magnesium spectrum on which, by means of the above described wave-length plate, the wave-lengths for each plate exposed could be scratched with a fine needle. Within the region 350 to 500 the density was measured every 25 μμ; from 500 onwards every 10 μμ the region required for the measurement of the density covered only 7 μμ. In all the experiments the plates used were the Perutz, of sensitiveness 11 Scheiner.

Sensitising was done in complete darkness, at a temperature of 66 F. As a rule, the plates were bathed for three minutes, being kept in constant motion; in cases where a different time of sensitising was adopted a note is made to the effect. The plates were dried at a temperature of 82 F. in an apparatus arranged as follows:—

A current of air was first led through a refrigerator at freezing point, thus depositing its moisture. It was then drawn through heating tubes entering the drying cupboard at a temperature of 82 F. This arrangement allowed of plates drying in half an hour.

The developer used throughout was edinol, prepared according to the following formula:—

A. Edinol	25 gms.
Sodium sulphite	250 gms.
Water	2,500 gms.
B. Potass carbonate, dry	300 gms.
Water	600 gms.

A and B were mixed shortly before use, and used at a temperature of 66 F., the time of development being 150 seconds. After a short time the plates were fixed for ten minutes in an acid bath.

Sensitising Experiments.

Sensitising in every case was done in baths, which contained as much of the dye solutions of each sensitiser employed as would have been necessary had each dye been employed alone. In most cases the composition of the bath was fixed quite empirically.

Whilst the eosine dyes, when in admixture, gave practical results, such was not the case with the isocyanines. Since good success had been obtained with pinacyanol and dicyanine, combined with homocol, according to Monpillard's formula, an attempt was made to combine the still better sensitiser, isocol, with these two dyes. However, isocol and dicyanine used together gave fogged plates. The bath used had the composition:—

Dicyanine solution 1:1,000 alcohol	3 ccs.
Isocol solution 1:1,000 alcohol	2 ccs.
Alcohol	50 ccs.
Water	100 ccs.

After three minutes' bathing the plates were washed, also for three minutes, in running water and put to dry. The developed and fixed

plate showed dense uniform fog. The following sensitising in separate baths was then tried:—

A. Isocol solution 1:1,000 alcohol	2.5 ccs.
Ethyl-alcohol	2.5 ccs.
Water	1,000 ccs.
Ammonia	1 cc.
B. Dicyanine solution	3 ccs.
Alcohol	50 ccs.
Water	100 ccs.

These formulæ are those found suitable for the respective dyes. A plate was given three minutes in A, two minutes in running water, three minutes in B, and, after two minutes' washing, dried. At the same time a second plate was sensitised with the same dyes, but using them in the reverse order. The two plates were clearer than those sensitised in the mixed bath, the maxima and minima being plainly distinguishable.

A series of experiments were now undertaken, varying the times of bathing, but no difference in sensitising action was noticed, and fog remained the same. The mottling or marking which occurs when the two baths are used is due to the repulsion of the liquid when a gelatine film is brought from an alcoholic into a watery solution. A wash bath of alcohol was therefore used, and gave distinctly better plates. After further experiments a completely satisfactory and fogless plate was obtained as follows:—Two and a half minutes in isocol solution; two minutes in a bath containing the same proportion of alcohol as the bath B (dicyanine); two and a half minutes in bath B; five minutes in 96 per cent. alcohol. A further experiment, omitting the alcohol wash-bath, gave a successful result; which was also obtained when using a bath containing the two dyes, but washing in alcohol for five minutes after sensitising. These methods were therefore employed when making the trials of mixed dyes, recorded below whenever a fogged or mottled plate resulted from a washing in water after sensitising. One advantage of the alcohol method is the rapid drying of the plate, which is of influence on the cleanness with which the sensitised emulsion works.

The only cases in which variations were made in sensitising are when using the glycin-red and pinacyanol together, and glycin-red and dicyanine. These combinations gave quite different curves, according to whether sensitising was done in solutions made up with water or alcohol.

Mixtures of the Eosine Dyes.

The strength of the sensitising bath was such that each dye was used at a solution of 1:7,500. A little ammonia was added to all the baths.

1. *Eosine-aureosine*.—On shorter exposure the maximum in the blue sensitiveness was at 450 to 460, the density at 550 being somewhat less than at 450; this was the case also on longer exposure. In this respect the mixture of the two dyes is better than that of either

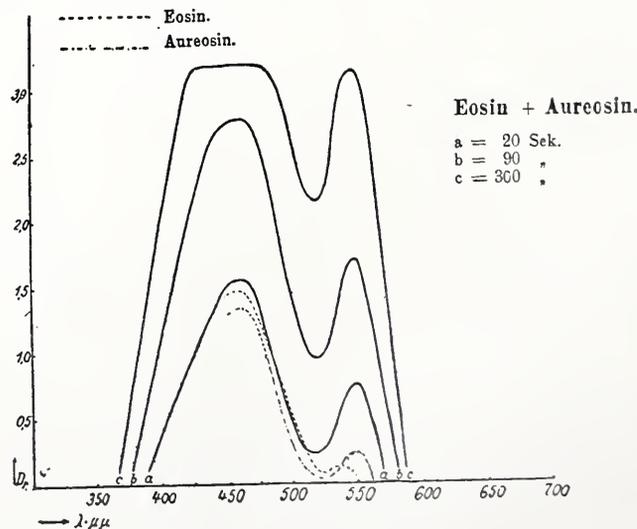

Fig. 1.

alone. Fig. 1 shows the curves for 20, 90, and 300 seconds, that for aureosine alone being for 20 seconds. There is a general rise in sensitiveness and in green sensitiveness. The curve for eosine alone, taken from Dr. Stenger's tables, could not be exactly compared with the others, as it was obtained under different conditions. As the

ratio of maximum sensitising to the blue maximum is very bad with eosine the mixture may be called good. The maximum of the two dyes being at 540 and 550, there is even sensitiveness in this portion, but the aureosine maximum at 550 is the more pronounced.

2. *Erythroline-aureosine* (Fig. 2).—The maximum is at 560, whence it would seem that the erythroline gives the curve its character. The ratio of maximum sensitising to the blue maximum is quite the normal, exceeding the general sensitiveness even at the shortest exposures, and, better still, on longer exposure. The question whether the increase of sensitising action is due to the aureosine or to a

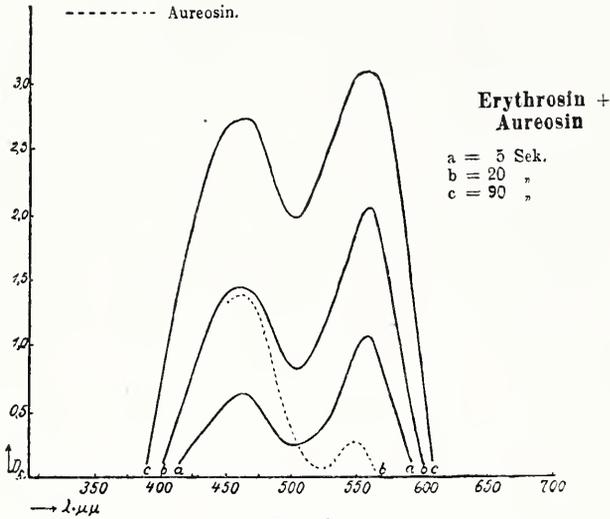

Fig. 2.

screening action dye to dyeing of the gelatine film must be answered by noting that there is no reduction of sensitiveness at 450 by screening, but that actually there is increase of sensitiveness at 560. Comparing the height of the curves for the same degree of exposure at wave-length 450, it is seen that the height for the mixture is the same as for aureosine alone.

3. *Rose-Bengal-aureosine*.—Fig. 3 shows the curves for exposures of 30, 90, and 300 seconds those for rose-Bengal and aureosine alone are for the same degree of exposure. The characteristic of the rose-Bengal curve is seen, its maximum being shifted about 10 μ towards

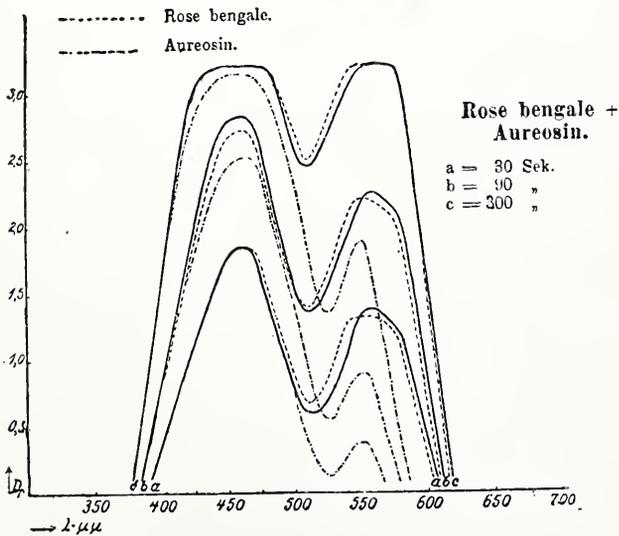

Fig. 3.

the right hand of the spectrum. An expected increase of the maximum at 550 is not observable. The aureosine, with maximum at 550, does not seem to have produced its effect. Also the sensitiveness curve in the blue 450 is that of rose-Bengal alone.

Eosine-erythroline.—This mixture showed the same ratios as No. 2. There is good action in the blue portion of the spectrum, and still better in the green at 560. Fig. 4 gives the curves for 5, 20, and 90 seconds. Comparing it with the curves for the same three times when using erythroline-aureosine, it is seen that the latter is inferior to the present mixture. For the same blue sensitiveness the maximum at 560 is better than the No. 2 formula, and better still on

longer exposure. The maximum action is reached with 60 seconds exposure, the curve flattening out at 90 seconds exposure.

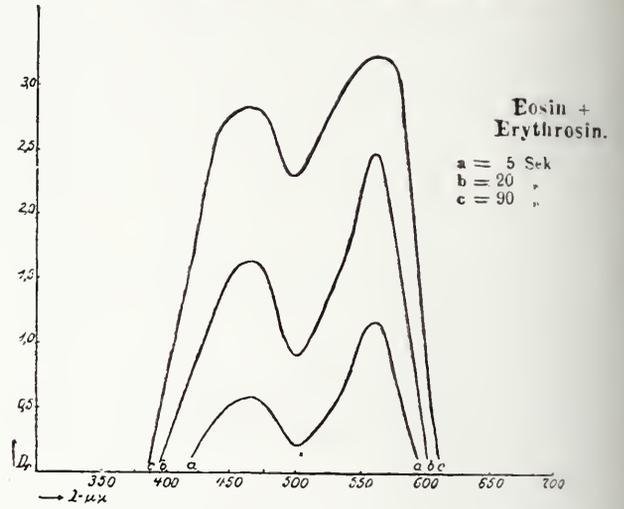

Fig. 4.

5. *Rose-Bengal-eosine*.—The general character of the curves, of which Fig. 5 gives those for 20, 90, and 300 seconds, is that of rose-Bengal. There is scarcely a sign of the influence of the eosine (maximum 450), nor is the rose-Bengal maximum shifted, as in

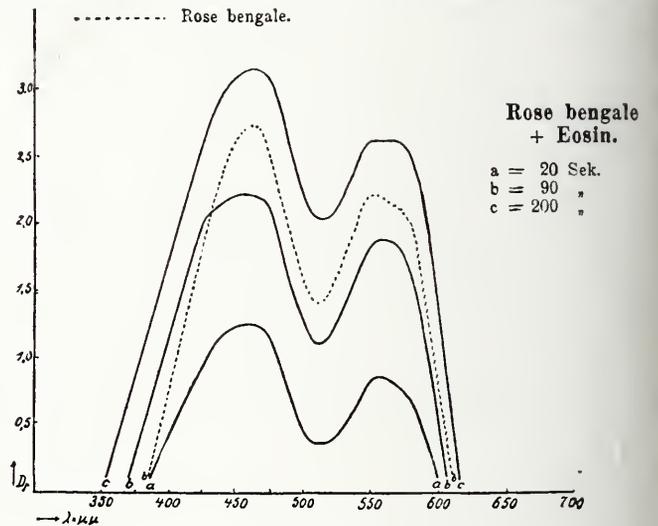

Fig. 5.

formula No. 3. The ratio of sensitiveness at 550 to blue sensitiveness is almost exactly those of rose-Bengal alone; only the general sensitiveness has suffered, as seen by comparing the two curves corresponding to 90 seconds exposure.

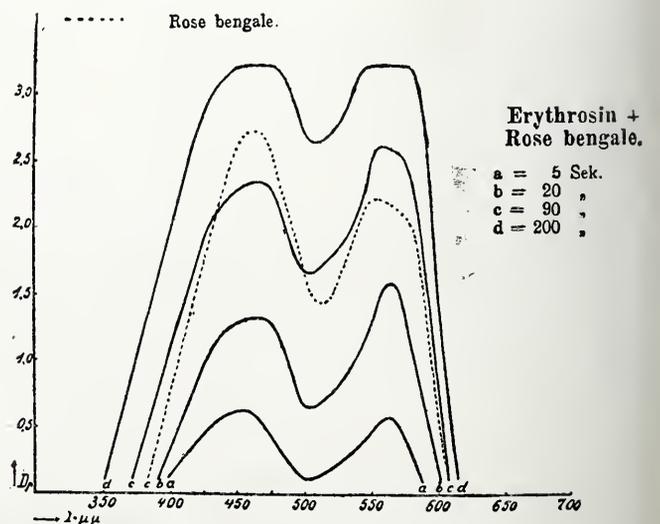

Fig. 6.

6. *Erythroline-Rose-Bengal*.—This mixture presents special interesting features. On short exposures there is a maximum sensitive

ness at 560, shown as about equal to that in the blue (curve *a* in Fig. 6). On longer exposure than 560 maximum increases much quicker than the blue maximum (curve *b*). It would appear that in the short and medium exposures the erythrosine curve is in evidence, the rose-Bengal affecting the curve more on the longer exposures. An exposure of forty seconds gave a curve almost exactly that of rose-Bengal, the maximum being at 550, and extending almost to 570. From this point the curve drops and does not extend beyond 600. The ratio of maximum sensitiveness to the blue maximum is much better than with rose-Bengal alone; compare the two curves for ninety seconds in Fig. 6.

As the result of experiments on dyes in this section it is shown that combinations with eosine have not produced very great variations—one or other of the dyes fix the character of the curve. The maxima remain for the most part at the same place, or are shifted about $10\ \mu$; the gaps in the blue-green at 500 remain, as was to be expected, unfilled. There is an appreciable difference in the ratio of colour-sensitiveness to blue-sensitiveness, the most favourable action being that with erythrosine-aureosine, which combination actually gives an increase in colour-sensitiveness.

G. DAUR.

(To be continued.)

Photo-Mechanical Notes.

Improvements Relating to Colour Photography.

In R. Merkel's patent (No. 8949 of 1908) the two claims are:—

(1) Method for the photographic and photo-mechanical reproduction of three or more coloured pictures. Monochrome positives or negatives are employed, which are retouched by covering the parts corresponding with the original with a layer which is unaffected by the material used for bleaching or colouring the said monochrome positives or negatives, so that from these positives or negatives "formes" are obtained which do not require retouching.

(2) Method for chemically retouching photographic monochrome-positives or negatives used for the production of "formes" for colour printing, consisting therein that the parts of the several positives or negatives which are correctly coloured are covered by a layer which is unaffected by the bleaching or colouring medium employed to correct the rest of the positive or negative.

The method described is one that could be used for retouching stained gelatine prints, and consists in covering any part that is correct with some unaffected material, such as shellac varnish, while further staining or reducing other parts. What possible advantage there is in this for photo-mechanical printing it is difficult to see, for the method is practically the same as fine-etching as practised at present. The patentee may mean that coloured gelatine prints should be made from the negatives. This would give a clue to how much the actual negatives might be reduced before proceeding to make the block, in the manner suggested. We can only say that this would require as much skill as fine-etching does at present, and there would be the added expense of first making the gelatine prints. Further, as the dyes used in staining seldom correspond with the inks used in printing there would probably still remain considerable fine-etching to do on the blocks themselves. We may be misunderstanding the patent altogether, but that is not our fault, as the wording certainly does not give one a clear idea as to how the improvement is applicable to photo-mechanical work, though that is one of the claims made. We have never before heard of the use of coloured negatives, unless to show the complementary colours, as for instance, in fixing a Lumière Autochrome before reversing.

The Removal of Scum.

One of the difficulties in connection with the enamel process of preparing the acid resistant print on metal is the frequent occurrence of "scum," i.e., an insoluble film of colloid which is not removed on development from the places between the dots which should be bare metal. There are many causes of this. Perhaps the chief is the fact that the dots on the negative are not opaque enough, and so light penetrates and renders the underlying film insoluble. Over-exposure when printing will, of course, give it; some samples of glue are very prone to be more or less undevelopable, especially if chromic acid is used in the formula. Insufficient development

of the print in cold water before placing in the dye solution, stale dye solution, and imperfect washing out after the dye, are also apt to show as scum. Naturally, it is better to have a print absolutely free from scum, which, by the way, is seldom discovered until after the enamelling, but it is quite possible to remove scum in most cases without detriment to the print if due care is taken. There are many formulæ for this; for example, acetic acid and salt, solution of chromic acid, a mixture of the latter and other acids, weak perchloride of iron, and finally a 5 per cent. solution of cyanide of potassium. The plate is either placed in one or other of these solutions and rocked for a few seconds, or obstinate cases are rubbed with a wad of cotton wool moistened with the liquid. The best of the solutions is, perhaps, the cyanide of potassium; it seems to effect the removal of scum in very severe cases without attacking the dot proper. Next to this is the weak perchloride of iron, say a solution at 25 deg. Baumé; in very bad cases this can be applied warm, and is generally found satisfactory.

Non-Warping Mounting Wood.

The patent mounting board to which we referred some time ago is now being supplied by the makers, Green and Sons, Mildmay Avenue, London, N., in lengths of about 30 in. of various widths, so that it may be sawn off as required, and the mount will always be clamped on both sides. The price is one shilling per square foot, which is about twice the cost of ordinary mounting wood; but then everyone knows the costliness of the troubles to which ordinary mounting wood gives rise.

Ink Rubbing off Proofs.

We have been asked as to the cause of inks sometimes rubbing away from the proofs directly they are touched. Unless the prover has been tampering with the inks, complaint should be made to the ink-maker, as the fault is entirely due to the ink containing either too little varnish or varnish of quite inferior character. But before blaming the ink-maker it should be made quite certain that the ink has been used exactly as supplied by him.

The Metzograph Screen.

In the current issue of "Le Procédé" MM. H. Calmels and L. P. Clerc describe a modification in the Metzograph screen, allowing of this latter being used in the ordinary carrier of the half-tone screen so as to bring the Metzograph screen into the necessary closeness of contact with the sensitive plate. As will be seen from the two illustrations the device simply consists in providing the Metzograph screen with a recessed border along each

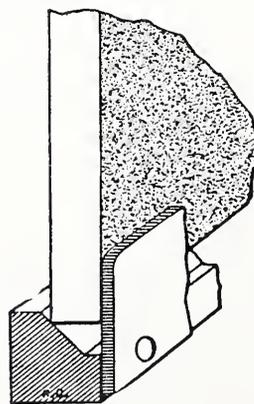

Fig. 1.

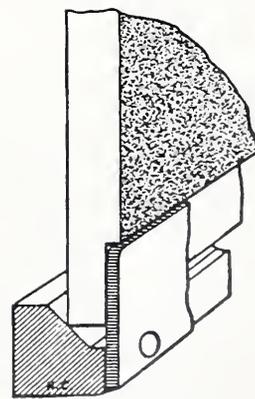

Fig. 2.

of two edges, so that the screen itself falls flush with the stops which keep it in place (fig. 2.). It has been found that this simple modification has led to much better results being obtained with the screens, particularly with Nos. 4, 5, and 6. Screens of this pattern have been placed on the market by the firm of H. Calmels, 150, Boulevard du Montparnasse, Paris, and it is further mentioned that three new varieties of the screen have been introduced, namely, an 00 for poster work, 0 for newspaper blocks, and a No. 7 for extra fine photogravure.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—
ENGRAVING.—No. 15,894. Photo-mechanical process of engraving printed surfaces. Henry Lewis Reckard, 65, Chancery Lane, London.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between July 5 to 10:—

WASHING.—No. 15,591. Contrivance for causing the pulsation of water for photographic and other purposes. Arthur Burchett and Arthur Harold White, 6, Granville Road, Littlehampton.

CINEMATOGRAPHS.—No. 15,693. Improved mechanism for the feeding of cinematograph films. Oscar Messter, 100, Wellington Street, Glasgow.

CINEMATOGRAPHS.—No. 15,841. Improvements in cinematograph films and process for the preservation of the photographic emulsion on such films. Ramee Donovan Dockree, 98, Station Road, New Southgate, London.

CINEMATOGRAPHS.—15,859. New or improved cinematograph display apparatus. George Percy Kent, 38, Chancery Lane, London.

CAMERAS.—No. 15,902. Improvements in photographic cameras. Fritz Levie, 31, Bedford Street, Strand, London.

PHOTO-TELEGRAPHY.—No. 15,918. Improvements in or relating to what is known as photo-telegraphy. Thomas Thorne Baker, and Pictorial Newspaper Co., Ltd., 7, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 16,129. Improvements connection with cinematograph display apparatus. George Percy Kent, 38, Chancery Lane, London.

ARC LAMPS.—No. 16,134. Improvements in electric arc lamps of the enclosed type, whereby they are made suitable for use in photography, when a non-fluctuating light is required in one direction and a limited space only is available. Westminster Engineering Co., Ltd., and Arthur George Way, Victoria Road, Willesden Junction, London.

PHOTO-TELEGRAPHY.—No. 16,175. Improvements in or relating to what is known as photo-telegraphy. Pictorial Newspaper Co., Ltd., and Thomas Thorne Baker, 7, Southampton Buildings, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DEVELOPING TANKS.—No. 20,092, 1908 (September 24, 1908). The invention relates to the development of photographic plates or flat films, in apparatus consisting of an outer tank and an inner container provided with vertical grooves and lids furnished with masked or light-trapped openings.

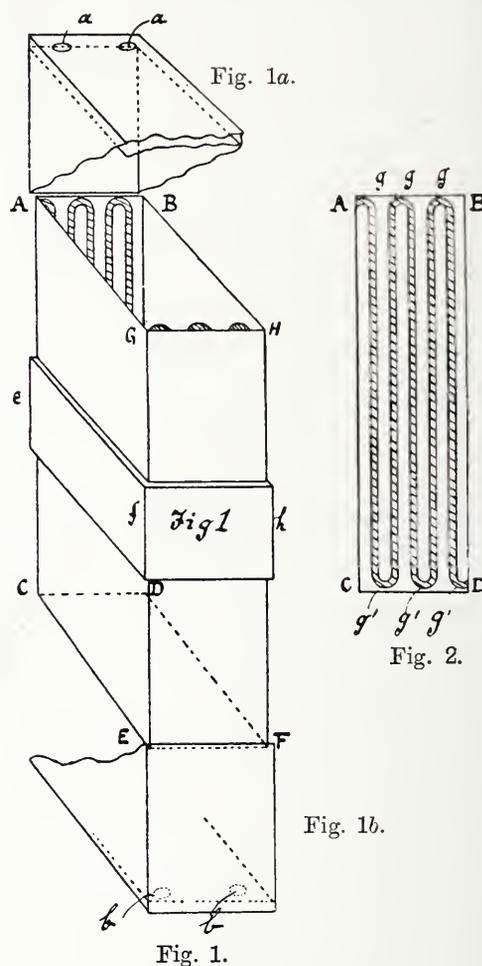

Fig. 1 with its subsidiary figures 1a and 1b is a perspective view of the inner container, with its top and bottom lids. Fig. 2 is an elevation of one side of the container showing the grooves.

There is a suitable outer tank for holding the developing solutions into which the inner container, with its lids figure in Figs. 1, 1a, and 1b, can be placed. It is convenient to provide a handle (not shown) by means of which the inner container can be lowered into and lifted out of the outer tank. The handle is preferably a wire loop pivoted at two points on opposite side of a central projection on the inner container (two sides of which are shown in Fig. 1 as *e f*, *f h*), against which the lids when closed abut so as to exclude light. The handle should be long enough when rotated about these pivots to clear the top and bottom of the inner container when the lids are closed.

The container A B C D E F G H (Fig. 1) is open, top and bottom, and is provided with grooves shown in detail in Fig. 2. These grooves are alternately open and closed at the top and bottom, the tops and bottoms of the closed grooves being of a curved or arched shape as shown in the figures at *g g'*, in order to facilitate the insertion of the plates or films in a dim light or in total darkness and by touch only. Instead of being arched or curved, the tops of the grooves may be pointed after the fashion of an inverted capital letter V, but the form shown in the drawings is preferable. The grooves may be formed of one continuous strip of metal or suit-

able material, by bending the same, or in any other convenient method.

The lids represented in Figs. 1a and 1b are provided with light-trapped openings, shown as *a a*, *b b*, whereby when the lids are

closed fluids can freely enter and pass out of the container, but light is excluded. A simple and well-known form of light-trap consisting of perforations masked by a false lid is shown in the drawings, but any suitable form may be adopted. The apparatus is adapted to hold six plates or films (or twelve if two plates or films are placed in each groove, back to back), but the apparatus may be constructed to hold any required number by increasing or diminishing the number of grooves.

The method of use is as follows:—In a dark-room, or by means of a changing bag, one half of the total number of plates or films (in the apparatus shown three plates or six arranged back to back in pairs) are slid into the open grooves at the top. The lid shown in Fig. 1 is then put on and pushed down till it meets the central projection *e f h*. The apparatus is then turned over, the tightly fitting lid retaining the plates just inserted, and the remaining plates (three or six as before) are inserted in the same manner as before, and the lid 1b is also put on and pushed down in the same manner as before. If necessary, the lids may be secured to the central projection by suitable catches, but in practice, if they fit tightly, this is not necessary.

The inner container with the enclosed plates or films is now lowered into the outer tank containing the developer, and development carried on in the usual manner. The plates may afterwards be fixed and washed in the same manner as they were developed, all these operations, subsequent to the insertion of the plates in container, being capable of being carried out in full daylight. It is generally considered necessary, in order to avoid streaks or markings, either to agitate the inner container while in the developer or to reverse it once or twice. These operations, owing to the construction of the apparatus, may be easily performed, especially if the inner container is provided with a reversible handle, as previously described. Horace Handley O'Farrell, 61, The Avenue, Kew Gardens, London, S.W.

DEVELOPING APPARATUS FOR ROLL-FILM.—No. 18,570, 1908 (September 4, 1908). The apparatus consists of a perforated disc or plate A, having in the centre a stem or handle B, which is preferably made detachable by a screw device. Encircling the base of this stem or handle B, with its lower edge resting on and attached to the disc or plate A, as a ribbon or band C, so coiled that a space is left between the coils and the ends D, D¹ are open. Suitable devices are provided at or upon the ends to hold the film in its place. This ribbon or band C (henceforth referred to as the "coil") may be plain or perforated as preferred, and it may be of a width corresponding with the width of the film to be developed

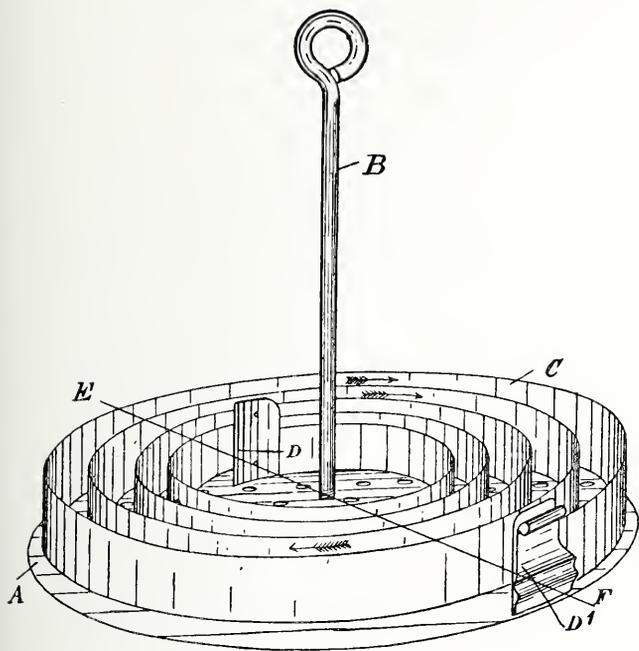

Fig. 1.

upon it, or it may be of a lesser width as may be found most convenient, and at either or both of the ends D, D¹, the width may be increased so as to afford additional support to the film at those points. Likewise the length of the coil may also vary to correspond with the varying lengths of the films in use.

In practice a loop is formed at one end of the strip of film to be developed through which the stem or handle B is passed, and being screwed into the disc or plate A forms a support for the end of the film and holds it in its place. The film is then passed in at the open end D, and wound upon and along the convolutions of the coil C as indicated by the direction of the arrows, in such a way that the back of the film lies against the coil and the face or

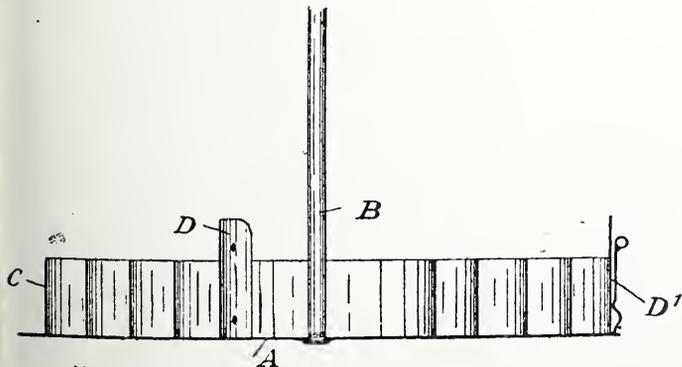

Fig. 2.

sensitised side is turned outwards. The entire length of the film having been wound on the coil is held in place by being passed through the divided outer end of the coil at D¹. The apparatus is then immersed in a suitable vessel containing the developer, and allowed to remain until the allotted time of development has expired, when it is removed for washing and fixing. James Jerome McGhee, 65, South Side, Clapham Common, London, S.W.

CINEMATOGRAPH MECHANISM.—No. 9,864, 1909 (April 26, 1909). The claim is for a film-gate for bioscopes constructed with adjustable runners, which are backed by springs interposed between the runners and bearing pins resting against a bearing plate which is adjustable by a fine screw. Frank Porter and The British Bioscope Manufacturing Company, Limited, 11, Long Acre, London, W.C.

New Trade Names.

NOXONA.—No. 312,017. Photographic paper. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., manufacturers. April 5, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Photography for Decorative Purposes.

A form of decorative photography (writes Mr. M. Earle in "Photography and Focus" for July 20) which has produced some very charming results is the making of Christmas and other greeting cards. A series of dinner menus which I made last winter, however, may be worth mention, as the process was not the ordinary one. A little still-life group, kept as simple as possible on account of the reduction, was made right down in one corner of a half-plate. It was taken against a white background, or rather some distance in front of a white background, and so it was easy to vignette it on to one corner of a piece of platinum paper, leaving the whole of the rest white. The menu was printed on to the paper from a separate negative with a mask, so that the lettering appeared on a slightly tinted patch on the menu. The little still-life group was brush vignettied by means of the glycerine process, the whole of the paper being covered with glycerine, the wording developed, and the development of the vignette made the last operation. It took a little trouble and designing, though I think the result in the end was one that was worth it, but it would not be suitable where there were many to be done, as each print required separate treatment.

New Books.

"The Photographic Annual, 1909." Edited by H. Snowden Ward. London: Dawbarn and Ward, Ltd. 1s. net.

This volume constitutes the second annual issue as a periodical publication, and the fifth edition of the "Figures, Facts, and Formulæ" under which title it originally appeared. Mr. Snowden Ward has retained the general arrangement, but has added to and revised the matter so that Vol. II. of the "Photographic Annual" is quite a distinct work from Vol. I., and contains an immense amount of further information. The section "Orthochromatics" contains the formulæ for Autochrome, Thames, and Omnicolore transparencies, in addition to numerous useful prescriptions for sensitisers, light filters, and safe lights. "Artificial Light" for portraiture and printing occupies four pages. The section on "Developers" and "Development" is one of the largest in the book, and contains an immense number of prescriptions for time, stand, and fractional development. In the section on self-toning papers a useful epitome is given of the directions for the use of the papers on the market.

Prominence is given to the modern printing processes, oil, bromoil, and gum, for which the necessary formulæ are given, although curiously enough, not that of Mr. Welborne Piper, which is probably as much used as any other. Optical and chemical

facts and tables, facts of copyright, and process formulæ conclude a volume which is a veritable mine of information. Under "Toilet and Hygiene," a human touch is given to the compilation by the inclusion of recipes for eye-lotions, skin emollients, etc., though why among these it should be thought useful to include remedies for cinders in the eye, tests of death, and measures to be taken in the event of bites from a snake and mad dog, we confess to being at a loss to understand. But the compilers have succeeded in compressing an enormous amount of information into the 287 pages of the book.

"PHOTOGRAPHIC PROGRESS."—Under this title a new photographic monthly publication is issued by the Rittenhouse Press Inc., Lafayette Building, Philadelphia. Its declared policy is the advancement of professional photography in America, in pursuance of which it quotes (with acknowledgment, we hasten to say) from the "British Journal of Photography." Its get-up as regards printing and illustration is of the best, and its matter to the point. The personnel of its editorial staff will be noted with interest by readers of the "B.J." It is: Managing editor, A. K. Boursault; technical and scientific editor, Thomas Bedding, F.R.P.S.; editor, J. Nilsen Laurvik.

STEREOSCOPIC PHOTOGRAPHY (No. 98 of the "Photo-Miniature").—Popular as stereoscopic photography is rapidly once again becoming, there has hitherto been no convenient manual on the subject which is reasonably up to date. This breach in photographic literature is now filled by the current issue of our New York contemporary, obtainable in America from Tennant and Ward, 122, East 25th Street, New York, and in London from Dawbarn and Ward, Limited. The author, Mr. Nathan T. Beers, makes a point of the usefulness of the quite small stereoscopic cameras, such as the "Verascope" of Richard, the "Stéréophoscope" of Voigtlander, and the "Stereo-Tenax" of Goerz, referring his readers for other instruments on the English market to the "British Journal Almanac." But he gives particulars also of the larger stereo cameras, has strong recommendations to make on behalf of the stereo-reflex cameras (the "Challenge" instrument made by Lizars is recommended), and he approves also of the duplicating attachment devised by Mr. Theodore Brown for stereoscopic work with an ordinary camera and a single lens. The suggestions as to choice of subject, development, lighting, printing, and mounting are concisely put, and afford in a few words the information which the amateur worker in stereoscopy needs to have. We may not agree with the writer's statement that the method of printing direct from the negatives, followed by cutting and transposing the print, is now obsolete. It is a method which is probably more largely practised in this country than any other, as time is saved in printing, and it is easier to obtain a pair of prints of equal depth. It is satisfactory to find that the author advises the lens separation of $3\frac{1}{4}$ in. for general work. This is no doubt the best distance when a fixed separation is necessary, and its use would minimise the number of badly trimmed slides which are frequently to be seen. Clear and explicit as the "Photo-Miniature" succeeds in being, we may, perhaps, be allowed to suggest that in a reprint of the present monograph the sentence on p. 55, that "the left-hand picture must be printed in the right-hand position, and *vice versa*," might be freed from ambiguity, although the writer's meaning is quite clear on p. 81, where it is explained that the right-hand picture formed in the camera is, of course, still the right-hand picture in the finished slide.

MR. DEAKIN, the Prime Minister of Australia, has accepted a unique gift for the Commonwealth from Messrs. Pathé Frères. The firm named took a cinematograph record of the landing at Sydney of Lord Dudley, the new Governor-General. Only one film was in existence, and this was presented to Mr. Deakin.

HOLIDAY BOOKLETS.—Recent additions to the series of guides published by the Health Resorts Development Association, of 29, John Street, Bedford Row, London, W.C., relate to the districts of Basingstoke, Egham, Esher, Reigate, Richmond, and Poole. These are similar, both in general appearance and also in the method of treating the particular places dealt with, to those previously mentioned in our columns, and copies may be obtained by addressing a written request to the respective Town Clerks.

New Materials, &c.

"Wisto" (Sepia) Paper. Made by the "Wisto" Works, Hayes, Middlesex.

A distinct departure from the ordinary methods of photographic printing on development papers is embodied in a new paper, opportunities for a trial of which we have had within the last few days. The paper, which is the invention of Mr. B. J. Edwards, serves for the making of sepia and other warm-tone prints by direct development with normal exposure. The paper, as manufactured at the "Wisto" Works, is of the gaslight variety, allowing of development by ordinary gaslight (not incandescent) or electric light, although, of course, if the simple precaution be taken to handle the paper within the shade of a screen—that is to say from direct light—the paper can be readily manipulated in a stronger illumination. The exposure to daylight is very short, a second or so, and therefore the most convenient method of exposure is to artificial light. An idea of the sensitiveness of the paper it may be said that, using a plucky but quick-printing negative, $1\frac{1}{2}$ to 2 inches of magnesium ribbon burnt at a distance of 18 inches from the negative gave a correctly exposed print. The colour is to a certain extent dependent upon the exposure; that is to say, that the very best results from the negative, as regards gradation and detail, are obtained for a given colour with a certain correct exposure. On development the print first appears of a pale lavender grey, which quickly turns to red, the print then gaining in vigour until it reaches its full strength, when the colour quickly changes to sepia, which sepia becomes colder the longer the development is continued. It will thus be understood that if the print is under-timed the details may not all be fully out at the stage of development giving the warmest sepia, and the result, therefore, of further continuing development is to give a somewhat colder sepia. It may thus be taken as a general rule that for cold sepia the exposure may be a little under, and for warm sepia to red a little over, the normal time. Still these differences are not very great, and, except in the case of negatives, parts of which are of such density that the print requires forcing, the normal exposure will allow of a satisfactory picture being obtained through a considerable range of tone, the exact point at which to stop development being very plainly seen, whilst, so far as the prints which we have made go, the alteration of colour on drying is practically nil. The print gains in depth a tone or two, and that is all.

Even in the case of prints which owing to over-exposure are of too great intensity by the time the desired sepia tone has been reached in development, it is quite easy to bring back the depth to the required degree by the use of a very weak bath of Farmer's reducer, prepared according to the following formula given in the instructions for the "Wisto" paper:—

A. Potass. ferricyanide	60 grs.
Common salt	120 grs.
Water	20 ozs.

This solution keeps well and is always ready for use.

B. Hyposulphite of soda	2 ozs.
Water	20 ozs.

To make the reducer add, just before use, four or five drops of A to each ounce of B.

The prints are fixed in a bath of hypo of 2 ozs. to the pint, with or without the addition of soda or potash metabisulphite. Plain hypo answers quite well, although it soon becomes discoloured. When the acid formula is used it is recommended that a fresh batch of bath, say 6 ozs., should be taken for each dozen prints. The time of fixation is two minutes only, after which the washing of the prints for half an hour completes the process. The makers have found that prints treated in this way are absolutely permanent. The developer is supplied in powder form at a cost of 2d., sufficient to make 6 ozs., 4d. for 20 ozs., or 2s. to make one gallon. The paper itself is made in three grades—smooth-white, rough-cream, and glossy, the smooth-white having a semi-matt surface of the kind which is frequently described as "carbon"; whilst the rough-cream is a tinted paper of not a very great degree of roughness and very suitable for all kind of negatives.

The tone given by the papers is a most pleasing sepia, and quite distinct from the brown and reddish-brown tones which are frequent

the result of sulphide-toning. Tones more akin to these latter are just as easily obtained in the earlier stages of development, but the makers, rightly we think, emphasise the excellence of the true sepia in preference to the brownish-reds and reddish-browns which frequently pass by that name in photographic printing. Although a gaslight paper, "Wisto" may be used under favourable conditions for the making of enlargements, but it is primarily manufactured for contact printing, and is undoubtedly a most valuable addition to the printing media at the photographer's disposal. The readiness and certainty with which a whole series of sepia prints may be rapidly turned out is its distinguishing feature, whilst the other qualities of the paper—such as permanency and range of gradation—are excellent. Both professional and amateur workers, we anticipate, will be anxious to investigate the properties of the new paper, which is issued at prices based on 1s. for a sheet 24½ x 17, or 12 quarter-plate pieces at 6d., 12 half-plate 1s., and six pieces 10 x 8 for 1s. 6d.

"Challenge" Self-Toning P.O.P. and Cream-Crayon Bromide Papers. Made by the Challenge Works, Macclesfield, Cheshire.

Samples of these materials, just added by the Challenge Works to the list of printing papers manufactured by them, have come under our notice. The self-toning paper is a gelatine emulsion, the prints on which tone to a very good purplish-brown in a bath of hypo only, 3 oz. per 20 oz. of water. Six minutes' immersion in this solution suffices for the toning and fixation of the print, the surface of which is a very pleasant semi-matt.

The "cream-crayon" bromide is a semi-rough paper, which we found to yield enlargements of first-rate quality, toning well in the sulphide bath and yielding results which harmonise well with the cream tint of the paper. The two materials fully maintain the high standard of quality which we have invariably found to characterise the "Challenge" papers.

Dew Apparatus, &c.

The "Ensign" Development Tank. Made by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

Several good features are embodied in this piece of development apparatus which Messrs. Houghtons have just placed upon the market. For both professional and amateur use the services of some form of tank are now requisitioned, perhaps almost as generally as the old-fashioned dish. The saving both of space and of time in the dark-room is one paramount reason for adopting a tank

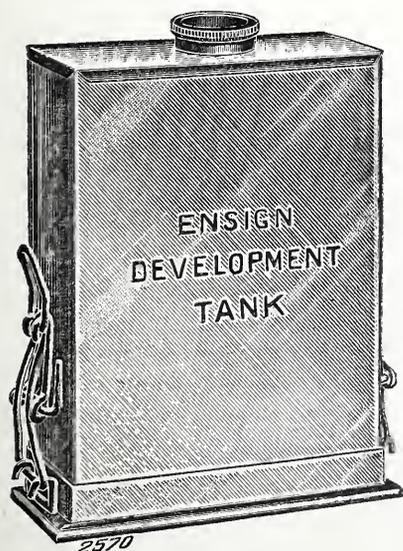

Fig. 1.

method of development. All may not elect to develop by time, and all may not wish to avail themselves of the opportunity of dispensing with the dark-room, but apart from this consideration the use of a tank possesses undoubted advantages whenever any considerable number of plates have to be developed, or even, in the case of some patterns of tank, when only two or three have to

be treated. In the tank now used by Messrs. Houghtons, the rack, constructed of lacquered brass, is made separate and thus allows of the plates being more readily inserted. The plates in the rack are put in at one end of the tank, whilst the developer is inserted at the other through an aperture one inch in diameter, which is closed by a screw stopper. The other end of the tank is likewise closed by a full-size lid provided with a rubber washer, the lid being fixed forming a water-tight joint with the top of the tank by means of the strong wire springs. One advantage of this latter mode of securing the lid is that if the spring should chance to become slightly weaker with use, it is only necessary to bend one of the pieces somewhat in order to secure the firm adhesion of the lid. It will thus be seen that, if desired, the rack and tank can be placed in a changing bag with the exposed plates, the latter placed in the rack and the whole removed with the plates perfectly protected from light into the daylight. The developer is then applied through the circular aperture, the cap screwed on, and development allowed to proceed.

The greatest point of advantage in our judgment of the apparatus is that it can be used in either position, with the result that mark-

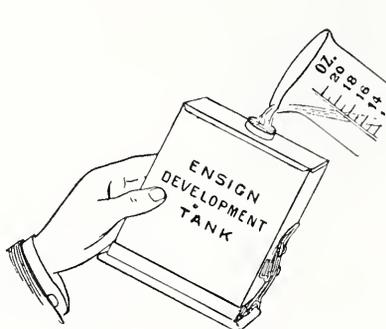

Fig. 2.

Fig. 3.

ings which occasionally result from allowing the plates to remain in one position throughout the whole time of development are avoided; all that is necessary being to quietly reverse the position of the tank, allowing it to stand upon the lid for part of the time, and for another period on the screw cap. The apparatus is very strongly made in nickelled brass, and the only caution which perhaps needs to be given in connection with its use is that the tank should not be put away with the lid clamped down, otherwise the pressure of the metal on the rubber is apt to cause the latter to perish and to lose its power to make a water-tight joint. The tank may be used for both developing and fixing, but practical

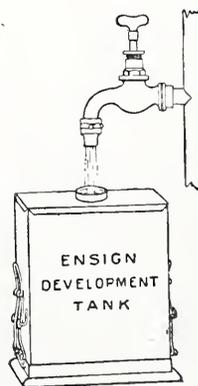

Fig. 4.

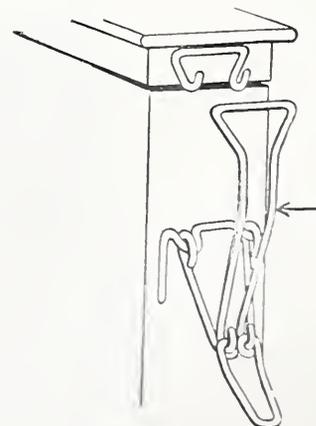

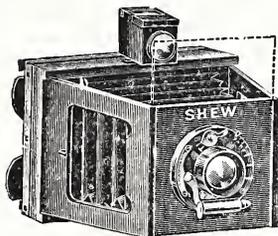

Fig. 5.

photographers will agree with the makers' recommendation that the plates after the developer has been poured off, as in fig. 3, should be set to wash for a short time as in fig. 4, and the rack then quickly removed and placed in a second tank containing the fixing bath. The price of the tank in quarter-plate size is 7s. 6d., in 5 by 4 or postcard (5½ by 3½), 10s. 6d., and in half-plate, 12s. 6d. The brass racks are supplied in these four sizes at 2s., 2s. 6d., and 3s. 6d., whilst brass tanks, complete with racks, but without the other fittings, are sold at 4s., 5s., and 7s., respectively.

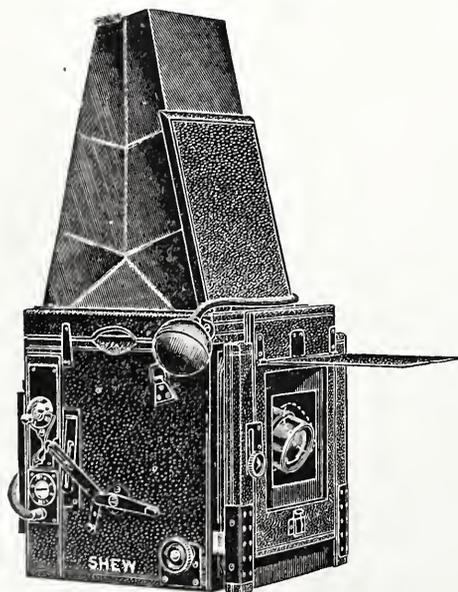

The "Euxit" pocket camera. Made by J. F. Shew and Co., 88, Newman Street, Oxford Street, London, W.

Pronounced "Use It" in reference to its response to all kinds of practical requirements, this new pocket camera is an addition to the large family of "Xit" cameras made for many years past by Messrs. Shew, and rightly esteemed for their working qualities. The "Euxit" embodies the same system of side flaps employed in other models of the "Xit" cameras. It is made to take a plate $3\frac{1}{2}$ by $2\frac{1}{2}$ inches, being fitted with a Cooke focussing lens of 4.4 inches focal length mounted in the well-known "Compound" shutter. The lens mount thus provides the necessary focussing for objects within 9 feet of the camera, and the lens itself affords a rise of one inch the landscape way of the plate, together with a cross front movement which is available as rise when the camera is held the upright way of the plate. The finder is of the "Iconometer" type, a sliding rod being used in conjunction with a wire frame the full size of the plate. This very simple device has the further advantage that the frame moves up along with the lens, and there-

fore gives a correct idea of the amount of picture included on the plate, provided that care is taken to hold the camera level. The "Euxit" is fitted with focussing screen which instantly clamps into the back of the camera, and with six single metal dark-slides which are similarly placed quickly in position. The apparatus is very strongly made in mahogany, aluminium bound, and is an actual pocket instrument, the total dimensions of the camera with dark-slide ready for exposure being $4\frac{3}{4}$ by $3\frac{3}{8}$ by 1 3-5 inches. The price complete with the Cooke lens, series III f/6.5, and with purse for the six metal slides, being £9 9s. The instrument is strongly made, and may be recommended for withstanding a great deal of hard usage. It should be added that it is fitted with bushes for attachment to a tripod.

THE SHEW REFLECTOR CAMERA.—"Shew me a Shew" is a phrase coined by Mr. W. J. Ramsey on taking over the business of Messrs. J. F. Shew and Co., and particularly in reference to the "Press" reflex cameras, which have been made by Messrs. Shew and largely

used by press photographers for years past. The latest model of the press reflector, shown to us on a recent visit to Newman Street, is fitted with a swing front allowing of the lens being pointed upwards or downwards through a considerable angle. The movement

is obtained by mounting the lens on the hinder of two frames made something like the swing-back of old-fashioned cameras, the two frames being connected by flexible cloth. The position is fixed by means of a short lever having a series of slots in it, any one of which catch on a pin placed in the main front of the camera. In this way the lens may be fixed at any one of several inclinations up or down, or may be similarly placed "square" to the plate. The movement is not illustrated in Messrs. Shew's latest list, so that we reproduce here an electro showing the arrangement. For other details of the forms in which the "Press" reflector is made, and the prices of them and of the smaller models of Shew reflex cameras, the full list obtainable on application to 88, Newman Street should be consulted.

1,000 CANDLE-POWER GAS LAMP.—The announcement is made of the introduction within the course of the next few weeks of a new self-intensive incandescent gas lamp of the great power of 1,000 candles. The lamp is the invention of Mr. Paul Lucas, already known as the inventor of a lamp of this pattern giving 700 candle-power, and also of the "Thermopile" high-power lamp of 1,200 candle-power, which perhaps represents the most intense and economical light in existence. The new lamp, therefore, which it is expected will be placed upon the market by Messrs. Moffat, Ltd., 13, Farringdon Road, during September, is on the same principle as the previous Lucas self-intensive lamp, but is of the inverted mantle pattern, and possesses other improvements. It is quite free from working parts, it calls for no extra pressure of gas, only one mantle is used, gauze is dispensed with in the construction of the burner, and by an ingenious device that back lighting of the gas, it is stated, is entirely got over. These advantages are obtained within a smaller lamp than the previous model, and it would seem that a gas lamp of this power, although manufactured primarily for outdoor lighting, possesses applications for photographic portraiture, printing and enlarging, which should interest those engaged in these occupations.

CATALOGUES AND TRADE NOTICES.

FINE CHEMICALS.—Messrs. Harrington Bros., 4, Oliver's Yard, 53, City Road, E.C., send us their current price-list of photographic and other chemicals.

LIESEGGANG CINEMATOGRAPH APPARATUS.—The catalogue for the current year reaches us from Ed. Liesegang of Düsseldorf. It contains particulars of the firm's latest apparatus for taking and projecting animated photographs.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 24.

Southend-on-Sea Photographic Society. Outing to West Tilbury.
Birmingham Photographic Society. Excursion to Ombersley.
South London Photographic Society. Excursion to Oxford.
South Suburban Photographic Society. Excursion to Bexley.

TUESDAY, JULY 27.

Hackney Photographic Society. "Masking and Binding Lantern Slides." W. I. Witts.
"Stereoscopic Photography." S. W. Shore.
Birmingham Photographic Society. Ramble to Coleshill.

WEDNESDAY, JULY 28.

Manchester Amateur Photographic Society. Ramble to Dovedale.
Sale Photographic Society. Print Selection for Folio.

UNDER THE SKYLIGHT.—"He's not what you call strictly handsome," muttered the photographer from under his focussing cloth while sharpening on a homely baby that lay howling in its mother's arms; "but it's the kind of face that grows on you."
"It's not the kind of face that ever grew on you!" was the indignant and unexpected reply of the maternal being.

Commercial & Legal Intelligence.

THE NORTHERN PHOTOGRAPHIC COMPANY.—In the Carlisle County Court last week Mr. Crute applied for an order for the winding up of the Northern Photographic Company, on the ground that it was unable to pay its debts. He said the company was incorporated in May, 1906, and had its registered office at 18, Bank Street, Carlisle. The object for which the company was established was to acquire and carry on the photographic business of Thomas Maitland Laws, and to take over all his assets and liabilities. The company was indebted to the creditors, who had presented their petition for its winding up in the sum of £325, and although the creditors had repeatedly rendered an account, they had not been able to obtain payment. The company also had premises at Workington, as well as Carlisle, but both places of business had been closed for some time. There was no opposition to the application, and his Honour made an order for the winding up of the company.

LEGAL NOTICES.—A dividend is to be paid in the bankrupt estate of Henry Morton Pearce, carrying on business at 26 and 28, County Arcade, Leeds, under the style of Morton's Star Photo Company. Mr. John Bowling, Official Receiver, 24, Bond Street, Leeds, will receive proofs up to the 30th inst.

In the bankruptcy of Frederick Hartmann and Christian Linck, carrying on the business of fine art publishers under the name of F. Hartmann at 45, Farringdon Street, E.C., a dividend is to be paid. Proofs will be received by Mr. C. J. M. W. S. Gilchrist, 23, Queen Victoria Street, E.C., up to the 24th inst.

A first and final dividend of 3s. 1½d. has been declared in the bankrupt estate of Joseph Sharples (trading as the Romanus Publishing Company), photographer and publisher, 54, Church Lane, Marple, Cheshire, formerly of Hollinside, Stockport Road, Marple.

NEW COMPANIES.

SARONY AND Co., LTD.—Capital £2,000, in £1 shares. Objects: To take over the business carried on at Scarborough and Harrogate by a company of the same name; to acquire the leases of 17, Nicholas Street, Scarborough, and the tenancies of 52-54, Parliament Street, Harrogate, and to carry on the business of photographers, painters, artists, designers, picture dealers, publishers, carvers, gilders, frame makers, dealers in Photographic requisites, etc. Private company. Registered office, 54, Parliament Street, Harrogate.

News and Notes.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—At the annual meeting, held on July 13, the reports of treasurer and secretary showed the affairs of the society to be in a satisfactory condition, both financially and in regard to the number of members and their work. Many of the officers were re-elected, among them being the president, Mr. J. W. Wright; the treasurer, Mr. T. G. Hibbert; and the hon. secretary, Mr. H. Merrill, 22, Harbord Road, Norton Woodseats, Sheffield, who will be pleased to give information respecting the society to any wishing to join it.

THE R.P.S. FELLOWSHIP.—For some time past it has been felt that the regulations under which the Fellowship is awarded have not been sufficiently elastic to meet the conditions now existing, and that the division of qualifications into "Pictorial" and "Scientific" might deter some members who are well qualified for the Fellowship by expert knowledge, from making application. It was found impossible to specify every branch of photographic and allied subjects, proficiency in which would warrant application for the Fellowship being made, but the Council have now arranged the bases for application in a way which will preclude no one worthy of the Fellowship from obtaining it.

PHOTOGRAPHIC TRADE IN BERLIN.—The annual British Consular report on the trade of Berlin, which has just been issued, says the manufacture of photographic paper was especially unfavourably

influenced during 1908 by the circumstance that the exports, on which this branch of industry largely depends, showed a marked falling off. Italy, which formerly covered its requirements in Germany, had developed a very flourishing photographic industry which manufactured in particular sensitised papers. The United Kingdom and America, the best buyers of German photographic articles, also diminished their purchases. The share of these two countries in the export of sensitised paper from Germany was approximately as follows:—1907, total exports 1,149 tons, valued at £574,119. Of the foregoing 540 tons went to the United Kingdom, and the value was £269,679. To the United States 115 tons went, valued at £57,525. In 1908 the total exports amounted to 1,061 tons, valued at £530,361. Of the foregoing 480 tons went to the United Kingdom, the value being £240,031. Forty tons, valued at £20,158, went to the United States. The home trade was likewise unsatisfactory, as demand increased, and resulted in an over-production and a consequent limitation of the output. In the course of the year a convention between manufacturers and dealers was successfully formed, which is expected to put an end to the cutting of prices.

PORTRAITS OF L.C.C.'S.—The Records Committee of the L.C.C. have had under consideration a suggestion that photographs of members of the Council should be preserved in the Council's library, and they are of opinion that such a collection is desirable. The committee have accordingly requested the clerk of the Council to communicate with past and present members of the Council, informing them of the proposal, and asking them whether they have photographs, preferably of cabinet size, which they will present to the Council. The photographs will be kept in suitable albums in the Council's library, and the collection will be kept up-to-date as far as possible.

THE RESOLVING POWER OF LENSES.—Mr. P. G. Nutting, in a paper presented at the Washington meeting of the Physical Society, states that with a half-tone screen of about 200 lines to the inch illuminated with monochromatic light as object, the resolving power of a $f/3$ to $f/20$ lens may be determined with considerable precision. Theory gives

$$\phi = a \frac{\lambda}{h}$$

as the least angular separation between two objects just resolvable by a lens of diameter $2h$ used in light of wave-length λ . Viewing two stars, the image of either is calculated to lie at the centre of the first dark diffraction ring surrounding the other when $a=0.61$.

With the half-tone screen the following determinations of a were made:—

All structure leaves image when	$a=0.48$
Nature of object apparent when	$a=0.54$
Image shows proper form but lacks contrast when	$a=0.65$
Shadows just perceptibly hazy when	$a=0.95$

Hence the theoretical value of a assumes an image agreeing in form with the object but greatly lacking in contrast and without clear shadows.

THE DALLMEYER BEANFEAST was held this year at Southend, where a pleasant time was spent. The weather was fortunately fine and tempted many of the party to make the journey by water. A Dallmeyer cricket club has just been formed among the firm's employees and expects to turn out a fine team for next season. The president is Mr. Cyril F. Lan-Davis, the vice-president Mr. L. B. Booth, and the hon. secretary, Mr. John H. Sims, 107, Denzil Road, Neasden, N.W., to whom all communications should be addressed. This is not the first Dallmeyer cricket club, as some years ago there was an energetic eleven, for which on occasion the late Mr. T. R. Dallmeyer played.

THE COLLECTION OF PHOTOGRAPHS.—At the annual conference of the Museums Association, held at Maidstone last week, Sir Martin Conway read a paper on "General and Local Photographs in Museums." He said he had for many years bought photographs right and left, but the result was confusion. Then he stopped for some years. Seven years ago he began collecting on another method—gathering not only photographs, but prints of all kinds and on all subjects, but specially on art. He kept one unit of size, cutting down the illustrations if necessary, placing them all on suitable

mounts. In this way he had got together over 60,000 photographs, etc., which were all classified and formed the nucleus of an illustrated card catalogue to knowledge chronologically arranged. He found it a great saving in many ways. People carried about an enormous amount of unnecessary learning in their heads, which was one of the things that made them so stupid. He thought the collection of photographs might very well take the place of the hobby of collecting postage stamps. He cut up magazines, and even books, to get the desired illustrations. He commended the suggestion to museum authorities.

Mr. Henry D. Roberts (Brighton) suggested that the collecting of local photographs and prints might be left to the county photographic record societies which were springing up all over the country. That relating to Sussex, he said, had its headquarters at the Brighton Library and Museum. The arrangement of the material was geographical, based on the ordnance survey maps.

MESSRS. T. ILLINGWORTH AND Co.'s ANNUAL OUTING.—On Saturday last the staff of the famous Willesden Photographic Works, together with a number of friends, held their annual outing, Chertsey being the spot selected for this year's visit, and the journey performed by rail to Richmond and thence by steam launch. The weather, which has been exceedingly capricious of late, suddenly changed, and the party were favoured with a day of steady sunshine and heat, which added not a little to the enjoyment and success of the excursion. The afternoon was chiefly devoted to sports of

Correspondence.

- *• We do not undertake responsibility for the opinions expressed by our correspondents.
- *• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

LANTERN SLIDES DIRECT.—A CORRECTION.

To the Editors.

Gentlemen,—In the article on the above subject in your issue of July 9 I am responsible for the following statement:—"I have nevertheless never seen any specific allusion to the following simple deduction from the law of conjugate planes, taken in conjunction with the law of inverse squares, viz., that if the source of illumination is at the anterior focal point of the lens and the time of exposure kept constant, the plate must always receive the same effective exposure per unit area, whatever the scale of reproduction may be."

Mr. Welborne Piper has very cogently suggested that the absence

various kinds, including some races of a novel character, all of which were entered into with enthusiasm and keenly contested, and one of the most popular features in the evening's entertainment on board the launch was the distribution of prizes to the successful competitors. The visitors included, among a large number of others whose names are too numerous to mention individually, Mr. and Mrs. Birnie and Mr. Fryer of Glasgow, Mr. and Mrs. Percy Wright and Mr. Smith of Houghtons Limited, Mr. and Mrs. Mallabar, Mr. Dahl, Mr. Edwards, and Mr. Jack Lewis. The party, which started some where about the early hour of 7 a.m., reached their homes again shortly before midnight, for the firm of Illingworth plays with the same amount of zest and energy as that with which it works. The accompanying reproduction of a photograph taken on the occasion of the outing will give an idea of the number of those who availed themselves of this occasion of spending a pleasant day up the river.

ROYAL PHOTOGRAPHIC SOCIETY.—The Council is pushing forward with all possible speed the completion of the society's new premises at 35, Russell Square, but as difficulties have been met by the builders in connection with the new structural work, it is improbable that the house will be ready for occupation until the end of the first or possibly the second, week in August. Ample locker accommodation will be provided at a rental of 2s. 6d. and 5s. per annum for each locker, according to size. Applications for lockers may be made to the secretary at once, and should be accompanied by postal orders for 2s. deposit upon the key, and for an amount equal to one-third of the annual rent.

of specific allusion referred to may probably be accounted for by the fact that the relationship alleged does not exist. The relationship would hold only in the event of the whole light diffused by the object (or a constant fraction thereof) contributing to the image formation. In other words, I have omitted to take into account in my calculations the variation of the solid angle subtended by the lens aperture at the varying distances of the object plane. I find that when allowance is made for this variable factor the statement quoted is practically valid if instead of "anterior focal point" we read "back working focus." The distances of the back working focus from the object for various scales of reproduction is quoted in the annexed table under Column II. If the radiant be located at these distances then with constant exposure time the relative exposures the plate receives are as quoted under Column III.

I. Scale of reproduction.	II. Back focus.	III. Relative exposures.
Full size	4 f	1
$\frac{1}{2}$ "	$4\frac{1}{2}$ f	1.4
$\frac{1}{3}$ "	$5\frac{1}{3}$ f	1.29
$\frac{1}{4}$ "	$6\frac{1}{4}$ f	1.03
$\frac{1}{5}$ "	$7\frac{1}{5}$ f	.9

The values in Column III. are not absolutely constant, but the deviations from the mean value are not great enough to be of importance in practice.

In my experiments the radiant was always placed well behind the lens to prevent all possibility of flare, and hence the constant

ime exposures for all scales gave negatives of practically constant density. In fact, empiricism was my friend, not theory.

I might add that in order to get crisp negatives the light should not fall perpendicularly (or nearly so) on the diagram. If the light be incident at an angle of 45 deg.—i.e., if the radiant is always placed in the same plane as the focussing screen, and as distant from it as the screen itself is from the object plane, the values quoted in Column III. for relative exposures still holds good, and all possibility of degradation from regular reflections from the blacks of the picture into the lens are avoided.

Apropos binding-strips. Since writing the article I have learned that the Lumière company have placed a dry adhesive binding strip in the market. On trial, I find it to be admirable in every way. For myself, at any rate, the gummed strip is henceforward obsolete.
-Yours faithfully,
Blackheath, S.E.

DOUGLAS CARNEGIE.

PHOTOGRAPHING FINGER-PRINTS.

To the Editors.

Gentlemen,—In a comparatively recent number you replied to a correspondent who sought information about photographing finger-prints. You recommended him to trust to colour-sensitive plates and appropriate screens. Well and good; but in practice these will often fail. It is better to have a variety of resources at one's command, and to adapt the method to the circumstances.

For example:—

1. Finger-prints in dust.
 - (a) On colourless glass; illuminate by transparence with oblique light; dark background.
 - (b) On dark surfaces (a very easy subject); illuminate by direct light.
2. Fingerprints in grease (ordinary finger prints).
 - (a) On light surfaces such as china plates; dust on dry, very fine graphite powder; blow off with bellows, etc., *not with breath*. The "dusting on" is best effected by charging a heavy flat-ended camel-hair brush with the powder, holding it near the surface and jerking it by a blow on the hand holding it.
 - (b) On dark surfaces, such as the black or green paint of a safe,

Door of safe with finger-prints. Stamp included to control reduction.

mahogany furniture, etc.; treat similarly, using fine, dry white-lead powder.

- (c) "Invisible" finger-prints on paper. Develop with aqueous solution of silver nitrate (5 to 8 per cent.).

Finger-prints in blood on dark surfaces (e.g., black bottles). In dark-room illuminate by direct rays of arc or magnesium light, preferably concentrated. You may get reflections, but the pattern of the papillary ridges will stand out clearly.

I am sending you three photographs that I happen to have by which your correspondent might care to have. They illustrate 1), 2 (b), and 3.

They are far from beautiful, nor are they even the best I possess, but they happen to be spare copies, and have the merit of—(1) Being genuine cases, and not academically prepared specimens; (2) being made with materials and apparatus found at hand and used in emergencies.

Should your correspondent desire further information on this

Finger-prints in blood on a dark-blue bottle.

subject, or on the application in other ways of photography to criminal investigation I should be happy to afford any that I possess, and for this purpose enclose my card.—Yours truly,

Ministère de l'Intérieur, Cairo. H. NOLAN, Controller.
July 10, 1909.

[We reproduce two of the photographs sent by Mr. Nolan, but it should be said that the subjects do not lend themselves to reproduction, and scarcely give an adequate idea of the success with which these difficult subjects have been photographed. The print referred to in the last line of the previous column, 1 (a), as illustrating the photography of a finger-print in dust, could not be given even this degree of reproduction by the half-tone process.—Eds. "B.J."]

PHOTOGRAPHY AND ART—A MORAL.

To the Editors.

Gentlemen,—There is no doubt that many of those present on the occasion of the opening of the Convention at Canterbury were very favourably impressed by Mr. H. Snowden Ward's well-written address, and although some of the arguments advanced required several grains of salt before they could be swallowed comfortably, and the names of some of Mr. Ward's apostles of the camera (at whose feet many of the R.A.s ought to think it a privilege to be allowed to sit) caused many a quiet smile, still, on the whole, the address was considered one of the best with which a Convention had been favoured, and commendation was general.

But on the Thursday evening, "Oh, what a falling off was there!" Then, to ram his arguments home, Mr. Ward elected to exhibit some lantern slides. They were mostly shown in pairs. First, the unpromising subject, and then the "work of art" which had been evolved from it. In each case the result was the same—viz., the unpromising subject was, to say the least of it, a fairly good photograph; while the "work of art" appeared as a flat, faked-up fraud—a veritable lamb in a lion's skin.

The moral of all this seems to be that the makers of patchwork productions (such as were shown on this occasion), which have been glorified as works of art at exhibitions, would do well not to have lantern slides made from them, or the pictures which have, at the hands of good-natured and sympathetic judges, been awarded medals may, as lantern slides, only provoke ridicule.—Yours truly,

DROP-SHUTTER.

Answers to Correspondents.

- *• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- F. W. Fielder, 26, Broadway, Maidstone. Photograph of the Very Rev. the Bishop of Lewes (L. H. Burrows.)
- H. M. Veale & Co., 98, Victoria Street, Bristol. Two Photographs of Winner (Miss Annie Massey) of Empire First Grand Beauty Competition, Bristol, July 2, 1909.
- J. Mills, 11, Gold Street, Northampton. Photograph of J. G. Shipman, M.P.
- M. Lautenberg, 56, Waterloo Road, Widnes. Three Photographs: Waterloo Road, Widnes, showing Gossages Soap Works. West Bank, Widnes, showing Transporter Bridge and Runcorn Bridge, and Runcorn in the Distance. West Bank, Widnes, showing Transporter Bridge and Runcorn in the Distance.
- Rawlinson Brothers, Albion House, High Street, Llanhilleth, Monmouthshire. Eight Photographs: Glandore, Welsh Baptist Chapel, Llanhilleth; Llanhilleth English Baptist Chapel; Pleasant View, Llanhilleth; St. Mark's Church, Llanhilleth; Wesleyan Church and Commercial Road, Llanhilleth; Llanhilleth Institute and Station; High Street, Llanhilleth; New Parish Church, Aberbeeg, Monmouthshire.

ANILINE DYES.—Would you kindly let me know of a book dealing with aniline and other dyes or chemicals used for the preparation of filters and the sensitising of plates, and also dealing with the manner of testing and proportions for making up for use with spectroscope?—A. H. L.

There is no book which deals with the most recent and really useful dyes. We believe an atlas of such dyes is in preparation by Dr. Mees; but meanwhile the latter's papers, notably those in our issues of May 21 and 28 of this year, may be referred to.

COPYRIGHT.—If a photographer has a print registered, but does not mark on the prints sold afterwards the words "Copyright" or "Registered," and another man copies same and sells them, not knowing they are copyright, is this man liable for damages?—**QUERY.**

Yes, he is. There is no need to mark a print "Copyright," and ignorance is not held by the Act as any excuse for infringement.

DEVELOPER.—Can you tell me of a good developer—not metol-hydroquinone, which affects my skin, or diamidophenol—suitable for bromide or gaslight postcards in large quantities, and which will work out at a reasonable price, and not upset one's skin?—**DOLPHIN.**

We should advise you to use pyrocatechin, which is very suitable for these classes of work, and is not expensive.

CAST.—Perhaps the lighting is somewhat too much to the back, rather too "Rembrandtesque" for ordinary work, but otherwise shows very careful adjustment of the light. For persons of strong features such a lighting would be very suitable, but we should prefer one of softer character for sitters of less pronounced type of face.

PORTRAIT STYLES.—(1) A few days ago I saw some high-class work which had more the appearance of pen-and-ink photographs or sketches of the persons depicted. They were upon white grounds and mounted upon white cards, and certainly looked exceedingly beautiful. You could, however, see they were photographs, and not pen work. I presume the manner of lighting was the key to the results. I should think they were printed on platinotype. Can you, through your valuable paper, tell me how they are secured? (2) At another place I saw some sepia prints, mostly heads and shoulders, in which just the head alone was prominent, the neck and shoulders being much subdued and fading away to plain white of the background. Is this effect obtained in the camera or by masking during printing, or by both of these means? I am an amateur, and have built a small studio with a north light, in which I experiment a little for a hobby (not for business at all), and would like to try to get similar effects to those mentioned, therefore I ask your advice. I have taken the "B.J." in for some four years regularly, and have picked up much valuable informa-

tion from it. (3) If you could name me some really good books on lighting and posing, with prices and where to be got, I should esteem it a favour.—**PILATUS.**

(1) From your description we should say that the faces in the photographs are printed from the negative and the body and background sketched in by hand on the print. This method is a good deal followed at present. (2) Without seeing the examples we should say that the effect is obtained solely by vignetting during printing, the negative having been taken in the first instance against a very light background. (3) "Artistic Lighting," by Jas. Inglis (2s. 6d.); "Lighting in Photographic Studios," by Duchochois (1s.). You can obtain these from Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C. "The Photo-Miniature," No. 2, or the "Pose in Portraiture," is now out of print, but if you can by chance obtain it from a dealer, it will give you a number of useful hints on composition in portraiture.

WATER ANALYSIS.—I am wanting to analyse some water. Can you advise me of any book explaining the method?—**J. S.**

Water analysis calls for a good deal of experience and apparatus if the results are to be of any value. If you wish to make test of hardness only you may obtain some useful data. We advise you to apply to a chemical apparatus firm, such as Mr. A. H. Baird, 33-39, Lothian Street, Edinburgh, for prices of an outfit. There are several books on water analysis, but they are of little use to those unprovided with a laboratory.

G. J. P.—Barton's, 38, John Bright Street, Birmingham; Houghton Ltd., 88-89, High Holborn, London; Trapp and Co., 89, Chiswell Street, London, E.C., to name only three of a number of firms.

GRANULATION OF PLATES.—During very hot weather (say more than 90 deg.), after fixing the negative, either with acid fixing bath or with simple one, I often observe the negative, as soon as I put it in washing water, to become very granulated, and after drying the negative remains unchanged. I observed that granulation less on reduced silver, while too much on shadows, therefore I thought that perhaps the cause is air in water, but I have not tried boiled water. The thing which provoked me is that to-day I have developed six plates from the same box with the same developer, the same fixing bath, the same washing water, the same time, and climate, but I found that four of them have been granulated and ruined, while the other two are quite as good as if made in winter.—**TADROUS HANNA (Assiout).**

The granulation is no doubt due to the partial decomposition of the gelatine, and the best way to prevent it would be to use hardening bath. You might try Namias' fixing and hardening bath the formula of which is as follows:—

Chrome alum	24	grs.
Hypo	1 3/4	ozs.
Sodium acetate	80	grs.
Water	7	ozs.

Your last experience is not uncommon. Granulation does not necessarily occur with every plate in similar circumstances. One or two may escape.

J. H.—We have not come across a defect of this kind before. You are inclined to attribute it to exposure of part of the roll to light while in the fixing bath, but we can hardly suppose that this is possible in your case. We will see if we can hear of similar troubles and write you next week.

*• **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

An exhibition of the results obtainable by the latest method in the mounting of photographs will open at the house of the "B.J." on Tuesday next, August 3, at 10 o'clock.

The oft-condemned plan of washing prints by allowing the tap to run into a dish containing the prints is actually less inefficient than is made out to be if a certain trick be used. A note on this point appears on p. 586.

In washing cut-films by this method damage of the films by one another will be avoided by rounding the corners prior to development. (P. 586.)

Details of the recognised method of washing a batch of prints are given in the article on the albumen process on p. 588.

A paper of gaslight rapidity and P.O.P. effect has just been placed on the market by the Paget Company. (P. 599.)

Some notes suggested by the visit paid by professional photographers last week to the Speaight "Fair Children" Exhibition appear as a leading article on p. 587.

M. G. Underberg, in continuing the notes on the acid diamidophenol developer, strongly commends this reagent as a developer for bromide and gaslight papers. (P. 591.)

Reports of meetings dealing with proposed photographic exhibitions appear on page 601.

A developing tank, with a thermometer as a fixture therein, figures among other patents of the week. (P. 596.)

A hint on framing photographs in passe-partouts, which may perhaps serve further to remind professional photographers of the frequent use to be made of this method, is given on page 586.

"Health Conditions in Engraving Shops," "Transparent Drawing Surfaces," "Collecting Dust," etc., are topics of process interest treated under "Photo-Mechanical Notes." (P. 595.)

"Exposure in Copying," "Direct Positives from Originals," and the "Pepper Process" appear under "Correspondence." (P. 603.)

A graphic method of identifying a series of objects in a landscape by reference to a map of the district has been recommended by a writer in a contemporary. (P. 589.)

EX CATHEDRA.

At the "B.J." House from August 3. We would further draw the attention, particularly of our professional readers, to the exhibition and demonstration which will open at 24, Wellington Street, Strand, W.C., on August 3, and will remain open daily from 10 to 4.30 (Saturdays 10 to 12-30) until August 14. The exhibition will take the form of the results producible in the way of professional mounted portraits, portraits in folders, etc., by means of the method of simultaneous dry-mounting, plate-marking, and blocking done according to the recently invented system of the late Mr. G. W. Morgan. The late Mr. Morgan's son will act as demonstrator, and by means of a complete equipment for the process will show the method of working. As the process has already been taken up by several leading photographers, amongst others, there is little doubt that the convenient opportunity thus afforded will be largely taken, and we would suggest that visitors anxious to have the process demonstrated to them at special length should time their visit as early as possible after the hour of opening. In addition to the mounting demonstration, the visitor can see the working of a mercury-vapour portrait installation, and, if he wishes, actually expose his own plates and develop them upon the spot.

* * *

A Quickly Made Focussing Screen.

The usual directions for making a focussing screen in an emergency are to rub two pieces of glass together with a mixture of flour-emery (knife polish) and water between them. If "Carborundum" powder be used in place of the emery the desired result is obtained in far less time. The "rubber" should be a piece of plate glass of small size (an old c.-de-v. cutting shape does well), so as to get into the slight undulations of the glass to be ground. A half-plate can be nicely "matted" in five minutes by this method. Although the result is not quite so fine as most focussing-screens sold at dealers', the difference is very slight, and the "Carborundum" screen will be found quite good enough for ordinary purposes. The powder can be obtained from any motor-garage, as it is now used instead of emery for grinding in valves. The finest should be asked for, as there are several grades, and a few pence should cover the cost.

* * *

Reversing Portraits.

Probably very few photographers now use the single-transfer carbon process for printing from their portrait negatives, but occasionally it is desired to reverse one of a pair of enlargements to make them "match." This should not be done without showing the customer how the portrait will look when reversed, as, though to the photographer the likeness will appear the same, the near relatives of the subject may find

fault. This is, of course, more likely to happen when the two sides of the face differ greatly. This point was very forcibly brought home to one of our professional readers the other day. He had made an excellent full-face negative of a very near relation, but on bleaching the plate with mercury (to intensify it), there seemed to be something strange about it as a likeness. On examining the back of the plate when bleached, the likeness at once became perfect. It was at once seen what had happened: the two sides of the lady's face were very different, and the reversal of right and left altered her appearance. This last may account for some of the cases when a sitter is dissatisfied with a portrait, while her friends are pleased. To show a customer the difference in appearance that would be caused by reversal, the simplest way is to take two prints, and, holding one opposite a mirror, to place the other with its back flat against the glass, so that it appears at the side of the reversed image.

* * *

Framing in Passe-partouts.

Framing photographs in passe-partouts is sometimes difficult in the case of prints that have been mounted and become even slightly warped. Fortunately, it is quite a simple matter to make them perfectly flat, when binding becomes quite easy. To flatten the mounts, the backs should be well sponged with water, and the harder and thicker the mount the more water should be used. Then the mounts should be laid between two sheets of cardboard and placed under a board and pressed for a few hours. The same procedure is advised in the case of rough-mounted prints to be mounted under "cut-outs." A flat print is infinitely easier to mount neatly than one with a warp in it. A piece of brown paper pasted on the back of a "rough mount" does not entirely counteract the warping, although it is of great assistance. A sheet of "salvage" plate-glass about "Imperial" (32 by 22) size laid on a few sheets of cardboard of the same size is an improvement on the weighted board, and forms a cheap and very efficient press, both for flattening mounted prints and for mounting under cut-outs, which require a flat pressure for some hours to ensure perfect adhesion. The glass is heavy enough to flatten the thickest cardboard in a few hours, and it is not too heavy for convenient handling, besides which it forms a good bench for trimming prints, whether in or out of use as a press.

* * *

Washing Under the Tap.

Photographers are often told that washing prints in a dish into which water is kept running is a very inefficient method of working, nevertheless it is a highly convenient one, and it is very often used, even, we suspect, by those who deprecate it. The alternative method of soaking in frequent changes of water is no doubt very effective and economical as regards water, but it is not so economical in respect to time, and the continued attention required is often shirked. If we use enough water and arrange the dish properly the "running water" method is quite efficient, though it seldom is so as ordinarily conducted. We may say at once that it is quite useless to simply let the tap dribble into a dish crowded with prints; neither is it of any use to get up a violent whirl of water in the centre of which a mass of prints revolves. We have seen water-pipes carefully arranged all round a dish so as to keep up a beautiful whirl, but the only result was that the prints kept together in a mass, and some of them were never properly washed at all. The following, which is the best method we know, requires no extra taps or pipes, one tap to each dish being all that is required. Select a dish in which the sides slope outwards very slightly. The majority of porcelain dishes have the requisite slope, and

the only ones not suitable are those with quite vertical sides. Arrange the dish so that a fairly strong stream of water falls vertically on the centre of one of the shorter sloping sides. If the water in the dish is stained a port wine colour with permanganate, it will be found that the whole of the colour in a 10 x 8 dish will disappear in two minutes or less. This is the test for efficiency in changing the water. Then place twenty or thirty quarter-plate prints in the dish. If the water is running with a sufficient force the whole will keep constantly on the move, each print continually changing its position, and never clinging to any other print.

* * *

Washing Cut Films.

Cut films can be washed in a dish in running water just as well as prints, if we observe the precautions described as necessary in another paragraph, but films are liable to become more or less damaged in the process. As they whirl around, the sharp corner of one film may easily dig into the soft gelatine of another and produce a small triangular tear that requires a lot of spotting out. To prevent this, it is as well to snip the corners off the films before wetting them at all, and an ordinary pair of nail nippers will produce a nicely rounded corner that will not effect much damage. It would be a material advantage if manufacturers would round the corners of their cut films, as the tearing tendency of the sharp angles is often a great nuisance. In addition to snipping off the corners, care should be taken to see that all the films are put the same way up in the dish. Every film has a slight tendency to curl up at the corners on the film side, but if all are either film up or film down the likelihood of damage is much lessened.

* * *

Incongruities in Portrait Photographs.

There is still need to remind photographers of the mistakes which may easily be made in portraits taken with the aid of painted backgrounds. As "Abel's Weekly" (New York) writes in its current issue, "one expected that in the days gone by, when men in walking suits were made to come down the stairs of Arabian Nights palaces, and ladies in fascinating décolleté toilettes were discovered leaning against massive stucco pillars, but we do not look for it to-day, when our photographers have for years been drilled with the motto: "Observe the proprieties." Yet in a current annual we find two of our best photographers committing incongruities which are all the more noticeable because of the names under the pictures. In one otherwise excellent picture the photographer rests the hand of his subject on a little side table with elaborately turned legs, the rear of the table merging into a background of sycamore and fir trees, and appearance of lake and mountain in the midst. There is not even the excuse of the subject being on a porch, for she stands with her back to an enormous tree trunk. How *did* that table get into the scene? In another instance a group is marred by introducing a modern drawing-room chair into the wild background landscape. With the present craze for worked-in landscape backgrounds, are not photographers a little careless in observing the proprieties?"

* * *

Rubber Corks.

Many of the ready-made solutions now on the market are put up in bottles fitted with rubber corks, so this article is becoming a more familiar object in the photographic workshop than used to be. Unfortunately, rubber corks have some peculiarities that greatly perplex those unfamiliar with them, and the better the quality of the cork the more eccentric is its behaviour. One of its most troublesome tricks is that of jumping out of the bottle almost as rapid

s it is put in. Though forced into the neck as far as it will go it is probably right out before the bottle has been replaced upon its shelf. This often happens when both cork and bottle neck are wet with the solution, and an obvious remedy is to wipe both dry. If this fails a certain remedy is to make a few shallow cuts around the cork with a sharp knife. Another trouble is the sticking of the cork to the neck of the bottle. This does not often happen with the cheap hard vulcanised corks, but it frequently does so with the soft and elastic best quality ones, for which reason it is not advisable to use these for general purposes. They are excellent for temporary use as they make a far more airtight plug than any stopper, but they are soon spoilt if used permanently. One of the most efficient and cheapest rubber corks that can be devised is a home-made one, produced with the aid of an ordinary cork, a piece of string, and an old tobacco pouch. Cut a piece of rubber from the pouch and lay it over the neck of the bottle. Then force in a rather small size ordinary cork, and when it is well in gather up the overlapping rubber around the upper part of the cork and fix it by tying the string tightly around. On trimming off the superfluous rubber a cork is obtained that will do good service for several years. Seeing that good rubber corks for pint bottle cost fivepence or sixpence each, and sometimes more, this economical method of producing corks that are just as effective is worth remembering.

MORALS FROM THE SPEAIGHT EXHIBITION.

THE photographers who, as reported on another page, visited the exhibition of photographs of "Fair Children" at Messrs. Speaight's galleries last week are not likely to forget the evening. It is to be hoped that they will not allow themselves to do so, because the occasion, in our judgment, and, we believe, also in theirs, stands for a good deal in professional portrait photography. To begin with, every professional photographer must surely appreciate the great success which has attended the conduct of the Speaight business of late. It goes without saying that such success is necessarily based on photography which is thoroughly good from first to last. At the same time mere technical excellence, of whatever degree, could not have achieved the success except in conjunction with business management of no ordinary kind. Everybody knows that commissions to photograph the children of crowned heads in different capitals of Europe do not come tumbling in to photographers, even in the West End of London, by every post. Messrs. Speaight have worked for the *denouement*, which has taken the form of the exhibition now closing, for years past, not solely by mere solicitation, which probably of itself could have proved futile, but first and foremost by attaching a certain character to their business and to their business methods. They have made themselves known among the classes of people from whom they aim at drawing their custom, not only as photographers, but also as citizens of London, who have manifested their citizenship in a notable way. We should, perhaps, in speaking of this side of their activities write of them in the third person singular, since it is an open secret that Mr. Richard Speaight, the younger brother, confines himself almost altogether to the photographic side of their enterprise, whilst the business—or should we say the "stage"?—management is the work of the elder, F. W. Speaight. The latter's persistent and successful advocacy of alterations in the Marble Arch is only one piece of public work which has made the name of Speaight familiar in newspapers during recent years. The proposition for modification of the Horse Guards' Parade is the subject which

currently absorbs Mr. Speaight's surplus energy. Both, as we know, have brought to the studio many public men and women, who very likely learnt for the first time of the existence of a photographer at 157, Bond Street, on paying a call there for quite another reason. Thus in launching an exhibition such as that which is just closing, the Speaight brothers approached the proposition very fully equipped in the way of prestige and standing, and to that fact undoubtedly—just as much as to the excellence of the photographic work—must be attributed the success with which they have held an exhibition of portraits of Royal and other titled children, which has been largely visited on the same terms as other art exhibitions in Bond Street, namely, payment of one shilling, and has during the past week received the distinction of having been visited by three Royal Princesses—T.R.H. the Princess of Wales, the Crown Princess of Sweden, and Princess Alexandra of Teck. And those who happened to see the daily and weekly Press at the time of the opening of the exhibition in June will call to mind that the little exhibition at Messrs. Speaight's galleries was very largely noticed—in many instances by whole-page or double-page reproductions—in such papers as "The Sphere," "The Ladies' Field," "Black and White," "The Bystander," "The Gentlewoman," not to mention other daily and weekly periodicals.

Let us admit at once that in achieving this success Messrs. Speaight have worked in a field which does not stand open to the great majority of photographers in the provinces, or even in the outskirts of Greater London. We can imagine a reader of the "B.J." in, say, Swindon, Wilts, saying to himself that such enterprise as that we are now alluding to is out of the question for him; but, after all, notability is only a matter of degree, and even when notable personages are as scarce in a district as Grand Dukes in Whitechapel there are still other sections of a photographer's public which may be drawn upon for the purpose of valuable and at the same time inexpensive advertisement. Pretty children—even when their parents have no handles to their names—are a constant attraction to the public; and since we first visited Messrs. Speaight's exhibition we have received one circular from a photographer in Yorkshire advising us of the holding of an exhibition of portraits of beautiful children at his studio, which he tells us he has had in contemplation for a year or two past. And still another instance comes before our notice of a Surrey studio, where a similar exhibition of portraits of local notabilities has been held with considerable success. Our object, therefore, in calling attention to the ways and means by which the Speaight exhibition has come into existence is to suggest to portrait photographers in all kinds of places that a lesson may be learnt in the methods of attracting the public. Yet it must not be supposed that this is a thing which can be done at a fortnight's notice. Steps to securing such a result are painful and slow, and mean diplomacy and taste at every point of contact between the photographer and his clients. In matters of letter writing, even in details of stationery, note headings, and the score of minor matters which are of little importance commercially, but stand for a good deal in showing what manner of man the photographer is—there is an opportunity for persistent discretion, and it would, perhaps, surprise some to know of the pains expended in the Speaight establishment on such things as envelopes and invoice forms.

But we must not dismiss the recent exhibition without a reference to one incident which has been an admirable result of it, namely, the forgathering there on Wednesday in last week of quite a number of professional photographers. To the invitation made through our columns

a large number of photographers responded, and the reception-room and gallery during the two hours which the function occupied was uncomfortably crowded. The visitors included the president and chief officers of the Professional Photographers' Association, in addition to several proprietors of West End studios. It is the first occasion, so far as our knowledge goes, of professional photographers hobnobbing in friendly concourse at a studio which admittedly is in competition with, at any rate, those of a few of the visitors. We have been accustomed to regard such fraternising as the prerogative of the American professional, and have usually ascribed its existence in the United States to the fact of the great distance between the large centres of population in that country. Therefore, the Speaight brothers, we may say, have not only brought to a successful issue a new idea in professional portraiture, but have further applied it to the eminently useful purpose of knitting more closely together the members of the profession—a dual result upon which we believe all those interested in the welfare of portrait photography will offer their congratulations.

PRACTICAL NOTES ON ALBUMEN PAPER PRINTING.—IV.

In the last article the process was brought up to the final stages, namely, the fixing and washing of the pictures. These latter operations are looked upon by not a few as being of quite minor importance, while, as a matter of fact, they are actually the most important of all when the stability of the pictures is a consideration. With respect to the strength of the fixing solution for the prints, some of those given in the text-books are, to our mind, too weak. The formula we always employ for albumen pictures is as follows:—

Hyposulphite of soda	2 lbs.
Water	1 gallon.

To this a few drops of liquid ammonia are added, just enough to give the solution a very slight smell, and no more.

The addition of ammonia is merely to ensure the bath being free from acidity. But with the purer kinds of hypo now on the market this is rarely necessary. The above formula gives us four ounces of hyposulphite to the pint of water.

The prints being ready in the washing water, after toning, the procedure is as follows:—The water is poured off, and the dish reared on end, with the prints left sticking to the bottom to drain; for it is not desirable that they should have much water upon them when put into the fixing solution, as it would tend to dilute it where in contact with the picture. A liberal quantity of fixing solution, according to the number of prints, should be used. It is poured into the fixing dish, which, by the way, should be large, the prints then taken one by one with the left hand, transferred to the right, and by that put, face *downward*, in the hypo solution, in which they should be kept moving about. Care should be taken that no air-bells get imprisoned, as they are certain causes of yellow spots. Minute ones will cause small yellow spots, which, while not showing at once, often make their appearance in a short time after the prints are finished and mounted. With the above method of procedure the left hand is always kept free from contamination with hypo until all the prints are got into the fixing bath. When that is done, the dish is well rocked for a minute or two to keep the prints separated, as on no account should they be allowed to stick together, or to the bottom of the dish. They are then turned over, one by one, so

that they will all then be face upward. Here both hands may be used. When all have been turned over, the operation is repeated with occasional rocking of the dish to prevent any sticking together. This work is continued for not less than a quarter of an hour. It was the custom with some of the older workers, with whom permanence was a great consideration, after the pictures had been in the fixing bath for the usual time, to put them into a fresh solution of hypo for a similar time, with a view to ensure perfect fixation.

At the end of the time, the fixing solution is poured down the sink, and the dish reared on end, leaving the prints adhering to the bottom to drain off the hypo for two or three minutes. While in that position it is a good plan to spray them with a rose attached to the tap with a foot or two of rubber tubing. The dish is then put under the tap and quickly filled with water, and the prints well sluiced about in it, and the water quickly changed—indeed, the tap should be kept running all the while, for the quicker the hypo, in the first instance, is got rid of, the better. The prints, when first put into the fixing bath, will become somewhat of a lighter colour than they were after toning, but they will regain their original tone when dry.

The temperature of the fixing bath is of some importance; the best is from 60 deg. to 65 deg. F.: if it is much lower than the former, allowance must be made for it by allowing the prints a longer time in the solution. When hypo is dissolved in water its temperature falls many degrees, and, unless that be taken into account, the fixing bath may be used at an unsuitable temperature. If the bath has to be used at once, and if, in the solution of the hypo, the temperature has fallen much below 60 deg. F., a little boiling water should be added to bring it up to that heat.

As regards washing, the time of washing depends very much upon the way it is done, for the prints—provided the hypo silver salts are got into a perfectly soluble state (which means full and individual treatment with plenty of fresh hypo)—may be as effectually fixed from the hypo in half an hour as they can be with many hours' soaking even in running water. The plan we prefer is hand-washing in continual changes of water. One method is to have two large dishes of water, and transfer the prints singly from one to the other. When all the prints have been put into the first dish and well rinsed about, they are transferred, one by one, to the other. The first dish is then emptied, refilled, and the prints put back again: these changes are repeated. After half an hour, or three-quarters, the prints may be considered as perfectly washed. Another way of hand-washing is to have a single large dish of water, putting the prints singly into it, and well sluicing them about in it for five or six minutes, pouring the water off and rearing the dish on end, with the prints adhering to the bottom, to drain for two or three minutes. It is then filled up again with water, and the sluicing and draining repeated. With this treatment for three-quarters of an hour or so the prints should be free from hypo. In winter (*i.e.*, if the tap water is very cold) it is a good plan for one or two changes to be made in warm water, since the hypo is then more readily dissolved. Quite hot water may be employed with albumen. Indeed, some older workers, we know, used to make it a rule to use two or three lots of hot water in washing their prints even in summer.

A not unimportant precaution in connection with the fixing and washing the prints is that the temperature of the fixing bath and of the washing waters, at the first stage, should be as nearly as possible the same. With some papers, if the prints are put direct from the fixing bath into water at a quite different temperature, blister

ing is apt to arise, and in the final washing waters the blisters may assume a large size and break. In other instances they may be so small that they can only be detected by the touch; though they may not increase in size, they will usually show as dark spots when viewed by transmitted light, and almost always also when the pictures are mounted. Blisters are chiefly caused by trans-

ferring the prints direct from a medium of one density to that of another, as, for example, from the fixing bath to the washing water. In order to avoid this trouble some workers dilute the hypo bath—after the fixing is done—with an equal bulk of water, and allow the prints to remain in that, with constant turning over for five or six minutes, before putting them in the washing water.

PHOTO-SURVEYING METHODS FOR THE AMATEUR.

[In the current issue of "Photographische Mitteilungen," an article appears by Dr. R. Defregger, which, while addressed to photographers whose work lies amongst mountain ranges, the peaks of which they may wish to have some means of identifying in the negatives, yet conveys an elementary explanation of the principles upon which photo-surveying is based, and may be usefully translated.—Eds. "B.J."]

In the many cases in which photographs of mountainous regions have been photographed, photographers have frequently occasion to value some ready method by which the separate summits in the photograph may be identified by name on reference to a map. A good many mistakes may readily be made if judgment is left to the unaided eye in this matter, and in such cases the method described below has been found to give very useful and accurate results. The problem consists in finding a means whereby the unknown objects in the photograph may be identified on the map. If we represent the view point as A (Fig. 1) and four points seen from A as a, b, c, d , of which a only is known, then the lines Aa, Ab, Ac, Ad , from the view point of the four objects may be called "lines of view." If we could draw these lines accurately on paper identification of the unknown points would offer no further difficulty. The diagram, as shown in Fig. 2, is drawn on a piece of tracing paper and laid on the map so that the point A occupies the position of the standpoint of the observer. The piece of tracing cloth is then turned round A as an axis until the line Aa passes through the known object a on the map. As represented in Fig. 3, we then require to find from the four points of the map only those which lie on the view lines Ab, Ac, Ad , in order to ascertain the three unknown points b, c, d , the names of which are then obtained from the map. We have thus to make a "view-line diagram" (Fig. 2). The surveyor simply takes his theodolite, observes the points one after the other, reads off the corresponding horizontal angle on his divided scale, and makes out the diagram on his return. We are proposing to use the camera for this purpose. We assume that the four points are obtained on one plate. If they are so far apart as to preclude this, several exposures require to be given, on each of which one or two points are included, the process to be described being then applied to each plate. Let o in Fig. 4 be the lens, the viewing lines passing as chief rays through the lens to the plate, a section of which is shown as pp . We there obtain the image of the four points, a^1, b^1, c^1, d^1 . The distances of the points a^1, b^1, c^1, d^1 , from each other are set off with a scale or by means of a transparent print on to the negative. If we know the focus of the lens sufficiently accurately we can then draw mo perpendicular to the centre of the plate pp . We have then in o the perspective central point of our drawing, and we require only to connect o with the image points a^1, b^1, c^1, d^1 , in order to obtain the necessary view line diagram. This is briefly the method employed; in practice there are, however, certain difficulties to be overcome.

The first of these is that in many instances the focal length of the lens is not known with sufficient accuracy. The numbers engraved on the objectives themselves are usually average figures from which the particular lens may to some degree depart. The method for ascertaining the true focal length of a lens requires considerable care and skill. In my experience it is scarcely possible, except by special apparatus, to measure the

focal length correctly within one to two per cent. The most usual method is to focus the camera upon an indefinitely distant object and to know the position of the lens. The camera front is then racked out until some object placed nearer to the camera is recorded on the plate, exactly same scale. The distance which the lens has had to be moved to effect this result is its equivalent focal length. Although it is easy to adjust the focus accurately when focussing on infinity, yet when focussing on the same size object there is a considerable latitude in obtaining the focus, and a number of different observations will give results differing from each other by several per cent. The mean of this separate measurement is obviously preferable to any single value.

However, the trouble of making a determination of the focal length may be obviated, and the errors in the process disposed of, if the line om fixing the construction of the diagram be obtained from the photograph itself. This can readily be done if two points which can be recognised on the map are included in the photograph. An exposure is thus made so that the one point falls in the centre of the horizontal edge of the plate, or near to the centre, as in a^1 , Fig. 4. If b is also known from the map, then by tracing the three places, A, a , and b , or more accurately obtaining these loci by passing a fine needle through the map on to a sheet of writing paper below at the angle baa is obtained. The construction is shown in Fig. 5.* A perpendicular line me is drawn to the view line Aa at any desired spot, but further from A than the approximately known focal length. On this line the distance $a^1 b^1$ obtained from the negative is set off and the point g thus obtained. A parallel line drawn from g to the second view line Ab gives the intersection point with Aa in o , and om is the focal length required. This construction is the easier to make the less acute the angle at A, or, in other words, the further the separation of the two points in the landscape. Care is also taken so to choose the points that one comes as near as possible in the centre and the other at the edges of the field. If the distance, a^1, b^1 , is carefully taken there will be, as already shown, no effect upon the accuracy of the result if a is not quite, but only approximately, in the centre of the field.

The above construction requires amendment in a second direction. Only in a perfectly flat country are there to be obtained two points precisely at the same horizontal level. In the case of a mountain range one of the points may be the peak of a summit, whilst the other may be a church tower lower down. In such cases the two points must be brought to a horizontal level. This is very simply done by drawing in the negative, or on a print on matt paper, a horizontal line

* Or more carefully the distance which is of importance in this exposure, namely, that of the rear chief plane of the lens from the plate. A determination of the focal length on this basis has the same inaccuracy as measurement which depends on sharp focussing on the ground glass. The errors of focussing, however, as will easily be seen, are completely dispensed with for our purpose, the results being quite correctly obtained even if the plate has been focussed by means of a small stop with the lens away from its infinite position.

in the sky, and letting fall from all the points which we wish to include in our measurement perpendicular lines on to this horizontal line, as diagrammatically shown in Fig. 6. The points in which these perpendiculars meet the horizontal line, namely, a^1, b^1, c^1 (Fig. 6), are those to which the process already shown in Fig. 4 is applied. An example will make the use of the method clear. Let us suppose we are making the exposure

in question is covered thereby on the map, we draw a straight line, lay this on the horizontal line in the print, and draw carefully through the points of intersection of the horizontal line and the perpendiculars and also through the previously marked central point in the long side of the plate. From this point, m , on the tracing cloth we then draw a perpendicular of the length of the previously found equivalent focal length,

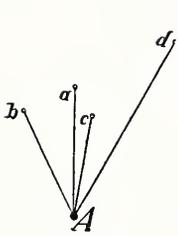

Fig. 1.

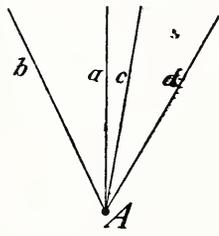

Fig. 2.

Fig. 7.

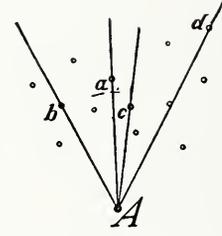

Fig. 3.

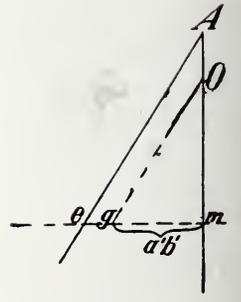

Fig. 5.

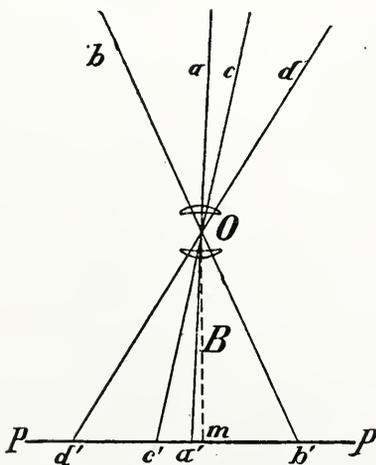

Fig. 4.

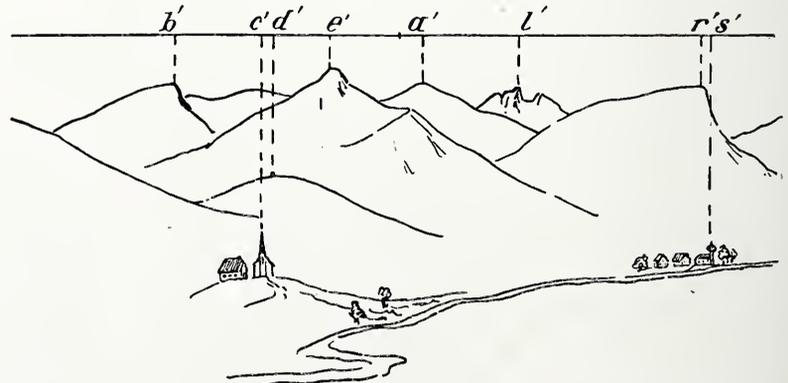

Fig. 6.

of the mountain range shown in Fig. 7, in which the two summits, a and b , are known. We draw the horizontal line and draw from the point to be measured perpendiculars to this horizontal as shown in the dotted lines. By means of the angle taken from the map between the standpoint and the two summits a and b , in conjunction with the distance, a^1 and b^1 , we follow out the construction given in Fig. 5 on a separate sheet of paper. On a sheet of tracing cloth of the size that the area

and thus obtain the point A , which we connect, as shown by the solid lines in Fig. 7, with the various points upon the horizontal. This gives us our view line diagram. It is laid upon the map so that the point A lies upon the standpoint taken by the camera, the two lines Aa^1 and Ab^1 being brought into coincidence with the two points which they represent; the other points of the unknown portions in the view are then identified on the map.

R. DEFREGGER.

FURTHER NOTES ON ACID DIAMIDOPHENOL DEVELOPER.¹

[The conclusion of the notes on the use of diamidophenol, the first portion of which appeared in last week's "B.J.," deals with the use of this developing formula for bromide and gaslight papers, and for the making of direct positives on bromide paper in the camera.—Eds. "B.J."]

If the acid diamidophenol developer is capable of giving remarkable results in the case of negatives, there are yet certain developers which may be said to approach it, such as edinol-hydroquinone and pyrogallic acid. But in the development of bromide prints it remains without a rival, and that whatever the description or brand of paper, whether rapid bromide or one of the gaslight variety. Its superiority consists in the fact that whatever the exposure or the time of development the high-lights of the picture remain pure, the shadows never acquire a greenish colour, there are no stains, and as a result of the slower action it is rarely that any spots, due to air-bells, or any markings occur during development. Granted, of course, that the exposure is reasonably correct, but even if it be half or double the correct time the result is still satisfactory.

The image appears slowly and steadily, and the correct depth desired in the print is obtained without any of the almost frenzied haste which is necessary in the case of the rapid developers employed, particularly for gaslight papers. I am not aware of any developer, not even the much-used metol-hydroquinone, which will give the same results, and one great advantage of the formula employing diamidophenol is that it is suited to every brand of paper and absolves the worker from the necessity of making up a particular maker's formula. And, further than this, a single formula may be used for papers both slow and rapid. My own experiments—which are confirmed by that of numerous friends and correspondents—have led to the following formula:—

Solution S*	$\frac{1}{2}$ oz.	15 ccs.
Diamidophenol ..	8 grs.	5 gm.
Solution BB*	85 to 135 mins.	5 to 8 ccs:
Water to make	3 $\frac{1}{2}$ ozs.	100 ccs.

A greater or less quantity of the bisulphite solution is used according to the slowness with which the developer is desired to work. With 8 ccs. a fairly restrained developer is obtained, and it is this quantity which I invariably employ in summer. In winter, when the lower temperature itself restrains the bath, I employ only 6 to 7 ccs.

The paper is immersed in the developer and the film side gone over with a piece of soft cotton-wool, which removes air-bells. There is no need to place the paper first in water. The acid bath, by its steady action, does not give rise to stains and very rarely to white spots due to minute air-bells. If the image happens to come up too slowly it is well to turn it over face down, by which action the development appears to take place more quickly. The formula given above may be further diluted

* See last week's "B.J.," p. 570; also p. 603 of this issue.

up to 300 ccs., such a dilution being particularly advisable in the case of enlargements where softness is desired, or where it is found necessary to resort to local development. For this latter a camel's-hair brush is dipped in solution BB more or less diluted. A thin image having been developed, the solution is poured off from the paper, and those parts which are to be held back gone over with the brush, after which the developer is reapplied. By repeating this operation several times the desired degree of restraint may be obtained without any fear of yellowness of the high-lights or of unequal action. After development the print is rinsed, fixed for at least fifteen minutes, washed, and put to dry.

Direct Positives.

The acid diamidophenol formula gives quite the best results in this process. Using ordinary bromide paper, it is well, however, to add 10 ccs. of 90 per cent. alcohol to the bath, this addition allowing of a more rapid penetration into the sensitive film, and therefore of development more intensely in the depth of the film. In this process a full exposure is given, the print is fully developed, rinsed, drained, and placed on a piece of black ebonite or on the bottom of a black ebonite dish and exposed to daylight until the high-lights assume a deep lilac colour. The prints should be fully exposed at this stage to daylight. Then, again, in the dark-room the print is placed in water and then immersed in the acid permanganate bath (Lumière formula).

Potass. permanganate	70 grs.	2 gms.
Sulphuric acid	6 $\frac{1}{2}$ drachms.	10 ccs.
Water	80 ozs.	1,000 ccs.

It is rinsed, placed in a bath of bisulphite and alum, in which the brownish image, formed of manganese peroxide, is bleached in two or three minutes. An excellent formula for this bath is that of M. Dillaye:—

Potash alum	$\frac{1}{4}$ oz.	10 gms.
Bisulphite solution ..	5 drachms.	25 ccs.
Water	25 ozs.	1,000 ccs.

Here, again, the acid diamidophenol, with alcohol added, gives an image well fixed in the thickness of the film, and at the same time hardens the gelatine surface. The print is absolutely free from veil (it is preferable to dilute the formula for ordinary bromide papers two or three times).

With acid diamidophenol, as with almost all developers, the temperature should be from 60deg. to 70deg. The developer loses its activity at a low temperature, shadows are not obtained of proper strength, negatives are flat, and positive prints lack vigour and strong blacks.

G. UNDERBERG.

A CAUTION TO THE BENEVOLENT.—About a month ago a man named Alfred Montagu Sims, called at the studio of Mr. Trotman, photographer, of New Road, Chippenham, and said he was a photographer in search of work. He begged Mr. Trotman to give him a job. Mr. Trotman found him clothes, provided him with lodgings and food, and arranged for him to have a bicycle to get about the country. The man worked very well, and was entrusted with the key of the studio, and did various photographic work. Mr. Trotman afterwards found that £8 10s. in gold and between £2 and £3 in silver had been taken away. Sims admitted he took the money, and on being searched at the police station he was found in possession of £1 12s. 10d., a bunch of keys, and a latch-key, the latter being the

property of Mr. Trotman. On the way to Chippenham accused stated that he did not steal £10, it was only £8. Supt. Moore took possession of the keys, and found that one of them fitted the lock of the drawer from which the money had been taken. Charged with the offence, the prisoner at first said he would reserve his defence, but altered his mind and said he wished to state that he had been "on the drink" and did not know what money he had taken, but he did not think it was so much as Mr. Trotman said he had lost.—Supt. Moore informed the magistrate that prisoner was well known at Bristol, and handed in a list of some thirteen previous convictions against him.—Prisoner was committed for trial at the next Quarter Sessions.

MIXTURES OF DYES AS SENSITISERS OF GELATINE PLATES.

II.

[The following is an abridged translation of a thesis by Guido Daur, presented for the degree of Doctor of Philosophy at the Münster University. The experimental work was done on the suggestion of Professor Miethe, to whose colleague, Dr. E. Stenger, the author of the paper, he tenders his thanks for much advice and assistance. The full text of the paper occupies a book of 105 pages, published by E. Grieser, Frankfort a/M.—Eds. "B.J."]

Mixtures of the Isocyanines.

Of the combinations of this class of dye, whether employed in baths or compounded with a proportion of each dye, that adopted was the one found to be the best when the dye was used alone.

7. *Pinaverdol-ethyl-red*.—Two plates were sensitised, one washed in running water for five minutes before drying, and the other for the same time in 96 per cent. alcohol, the further treatment of

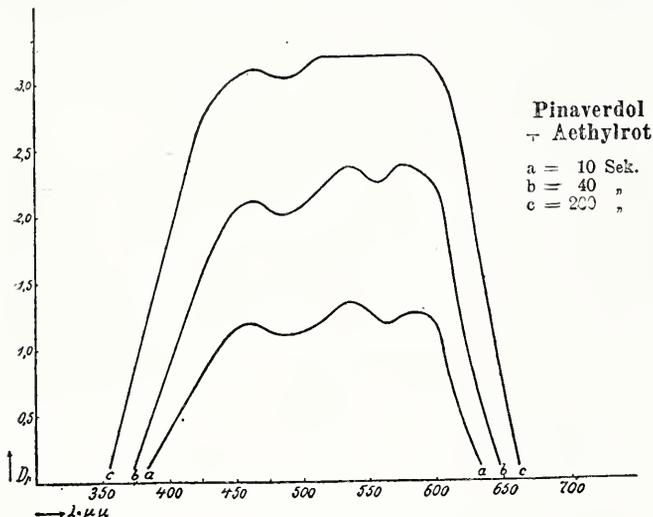

Fig. 7.

each being the same. The alcohol plate was the better, showed less fog, and more pronounced sensitising. As both dyes have their maxima at the same place—530 to 580—and both also show a very slight gap in the green, no pronounced increase of sensitiveness for the blue-green and yellow-green was to be expected. Fig. 7 shows the curves obtained for 10, 40, and 200 seconds exposure, the result not coming up to expectation. There is some increase of

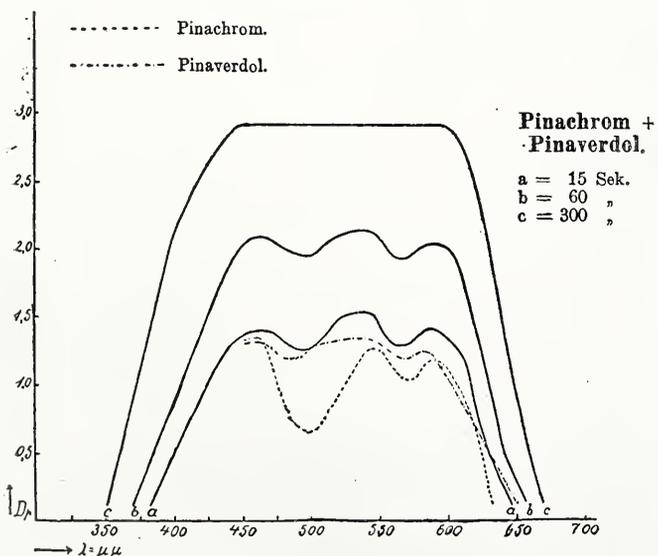

Fig. 8.

colour-sensitiveness over blue-sensitiveness, but the rise of the curve at 530 to 580 is slight. The maxima retain their positions, as does also the minimum between them at 560. At long exposure (see curve for 200 seconds) a spreading action has filled up the gaps at 560. The blue-green gap remains, corresponding to that of pinaverdol, the region of the total sensitiveness is about that obtained from, either constituent, reaching from 350 to 560.

8. *Pinaverdol-pinachrome*.—Two plates were again prepared. The one washed in water after sensitising was useless, whilst that bathed in alcohol showed good sensitiveness. Pinaverdol has its maxima at 530 and 580, and a minimum at 560, the maxima of pinachrome being at 560 and 590, hence the two dyes might be expected to supplement each other, and the pinaverdol to fill up the rather deep gap in the green of the pinachrome. Fig. 8 shows two curves of the constituents for the same blue-sensitiveness, the curve of the mixture is of the pinaverdol type. There are slight gaps in the green, and the two maxima at 540 and 590 have been shifted about 10 μμ towards the right. On shorter and medium exposures the green maximum 590 is prominent, meeting the yellow maximum on longer exposure. The gaps lying between the two at 565 become constantly smaller, disappearing at 200 seconds exposure. On greatly prolonged exposure uniform density is obtained from 450 to 600, the slight gaps at 500 and 565 disappearing completely.

9. *Ethyl-red and pinachrome*.—The curve for this mixture might be expected to resemble No. 8, since ethyl-red resembles pinaverdol in the position of its maxima at 530 and 580. The gap, however, at 500 is somewhat greater in the case of ethyl-red. A water-washed plate did not give quite so good or clear a result as that bathed in alcohol. The curves shown in fig. 9 are for 20, 30, 90, and 300

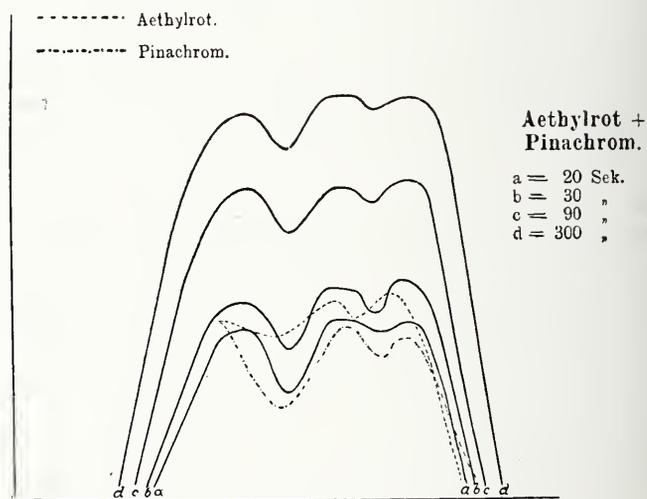

Fig. 9.

seconds exposure. There are also reproduced the curves of the two components for the same height in the blue. The height of the curve from 530 to 550 appears to be the result of fusion of the maxima of the two dyes; the same is the case as regards the second maximum at 580 to 600. There is an appreciable minimum at 500, a negligible one at 565. Whilst in the formula No. 8 the pinaverdol was most marked in its effect, the present curve more resembles pinachrome. The ratio of colour-sensitiveness to blue-sensitiveness is that of pinachrome, and the region of sensitiveness is also the same.

10. *Pinaverdol-isocol*.—The water-washed plate showed fog, whilst that treated in alcohol was completely clear and showed sensitising, commencing gradually at 400 and reaching a maximum at 540. The second maximum was at 590, the curve ending at 660 to 670. The colour-sensitiveness is thus distinctly depressed, a green gap being filled up. Both dyes have a minimum at 530. This is shifted 10 μμ, spreading over the second maximum. The third isocol maximum at 620 does not come up on short exposure, showing plainly at 670 on longer exposure. A plate was exposed on the Hübl colour chart. It reproduced yellow and green very well, over-powering the sensitiveness for blue and violet. A comparative experiment with a "Perchromo" plate showed that the pinaverdol-

isocol, as regards colour-sensitiveness (fig. 10) is only slightly inferior to the "Perchromo." It showed, on the other hand, distinctly

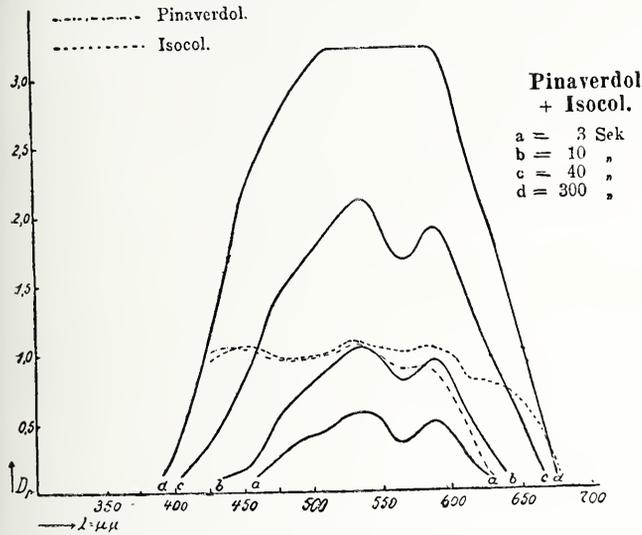

Fig. 10.

greater general sensitiveness. The dye mixture thus allows of a much lighter yellow screen and of shortened exposure (fig. 10).

11. *Ethyl-red-isocol*.—The curve of this mixture, as was to be

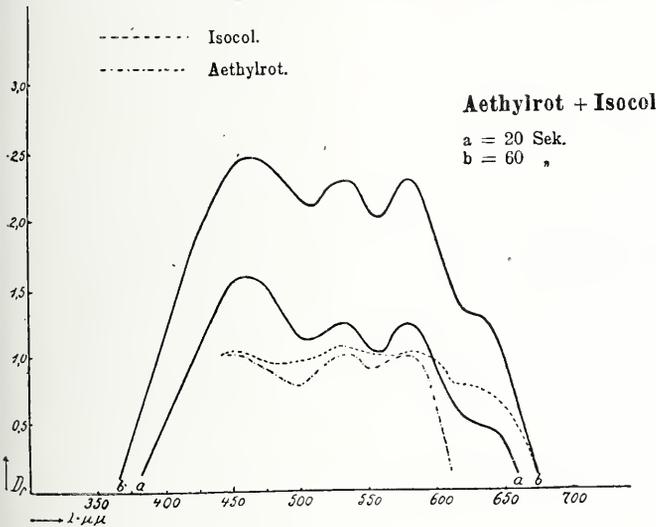

Fig. 11.

expected, is quite different from that of formula No. 10. The curves of the two dyes (fig. 11) show maxima at 530 and 580. The rather big gap in the green and the gaps at 560 belong to the ethyl-red

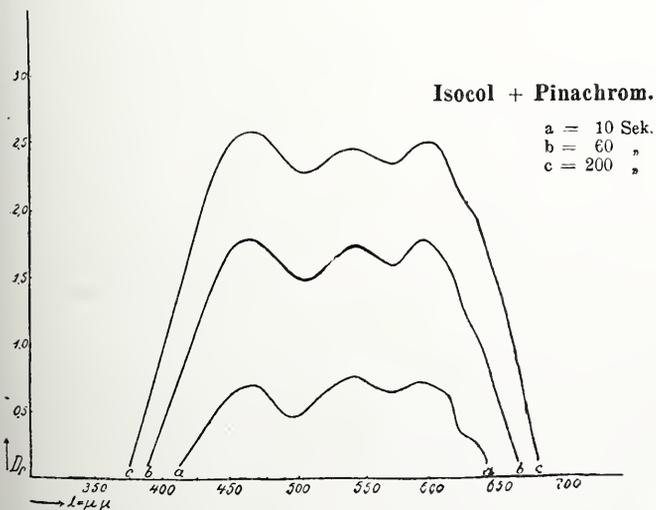

Fig. 12.

curve, the isocol having failed in filling up the gaps at 500 and 560. On the other hand, the third isocol maximum at 620 gave a curve extending further into the red, as shown by the region at

630 and 640. The blue-sensitiveness is seen to predominate both on longer and shorter exposure. The alcohol-washed plate is the better.

12. *Isocol-Pinachrome*.—As anticipated, the character of the curve given by this mixture was that of pinachrome. The influence of isocol is seen in the shifting of the pinachrome maximum 550 $\mu\mu$ towards the blue, and in the only moderate strength of the third isocol maximum at 620, which is shifted to 630. The maxima at 540 and 590 are about equal to the blue maximum, again as with pinachrome alone. The plate bathed in alcohol showed somewhat more fog than that in water, but the latter showed markings, so that the alcohol-washed plate was used for the measurements.

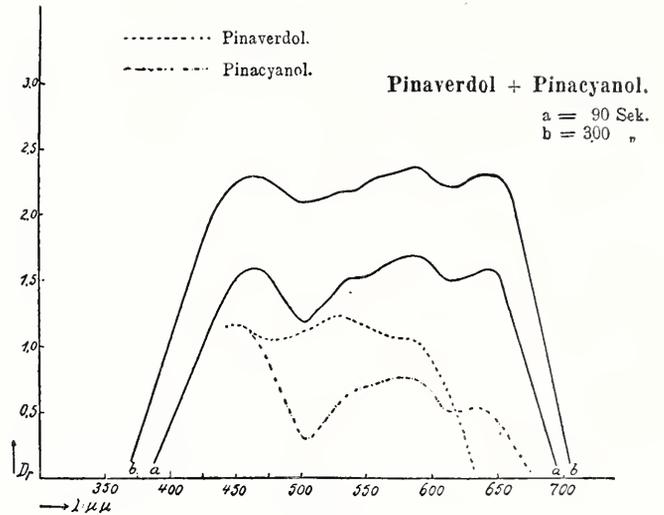

Fig. 13.

13. *Pinacyanol-pinaverdol*.—Fig. 13 gives the sensitiveness curves for 90 and 300 seconds, and indicates either slight general sensitiveness or considerable fog. In the present instance it is the rather strong fog which causes the lesser height of the curves. The general character is that of pinacyanol, the pinachrome has diminished the gap at 500 and its maximum occurs, though not prominently, at 530. The two pinacyanol maxima at 580 and 630 are shifted 10 $\mu\mu$ towards the right. The mixture thus gives a plate of much greater

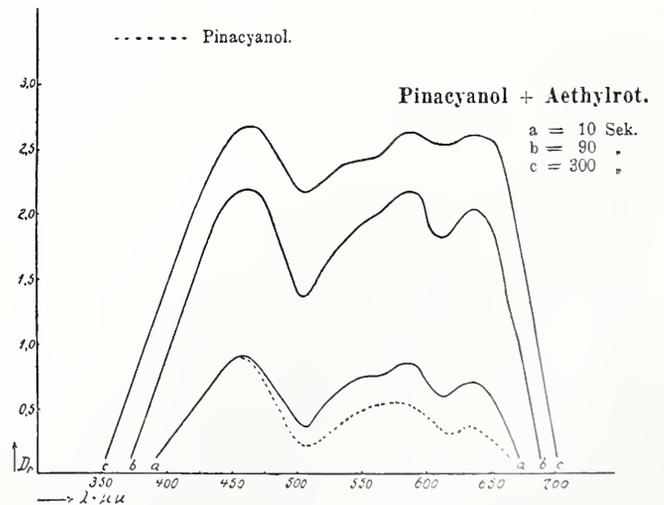

Fig. 14.

red-sensitiveness than pinacyanol alone, and one with the red-sensitiveness extending further. There is also an improvement in the ratio of colour-sensitiveness to blue sensitiveness, due probably in this case to a fogging action causing reduction of action in the blue part of the spectrum. Both plates, one washed in water and the other in alcohol, gave relatively good results; the measurements were made with the water-washed plate.

14. *Pinacyanol ethyl-red*.—The water-washed plate gave more fog than that treated with alcohol, which latter was fairly clear, and was used for the measurements. As ethyl-red shows a stronger gap in the green than pinaverdol, no special improvement in this respect was anticipated. The curves (fig. 14) have the pinacyanol character,

which is here more clearly shown than in formula No. 13. The ethyl-red maximum of 530 is shifted up 15 to 20 $\mu\mu$; that is, to 540 and 550. At the wave length of 580 $\mu\mu$ there is a notable increase in the sensitising, apparently produced by the conjunction of two maxima, one from each of the dyes, at this spot. The second pinacyanol maximum is improved and shifted a little towards the red; moreover, the ratio of colour-sensitiveness to blue-sensitiveness is better.

15. *Pinachrome-pinacyanol*.—The alcohol-bathed plate gave the curve shown in fig 15, having rather deep gaps at 500 $\mu\mu$. The first maximum at 560, obviously that of the pinachrome, shifted 10 $\mu\mu$

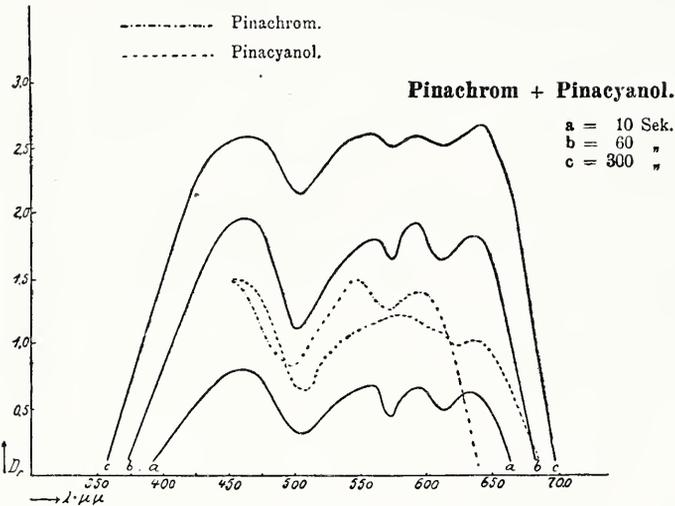

Fig. 15.

towards the red. The second maximum is at 590; this runs into the other, as it is probably the pinachrome maximum of 590 intensified by the pinacyanol maximum of 580. The third maximum at 630 is that of pinacyanol. The colour-sensitiveness is about equal to that of the blue-sensitiveness, and the region sensitised corresponds with that of pinacyanol.

16. *Isocol-pinacyanol*.—The curve (fig. 16) is of the pinacyanol type. The gap in the blue-green has become deeper and a little broader. The first pinacyanol maximum has shifted from 580 to 600, the second from 630 to 640. As in other combinations of pina

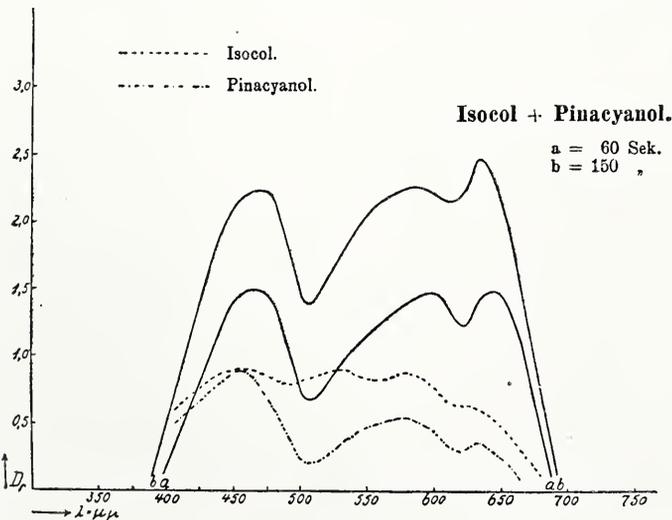

Fig. 16.

cyanol a maximum at 630 is seen. With short and medium exposures the maxima at 600 and 640 are about equal, but that at 640 becomes much more pronounced on longer exposure. This may be due to the influence of the isocol, which has a maximum at 630, otherwise there is not much evidence of the action of isocol, neither as regards bridging the gaps between blue and green, nor in giving its characteristic maximum at 530. The values of the colour maxima are smaller for short exposures than those of the blue, but rapidly increase and exceed the latter on longer exposures to a notable degree.

17. *Dicyanine-pinaverdol*.—The sensitising produced by this mixture is very similar to that of formula No. 16. In both the curve rises slowly to 400; there is no appreciable blue maximum, but a gradual rise of sensitiveness up to 540. There is a slight gap between the maxima at 590, from which point the curves gradually drop. The dicyanine maximum is at 610, causing a small hillock in the curve at 630. There is also a dicyanine maximum at 685, as the result of a shift of 15 $\mu\mu$ towards the blue. The two dyes thus supplement each other excellently, the big gap of the dicyanine with its deepest point at 510 has been completely filled up by the pinaverdol, whilst the latter's maximum at 530 improves the curve.

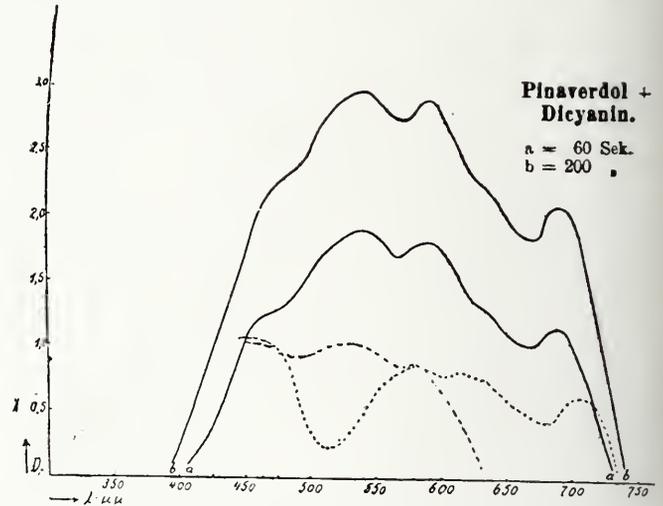

Fig. 17.

Its action at this latter point is better than that of the maximum at 580. The dicyanine maximum at 610 does not show appreciably, though its maximum in the red is strongly developed. No use could be made of the water-washed plate which gave heavy fog, that treated with alcohol gave a very clear negative.

18. *Ethyl-red-dicyanine*.—As shown in fig. 18, the ethyl-red maximum of 530 falls in the dicyanine gap in the blue-green at 540—both dyes have a maximum at 580. The next dicyanine maximum of 620 is prominent at 640, whilst the dye also shows up at 700, the maximum, as in formula No. 17, being shifted about 20 $\mu\mu$

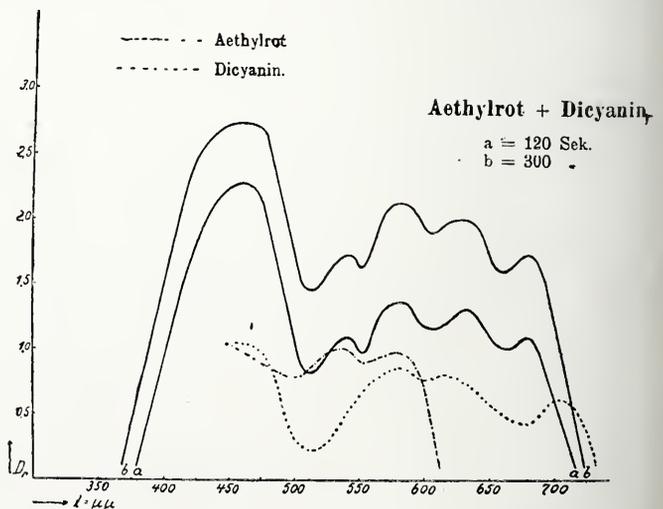

Fig. 18.

towards the blue. The colour-sensitiveness does not come up to the blue-sensitiveness, though the ratio is better with increasing exposure. The water-washed plate was of no use, being marked with fog and mottling over its whole surface, and measurements were made with the alcohol-washed plate.

19. *Pinachrome-dicyanine*.—The first part of the curve (fig. 19) is that of pinachrome with maxima at 550 and 590; only the deepest part of the minimum has been put back from 500 to 510. The dicyanine shows at 600, its maximum at 610 is clearly noticeable at 630, and on longer exposures it is shifted somewhat further

towards the red, and gives slight rise to the curve. The last dicyanine maximum at 700 imparts a strong rise to the curve at 680. The shift of the last dicyanine maximum towards blue to the extent of 20 μ is the characteristic feature of the mixture.

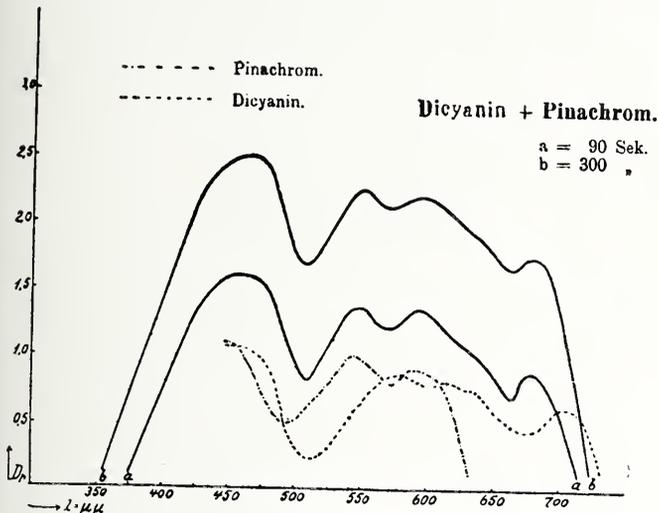

Fig. 19.

The colour-sensitiveness is inferior to the blue-sensitiveness. Like all the other dyacinine mixtures examined, only the alcohol plate was of any use.

G. DAUR.

(To be continued.)

THE ARCHITECTURAL AND TOPOGRAPHICAL SOCIETY.

THE honorary general secretary of the Society, Mr. W. Travers, 33, Old Queen Street, Westminster, S.W., has issued an appeal for help in a work which has been described as one of National interest, namely, that of making complete historical records of the ancient buildings of these islands, from the introduction of civilization to the year 1800, and the need for such a work has been admitted on all sides, and ought to have been undertaken long ago, for it is now almost impossible, after a century or more of destructive so-called "restoration," to obtain exact information as to the previous condition of much of our historic architecture.

Although the society is unable to act in any manner directly calculated to prevent such destruction, yet, by recording precisely, and in detail, the present state and the nature of the buildings and the monuments, it is able to some extent to counteract the effects of such vandalism, and owing to the accessibility of its publications to all, there is a potential educational value in their work.

The expenses of printing and publishing records of buildings, with sufficient illustrations fully to explain the text, must be practically the same whether the circulation be 200 or 1,000; therefore, the ratio of revenue to expenses must, until the subscription list approaches the latter figure, be too low to make the society self-supporting.

On these grounds alone the society lays additional stress on the following points, *i.e.* :—

- (1) Since the foundation of the society, rather more than twelve months ago, complete accounts of the buildings in seventeen parishes have been published.
- (2) The value of the work has been endorsed by the fact that many of the leading societies interested in this subject are now subscribing.
- (3) There are at present some twenty parishes partly completed, in addition to those already published, and several more are definitely promised. The fact that the society can obtain work of this nature entirely gratuitously shows how greatly the need for such records is felt by those who have expert knowledge of the subject.
- (4) The recent appointment of Royal Commissions to make an inventory of the ancient monuments of England, Scotland, and Wales shows that the State appreciates the need for such work; and by its terms of reference, the commission is only intended to make inventory, and does not in any way cover the ground of this society's labours.
- (5) The other part of the society's work, which includes the collection of carefully made re-

cord drawings, notes and photographs, etc., is progressing, and a considerable number of such records are now either promised, or are already in our possession. (6) All the work done for the society is purely honorary—therefore its funds are expended entirely on the work, and not in any way upon the workers. (7) A large sum of money is subscribed annually towards the furtherance of similar work in the ancient world of Egypt and Rome, and it would be unworthy of our National traditions should researches into the history of our country fail for want of funds.

The minimum sum of £500 is required to ensure the effective continuation of the work of the society until such time as the annual subscription list shall be equal to the necessary disbursements; a further contribution would enable the rate of progress to be made more consonant with the amount of the work to be done.

In conclusion an appeal is made to all who take an interest in the history of their country to help the work in some degree. All communications should be addressed to the offices of the Society at 33, Old Queen Street, Westminster, S.W. Donations will be treated as subscriptions to the society, and donors of half a guinea or more will receive the Record for the current year, whilst those of seven guineas and upwards will be entered on the Society's list of Life Members.

The appeal is signed by Lord Plymouth, Lord Avebury, Sir Aston Webb, R.A., and Messrs. Francis Bond, J. A. Gotch, Emslie J. Horniman, M.P., Thos. G. Jackson, R.A., Mervyn Macartney, and Edward S. Prior.

Photo-Mechanical Notes.

New Transparent Drawing Surfaces.

Two patents have recently been claimed, one by Emile Laporte, of Fribourg, for rendering sheets of celluloid available as a drawing surface by graining one side by various mechanical means; the other by Ozias Dodge, of Norwich, Connecticut, for rendering sheets of gelatine available in the same way, the graining in this case being done by allowing the gelatine to set on grained glass and afterwards stripping, exactly the same principle as is adopted when matt surfacing a glossy P.O.P. or glossy bromide print.

The sheets can be used in every respect as a drawing paper—some of the gelatine sheets being, in fact, made up as sketch-books—and are of especial advantage when the drawing has to be traced.

The applications of these materials in photo-mechanical work are chiefly in avoiding the use of the camera when reproductions of the sketch can be made the same size. Thus, many of the big cartoons of the New York daily newspapers are drawn on this grained gelatine sheet. The artists find it an agreeable surface to work upon, and it is susceptible of alteration by scraping or rubbing out with bread or india-rubber, exactly as paper would be. After the drawing is made, the sheet is flowed with collodion, which renders the surface perfectly transparent, then a negative is made on a dry plate, or on a film, developed and printed on to metal just as a negative would be if made in the camera. Or, of course, the Vandyke process may be used, and the print made at once from the drawing on to the zinc plate, reversed and then etched. The sheets are also recommended for making intaglio plates by the enameline process, which, on printing after etching, give results very similar to "soft ground" etchings. Mr. Dodge also has another patent for making printing surfaces by electrotyping, using a common fish-glue method of getting the image on to the copper plate and then depositing. The application of the sheets in other directions are very numerous. Thus, in lithography the gelatine can be used instead of grained transfer paper, and in ordinary photography retouching can be done on a grained sheet attached to the negative instead of with varnish, or papier mineral.

Health Conditions in Engraving Shops.

The International Photo-engravers' Union of America has paid much attention to the sanitary and other conditions in the work-shops with regard to the safeguarding of the health of the men at work in them, and has recently issued a report embodying the result of their enquiries, and making recommendations. From this

it would appear that the American workman is in general far more favourably situated than are workmen here, as many shops appear to be fitted with all the conveniences the Union think necessary, such as sufficient accommodation for outdoor clothing, ventilation, lavatories, enclosed closets for dragon's blood powder with fans to draw off the dust, acid baths placed in fume cupboards, with proper exhaust for the fumes, and so on. With regard to nitric acid, the report lays great stress on the necessity of having at hand some means of quenching the fumes in case of spilling. They recommend that bicarbonate of soda should be placed handy and labelled as to its purpose, and that a warning should be added against the throwing on of sawdust, which ignorance sometimes dictates. We have found ordinary whitening more effective than soda for this purpose; certainly some such safeguard should be found in every etching room.

Mercury Vapour Lamps.

We referred recently to the fact that one leading house in England had adopted these lamps for their black and white work. We are now informed that six of the principal New York establishments use mercury vapour exclusively for their black and white photography, and for printing on to metal as well.

A Dictionary of Printing and Process Terms.

"Handlexikon für die Papier Industrie und das Buch Gewerbe" (published by Gustav Schacht, Leipzig).—The first part of this encyclopædic dictionary of the printing and photographic industries is just published, and if it maintains during the 75 parts which will complete the work the high standard shown by the first, it will be a truly invaluable publication. There is a full description in German of the meaning of all the technical terms encountered; the term itself is also translated into four languages—namely, English, French, Italian, and Swedish. There are also numerous illustrations in the text and several supplements affording examples of the matters described. The price is M1.25 per part, or to subscribers who take the whole 75, M1 each.

A Text-Book of Colour.

"The Colorist." By J. S. H. Hatt. Published by E. and F. N. Spon.—This is an American book, in the preface of which the author states it is his object to give precise data whereby a colour scheme may be analysed and beauty in colour appreciated and produced. He claims that the book contains, for the first time in colour literature, either scientific or artistic, a complete unity between science and practice, as well as a consistent law for colour harmony and beauty in colour, which the author confidently believes will stand the test of time and the fullest investigation. Though the book may be of great service to some artists and colour printers, we are afraid we cannot quite concede all that the author claims. In endeavouring to make the theory simple he is often a little misleading, and in trying to explain all the phenomena of colour his theory is sometimes at fault. The book is illustrated by two colour charts, and is full of useful practical hints regarding colour for the artist and designer, who, after a careful reading of it, will certainly no longer regard yellow, red, and blue as the three "primaries."

The Dust Problem.

We have frequently referred to the troubles caused by dust in the photo-engraver's establishment, particularly in the studio, and other industries, of course, suffer from this cause. A note in the "British and Colonial Printer and Stationer" calls attention to preparations containing oil which are sold to be used when sweeping the floor. Where the commercial preparation cannot be obtained one can be made by taking sawdust and adding one-fifth of the quantity of common barrel salt and sufficient oil to give the sawdust adhesiveness. Any oil may be used, even used-up lubricating oil, taken out of oil drips. Care must be taken not to use too much oil, and it must be given time to thoroughly soak into the mixture. When sweeping, a small quantity is thrown on to the floor and swept over the surface of the room. It is claimed that it will attach to itself the dust much better than tea-leaves or wetted sawdust.

Pyroxline.

When making one's own collodion it is often found that the pyroxline when purchased is not quite free from impurities, which cause trouble when the collodion is made up. In general these may be removed by a simple washing with ordinary water, followed by a rinse in clean distilled water. The cotton is then squeezed in

a clean cloth and allowed to dry, when it is ready for dissolution in the ether and alcohol. If a sample even after this treatment does not behave quite as desired, it is advisable to dissolve it in a small quantity of methylated spirit (new industrial) and ether, and then to pour the collodion in a thin stream into a vessel of distilled water. This will precipitate the cotton, and after stirring well with a glass rod in several changes of distilled water it can be collected and dried, and will then be found in almost every case to be thoroughly satisfactory.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between July 12 and 17:—

SCREEN PLATES.—No. 16,513. Improvements in photographic screen-plates for natural-colour photography. Henry William Hamblin Palmer, 52, Stephen's Road, Tunbridge Wells.

CAMERA.—No. 16,398. Automatic hand camera. James Edgar Gould, Elswick, Newcastle-on-Tyne.

CINEMATOGRAPH.—No. 16,441. Improved cinematograph apparatus for the continuous exposure and projection of photographic plates. Rene Achille Robin, 7, Southampton Buildings, London.

GRAPHIC IMPRESSIONS.—No. 16,636. Improvements in and relating to the production of inimitable graphic impressions. Rosi Lamp'l (née Müller) and Paul Julius Lamp'l, 7, Southampton Buildings, London.

DEVELOPING APPARATUS.—No. 16,725. Improved appliance for developing multi-picture photographic films. William Kennedy-Laurie Dickson, 33, Cannon Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DEVELOPING TANK.—No. 14,024, 1908 (July 2, 1908). The claim is for a developing tank fitted with a thermometer by which the temperature of the solution in the tank can be read outside the tank.

The tank A is made with a vertical recess or groove *a*, into which the stem or tube *b* of a thermometer is placed, the bulb *b*¹ being inserted in the interior of the tank through a sealed hole *a*¹ near to the bottom thereof and the upper end of the stem into a hole

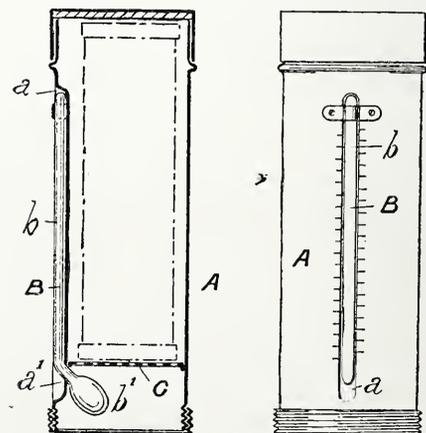

Fig. 1.

Fig. 2.

near the top of the tank. The stem *b* of the thermometer is bent to place the bulb *b*¹ inside the tank and a perforated grid or false bottom *C* is fitted in the interior of the tank to protect the bulb of the thermometer. The gradations or scale of the thermometer

may be inscribed on the stem or on the wall of the developing tank as preferred.

In another form the photographic developing tank is made with a vertical recess or groove with holes at both bottom and top thereof, through which a straight thermometer is inserted, the recess being of such a length that the bulb of the thermometer and the upper end of the stem remain within the interior of the tank. The holes are sealed after the thermometer is inserted. J. O. O'Brien for John Edward Thornton, Philadelphia, U.S.A.

SUN-COPYING PRINTING-FRAME.—No. 773, 1909 (July 1, 1909). The invention consists of a frame for printing from large tracings or drawings. The frame consists of a flat spring board or sheet, over which the original and printing papers are arranged. These latter are gripped together by special devices, and the apparatus also contains parts which serve as feet and legs when in use.

The frame comprises a flat bendable sheet *a* of any suitable material, such as three-ply board, and two end clips, each comprising a longitudinally grooved strip of wood *b* and a lever or arm *c*. The

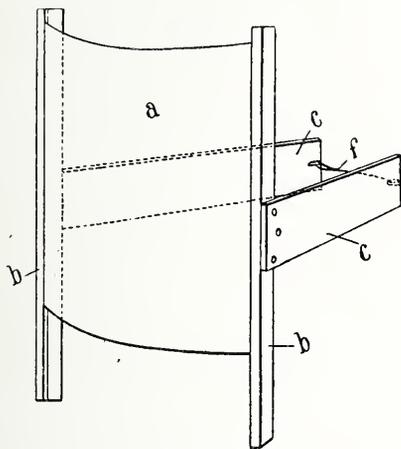

Fig. 1.

groove *d* in the strip *b* may be either parallel or tapered, that shown being parallel, but in the latter case it could then equally well be employed with papers of varying thicknesses.

To further improve the pressing of the sensitised paper against the tracing, a sheet of felt is fixed on the right side of the flexible board; the felt may or may not be turned over the edges of the board. If the latter, then the grooves must be made wider and deeper, to counteract the added give or liability to compression of the felt.

The sheets of material *e* are first folded over the edges of the board along two of their sides, and the clips *b* are then pressed over the edges of the sheet or board whilst it is quite flat. When the two clips *b* have been placed in position the levers *c* can be drawn together and secured—*e.g.*, by the cord *f* that is attached to one lever and engages at its free end a hook *g* on the other lever. The act of bringing the two outer ends of the levers *c* together not only

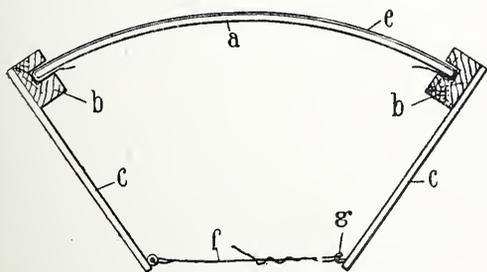

Fig. 2.

serves to give the required curvature to the board or sheet *a* to tighten the paper, but at the same time even if the groove is somewhat loose over the edges of the paper when the board is flat it will become tight before the board is bent and increase its grip correspondingly to the distortion of the board.

The boards may of course be made to any size, but they would in practice preferably be rectangular so as to be capable of being used for several sizes of paper, for instance large sheets could be

attached to its two ends, whilst small sheets would be arranged crosswise thereof from side to side, and in this case the board would be bent longitudinally instead of as shown. In order that this latter arrangement may be rendered possible the two clamping strips *b* are made of a greater length than the board, and, as in Fig. 1 conveniently serve as supports in conjunction with the two levers *c*. Robert Alwyn A. S. Piercy, Far Ben, Sérubwood, Wendenover, Bucks.

PLATE OR FILM PACK.—No. 13,999, 1908 (July 2, 1907).—The invention consists of a package for plates or films with light-proof interposition sheets, characterised by the fact that the plates or films and light-proof interposition sheets are alternately and separately so arranged in a case that the light-proof sheets project from the case at one end through a light-tight slot. The package illustrated in Figs. 1 and 2 is inserted into the case or frame illus-

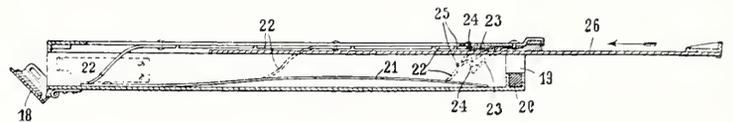

Fig. 1.

trated in Fig. 3 when it is desired to expose the plates contained in the package. In order to insert the package into the frame, the door 14 is opened by pressing on the lateral springs 15, and the package is inserted into the opening exposed by the door 14. The door 14 is then reclosed. The package and frame are then inserted into an outer box, Fig. 4. Before the insertion of the frame and package into the exposing-box the slide must be pushed in. After

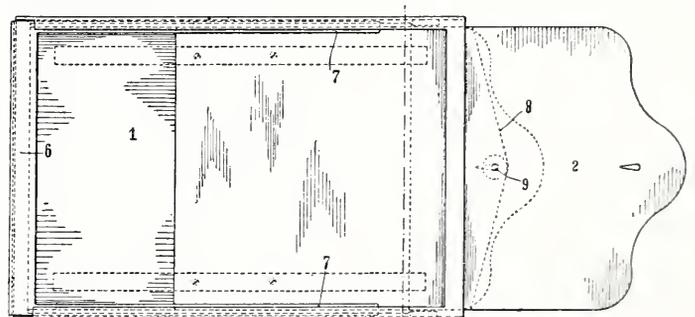

Fig. 2.

insertion of the frame with the package into the exposing-box the door is again closed. The dark slide may now be withdrawn. In order to expose the uppermost plate the sheet 2 covering same is disengaged from the stud 9 and drawn out. After exposure the package is drawn out, by means of the holder 8, through the opening 19 of the box. The closing member 6 of the package is

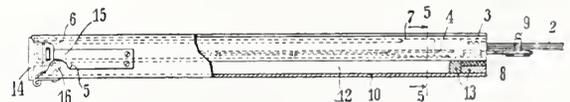

Fig. 3.

retained by the catch 16, so that the package is opened. The jaws 24 of the member 23 engage the front edge of the exposed layer-carrier. As the package is withdrawn through opening 19, the springs 22 press the exposed plate towards the bottom 10 of the box. The package is drawn out till the stop 5 engages the ledge 13 of the carrying frame. When the package has reached this position the exposed plate is so far removed from the package

Fig. 4.

that its front edge can be pressed by member 25 and springs 25 against the bottom 10 of the carrying frame. If hereafter the package is again pushed into the box, the exposed plate remains in the chamber 12 below the package. The changing operation may be repeated as many times as there are plates in the package.

When all plates have been exposed the frame with the package may be removed from the box by daylight. The plates may then be removed from the change-box in a dark-room. Optische Anstalt C. P. Goerz, Aktiengesellschaft, 44/46, Rheinstrasse, Friedenau, Berlin, Germany.

CINEMATOGRAPH MECHANISM.—No. 9,876, 1909 (April 26, 1909). The invention consists of a spool-box provided with a hinged spring-controlled door for closing the mouth or opening of the box, and trigger mechanism controlled by the operator for retaining and releasing the door. Frank Porter and the British Bioscope Manufacturing Company, Limited, 11, Long Acre, London, W.C.

CINEMATOGRAPH MECHANISM.—No. 8,548, 1909 (April 8, 1909). The invention consists of apparatus (for imparting intermittent feed movements to cinematographic films) having a pair of arms provided with claws for engaging the film, and for intermittently feeding it and operated by a crank on a shaft, the combination of a bell-crank lever, operated by a cam on the same shaft, and connected with the arms so as to give the engaging and disengaging movements. Charles Urban, 89, Wardour Street, London, W.

CINEMATOGRAPH MECHANISM.—No. 8,338, 1909 (April 6, 1909). The claim is for a film steadier for moving picture machines having a swinging carrier provided with a friction roller and capable of being swung with roller towards and away from the guide roller of the machine: also for means for retaining the friction roller in position co-operating with the guide roller. John Louis Hammond and John William Patton, Macon, Missouri, U.S.A.

CINEMATOGRAPH-PHONOGRAPH.—No. 7,426, 1909 (March 27, 1909). The invention consists of means for synchronising the action of a cinematograph and a talking machine, comprising a differential gear of known type which is connected to both machines and has an indicator for the purpose set forth. Both the cinematograph and the talking machine are in direct proximity to the differential gear, and not only the cinematograph but also the talking machine are connected to the differential gear by flexible shafting. Jules Greenbaum, 236, Friedrichstrasse, Berlin.

CINEMATOGRAPH MECHANISM.—No. 27,256, 1908 (December 15, 1908). The first claim is for apparatus having a pair of film-roll supporting members, and mechanism for unwinding a film-roll from one of the members in one direction, and for winding the film into a coil upon the other member in the same direction. Charles Randolph Uebelmesser, 102, Beekman Street, New York, U.S.A.

CINEMATOGRAPH-PHONOGRAPH.—No. 15,140, 1908 (July 17, 1908). The invention consists of improved means for driving cinematographs and gramophones in synchronism, comprising a motor generator the motor part of which drives the cinematograph while the generator part generates alternating current which drives a synchronously wound motor geared to the gramophone, or vice versa. Albert Lewis Davis, St. Saviour's Parsonage, 419, Oxford Street, London, W.

NEW PRESTON SOCIETY.—At a meeting held recently at 137, Friargate, Preston, to discuss the advisability of forming a photographic society to be devoted to pictorial photography, it was decided, by the unanimous vote of those present, to form a society to be called "The Preston Pictorial Photographic Society." The society already comprises nearly all the leading pictorialists in the district, and from these the following officials were elected:—President, Mr. G. A. Booth; vice-president, Mr. W. Phillips; hon. secretary, Mr. A. W. Cooper; hon. treasurer, Mrs. L. Ainslie Cox; hon. auditor, Mr. W. A. Beardwood; committee, Miss Marsden, Mr. D. Adams, and Mr. H. Ainslie Cox. Until suitable rooms are found the meetings will be held every Friday evening at 137, Friargate. The membership roll is to be limited to 25, and already this number has nearly been reached. Intending members have to be proposed and seconded by existing members of the society, upon which a ballot is taken. An entrance fee of 5s. is also required, the annual subscription being 7s. 6d. It is intended to join the Lancashire and Cheshire Photographic Union, and a folio work is being completed for the winter season. A case of photographs will also probably be sent to the annual exhibition of the Royal Photographic Society. The society intends to keep in touch with everything relating to pictorial photography, and demonstrations will frequently be given of all the latest processes in this branch of work.

Analecta.

Extracts from our weekly and monthly contentporaries.

Shop Window Reflections.

A task which the amateur photographer sometimes wishes to attempt (writes Mr. Cyril Yoft in "Photography and Focus" for July 27) is the photography of a shop window; and, as sure as ever he tries to do this, he finds himself in trouble with the reflections in the glass, and wonders how they are to be avoided. There is very little that can be done beyond the selection of the best standpoint and of the most favourable time for the work. The standpoint is governed by the nature of the things reflected. We have to remember that "the angle of reflection is equal to the angle of incidence," and, remembering this, it is not difficult to find the place where the reflections will give least trouble. If it is the sky that is reflected, it can generally be dodged by selecting as high a standpoint as possible, lowering the front of the camera if necessary. If there is some very bright object to one side of the window we can get rid of it by taking the photograph from that side. The most favourable time is, of course, when the sun is shining on the shop window, but not so as itself to be reflected into the lens, and the objects opposite the window are in the shade. A single bright object may sometimes be covered up for the time of photographing.

A Simplified Method of Working Bromoil.

Mr. J. M. Sellors, in the course of an article describing a more rapid bromoil process, in "The Amateur Photographer and Photographic News" for July 27 says: The bromide paper is exposed in the usual way, soaked for a few seconds in plain water, and developed with amidol. After vigorous washing with a spray for one minute to clear out the developer, it is placed in the bromoil bleaching bath, which is heated to a temperature of between 80 deg. and 90 deg. Fahr. The bleaching usually takes from two to three minutes. After bleaching, the paper is again washed under the spray for one minute and transferred to the 5 per cent. sulphuric acid bath, in which it remains for from three to ten minutes. After another minute's wash under the spray, it is put into an ordinary acid fixing bath, made up with hypo, sodium sulphite, and sulphuric acid, and allowed five minutes for fixing. The paper is then well washed for ten minutes, first with a spray and afterwards in a circular washer, and at the end of that time is ready and fit for pigmenting.

It will thus be seen that the entire operation only takes from twenty-six to thirty-four minutes. Compare this with the old method—say, three minutes' development, ten minutes' fixing, thirty minutes' washing, and thirty minutes at least for bleaching, etc. total about one hour and a quarter. This does not take into consideration the fact that it is usually recommended to dry the print before bleaching, which involves a further very considerable delay.

Separating a "Stuck" Print from a Negative.

Writing on this subject in the August issue of "The Photographer Monthly," Mr. Fred G. Palmer gives the following advice:—"To remove the damage the following will be found simple and expeditious. Tear away all the paper which has not adhered to the film, and then place the whole in a bath made up of—

Hypo	1 oz.
Citric acid	10 grs.
Water	4 ozs.

Leave it in this for twenty minutes. It will remove the unchanged silver. Then wash thoroughly to free the negative from hypo, and soak in methylated spirit for about twenty minutes. Cover the front of the negative with a duster and gently rub at the paper. As it begins to get dry, moisten again with spirit and keep doing this until all the paper has been removed. If it should happen that there is still a stain left on the negative, immerse it once more in the hypo bath and apply a drop of dilute ferricyanide solution with a camel's hair brush to the affected part. Then wash as before.

This method is a little troublesome, but in the case of a valuable negative that cannot be replaced without a great deal of trouble.

expense it is worth trying. The best preventive for "sticking" paper is, of course, to have both negatives and P.O.P. bone dry, then such an accident is impossible; but it is always easy to be wise after the event.

New Materials, &c.

Paget "Phosphate" Paper. Made by the Paget Prize Plate Company, Ltd., Watford, Herts.

Those who have watched the trend of events in the manufacture and use of photographic printing papers, particularly by amateur photographers, have recognised that within the last year or two the two types of paper which have gained favour with the amateur worker have been the self-toning P.O.P. and the gaslight or development paper. Between these two varieties of printing paper—one pre-eminently suited for a vigorous black-toned print and the other yielding with the greatest ease brown and sepia prints—the ordinary P.O.P. which requires to be toned either by the separate method or in the combined bath has lost a certain degree of favour. As regards manipulation, perhaps the gaslight paper, on account of being available for use without daylight, has rapidly attained a large amount of patronage, although it requires a somewhat greater degree of skill in its use than a daylight self-toning paper, and, moreover, many brands of it do not readily yield warm tones by modification of the developer, although among this category cannot be included the "Gravura" paper made by the Paget Company, which is specially adapted for securing a wide range of colours. However, it would seem that a type of paper which may be printed by artificial light, and at the same time yields with the greatest ease prints both of warm and cold tone, is one which the amateur worker in particular will welcome, especially when these qualities are associated with certain other features which reduce to an almost infinitesimal fraction the proportion of spoilt prints. The new printing paper, just introduced by the Paget Company under the name of "Phosphate" (presumably in reference to the sensitive salt of silver used in it), embodies these desiderata in a remarkably perfect form. In sensitiveness it is a gaslight paper, and it resembles so a gaslight paper as regards the contrast which may be obtained in the prints. But as regards the effect of incorrect exposure, it is totally distinct from a gaslight paper, the time for which must be carefully given if a good print is to be obtained. With the "Phosphate" paper, on the other hand, exposure may be six or more times that which will give a good print, and yet the result is quite satisfactory, the only difference being that the print is warmer in colour and somewhat softer in contrast, but not excessively so. In addition to this, the nature of the emulsion allows of very rapid development and of a much shorter time of final washing.

In enumerating these points we have given the salient features of the paper, a number of excellent results on which we have had the opportunity of making within the past few days. The simplicity of manipulation and the rapidity with which a number of prints are finished off will be understood on our briefly stating the procedure necessary. The paper is exposed behind a negative either to daylight for a few seconds, to incandescent gas for about a minute, or to one to two inches of magnesium ribbon burned at 12 inches from the printing frame. A developer consisting of a weak solution of metol made fairly acid with acetic acid is poured over the print as it comes from the frame, and the image builds itself up gradually, retaining full vigour in from one to three minutes. The print is given a brief rinse, fixed for half to one minute in a weak acid hypo fixing-bath, and placed to wash for a time, which need not be longer than half an hour, and may possibly be much shorter.

The range of tones is governed by the exposure, and the degree of exposure is seen roughly by the readiness with which the print develops. With the minimum exposure which can be given an almost blue-black print is obtained, closely resembling that obtained with metol-hydroquinone on a gaslight paper. If exposure is cut down below the time necessary for this result the effect is to fog the print in the course of the protracted development necessary to bring out the image. As a further degree of exposure is given, the tones are obtained first resembling those obtained on P.O.P. by

gold-toning and then of a warmer brown or sepia. It will be noticed that as a fuller exposure is given the contrast of the print obtained is less, but if full vigour is required in a warm-toned print all that is necessary is to use the developer at a lesser degree of dilution. In a word, short exposure with normal weak developer gives cold and purplish tones and full contrast: full exposure and normal weak developer gives soft prints and warm colour, and full exposure with stronger developer gives warm prints of full contrast. It is thus seen that the process allows of the worker readily adjusting his conditions to the character of his negatives. Even if he neglects the simple means which are thus afforded, it is nevertheless not an easy matter for him to make a useless exposure. He may be a good deal out, but he will still obtain a passable print. The developer recommended for normal work is made from the following stock solution:—

Metol	¼ oz.
Acetic acid B.P.	3 ozs.
Water to make	20 ozs.

For use with ordinary negatives 1oz. of this stock solution is diluted with water to 20ozs. For extra contrast the 1oz. is diluted only to 10ozs., or even to 5ozs. The acid fixing-bath is made by adding ¼oz. of metabisulphite of soda to a solution of hypo 3oz. in 20ozs. of water.

It should be added that any prints over-developed readily reduce in a weak Farmer's reducer, whilst any which may be finally obtained of too warm a tone are easily converted to a colder colour by five or ten minutes' immersion in an ordinary combined toning and fixing bath. The colour of the prints undergoes no alteration in fixing. On drying the warm tones cool somewhat, a print which looks yellowish whilst wet drying to a very pleasing brown. Perhaps the only two points on which a caution is needed in the ears of the amateur worker are first to throw away the developer after it has been used twice (1oz. suffices for two quarter-plate prints), and, secondly, to observe strict cleanliness in the dishes. Our own practice is to use a glass dish for development, to pour off the developer from the print, and, without touching the latter, give it a rinse under the tap as it lies in the dish, then removing it by one corner to the hypo bath.

The paper is made in both matt and glossy varieties, and is put up at a price based on twenty-two quarter-plate pieces per shilling packet. Tubes of two sheets, 24½ by 17, are sold at 2s. 4d., whilst postcards of the standard 5½ by 3½ size, are issued in packets of fourteen, complete with two masks, for 1s.

The attractiveness of the process, even to advanced workers who are apt to regard printing from negatives as an irksome task, should bring many inquiries for the paper at the dealers, whilst professional photographers, those in particular working for the Press, should not underrate the value of the paper in affording them the means of turning out prints indistinguishable from P.O.P. without the need of daylight, and within a few minutes. Space does not allow us to deal at length with the considerations concerned with the permanency of the prints, but the chemical nature of the process affords every assurance that the prints are fully permanent, as permanent as the gelatine which carries the image.

The M.C.C. "Lightning" Fixing Solution. Sold by the Midland Camera Co., Slaney Street, Birmingham.

This fixing solution is supplied in 5 oz. bottles at the price of 9d., being diluted with four times its bulk of water for use with plates and with ten times the bulk when fixing papers. In making a test of its rapidity of action we compared it with a bath of ordinary hypo containing 4 ozs. to the pint. The "Lightning" solution was mixed with four times its bulk of water as directed, and on placing an unexposed dry plate from the same packet in each bath, the silver bromide disappeared completely in the "Lightning" solution in the time of one minute, whilst the 4 oz. per pint hypo bath required three minutes to give the same result. It is evident, therefore, that the special fixing solution is very much more rapid in its action. In fact, a single trial will convince the worker that the bath is extremely rapid in its effect, and the beginner, particularly, will be well advised to make use of such a preparation for the reason that he is then less liable to obtain insufficiently fixed negatives or prints.

ROYAL ACADEMY MOUNT PAPERS AND BOARDS.—Messrs. Barton's, whose business is now conducted at 36, Cornwall Street, Birmingham,

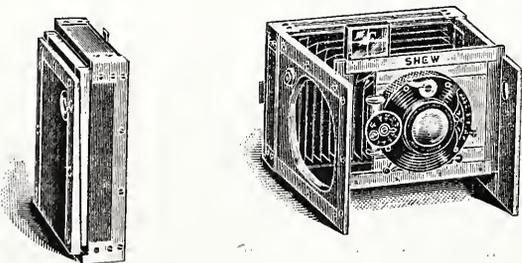

have just issued a new set of samples of the mounting boards and papers sold by them. The set is very conveniently put up in a series of booklets each holding about a dozen tints. The whole is supplied post free for 6d., and it certainly provides both the professional and amateur photographer with the most convenient reference he can desire as to the choice of mounting papers available. We are glad to see that Messrs Barton's recognise the uselessness of papers of pronounced or *outré* colours; almost all their papers are pleasing shades of grey, brown, cream, and green, produced in a choice of surfaces and some of them obtainable with a deckle edge. The photographer must be hard to please who cannot discover among them a series of papers answering his own requirements.

New Apparatus, &c.

M.C.C. Pocket Electric Dark-room Lamps. Sold by the Midland Camera Company, Slaney Street, Birmingham.

A lamp which occupies the minimum of space, is perfectly free from the grease of oil or candle, and at the same time is instantly ready for use, is quite a desideratum for the tourist photographer. These requirements are admirably fulfilled in the case of the tiny electric lamps just placed on the market by the Midland Camera Company. They are made in two varieties—the A pattern, price 3s. 6d., being fitted with a dry battery, duplicates of which, capable of being kept in condition for three months, may be obtained at the price of 6d. each, whilst a reserve wet battery, purchased dry and prepared for use simply by adding water, is sold at 1s. The lamp measures less than 1 by 4 by 3 inches, and is very nicely made in nickelled metal. The B pattern is a shade smaller, and is provided with a special form of accumulator battery cased in celluloid, which can be recharged, and may be kept in use uninterruptedly for a long period. Likewise made in nickelled metal, the price of the B or "extra" pattern is 7s. 6d. Either lamp certainly represents the height of convenience in use. Although the illuminating area is small, the light is amply sufficient for changing plates *en route*, and, if care be taken to keep it in action for no longer than necessary, will last for a considerable time without recharging.

THE SHEW EUXIT POCKET CAMERA.—By an error the review of this new camera in our issue of last week was wrongly illustrated, the block there printed being that of a somewhat old pattern of Xit

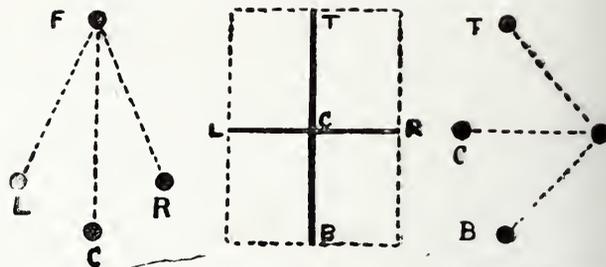

camera. The mistake unfortunately was not discovered until too late, but we hope that the two drawings herewith reproduced will correct any misapprehension due to the block employed last week.

An Infallible View-Finder for Magazine Cameras. Made by A. Arnold, 204, Woolwich Road, London, S.E.

This is an adaptation of the old method of using three fixed aiming sights on top and side of camera. Mr. Arnold supplies a complete outfit of six sights, two eye-pieces, a special focussing screen, fitted to a sheath for use in the camera, and a 6-inch periscope lens to serve as a magnifier when copying on a large scale, together with screws, clips, etc., for the sum of half-a-crown. The purchaser can then very easily adapt all the fittings to his own camera, the sheath holding the focussing screen being perforated in such a way as to show at four different points (L, T, R, B on diagram), the particular parts of the subject to which the sights should be directed. The sights are arranged so that the first one, F, is situated approximately over the nodal point of the lens. Two others, L and R, are fixed near the back of the camera, one on either side, so that the angle

L F R represents the exact angle of view included on the plate; while at C an eye-piece, consisting of a perforated brass plate, is fixed. The angle included is determined by glancing along the lines L F and R F, or T F and B F at the side of the camera, while a direct central aim is secured by sighting along the lines C F. It is suggested that when aiming along C F at the top of the camera it is best to steady the camera against the cheek bone, while, when

Horizontal Finder.

Screen.

Vertical Finder.

using the side aiming sights C F, the camera should be steadied against the forehead. Both these methods of holding the camera are very convenient in practice. The focussing screen is fitted to a sheath belonging to the camera, and the price includes the adaptation of this sheath—that is, perforating it at the points L, T, R, and B, and also at C, so that it may be used as a focussing screen in the ordinary way. Spring clips are also fitted to it, so that it may be held in position and up to register. The No. 12 sheath should be sent for the purpose of fitting, and when adapted for focussing purposes its use as a plate carrier is in no way impaired. There is no doubt that this method of securing a direct-vision finder on a magazine camera is excellent in practice, for a very low view point is compulsory with the usual reflecting finder. If the camera is of the fixed focus variety, near objects being focussed with the aid of magnifiers, the Arnold finder, once properly fitted, will always give the correct view angle. It will also do so when the front sight is so fitted as to move with the lens in a focussing camera. The only types of magazine camera in which the indications will not correspond perfectly with the results on the plate (in the case of near objects) will be those in which focussing is effected by a flange, but even in such cases the sights will give the correct angle for the greater portion of ordinary work. There is no difficulty whatever in fitting the sights when the focussing screen is available, while the latter accessory alone is a very useful addition to a magazine camera. We consider these very simple devices introduced by Mr. Arnold to be very useful, and we would strongly advise all users of magazine cameras to make a point of obtaining them.

CATALOGUES AND TRADE NOTICES.

"HOUGHTONS' QUARTERLY."—The current issue of this "journal of photographic information," issued by Messrs. Houghtons Ltd., contains the announcement of a new variety of "Ensyna" paper, giving a higher degree of contrast, and in one or two other respects modifying the process. A special sample packet of this new vigorous "Ensyna," complete with the necessary developer, is offered by Messrs. Houghtons for 7d. in quarter-plate size, 1s. 1d. in half-plate

A PRESERVATIVE FOR PHOTOGRAPHIC PAPERS AND FILMS.—According to a statement in the Washington Bureau of Manufacturers Consular reports, a representative of a United States photographic company has found a chemical composition which, when added to the regular developer, counteracts the bad effects which the tropical climate has on photographic papers, plates, and films. He claims that materials that heretofore have been guaranteed for one year only in Brazil can, on account of this discovery, be safely guaranteed for three years. Developing papers which had been in this climate three or four years, and were considered useless by a photographic supplier in Bahia, and which, when placed in the regular developing solution turned black before the picture appeared, were treated with the extra chemicals, which seemed to retard the oxidation formed under the severe climatic conditions, and brought out the exposed picture as well as if the developing paper had been only six weeks in this climate.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, AUGUST 3.

United Stereoscopic Society. Paper: "Portraiture and Figure Studies."
Kinning Park Co-operative Camera Club (Govan). Business Meeting.

SOUTHAMPTON CAMERA CLUB.—Mr. F. G. Ryder lectured before the above society on Monday in last week on "What Makes a Picture?" As a basis for his remarks, the lecturer stated that "there are no orthodox rules in art." A picture should possess that quality which recalls some familiar scene or possesses some pleasing sentiment which one can look on again and again, and yet see some fresh charm. Although a picture may not have the orthodox rules, such as good line and balance, in its composition, the subject would be familiar, and that alone should be the principal expression to be adopted in all pictorial work. The lecturer also did not agree with submitting any picture to the opinion of a judge, because the pictorialist should possess some definite aim with his efforts which a judge may not interpret. He therefore contended that a photographer is the best judge of his own work, and should refuse to be influenced by any hard and fast rules by which the merits of pictorial work are usually decided. Mr. Ryder emphasised his arguments by referring to numerous illustrations of different schools in photographic work, and strongly denounced any effort which appeared to him artificial and unreal. The lecturer summed up his discourse by advocating that photographers should produce work which possesses the closest resemblance to nature, and not be influenced by anyone's dictum, this, to his view, being the foundation of all good pictorial work. After a discussion, in which many agreed with Mr. Ryder's contentions, a hearty vote of thanks was accorded the lecturer, and the meeting terminated.

News and Notes.

AN ALLEGED CINEMATOGRAPH NUISANCE.—At the Thames Police Court last week a gentleman complained to Mr. Dickinson about a nuisance arising from a cinematograph exhibition, held at a shop in Whitechapel Road, and he also handed up a paper signed by a large number of neighbouring tradesmen. The noise and nuisance, he said, was kept up until eleven o'clock at night, and was worse on Sundays than on other days of the week.

Mr. Dickinson: It is a common nuisance. Have you been to the police?

The Applicant: Yes, and they say they can only deal with an obstruction on the pavement.

Why don't you go to the Borough Council?—I was advised to come on here.

Mr. Dickinson: I know of no Act that could deal with the case, but I believe there is a borough by-law which could be put into operation. See the Clerk of the Council and tell him you want to put the by-law into operation. Otherwise you would have to go to the High Court to get an injunction. His Worship afterwards said that the applicant had better go to the Town Clerk and call his attention to By-law 2 of the Stepney Borough Council's by-laws, and say that he and his fellow tradesmen wanted protection.

PROPOSED PHOTOGRAPHIC EXHIBITION.—A meeting of the photographic trade was called for Thursday afternoon of last week by Mr. Arthur C. Brookes, editor of "The Photographic Dealer," with the object of discussing the views of trade houses as to the desirability of a photographic exhibition, to be held in London in the spring of next year. Representatives of a very few firms only attended the meeting, among those present being Messrs. Bradford (W. Watson and Sons, Ltd.), A. Linstead (Burroughs, Wellcome, and Co.), T. K. Grant (Lumière N.A. Co.), F. E. Greenwood (Elliott and Sons, Ltd.), W. J. Ramsey (Shew and Co.), and C. J. Miller (Gevaert, Ltd.). Mr. Brookes explained that he had issued a circular letter to the trade asking for their views as to an exhibition, and in response had

received replies from twenty-three firms, to the effect that they were favourable to the holding of such an exhibition, and would be represented in it. A further fifteen firms had replied that they would probably take space in the exhibition if it were held, whilst several other houses had expressed themselves opposed to the scheme. Mr. Brookes further announced that the Horticultural Hall, Westminster, would be available for an eight-days' exhibition, Saturday to Saturday, a fortnight after Easter, 1910. Some little discussion took place, and one or two questions as to the proposed character of the exhibition were answered by Mr. Brookes. It was stated that the intention of the promoters is to advertise the exhibition thoroughly in order to attract, not only photographic dealers, but also the general public, and reference was made to the very large attendance at other exhibitions which have been held at the Horticultural Hall. Plans and further particulars may be obtained on application to Mr. A. C. Brookes, 15, Harp Alley, Farringdon Street, London, E.C.

PHOTOGRAPHIC EXHIBITS AT THE BRUSSELS 1910 EXHIBITION.—On Thursday in last week, immediately following the meeting above reported, a small gathering of the photographic trade and others interested was held at the offices of the Platinotype Company, by kind permission of Mr. E. J. Humphery, who was unavoidably prevented from being present. Mr. Snowden Ward, the convener of the meeting, explained the circumstances under which he had consented to obtain the views of the photographic trade as to the desirability or otherwise of acting in concert as regards the representation of British photographic manufactures at the Brussels Exhibition. He explained the assistance which the new Board of Trade Commission was prepared to render to British exhibitors, details of which facilities have already been described in a memorandum from the Board of Trade published in the "B.J." for July 2. The discussion which followed centred round the question of the character of display admissible in a collective exhibit of British firms. Mr. Child Bayley, as a member of the sub-committee appointed by the Royal Commission to deal with photographic exhibits, said that exhibitors were under no obligation to make use of the show-cases, etc., offered them by the Board of Trade, and he thought that any stand or exhibit of a character in keeping with the general arrangements of the exhibition would be admissible. Mr. A. Linstead, of Burroughs, Wellcome, mentioned, on the other hand, that a stand of quite classical design submitted by his firm in the surgery and medical section had been refused as of unsuitable design. Several other speakers laid stress on the apparent necessity of obtaining a general statement from the Board of Trade as to the character of stand that would be acceptable for the collective British exhibit, and Mr. Bayley, speaking for the Commission, thought that a general question such as that could only be answered in general terms, and he thought the only course open to exhibitors was to describe definitely the proposed stand or stall, when a definite answer would be given. On Mr. Snowden Ward desiring to pass a resolution arising out of the proceedings of the meeting, it was proposed by Mr. C. J. Miller (Gevaert, Ltd.), and seconded by Mr. W. E. Dunmore, that an advisory committee be formed to act in conjunction with the committee of the Royal Commission as regards British exhibits. Votes of thanks to Mr. Humphery for his hospitality and to Mr. Snowden Ward for his services brought the meeting to a conclusion.

CAMERAS AT COUNCIL MEETINGS.—Before Mr. Plowden at the Marylebone Police Court last week, three beables in the employment of the Paddington Borough appeared in answer to a summons charging them with having assaulted Councillor J. F. Waycott.

In opening the case, Mr. Nonweiler said there was some excitement at a recent meeting of the Paddington Borough Council because a member had put his fingers to his nose and pointed them at another member. At the next meeting this gentleman was called upon to apologise before the minutes were confirmed, and during the scene which ensued Mr. Waycott was observed to be holding a camera. Some members came to the conclusion that he intended snapshotting them, and called the attention of the Mayor. Mr. Waycott was carried out of the Chamber and laid on his back in the lobby. The Council had no standing order or regulation to order the ejection of Mr. Waycott; and Mr. Nonweiler contended that Mr. Waycott committed no breach of order, and the Mayor could not order him to be removed.

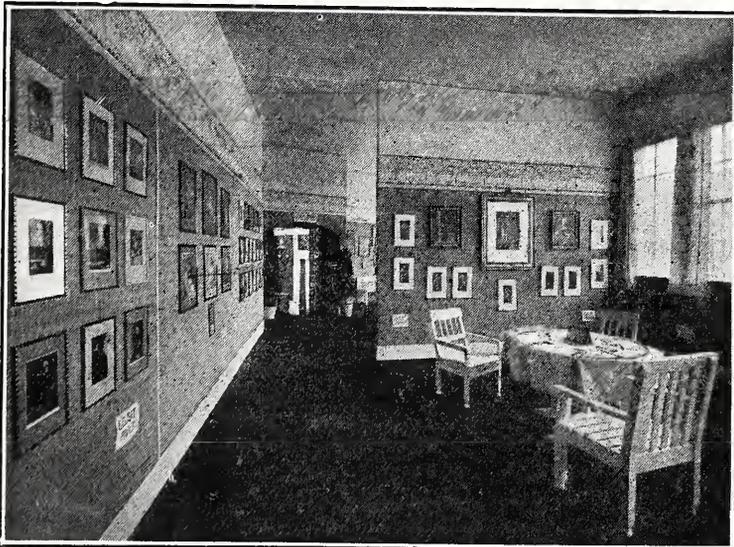

Mr. Waycott then went into the box and described the incident.

Immediately after prayers, he said, an alderman suggested to the Mayor that that was a fitting opportunity to call upon another member to apologise for putting his fingers to his nose at the previous meeting. At that moment the witness had a camera in his hand, it having been handed to him about a minute before. The Mayor's attention was called to this, and in a very severe tone of voice he told the witness to desist. The Mayor's tone did not, in the witness's opinion, entitle him to much consideration, and he refused to desist from handling the camera, stating that he had committed no breach of decorum and order. The Mayor then ordered the witness to withdraw, but he refused to do so, insisting that the Mayor had no power to give such an order. The Council adjourned, and after an interval the Mayor again ordered the witness to withdraw. On his again refusing the Mayor called on the beadle to eject him. After being landed on his back at the feet of the police the witness shook hands with the beadle and invited them to come and have a drink. (Laughter.)

Cross-examined by Mr. Bodkin, the witness denied having pointed the camera at the Mayor, but admitted telling the Mayor that he had a right to take a photograph of any public man in a public place. even the Mayor.

Mr. Plowden said no reasonable person would say that Mr. Waycott's proceedings could be described as anything less than frivolous and unseemly. No doubt Mr. Waycott felt aggrieved and desired to challenge the Mayor's conduct, but he (Mr. Plowden) was not trying the Mayor, and declined to give any opinion as to the legality or otherwise of the order. The assault was admitted, but the beadle, who were there to keep order, only carried out the instructions given them, and therefore the legal justification was complete. On that ground, and without going into the question of the Mayor's right to give the order, he dismissed the summonses. He expressed the hope that these proceedings would prove a warning to Mr. Waycott.

GEVAERT PAPERS.—An announcement of interest to all classes of photographers is that to the effect that during the present week the printing papers manufactured by the firm of Gevaert and Co., Antwerp, are being placed on the British market by the agency firm of Gevaert Limited, 26 and 27, Farringdon Street, London, E.C., directed by Mr. Charles J. Miller, known to the photographic trade

Gevaert Professional Room at the Dresden Exhibition.

by his managership for the past five years of the photographic department of the Rotary Photographic Co. Though hitherto not known in England, the name of Gevaert is recognised all over the Continent as the mark of excellence in photographic printing papers. The parent firm was founded in 1894 by its present director, Mr. L. Gevaert, and during the fifteen years of its existence has developed most rapidly, having now a factory covering an area of 45,000 square yards, and branch offices at Vienna, Copenhagen, Berlin, Milan, Moscow, and Barcelona. All that technical knowledge and organisation can do has been applied in the Gevaert factory to the manufacture of papers of the highest grade. The standard articles are collodio-chloride, bromide, gaslight, and P.O.P. papers. These

we shall report on in due course in these pages, but meanwhile the full price list of the Gevaert papers may be applied for. It is sent free from 26 and 27, Farringdon-street, E.C. Professional photographers in Germany and other Continental countries have long been making large use of Gevaert papers, and in the present Dresden Exhibition one of the series of exhibits devoted to the firm's product is composed wholly of prints by leading German professional workers.

THE SPEAIGHT EXHIBITION.—Professional photographers in considerable numbers assembled at Messrs. Speaight's Galleries, 157, New Bond Street, on Wednesday evening in last week, to inspect the portraits of Fair (and titled) Children, which has been held for some two months, and closes to-morrow, July 31. Among those who signified their presence by card or in writing were: Misses E. B. Aldridge, Amy Cassels, Lena Connell, Curtis (Messrs. Parker's), J. X. de Ferranti, and F. W. Dewsnap, Macnaghten, Mason, Norman, Painter, Smith, Walter Corin, Tissier, Messrs. Basil, George Bell, J. Bender and Co., H. Bentley, F. A. Bridge, George E. Brown (Editor of "The British Journal of Photography"), Herbert W. Busbridge, Gordon Chase, J. Chisholm (Messrs. Parker's), W. Coles, Harry Cooper, H. Essenhigh Corke, J. G. Cowley (Hana Studios, Ltd.), Debenham, Charles F. Dickinson, C. E. Dixon, Eastman and Sons, Edwards and Co., Alfred Ellis (Past President P.P.A.), Charles F. Emeny, Chas. H. Fisher (Sir Joseph Causton and Sons, Ltd.), S. H. Fry, E. G. Ganley (Burnett and Ganley), Rodway Gardner, William Gill, Gregg Couper and Co., W. E. Gray, John B. Harrison, Hearon Bros., R. Herman (The City Studio), H. Edmonds Hull, W. Illingworth, Wilfrid L. Jenkins, Louis Langfier, Louis Langfier, jun., Alex. Mackie (Secretary P.P.A.), Maull and Fox, Frank Mills, John Mills, W. Bevois Parker (Messrs. Parker's), Will Parsons, Plumtree and Stewart, D. Prodger, H. J. Rigden, Ralph W. Robinson, Edgar Scamell, Scott's Studios, Ltd., R. Lang Sims (President P.P.A.), Skillmann's Studios, Henry Spink (Past President P.P.A.), Tanner (Mills and Co.), Herbert Vandyk, Frank Wakefield, H. Snowden Ward (Editor of "Photographic Monthly"), W. H. West and Sons, Frank Wilkins, Wilkins and Holyoake, Window and Grove, and Youell (Mills and Co.).

Letters expressing their regret at their inability to be present were received from Messrs. J. C. Burrows, H. Hawkings, Lewis R. Prothero, C. St. John Vaughan, and W. Warrington.

Letters of thanks and hopes of being present were received from Messrs. Ernest C. Elliott (Elliott and Fry), Percy W. Marshall (Hensman and Marshall), C. H. Skillman (Skillman's Studios), and R. Fellows Wilson.

The second year photography pupils of the L.C.C. Trade School for Girls, Queen Square, Bloomsbury, W.C., accompanied by Miss Barclay, visited the gallery in the early part of the day.

Individual photographers who were unable to be present on the 21st have been made welcome by Messrs. Speaight. A Pretoria reader of the "B.J.," Mr. A. L. Gilham, arriving in London and securing his copy of last week's "Journal," proceeded to 157, New Bond Street, to inspect the portraiture.

Light refreshments were served in the lounge, and an interesting tour was spent in the inspection of the photographs, and of the architectural features and furnishing of the beautiful premises.

On the proposition of Mr. Lang Sims (President of the Professional Photographers' Association), a vote of thanks was accorded to Messrs. R. and F. W. Speaight for the opportunity given to their brother photographers of seeing and admiring the collection of work. Mr. Sims said that the courtesy was one which all those present would appreciate, and he was sure that any of them who had the opportunity would reciprocate on a future occasion.

Mr. H. Snowden Ward, in seconding the vote of thanks, pointed out that much of the work shown had been done by Mr. R. Speaight away from his studio, and therefore could not be taken as representative of the portraiture done at Bond Street. He thought that the Speaight Brothers were to be congratulated on having organised an exhibition on the same lines as those on which other art collections were shown in Bond Street, and even more on having drawn together a large number of their confrères.

Mr. F. W. Speaight, in briefly acknowledging the vote of thanks on the part of his brother and himself, said they both felt pleased and honoured that photographers had accepted their invitation. He believed it was the first instance of such a meeting, but he hoped it would not be the last.

THE PEPPER PROCESS.

To the Editors.

Gentlemen,—I notice on page 470 of June 18, 1909, issue, under the title of "Local Intensification," the oft-repeated powder process is given. May I place before your readers something a little fresher, which was once the subject of a patent, but is now free for anyone to use? It consists of a sensitive oil, made hard by the addition of some resin. The formula is as follows:—

White pepper	½ lb.
Benzole	15 ozs.

Filter and add, say, one ounce of a ten per cent. gum dammar solution in benzole. If it is desired that the powder should adhere more strongly, a little indiarubber solution is added. This is essentially a "no water process," and is simplicity itself to manipulate.

If the solution is thinned down sufficiently, five minutes in the sun or thirty to forty minutes in the shade is sufficient.

Most powders take too heavily and cause degraded high-lights. Such powders require grinding with gum solution; drying and re-grinding they will then be found to powder the picture clean.

The glass plates are coated by hand or whirler, and dry very rapidly. This process is especially useful for cheap magic lantern slide-making or the intensification of negatives, being clear as water, simple to use, and absolutely permanent.—Sincerely yours,

The Globe Hotel, Fort, Colombo, Ceylon. W. W. WALL.
July 6, 1909.

DIRECT POSITIVES FROM ORIGINALS.

To the Editors.

Gentlemen,—In an article in your valuable journal by Mr. D. Carnegie on July 9 last, a reference is made to a future description of a method for the elimination of the mediacy of the camera in the direct reproduction of a positive from an original. Now, I consider any design (partially patented) to be the right and simple contrivance or that purpose. It consists of a mirror mounted on a copy-board, lidable to and from the lens. The original print is affixed to a carrier near the lens. The mirror and original are turned parallel to one another, mirror being at right angles to the lens. By bringing the mirror nearer or further from the lens the size of the resulting picture is regulated. Illumination is effected from behind the copy-board, between original and mirror. I am preparing specifications of further improvements to the patent, and will supply same to concerned parties on request.—Yours most respectfully,

1, Henry Place (opposite the G.P.O.), Dublin. A. COHEN.
July 23, 1909.

EXPOSURE IN COPYING.

To the Editors.

Gentlemen,—I have noted with interest your article on "Exposure in Copying." Surely this is a case where a simple mathematical expression would be of more use than all the tables one could possibly construct. The following is the whole thing in less than a nutshell:—

$$x = \frac{2d}{n+1}$$

Then d is the distance of the radiant from object when copying same size; n the scale; and x the distance of radiant for any scale of enlargement or reduction. Focal length does not enter into the expression, but, of course, different lenses must be used at the same aperture relative to their principal foci. It will be seen that the luminant, instead of moving with the lens on its back focus, rather tends to move with the object; for the greatest value x can take is twice d , even when our object is a mile away. In fact, the formula shows at a glance the impossibility of constructing a table of general utility, for whatever value we may assign to d for convenience in copy-

ing same size, the source of illumination will persist in getting between the lens and object, both when n becomes either very large or small.
29, The Green, Richmond.

CHARLES J. STOKES.

July 26, 1909.

[We believe that Mr. Stokes is correct in saying that the source of illumination will persist in getting between lens and object when n is either very large or very small; but in practical copying work a very big range of scales is seldom required, and it is easy to arrange the standard exposure so that this trouble shall not occur in more than a few exceptional cases. We think also that most operators would prefer a table to a formula.—Eds. "B.J."]

Answers to Correspondents.

- *• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- *• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

H. Bell, Grinstead View, East Cliff, Rye, Sussex. *Photograph of an old man standing with his back against the Armada Anchor in the Gungardan Battery at Rye, Sussex.*

COLOURING POSTCARDS.—Can you tell us the best way to colour glossy postcards cheaply and effectively, and how to glaze the cards after colouring without the colours running?—MARKEM.

Special colours for the purpose are sold at all the large photographic warehouses. The "Bertha Colours," made by the Vanguard Company, are good. The colour may be applied to glazed prints, and they will require no glazing afterwards. Messrs. Fallowfields also supply suitable colours.

DIAMIDOPHENOL.—It would be a boon to myself and many others if a formula for a soft-working acid diamidophenol developer was given in plain English measure. I have read your article thereon, but have failed to grasp it properly.—JOHN ACKROYD.

In English measures the formulae for a soft-working developer are as follows:—

Solution S.	
Soda sulphite cryst.	1¼ ounces.
Hydroquinone	1½ grains.
Water	5½ ounces.

Solution B.B.	
10 per cent. potass. bromide solution	2 ounces.
Bisulphite liquor (commercial pure)	4 ounces.

Developer.	
Solution S	1 ounce.
Diamidophenol (dry)	8 grains.
Solution B.B.	24 drops.
Water	8¾ ounces.

RICHARD PAYNE.—See reply to John Ackroyd. We have not tried the time of development with the plates you mention; we suggest that it is not difficult for you to do so.

PAUL LEMAIRE.—1. Both developers will give equally good negatives, but that made according to the formula will not keep well. 2. We cannot say. We do not know the gentleman.

H. A. MATHER.—Trapp and Co., 89, Chiswell Street, E.C.; Houghtons Ltd., 88-89, High Holborn; Marion and Co., 22-23, Soho Square, London, W.; Butcher and Sons, Camera

House, Farringdon Avenue, E.C.; and Witt and Wesley, Grove Road, Tottenham, N. (2) If the damage is anything more than a good sized pinhole, the best plan will be to make a glass transparency by contact; retouch that, and from it prepare a new negative.

BOOKS.—Can you give me also the names of any good books on studies of the human figure or figure studies, etc., and their prices, and where to be obtained, as I am anxious to take up that branch particularly?—**PILATUS.**

1. "The Human Figure: Its Beauties and Defects," by Ernst Brücke (translated by the late Prof. Anderson), Grevel and Co., King Street, Covent Garden—used to be 7s. 6d., but we think a cheaper edition is now available. 2. Hatton's "Figure-drawing for Art Students," Chapman and Hall, 7s. 6d.; an excellent and thoroughly practical work.

GLAZING PRINTS.—Could you tell me, through the "B.J.," if there is any other way to enamel cards besides putting them on the slab? Is the enclosed done in this way where there are many to do?—**J. E. P.**

A polishing medium can be used, such as those given in the current "Almanac," page 803, or the Vanguard "Lustralene." This will give a considerable gloss, though not the kind of glaze obtained by stripping. The latter is the commercial method. The sample you enclose is undoubtedly stripped, the sheets of cards, each of about two dozen, being treated in this way.

PRINTS FROM AUTOCHROMES.—Where am I able to buy "Uto" paper for colour photography? Is there any method of printing from Autochrome plates in colours?—**W. A. MAIER** (Elmhurst, L.I., New York State, U.S.A.).

So far as we know, the "Uto" paper of Dr. Smith is not on the market at present. The method of preparing paper prints from Autochromes consists in making three colour-sensation negatives from the Autochrome by contact on panchromatic plates, using the suitable light-filter in each case. From this set of negatives composite (colour) prints are made by the carbon or pinatype processes.

BLISTERS ON FILMS.—Could you tell me the cause of the small blisters on the enclosed film?—**FILMAX.**

Blisters can be caused in so many ways that it is quite impossible to tell you the exact cause of these, but it looks as if you had applied some acid bath too soon after an alkaline one. If you simply develop, fix and wash in the ordinary way, and take care that the solutions do not vary greatly in temperature, you should have no trouble at all.

CARICATURE PORTRAITS.—There is a photographer producing post-cards while you wait, using caricatures for the figures. I should like to know if there is any patent about it that would prevent me doing the same, as I do not wish to infringe.—**ALERT.**

It is open to anyone to produce caricature portraits in the well-known way directed for the use of the comic caricature backgrounds. We think it very unlikely that the photographer has any patent rights in a method; certainly he can have none in the idea.

FEROTOTYPE.—We are afraid we do not understand your difficulty. You cannot take prints off ferrotype plates. One positive picture is obtained on each plate by development.

H. E. W. UPSHER.—(1) The retouching is very fair; a little over-done perhaps. (2) We advise you to use the maker's formula.

COPYRIGHT BLUFF.—Your valued opinion on the following will be gratefully received. A very elaborate monument has just been erected in the cemetery here, and the day it was finished a photographer in the town photographed it for postcards. The next day I photographed it with the same end in view. While I was taking the picture the other man saw what I was doing. This morning I received a lawyer's letter warning me that Mr. — had made a photograph of the monument and registered it, and that if I published photographs of it immediate proceedings would be taken against me under the Copyright Act for "penalties, damages, and costs." I have just learnt that the writer of the letter is not a proper lawyer, but a lawyer's clerk. What shall I do?—**J. R. C.**

Publish your pictures as you intended to do, for no one can prevent you. The fact that the other photographer has registered

the copyright in his picture makes no difference, as that gives him no copyright in the subject. We may tell you that the man who has attempted to bluff you, by pretending to be a solicitor, has acted illegally, and if his conduct is brought before the Incorporated Law Society he will probably be proceeded against, and possibly have to pay a heavy penalty.

CHLORIDE OF GOLD FROM COIN.—For some years past I have been making my own chloride of gold, using half-sovereigns or sovereigns for the purpose. On mentioning this to a friend the other day, he said that what I was doing was illegal, and that I should find myself in trouble if it was found out. Can this be correct, as surely I am entitled to do what I like with my own money?—**STAFFS.**

What your friend tells you is quite correct. It is illegal to deface or destroy current coin of the realm, though it is being constantly done by jewellers and others—so far as gold coin is concerned; also by photographers who, like yourself, make their own chloride of gold. Although the thing is illegal, we cannot call to mind any prosecution for utilising gold coin for manufacturing purposes.

COPYRIGHT.—Last year I took on my holiday a number of negatives (half-plate size) of haymaking and harvesting scenes that were very successful and some of them of exceptional local interest in the neighbourhood. I did nothing with them at the time except give a few prints away to friends. Since then circumstances have changed with me, and it has occurred to me that I might make a little by them if I were to publish them. Will you please tell me if it is possible to make them copyright now that so long a time has elapsed since they were taken—now about a year.—**H. H. H.**

Certainly you can register the copyright in the pictures. There is no limit as to the time within which registration must be effected. It may be done—by the author of the work—year afterwards.

MASTER.—Some four years ago I took a young fellow as apprentice. He is now getting troublesome and threatening to leave, though he has yet another year to serve, which, of course, will be the most valuable one to me. The agreement, I may mention, was not a stamped one, but it was in writing.—**F. O.**

If the indenture was not stamped it is not binding, either on you or him. He has been merely a weekly servant all the while and can leave when he likes on giving a week's notice.

ENSIGN FILM COMPETITION.—Mr. James E. Tyler, North Street, Halstead, Essex, is the winner of the "Ensign" Roll Film Competition for July. Houghtons Limited offer a three-guinea camera every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free, and a competition form enclosed with every spool of "Ensign" film.

GUIDES FOR THE HOLIDAYS.—The latest additions to the series handy little guide books published by the Health Resorts Development Association deal with the towns and surrounding districts of Hitchin, Lytham, Sheringham, and Windermere, and, like others in the series, may be obtained free by addressing a postcard application to the respective Town Clerks.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

FRAUDULENT SUPPLY OF PHOTOGRAPHS.—A case of considerable importance to the photographic profession was heard at Southampton last week. Mr. S. G. Kimber, F.R.P.S., summoned a firm of photographers in reference to the supply of silver prints as carbon photographs. A full report of the case appears on page 612, whilst in an editorial article on page 606 we draw the attention of our professional readers to the fact that the case should apply a check to the fraudulent supply of the cheaper class of photographic print in place of carbons or platinotypes. It is to be hoped, too, that the case will remind manufacturers of the opportunity for fraud on the part of the less reputable photographers created by the lack of sufficient explicitness in descriptive terms applied to printing papers other than those for the carbon and platinum processes.

The exhibition of results by the Morgan system of dry-mounting, etc., continues open until to-morrow week, August 14. Mr. Morgan, Jun., gives daily demonstrations from 10.30 to 4.30. (P. 609.)

Mr. Harold Baker in the current issue of "Photographic Scraps" describes an extra-rapid method of developing the Ilford "Zenith" plates, the results being superior to those obtained in the longer time by the usual process. (P. 609.)

The L.C.C. school of photo-engraving is to be rebuilt, the London County Council having sanctioned the expenditure of £20,000 for the purpose. (P. 614.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. Colin N. Bennett contributes an article on the use of the separate "Thames" plate method of colour photography, in which he describes the knack of registering the transparency with the screen-plate. (P. 57.)

M. Monpillard has given the formulæ for a compensating light-filter to be employed when using limelight as the illuminant in photo-micrographic work on the Autochrome plate. (P. 61.)

The precautions to be taken in adopting a lens separation when making stereoscopic Autochromes is the subject of a note on page 59.

The use of flashlight in making instantaneous exposures on the Autochrome plate is dealt with by M. H. D'Osmond. (P. 60.)

A French worker has recorded his method of working the Autochrome plate without a dark-room whilst on tour. (P. 60.)

Several hints on the manipulation of the Autochrome plate are given by correspondents on page 64.

Dr. W. Scheffer has recently published some notes on the fineness which is necessary in screen-plates to be viewed under various conditions. (P. 62.)

EX CATHEDRA.

Judges as Judges. A magistrate has been called upon to judge a photograph of a baby. The parent objected that the photographic enlarger tried to pass off the presentment of another baby upon him. "Why, it's got a different pinafore on, and in the large photo the baby is sitting on a mat, while my baby sat on a cushion," the plaintiff pleaded, further stigmatising the enlarged infant as "cock-eyed," and adding "Mine ain't." It must have been a flagrant case of "control"—an abortive attempt to foist art in lieu of photography upon an unready public. The magistrate urged that some licence should be allowed to the artist; but the outraged parent considered that cock-eyes were no artistic advance upon the "straight" condition of the original. He was told to be satisfied with it, nevertheless, especially as it was not a first-class advertisement for the photographer. Evidently the magistrate does not know what constitutes a good advertisement in latter-day portraiture. The fond father promised to give the photographer an advertisement when he met him.

* * *

Cutting Stereo Prints. In reviewing a book on stereoscopy lately, we remarked that by printing direct from the original negative, and then cutting and reversing the prints, we obtained more even results, and got through the work more quickly than by using a reversing frame and printing the two pictures in succession in their right positions on one piece of paper. A correspondent takes exception to this, but has apparently misread our statement altogether. He advocates, so far as we understand him, cutting the negative and transposing the two halves before printing, which is naturally one of the quickest ways of working, but one not referred to in our review as it was not mentioned in the book. Our correspondent goes on to refer to the method of cutting and trimming the print as not only obsolete, but untrue, and also as "an operation using more material than is necessary, solely for the purpose of cutting it away as waste." In point of fact, however, the trimming does not waste any more material than does the masking, which is necessary by the other method, and it enables us to utilise mounts and borders of any colour. The method of cutting the negative is, however, a very useful one, and if film negatives are used and trimmed down, we can produce prints with dark borders that give a very good effect. As regards truth of effect, this is not in any way affected by the mode of printing. If we cut the prints we must trim them properly, and if we cut the negatives we must mask them properly. A certain amount of adjustment is generally necessary if the lens separation is fixed, though with an adjustable separation we can, of course, arrange everything perfectly on the focussing-screen.

Modes in Mounts.

Fashion and the dry-mounting process having displaced the solid, stiff mount to a large extent, there must be large quantities of such mounts which are so much dead stock to photographers until fashion changes again. We know of one firm, and not a very big one, which some time ago had twenty to thirty thousand wood mounts, but has used nothing but paper during the last year in order not to lose prestige or fall behind rivals. Many stiff mounts, if not more than eight-sheet thickness, could be used up by having a harmonising paper folder and tissue stuck on them. They can certainly be pushed as most serviceable, for, after all, the paper mount must be framed, or kept in a portfolio. The latest mount, so-called "the booklet," consisting of mount with flap and tissue stuck on the top and tied with silk ribbon, with artistic head, embossed on the centre, is very popular, and for the best work may displace the mount in the more usual folder. The flexible vellum has long passed the height of its popularity, whilst the rather vulgar six-sheet plate-marked vellum surface mounts, with fancy brown lithographed design, that ran through 1908, have, we think, had their day. From inquiries we find that the "Cosway Mount," consisting of card printed with imitation engraving border to the edges, is very popular with a cheaper class of customer.

* * *

Some Current Styles in Mounts.

Fancy plate-marks show no signs of dying out, though we think the worst of printed and embossed borders have been seen. The oval shape and the panel is dying, whilst the circle, that was all conquering three years ago, is dead. Everything considered, we think the general trend is a recurrence to the simple style of mount. The old-time square cabinet is the principal shape, whilst in stiff mounts the white is regaining its popularity, though the very beautiful combinations possible by the use of tinted mount and tint are likely to be most used for the best work. It is rather peculiar to note that in the old days of the album mount dark Bristols were used for the best mounts. As the flexible mount has rendered useless big stocks of large stiff cards, so did the latter turn the small black and brown gold edged and gold blocked mounts into useless lumber. Since these were ordered in great quantities at a time, for only one mount was used for all cartes, one for cabinets, and so on, it would be interesting to peep into the stockrooms of half-a-dozen establishments with a pedigree. It is thankless work prophesying, but it seems almost certain that there will for many years be no recurrence to this style. From the ever and rapid changing mounts of the present day it is certainly sound advice to order in small quantities only. Many varieties, designs, and outside sizes are, however, a snare, being a bother and constant source of worry, friction, and mistakes from beginning to end.

* * *

Cinematograph Literature.

As evidencing the phenomenally rapid growth of the cinematograph trade during the past year or two, attention may be called to the list published in the current number of our contemporary, "The Kinematograph and Lantern Weekly" of the periodicals relating to the trade published in different parts of the world. These number almost a score, and come from such distant parts of the globe as New York, Vienna, Paris, Berlin, and Budapest. The cinematograph, as a means of popular entertainment, has within the last few years reached a degree of popularity which shows no signs of diminution, and with the possible introduction of natural colours by a photographic process into the pictures it would seem that for some years yet

animated pictures will continue to be a staple form of popular entertainment.

* * *

A Souvenir of Messina.

We have received from the Italian Photographic Society, 50, Via Degli Alfani, Florence, the illustrated prospectus of the souvenir volume dealing with Messina and Reggio, which that body is shortly publishing as a souvenir of the disaster of last year. The volume is to run to 300 pages, the text matter being in Italian, French, English, and German. There are to be over 550 illustrations, and the proceeds of the sale are to go to the relief of those rendered orphans in the disaster, a project which has the patronage of H.M. the King of Italy. The price of the volume, unbound, is 10 lire; bound, 15 lire.

FRAUD IN THE SUPPLY OF "CARBON PHOTOGRAPHS."

A CASE of considerable importance to all those whose interests lie in reputable professional photography was heard at the Southampton Police Court on Thursday in last week. It concerned the supply, by a Southampton firm, of photographic prints which were advertised and invoiced as carbons, but were, as a matter of fact, a form of silver print. The Police Court proceedings are fully reported in another column, so that there is no necessity for us to detail at length here the circumstances of the case. Briefly it may be stated that the summons was taken out by Mr. S. G. Kimber, F.R.P.S., secretary of the Southampton Camera Club, against Messrs. Freeman and Co., in reference to photographs supplied to Mr. Kimber in fulfilment of an order which he gave the defendant firm, as the result of seeing their advertisement in a local paper, in March last. The advertisement ran as follows:—

WANTED, all ladies and gents to inspect our high-class studies; carbon cabinets 2s. 6d. per half-dozen, usual price 30s. For six days only.—Freeman and Co., artists, Above Bar, Southampton.

It will be obvious to anyone in the photographic business that such an advertisement professes to give at a low price the carbon prints which are usually supplied by high-class professional photographers at prices frequently comparable with the 30s. per half-dozen cited by the advertisers. In execution of Mr. Kimber's order there was supplied to him, however, not carbon or pigment prints, but toned P.O.P.'s of the so-called carbon surface. As will be seen from the Police Court proceedings, the defendant described these prints as carbons on their invoices, and the supply of them therefore brought them within the Merchandise Marks Act of 1887, under which it is unlawful to apply a false trade description to goods supplied.

As pointed out by the plaintiff's solicitor in the course of his remarks, the question involved in the case was not whether the carbon-surface silver prints were equal in appearance or permanency to a genuine carbon print. The customer gave the order on the assumption that he would obtain genuine carbon prints, and therefore he was entitled to receive them. The defendants put in a formal plea "guilty" to the charge, and through their solicitor made sundry excuses to the effect that there was no intention of defrauding. A fine of 5s. was imposed in each of two distinct charges, together with costs, which the plaintiff agreed to accept at three guineas, making £3 13s. in all.

We are able to supplement the report of the proceedings by some additional particulars. It will be noticed that there were two summonses: one with regard to the advertisement and the other with respect to the actual prints delivered. With regard to the latter, the defendants had

not acted with that 'cuteness one would expect, for the receipt given to Mr. Kimber for the amount paid set forth that it was for "six cabinet carbons"; thus there was a fatal definiteness in the contract which in itself nullified a statement made by the defendants by letter in reply to Mr. Kimber's complaint that the prints delivered were not by the carbon process, that the prints supplied were as ordered, and were "carbon matt" prints. This admission that there was a difference between a carbon print and a carbon-surface print, however, did not come out in Court, and the defendants' advocate made the most he could of the opportunity afforded by the common use of the expression "carbon" to describe the surface and appearance of prints on certain papers which otherwise have no connection with the carbon process. In a quite pathetic appeal to the magistrate, he represented that his client was himself deceived. He had bought the paper as carbon paper, and had therefore described his prints as carbon prints. This was the only shred of an excuse possible; but it was unavailing, for although the prosecuting solicitor expressly stated that the prosecution was satisfied with the plea of guilty, and did not ask for a fine, the magistrates imposed a fine of 5s. in each case, thus showing inferentially that they regarded the matter as something more than the innocent mistake of a guileless photographer.

Although the substitution of a cheaper form of print has constituted a form of disreputable competition of which professional photographers of standing have long complained, there has never been, so far as our memory serves us, a case in which such fraudulent practice has been brought to book, even in a police court. It will be remembered, perhaps, that some years ago the "Daily Telegraph" made sweeping accusations against photographers in general to the effect that it was a common practice among them to supply bromide prints for platinotypes, and though on behalf of the profession generally such a charge was at that time keenly repudiated, and may still be repudiated, yet the growth of the cheaper class of business during the last few years has, we fear, led to such an accusation being more justifiable at the present time than when our contemporary wrote its article in 1901. We are not writing now of photographic studios of reputation and commanding reasonably good prices, for to these the difference between the cost of the raw material employed in making a silver and a platinum print respectively does not bear the same proportion to the cost of the finished article which it does in the case of many firms who are now offering photographs to the public at almost incredible prices. So long as this cheap business is done on lines which may be legally defensible, if morally discreditable, no action on the part of the better-class photographer is possible other than to convince the public of the superiority of his own work and of the better conditions under which his assistants are employed. But when it comes to resorting to fraudulent methods, such as the substitution of an admittedly cheaper class of print for a carbon or platinotype, there is every reason to visit the offenders with the penalties of the law. All photographers, therefore, who have at heart the status of the profession will applaud the public spirit of Mr. Kimber in taking this case into Court. It constitutes a precedent which, we hope, will not be forgotten by all those who may have similar illegitimate conditions to face, and from what we can hear a good deal of this kind of substitution is being practised. We believe it is not altogether unknown among those firms who do printing for photographers for printing orders in bromide to be received with the shameless request that "a good job may be made of them," as it is proposed to sell them as platinotypes. The absence of actual conviction under the Merchandise Marks Act has perhaps led such persons to suppose that they can indulge in this practice

with impunity, and we may therefore hope that the case which has just been heard at Southampton may have the salutary effect of proving to this kind of trader that he is jeopardising what reputation he may have by offering for sale such fraudulent substitutes for genuine articles.

There is a matter arising from this case that deserves the serious consideration of manufacturers of some photographic papers, and that is the very loose application of the terms used to describe their qualities. From the above it will be seen that the defendant, through his solicitor, stated that he bought the paper which he used as carbon paper, and thereupon described his prints as carbon prints, and in proof thereof he held up a box inscribed in print large enough to be read all over the court: "So-and-So's Carbon," and it required somewhat careful examination of the box to discover that what appeared as a decorative monogram contained the letters "P.O.P." To a bench of magistrates, none of whom were acquainted with photographic matters, this exhibit might have lent colour to the excuse put forth. All who do practise photography quite understand the sense in which the expression "carbon" is used as merely to indicate the nature of the surface, but with this want of explicitness it might have been difficult to convince laymen that the word "surface" was presumed to be expressed. In legal proceedings of this kind the prosecutor has to state his case and support it by evidence, and after his case is closed he can produce no further evidence. The defendant then has his turn. It is necessary, therefore, for the prosecution to anticipate the defence and meet it in advance. In this particular case it was anticipated that the defendant would rely upon the defence that actually was used as his excuse. The hon. secretary of the Professional Photographers' Association, who, with a representative of the Autotype Company, was to have given evidence, informs us that in getting up his evidence he started with the idea that he could show positively that all manufacturers of paper used the word "surface" in describing the surface of their paper; but on investigation he found the word frequently dropped—almost more often than not. This is a matter that does not affect photographers; for, as we have said, no one practising photography can be deceived by such expressions as platinobromide or carbon P.O.P.; but it is otherwise when these or similar terms are applied outside the photographic circle, and the repetition of them may become the cover for fraud of a most despicable kind. We do not for a moment suggest that any manufacturer would knowingly choose a descriptive expression that could be misused, for British manufacturers of photographic materials as a rule stand high in the scale of commercial morality; but here is a concrete instance of a term that has an esoteric and an exoteric meaning actually used to deceive the public. Perhaps it is too much to ask those who have made their manufactures known under descriptions to which these comments apply to alter their nomenclature, but it is not too much to ask them to see that in future issues of descriptive matter, labels, etc., there is sufficient explicitness to render impossible such an absurd excuse as that seriously made by the Southampton photographer.

FIFTY YEARS OF PHARMACY.—We have to congratulate our contemporary, the "Chemist and Druggist," on the production of its jubilee and summer issue. The publication is a massive volume of text and advertisements, with which is presented as a supplement a facsimile of the first issue of the "Chemist and Druggist" as a monthly trade circular in September, 1859. The long and intimate connection of the "Chemist and Druggist" with the drug trade is suitably emphasised by a history of the journal and some very interesting biographical notes of persons in the trade. We felicitate our contemporary on finding itself in a state of such robust health after fifty years of strenuous life.

LARGE DIRECT NEGATIVES WITH MEDIUM-SIZE CAMERAS.

It is no unusual thing for professional photographers to find themselves called upon to produce a photograph of a larger, possibly much larger, size than the apparatus at command will permit of. The camera may not be large enough, and even if it were there may not be a lens available that would cover the necessary size picture. How, then, is the work to be done? One way that would naturally suggest itself would be to take a small negative and make an enlargement from it. But it may happen that if that were done the small negative would not include all the subject that is necessary either in one direction or the other. The subject may be a factory, or a landscape for that matter, and the distance from which the camera can be placed from it will not permit of the whole of the subject being included even if a very wide angle lens is employed. Under these conditions the only thing to be done is to take negatives piecemeal and combine them afterwards. This would be looked upon by some as a very difficult job to undertake, but it is really not so in practice. Suppose the picture required is 18 x 11, or, may be, 15 x 7, and the only cameras and lenses available are 12 x 10 or whole-plate respectively. With either of the above sizes it is easy to obtain two negatives that can be combined into one afterwards. Still larger sizes may be obtained by taking more negatives, but I shall here confine myself to two; more may be combined on the same principle, and various ways of doing this class of work have been given at different times in the "Journal." The one, however, now to be described differs somewhat from these, inasmuch as paper is the medium employed for the negatives. At the present time rapid bromide papers are on the market, and these, though slower than rapid plates, are sensitive enough for our present purpose—under most conditions. Objection may be raised against paper negatives on account of the grain of the paper showing in the prints, but the objection is more imaginary than real. The loss of fine detail is less conspicuous than when enlargements are made on bromide paper from small negatives, and it is this that I have under present consideration, it being assumed that the results are required for commercial purposes—process blocks, collotypes, etc., for show-cards, catalogue illustrations, or the like.

The procedure is as follows:—If the paper is bought in cut pieces it will probably lie quite flat when put into the dark slides, with simply a piece of glass at the back to press it close in contact with the rabbet of the slide. If it has a tendency to curl, glass plates, free from air-bells and perfectly clean, are put into the slides first, and the paper pressed in contact with them with two or three sheets of blotting-paper. It goes without saying that if the largest size is required, the longest diameter of the paper must be placed vertically in the slide. The slide, or slides, being filled the camera should be planted firmly and perfectly level before the centre of the subject; here a spirit-level will be found very useful. It must be kept in mind that on no account must the position of the camera be altered, however many negatives have to be taken. The image is then gauged and focussed on one-half of the subject so that it includes about an inch or so of the other half, and the exposure made. The camera is then rotated on its axis by loosening the camera-screw, so as to include about an inch of the subject in the first negative in the second exposure. The two exposures, it is unnecessary to say, should be as even as possible. The

development of the two negatives, if possible, should be done in the same dish. If not, it is best done in two dishes placed side by side so as the easier to get the two negatives as nearly as possible of the same density, which latter must be judged of by looking through and not down upon them. The negatives must be made somewhat dense, as the grain of the paper will then be less noticeable in the print. A full exposure should be given, but no more, as over-exposure would lead to flatness, and add to the granulation of the paper. The negatives are then fixed and washed in the usual way, and dried flat between blotting-paper. In taking the negatives it is advisable to expose in duplicate, and when that is done it is best to develop the two in one slide together, as then there is a better opportunity of getting uniformity in the pair.

The negatives—two or more—having been obtained, the next thing is to combine them into one so as to print on a single piece of paper. A piece of glass an inch or two larger than the combined negative is to be cleaned, placed on the retouching-desk, and one of the negatives (in the rough)—we here assume that only two are to be combined, though any number may be in the same way—is taken and adjusted on one half of the plate and secured in position with a few touches of india-rubber cycle cement. The other negative is similarly secured in its position, the overlapping portions of the two negatives serving as a register for accuracy. When the cement has become quite firm a sharp trimming-knife or a keen-edged pen-knife is taken and the two overlapping edges cut through to the glass with one cut and the detached portions removed. In making the cut it is well that it should not be in a formal straight line, but taken through unimportant parts of the picture, as round the margins of buildings or through or about trees.

The combined negative is now ready for printing. Should the edges of the negatives at the junctions show a tendency to curl away from the glass a touch or two of the cycle cement will hold them down. Of course, the negatives can be taken off the glass and be fixed to it again with any mountant; but that is not advisable, as any aqueous cement will cause an expansion of the paper, and perhaps unequally, so that an accurate juncture will not again be obtained. Some cycle-cements have but little colour, and if in attaching the negatives to the glass it is but sparingly used its colour, if applied only to the denser portions of the picture, will not show in the prints. When the combined negative is finished, if one of its components is seen to be thinner than the other, the back of the glass of that one may be coated with matt varnish or with mineral paper. Clouds can, of course, be introduced in the negative by stumping plumbago on the paper in the usual way. This, if judiciously done, will hide the juncture in the sky portion of the picture.

Prints made from bromide paper negatives show but little or no granularity. The printing is slow, but that is of little moment, for, as a rule, only a few prints of such subjects as we have in mind are required. If many are wanted they may quickly be produced by printing on bromide paper or gaslight paper. If the negative be made transparent with wax, paraffin, castor oil, or the like, it will print quicker; but it is a curious fact that when that is done the granularity of the paper becomes more pronounced than when it is left in its original condition.

F. P. RENTER.

THE MORGAN SYSTEM OF DRY-MOUNTING.

As already announced in our two last issues, there is now being held in the "Little Gallery" at the Offices of the "British Journal" an exhibition of the results obtainable by the method of combined dry-mounting, embossing, and blocking, invented some year or so ago by the late Mr. G. W. Morgan. The details of this system of preparing mounted portrait prints have been described in past issues of the "Journal," since when certain further improvements have been made in the process, which, as now available, is adjustable to the most varied conditions of the business of a professional studio. Although the best method of forming an idea of the capabilities of the process is to witness the demonstration which the late Mr. Morgan's son is now giving at the exhibition, some few words require to be said as to the facilities provided by the process.

The Morgan system is based on the use of, first, an adhesive material which, under hot pressure, cements the print to the mount, and, secondly, of a specially designed mounting folder. This consists of a pair of metal plates hinged together. One of them is provided with a die in which the design for the surround of a mount is engraved, the opposite plate having on it a matrix registered with the die and providing the necessary pressure when the hinged folder is placed in the dry-mounting press. The one plate of the folder is further provided with a stop adjustable in two directions with the mount, so that a folder which is provided with a die suitable, say, for cabinet prints, may be used for all sizes of mounts up to 16 x 12 or 18 x 12 inches, and can be instantly set so that any series of mounts of a given size may be immediately placed on the folder in correct registration or a given position of the print upon it.

The design of the dies, too, in all cases is suited for both square and oval prints, so that at the one expense of 35s., which is the cost of a folder complete with die, matrix, and adjustable stops, the photographer is in the position to turn out mounted prints of quite a series of different sizes. Any number of different folders may be used in the press, so that

the outlay of a few pounds in this way allows of considerable variety in the output of a studio.

The operation of mounting, embossing, and blocking is as follows:—The metal folder is first placed in the press for a minute or two to become warm, is then removed and opened out, and the print laid, face down, in position on the die. The stops having been adjusted for the correct position of the mount, the latter is pushed against them and brought down upon the print, which is thus pressed between the die and the mount and held in position. The upper half of the folder is then brought down on both mount and print, and the whole pushed into the press and given a hot pressure of about four seconds' duration. The result is a neat design in relief around the print, a perfect mounting of the latter on the board, and also, if means have been taken, an embossed marking of the photographer's name on the mount, these three operations being produced by the single pressure.

The process is also amenable to the application of a pasted-on tint surrounding the print. In producing this effect the print is laid face down on the die, the tinted paper laid face down upon it, and the mount over all, a single hot pressure then serving to cement the print to the tinted paper and the latter to the mount, together with the production of a plate-mark around the tinted border. These operations, difficult to describe adequately in print, are performed with swiftness and certainty by the use of the metal folders, and it is hoped that those who are interested in this latest development of photographic mounting methods will not fail to pay a visit to 24, Wellington Street, before the exhibition closes—namely, on August 14.

It should be added that, along with the demonstration of the Morgan dry-mounting, the opportunity is also offered of making trial of the mercury-vapour Cooper-Hewitt light for studio purposes, the necessary installation having been provided, and a camera, background, and facilities for developing photographers' own exposures (half-plates) being at disposal.

"ONE MINUTE DEVELOPMENT" AND ZENITH PLATES.

A paper in the current issue of "Photographic Scraps."

ONE-MINUTE development is carried out by bathing the plate in the "reducer" constituent of the developer for 30 seconds, and then bathing in the "accelerator" for 30 seconds more, without washing off the first solution. At the expiration of the minute the plate is rinsed and fixed.

My solutions are:—Reducer; metol 4 drams, hydroquinone 8 drams, potassium metabisulphite 2 ozs., potassium bromide 4 drams, water to 100 ozs. Accelerator; sodium carbonate 12 ozs., water 100 ozs.

I was working with the mixed developer until I applied the one-minute method to Zenith plates, when I was so pleased with my results, that I have since developed all my portrait negatives, without exception, in the "one-minute" way.

The time in the two solutions may be varied to suit the exposure, whether under or over, and also to produce the kind of negative desired. If I find the exposure has been a little too short, the bathing in the "reducer" solution is shortened, and the time in the alkali or "accelerator" is prolonged until proper density is obtained. This also applies when there are violent contrasts in the subject. In such cases the plate may be kept in the first bath for about 30 seconds, followed by one to two minutes in the second bath, as may prove necessary.

For normal exposures, where good density is desired, the first bath may be given for quite a minute, followed by the same time in the second bath. If over-exposure is suspected or known to

have occurred, the first bath may be prolonged to two minutes or even more, and the time in the second bath be much shortened.

It will be found that a first plate developed by this double method will be too soft and delicate, and it will also be very yellow in colour. A second plate developed in the same solutions will be stronger and less yellow, and each succeeding plate will be denser and still less yellow. I think the yellowness is due to the absence of sodium sulphite in the second solution, the proportion of sulphite to alkali being far less than in the ordinary mixed developer. The gain in density is accounted for by the fact that each plate carries in its film a certain amount of the "reducer" into the "accelerator." After a few plates have been developed, the increase of density appears to cease, but it is not advisable to run the second bath too low, or to use it too long without adding some fresh solution. The addition of a small quantity of sulphite to No. 2 solution prevents yellowness, but I find a better method is to add a small quantity of No. 1 solution to the dish of No. 2 before beginning to develop, as this not only prevents the yellowness of the image but the thinness also. After six or eight plates have been developed a little fresh alkali should be added to bath No. 2, which will need freshening up when the image is seen to appear too slowly.

When a batch of plates has been developed, any of number one solution that may be left over may be poured into a bottle for use next time. It is well to roughly filter it through a tuft of cotton

wool. I always pass the ball of a finger gently over each plate, as soon as it is put into the first solution, to remove any small particles which may be adhering to the gelatine. If this is not done the moment the plate is wetted, such particles cannot be removed without the formation of nasty spots which call for very careful spotting, in both negative and print.

The second bath will not keep after use, and any left over should be thrown away. The surplus of number one solution should be kept in a separate bottle, as it always has a cloudy appearance, and leaves a deposit on the sides of the bottle. When using it again I always add a third or more of fresh solution, in order to keep up the quantity, so that plates shall be well covered.

The advantages of this method of development are obvious. In the first place there is a great saving of time; good portrait negatives can be developed in 30 seconds in each solution, one minute in all, if the solutions are sufficiently concentrated. My solutions are just about the right strength for 30 seconds in each with Zenith plates; they give me portrait negatives that print well on Ilford Carbon Surface Bromide paper, and also give good prints in carbon. The second is economy of developer; this can be applied to a large number of plates, and be used repeatedly if a little fresh be added. The third advantage is reduction of exposure, and this is a great gain to the portrait photographer, even in these days of rapid plates.

The greatest advantage of all, however, is the marked superiority of the portrait negatives it produces. One of the difficulties of the studio operator is the false values given by the ordinary plate

developed in the ordinary way. The face, as a rule, is too dark with exaggerated shadows, especially if the sitter is wearing light clothes. Very often matt varnish and other dodging must be used to keep the face light enough, while printing sufficiently deep to render detail in the dress.

The "one-minute" method of development gives results far surpassing those produced with a mixed developer. The face will need less retouching, the high-lights will show soft delicate detail, the shadows will be more luminous and will also have more detail in them. The print will not present those blank patches of white high-lights and black shadows, which one often sees in portrait photographs. These advantages should induce photographers to at least give the method a trial, for if economy of time, economy of developer, shorter exposures and better results do not appeal to them I do not know what will.

If I can help it I never allow anyone else to develop plates have exposed, and the advantages mentioned are those I have personally experienced in daily work. Those who feel doubtful of starting a new method should try an experiment; expose a plate in the studio as usual, and, before development, cut it in two, develop one half in the old way, and the other half in the new and compare the results.

I do not say the new method will suit every plate. I tried one which failed to give good results by it; but there is no doubt about its suiting the Zenith, which, by the way, is the finest plate for portrait work I have ever used.

HAROLD BAKER.

MIXTURES OF DYES AS SENSITISERS OF GELATINE PLATE

III.

[The following is an abridged translation of a thesis by Guido Daur, presented for the degree of Doctor of Philosophy at the Münster University. The experimental work was done on the suggestion of Professor Miethe, to whose colleague, Dr. E. Stenger the author of the papers renders his thanks for much advice and assistance. The full text of the paper occupies a book of 105 pages published by E. Grieser, Frankfurt a/M.—Eds. "B.J."]

20 and 21. *Isocol-dicyanine*.—Fig. 20 represents the results obtained with a mixed bath of these two dyes; fig. 21 gives the curves obtained by using the dyes in separate baths. It was found necessary to wash plates in alcohol. The curve is of the isocol type without gaps in the green, a maximum at 530, a second at 580, and a third at 630. The minimum between 530 and 580 is somewhat

In fig. 21 three curves are given, each for an exposure of 60 seconds. I. Dicyanine-isocol used in one bath. II. Dicyanine-isocol used in separate baths in the order isocol-dicyanine. III. Isocol-dicyanine used in separate baths in the order dicyanine-isocol.

The position of the maxima is the same in all three curves. They lie in the green-blue, green-yellow, orange, and red. In the

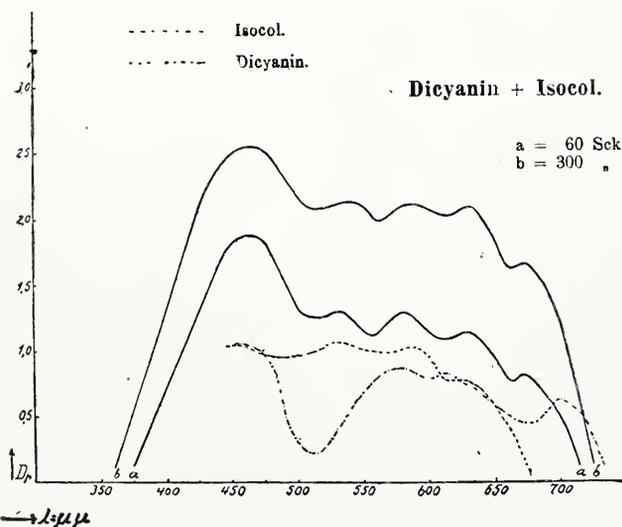

Fig. 20.

The dyes were used in mixed bath.

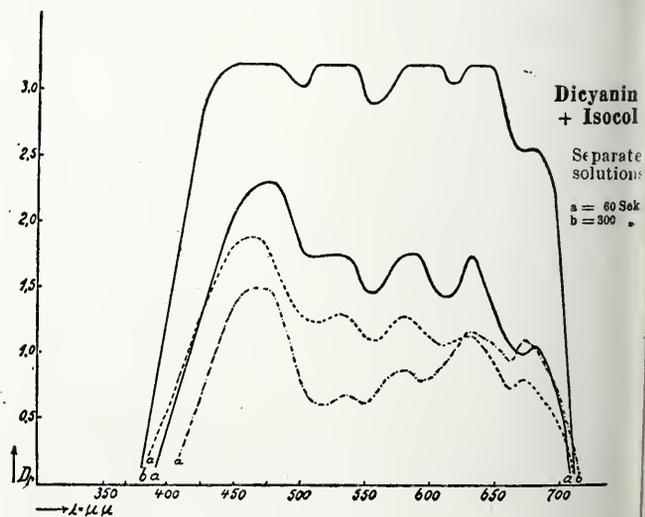

Fig. 21.

— Plate sensitised, first in isocol, then in dicyanine.
 Plate sensitised, first in dicyanine, then in isocol.
 - - - - - Plate sensitised in mixed bath.

deeper than with isocol alone; the maximum at 630 is considerably higher than when using the dye by itself. The reason for this no doubt is that at this point the dicyanine maximum of 610 is apparently obtained. The last dicyanine maximum of 700 also comes up, prolonging the curve towards the blue, owing to a shift to 670. The colour-sensitiveness, as also the general sensitiveness, leaves much to be desired.

of I. the sensitiveness for the rays of the first three colours is almost equal, the red-sensitiveness being only a little less. For II. the sensitiveness for the first three colours is almost equal and the action in the red very much inferior. It is also worthy of note that the minima lying between the various maxima appear more pronounced. In III. the ratio of sensitiveness of the spectral rays

very different. From greenish-blue through greenish-yellow to range the density steadily increases, remaining constant in the red. The general sensitiveness of the plate, however, is much less, so that the relatively strong action in the red is about equal to the lesser action of II. The general sensitiveness is greatest in II., the colour-sensitiveness in this case rapidly increasing with increase of exposure. Whilst in I. the blue maximum does not reach the normal density, even after an exposure of 300 seconds, in the case of II. all the maxima are equal to that in the red.

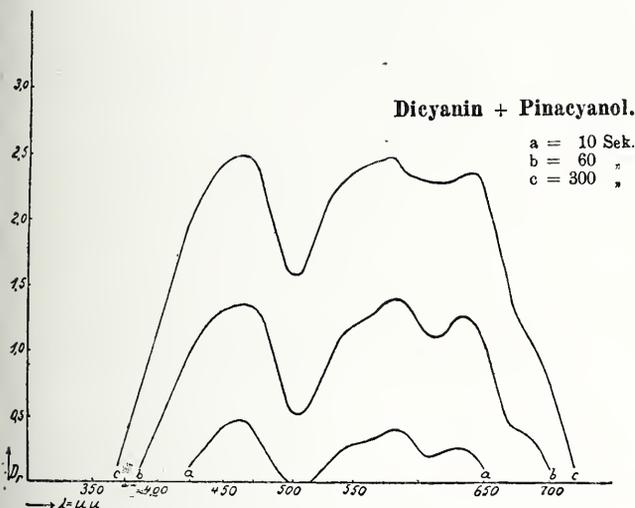

Fig. 22.

22. *Dicyanine-pinacyanol*.—The general character of the curve (Fig. 22) is that of pinacyanol; the strong dicyanine maximum of 400, which in other combinations is shifted 20 to 30 $\mu\mu$ towards the blue, is not to be found on short exposures. On longer exposures it comes up slightly and gives slight prolongation of the curve. As anticipated, no filling up of the gaps in the green takes place. Both dyes give a maximum at 580, hence the spreading of the maximum at this point. It was to be expected from the 610 maximum of dicyanine that the gaps shown by the pinacyanol at this point would be filled up. It should also be noted that the shift of the maximum 20 $\mu\mu$ towards the red, noticed in the case of formulæ nos. 18 and 19, also takes place here (630). As the colour maxima

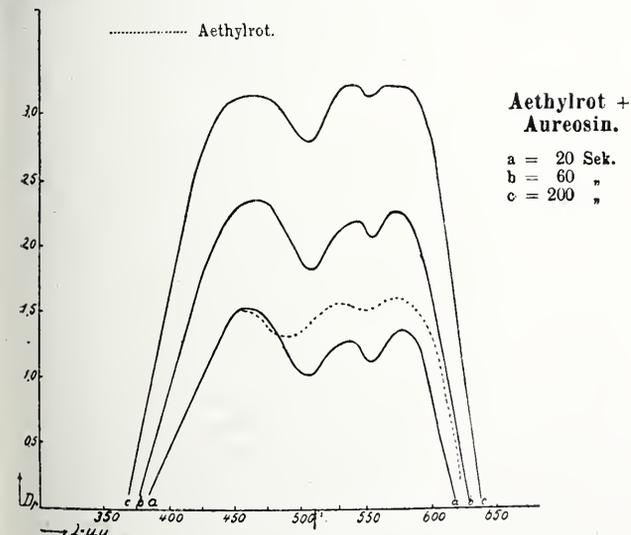

Fig. 23.

about the same value as that of the blue, it is probable that there is some screen action, also the fog is very strongly marked (7). The water-washed plate could not be used.

Mixtures of Eosines and Isocyanines.

It was not found that these dyes were incompatible. The solution, being left standing in the air after use, deposited an insoluble precipitate, probably a combination of the cyanine base with the acid of the ethrosine. Ethyl-red was chosen as the isocyanine to be used in mixture with each of four eosines.

3. *Ethyl-red-aureosine*.—Contrary to expectations, the curve is

almost wholly that of ethyl-red, in the case of the short exposures only the ratio of colour-sensitiveness to blue-sensitiveness being affected. From the ethyl-red curve, which is so chosen that its height in the blue corresponds with that of the last curve of the two dyes, this can be clearly seen. There is a shift of both maxima about 10 $\mu\mu$, the new positions being 540 and 570. There is also a certain contraction of the maxima. The gap at 500 is somewhat enlarged. The maximum at 590 is of the same value as that at 540 on short exposures, but increases with longer exposure, and with a time of 200 seconds exceeds even the maximum in the blue.

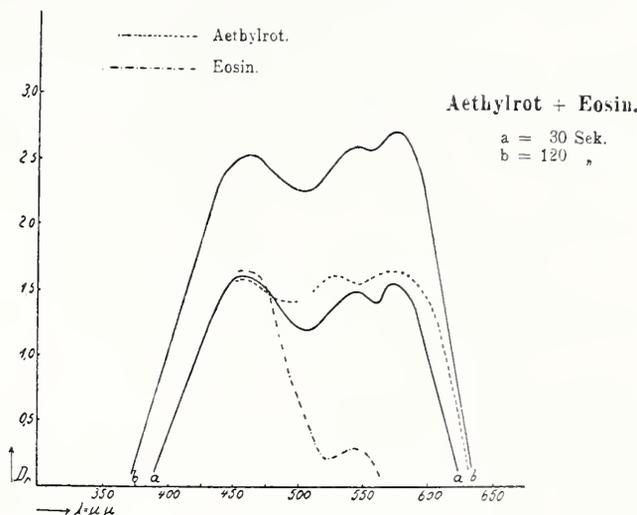

Fig. 24.

24. *Ethyl-red-eosine*.—As shown in Fig. 24, the above relations hold good when eosine is used, although this dye is a much weaker sensitiser than aureosine, but the result is very much the same. The two maxima at 530 and 590 are thrown together at 540 and 585; the gap in the green has become accentuated. The colour sensitiveness at short exposure is less than that of the mother emulsion, but becomes equal to this on longer exposure, and exceeds it in the case of the greatest exposures. The maximum at 585 is also intensified on increasing exposure. With 200 seconds the minimum lying between the two maxima is scarcely noticeable, and disappears on still longer exposure.

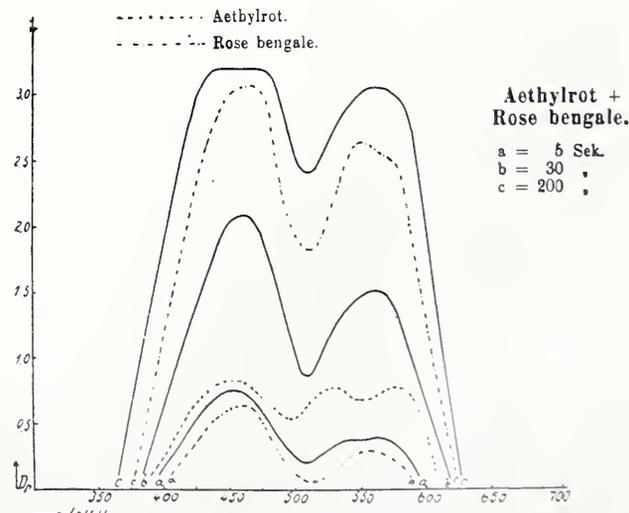

Fig. 25.

25. *Ethyl-red-Rose-Bengal* (Fig. 25).—The curve here is that of the strongly sensitising rose-Bengal, which has a rather deep gap in the green and a maximum at 550. The ethyl-red raises the curve somewhat at 500, and its maximum at 530 produces a considerable excrescence of the steeply rising curve of rose-Bengal. The maximum of ethyl-red at 580 has disappeared. In Fig. 25, alongside a curve for ethyl-red showing the same blue-sensitiveness obtained by giving five seconds' exposure with the two dyes, is shown the rose-Bengal curve for the same degree of light action. It will be seen that the general sensitiveness is increased. The ratio of the colour-

sensitiveness to the blue-sensitiveness remains the same as for rose-Bengal used by itself.

26. *Ethyl-red-erythrosine*.—Erythrosine, owing to its strong sensitising powers, fixes the shape of the curve, and there is scarcely a sign of the effects of the ethyl-red; there is no improvement of the gaps in the green. The ethyl-red maximum at 530 is in evidence on short exposures at 520. The slight prolongation of the curve towards the red end of the spectrum is to be ascribed to the ethyl-red. The ratio of colour-sensitiveness to that in the blue is, however, extremely

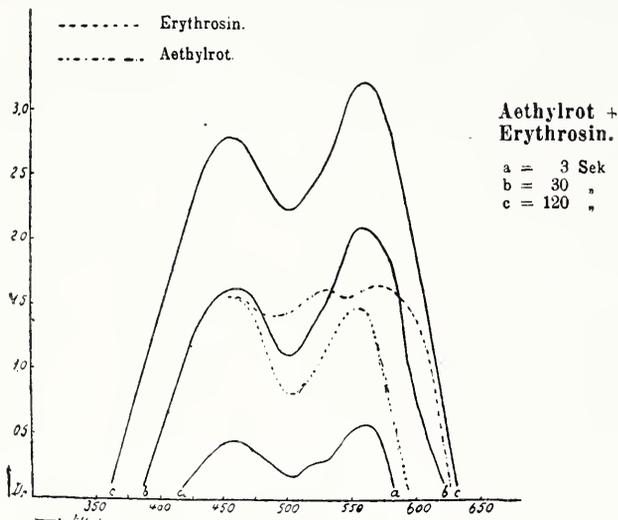

Fig. 26.

good. On short exposures the density at 560 is greater than in the blue. Exposing 120 seconds the maximum is in the green, 200 seconds being necessary for the same density in the blue.

27. *Pinacyanol-eosine*.—Contrary to experience with other mixtures of eosines and isocyanines, the plate bathed in alcohol was much the better of the two. The curves are of the pinacyanol type and exhibit in a striking way the deep and broad gaps in the blue-green to a degree not exhibited by pinacyanol alone. The depth is perhaps to be explained by the considerable increase of the first pinacyanol maximum at 580. The pinacyanol curve gradually rises from the minimum to its first maximum at 580. The curve of the combination, however, rises in a perfectly straight line instead, as

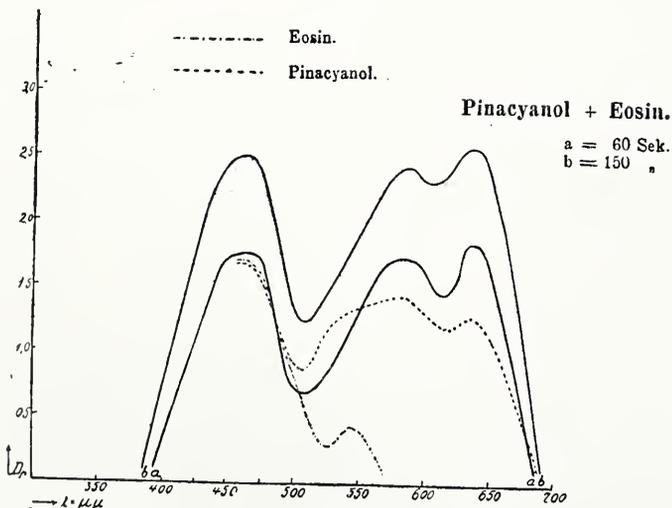

Fig. 27.

might have been expected, showing a rise between 530 and 550. The maximum of the eosin at 540 is thus without effect in admixture with the other dye. There is scarcely a sign of any shift of the pinacyanol maximum. The colour-sensitiveness compared with that for the blue is good.

28. *Pinacyanol-erythrosine*.—It was to be expected that the erythrosine would affect its companion dye quite differently from eosine; the latter but slightly affected the pinacyanol curve, whilst the strong maximum at 560 of the erythrosine might be expected to make itself felt. And as seen from Fig. 28, the first maximum

of the pinacyanol is not to be seen at all. The erythrosine maximum encroaches upon not only the maximum of the mother emulsion at 450, but also the orange maximum at 640. It is notable that the pinacyanol maximum 630 has shifted 10 μμ towards the red. The combination of pinacyanol with eosine would seem on this

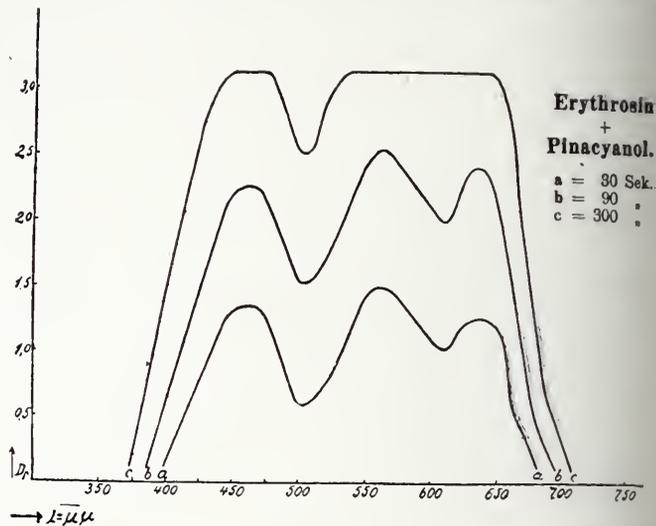

Fig. 28.

account to be undesirable, as any alteration of the pinacyanol curve by this sensitiser is not likely.

G. DAUR.

(To be continued.)

FRAUD IN THE SUPPLY OF CARBON PHOTOGRAPHS.

A CASE of importance to photographers, both amateur and professional, occupied the attention of the Southampton Borough magistrates on Thursday morning, when L. B. Freeman, H. Metcalf, and L. Barron were summoned by Mr. S. G. Kimber, F.R.P.S., the well-known secretary of the Southampton Camera Club, that on or about March 1 last they unlawfully, and with intent to defraud, applied a false trade description within the meaning of the Merchandise Marks Act, 1887—to wit, carbon cabinet 2s. 6d. per half-dozen usual price 30s., to certain goods, to wit, certain photographs. The second summons was to the effect that on or about March 5 last they did unlawfully and with intent to defraud apply a false trade description within the meaning of the Merchandise Marks Act, 1887—to wit, six cabinet carbon, to certain goods, to wit, six photographs.

It was intended to be a test case, and no pains had been spared to ensure success. At an early stage the Professional Photographers Association had been appealed to to assist, and the committee recognising the importance to the profession of a decision upon the question raised, had instructed their honorary secretary to attend the Court to give evidence. The Autotype Co. had also provided an expert witness connected with their firm, and in addition there were other witnesses in support of the prosecution. The careful preparation of the case involved an expenditure far beyond the three guineas which, by arrangement between the legal representatives of the opposing sides, the defendant agreed to pay costs, and it is unfortunate, therefore, that the proof of the prosecutor's case by the evidence of the witnesses was not required, as it would have remained on record to form a precedent for future proceedings on the same lines.

Mr. G. Dominy was the presiding magistrate, and there were also on the bench Messrs. J. Lemon, R. Chipperfield, L. Button, C. Thomas, W. J. Baker, and W. Wright.

Mr. A. C. Hallett appeared for the prosecution, and Mr. Lampport defended.

Mr. Lampport put in a formal plea of guilty, admitting that the case came within the Act, and pointed out that the defendant was Mrs. Laly Barron Freeman, and stated that the other two names had nothing to do with her, and had not for some time, the firm having been dissolved. His friend did not know that, hence the summons against the three persons.

Mr. Hallett read the summonses again, and then proceeded to make a statement of the facts to the bench, as, he stated, arrange

between Mr. Lamport and himself. He pointed out that it was a case of great importance. The gentleman who laid the information was his client, Mr. S. G. Kimber, a brick manufacturer, and for many years past Mr. Kimber had taken very deep interest in photography, and was, he thought it would be admitted, one of the best, if not the best, amateur photographer in this part of the country. He held medals and various other distinctions, and was a Fellow of the Royal Photographic Society. The case came about in consequence of an advertisement which appeared in the "Southern Daily Echo" of March 1, and the advertisement read in this way:—"Wanted, all ladies and gents to inspect our high-class studies, carbon cabinets, 2s. 6d. per half-dozen, usual price 30s. For six days only.—Freeman and Co., artists, Above Bar, Southampton."

Mr. Lamport: You will notice I am not objecting.

Mr. Hallett: I stipulated when I accepted the plea of guilty that I should make this statement. I have got the original advertisement here if my friend cares to withdraw his plea.

Mr. Lamport: Don't get cross.

Mr. Hallett: It is not a question of getting cross. It is a question of duty. I say again, sir, I have a gentleman from the "Echo" office, who comes here upon compulsion to produce, if necessary, the original advertisement. There can be no doubt that advertisement was inserted by these defendants.

Proceeding, Mr. Hallett said that after reading this advertisement Mr. Kimber, on March 5, went down to defendants' studio, which was then in Above Bar, Southampton, and then carried on business as professional photographers. There he saw a lady, no doubt in their employ, whose name he did not know. He said: "I want six carbon cabinet photographs, as advertised in the 'Echo,' at 2s. 6d." She asked his name and address, which he gave, and she entered it in a book in his presence. He noticed she wrote the word "advertisement" in brackets opposite the entry made. He gave her the sum of 2s. 6d., and she handed him a receipt which read:—"No. 8,723. March 5, 1909. Received from Mr. Kimber the sum of 2s. 6d., six cabinet carbon photographs. Freeman and Co., Southampton. 2s. 6d." She showed him various specimens, and asked him what sized photograph he required. He said a three-quarter length. She directed him to the studio, where he saw another lady operator, and she, he supposed, took his photograph. On Tuesday, March 9, he received a printed circular from the firm which asked him in consequence of having slightly moved, which they found on examining the negative, whether he would give them, at his earliest convenience, the opportunity of taking another photograph. The next day he called again at the studio and there saw a gentleman. He took another photograph. Nothing further was heard of the matter until about three weeks later, and then Mr. Kimber, thinking it time something was done, went again to the studio, which he found to be closed. On making certain inquiries he was directed to 75, Bernard Street, where he found a photographic shop had been opened with the name of Freeman and Co. written over the door. It was only fair to say that he (the speaker) understood they had disposed of their business and transferred it to Bernard Street. There Mr. Kimber went in and saw a young girl he had never seen before. He asked whether he could have his photographs. She asked him his name, and he told her. Then she said she was unable to find the negative, but would give him another sitting if he wished. He said he would like another sitting, and she took him to the studio, and there she exposed one plate upon him. He called again on Saturday, the 29th, and saw another young girl, and she handed him six photographs. He (Mr. Kimber) would produce those photographs were he to be called into the witness-box. He (the speaker) now proposed to produce the photographs to the Bench.

Mr. Lamport: I think the point is that we applied a false trade description.

Mr. Hallett: I am coming to that.

Mr. Lamport: I know; it is not a question whether he got them or not.

The Chairman (after looking at the photographs): We simply see them as they are; I am no judge.

Mr. G. Forbes Bassett (the magistrate's clerk): You have seen these—they are simply put in to show six photographs.

Mr. Hallett: I think it is necessary. I am going to point out how

the false trade description arose as I continue. He (Mr. Kimber) got those six photographs from the young girl and proceeded to test one of them with a bleaching solution of hydrochloric acid and bichromate of potassium, and this demonstrated at once it was not a carbon print. There were, he continued, carbon prints in court which would show what a carbon print really was. Putting it in his own unprofessional language, he would say these were what are called silver prints. The carbon print, he understood, was a permanency. That was to say, if this particular solution was applied to a carbon print it would have no effect upon it at all. If the magistrates would look at the two prints which had been tested they would find they yielded immediately to the test. In fact, three had been tested—one by Mr. Kimber, and two by experts, who had come to say they were not carbon photographs at all, but were silver prints. Proceeding, Mr. Hallett said that on the 4th of June Mr. Kimber wrote a letter; but he was not going to trouble them with the whole of the correspondence, but merely make a reference to it. Mr. Kimber wrote complaining that the prints were not carbon prints at all, and in one of her letters, dated June 29, the defendant stated that she was surprised at the letter of Mr. Kimber, and said that the photographs he received were as advertised, "carbon matt," as the specimens shown at the time of the order. Not being satisfied with that explanation, Mr. Kimber made certain inquiries, and amongst other things he came to consult him (Mr. Hallett). Of course, it struck him at once that this was undoubtedly a case in which they should look for information in this particular Act, and, therefore, he formed these informations on the two summonses. The summonses were served, and on the Saturday after a letter was written in which defendant offered to do anything she could to please Mr. Kimber. His friend pleaded guilty to the information. The magistrates would probably recollect that as far back as the year 1890 there was a decision of the Queen's Bench to the effect that the only necessary ingredient in a case of this kind was—did the purchaser get the thing he bargained for? It was not whether it was worth any more or less. The question was: Did they get six carbon photographs? Undoubtedly they did not, and they had gone to very considerable trouble and expense over this matter. He had in court three experts—one local gentleman and two others from London. With the magistrates' permission, he desired to say that it was not the wish of Mr. Kimber to do other than have this thing exposed, to show to the public that this was not a carbon process at all, and that in describing it as a carbon process defendant had applied a false trade description to this particular class of goods, and had placed herself within the Merchandise Marks Act. As to the question of costs, his friend had consented to pay three guineas towards the costs. Of course, three guineas would not pay those costs, as, Mr. Hallett went on to point out, there were gentlemen from London and Mr. Kimber's personal expenses to be considered. He trusted the magistrates would consider he had done right in bringing the matter before them, and, in conclusion, stated that his friend was going to give an assurance that this should not occur again, and with the permission of the Bench he proposed that the matter should end there for the present.

Mr. Lamport said he had received instructions from his client to enter a formal plea of guilty, and also to agree to pay the sum that had been stated, and with that he hoped the magistrates would say that there was no necessity to go further than the payment of that sum. He would like to say that defendant had never any intention to defraud and mislead, and he was bound to say that his client thought she had unconsciously come within the law. The defendant had been in business for many years in Above Bar Street, and occupied premises there, next door to one of their Worships. That was recently sold, and in the confusion of moving, evidently, according to the correspondence read, the negative was mislaid. In opening his friend had given Mr. Kimber an advertisement as an amateur photographer, and he (Mr. Lamport) would second all that had been said with the greatest pleasure. Defendant had got some new carbon paper: they called them carbon photographs, and it turned out they were not, directly a test was made by an expert from Southampton and two from London, who said it was not what defendant had suggested. They were very sorry. They did not want to prejudice any amateur photographer, and they did not want to injure the trade. They did try to make pretty pictures at times, but there were occasions when they failed. The defendant

offered to pay the £3 3s. and promise never to offend again. His client did not wish to fight; there was a technicality, she was wrong, and was sorry that should have happened.

Answering one of the magistrates,

Mr. Lamport pointed out that the photographs were supplied, although they did not answer the description given on the receipt. Surely if the prosecution were content, they (the magistrates) did not desire to go further. On behalf of his client, he gave an undertaking that it should not occur again, and the defendant would pay £3 3s. on account of costs. That being so, surely the court did not want more than the prosecution. There was never any admission to defraud.

Mr. Hallett: There is an admission within the meaning of the Act.

Mr. G. Forbes Bassett (magistrates' clerk): You had better plead not guilty, and you might get off with 10s. and costs.

Mr. Lamport was of opinion that the offer made should meet the case. He did not ask for permission to withdraw his plea if there was no desire of imposing a fine.

Mr. Hallett: I don't mind you withdrawing your plea.

Eventually the magistrates agreed that defendant must pay 5s. in each case, and the £3 3s. as arranged—in all £3 13s.

Photo-Mechanical Notes.

The London County Council School of Photo-Engraving and Lithography.

THE London County Council decided at its meeting on July 27 to acquire the ground on which this school stands, pull down the present building, and rebuild suitable premises. We have long thought the present premises were of no particular credit to the Council, and though no doubt reasonable while the school was an experiment, they should have been replaced long ago when it was evident that it was an assured success. It is interesting to remember that this was the first technical school undertaken by the Council through its Committee, the late Technical Education Board. The school owed its origin to the efforts of a few lithographic artists to improve their education. They induced their trade union to levy 1d. a week per member, which, together with voluntary subscriptions, enabled them to hire a floor of a disused warehouse in the Clerkenwell Road and engage a master and models for drawing. Naturally the funds were insufficient to carry on the work properly, and so they appealed to the then newly formed Technical Education Board for help. This was granted, with an intimation that further aid could only be given when better premises were found. Subsequently the present premises at Bolt Court were discovered, and the Technical Education Board hired them; the school was transferred there and commenced work in May, 1895, being formally opened in November of that year. The lithographers appealed to the Council for help on the ground that they should have the opportunity of studying photo-mechanical processes which they felt were beginning to supplant lithography, and so the school had added to it a photo-process department. Among those reporting to the Council about the school in the early days were Sir W. Abney and Mr. Emery Walker, the latter still chairman of the Advisory Sub-committee. Mr. Snowden Ward is another gentleman on the present Advisory Sub-committee who was also on the first. The numbers attending the school were not very large at the commencement, but they have gradually grown until there are now every year upwards of six hundred individual students. From the process side being subsidiary it has now become by far the most important, the numbers attending these classes showing large increases every year, while the lithographic side remains practically stationary. Mr. Charles W. Gamble was appointed the first director of the school. He resigned in 1902 in order to accept the position of head of the photographic and printing crafts' department at the Manchester School of Technology. The present principal, Mr. A. J. Newton, was then appointed, and he has so worthily carried on the work commenced by Mr. Gamble that the repute of the school is now deservedly world-wide. The school has frequently exhibited its work, always receiving high awards. It also issues every year a volume of specimens of work done by the students, a handsome

evidence of the practical character of the work of which we have frequently expressed our appreciation. We have no doubt the new building will afford further opportunities for increasing the usefulness of this valuable institution. The cost of the new school is to be £20,000, of which £15,500 is for the site.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between July 19 and 24:—

CINEMATOGRAPHS.—No. 16,984. Apparatus for projecting cinematograph and the like pictures. Silvio Doccetti, 4, Corporation Street, Manchester.

PRINTING FRAMES.—No. 16,992. Improvements in photographic printing frames. Rudolf Gissingner, 345, St. John Street, London.

STANDS.—No. 16,994. Improvements in supports for photographic or similar apparatus. Ernst Kehrer, 345, St. John Street, London.

FILMS.—No. 17,009. Machine or apparatus for the manufacture of photographic films. Philip Arthur Newton, 6, Bream's Buildings, London.

ANIMATED PICTURES.—No. 17,021. Improvements in apparatus for taking or reproducing animated pictures. Louis Henri Huet, 53, Chancery Lane, London.

CINEMATOGRAPHS.—No. 17,130. Method of and apparatus for regulating the light thrown on the picture film of cinematographs and the like. Bronislaw Gwozdz, 7, Southampton Buildings, London.

COLOUR PHOTOGRAPHY.—No. 17,198. Process for producing coloured portraits and photographs and accessories used in connection therewith. Ludovic Maurel and Samuel Achour, 110, Strand, London.

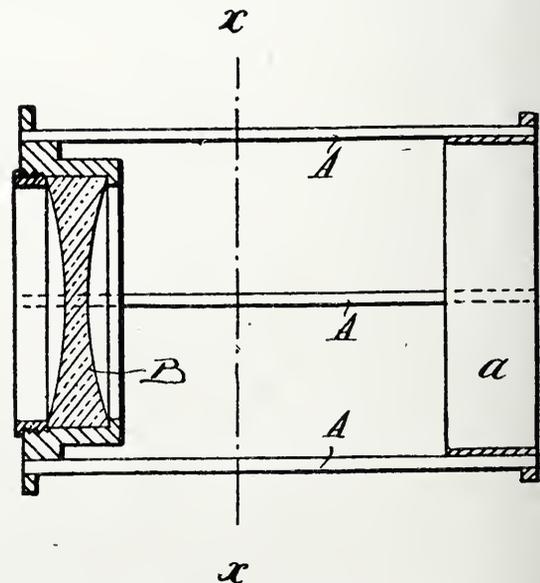

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TELEPHOTO-LENS MOUNT.—No. 20,415, 1908 (September 29, 1908).

The invention relates to a method of mounting the positive and negative elements of a telephoto system which reduces the internal reflection to a minimum by dispensing with a tubular connection. The negative element is carried at the end of a light removable framework built of a number (usually three or four) of strong

metal wires or rods projecting into the camera from the inside of the front panel or from the mount of the positive element. The positive lens mount is of the focussing type, actuated preferably by a small lever arm and screw movement to vary the separation of the two elements according to the magnification required and to the camera extension.

Thus the frame, A, carrying the negative lens, B, consists of four stout metal wires or thin rods fixed to the lens at the inner ends and to the ring or short tube, *a*, at the outer. The tube, *a*, fits tightly on the outer tube, *c*, belonging to the focussing mount, C, and fixed upon the front panel, D, of the camera so as to project for some distance inside. The positive element (not shown in the drawing) is screwed into the outer end of the sliding focussing tube, *c*¹, which is operated by the intermediate tube, *c*², having a small handle or lever, *c*³, and helical slot, *c*⁴. The outer tube, *c*, has a longitudinal guiding slot, *c*⁵, and a pin, *c*⁶, on the sliding tube passes through both slots. On turning the tube, *c*², the positive lens is moved away from or towards the negative lens or element and the separation thus varied in the manner described. It will be seen that, owing to the absence of a continuous tube between the two elements, the internal reflection is almost eliminated, the rods of the light frame reflecting only a very small fraction of the light directed towards the sides. Owen Edleston Wheeler, "Strathmore," Prince's Road, Weybridge.

CAMERA SWING-FRONTS.—No. 15,608, 1908 (July 23, 1908). The object of the invention is to construct the apparatus in such a way that a swinging front can be firmly and rigidly supported upon a single stretcher. A stretcher bracket to which the stretcher, *g*, is pivoted is provided with a slotted arm or bracket, E, of quadrant or other form with a clamping screw passing through a slot in the bracket and a slot in the stretcher by which the latter can be clamped in any position, either vertical or at any inclination thereto to which the

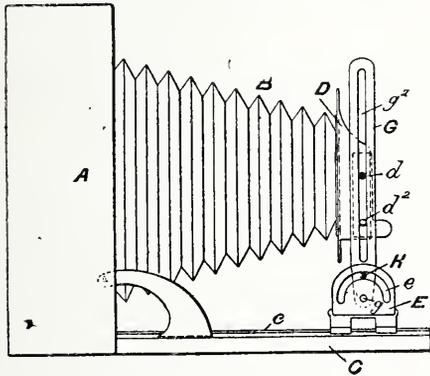

Fig. 1.

stretcher may be swung. In one form the stretcher bracket is provided with a pin or pivot, to which the lower end of the stretcher is pivoted with a slotted arm or bracket rising above the pivot. This arm is preferably of quadrant form, but may be straight, inclined, curved, V, or other suitable shape. The slot in either variation may be stamped or cut in a plate without forming a separate arm or member.

In another form the slotted arm or slot may be below the pin or pivot, with the stretcher pivoted some distance above its lower end, the lower end of the stretcher being slotted to engage the clamping screw passing through the slot in the bracket. The slot

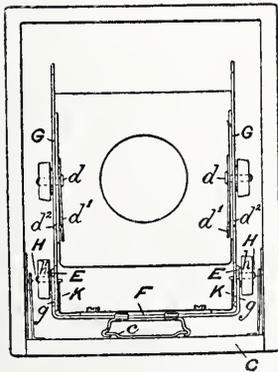

Fig. 2

either in an arm or in the plate is preferably of quadrant form, but may be straight, inclined, curved, V, or other suitable shape.

In the form shown in Figs. 1 and 2, which is the form at present preferred, the stretcher bracket or plate, E, is made of quadrant form, and the strut or stretcher, G, pivoted thereto at

its lower end on the pin, *g*. A curved slot, *e*, is formed in the bracket, E, above the pin, *g*, and the clamping screw or bolt, H, is passed through the strut or stretcher, G, and through the slot, *e*, the strut or stretcher being rigidly clamped by the nut, *h*, and washer, *h*¹, thereon. Thornton-Pickard Manufacturing Company, Limited, Arthur Gray Pickard and Arnold Shepherd, Altrincham, Cheshire.

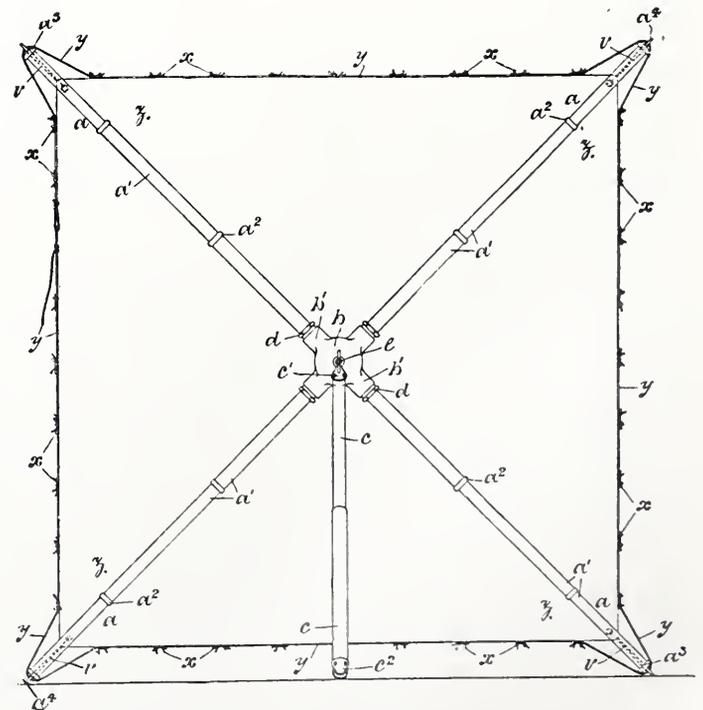

LANTERN-SCREEN STAND.—No. 18,471, 1908 (September 3, 1908). The stand comprises a series of radial pieces detachably attached to a centre socket piece, these pieces being provided with junction plugs whereby the several parts constituting the pieces can be connected to each other and held in their relative positions when the stand is in use, while they permit of the several parts being easily and quickly disconnected and telescoped one within the other when not in use, and of being stowed away in a small compass suitable for travelling purposes; further, the parts are detachably connected to a centre junction, to which is also loosely connected the stay or strut whereby the stand is supported in position.

The stand comprises a number of collapsible stays, *a*, connected together by a central socket or junction piece, *b*, and to this piece is connected the strut, *c*, whereby the stand is supported in an upright or other approximate position.

The parts, *a*, are composed of a series of tubular lengths, *a*¹, which are adapted to telescope one within the other, and are provided with junction plugs, whereby the tubular lengths are maintained in alignment at predetermined distances apart.

The central junction-piece, *b*, comprises screw-threaded sockets, *b*¹, which are adapted to receive screw-threaded conical sleeves, *d*, which are split, and adapted to receive and grip the inner lengths of the members, *a*, when the same are engaged with the sockets of the junction-piece, *b*, as shown in Fig. 1.

The outer ends of the parts, *a*, are provided with plugs, *a*³, having rings, *a*⁴, as shown, which serve as guides for a cord, rope, or the like, as hereinafter described. Pulleys or other means may be employed in place of the rings, and where such pulleys are made use of the same may be mounted in bifurcated ends formed in the outer ends of the outer lengths of the members, *a*. The plugs, *a*³, serve to hold the rings, rollers, or the like in position and enable them to be removed when the screen and stand are to be collapsed.

The parts, *a*, can be adjusted longitudinally, relatively to each other and to the centre junction-piece, by means of split conical sleeves, which are adapted to grip any part of the length of the inner tubular lengths. A further means of adjustment may be provided by screw-threading the junction-plugs, *a*², and the ends of the tubular lengths.

The strut, *c*, is fitted with lugs or tongues, *c*¹ and *c*² respectively, at the upper and lower ends, the lug, *c*¹, at the upper end being adapted to engage with a pin, *e*, loosely connected to the centre junction-piece, and held loosely thereto by a nut or its equivalent as shown, and the lug, *c*², at the lower end being provided with a screw or other means whereby the strut may be supported on or engage with a platform, floor, or the like. The connection at the upper end of the strut enables the stand to be tilted and arranged at varying angles relatively thereto, and the platform or floor.

In fitting up the stand and screen (as shown in Fig. 1) the members, *a*, are fitted in the sockets of the centre-piece and the strut attached, after which loops or loose portions of the cord or rope at the corners of the screen are engaged with the outer ends of the members and the screen tightened up on to the stand. The corners of the screen are fitted with tapes or the like, *v*, for holding these outwardly when the screen is fitted on the stand.

Where the cords or the like pass through rings attached to the removable outer plugs, these may be more or less permanent attachments to the cords. The portions of the stand and strut which rest on the floor or other like plate may have means, such as cushioned attachments, to prevent damage in the use of same, and also means for engaging with the floor or other places. William Laurence Parkinson, 5, Commutation Row, Liverpool.

FOLDING OPTICAL LANTERN.—No. 17,027, 1908 (August 13, 1908). The invention consists of a lantern suitable for optical projection of lantern-slides, etc., made so that when not in use it can be compactly stowed and packed in a small space, or in a small packing case, which renders it capable of being carried about by hand with relative ease; while at the same time it shall be also light and strong, and shall have all the optical qualities which lanterns of the usual type have.

With regard to the body portion of the lantern, the partition or wall forming the front end of it, carrying the condenser, is adapted to be moved out of its normal, that is, the vertical position, and to be placed in the horizontal position, parallel, say, with the base. This is best obtained by hinging this front frame at its lower edge to the base so as to fold towards the back, with the condenser under it, and lying on the floor of the lantern. Generally, this movable portion carries a guide for the lantern slide carrier frames or the slides.

The sides of the body portion are movable, having fastening devices adapted to engage with the condenser carrier frame or back wall, and with the base, and so adapted as to be readily placed up in position, or taken down. These parts not only serve as the sides of the body, but, when fitted and attached, they also fix the condenser carrier frame or part referred to, in the vertical position. Or these sides may be arranged to fold about hinges or joints, either in single or multiple folds, and take the horizontal position when folded.

The upper part or roof of the body is also removable; and it may be provided with grooves, in which the upper edges, or parts thereon, of the condenser frame or back end, and the side boards or sides, may fit, so that it and the other parts will be held in place.

The frame or front of the lantern carrying the objective is also capable of being moved into a horizontal position, say, by hinges or connections. In one form, the lower part of this front may be hinged to the sliding frame which carries it, and which is racked out and in, in the base of the lantern; and it is adapted to fold inwards about these hinges into the horizontal position, so that it will fold down, and be stowed compactly in the front portion of the frame, with a bellows portion which is connected with it, folded beneath it. When this end, carrying the optical lens is in the vertical position, it can be held and fixed in this position by sliding pins and slotted plates, hooks, clamps, or other suitable means.

When the various movable or collapsible parts are moved in their position of use, to the packed or stowed position with the sliding frames slid in the lantern will occupy a space of about 15 inches long, by 7 inches wide, by 4 inches deep, which, relatively, is a small space for a full-sized lantern to occupy, so enabling it to be carried about in a packing case, or bag of comparatively small size. William Laurence Parkinson, 5, Commutation Row, Liverpool.

New Trade Names.

SYNOLOIDS (DEVICE OF SUN AND GAS-FLAME). No. 311,986. Chemical substances used in manufacture of a photographic developer. Synoloids, Ltd., 14, Harlesden Park Parade, Harlesden, London, N.W., photographic paper and chemical manufacturers. April 3, 1909.

SODAX.—No. 313,551. Chemical substances used in manufactures, photography, or physical research and anti-corrosives. Joseph Crosfield and Sons, Ltd., Bank Quay, Warrington, Lancs, soap manufacturers. May 28, 1909.

PRINTEX.—No. 313,831. A self-toning emulsion being a photographic chemical solution. Lothar Fiedler, 6, Eversleigh Gardens, Loughton, Essex, electrical engineer. June 9, 1909.

MONGOOSE BRAND (DEVICE, A MONGOOSE).—No. 314,057. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Hanger, Watson, and Harris, Ltd., Stoneferry Works, Hull, and 28, Wellclose Square, London, E., paint, colour, and varnish manufacturers. June 17, 1909.

L. C. Co., LTD. (DEVICE, CAT IN CIRCLE).—No. 314,112. Cinematograph films included in class 8. London Cinematograph Co., Ltd., 154, Charing Cross Road, London, W.C., manufacturers and merchants. June 18, 1909.

SYNOLOIDS (DEVICE OF SUN AND GAS-FLAME). No. 311,987. Photographic printing papers. Synoloids, Ltd., 14, Harlesden Park Parade, Harlesden, London, N.W., photographic paper and chemical manufacturers. April 3, 1909.

Noxo.—No. 312,016. Photographic paper. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., manufacturers. April 5, 1909.

New Materials, &c.

“Vigorous” Ensyna. Made by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

Under this name a new variety of the distinctive and well-known Ensyna paper introduced last autumn has now been placed on the market by Messrs. Houghtons. As the name indicates, “Vigorous” Ensyna is designed primarily to give prints of somewhat greater contrast than the ordinary brand, and, therefore, it is more suitable for the thin and somewhat flat negatives which constitute a considerable proportion of the output of the beginner in photography, to whom particularly the ease and rapidity of the process make a special appeal. Apart from this quality in the new paper there are several other features which show that in the new Ensyna emulsion the makers have secured certain special effects. The development of a sufficiently exposed print takes place much more quickly—within one to one and a half minutes—and there is therefore a lessened danger of the careless worker obtaining defective prints due to fogging from unsafe light during development. Further, in addition to the matt and glossy brands, there is a new grade known as “Carbon” Ensyna and giving prints of very pleasing semi-matt surface.

Our own trials of the new paper were made with one or two of the sample packets which during the present month are being offered by Messrs. Houghtons at the prices of 6d. in quarter-plate size, 1s. half-plate, post free and complete with developer. Taking a thin and delicate negative—one just about right for a P.O.P. print—was obtained on the “Vigorous” Ensyna, giving the minimum exposure. a print of cold purplish tone, with somewhat too great a degree of contrast. It is evident that with negatives of greater flatness the results with the new paper will be of just about the degree of brilliancy to satisfy the average worker. But, further, by giving a greater degree of exposure and thus securing a warm purplish to brown and warm brown tone, the contrasts in the print are somewhat softened, although not to anything like the pronounced extent which a similar degree of over-exposure would bring about in the case of a development paper. In this respect we find that “Vigorous” Ensyna differ markedly from the ordinary grade, and it thus places the worker in the favourable position of being able to deal with negatives of quite different character by modification of the exposure. In all cases the tones are of a very agreeable colour whilst the great readiness with which the exact depth of colour is hit in the developer should be one of the chief factors in enhancing

the process in the eyes of the amateur worker. There is no loss in depth in the fixing bath, although in the case of the matt paper the usual allowance must be made for the slight cooling in colour which takes place on drying. In manipulation the new paper resembles that of the ordinary grade. The paper is wetted by a half-minute's immersion in water, which is then poured off and the developer applied. The print is fixed as before for half a minute in an acid hypo bath, and is then given a short wash, the whole operation being carried out within the space of a minute or two. We feel sure that further notice will be drawn to this new type of printing paper by the introduction of the "Vigorous" Ensyna, and attention may therefore be drawn again to the opportunity afforded by Messrs. Houghtons for a trial of the new material on a sufficiently extensive scale for a trifling sum.

"Victol" One-solution Developer. Sold by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

A one-solution liquid developer suitable for all kinds of photographic work has so gained in popularity during the last year or two that it is not surprising to find a preparation of this kind being introduced to their numerous customers by Messrs. Houghtons. The developer is issued by them, under the name of "Victol," in 3oz. bottles at the price of 1s. 3d., this quantity making 72oz. of the normal strength developer suitable for negatives. For use in the case of normal exposures one part of the concentrated solution is diluted with water to 24 parts, or to twice this amount if under-exposure is apprehended, whilst in the case of over-exposure only about two-thirds of the water should be taken. Our own trials of the solution on a batch of plates exposed during the holidays showed us that the developer responds excellently to the wants of the photographer. Although the image appears immediately, density is built up very readily, with the result that the development may be stopped at a point where a thin detail-full negative is produced, or may be pushed further to obtain any required degree of vigour, and this without unduly protracting the time of development. If a highly vigorous negative is obtained we have found it well to use a 1:10 or 1:15 developer with a little bromide added, an alternative method recommended by the makers being to bring up the negatives for four or five minutes in a 1:24 solution, following this with two or three minutes in a 1:12. For both bromide and gaslight prints "Victol" at a suitable dilution gives prints of excellent colour and vigour, a little bromide being added in each case to secure the full brilliancy of the high-lights. The developer in all cases may be used repeatedly without showing any signs of stain or markings, and is evidently a preparation which is suitable for all the purposes of photographic development, and represents the most convenient form of photographic developer.

CATALOGUES AND TRADE NOTICES.

AUTO TYPE ENLARGEMENTS.—The Autotype Co., 74, New Oxford Street, London, W.C., have just issued a new edition of their "trade enlargement list," which very conveniently supplies the prices of carbon enlargements from negatives, paper prints, daguerreotypes, etc. The list further supplies and illustrates the very attractive forms of portrait made by the Autotype Co. for photographers, such as the "Michallet Sketches," "Lawrence Portraits," "Stained Drawings," and "Engraved Border" enlargements. These represent most charming and effective work, either wholly photographic or on a photographic basis, and are supplied by the company either mounted or in a suitable neat frame. Enlargements on canvas, carbon miniatures on ivory, and carbon prints in quantity are also dealt with in the new list, which quite adequately represents the great facilities of the Autotype Co. in the way of carbon work for all classes of professional portraiture. As no printed list can convey an idea of the quality of the work it may not be irrelevant for us to add that we have never known an instance in which an Autotype print or enlargement has fallen below the consistently high standard which the Company maintain.

FACTS AND FALLACIES.—Under this title Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C., have issued a booklet of instructive reading dealing with the necessity of pure and freshly dissolved chemicals, and emphasising the quality and portability of some notable tabloid photographic chemicals, such as the economical "Rytol" developer and sulphide toning compound. The booklet is sent free on application.

PHOTOGRAPHIC DEALERS should make a note of the private special discount list just issued by the firm of Jonathan Fallowfield, 146, Charing Cross Road, London, W. The list forms a key to the encyclopædic "Fallowfield's Annual," and under its alphabetical arrangement supplies a rapid reference to the discounts given for the different classes of goods. It is issued for private circulation only to bona-fide dealers.

A NEW LIST has just been issued by the Service Co., 292, High Holborn, London, W.C. It provides a very full description of all classes of photographic apparatus and materials, and is sent free on application to the firm.

"SYLVIA" SPECIALTIES.—A list reaches us from J. Abley Bros., Copthorne Road, Shrewsbury, giving prices for "Sylvia" bromide and gaslight paper, "Sylvana" P.O.P., C.C., and albumenised papers in addition to plates and several developing preparations. The list, with terms to professional photographers, is sent free on receipt of trade card.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 7.

Kinning Park Co-operative Camera Club (Govan). Outing to B'shopton.
Hackney Photographic Society. Outing to Otter's Pool.

MONDAY, AUGUST 9.

Kinning Park Co-operative Camera Club (Govan). Committee Meeting.
Southampton Camera Club. Short Demonstrations. C. Daw, R. E. Parson, and W. H. Trigg.

TUESDAY, AUGUST 10.

Hackney Photographic Society. An Evening with the Portfolio.

Commercial & Legal Intelligence.

AGENT'S BANKRUPTCY.—Before Mr. Registrar Hope in the London Bankruptcy Court on August 2, the public examination was held of E. Alexander, a dealer in picture postcards and fine art prints, formerly in business at 101, Southampton Row, W.C. In answer to the interrogatories of Assistant Official Receiver Bowyer, debtor stated that he was a German subject, and came to this country about 1900, and from March of that year until December, 1903, was employed in London by a local firm of fine art publishers. In January, 1905, debtor became the London agent of the "Arnstophot" Company, a concern engaged in the manufacture of picture postcards in Germany, and in March, 1905, took premises at 104, Southampton Row. In addition to acting as agent for this German firm, debtor carried on a business as a fine art publisher on his own account. In September, 1906, debtor moved the business to 101, Southampton Row, and in June, 1908, sold the business to a limited liability company, trading as E. Alexander, Ltd., and which continued until February, 1909, when it went into liquidation. Debtor's consideration for the sale was £3,000, represented by 200 debentures at £10 each and 1,000 fully paid up £1 shares in the new company, of which debtor was made managing director at a salary of £10 a week. After the company went into liquidation debtor obtained a situation with a firm of fine art publishers at £5 a week. Debtor had guaranteed two debts of E. Alexander, Ltd.; one of £850 to the Photo-Chenile Company of Germany for goods supplied, and £375 to his mother for money advanced as a loan; he had given no other guarantees. The examination was concluded.

HOLIDAY GUIDE BOOKS.—Aldeburgh, Salisbury, Skegness, and Whitley Bay are the latest additions to the series of popular little guides published by the Health Resorts Association, 29, John Street, Bedford Row, London, W.C., any of which may be obtained free by sending a postcard request to the Town Clerks of the respective localities. Tourists and holiday makers, whatever may be their aim in visiting any special district, will find these little booklets of interest and use, whilst the photographer should find them specially serviceable as giving in concise form and small space the chief points of interest in any town and its surroundings, thus enabling the tourist, who perhaps has but little time at his disposal, to secure the most desirable records of his visit in the least possible time.

News and Notes.

THE MARRIAGE of Mr. H. Essenhigh Corke, of Sevenoaks, with Miss Evelyn Ward Seymour, took place on Thursday in last week. Mr. Corke will be known to a large number of our readers both as a Fellow of the Royal Photographic Society and also as a contributor to our pages.

THE TRANSLATOR.—We are in receipt of copies of this publication, issued fortnightly, as an aid in the study of foreign languages, and obtainable from the publisher, La Chaud des Fond, Switzerland, price 2 francs 50 for six months, or 5 francs per annum. The journal consists of passages in both English and German from various authors, together with examples of commercial correspondence in the two languages and notes on some of the uncommon words and phrases. In addition to a German-English issue, there is also an Italian-German and a French-German version of the publication, the arrangement and price being as already mentioned.

PHOTO SURVEYING METHODS FOR THE AMATEUR.—A correspondent points out the following corrections in the translation of Dr. R. Defregger's article which appeared in our last issue:—Fig. 5, page 590, omits the letters *a* and *b*, which should presumably be at the following positions:—

The sixteenth line of third paragraph, page 589, reads:—"A parallel line drawn from *g* to 'the second view-line *Ab*' should read:—"A line drawn from *g*, parallel to the second view-line *Ab*." The phrase on line 11 of third paragraph should presumably read:—"Obtaining these loci by passing a fine needle through the map on to a sheet of writing paper below, the angle $\angle Aa$ is obtained."

HOLIDAY LITERATURE.—The Great Western Railway has this year published quite a budget of books dealing with the many holiday districts accessible by the company's lines and connections. That entitled "Holiday Haunts" gives particulars of features of interest, and of apartments, boarding establishments, hotels, and farmhouses in many of the most beautiful portions of England and Wales, and particularly in Devon and Cornwall, Herefordshire, Somersetshire, and South Wales. The book is very fully provided with maps and illustrations, and is obtainable for threepence from the company's bookstalls and offices, or post free on application to the superintendent of the line, Paddington Station. "Beautiful Brittany" is quite a new piece of holiday literature, in which the Great Western Railway Company give an altogether excellent idea of the attractive country accessible from the port of Brest, easily reached now by the new service of G.W.R. steamers from Plymouth. Through this new gateway into Brittany the holiday maker may explore a country which has a thousand fascinations in the way of coast scenery, chateaux, and cathedrals, not to mention the picturesque archipelago or inland sea of Morbihan and the estuary and valley of the Loire, whence the tourist may journey to Paris. Without professing to be a guide book, the glimpses it gives of picturesque Breton life and costumes make it an excellent volume to be first consulted by those who would explore this old-world country lying comparatively near at home. The price is sixpence at the company's bookstalls, or post free on application to the company at Paddington Station. A further booklet entitled "Rural London" deals with the attractions of Buckinghamshire towns and the Thames Valley as places of residence. New railway facilities have opened up old-world towns, such as Chalfont St. Giles, Beaconsfield, and High Wycombe, as possible for the city man, and the volume gives particulars as to railway travelling, educational, and other features. The booklet is sent free.

UXBRIDGE PHOTOGRAPHER BURNT OUT.—A disastrous fire occurred on Wednesday of last week at the premises of Mr. T. H. Billingham, photographer, of 56, St. Andrews, Uxbridge. At the time the outbreak was discovered, there was nobody on the premises. Neighbours gave the alarm about 9.30, but the fire evidently originated in a small office, in front of which were stairs, so that an up-draught was created, and almost the whole of the upper premises was quickly ablaze, the flames shooting out fiercely

through the roof. The interior of the premises was practically gutted, and valuable furniture, trade appliances, and negatives destroyed by fire and water. The studio, some twenty yards from the house, was unharmed, but the shops on either side were damaged. The fire was not extinguished by the Uxbridge brigade until one o'clock the next morning. Fortunately most of the damage is covered by insurance.

DEATH OF MR. WALTER TYLER.—We regret to have to announce the death of Mr. Walter Tyler, head of the well-known firm of Walter Tyler, Ltd., Waterloo Road, London, S.E. Mr. Tyler, who for nearly forty years has been a prominent and leading member of the optical lantern trade, retired from active business life about three years ago, hoping to spend some years of ease and recreation at his residence at Teddington, but unfortunately this period of well-earned rest was all too brief, and after a short but severe illness Mr. Tyler passed away on Wednesday of last week at the age of sixty-two.

BABY'S PORTRAIT.—A fond parent walked into the box at the Thames Court last week and handed the magistrate (Mr. Dickinson) copies of photographs of "baby," alleging that the photographer, in enlargement, had substituted the negative for that of another, and, of course, a less inspiring and captivating infant.

The magisterial eyes closely inspected the photographs. The magistrate observed that the enlargement was clearly from the same plate as the smaller copy. But the father agreed not with him.

"Why, it has got a different pinafore on, and in the large photo 'the baby is sitting on a mat while my baby sat on a cushion,'" he indignantly pointed out.

Mr. Dickinson: You must allow some license to an artist.

Fond Father: License? Why, the baby in the large photo is cock-eyed. Mine ain't.

Mr. Dickinson: How old was the baby when the photo was taken?

Fond Father: Nine months.

Mr. Dickinson: At that age they do not focus well. While I am satisfied the photo does not do justice to your baby, I am afraid it's the same child.

Fond Father: Can I have a summons?

Mr. Dickinson: Oh, no, no. It may not be a first-rate advertisement for the photographer, but you must be satisfied with it.

Fond Father (grimly): I'll give him an advertisement when I meet him.

Correspondence.

** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

JOHANNESBURG PHOTOGRAPHIC EXHIBITION.

To the Editors.

Gentlemen,—An exhibition is being organised by the Johannesburg Photographic Art Circle, and will be held in Johannesburg from November 3 to 6. It will be open to all pictorial workers, but limited to South African work, and all pictures submitted will go before a selection committee. No medals will be awarded, but a certificate issued to every exhibitor whose work is accepted. No more than eight pictures may be submitted, and there will be no charge for wall space. A catalogue will be sent to each exhibitor. Entry forms with full particulars, may be had from the hon. secretary, and must be returned by October 12. Exhibits to reach Johannesburg by October 20.—Yours faithfully,
HAROLD SMITH, Hon. Sec.
71, Cuthbert's Buildings, Johannesburg, July 12, 1909.

THE RETURN OF SPECIMENS.

To the Editors.

Gentlemen,—With reference to the warning you publish as to the non-return of specimens, there is another matter worthy of attention, and that is the return of specimens in a damaged condition. Some time back I sent up, in answer to an advertisement in your pages, some half-dozen half-plate prints, protected with cards on bot

des, and enclosed suitable stamped envelope for return. The specimens were returned in the envelope without any protecting cards, and, of course, were entirely ruined, the postmark penetrating rough besides crumpling. I complained to the firm, but received no reply.—Yours faithfully,

E. F. GURTON.

16, Royal Square, Jersey, July 30, 1909.

[We think employers should show more consideration than did those referred to by our correspondent. Those applying for situations should also pack their specimens in reversible wrappers addressed for return on the reverse side) in order to make the packing as easy a matter as possible.—Eds. "B.J."]

Answers to Correspondents.

PRICE OF BUSINESS.—What is the formula by which one may arrive at the price to be paid for a business, as a business, the stock, etc., at a valuation? For instance, would two years' profits be about the cash value of a business? I have read "How to Buy a Business" recommended by you.—**BUSINESS.**

Something will depend upon the class of business. One and half to two years' nett profits would generally be a fair price.

OXGALL—Have heard somewhere of the use of oxgall in preparing glass plates for enamelling, but cannot remember the procedure. Can you help me?—**STICKERS**

The oxgall is simply rubbed over the plate and then wiped or polished off. It is a thing not much used on account of its unpleasantness, unless it is used quite fresh, or the refined kind as supplied by artists' colourmen be employed. Wax or French chalk is what is generally used.

BARRATT.—(1) We believe both English and American sizes are largely used. We suggest you should write Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C., for their advice. (2) St. Louis and Canadian Photographer, 911, N. Sixth Street, St. Louis, Mo., U.S.A.

PURE ALUM.—With reference to an article in the "B.J." re bad alum, we have had exactly similar trouble, and would be pleased to get your correspondent's address for our mutual satisfaction. We are sending two samples of alum (1) and (2), and No. 1 is the sample which has caused our prints to turn so badly. Would you let us know if this is a similar quality?—**ALUM.**

The samples you send are both very impure, and both form excellent reducers, though neither is so impure as the sample referred to in our note. We think you must have confused the samples sent, as No. 2 appears to be the worse of the two. Both reduce and change the colour of P.O.P. prints, and both contain a quantity of ferrous and ferric salts. The trouble is no doubt due to the latter, as a mixture of pure alum and ferrous salt has no such effect. The samples are also mixed, as regards the alums, they apparently contain both potassic and ammonia alum. Though they reduce P.O.P. prints, they do not appear to act similarly on negatives. Therefore, they might safely be used for negative work if no ferricyanide be afterwards used for reduction or intensification purposes.

RETOUCHING (Reply to "Business.")—Whoever taught you retouching imparted one most important quality to your work—the full retention of the likeness. You also differentiate in your touch for men and women—an excellent feature, but your work lacks the finish demanded by the best firms, and we advise you to direct all your energy and thought to the attainment of a brighter, cleaner grain, and general improvement of the modelling. A few finishing lessons from a good teacher should put you right, and make a first-class retoucher of you.

VARIOUS.—Kindly let me know the following:—(1) Which are the practical uses of a 2-in. extension, the so-called W. A. movement, provided with rack and pinion in many modern cameras? (2) How can one make wooden dishes for enlargements?—**PROGRESS.**

(1) When using a lens of extreme wide angle, but such a very extreme movement as two inches only from front to back of camera would rarely be of any use since three inches is about the shortest focal length of wide angle lens which can be got. (2) The usual plan is to make four centred pieces, each having a groove in which the glass plate can slide, forming the bottom of the dish. The glass must be tightly fastened in with red lead and putty.

VULCANITE, ETC.—(1) Would you kindly inform me where I can obtain the material (vulcanite, I believe) used in making the dark slides of modern hand cameras? (2) Also could you let me know of a good manual on dry-plate and paper making?—**GEORGE S. STEWART.**

(1) Try Frederick Hill and Sons, 108, Bishopsgate Street Within, E.C. (2) There is no book which deals with emulsions for plates and papers in a way which is of any commercial use.

GOLD COINS FOR CHLORIDE OF GOLD.—In your note on a communication from "Staffs" to-day I see that you state that the conversion of coin into gold chloride is illegal. Are you right? I am not a lawyer, but I find in a book of reference that 'defacing the current gold, silver, or copper coin by stamping thereon any names or words, whether such coin shall or shall not be thereby diminished or lightened or using any machine or instrument for the purpose of bending the same, is an indictable misdemeanour. And if any person shall tender or put off any coin so defaced, stamped, or bent as aforesaid, he will be liable to a fine not exceeding 40s., recoverable summarily.' Melting or dissolving coin is not, I think, in any way defacing. No one would dream of destroying silver or copper coins, which are far more valuable than their weight in metal; but gold coin is worth just its nominal value when within the legal limit, and it is just worth melting down or dissolving. But I would suggest to those desirous of making their own chloride that they should buy from an assayer gold cornets, which are practically pure gold and save themselves the trouble of purifying. I have myself never found any necessity for purifying, however, if the impurity is allowed for in making toning solutions.—**J. F. TENNANT.**

We are quite right in what we said. Gold coin contains the full value of the metal, hence the mint lose upon it to the extent of cost of the coining. That is not the case with either silver or bronze. The reason why gold coins are sometimes used by jewellers and photographers is that they have the guarantee that the metal only contains the proper proportion of base metal and no more. The small amount of alloy, if left in, will make no practical difference in making chloride of gold.

MEZZOCHROMES.—Can you inform me where mezzochromes are obtainable?—**C. E. F.**

The Burlington Fine Arts Company, 29a, Charing Cross Road, London, W.

RETOUCHING.—Reply to E.R.—Your work is very fair, but open to considerable improvement in the modelling and general finish. The touch used for the young girl is much too strong for a glossy paper print, but might serve well enough for some of the matt papers. You retain the likeness very well, and that is certainly the best feature in your work. When increasing the highlights carefully avoid leaving too decided an edge, and you will improve your effect. There is no reason why you should not attain to the highest finish in time.

DIAMIDOPHENOL.—In the two last numbers of "British Journal of Photography," there is reference to diamidophenol developer. I have spent some two hours trying to get a simplified oz. formula from the three articles, but have quite dismally failed. (1) For example, in making the "bisulphite" liquor with acid, etc., how much water is wanted? (2) Could we have in next number a simple formula on these lines?—Water, say, 20 ozs., sulphite dry, sulphuric acid, hydroquinone dry, bromide dry, diamod dry, for contrast prints? We could then easily mix up all we require.—**A. E. SMITH.**

The quantities are as follows:—Sulphite, 1 ounce; hydro-

quinone, $1\frac{1}{4}$ grs.; potass bromide, 15 grs.; sulphuric acid, 50 drops; diamidophenol, 45 grs.; water, to make 20 ounces. In the event of the mixture being made up in one solution as above, it is doubtful if there is any real advantage in using the hydroquinone.

COPYRIGHT.—I beg you to inform me the following through your paper:—(1) Is it permitted to copy a copyright photograph to sell it only at a country which is not within the domain of the author's country? For example, if a French copyright photograph, registered by a French subject at France, can any Englishman copy it for selling only at England or another country out of the domain of France without permission of the owner of copyright?—T. HANNA, Assiout, Egypt.

Certainly not. Under the terms of the Berne Convention of International Copyright, the compliance with the formalities in the country of production confers copyright privileges upon the photographer in all the countries of the convention, among which are the chief civilised nations of the world.

DEVELOPER.—Will you kindly inform me if the pyrocatechin developer (one solution), page 777, "B. J. A.," is suitable for the development of plates and papers, and is it cheaper than the M. Q. developer? I am at present using the following:—Metol, 28 grains; hydroquinone, 110 grains; sodium sulphite, 2 ozs.; carbonate, $2\frac{1}{2}$ ozs.; water, 20 ozs. for plates; then I dilute with equal parts of water for papers. What I would like to know is, What proportion must I use of the pyrocatechin developer on page 777 of the "Almanac" for plates, and if dilute for papers? The formula I refer to is one solution:—Sodium sulphite, 5 ozs.; water, 20 ozs.; caustic soda, 260-300 grains; pyrocatechin, 400 grains; dilute with 20 times its volume of water for use.—COGAN.

We should try it diluted with 20 times its volume of water for plates, but whether further dilution is desirable for papers can be told only by trial. We doubt if it is cheaper than M. Q. developer, which is about the cheapest known.

SPOTS ON NEGATIVES.—Please inform me through the medium of your columns as to the causes of the black spots on the enclosed negative? I have tried various makes of plates, but all the same, especially the rapid grades. I might say that these spots generally appear in the fixing bath or in the final washing. I use a pyro soda developer.—TROUBLED.

These spots are due to dirt in the manipulation. Make certain that all the pyro is dissolved in the developer and also all the carbonate of soda. It is almost certain that the spots are produced in the developer, but probably you do not notice them until the plate is fixed.

PUTTY FOR STUDIO.—Will you be good enough to inform me in the "Journal" where I can obtain "putty" suitable for glazing a studio roof?—W. M.

Ordinary good glazier's putty is what is generally used. Messrs. Carson's, we believe, make a special elastic putty which may be obtained through all large dealers in builders' material. It is said to be preferable to the ordinary putty for glazing glass roofs.

REVERSING PLATES.—I have been trying to follow the directions given by E. Fenske in your issue of June 4, for producing positives direct on gelatine plates, by means of reversal by bichromate, but so far with no success. I over-developed, as directed, but on immersion in the potassium bichromate solution the image did not disappear, though left in the solution for a considerable time. In several cases, the film frilled or blistered badly. The result in the most favourable case was a transparency much too dull and dense for practical use. Probably the fault was on my side, and I am anxious to know what I did amiss. I used Imperial "N.F." plates; is the film, perhaps, too thick for this process? Does the exact amount of sulphuric acid in the potassium bromide 5 per cent. dilution make the difference between success and failure? I notice that no precise directions are given by your correspondent as to the proportion of sulphuric acid to be used. Lastly, may I ask whether the permanganate and sulphuric acid solution, used in the reversal of Autochrome plates, would be a reliable agent in the process of reversing an ordinary negative?—J. M. J.

We have not tried the process. We should think you would

succeed better with the reversing method given by Mr. Douglas Carnegie in the "B.J." July 9, p. 529. With ordinary (gelatine plates permanganate is very liable to give rise to stain.

BUILDING LAWS.—I am desirous of building a photographic studio in this neighbourhood, to be of wooden structure and iron roof size 30ft. by 12ft., and to be 8ft. back from the road, and any thing between 5ft. to 10ft. clear of any building. In fact it is intended to be built in a garden and approached by a small gateway 3ft. wide, and a path leading to the entrance. Below I give sketch of block plan as I intend building. I have placed the plan before the council, but they returned it stating same was not in their by-laws. I have since seen some of the council members privately and have asked their objection to erecting this studio. They can give me no definite reason except that it is outside their by-laws; in fact, they hint as much as to say "build it," and say that they do not think they have any voice in passing more than passing a small cot or other shed. As I do not wish to go to the expense of building this studio, and then find I cannot make use of it, I shall be glad if you will kindly give me your advice on the matter, namely, can I build without the seal of the council? I may add that it is to be a temporary structure, and on ground leased from year to year.—HARRISS.

We have read through the 52 pages of the by-laws, and can find nothing in them that will permit of such a building as you propose being erected, as it would contravene them. If you make the sides of iron and glass only we should think the plan would be passed. On this matter you had better see the district surveyor. Of course your interview, privately, with members of the council really goes for nothing officially, and if you put up the building without the sanction of the council you do so at your risk.

REDUCER.—Yes, if they are properly reduced, the permanency in no way affected.

MAC.—We think that the P.O.P. will give a slightly better result than the bromide paper.

ELECTRIC LIGHT.—1. We have had no experience with the lamp named, but its value will, of course, depend upon the conditions it is in, so can express no opinion as to that. 2. The best lens for portraiture is the ordinary portrait lens, on account of its rapidity, and that is an important point when artificial light is employed. If you want a second-hand one you should apply to the second-hand dealers who advertise in our columns for their lists. 3. The lamp named is a good one, so is the Westmins enclosed arc. 4. The firm is a very respectable one.

RIGHTS—PRINTS.—Will you be good enough to state whether your opinion an individual taking negatives from a photographer's premises under a judgment of the County Court for arrears of rent would be justified in making prints from them and disposing of the same for money towards the satisfaction of the debt?—WILLIAM DAY.

We see no objection provided they are orders from the persons who paid for the portraits being taken. The copyright in the pictures is vested in them, and if they register that copyright, they can prevent the sale of copies. The negatives, of course, belong to those who seized them under the judgment of the County Court, though the sitters may prevent the sale of copies.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Photographers' Association of America has just held, at Rochester, New York State, a Convention which certainly would seem to be a record for meetings of this kind. Close on 1,800 persons attended it. The impressions of an English visitor, Mr. F. Marriott, are given on page 624, following which are accounts of the way in which the Convention was entertained by Mr. George Eastman and the Board of the Eastman Kodak Co., and of the kind of demonstration by which photographers in the States exchange ideas and knowledge.

MM. Lumière and Seyewetz have extended their recent researches on the behaviour of developers to a comparison of the powers of the principal developers for rendering weak impressions of light. The degree to which developers are affected by rise or fall of temperature as regards degrees of contrast given is also investigated. The results and formulæ used are given in the article on page 627.

In a note on page 621 attention is drawn to the frequent advantage which may be taken of the chromium intensifier for the improvement of bromide prints, either as regards colour or for giving a little extra pluck.

The conclusion of a series of editorial articles on the working of the albumen process appears this week on page 622, where some hints are given as to the most common causes of failure.

An instance of one way in which the sudden accession of hot weather may give rise to difficulty in hand-camera work is the subject of a note on page 622.

The days for receiving pictures to be offered to the Selecting Committees of the Salon and Royal are August 30 and September 2, respectively. (P. 621.)

A five-lens objective and a method of preparing paper prints from screen-plate transparencies are included among "Patents of the Week." (P. 634.)

The "Mechanical Mounting of Half-Tone Blocks" and the "Choice of Lenses for Process Work" figure under "Photo-Mechanical Notes." (P. 633.)

EX CATHEDRA.

The Two Exhibitions. Only a week or two has to elapse before prints for the Photographic Salon and the Royal Photographic Society have to be sent in. The last day for receiving exhibits for the Salon is Monday, August 30, on which day they must be delivered by hand at 5A, Pall Mall East, between the hours of 10 a.m. and 6 p.m. If sent by carrier, exhibits must be addressed to Messrs. Selfridge and Co., Dept. 134, and must arrive not later than Thursday, August 26, accompanied by the entry form. We understand that the Linked Ring have appointed a selecting committee, consisting, we hear, of the English members only who formed the selection committee last year. Although no official announcement has been made of the fact, it is an open secret, we believe, that the organisers of the Salon are anxious to include in the exhibition an adequate representation of the work of those who are not members of the Linked Ring. This being their aim, it is a pity, we think, that they have not made an earlier announcement of the exact composition of the selecting committee. In the case of the Royal, the last day for receiving frames by hand is September 2 at Messrs. Bradley and Co.'s, 81, Charlotte Street, Fitzroy Square, W., between 10 and 6. If sent by carrier exhibits must reach Messrs. Bradley at the above address on Wednesday, September 1

* * *

The American Convention. As shown by the article on another page of this issue, the Photographers' Association of America has beaten all its records at the National Convention held at Rochester a few weeks ago. An English photographic pressman, writing in one of our American contemporaries, sums up the characteristic of the American Convention in the word "strenuous," and offers the opinion that if this serious strenuous element were introduced into the Photographic Convention of the United Kingdom it would mean the death and burial of that body. Whether this would be the result or not, it is evident that at Rochester in the latter part of July the American professionals have given the greatest demonstration of their solidarity as a body. They have shown the utmost readiness to exchange both ideas and acquired knowledge; to such a degree, in fact, that the Convention has been described as "one great photographic school with sympathetic professionals, masters, and teachers and willing and earnest students all of one mind."

* * *

The Colour of Bromide Prints. Although we are never advocates of those methods of chemical jugglery which many delight to apply to prints or negatives which are defective, yet there is one process which we think deserves to be kept in mind by bromide printers more than it appears to be. This is the chromium intensifier, used now to a considerable extent for negatives, and

consisting of a weak solution of bichromate of potash made acid with hydrochloric acid. The proportions need to be adjusted carefully, and the formula given in the "Almanac" may therefore be referred to. A bromide print which just lacks a touch of brilliancy or which is not quite up to the standard as regards colour is very greatly benefited by being put through this intensifier, one application of which scarcely increases the actual density of the print, but merely gives the improvement in pluck which is wanted. It has the advantage that there is no need to subject the print to long washing before the process is applied. A brief rinse under the tap and the print is ready to be bleached. It is then again given a short washing for about ten minutes and re-developed. All developers are not equally suitable for this latter purpose. One of the best as regards quickness of action and colour of deposit is the "tabloid" Rytol, introduced some months ago by Messrs. Burroughs Wellcome.

* * *

A Hand-Camera Mystery.

An instance of the minor problems which trouble the photographic amateur, and are by him referred to the unfortunate dealer, has recently come under our notice. The camera was one of the fixed-focus type, provided with a focussing scale and an excellent lens of $f/5.6$ aperture. When taken out for use on the recent appearance of fine weather, all the negatives proved to be distinctly out of focus, so that it was found necessary to give a certain extra movement to the lens in order to get a sharp negative. Then a week or so later it was found that this extra adjustment became unnecessary, the camera giving sharp pictures on the focussing scale if properly set in the usual way. The explanation proved to be one which no doubt would puzzle the beginner. Owing to the damp conditions under which the camera had been stored, the wood had expanded sufficiently to throw the lens out of adjustment when in use at its full aperture, but a few days' use out of doors in the warmth of the sun has led to contraction of the casing to its original dimensions.

* * *

Glazing the Studio Roof.

One of the troubles which are constantly before the portrait photographer is the difficulty of securing a perfectly water-tight joint in the glass of the studio roof. A considerable period of heat will cause the putty used in fixing the panes to become almost brittle, in which case it fails to keep the joints water-tight. This is usually due to the use of unsuitable putty in the first instance. The best material should be stiff and become yellowish as it dries; a soft and white putty is likely to give rise to trouble. A special form of putty is, we believe, manufactured for use under these somewhat trying conditions, and we recollect some years ago seeing a recipe for a composition intended to serve the same purpose. The basis of the mixture was cheap paper torn into pieces and covered with a little strong caustic potash solution. This was boiled up and about one-third its volume of turpentine added to it. To the hot mixture there were then added pitch, resin, gutta-percha, and wood tar, the whole being boiled until it formed a stiff paste. We scarcely envy those people who undertake the preparation of this mixture themselves—for one thing, most of the ingredients are very inflammable—but it is possible that a commercial preparation resembling it may be obtainable.

PRACTICAL NOTES ON ALBUMEN PAPER PRINTING.—V.

THE recent articles, to which the present series of notes forms the conclusion, has, we know, proved of considerable interest to many printers whose experience has hitherto been confined to producing prints on P.O.P., bromide, gaslight papers and other papers. This is evidenced by the number of queries we have received from printers as well as from some employers who are unable to enlighten their employees on the causes of their failures. Instead of replying to the queries as received, we have thought it better to devote a special article to the causes of troubles that may be met with and their remedies.

It may as well be pointed out here that somewhat greater care as regards cleanliness in the manipulations is necessary when working albumen paper than in the case of P.O.P. This will be recognised when it is remembered that with the former the albumen is spread direct on the raw paper, and that the film contains a far larger proportion of free nitrate of silver than does the latter. Furthermore, in the case of P.O.P., the gelatine emulsion is spread on an insoluble baryta coating which insulates it from the paper; hence the back of it is not so susceptible to slight contaminations as when the coating is on the bare paper.

One of the troubles that the beginner may meet with is that the prints when washed and dried are yellowed or show yellow patches. There are several causes of this. The most probable one is that, in the case of patches, the prints were not kept in continual motion while in the fixing solution, so that some stuck to others or, possibly, to the bottom of the dish, with the result that the hypo did not have free and equal action. Another reason may be that the solution was too weak or exhausted, or that too short a time of immersion was allowed for complete fixation. When the solution is very cold a longer time in it must be given than at a more moderate temperature. Another, and very prolific, cause of yellowness is fixing a large number of prints in a small quantity of solution. A good quantity of solution is necessary for a comparatively small number of prints in order to permit of their being kept well separated from each other. Hypo is cheap enough now to permit of its being employed on a very liberal scale. One other prolific cause of yellowness in the prints is that, when they are taken out of the fixing bath, they are put into a dish of water and allowed to remain quiescent. When that is done the prints are almost sure to become more or less yellowed—either in patches or all over. This is completely avoided by having the dish under a running tap and continually turning the prints over and over as when in the fixing bath. The sooner the major part of the hypo can be got rid of, the better for the pictures.

Mealiness or, as it is sometimes termed, "measles" is always more pronounced in the shadows than in the lighter parts of the subject, and destroys the vigour of the picture. It is generally due to attempting, by prolonged toning, to obtain deep tones in prints made from feeble negatives. From such negatives nothing beyond a warm red-brown should be attempted, and that can usually be satisfactorily obtained. Another cause—in the case of the use of the acetate toning bath—is that the solution was used too soon after mixing. The remedy in this case is to keep the bath, say, 24 hours longer; it will then generally be found to work quite satisfactorily. Another cause may be that the sensitising bath, by use, has become too weak; here the remedy is obvious. A guide to the strength of the bath for the paper used is that the deepest shadows become fairly bronzed without the lights being over-printed. As a preventive of mealiness it may be mentioned that, in toning, when the lights are sufficiently toned it is ne-

THE PARTNERSHIP between Messrs. George Henry Herbert and Raymond Lloyd Reece, carrying on business as photographic artists at 17, Biggin Street, Dover, under the name of "Martin Jacolette, Dover (successors Herbert and Reece)," has been dissolved. The business is to be carried on by Mr. Reece.

to impossible to carry the toning further without getting mealiness in the shadows.

Impure whites, as in vignettes, may be due to the paper being sensitised on a bath that has become discoloured by use. The avoidance of this defect was explained in the second article ("B. J.," July 9, 1909, p. 527). It may also be due to the paper having been kept too long after sensitising—or, possibly, to exposure to light before printing—or may be due to a too strong light while toning, or in the first stages of fixing. It may also be due to the dish in which the silver is washed out of the prints being contaminated with hypo. If this is the cause it will usually be seen by the water becoming discoloured during the washing. The remedy in this case is again obvious.

Blisters are a prolific source of trouble with some papers—particularly the highly albumenised ones—and various remedies have from time to time been suggested. One was referred to in the last article ("B. J.," July 30, 1909, p. 589). Another advocated by some in place of diluting the hypo after fixing, as there directed, is to put the prints into a solution of common salt and gradually dilute this latter bath before putting them into the washing water. Another remedy which has been recommended is to use a weak sensitising bath—say, thirty-five grains to the ounce—and float the paper on that for double the usual time. This sometimes proves a remedy, but then the prints often suffer—having a more or less sunken-in appearance, and lack vigour. One plan which has never failed in our hands, even with the most refractory paper, is, after printing, to pass the still dry prints through methylated spirit and then wash, tone, and fix in the usual way. There is a little drawback to this method, inasmuch as the spirit renders the paper somewhat transparent, and the action of the toning bath is not so easily seen until one gets somewhat familiar with the appearance.

Lack of contrast, when vigorous negatives are employed,

is generally due to the sensitising bath being too weak; the remedy, of course, is to strengthen it. Insufficiently deep printing may also be the cause.

Prints of too black-and-white a character generally arise from the silver bath being too strong for the paper. The dilution of the solution is a remedy. The defect may arise also from the prints being made from hard negatives—lacking in half-tones. In this case the trouble may to an extent be mitigated by using a weaker sensitising bath, and, before printing, exposing the paper to light just enough to destroy the purity of the white and no more.

Marble-like marks on the paper before printing are due to floating the paper on a bath on which a surface-scum has accumulated by the bath standing some time in the dish.

Finger markings on the back and front of the prints are caused by handling the paper with fingers contaminated with hypo or, may be, in hot weather, with perspiration.

White spots on the prints are usually due to minute air holes or adhering to the paper while on the sensitising solution. Minute black spots are generally caused by particles of metal in the raw paper, or, more probably, by particles of iron in the water in which the prints are washed previous to toning. The remedy in this case is to tie loosely one or two thick tresses of fine flannel over the nozzle of the supply tap.

Minute cracks in the albumen seen after the prints are mounted are likely to occur only in exceptionally dry weather and with highly albumenised paper. Their occurrence comes about as follows:—The prints when laid out to dry curl up, sometimes tightly, and in uncurling the dry albumen cracks. The remedy in this case is to mount the prints wet as they come from the final washing water or to dry them between blotting boards under slight pressure so that they are kept flat until they are mounted. It is the curling up and the uncurling that causes the mischief.

THE CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

ANNOUNCED for some weeks past in almost frenzied terms of exhortation in our American contemporaries, the annual Convention of the Photographers' Association of America was held at Rochester, New York State, from July 19 to 24, under the presidency of Mr. Frank R. Barrows, of Boston, Mass. The Convention has proved to be the largest ever held in connection with photography, the official attendance figures being 1,365 men and 420 women, or a total of 1,785. The nearest approach to these figures are those representing the attendance at the Boston Convention of 1907 with the number of 1,175. Six crowded days of professional photography made up the proceedings of the Convention, which from both press and private sources of information were evidently characterised by a degree of enthusiasm and informality to which we are unaccustomed in this country. The business of each day commenced at nine in the morning, and would appear never to have concluded before midnight, whilst the activity with which the Convention was supported by the Press is shown by the fact that during the six days two daily photographic newspapers were produced: "The Bulletin of Photography" edited by Frank V. Chambers in the morning, and "The Day's Development," by J. C. Abel each evening. Quite characteristic was it of the superfluous energy of an American conventioner that a vice-president of the Association, Mr. J. H. C. Evanoff, should have promptly accepted a challenge to edit the daily "Bulletin." Two characteristic personal paragraphs may be culled from page four of the issue of our contemporary, produced with "Jimmy" Evanoff in the chair:—

"Tot Townsend was recently summoned for jury duty. The

judge asked, "Are you a free holder?" "Yes, sir, I am." "Married or single?" "Married last October." Have you formed or expressed any opinion?" "Not since last October."

When Harris got into town he went straight to the Seneca and registered. "Beg pardon," said the hotel clerk, "but what is your name?" "Name!" exploded Harris, "don't you see my signature there?" "I do," said the clerk calmly, "that is what aroused my curiosity."

They know how to make things go at a Rochester Convention. Excursions, as we know them at English Conventions, are impossible things at meetings pushed along at the rate of the functions of the Photographers' Association of America, which marked everywhere on its programmes, "be on time as everything is going to be according to schedule." With the exception of the visits to Kodak Park, the headquarters of the Eastman Kodak Company, and to the works of the Bausch and Lomb Optical Company, the purely recreative items in the week's proceedings consisted in the evening spent at Ontario Beach, with again the Eastman Kodak Company as a host. "From morn to afternoon, from afternoon to night," a series of demonstrations, meetings, and discussions kept the 1,800 visitors to the Convention in the neighbourhood of their headquarters. A great feature of the Convention has been the series of photographic schools, conducted each day by different acknowledged leaders of professional portraiture in different parts of America. A special building was arranged for this purpose, and among those who thus gave their time and knowledge for the benefit of their fellow workers were Messrs. Ryland W. Phillips of Phila-

delphia, F. Milton Somers of Cincinnati, E. B. Core of New York, F. Scott Clark of Detroit, A. F. Bradley of New York, and Will H. Towles of Washington.

At one evening meeting Ryland W. Phillips gave a very elaborate lantern lecture, entitled "With Other Photographers"—a demonstration of the individual methods of prominent professional workers. Mrs. Gertrude Käsebier followed with a paper,

AN ENGLISHMAN'S IMPRESSION OF THE ROCHESTER CONVENTION.

The greatest photographic Convention of all time was held at Rochester, commencing on Monday and ending on Saturday, July 24 last. Rochester, situated some 100 miles from New York, is the largest and most important photographic city in the world. The city presented a very gay appearance when I arrived, being festooned with flags and words of welcome to the Conventioners and their friends, being also illuminated at night by countless electric lights in honour of the occasion, or, as the "Rochester Herald" has it: "Main street is a sea of colour by day and a blaze of light by night."

There were about 2,000 members of the Convention present at its various functions and pleasures, and they came from all parts of the United States and Canada (whose representatives alone numbered at least two hundred).

The Conventioners brought with them, too, their wives, their children, their sisters, their cousins, their annts, and their friends, forming a crowd of men and women representing photography as practised in all parts of the United States.

A quotation from the Mayor of Rochester's speech may interest your readers. It is:—

"This is the centre of the photographic world, and you represent here now the highest type of the profession. Your needs we minister to here. It is true that much of the output of our establishments is devoted to filling the wants of the amateur or inefficient, yet the amateur and the professional march side by side, and to the amateur you owe a debt of gratitude, who by his large demand has helped the manufacturer to cater more efficiently to the specialist.

"I think the smallest manufacturer here is larger than the largest outside the city. We have also the largest manufacturers here of lenses. It is estimated that in the factories here is made more than 90 per cent. of the moving-picture films of the world—500 miles a day, a greater distance than the Empire State travels in one direction over the New York Central line. Every week a ton of silver is used at the Kodak Works; that is the largest supply of silver of any consumer in the world outside of the United States Mint. The Kodak Works are also the largest consumers of aluminium in the United States, and probably anywhere, and in their paper storage warehouse the rolls, 41in. wide, would stretch from here to San Francisco. Now there are made annually cartloads of films, thousands of acres of paper, and train-loads of chemicals; and when a new plate building in the Kodak Works is completed it will coat 1½ acres of glass in a day, and it will be the largest single building in the world devoted to the manufacture of photographic products.

"Thus you may see how largely the commercial prosperity of this city is dependent upon you, and how much we value your presence here, and also your patronage of the city product. This is our response to your material side; but we have still much to appeal here to your sense of the beautiful. The parks, lakes, river, falls, shaded streets, and drives are things to be proud of. We ask you to consider yourselves welcome within our gates. We wish you the best of good times while here, and ask you to come again, and that soon."

And this was the welcome extended to me on all hands, although a stranger from England.

It was a great, *practical* Convention, representative, as I have said, of the whole of American photography, truly national in

"Not Always My Way," forming an art criticism of photographs from her studio. We give below an article written by a London reader of the "British Journal," Mr. Fred Marriott, who was present at the Convention, which account we supplement by a report of some of the other proceedings condensed from the Rochester "Democrat," which each day during the week very fully reported the proceedings of the Convention.

its scope and spirit, so that the humblest photographer in the United States will feel that he and his business interests are part and parcel of the aim of the Association.

It has their interests truly at heart, and such meetings and mutual helpfulness act as a stimulant and vitaliser to them in their work. It is also a natural development, and one bound to lead to the raising of professional photography in public estimation.

A business show pure and simple—pleasure next, business first; but the Conventioners overflowed, nevertheless, with good spirits, good-nature, and good-fellowship.

The lessons in photography were a very popular feature of the Convention, and were closely followed even by the professional photographer. It was a great photographic school, and the manufacturers joined hands in hearty co-operation, being desirous not merely of selling their goods to the photographer, but teaching him at the same time how best to use them; and, what is more, the photographer seemed only too willing to listen and learn. Many have travelled vast distances to do it, and, to my personal knowledge, at considerable inconvenience and expense.

The daily demonstrations were crowded; and here is a note I take from one of the daily papers published on the spot verifying my statement:—

"The morning school of photography under the north gallery at Convention Hall is proving the most popular feature of the programme. The room has been partitioned off from the rest of the hall, the front door has been removed, a huge glass casing installed, and seats have been raised in tiers. The only criticism heard of the arrangement is that the room is too small to accommodate all the members who wish to attend the school. Nearly a thousand pupils were jammed into the school-room yesterday morning, and they remained persistently throughout the long session, despite the heat and the lack of seating accommodation."

Again: "The first lecture of the evening was by R. W. Phillips, of Philadelphia. His subject was "With Other Photographers." By a series of lantern-slides he showed photographers at work in their studios with subjects, and followed each studio view with a reproduction of the work in which the artist was engaged at the time the first slide was taken. The use of screens for lighting effects was gone over in detail, attention being called to the methods of some of the best known photographers in the world."

Mr. Phillips's talk was listened to with not only close attention but with great enthusiasm. The conditions of the light, arrangement of accessories, background, and actual posing of the subject, with samples of the finished work, the manner in which the harsh lights are subdued, and the illumination brought in harmonious relation—or, in other words, how a photograph is transformed into a picture by various workers—being particularly instructive and interesting.

I had a chat with an expert photographer whose name is well known in London, and who is now resident in the States, and he told me he had gained much valuable knowledge and many hints from his visit to this Convention. Why could not our British brethren follow suit with mutual advantage to manufacturer, professional, and amateur alike?

Another distinctly good idea was the division into sections of the pictorial work of each State, an idea that would seem

stimulate competition, with the happy result of obtaining the very best work possible—a striving, as it were, by the representatives of each section to be first in the field. English photographic societies throughout the Empire might adopt the same as surely with excellent results.

Another good feature was that of a friendly competition amongst the Conventioners. The one furnishing the best idea or invention of most use to the photographer or the manufacturer in connection with photography was awarded a prize—in this instance it was a hundred-dollar gold watch—another hint for our Royal Photographic and other societies.

Finally, before referring to other matters I will quote the words of one of the Canadians here. He said: "We have come over here to gain some enthusiasm in our association work, and to strengthen our determination to carry the work forward to complete success. If we could take the personnel of this Convention into our home towns it would achieve the very elevation which we are seeking, and we should hold a position that we do not now hold in the estimation of the general public."

After expressing sentiments like that, is it any wonder that the association was a successful one?

WITH OTHER PHOTOGRAPHERS.

At no session was there the general interest that was manifested at the illustrated lectures which were given at the Hotel Seneca by Mr. Ryland W. Phillips and Mrs. Käsebier. Every seat was taken, and many persons stood at the sides of the room and the exits, while others sat upon the floor rather than lose the first opportunity which had come in the history of the association to hear exponents of the two schools of photography champion their opposing sides.

To one unacquainted with certain things which are matters of recent history in the photographic world, the lectures might have been nothing but a dry exposition of the uses of light and shades and draperies to produce desired effects, or, upon the other hand, freedom from such artificial effects in the production of a picture.

In essence it was the contest between what has come to be known as the recognised or established school and the school which some ten years ago was dubbed the "Secessionists." The "Secessionists" have been scoffed at because they dared to contend that the use of cameras was not a mechanical act, but that the photographer could employ his camera as the unassisted medium of personal expression in art, and that the resulting pictorial expression was not short of art itself, whatever the medium, but led out into the artistic as certainly as did the brush in the hand of the painter.

"With Other Photographers" was the matter-of-fact subject which was to be the medium of the conveyance of the argument of the established school of photography, and Ryland W. Phillips, of Philadelphia, was the expounder. As scene after scene was projected upon the screen, Mr. Phillips gave minute explanation of the attainment of the desired result.

He explained the position of the sky-light, the accomplishment of desired shadows by the skilful use of screens, the posing of the subject, the arrangements of draperies with the idea of producing an ideal picture.

Not only did Mr. Phillips show the finished portrait, but the interiors of studios were thrown on the screen from photographs, illustrating every step in the accomplishment of the photographer's work, including the picture of the subject in position, the screens in place, and the actual moment when the picture

was caught by the artist. The lecturer was repeatedly applauded as he illuminated some point which evades the ordinary photographer. The contrast was also presented between the "raw" and retouched negative.

In addition to exhibiting his own work, Mr. Phillips used slides made from the work of other noted photographers, which he criticised to the instruction of the audience.

As the representative of the "Secessionists," Mrs. Gertrude Käsebier, of New York, had been invited to address the association. Mrs. Käsebier's address was prefaced by the throwing on the screen of several interior views of her New York studio, showing the entire absence of any of the ordinary accessories which are supposed to be indispensable to the best results, from the view-point of the established school. In fact, the views looked precisely like those of a well-furnished drawing-room.

In thus fitting her studio, the idea of Mrs. Käsebier is to place her subject in the most natural surroundings, and while thus a part of a picture which in its make-up is natural rather than artificial, the subject is caught by the camera.

In explaining the later portraits, the artist incidentally showed the utter disregard for the conventional methods of admission of lights, and also showed the attempt to portray the subject simply rather than elaborately draped, and to represent with fidelity how the subject actually looked rather than how an idealic picture might look, taking the subject as a basis of construction.

At times the speaker brought a smile from the audience by saying, "Now this, as you can see, is made from a new negative, before we have assisted honest nature to be dishonestly beautiful."

That the speaker was not without support in the audience was shown by the considerable applause which she received at times. And that the audience was intensely interested was shown by the fact that, notwithstanding the discomfort which some sustained while listening in the crowded room, there was, save for the applause, approximately absolute silence, with no one leaving the room until the last word fell from the speaker's lips.

FRED MARRIOTT.

AT KODAK PARK: MR. GEORGE EASTMAN AS HOST.

Perhaps the greatest experience of the entire Convention for at least 2,000 of the delegates and visitors was the visit on Thursday to the Kodak Park plant of the Eastman Kodak Company. All the visitors had been through other plants earlier in the week, and during the forenoon of the Tuesday had seen

some of the wonders of the Bausch and Lomb Optical Company's great plant, but what they all wanted to see was the inside of that aggregation of immense buildings collectively known the world around as Kodak Park.

From this plant comes all the Eastman film that goes not

only to every part of the civilised world, but beyond, into the previously unknown wilderness. As one Conventioneer remarked, adapting the expression to the needs of the moment, the sun never sets on the Eastman film, a product of Kodak Park. North and south and east and west, to every part and the most distant points of the United States and Canada, to say nothing of lands across the sea, its fame has gone, and to every photographer, professional and amateur, it is as a word learned in childhood.

That explains why, earlier in the week, all the visitors who found it possible to do so called the first half of Wednesday afternoon a closed date.

"That's when we go to Kodak Park," they said, "and we want to go there if nowhere else."

And they went, more than 2,000 of them, according to estimates made by officials of the Photographers' Association of America. When the visitors arrived they found several tents erected on the lawn, with seats for all who came. At every point in and around the tents, and later about the works, were men wearing badges bearing the legend: "Ask Me; I Belong Here." The visitors asked, and every question was answered. Not many queries were heard in the tents, but they came in an almost unceasing stream later, when the inspection of the plant was in progress.

As soon as the tents were comfortably filled luncheon was served. Before and during the luncheon and after the inspection music was supplied by Dossenbach's Park Band.

After luncheon a line was formed including all the visitors who had arrived, and there were 1,240 present, and the inspection of the plant was begun. Everywhere along the line and through the plant were men wearing the tag inscribed: "Ask Me; I Belong Here." Of these, including those in the dark-rooms which formed a division of their own, there were not far from 375. Of this number 150 were from the company's force of travelling salesmen, twenty-five were from the drafting room, twenty-five to fifty included the superintendents and other attachés, and a group of fifteen included the managers of different divisions. In the dark-rooms were many who wore illuminated tags bearing the same inscription, the black showing distinctly against the red light. Mr. George Eastman, inventor of the Kodak and head of the great company that bears his name, was present, and wore one of the tags.

At the head of the column were Charles F. Hutchinson and Claude Van Houten, of the Kodak Park plant. Along the entire line men were stationed to direct the way and give such other assistance as might be needed. The column entered the plant proper through the gate to the north of the office building. Here a copy of the company's souvenir book was handed to each visitor.

From this gate the column proceeded to the compression ice plant, and thence to and through the machine shop, box factory, glass plate box factory, Velox and Azo cutting and packing room, Velox and Azo reeling, drying, and coating rooms, paper storage department, fan room, past the new plate building, to the "dope" department, filling room, coating room, distilling department, engine room, ice machine room, past the big chimney to the nitric acid and sulphuric acid plants, nitrating department, washing and drying room, patent papers building, coating department for these papers, glass and emulsion warehouse, auxiliary paper storage warehouse, men's dining hall, portion of emulsion cooling department, upper end of room in which all spool films are packed, London shipments room, locker rooms, and finally into the time room.

During the trip the visitors were informed that when completed the new plate building, which will cover an area 357 feet by 338 feet, will add five and a-quarter acres to the floor space of the plant, and will be the biggest building of its kind in the world. They were also informed that in the distilling depart-

ment all the solvents that are used in manufacturing the film are recovered and made ready for further use.

The acid department, in which both nitric and sulphuric acid are made, were full of interest for the visitors. Perhaps for the first time they learned that the Eastman Kodak Company is the largest manufacturer of silver nitrate in the world, and that they were looking upon a plant that has a capacity sufficient to convert 4,000 pounds of silver into silver nitrate every week.

In the men's dining room, which has a capacity of 400, the visitors were told that the women's dining room was on the floor above, and that the two have a combined capacity of 1,000. The time room was also very interesting, because of its arrangement and capacity. The time clocks are arranged with reference to the letters of the alphabet, and in such numbers that the entire force, now numbering about 2,200, can be checked out and paid off in ten minutes.

After the trip the column proceeded to the tents and broke up. Expressions of astonishment were heard on every side, and compliments without number were paid to the officials of the company. Mr. Eastman was there, and hundreds hastened to greet him, to grasp his hand, and to congratulate him upon what he has accomplished, and upon what has been built up, under his direction, at Kodak Park.

The remainder of the time the visitors stayed at the park was given up to visiting among both the men and women of the party. There were various officials of the Eastman company that the visitors desired to meet, and the introductions were made. A large number of the visitors had never met Mr. Eastman, and his hand was shaken hundreds of times.

Then there were Manager J. H. Haste, of the Kodak Park plant; Manager Frank W. Lovejoy, of the State Street offices; Assistant Treasurer Frank S. Noble, and the man of whom everybody has heard, and whose hand all of the visitors wanted to shake, L. B. Jones, the company's advertising manager. Those who were not personally acquainted with Mr. Jones were introduced, and those who knew him, shook his hand again.

A few left before three o'clock, but it was not until the rain came half an hour later that any perceptible decrease in the number of people was noticeable. Part of the crowd went out on the lawn and had a group picture taken. Before many had gone L. F. Hammer, of St. Louis, stood up on a chair and waved his hands.

"Speech by Hammer," somebody shouted, and the crowd gathered about him.

"Ladies and gentlemen, especially the latter," Mr. Hammer said, "I've got something to say that ought to be said at this time. We have all been through this wonderful plant, and have seen what Mr. Eastman has done; we have partaken of his generosity, and have had the great pleasure of meeting the man who has done so much for photography. Let us show our appreciation by giving three cheers for Mr. Eastman."

The three cheers were given, and were followed by a "tiger," while the women waved their handkerchiefs.

Then the rain came, and the cars cityward were crowded. At the same time, despite the rain, other visitors were coming, and until four o'clock, thirty minutes before the time fixed for the close of the visit, the officials were asked to permit the newcomers to go through the plant. As one of the visitors said, it was one of the greatest days in the history of photography in America.

Again, the day following the visit to Kodak Park, Conventioneers were the guests of Mr. Eastman and the Board of the Eastman Kodak Company at Ontario Beach.

In all conventions of photographers there never has been anything like it, and even in Rochester, the convention city, such a large number of people never before have been entertained so lavishly. It was a grand, good time from the moment the

ong line of 2,249 guests began to file on to the verandahs of Hotel Ontario until the owl car brought the last merry-maker home.

Carrying pass books, which contained everything needful for enjoying the park and all of its attractions, the guests began going to the park early in the afternoon, and when at six o'clock the bugle sounded the dinner call, there was a crowd which occupied every inch of space on the walks surrounding the hotel.

At the conclusion of the dinner the great throng gave three

cheers for Mr. Eastman, and the men in his immediate vicinity made vociferous demands for a speech. Mr. Eastman, after being lifted to the table, much against his will, made a brief speech, in which he spoke of the pleasure he felt in entertaining the photographers.

There was another speech by Joxie Collings, of the Eastman Kodak Company, when he presented to President Barrows, of the Photographers' Association, a gold watch and chain from the association. This presentation was also the signal for an ovation.

ON THE COMPARATIVE REDUCING POWER OF THE PRINCIPAL DEVELOPERS AND OF THE MEANS OF INCREASING AND REDUCING CONTRASTS IN NEGATIVES DEVELOPED WITH THEM.

THE various developers employed for photographic purposes have, as is well known, very different reducing properties. Some act with great energy and allow of development being completed within a very short time, whilst others, on the other hand, exert much slower action, and give rise to complete development only within a relatively long period. Moreover, the images produced with the different developers differ to a notable extent. Writers upon the subject of development have prescribed very different means for reducing or increasing the energy of the developer with the object of improving the result of over or under exposure or of varying the degree of contrast. We have, therefore, endeavoured to ascertain the differences which actually exist between developers from the point of view of their photographic reducing power, in order to ascertain if there is any actual foundation for the belief that certain developers are better suited for the development of very feeble effects of light, that is to say, of details in the deepest shadow of the subject photographed. We have also studied and compared the various means for increasing or reducing the contrast in the negative.

In a first series of experiments developers, according to established formulæ, were prepared of the following substances:—diamidophenol, metoquinone, pyrogallic acid, paramidophenol, metol, hydroquinone, metol-hydroquinone, edinol, glycin, adurol, hydramine, and paraphenylene-diamine. Plates coated with the same extra-rapid emulsion (the Lumière "Sigma" plate) were exposed under the graduated scale of the Chapman Jones sensitometer for a time sufficient to bring out some only of the patches in the sensitometer, say up to No. 15. These plates were developed each in a solution of the reagents above mentioned, the time of development in each case being sufficient for obtaining the maximum of detail in the shadows. It was ascertained that all the developers, whatever the formula employed, whether with an insufficiency or an excess of alkali, whether containing bisulphite (acid diamidophenol) or bromide, produced the same number of the sensitometer provided that a sufficient time of development was given. In a number of cases, however, this number was obtained on the plate only by resorting to a time of development which also gave rise to more or less intense fog.

Certain slow developers which exert a solvent action upon silver bromide, either by virtue of the developer itself (paraphenylene-diamine) or owing to the presence of potassium bromide or ammonium chloride, do not allow of the development of faint impressions of light to the same degree as do other developers. If all the developers not containing a large proportion of solvent of silver bromide are employed so as to give, at the same exposure, the same number of the sensitometer,

they show very pronounced differences so far as concerns the intensity of the developed images. In order to study the influence of the composition of the developer on the intensity of the contrast obtained, we employed as the formula for each substance that which is usually adopted, but omitting the bromide, in order to throw special light on the effect of increasing proportions of this constituent.

In the case of each developer we have studied the influence of the following factors on the increase or reduction of the contrast:—

- Temperature.
- Dilution.
- Proportion of sulphite.
- Proportion of carbonate or caustic alkali.
- Proportion of added bromide.

Influence of Temperature.

Experiments were made with the developer at the following series of temperatures—41F., 50F., 68F. and 86F. With all the developers the lower temperature necessitates increase in the time of development, but to varying extents, according to the nature of the developer. Some few developers, such as hydroquinone and adurol, give considerably greater contrast at a low temperature, but as a general rule temperature *per se* exerts only a slight effect upon the contrast obtained. The following were the results:—

Developer.	Reduction of contrast with rise of temperature.	Increase of fog with rise of temperature.
DEVELOPERS WITHOUT ALKALI.		
Metoquinone	No appreciable variation	Considerable
Diamidophenol	No appreciable variation	Considerable
DEVELOPERS WITH ALKALI.		
Pyro	Slight	Very considerable
Paramidophenol	Slight	Very slight
Metol	Slight	Slight
Hydroquinone	Very great	Very great
Metol-hydroquinone	Slight	Slight
Hydramine	Slight	Very slight
Adurol	Very great	Great
Edinol	Slight	Very slight
Glycin	Slight	Considerable
Eikonogen	Slight	Slight
Pyrocatechin	Slight	Very slight

Influence on Dilution.

Exposures which had been given under identical conditions were developed, employing solutions which contained one volume of the normal developer in admixture with 1, 2, 3, and 5 volumes of water. With the majority of the developers dilution has the effect of necessitating a greater time of

development (but without causing an increase in fog), and of lessening the contrast in the negative to a degree dependent upon the developer. The following are the results obtained:—

which work with alkali produces, as a rule, no appreciable alteration in contrast. In the case of metoquinone, which normally is used with an alkali, the addition of carbonate slightly in-

Developer.	Time of Development at various dilutions, that with normal developer being reckoned as 1.					Reduction of Contrast by Dilution of Developer.
	Volume of Water.					
	1	2	3	5		
Metoquinone	1	1.6	3.5	4	5	Very slight up to 3 times dilution: greater with further dilution.
Diamidophenol	1	1.5	2.0	2½	3	Considerable up to 3 times dilution: no appreciable action with further dilution.
Pyro	1	—	2.0	2.1	3	Considerable up to 3 times dilution: slight action with further dilution.
Paramidophenol	1	2	2.8	5½	6½	Same as for pyro.
Metol	1	1½	2	4	10	Considerable up to 3 times dilution: dilution beyond this point has no further effect.
Hydroquinone	1	1½	2½	3¾	5	Slight up to 5 times dilution.
Metol-hydroquinone	1	—	1½	1¾	2	Slight up to 3 times dilution: dilution beyond this point has very slight further effect.
Hydramine	1	1½	2	3	3½	No effect.
Adurool	1	1½	2	2.8	4	Slight up to 3 times dilution: dilution beyond this point has no appreciable effect.
Edinol	—	—	—	—	—	Slight effect on dilution: reduction of contrast is more marked on dilution with more than 2 volumes.
Glycin	1	1.2	2	2½	4	Considerable up to 5 times dilution.
Eikonogen	1	2.4	2.5	4.4	—	Considerable up to 3 times dilution: development very slight beyond this point.
Pyrocatechin	—	—	—	—	—	Slight up to 3 times dilution.

Influence of Sodium Sulphite, Carbonate, and Caustic Alkali.

The proportion of sulphite exerts an action on the contrast in the negative only in the case of developers such as diamidophenol, diamido-resorcin, and metoquinone, in which the sulphite takes the place of the alkali. With these developers the contrast is slightly lessened when increasing the normal proportion of sulphite for a given quantity of developing substance. Inversely, if the proportion of sulphite is reduced the contrast is slightly increased, and the time of development at the same time lengthened. The variations in the proportion of sulphite produce results which are more marked in the case of diamidophenol and diamido-resorcin than in the case of metoquinone.

With these three developers just mentioned it is thus feasible to reduce the contrast either by adding water to the developer or by increasing the proportion of sulphite. In practice, the best result is obtained by employing both methods simultaneously; that is to say, we get negatives of a lesser degree of contrast and quite free from fog (when employing diamidophenol) by diluting the developer with about three times its bulk of a 5 per cent. solution of anhydrous sulphite of soda.

Gradual increase of carbonate or caustic alkali in developers

increases the contrast, whilst a contrary effect is noticed in the case of pyrogallie acid, metol, and hydroquinone.

Influence of the Proportion of Bromide

Addition of potassium bromide to the various developers increases the contrast produced, whilst at the same time it lengthens the period of development. Moreover, if the developer tends to give veiled results small proportions of bromide will completely remedy it in this respect.

The effect produced varies with the nature of the developer. In a general way the maximum effect is obtained with a small quantity of bromide, beyond which the only effect is increase of the time of development. For each developer we have tried the effect produced by varying quantities of bromide, as follows, viz. :—

0.5	1	.25	.5	1 gm per 100 ccs.
These are respectively equal to:—				
½	⅔	1/10	2/5	4½ grs. per oz.

The preceding experiments show that all the developers examined, whatever their composition (with the exception only of those containing solvents of silver bromide), allow of development of faint impressions to the same degree.

Developer.	Per 100 ccs. of Developer.		Note on the effect produced on contrast.	Ratio between time of development with solution containing .05 gm. bromide per 100 ccs. and that with solution containing 1.0 gm. bromide per 100 ccs.	Influence of Bromide on Fog.	
	Minimum quantity of bromide, producing appreciable effect on contrast.	Quantity of bromide producing the maximum effect of contrast.			Without bromide.	With bromide.

Edinol... ..	.05	.25	"	4	Very slight fog	.05 gm. bromide per 100 ccs. suppresses fog.

Contrast can be modified by the following methods:—

Reduction of Contrast.

Among the means for reducing contrast the following must be mentioned:—

1. Dilution of the developer—addition of water three to four times the bulk of the normal developer.
2. Addition of sulphite of soda or simultaneous addition of water and sulphite, *e.g.*, addition of three times the bulk of the normal developer of 5 per cent. anhydrous sodium sulphite solution.
3. Increasing the proportion of alkali.
4. Raising the temperature of the developer.

Method No. 1 applies to all the developers we have used with the exception of hydramine. The developers least sensitive to his effect of dilution are hydroquinone, metol-hydroquinone, metoquinone, adurol, and edinol.

Method No. 2 serves only with developers requiring no alkali, and the best results are obtained in the case of diamidophenol. As already stated, it is best to combine methods Nos. 1 and 2.

Method No. 3 has no effect in the case of the majority of developers. The only instances in which the results are appreciable are with pyro-metol and hydroquinone.

Method No. 4 may be used in practice only in the cases of hydroquinone and adurol: other developers, when used at a higher temperature, give only a very slight reduction of contrast.

Increase of Contrast.

The following methods on improving contrast and thus remedying the effect of over-exposure may be mentioned:—

1. Reducing the alkali in the developer, or in the case of developers working with alkali reducing the quantity of sulphite.
2. Lowering the temperature of the solution.
3. Addition of bromide.

Methods Nos. 1 and 2 are merely the corollaries of the methods already given for reduction of contrast. A lessened proportion of alkali may be obtained by addition of an acid or of sodium sulphite to the developer.

Method No. 3 applies to all developers, and is the means which is of the greatest practical use. Moderate proportions of bromide are sufficient to produce the maximum effect. Developers which best lend themselves to the maximum increase of contrast are pyro, hydroquinone, adurol, glycin, and eikonogen.

The following are the formulæ employed for the various developers which have been made the subject of the above examination:—

DIAMIDOPHENOL.

Diamidophenol	44 grs.	5 gms.
Soda sulphite anhydrous.....	260 "	30 "
Water	20 ozs.	1,000 ccs.

METOQUINONE (NORMAL).

Metoquinone	80 grs.	9 gms.
Soda sulphite anhydrous.....	1½ ozs.	60 "
Water	20 ozs.	1,000 ccs.

METOL.

Metol	35 grs.	4 gms.
Soda sulphite anhydrous.....	165 "	19 "
Potass carbonate	130 "	15 "
Water	20 ozs.	1,000 ccs.

HYDROQUINONE.

Hydroquinone	90 grs.	10 gms.
Soda sulphite anhydrous ...	1 oz.	25 "
Potass carbonate	330 grs.	38 "
Water	20 ozs.	1,000 ccs.

METOL-HYDROQUINONE.

Metol	80 grs.	9 gms.
Hydroquinone	80 "	9 "
Soda sulphite anhydrous ...	800 "	90 "
Soda carbonate anhydrous ...	480 "	54 "
Water	20 ozs.	1,000 ccs.

One part of this stock solution is mixed with two parts of water.

PYROGALLIC ACID.

Pyrogallie acid	44 grs.	5 gms.
Soda sulphite anhydrous ...	130 "	15 "
Soda carbonate anhydrous...	60 "	7 "
Water	20 ozs.	1,000 ccs.

PARAMIDOPHENOL.

Parami dopn	44 grs.	5 gms.
Soda sulphite anhydrous ...	330 "	38 "
Caustic lithia	18 "	2 "
Water	20 ozs.	1,000 "

EDINOL.

Edinol	90 grs.	10 gms.
Soda sulphite anhydrous.....	2 ozs.	100 "
Soda carbonate anhydrous ...	2 "	100 "
Water	20 "	1,000 ccs.

GLYCIN.

Glycin	150 grs.	17 gms.
Soda sulphite anhydrous.....	265 "	30 "
Potass carbonate	70 "	8 "
Water	20 ozs.	1,000 ccs.

HYDRAMINE.

Hydramine.....	45 grs.	5 gms.
Soda sulphite anhydrous ...	130 "	15 "
Caustic lithia	27 "	3 "
Water	20 ozs.	1,000 ccs.

ADUROL.

Adurol	115 grs.	13 gms.
Soda sulphite anhydrous ...	1 oz.	50 "
Potass carbonate	1½ "	75 "
Water	20 ozs.	1,000 ccs.

EIKONOGEN.

Eikonogen	265 grs.	30 gms.
Potass carbonate	1 oz.	50 gms.
Soda sulphite anhydrous ...	1½ "	60 "
Water	20 ozs.	1,000 ccs.

PYROCATECHIN.

Pyrocatechin.....	90 grs.	10 gms.
Soda sulphite anhydrous ...	1½ oz.	25 "
Soda carbonate cryst	1 oz.	50 "
Water	20 ozs.	1,000 ccs.

A. AND L. LUMIÈRE.
A. SEYEWETZ.

PHOTOGRAPHS OF CASUALS.—The Committee of the Bethnal Green Workhouse are adopting up-to-date methods in the identification of the men who sojourn in that institution. A camera is to be purchased at a cost of £5 in order that photographs of the men allowed out on pass may be taken. At the present time, in the event of such men returning, they cannot be traced without great difficulty.

MOTORING AND PHOTOGRAPHY. It may be doubted (writes a contributor to the "Birmingham Evening Despatch") whether any readers have taken a photograph of themselves travelling in a motor car at forty miles an hour. Such was the feat accomplished by a

well-known Birmingham man a few days ago. At the side of one of the country lanes not five miles from the centre of the city he placed a camera of his own construction. The body of the camera was of the ordinary kind, but there was attached to it a rubber tube some three or four yards long. This was placed across the road, and the motorist starting from a point some distance away set the car off at a great speed. He then drove the wheels of the car over the tube, and thus "snapped" the picture. The mechanism was so arranged that when the first wheel passed over the tube the plate was exposed.

SOFT VIGNETTES IN ENLARGEMENTS.

THE majority of photographers who do any enlarging frequently experience a difficulty in obtaining soft and pleasing results when vignetting. It is very annoying to find that, after all our care to keep the vignetter moving during exposure, on developing the bromide paper we get a more or less distinct line showing the shape of the opening in the vignetter used. This is especially noticeable in cases where vignetting has to be resorted to with a negative which was never intended for that purpose, the background being several tones too dark to suit that particular style of printing. Nothing looks worse than a portrait with a dark background vignettted so as to show a distinct oval-shaped mass of dark with the head looming in the centre, and the usual expanse of pure white all round; but this is the kind of result which will always be obtained while using any of the ordinary vignettters, the reason being that the edges (no matter how much they may be cut up) always cast a hard shadow on the bromide paper, and the light coming through a lens and travelling in a straight line does not diffuse under the edges of the vignetter as it does when printing by contact, when sufficient room is left between the negative and the vignetter.

Such being the case, it is evident that some material other than that usually employed is required to make suitable enlarging vignettters; and, after experimenting with various transparent and semi-transparent materials, I have come to the conclusion that an enlarging vignetter should be semi-transparent, and have found that ordinary celluloid, matted on one side, answers the purpose very well. This allows a certain amount of light to pass through, but entirely destroys the image, softening the edges of the vignettted portion, and giving an all-over tint to the part usually represented by white paper. This gives an effect not unlike that obtained when vignetting in the camera. If this tint is not required, the vignetter can be covered with opaque paper, having about half an inch of clear celluloid round the opening, which will give a very soft vignette and still leave

the margins of the paper white. Personally, I prefer to use the celluloid uncovered, and have the paper tinted right up to the edges, which almost gives the effect of a solid print, but without hard detail near the margins. Even negatives with light backgrounds give a different result with this vignetter, the effect obtained being softer and more harmonious than when the ordinary opaque vignetter is used.

The celluloid sold by dealers for glazing and matting P.O.P. prints answers the purpose very well. The opening is cut in the centre as usual. A convenient method of cutting is to use a wheel cutter and the zinc shapes sold for the purpose of cutting oval and circular prints. Since the celluloid is so thin, it is best to support it by cutting an opening in two pieces of cardboard, the cut-out parts being about a quarter of an inch smaller each way than the outside size of the celluloid. The celluloid is then placed over one piece of the cardboard, and kept in place by a touch of mountant, the second piece of cardboard being pasted all over and laid on top. The whole is then placed under a weight until it is hard. This gives the vignetter bound in a cardboard frame, which keeps it stiff, and makes it much easier to handle.

The vignette is used in the ordinary way between the lens and the bromide paper on the enlarging easel, and kept moving as usual; but, even if it is kept stationary, a definite line does not result; in fact, in whatever way it is used, the effects obtained are softer than is usually the case with ordinary opaque vignettters. The fact that this vignetter is of no use for contact printing proves that it is different from others; and, although this difference may be very slight, still, it is there; and whilst the soft results obtained by its use may not appeal to everyone, nor be suitable for every vignettted enlargement, still, it is an added power in the hands of the photographer, and even the pictorial worker may on occasion find a use for it, if for no other reason than to soften down distracting detail near the margins.

J. PEAT MILLAR.

MIXTURES OF DYES AS SENSITISERS OF GELATINE PLATES.

IV.

[The following is an abridged translation of a thesis by Guido Daur, presented for the degree of Doctor of Philosophy at the Münster University. The experimental work was done on the suggestion of Professor Miethe, to whose colleague, Dr. E. Stenger, the author of the papers renders his thanks for much advice and assistance. The full text of the paper occupies a book of 105 pages, published by E. Grieser, Frankfort a/M.—Eds. "B.J."]

29. *Pinaverdol-erythrosine*.—The great difference between sensitizers such as ethyl-red and pinaverdol is shown by the properties

other hand, completely overpowers the effect of erythrosine. The curves for the two separate dyes are shown in Fig. 29, so that they

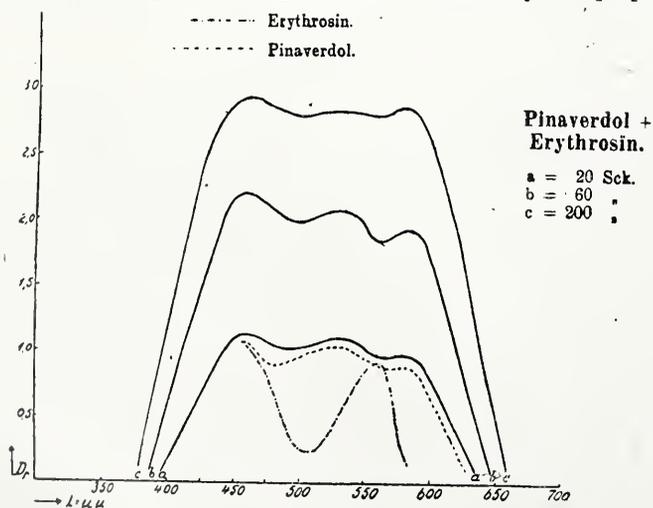

Fig. 29.

of this mixture. Ethyl-red, as has been seen, exerts hardly any action when combined with erythrosine, whilst pinaverdol, on the

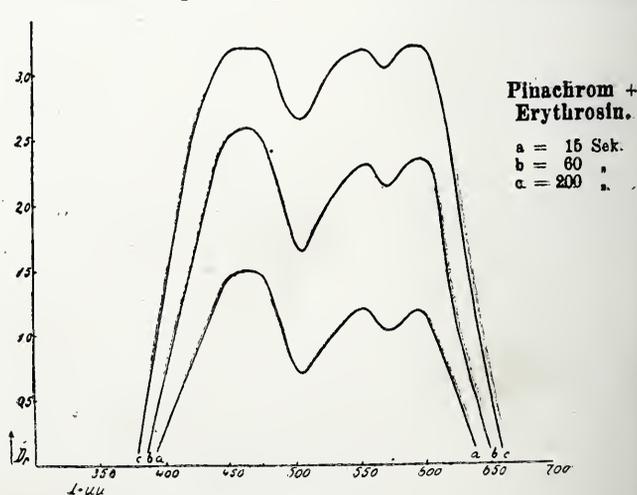

Fig. 30.

are comparable at 450. It is seen that the pinaverdol minimum of 560 coincides with the erythrosine maximum; nevertheless the resulting curve is that of pinaverdol. There is no shifting of the maxima.

30. *Pinachrome-erythrosine*.—The curve (Fig. 30) has largely the pinachrome character; the gap in the green is somewhat deeper than with pure pinachrome. On the other hand, the erythrosine appears to have influenced the maximum at 550 somewhat. The second pinachrome maximum is 5 $\mu\mu$ nearer the red end of the spectrum. The minimum appears somewhat enlarged by the increase of the first maximum. The colour-sensitiveness, which in the case of the pinachrome curve corresponds with that of the mother emulsion, is inferior in the case of the two dyes with short exposures, increases gradually, and at 200 seconds exceeds the sensitiveness in the blue. Water-washed plates develop heavy fog, and those bathed with alcohol were required for the measurements.

31. *Isocol-erythrosine*.—The curve is almost identical with that of erythrosine, but there is no filling up of the gap in the green. The second maximum of 530 comes out very faintly at 520, and the third maximum of 630 becomes evident only on fairly long exposure,

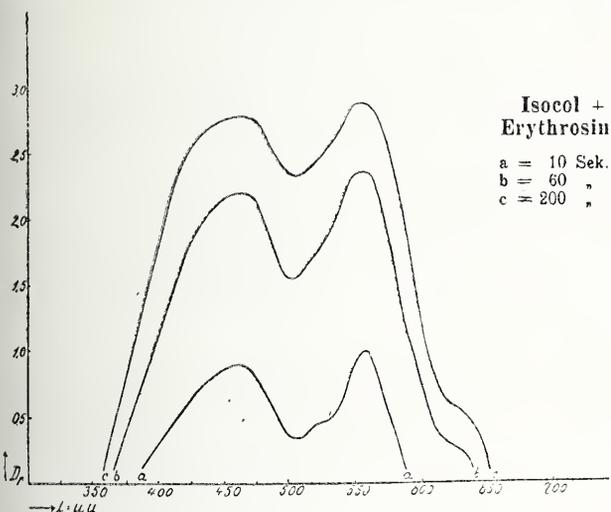

Fig. 31.

extending the curve to 650. The ratio of colour-sensitiveness to that of the mother emulsion is about 1 in the case of erythrosine, and is not appreciably improved in the case of the two mixed dyes. The water-washed plate was satisfactory, and was used for the measurements.

32. *Dicyanine-erythrosine*.—The plate, that washed with alcohol, showed three distinct maxima. Fog amounted to .48. As seen from the figure, the extremely slight colour-sensitiveness is remarkable, and even that to blue is not high. The green gap has its deepest point at 520; the erythrosine maximum, which is shifted 10 $\mu\mu$

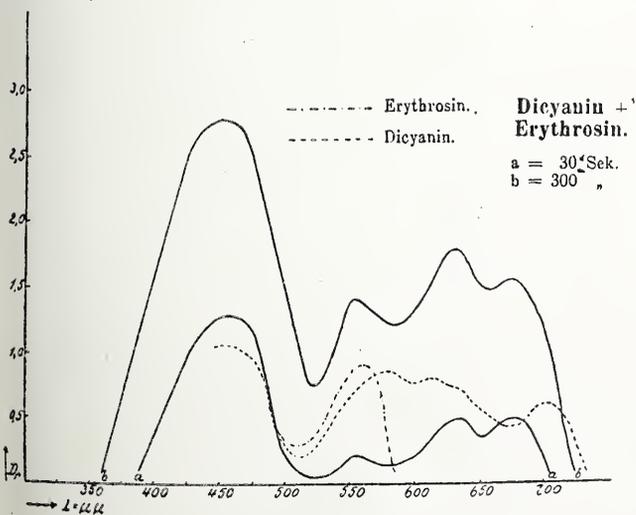

Fig. 32.

towards the blue, rises steeply up to wave-length 550. The dicyanine maximum of 610 comes out strongly; on short exposure it is somewhat more marked than the other maximum, but on longer exposures far exceeds these. There is a shift of the dicyanine maximum from the red from 700 to 725—that is, 25 $\mu\mu$ towards the blue.

33. *Mixtures of chinoline-red, glycin-red, and formyl-violet with eosines and isocyanines*.—Fig. 33 gives the curve of the sensitisers hitherto used for a time of exposure of 200 seconds. Chinoline-red, with its maximum at 570, shows the best action, and may be placed

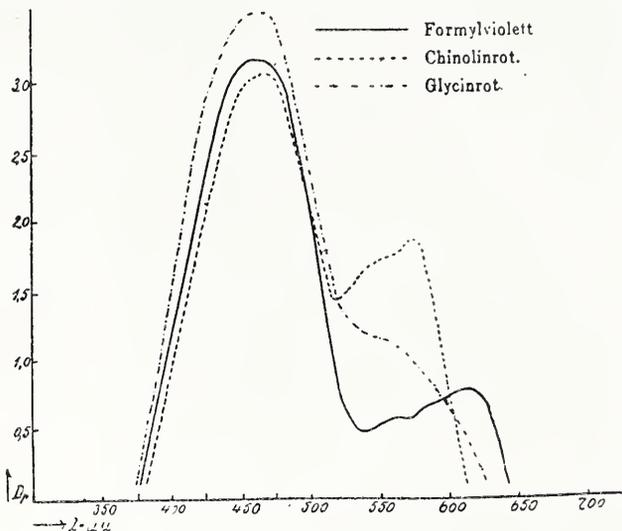

Fig. 33.

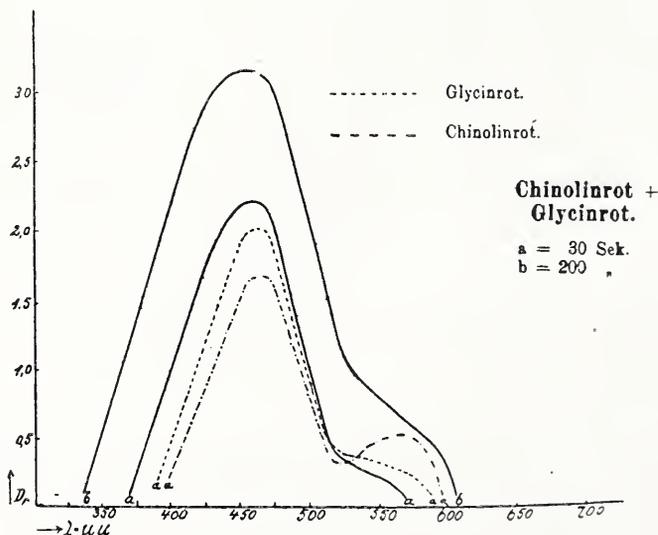

Fig. 34.

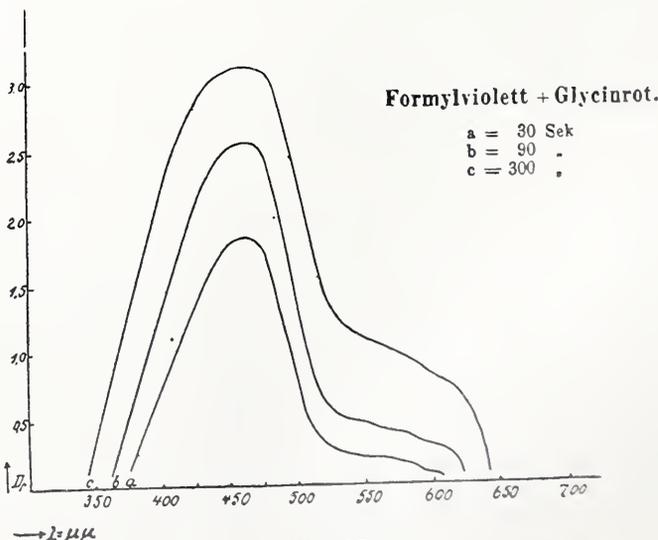

Fig. 35.

alongside aureosine as regards strength. According to Valenta, the best formula for sensitising is:—

Chinoline-red, 1 : 500 2 ccs.
Water 100 ccs.

Glycin-red is a far weaker sensitiser with chinoline-red, and shows

its best action at a dilution of 1:25,000. The added sensitiveness is far inferior to that in the blue, and does not reach beyond 620.

Of the three dyes the weakest action is given by formyl-violet used in accordance with Valenta's formula at a dilution of 1:20,000, with a slight addition of ammonia. It shows two maxima at 560 and 610; the curve rises steeply from the latter, and extends to 630.

34. *Glycin-red-chinoline-red*.—This mixture, as seen from Fig. 34, gives a glycin-red curve; there is no sign of the effect of the other dye. The curves are for exposures of 30 and 200 seconds, those for the separate dyes being for 30 seconds' exposure. It will be noticed that the mixture gives a greater sensitiveness to the blue.

35. *Formyl-violet-glycin-red*.—In this mixture the glycin-red decides the shape of the curve, the gradual fall from 500 being typical of this dye. The formyl-violet, maximum 610, has prolonged the curve somewhat in the yellow part of the spectrum.

36. *Formyl-violet-chinolin-red*.—The curves are for exposures of 60, 150, and 300 seconds, both for the mixture and for the single dyes. The chinoline-red proves the stronger sensitiser, the action being slight, with short exposure, more marked on longer exposure, and reaching its maximum at 570. The gradual fall is broken by

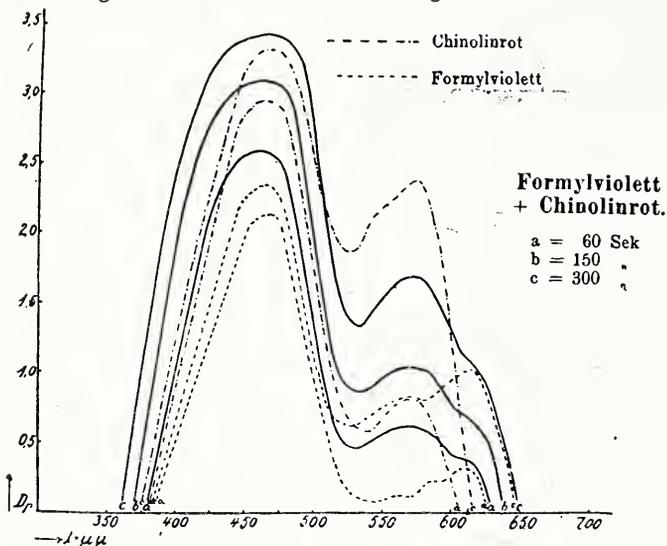

Fig. 36.

the formyl-violet, maximum at 610. With this mixture also sensitiveness to the blue is greater with the mixture than with either single dye. The colour-sensitiveness is distinctly inferior to that of chinoline-red.

37. *Formyl-violet-erythrosine*.—As anticipated, the strong sensitising powers of erythrosine are seen in the character of the curve—i.e., rather deep gaps at 500, from which the curve rises steeply with a maximum at 560, whence it quickly falls. On longer exposure the effect of the formyl-violet comes in. The maximum of the latter at

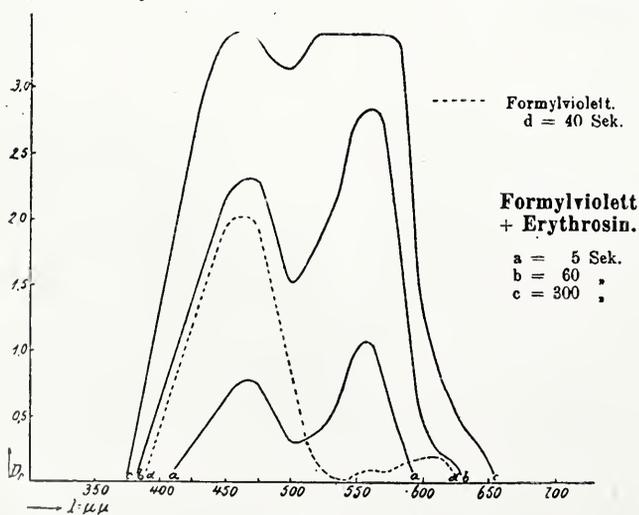

Fig. 37.

610 causes the erythrosine curve to bend outwards, thus prolonging it slightly. The colour-sensitiveness relative to that to blue is good; on short exposure the curve remains at 450 at a point close to the green maximum. The plate shows some strong red coloration.

38. *Chinoline-red-erythrosine*.—Here the curve is of the erythrosine

type, though its maximum in the green is altered somewhat. The chinoline-red maximum of 570 is apparently shifted 10 μm towards the blue.

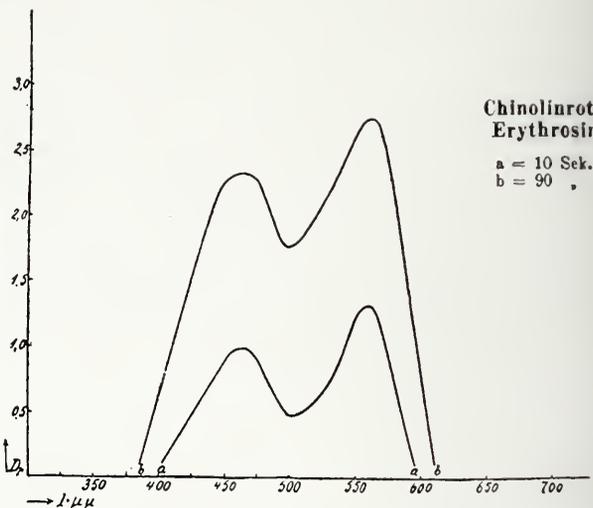

Fig. 38.

39. *Glycin-red-erythrosine*.—Here, again, the curve is that of erythrosine, the relative sensitiveness in the green to that in the blue being good, as also the general sensitiveness.

These results confirm the fact that a weak sensitiser, when used in

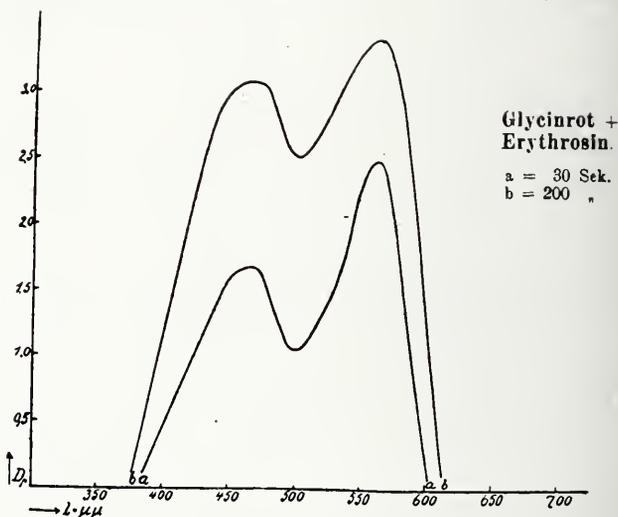

Fig. 39.

combination with a strong one, exerts as a general rule no influence on the curve of the latter, and affects only the relative colour-sensitiveness compared with that to the blue.

40. *Aureosine-glycin-red*.—It is seen that aureosine is here more powerful than its fellow dye, and fixes the course of the curve.

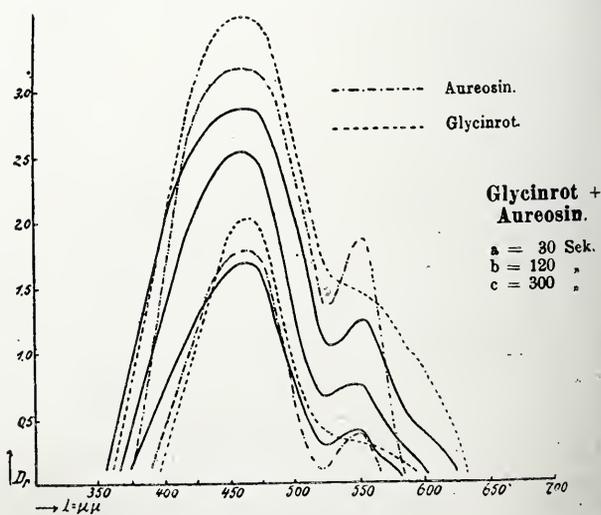

Fig. 40.

short exposures (30 seconds) the curve falls from the blue maximum less steeply than with aureosine alone. The gap at 520 in the blue

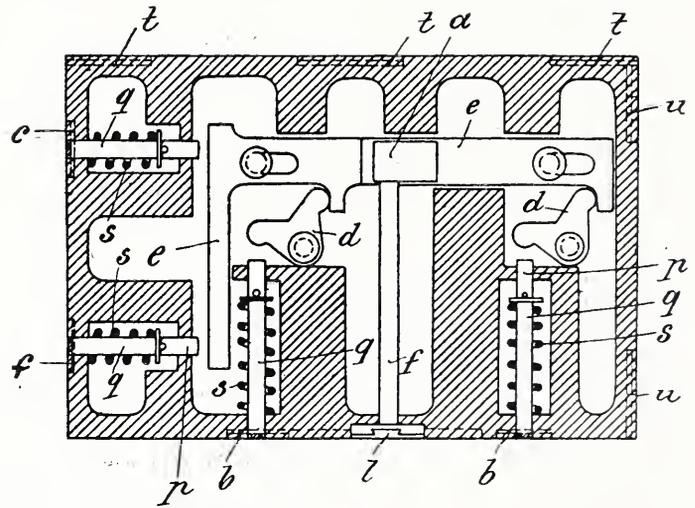

Photo-Mechanical Notes.

Mechanical Mounting for Half-tone Blocks.

A RECENT patent specification (No. 27,770, 1908), describes the device constructed by E. Wiessler, of 7, Erzgießerei Strasse, Munich, for the purpose of holding printing surfaces thereon, and more particularly to mounting-blocks of the type wherein these grippers are moved, against the action of the springs, by means of cams and bell-cranks arranged under the block. The object of the invention is to simplify the mechanism of these blocks, and the invention consists in using a cam-operated slide to act in part directly, and in part indirectly, by means of bell-cranks, on the grippers of the block.

Within the block there is a shaft *f* provided with a cam *a* adapted to displace the slide *e*. The latter has lateral projections by means of which it rotates two bell-cranks *d* during its movement towards the left of fig. 1. The shaft is rotated by means of a key, not shown in the drawing, adapted to engage a slotted disc *l* fixed to the shaft.

During part of its displacement towards the left slide *e* acts on

the inner ends *p* of two rods *g*, which carry abutments or holding devices *c* located at or near one of the upper edges of the block. At the same time the bell cranks *d* act on rods *g* carrying similar abutments *b*. The rods and abutments are by this means thrust outwards, from two contiguous sides of the block, against the action of spring *s*, which are placed on the rods between the walls of the block and collars carried by the rods.

While the abutments *b* and *c* are thus thrust outwards the plate with the printing surface is placed on the block. Then the shaft *f* is released, so that the springs *s*, acting on the collars referred to, can thrust the abutments *b* and *c* against the plate and hold the latter firmly against fixed abutments *t* and *u*, with which the block is provided.

Colour and Crime.

It has been suggested that the introduction of improved colour sensitive plates, and the diffusion of correct information about colour filters and their marketing, will make much easier the task of the forger of those bank notes that have hitherto relied largely on their intricate colour to prevent imitation. There is no doubt a grain of truth in this, but no well-executed note will ever be reproduced by the use of photography alone; it will still need so much hand work that it is probable that the real service of photography would be simply to supply the outline in order to ensure correctness of form and position, and this could often be done even with the common wet plate better than with any colour-sensitive dry plate.

Lenses and Process Work.

In the early days of process work, a long focus rapid rectilinear was the general type of lens chosen; in fact, at that time the recently introduced anastigmats were even condemned. Of course, by now, opinion has quite changed, and it is realised that an anastigmat lens is better than a rapid rectilinear for any purpose, though, if small stops are always used, as in process work, it is possible its advantages may be purchased too dearly. What is

green is distinctly improved by the glycin-red. The aureosine maximum of 550 does not, however, come up so strongly. The glycin-red influences the slow fall of the curve, which latter terminates at 600 to 620. On longer exposure the action of the aureosine is less marked; the maximum 550 no longer corresponds with that of the aureosine alone.

41 and 42. *Pinaverdol* was selected as an isocyanine which might be combined with other dyes, and was mixed with formyl-violet and

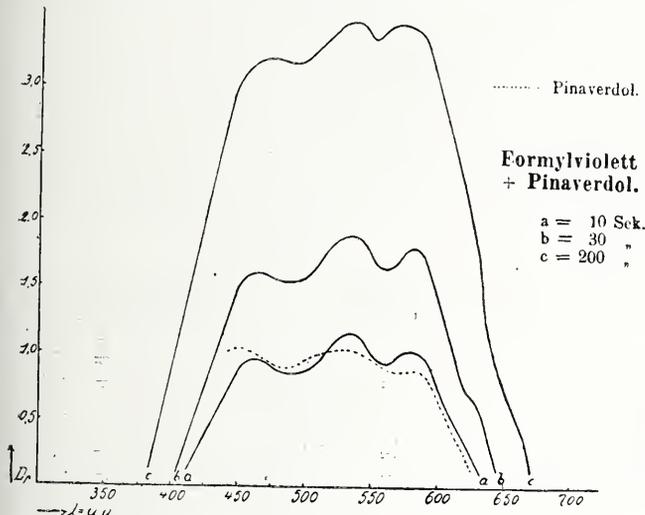

Fig. 41.

chinoline-red. In the case of pinaverdol-formyl-violet (Fig. 41) the expected prolongation of the pinaverdol curve was not obtained. The curve is that of pinaverdol showing the effect of the formyl-violet maximum of 610 at 630, due to a shift towards the red. The curve extends to 650. It will be seen that the maximum of 530 is more pronounced than any of the others, whilst that at 580 exceeds the sensitiveness in the blue.

Pinaverdol-chinoline-red (Fig. 42) has again the character of pinaverdol, and does not even show the filling up of the minimum

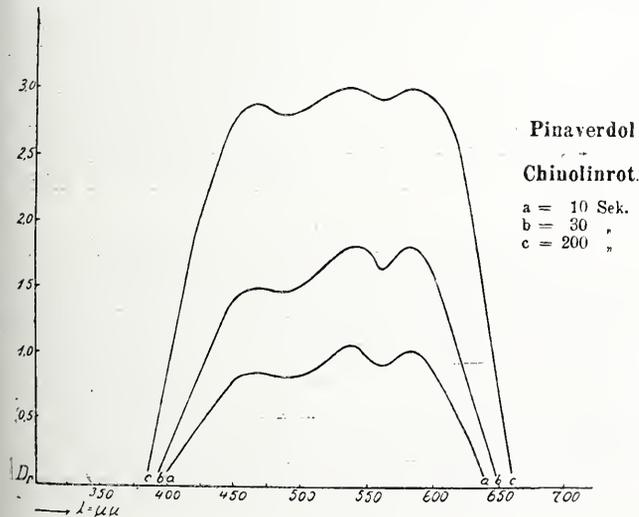

Fig. 42.

tween the two pinaverdol maxima which might have been produced by the chinolin-red maximum of 570. Pinaverdol being too strong a sensitiser for use with weak sensitisers, such as formyl-violet and chinoline-red, a trial was made on glycin-red in conjunction with the somewhat weaker pinaverdol. G. DAUR.

(To be continued.)

ENSIGN FILM COMPETITION.—Mr. Mintern Hiam, 63, Beresford Road, Canonbury, N., is the winner of the "Ensign" Roll Film Competition for August. Houghtons Limited offer a three-guinea camera every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

necessary to remember is that the value of R.R. lenses has, in consequence of the multiplication and cheapening of the anastigmat, much depreciated, so far as the amount they would fetch on selling now is concerned. The lens itself may be just as valuable for working purposes, and, in fact, French rectilinear lenses without name on mount may even have increased in price, but the R.R. with a name which cost perhaps £15 or £20 not so many years ago, is not saleable at £5, because the maker to-day recommends an anastigmat, and sells it for the same or very little increase in price.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

HALF-TONE PRINTING.—No. 17,303. Improvements in half-tone plates for printing purposes. John Oliver, 24, Norfolk Row, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between July 26 and 31:—

PAPER.—No. 17,324. Improvements in the manufacture of sensitised albuminised paper for photographic purposes. Charles Hollingsworth, 106, Hop Exchange, London.

STEREOSCOPY.—No. 17,537. Stereoscopic Christmas or other folding card. Frederick William Munro, 5, St. Paul's Place, Canonbury, London.

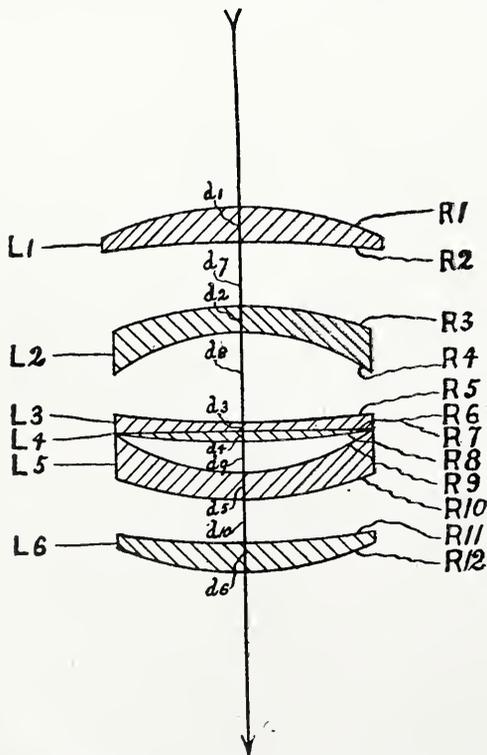

WASHER.—No. 17,689. Photographic plate, film, and print washer and drier. John Evan Jordan, 126, Newport Road, Cardiff.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FIVE-LENS OBJECTIVES.—No. 14,673, 1908 (July 10, 1908). The invention relates to an improvement on the method of constructing

Patent No. 27,180, 1906, allowing of the construction of an anastigmat lens with a very large aperture whilst retaining its corrections for astigmatism, spherical aberration, achromatism and coma.

The general form of the lens described in the Patent No. 27,180, 1906, is retained, but there is used instead of the lens L₁, a pair of lenses which may be cemented together, one element consisting of a negative lens of high dispersion and the other of a positive lens of low dispersion. By this means a lens is made with an aperture of approximately *f*/4 which will give good definition, practically free from astigmatism over an angle of about 60 deg.

Figure I. is a drawing showing the optical portions of a lens constructed according to this invention. L₁ L₂ L₃ L₄ L₅ L₆ represent the six lenses, the lens L₁ being furthest from the photographic plate R₁ R₂ . . . R₁₂ represent the radii of curvature of the various surfaces, the central thicknesses of the various lenses are denoted by the letters *d*₁ *d*₂ *d*₃ *d*₄ *d*₅ *d*₆ respectively. The axial thickness of the air space between the lenses L₁ and L₂ is denoted by *d*₇, that between L₂—L₃ by *d*₈, and that between L₄ and L₅ by *d*₉, and that between L₅ and L₆ by *d*₁₀.

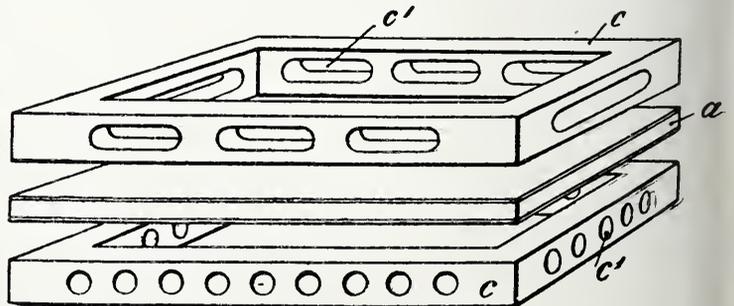

The optical data for constructing a lens of 10 inches focal length, the effective aperture about two-ninths of the focus, are as follows:—

Radius of Curvature in Inches.	Glass Constants.	Thickness of Lenses and Air Spaces in Inches.
R ₁ = 2.97	μ _D = 1.6065	d ₁ = .265
R ₂ = 9.72	✓ = 58.1	d ₇ = .55
R ₃ = 3.21	μ _D = 1.6193	d ₂ = .24
R ₄ = 1.86	✓ = 37.4	d ₈ = .75
R ₅ = 9.92	μ _D = 1.6193	d ₃ = .082
R ₆ = ∞	✓ = 37.4	d ₄ = .09
R ₇ = ∞	μ _D = 1.5193	d ₉ = .25
R ₈ = 7.87	✓ = 58.7	d ₅ = .265
R ₉ = 1.92	μ _D = 1.5703	d ₁₀ = .37
R ₁₀ = 3.25	✓ = 41.1	d ₆ = .267
R ₁₁ = 8.51	μ _D = 1.6065	
R ₁₂ = 3.74	✓ = 58.1	

Conrad Beck and Horace Courthope Beck, 68, Cornhill, London, E.C.

DRYING GELATINE PRINTS ON GLASS.—No. 26,298, 1908 (December 6, 1907). The invention is a frame for holding the glass plates on which to lay down gelatine prints which are to be stripped off with a gloss when dry.

The frame is placed over the glass and covers the edges by a width of from 1 to 2 centimetres. In this manner the drying of the edges of the print is retarded, and the frame is only removed when the middle of the proof is dry, when the drying of the edges takes place after a short interval. In this manner a uniform contact between the surface of the print and the glass is ensured until the end, which is important in obtaining a large uniform brilliancy.

The frame covering the edges may be of wood and of a suitable thickness. In the sides of the frames holes may be pierced in such manner that a current of hot air may be passed through the openings in the frames. These frames can also be made in metal—in zinc, for example. But in this case it will be necessary to cover them with felt at the places where they touch the paper. By placing one above the other several plates on both sides of which proofs are stuck, piles can be made, so that a number of proofs can be dried in a very limited space. Figure 1 represents two frames between which is a glass with proofs attached. Nicholas Ziegler, 5, Rue Brantome, Asnières, France.

PAPER COLOUR PRINTS FROM SCREEN-PLATE TRANSPARENCIES.—No. 15,050, 1908 (July 16, 1907). The author proposes a process of preparing prints in natural colours as the result of making an exposure on a panchromatic plate through a mosaic three-colour

screen-plate of geometrical pattern. From the screen-negative made in this way through a mosaic filter a transparency is made by contact. A print is taken from this on a special surface prepared as follows:—A rigid paper support is impressed with a three-colour pattern identical with that used as a filter in taking the original negative, the colour elements, however, consisting of the complementaries, namely, pink, yellow, and blue. This paper support bearing the three-colour pattern is coated with sensitive gelatino-bromide emulsion. It is laid in registration with the positive made from the original negative and the image developed and fixed. As a result, the transparent portions allow of the colours on the screen below being seen and producing the natural colours photographed in the first instance. Owing, however, to the degradation caused by the black deposit of silver which is used to obstruct the colours not forming part of the picture the author proposes to adopt the so-called "gouache" method of painting, namely, to bleach the black deposit and so obtain dilution of the colours with white instead of degradation with black. In order to secure a bleached image which will not afterwards darken in the light, the author uses a 1 to 2½ per cent. of bichloride of mercury, draining or blotting off the excess without washing. The excess of bichloride prevents the image from becoming brown in the light. Bichloride of copper in dilute solution may be used for the same purpose, afterwards thoroughly washing and impregnating the print with a weak mercuric chloride solution to prevent after darkening. Edmond Charles Guislain Caille, 49, Rue Rivay, Levallois-Perret (Seine), France.

CINEMATOGRAPH-PHONOGRAPH.—No. 27,717, 1908 (December 21, 1908). According to the invention a movement electrically controlled by the gramophone is imparted to an indicating hand, and at the same time the entire electrical mechanism is rotated in a contrary direction to that in which electrical mechanism is moving the indicating hand.

This rotation of the entire electrical mechanism is secured by gearing connected direct to the cinematograph mechanism; or it may be produced by means of electrically operated gearing in electrical connection with the cinematograph. When the gramophone and cinematograph are both moving at the designed relative speed to each other the movement imparted to the hand by the gramophone-controlled mechanism will be equal to that given to it in a contrary direction by the cinematograph controlled portion of the device, and, in consequence, no movement of the indicating hand will take place. If, on the other hand, one or other of the two instruments (cinematograph and gramophone) is working too fast or too slow, this variation from synchronism will at once be shown by a movement either to the right or left of the central or synchronous point marked on a fixed dial, and the amount of such movement will correctly give the number of revolutions necessary to again establish synchronism. Francis Alexander Thomassin, 20, Gleneagle Road, Streatham, Surrey, and Henry Raymond Nathan, 12, Little Newport Street, Leicester Square, London.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901:—

COLOUR PHOTOGRAPHS.—No. 17,198 of 1909. Process for producing coloured portraits and photographs and accessories used in connection therewith. Maurel and Achour.

New Trade Names.

ION.—No. 314,215. Plates and films included in Class 1 prepared for photographic purposes. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W., manufacturers of photographic materials. June 24, 1909.

FORTHCOMING EXHIBITIONS.

September 10 to October 23.—The Photographic Salon. Latest date, August 30. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 23 to October 30.—1.—Royal Photographic Society. Latest date (carrier) September 1, (hand) September 2. Sec., J. McIntosh, 35, Russell Square, London, W.C.

Extracts from our weekly and monthly contemporaries.

Prints Adhering to Glass During Glazing.

Writing on the subject of glazing cards and their adhering to the supports in "Photography and Focus" for August 10, "H. W. P." says: "Readers will feel grateful, I doubt not, for a simple hint by which this sticking can be annihilated. It is this: use formaline. Since I was first put up to its use by a professional photographer I have never had a print stick. It is not expensive. A Winchester quart stoppered bottle can be got from the druggist for a few pence. It is well washed out and four ounces of formaline are poured in, and the bottle filled up with water. This forms the stock solution, which will last a long while. It gradually loses its strength, but as long as it smells of formaline it is safe to use it, and that will be for some months, as far as the ordinary use by an amateur photographer is concerned.

"When the prints are sufficiently washed they are drained for a moment and then plunged, one by one, under the surface of this dilute formaline solution in a dish. They should be left in for five minutes after the last was put in, and shifted once or twice, to make sure that the liquid can act on all of them. They are then put back into the washing water for a minute or so, given one more change, and may be squeegeed straight away, without any fear of sticking. The formaline is poured back into its stock bottle for use on another occasion.

"It ought to be added that, to ensure success with this or any method, it is important to have the pulp boards, ferrotype, or glass, on which the squeegeeing is done, perfectly clean, and preferably with the slightest trace of grease. I use pulp, and give the boards a thorough washing with soap and water after every three or four lots of prints have been squeegeed on to them. They are then rinsed and allowed to dry, and then are rubbed over with a duster which has been slightly moistened with paraffin oil, and finally polished with a clean duster.

"Ensyna" for X-Ray Negatives.

Chance (writes Dr. H. D'Arcy Power in "Camera Craft") enabled me to find a valuable field for this new paper (Ensyna). The leading X-ray expert in this city recently remarked to me, whilst showing a plate of wonderful gradation, "If I could only get a print that would fully reproduce all we see in that negative"; and he went on to tell me that he was never able to get perfect reproductions of the finest gradations in his X-ray negatives. It immediately occurred to me that the surface image of Ensyna, with a very short fixing and no toning, ought to preserve detail and gradation that would not survive in papers differently treated. I asked to try the most difficult negatives he possessed, and succeeded in marking on Ensyna prints in which every particular of the negative was fully reproduced. It seems to me that for micro-photographs and X-ray work we have in this paper an excellent printing medium. In short, while I am unable to see that Ensyna adds anything to the armamentarium of the pictorialist, that of the technical photographer is enriched by its production.

THE HOLIDAYS: WHERE TO STAY AND WHAT TO SEE.—With the return of the holiday season, the comprehensive volume bearing the above title again reaches us, the present edition being fully up to the standard of previous years. It is divided into six sections, corresponding to the chief railway systems, each section containing—amongst a variety of other useful information—a list of hotels, boarding houses, country, farmhouse, and seaside lodgings; train, boat, and omnibus services, together with special particulars regarding tourist tickets, etc.; also a list of golf links, and brief notes on the towns and districts accessible by each route. The maps, which are very distinctly printed, are an important feature of the book, whilst the section "Where to Stay in London" will appeal to those visiting the metropolis. The book may be obtained at the railway bookstalls and from newsagents for the price of 1s., or direct from the publisher, Mr. Walter Hill, 67-69, Southampton Row, London, W.C., post free for 1s. 6d.

New Apparatus, &c.

The Dallmeyer Telephoto Calculator. Made by J. H. Dallmeyer, Ltd., Denzil Road, Neasden, London, N.W.

The suggestion made some time ago by Mr. Clifton at a meeting of the Royal Photographic Society—namely, to make use of a graduated tape in estimating the magnification given by a telephoto lens—

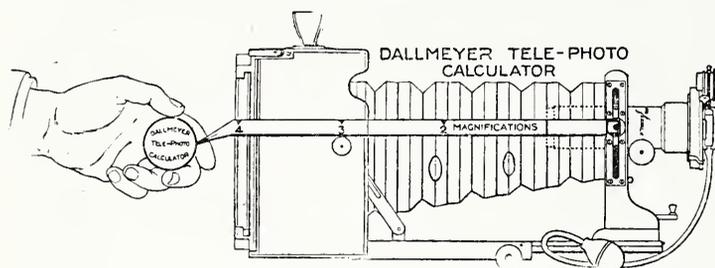

Fig. 1.

has been carried out in the very compact form represented by this little attachment. It consists of a spring stop measure, marked with a scale of magnifications corresponding with the negative attachment. The free end of the tape is provided with a small hook, which can be attached to the lens front, the camera extension thus serving to indicate at a glance the magnification at which the lens is working. The little accessory weighs a shade over one ounce, and, as shown in the second drawing, which is a full-size reproduction, may be carried in the waistcoat pocket. The reverse side of the tape is

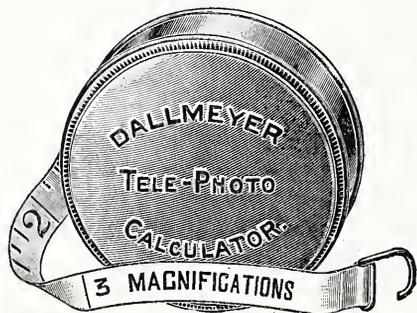

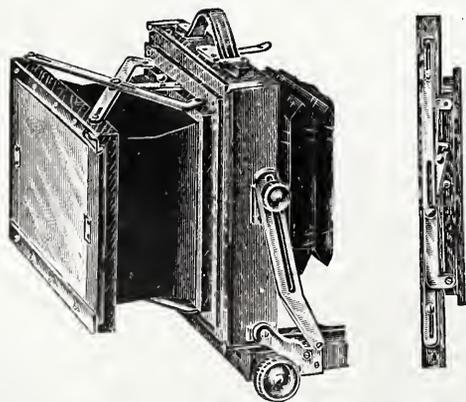

Fig. 2.

graduated in inches. In ordering the calculator it is necessary to specify the focal length of the negative lens, the distance from the back surface of the negative to the point on which the hook of the tape will be fastened, and also the approximate total thickness of the glasses composing the negative. Graduated for a particular lens, the price of the apparatus in brass is 2s. 9d. Additional scales may be marked at a cost of 1s. each, and a morocco case for the calculator is supplied at 2s. 6d.

LARGER NEGATIVES WITH MEDIUM SIZE CAMERAS.—In reference to the article last week by Mr. F. P. Renter, the Midland Camera

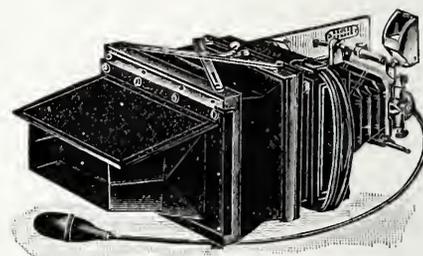

Model B.

Closed.

Company, Slaney Street, Birmingham, draw our attention to the adapters made by them whereby a larger plate may be exposed in

cameras of a given size. Thus, half-plate, 5 x 4, or postcard negatives by means of the adapter may be taken in quarter-plate cameras; whole-plate in half-plate. The adapter is made in two patterns, one in black wood, with nickelled fittings, and black leather focussing hood for hand cameras of the folding pattern, and in polished mahogany with brass fittings for stand cameras of the ordinary type. Perhaps the adapter most useful to our readers is the "B" model, fitting a half-plate camera, and including a whole-plate focussing screen and double dark slide. The price of this is 35s., extra double slides (whole-plate), 14s. 6d. No charge is made for fitting the adapter to cameras of standard make.

The second illustration shows the "A" or hand camera model, the adapter being provided with ground glass, with focussing hood, and single metal slide. The price of this pattern, to take postcard

Model A.

negatives in quarter-plate cameras, is 15s.; 20s. with double slide of the solid or pull-out pattern, with aluminium shutters. If extra slides are required they can be had in postcard size, at 2s. single, 6s. double, or in the half-plate size 2s. 6d. and 8s. 6d. For both amateur and professional purposes these adapters should prove of great service on many occasions, since their collapsible construction renders them very portable, whilst the anastigmat lenses now in universal use will suffice to cover the larger plate if stopped down a little, giving a considerable width of angle, or the single half of the lens may similarly be used to cover the larger plate.

CATALOGUES AND TRADE NOTICES.

PERFECT PRINTS ON SELTONA.—The Leto Photo-Materials Company, Ltd., 1, Crutched Friars, London, E.C., have just issued an eight-page pamphlet, written by Mr. W. L. F. Wastell, and describing the (very simple) procedure necessary in making perfect prints on Seltona paper. Dealers will find this a most valuable piece of literature to place on their counters. Mr. Wastell does not spare his praise of the excellent qualities of Seltona as a printing paper for amateurs, and rightly, too; the paper deserves all that is said of it. Supplies of the booklet are sent free on application to the Leto Company.

GEVAERT PRINTING PAPERS.—In issuing its first list of products Messrs. Gevaert, Ltd., have offered a few interesting particulars of the great factory at Antwerp where the papers are manufactured. The arrangement of the sizes of paper made and of the prices of the packets is very concise and easily referred to, and both users and dealers will appreciate the condensation carried out. Dealers, too, will note the facsimiles in colour of the Gevaert labels for P.O.P., C.C. bromide, and gaslight. The list is sent free on application to 26-27 Farringdon Street, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 14.

South Suburban Photographic Society. Excursion to Belvedere.

TUESDAY, AUGUST 17.

Handsworth Photographic Society. Council Meeting.
Kinning Park Co-operative Camera Club (Govan). Club Meeting.
Hackney Photographic Society. Questions and Answers.

Commercial & Legal Intelligence.

A BRIDGNORTH BANKRUPTCY.—Thomas Bromwich, photographer, Bridgnorth, Salop, appeared at the Shrewsbury Bankruptcy Court last week, with liabilities amounting to £337 12s. 2d., and put the deficiency at £302 5s. 1d. In reply to questions put by the Official Receiver, debtor said he began business thirty years ago, and at one time had an income of £600 a year, but in recent years he had not been so successful, and the takings declined to about £150, out of which he had to pay an assistant—required on account of failing sight—and to meet other expenses. The craze for picture postcards, he considered, to some extent, had been responsible for his undoing, as these took the place of carte and cabinet photographs. Debtor sold his furniture in December last, and out of the proceeds of £132 he paid several pressing creditors.

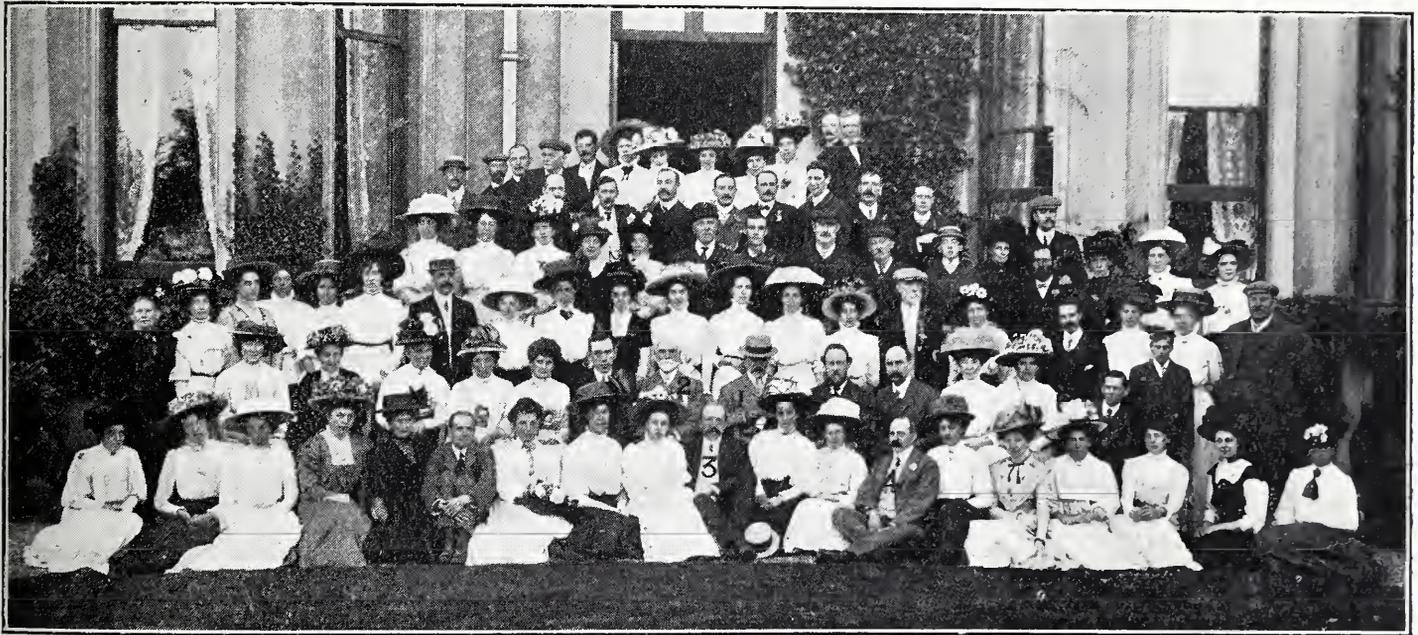

The Official Receiver (Mr. Cariss) remarked that it appeared to have been a case of "first come, first served." It would have been much better had debtor treated all his creditors alike.

The examination was formally adjourned for debtor to give an explanation with regard to the expenditure of a sum of £50 which he received on account of his furniture.

Roch, Paris; P. Azaria, 5, Rue Boudreau, Paris; J. Bariquand, 2, Rue A. d'Aubigne, Paris; and A. C. Bromhead, 5 and 6, Sherwood Street, Piccadilly Circus, W., manager to English branch. Private company. The number of directors is not to be less than two nor more than five. The first are: L. Gaumont, P. Azaria, J. Bariquand, and A. C. Bromhead. Qualification, one share.

News and Notes.

THE PLATINOTYPE CO. EN FETE.—They never do anything by halves at the Platinotype Co. When the whole of the staff spent last Friday at Eastbourne as the guests of the company, the company "did them well" from the early hours to little short of midnight. And they in turn entertained themselves and the company, not to mention one or two visitors representing the photographic press. Tired but happy they detained at Penge after seventeen hours of sunshine, laughter, and other forms of recreation. Somewhere in the seclusion of Penge, Surrey, the company's staff pass the major part of the year in turning out platinotype

Photograph by]

MAKERS OF PLATINOTYPE PAPERS.

[Weston & Sons, Eastbourne.

With the exception of the wives of several heads of departments and excepting also three photographic pressmen, all those figuring in the above group are engaged in the works of the Platinotype Co., founded thirty-five years ago by Mr. William Willis. The group was taken on Friday last in the grounds of the Grand Hotel, Eastbourne, on the occasion of the annual outing. The four persons numbered in the group are (1) Mr. William Willis; (2) Mr. John Willis; (3) Mr. W. H. Smith, Works Manager; and (4) Mr. W. E. Dunmore.

WATCH REPAIRER AND PHOTOGRAPHER.—At the Ashby-de-la-Zouch County Court, on July 30, an application was made for an administration order by John Goulson, watch repairer and photographer, 20, Belvoir Road, Coalville, who said his average earnings were from 20s. to 28s. a week, and he had a wife and two children, none of whom were earning anything. He attributed his position to slackness of trade, lack of capital, and keen competition. His furniture was the property of his wife, it having been purchased for her by her father ten years ago. He had no stock-in-trade, and his shop fixtures were valued at £5. His debts amounted to £42, and there were seven creditors, two having judgments against him, one for £13. He offered 9s. a month until 12s. 6d. in the £ had been paid. There was no opposition, and the application was allowed.

NEW COMPANIES.

GAUMONT COMPANY, LTD.—Capital, £12,000, in £10 shares. To cover the business of manufacturers of and dealers in cinematographic and photographic apparatus and appliances, carried on by Société des Etablissements Gaumont, under the style of the Gaumont Company, in Great Britain, India, and British Colonies and Dependencies. The subscribers are: L. Gaumont, 57, Rue St.

type papers from a factory which constantly grows in size. Once a year only do they appear before the public they serve so well, and then, alas for them, only to be made the butt of the photographer. We apologise to the many fair ladies for the scant justice done them in the engraving. It is only our absurdly prejudiced view that some curmudgeons of readers might object which restrains us from making them a series of full-page portraits.

RETURN OF PICTURES FROM THE DRESDEN EXHIBITION.—Mr. E. O. Hoppé, who has for two years past carried on the duties of English Commissioner for the above exhibition, asks us to announce that though in all other matters he continues to transact the business of the exhibition, all correspondence and business in connection with the return of the pictures will be undertaken by Mr. C. Wille, Deutsche Bank, George Yard, Lombard Street, E.C.

CINEMATOGRAPHY IN NATURAL COLOURS.—"The Tsar at Cowes," a new and brilliant series of animated pictures in the actual tints of nature, is now being included in the "Kinemacolor" exhibit at the Palace Theatre. Since the invention of the Urban-Smith system of bringing all the hues of the spectrum to the bioscope, no spectacle

has lent itself so readily to reproduction in colour as the splendid review in the Solent, and here is shown the complete pageant—from the approach of the escort of British battleships to the Russian Royal yacht, "Standart" (easily distinguishable by the double black eagle on the yellow standard flying at her mainmast), meeting the "Victoria and Albert" and coming to an anchorage with the Imperial armoured cruisers, "Admiral Makharoff" and "Rurik" immediately astern.

A PRIZE FOR CINEMATOGRAPHS OF BIRDS IN FLIGHT.—In connection with the International Aeronautical Exhibition now being held at Frankfurt-on-Main a competition has been organised by the Frankfurt house of the firm of Carl Zeiss, in which three prizes of 600, 300, and 100 marks will be awarded for the best series of photographs recording the flight of a bird. The photograph should show the different phases of flight and should contain the full period of movement on the one film. In making the awards regard will chiefly be paid to the number of exposures made within the period of movement of the wings, and also as regards the number of complete periods succeeding each other. Films which may be judged equal in these two respects will be further adjudicated as regards sharpness of the photographs. The films should be sent in not later than September 1. The competition is being arranged by Professor Grützner of Tübingen. Other judges will be announced later.

Correspondence.

- ** We do not undertake responsibility for the opinions expressed by our correspondents.
- ** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Will you kindly favour me by announcing in your next issue, if possible, that the address of the society is now 35, Russell Square, and that, although the house cannot be completely in order for some weeks, the dark-rooms will be so far arranged that they will be usable by the 16th inst.—I am, yours faithfully,

J. McINTOSH, Secretary.

35, Russell Square, London, W.C.,
August 9, 1909.

STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Referring to your comment on my letter in "Ex Cathedra," you remark that trimming is as wasteful as masking (we presume you mean when the masking is done to cover defects of centring. This we have never contested, as it is, of course, a simple fact, but the system we use—i.e., adjusting the separation of two plates until they come into the right fields of view—entirely obviates cutting, trimming, and even hacking of Autochrome stereoscopic work with a diamond, a procedure which the veriest tyro in stereoscopy would pronounce futile. No one capable of working glass could cut and pare stereoscopic pictures on plates correctly, except, perhaps, by some gauged mechanical grinding contrivance. However, these things we have no need to do—what we state we do—i.e., that not a grain of plate on paper is superfluously wasted in our process. We know that, given one fixed lens centre, plates may be adapted to get the correct amount of picture, but this is ridiculous, as no stereoscopist with any information on the subject will submit to confine his work to one only lens separation. In our process we fix our lenses at any separation of centres we feel is correct and suitable to the subject, we then proceed to adjust the plates until the centre of the object is central in both. Hence our contention that the cones of the fields of view are true, that there is no limitation of inter-lenticular separation, that there is no loss of

space in the finished print between the pictures through covering defects by masking, and for quickness, reliability, and accuracy it is the only process worth considering, especially for stereoscopic autochrome work. Hence our assertion that trimming (by which we include masking, centring, mounting, etc.) are time-wasting, obsolete worries, which render the general practice of stereoscopy unattractive and non-commercial, and may be relegated to that classification of things in which may be found the spectacle lens and cigar-box which we whittled out with a penknife to form a camera in boyhood days.—Yours faithfully,

9. Mary Street, Dublin.

August 7, 1909.

GILBERT DYAS.

TUITION VERSUS APPRENTICESHIP.

To the Editors.

Gentlemen,—One hears complaints of photographers' assistants of their want of efficiency and thoroughness in their work, but I am more and more convinced that the fault lies mostly in the present system of apprenticeship. I am not in the way of knowing so much of the young man's training, but with the girls my experience tells me that they have only poor chances of learning their work.

If a girl wishes to take up photography in serious fashion how can she gain a good all-round knowledge if, as an apprentice, she is kept only to the routine of mounting and spotting? She may probably give her services for a year or more, by way of payment, but she rarely gains adequate instruction in return for such payment, and the result are not satisfactory either to the budding assistant, the photographer who may employ her, or the public, if she eventually sets up a studio of her own. I write now to suggest that photographers should seek for pupils rather than apprentices, undertaking to give definite tuition in certain branches in return for a definite fee, using the studio and workroom as a technical school; and I should like to have the opinion of other photographers on the question.—Yours faithfully,

CAMERIST.

CARBON PHOTOGRAPHS.

To the Editors.

Gentlemen,—I have been much interested in the case heard at Southampton last week, and consider the public owes a debt of gratitude to Mr. S. G. Kimber, F.R.P.S., for his public spirit. Successful amateurs are proverbially of gentle manners and a retiring disposition, and many of them would not risk being pointed at, even in their own town, as "one of the best, if not the best, amateur photographers in this part of the country." The pity of it is that the general public, on whose behalf Mr. Kimber has risked this undesirable notoriety, don't care one straw what a picture is called, or how it is made, so that they like its appearance and get it cheap.

Q.

REVERSING PLATES.

To the Editors.

Gentlemen,—In your Enquiry column of last week there is an answer to "J.M.J.," who has been trying to make a reversed transparency in the camera by my formula, but failed. He says: "I used the exact amount of sulphuric acid in the potassium bromide, 5 per cent. dilution, make the difference between success and failure?"

Now if "J. M. J." has been using potass bromide instead of bichromate of potash, I am not surprised at his non-success. The reversing solution is:—

Bichromate of potash	100 gr.
Sulphuric acid	3 gr.
Water	10 oz.

This may be diluted for use with two to three volumes of water. The only difference between Carnegie's formula and mine is, that he uses the ammonium bichromate instead of the potassium, and advocates the exposure of the glass side of the plate towards the lens, which is always desirable.—Yours truly,

Thornton Heath,

August 10, 1909.

E. FENSI

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

A. Dean, 14, High Street, Rugby, Warwick. Two Photographs of the interior of the new Speech Room at Rugby School.

Photograph of the Hon. George Wyndham, M.P.

Photograph of Wedding Group, including the late Rev. C. Pickering Clarke, M.A., Vicar of Holy Trinity, Wimbledon.

Miss Norah Shelley, 16, Old Town, Clapham, London, S.W. Photograph of the late Rev. George Tyrrell.

Photograph of H.I.M. the Czar of Russia, H.R.H. the Prince of Wales, Prince Edward of Wales, and the Czarévitch of Russia. Photograph of Group of Their Majesties the King and Queen, the Czar and Czarina of Russia, the Prince and Princess of Wales, and their Families.

Frederick Beeston, 49, Bradford Road, Brighouse, Yorkshire. Photograph of the First Governors of Secondary School for Girls, Brighouse.

CHROMATE STAIN.—In making a thick bichromated film of gelatine on glass insoluble by the prolonged action of light, there remains after washing a greenish stain; could you kindly tell me in "Answers to Correspondents" if this can be removed and how?—A. EDGAR.

The stain can be removed by soaking the plates in a solution of sulphite of soda. Dilute hydrochloric acid may also be used for the purpose.

LOCAL-PLANE SHUTTER.—I have a reflex camera of unknown make (and no illustration in the advertisements in the "B.J. Almanac" shows anything just like it), half-plate size; I want to know how to find the speed of shutter, the milled knob which alters the width of slit also works an indicator with the figures: 10, 20, 30, 40, 50, and the T (for time); the tension spring also records at: 1, 2, 3, 4, 5, T (time), 6, 7, 8, 9, 10. When the slit indicator is at 10, the width of the slit is half-inch, can you tell me how to calculate the speed from these figures?—SPEED.

It is quite impossible for us to say from the above data what is the speed of the shutter. At the lowest tension and widest slit in is probable that the speed is from 1-10 to 1-20 of a second. Alterations in the width of the slit will give higher speeds in proportion to the width. We should advise you to make an exposure or two with lens at $f/6$ to see what combination of slit and tension will give you speed enough for moving subjects.

COPYRIGHT, ETC.—I should esteem it a favour if you would answer me the following questions, either through the "Journal" or by mail. 1. If a customer brings you to copy a photo taken by another photographer are you liable to proceedings for infringement of copyright? Ought the order to be refused? If the order is accepted and a form signed by your client releasing you from all responsibility for infringement you would, I presume, in case of an action, be held liable yourself, and you in turn would have to recover from your client, or would the letter of guarantee exonerate you? 2. If I photo some friends entirely free of charge and give them copies have I the right to use the photos without permission for advertising purposes, say on letter heads, or in pamphlet form, as specimens of my work, even if in some cases the sitters are not of age? 3. What is the method adopted in studios at home for hanging or fixing a number of backgrounds where space is limited? I mean a kind of holder for backgrounds in use. 4. How to avoid the straight dark line in standing portraits where the background touches the floor, when a continuous

foreground is not used? 5. What is the cause of reticulation of the film when a plate is intensified by the bichloride of mercury method, and why does the mercury not deposit the feathery crystals mentioned in the various formulæ? I have noticed that when the mercury does deposit the crystals the reticulation of the film seldom or never occurs. I, of course, add hydrochloric acid to the decanted liquid.—MERCURY, Shanghai.

1. Yes, certainly, if there is a copyright in the picture. If there is any doubt in the matter it is safer to refuse the order. The letter of guarantee will not exonerate you. You would have to recover from your customer. 2. Legally, yes, so long as the sitters are not held up to ridicule in any way. In any case it will be best to obtain their consent before making use of the photographs in the way you mention. 3. Assuming that you refer to backgrounds on stretchers, we should advise the plan described by Mr. W. Foster Brigham in the "B.J." December 15, 1905, p. 989. ("B.J. Almanac," 1907, p. 698.) A square stand or frame standing on two broad feet is provided with a series of three pairs of cross arms sticking out both back and front of the frame, each cross-arm having a series of slots cut in the upper edge to hold the projecting pins fixed to two opposite sides of the background stretcher. This is not easy to describe in words but you will see in a figure in the "Almanac." 4. One good way is to have a narrow piece of skirting board the same colour as the background to place along the floor. The upper edge of this may be chamfered off. 5. Non-deposition of the crystals can be due only to the quantity of bichloride not being sufficient to form a super-saturated solution, to omission to cool the solution made in hot water, or to not allowing a little time for the crystals to separate. Reticulation is most frequently caused by an extra strong mercury solution, but it sometimes arises from other (unknown) causes.

P.O.P. POSTCARDS.—Will you kindly inform me, through the medium of your paper, the cause of the yellowish markings on the enclosed cards?—L. A. F.

We should say that prints have been incompletely fixed. Evidently they have lain over each other in the fixing bath, as shown by the straight bands in which the stain is produced.

ALPHA.—We do not know of a list which can be called complete.

SPOTS ON C.C. PRINTS.—Could you inform me as to the cause of the enclosed prints fading as they have done? These had only been mounted four days, and were put away in a drawer after being spotted. If they were not quite dry, would that cause it? The prints were toned some in gold and some platinum. Those toned in the platinum were very thoroughly washed between baths and passed through an alkaline water before fixing, also well washed after fixing, dried and trimmed and mounted wet with starch and put away. Any reason you can give would be esteemed a favour.—TROUBLED.

Dampness immediately after mounting is one of the surest causes of such spots. It is advisable to put prints to dry in a warm place as soon as mounted. It does not seem to matter if they become damp afterwards, but immediately after mounting the print is very sensitive. As regards the working of C.C. papers, we advise you to turn to the "Almanac" of 1907, pp. 786-9, in which is a series of articles dealing with the cause of spots, etc.

SPOTTY BROMIDE PRINTS.—Would you be kind enough to let me know through your valued journal the cause of spots on enclosed bromide prints? It is carbon-surface paper. I have used it before and had splendid results until this last batch, of which I have used about three dozen pieces, and have not had one free from spots, some of them much more distinct than others. I develop with amidol, and fix in acid bath.—PERPLEXED.

It is uncommon to meet with these white spots. When they are not the fault of the paper (and it is rarely that they are), they are generally the result of dissolved air in the developer. Try soaking the paper in cold boiled water for a couple of minutes before pouring on the developer, and if that does not improve matters, hear what the makers can say.

H. W. GAULD (Brandon, Manitoba).—1. Yes, the consumption of current is very low. 2. Certainly, it is largely used here for that purpose and in the way you name. The largest firm of

enlargers here use it exclusively. 3. Fragility of the tubes and liability to go wrong. 4. Cooper Hewitt.

J. T.—1. A wood dish can be used, but it is not by any means as suitable because it is difficult to make it perfectly clean. We advise you to use porcelain. 2. The outlet limb of the syphon must be longer than the inlet. You had better fit the syphon tube to tank No. 2, and conduct the water from No. 1 into No. 2, either by a straight projecting pipe near the top of tank No. 1, or better by a syphon tube, the outlet limb of which is made to dip into tank No. 2.

VARIOUS.—1. What method do you consider best for shading off parts of prints, such as trousers of a full-length figure, or necktie? Dabbing on Prussian blue with finger or wool I find prints blotchy. 2. Can matt varnish be advantageously flowed over a second time, or more, with a view to increasing depth of shading, or can it be painted on with a brush and repainted? 3. In rubbing black powder on ground glass, if it is too thick in some places is there any way of getting off a part (except water) to even it over? 4. What is best for removing Indian ink lettering from negative film? 5. What is best for removing retouching medium and pencil from negative before intensifying it?—**OPAQUE.**

1. With the trousers they may be vignettted, and in the case of the necktie, dabbing with Prussian blue will probably be the best. It should not print blotchy if the work is skilfully done. 2. More than one coat cannot be successfully applied unless the first one is protected with some medium that is not solvent in it, such as albumen, gelatine, or gum. 3. The best way will be to wash it all off and begin again. 4. Soaking the negative for a time in water and then rubbing the ink off with cotton wool, or the finger. 5. Rub it off with turpentine or benzole on a piece of cotton wool.

MERCER BROS.—Both the lenses are excellent for cabinet pictures. It is quite against our rule to express an opinion on the comparative merits of different makers' apparatus.

PATENT QUERY.—I enclose sample of an autograph card which I am trying. These can be copied from any size photograph or taken direct from sittings. The method of producing them is entirely my own. What I want to know is, can I protect it in any way? If so, would you kindly tell me how to proceed?—**DAWES.**

The only thing you can do is to patent your method of producing the pictures, if it is original. We have seen many similar pictures before, but of course we do not know if they were made by the same method as yours. We should say that, commercially, the thing is not worth the cost of a patent.

O. B.—Apply to Doulton's, Lambeth, stating your requirements as to size and weight.

ROBERTS.—1. Certainly not, as you were not given any valuable consideration for taking the photographs. 2. Under the Copyright Act we do not think they can. You should have obtained the assignment of the copyright to yourselves in writing at the time of the sitting, or, failing that, have shown by the presentation of copies, etc., that the photographs were being made at your invitation. Still, we doubt if the parties can restrain you from making use of the photographs.

W. W.—We are much surprised that your local chemist could not supply you with the hypochloride of lime, and still more that he never heard of it. Had you asked for it under the name of chlorinated lime (which is the name given for it in the pharmacopoeia), or for chloride of lime, or bleaching powder, you would have got what you require. The nearest oilshop will supply it, if you ask for chloride of lime, or for bleaching powder—they are all one and the same thing, under different names.

G. F. J.—So far as we are aware there are no patents in existence relating to photo-ceramics. What have been taken out in connection with this branch of photography, so far as we know, have expired. That, however, will not preclude you from taking out a patent for a ceramic process, provided it is really new and novel—or even if it is a substantial improvement on what has been done before.

FAULTY LENS.—Will you please say if you think the lens with which the enclosed portraits were taken is at fault? It was sold to me as a whole-plate. It is three and a quarter inches dia-

meter, and seems to be about nine inches focus from the stops to the ground glass. There is no maker's name on it and is, by the appearance of the mount, a pretty old one. You will see that the corners are all very dark with no detail in them, though the centre of the picture is quite sharp.—**S. BROWNING.**

It is evident that the lens does not cover the whole-plate. It is not to be expected that a lens of the Petzval type of nine inches focus will take a whole-plate portrait sharp and well-lighted to the corners. We should imagine that the lens was made in the Daguerreotype days for the half-plate size, and judging from the examples sent it will do very well for that—for sitting figures. But by reason of the roundness of the field it will not do for standing ones unless it is well stopped down.

LANTERN.—1. There is no copyright in the Bartolozzi engravings neither is there in those of Hogarth, and you can reproduce lantern slides from them if you copy from the originals. But there may be copies of them in which there is a copyright, and you would get into trouble if you copied those. 2. To obtain permission to photograph any of the pictures in the National Gallery application must be made in writing to the Trustees. This is rarely granted to others than professional photographers who want the reproductions for publication purposes.

ALBUMEN PROCESS—I shall be greatly indebted to you if you will kindly enlighten me in the following: I am anxious to make some stereo transparencies by the albumen process. I prepared a dozen plates according to instructions given in an article in the "Journal" many years ago. They were evidently failures so they were at once cleared off. Then I made another dozen prepared according to a more recent one, which, by the way, does not differ much from the first, and acted strictly according to the instructions, so far as I am aware, but this last lot turned out just like the first—the film too thin. There was only a slight opalescence in it, and it would be impossible with that to get a picture. If an image (?) could be developed upon the plates, would, of course, be too thin to be of any use.—**J. BOWEN.**

If the plates were prepared according to either of the articles they are doubtless all right. The film of an albumen plate should be only slightly opalescent, much less so than that of a collodion one, and infinitely less so than a gelatine one. If you develop the plates you will probably find them all right.

VALUE OF RESIDUES.—I sent a parcel of waste to ——— they weighed three pounds and a quarter. They were paper ash residues from washing waters and from fixing baths, and were thoroughly dry. Will you please say what I should have received for them as I am very dissatisfied with the return made by the refiners?—**DISAPPOINTED.**

We cannot give any idea whatever, as the weight of the stuff is no criterion as to the amount of silver it contained. The only way of arriving at that would be to have made an assay. That were done before the residue was sent you would know exactly what should be received for it. We may tell you that the firm is a highly respectable one, and you may rely upon that you have got its full value. You must bear in mind that the price of silver at the present time is very low—only about 2s. an ounce for standard—and that got from photographic wastes is rarely up to that.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The "B.J. Almanac."—We would advise our friends who have any suggestions for the forthcoming issue that such should be addressed to us without delay. (P. 641.)

Mr. Thomas Bolas, in an article on p. 643, describes the results of recent researches on the properties and preservation of solutions of sodium sulphite.

Mr. Harry E. Smith has improved his process of toning P.O.P. prints to sepia without gold by means of thiomolybdate. He has worked out a bath of ammonium phosphate and carbonate, in which prints are immersed direct from the frame, after which they are fixed, and toned in the thiomolybdate. (P. 646.)

A writer in a German contemporary has called attention to the use to be made of stencils in the decoration of postcards in colour. While there is nothing really novel in the method, we give a description of the *modus operandi* on p. 645.

A review of the principles of the process of printing without light, given as catatype, and of the methods by which it is carried out is given on p. 647 from a recent treatise on the subject by Dr. E. Stenger.

A review of the principal features of the photo-mechanical section at the Dresden Exhibition appears under "Photo-Mechanical Notes" on p. 653.

Major-General Waterhouse has pointed out that a description of portable camera was given by Robert Boyle in 1669. (P. 642.)

The names of the Selecting Committee for the forthcoming Salon have been announced by the Linked Ring. (P. 641.)

The programme of lectures to be delivered at the New Gallery during the forthcoming exhibition of the Royal Photographic Society is published on p. 652.

The Royal Photographic Society has issued revised regulations as to the admission of members to the Fellowship. (Pp. 641 and 652.)

The gum process, enlarging apparatus, and print-trimmers compare with other inventions under "Patents of the Week." (P. 654.)

The demerits of an enlarging camera of "1,000-times power" are laudably insisted upon in a circular issued by a firm practising a variety of the free-portrait business. Our contemporary the "Star" as shown up this ingenious argument. (P. 658.)

Some notes on the chief precaution to be taken in the manipulation of collodion paper appear as an editorial article on p. 642.

EX CATHEDRA.

The Salon Selecting Committee.

Just too late for announcement in last week's issue we received the names of the committee appointed by the Linked Ring which is to undertake the selection of pictures to be shown at the forthcoming Photographic Salon. These are as follows:—

J. Craig Annan.	George Davison.
Fredk. H. Evans.	J. Dudley Johnston.
Walter Benington.	M. Arbuthnot.
F. J. Mortimer.	Reginald Craigie (<i>ex officio</i>).

It will be seen that the above-named gentlemen form a fairly well-balanced committee. Although no intimation is made of the fact, we hope that the Linked Ring continues to have the help of M. Demachy and his colleagues as regards the French work. In any case, we may say, for the information of pictorial workers here and on the Continent, that though the aim of the committee may prove to be at an advanced or unorthodox type of photographic picture, yet their work of selection will be done in a modest spirit, and the works of all comers will be considered for inclusion in the exhibition.

* * *

The "B.J." Almanac, 1910.

The receipt within the past day or two of several orders from dwellers away on the fringe of the Empire for copies of the forthcoming "B.J. Almanac" leads us to remind our friends at home that the preparations for the next issue of this publication are now being made. It may be mentioned that there are in the "Almanac" some 500 and more pages of letterpress, the production, revision, proof-reading, and indexing of which do actually give those responsible for it something to do in odd moments when more fortunate beings are basking in the heat of a long-expected summer. This apropos of the intimation that any suggestions or corrections, such as we greatly appreciate from our readers, should be sent in immediately, in order to permit of advantage being taken of them.

* * *

F.R.P.S.

It is satisfactory to find that the Royal Photographic Society, in revising the regulations relating to the admission of members to the Fellowship, have made a clean sweep of the greater part of the quite superfluous conditions, and at the same time have shown that their desire is to broaden the basis on which members may claim to be elected Fellows. They specifically include "professional" portraiture in the heads under which applicants may submit their qualifications, whilst technical and "process" applications of the camera are likewise emphasised as departments of photography for original or special work in which the Fellowship may be granted. Apart from the exact letter of the regulations, the intention of the Society appears to make it easier for persons of widely different qualifica-

tions to be admitted as Fellows. At the same time much depends upon the standard taken by the Admissions Committee, and again upon the view taken by the Council of its Committee's recommendations.

* * *

A Portable Camera in 1669.

According to a note by Major-General Waterhouse published in the current "Photographic Journal," the Hon. Robert Boyle, in addition to being the Father of Chemistry and the brother of the Earl of Cork—how one was expected to laugh at this chestnut of the professorial humorist!—must also be acknowledged as the inventor of the portable box form of the camera obscura. General Waterhouse has discovered a passage in Boyle's paper of 1669 on "The Systematic or Cosmical Qualities of Things," in which occurs a very quaint description of the formation of an image on a translucent screen by means of a lens. Boyle's theory of the action of a lens, though not altogether opposed to modern knowledge, reads very curiously in these days. It is that "there must be all day long in all parts of the air where this phenomenon can be exhibited, either certain effluvia emitted every way from the objects or certain motions of insensible corpuscles, which, rebounding first from the external object, and then from the paper, produce in the eye the images of these objects, so that the air is everywhere full of visible species, which cannot be intelligibly explicated, without the local motions of some minute corpuscles, which, while the air is enlightened, are always passing through it."

* * *

Trimming Prints Square.

When trimming down a large print, there is often a difficulty, in the absence of a big trimming shape, to make sure of all the cutting being done truly to square. In these circumstances it is useful to remember that if one corner of the print be cut or marked to a true right angle the other three corners may be obtained in correspondence by measurement. In doing this we work on the principle familiar to us from the days when we learnt our Euclid, that a rectangle has its opposite sides parallel and its angles right angles. If we make sure of one right angle, and secure the parallelism of the opposite sides, as we easily can do by measurement, we shall arrive at a proper rectangularity of the print. In other words, our method is to trim first the base line (parallel with an horizon or vertical line in the subject), and then the top line (opposite to the base), by measuring off at each end of the base line an equal perpendicular distance and cutting (or drawing) between the two points thus obtained. We have now to deal with the two ends of the print. For the first we lay off a perpendicular by very careful adjustment of the set-square to the base line, and this having been done, we again measure two equal distances along the base and top line respectively, and on joining the two points thus given we get the two right angles at each end of the last side.

* * *

Phosphate in the Sulphide Toning of P.O.P.

In the communication to the Royal Photographic Society, which we reprint on another page of this issue Mr. Harry E. Smith has recorded a further improvement in the use of his thiomolybdate method of obtaining pleasing sepia tones on silver print-out papers. It is now directed to place prints before fixing (that is, from the printing frame) in a solution composed of ammonium phosphate 10 per cent. solution, three parts, and ammonium carbonate solution, made as given in the paper, one part. After ten minutes in this bath prints are transferred to the hypo bath, to which is added a fair dose of ammonium carbonate, and then, after washing, are sulphide-toned simply by immersion, without bleaching, in the prepared thiomolybdate bath. The

advantage of the preliminary phosphate bath is that the high-lights of the prints are kept pure even when exposed under trying conditions. Even without the bath many papers will show no deterioration in this respect in ordinary circumstances, but the very simple use of the alkaline phosphate bath, in conjunction with the hypo made up with ammonium carbonate, is an improvement in the method and should further recommend it where a permanent, but at the same time cheap, sepia tone is needed on P.O.P.

A NOTE ON THE COLLODIO-CHLORIDE PROCESS.

THERE can be no question that the collodio-chloride process of photographic printing is more extensively employed on the present day than ever before. Some look upon it as being a comparatively new process, whereas it is a very ancient one. As a matter of fact, it was invented and published by the late Mr. G. Wharton Simpson, then editor of the "Photographic News," in the year 1865, but, like some other good processes—for example, platinotype and carbon—it lay practically dormant for many years. We should like to think that such should be the case it is a little difficult to conceive, but so it was.

The C.C. process, while it yields most excellent results, is also a very simple one to work, and the pictures obtainable by it are not surpassed by those of any other silver process. Moreover, they are as permanent—theoretical, more so—than direct silver prints by other processes. A certain Scottish photographer, now deceased, used C.C. in his business from about the time of its introduction to the time of his death, and he told us a few years ago that he had not known of a case of his pictures fading. The paper he used, from the first, he obtained from Germany. During the last few years, however, we have heard of cases of deterioration of C.C. prints, and of their showing spots, etc., within a brief period, and therefore it will be well to inquire as to the probable cause.

It may be as well to mention here that the collodion emulsion will not adhere to quite plain paper, as it tends to split or peel off, hence a substratum is necessary. That used by the inventor, Mr. Simpson, and the earliest workers was arrowroot, and the paper employed was the Saxony Rives, as then used for albumenising. Now the papers used are substratumed by the makers, similarly as are those used for gelatine P.O.P.s, and the raw papers are not of the same quality as those just alluded to. Of course, the pigment used in the surfacing may be quite inert, but it must be kept in mind that it has to be mixed with a medium to fix it to the paper. If that be one that contains a compound with the free nitrate of silver, which is essential in this process, it may possibly have some influence on the stability of the prints. The paper being a less pure kind than that first used is of minor importance, as the sensitive film is practically insulated from it by the substratum.

The old collodion prints that have withstood the test of time—some forty years or more—were toned in the gold sulphocyanide bath, which yielded excellent tones as permanent results. Of late years, however, a method of double toning has been introduced, with the view of obtaining colder and blacker tones than are given by gold sulphocyanide alone. This is by first toning them to a certain depth in a gold bath, and subsequently continuing the toning in a platinum solution. Excellent tones are obtained in this way which could not be got with gold toning alone. It is a noticeable fact that in the majority of cases of deterioration that have been brought to our notice, this has been the method of production. No doubt it would seem that there is nothing that should have a deleterious effect in depositing a certain amount of

platinum on a gold-toned print, seeing that both metals are the most stable of all. It is in the manipulation, we think, that the want of stability must be sought for.

Let us now look at the way the compound toning is carried out, according to the formulæ issued with the different papers. For the gold toning any of the well-known baths can be used, such as the acetate, borax, or sulphocyanide, the carbonate, etc. There is nothing in any of these baths that need be suspected. But when we come to the formulæ for the platinum baths, it will be found that all of them contain an acid. Indeed, an acid is necessary in all platinum toning baths, and in liberal proportions, too. The following is the formula for the platinum bath issued with a well-known brand of paper, and it is almost identical with one given with another well-known paper. It stands thus:—

Potassium chloroplatinate	12 grs.
Citric acid	180 grs.
Water	20 oz.

In some other formulæ phosphoric acid is given in place

of citric. In any case, the prints, when they are taken from the toning solution, contain a considerable amount of free acid. It is here, we surmise, the trouble arises when prints are found to deteriorate. If this acid is not completely removed from the prints before they are put into the hypo solution sulphur will be set free in the paper, and, as one may fairly assume, may sooner or later act injuriously on the pictures, since, after all, the actual foundation of the image is silver. We have little hesitation in saying that when the C.C. process is worked with care—particularly when platinum toning is employed—it is one of the most, if not the most, permanent of all silver printing-out processes. But with perfunctory manipulation it may be different, as the pictures when finished may contain within themselves the elements of their ultimate decay, particularly if they are exposed to continual moisture. A trouble sometimes heard of with regard to this process is that the prints after mounting show spots, and the remedy suggested for this is to dry them quickly after mounting. This remedy tends to show that the evil remains, but is held in check by the absence of moisture in the prints.

SODIUM SULPHITE AND ITS PHOTOGRAPHIC USES: OLD FACTS AND NEW RESEARCHES.

THE June issue of the "Journal of the Chemical Society" contains a long and detailed account of a research on "Sodium Sulphite and its Equilibrium with Water," the authors being Messrs. H. Hartley and W. H. Barrett. Our account of this paper may be usefully prefaced by short notes as to the leading uses to which sulphite of sodium has been applied in connection with photography, and these notes may be supplemented by practical considerations arising out of the paper.

As far as I am aware, the earliest definite recommendation to use sodium sulphite as a constituent of the developer came from M. Carey Lea, of Philadelphia, in 1880, or twenty-nine years ago. The ferrous oxalate developer is one of the many methods of working which we owe to M. Carey Lea, who was one of the leading investigators in the mid-photographic period, the original instructions for the preparation of a ferrous oxalate developer being a part of two sequent articles on "New Developers and Modes of Development" which Lea contributed to the "B.J." during 1877, the articles being on pages 292 and 304.

In the course of these articles on "New Developers and Modes of Development" there is much which has since been "rediscovered," more especially as to acetone and as to the possible use of sodium sulphite as a substitute for an alkali, but at this stage Lea made no definite recommendation of sulphite. He then realised certain facts in relation to sulphite, but he does not appear to have then recognised the practical value of a sulphite as a preservative of the developer, but a recognition of the practical value came three years afterwards, or in 1880.

Carey Lea's Sulphite Developer of 1880.

This was a ferrous oxalate developer containing sodium sulphite, and as it is an admirable developer for under-exposures, it may be worth while to quote the instructions given for its preparation on page 292 of the "B.J." for 1880. Potassium oxalate, 440 grains; Sodium sulphite, 60 grains. Dissolve in as much hot water as will make six ounces, and then add 160 grains of ferrous sulphate. Shake until solution is complete. This is stated to keep better than the plain oxalate developer. Lea mentions the keeping of a sample for a month, and it was still good.

Berkeley's Sulphite-Pyrogallol Developer.

I well remember Mr. Herbert B. Berkeley at the Technical Meeting of the Photographic Society of Great Britain (now

"Royal"), that was held in January, 1882. Mr. Berkeley held in his hand a bottle of pyrogallol developer containing sulphite. This developer had been prepared eight months previously, and it was still good. The advantages which Mr. Berkeley claimed for sulphite were that it not only protects the pyrogallol (pyrogallol acid) from oxidation, by virtue of its remarkable power of first seizing on the free oxygen, but also that it acts as a preventive of the brownish-yellow stain which up to that time had been a notable disadvantage of the "pyro" developer.

In the following number of the "B.J." (January 27, 1882) there was a leading article on the subject, together with a long account of Mr. Berkeley's experiments. From this time forward the use of sulphite of soda, as an addition to the developer, became general.

Abney's Use of Sodium Sulphite for Fixing Prints.

The hyposulphite of sodium (as it is popularly called) has a bad name as a fixing salt, and Sir William Abney has pointed out that a solution of sulphite of sodium has sufficient solvent action on silver chloride and on other insoluble salts of silver to make sodium sulphite a satisfactory fixing agent for silver prints. The sulphurisation of the print is impossible when pure sulphite of sodium is used, and the method is in all respects satisfactory if the sulphite is reasonably free from sulphate and other impurities. Any considerable amount of sulphate (5 per cent. or more) materially reduces the solubility of the silver chloride. For use, one part of the crystallised sodium sulphite should be dissolved in 4 parts of water, and a quart of this should be allowed for each sheet (18 x 25) of paper, double the time being allowed that is required for the apparent disappearance of the silver chloride. Considering the busy and superficial tendencies of our time, this method of fixation is not likely to come into general use.

The Recent Researches of Messrs. Hartley and Barrett.

In the opening section of the paper, references are given to the principal investigations on sodium sulphite, and apart from the true or anhydrous salt, mention is made of the two crystallised hydrates: the hepta-hydrate, or usual commercial crystallised form, $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$; and Muspratt's deca-hydrate, which

is only formed under exceptional conditions, and has no industrial importance.

A method is then described by which the anhydrous form, Na_2SO_3 , may be obtained in a condition of complete purity. Into a solution of pure sodium carbonate of suitable and known strength a current of sulphur dioxide was passed until the increase in weight showed that the conversion into sodium-hydrogen sulphite was complete; whereupon a quantity of sodium carbonate solution equal to that originally used was added. On heating to a temperature a little over 100 degrees Centigrade, the anhydrous salt was deposited, and a further yield was obtained by evaporating the solution in a stream of hydrogen. The various precautions that were taken need not be detailed, but the notable fact is that the sulphite was obtained completely free from sulphate: further, it appears probable that by slightly modifying the method, a commercial product might be obtained of high purity and nearly free from sulphate, the presence of sulphate being more than a mere loss of strength, as sodium sulphate retards development in a remarkable manner, more especially in the case of thickly coated plates.

Our authors find that the completely pure and really anhydrous sodium sulphite does not suffer deterioration by oxidation provided that moisture is excluded, although the usual crystals (hepta-hydrate) oxidise very readily in the air. Here we have confirmation of the view put forward by MM. Lumière and Seyewetz that the only hope of accuracy in the photographic use of sodium sulphite rests in the employment of the anhydrous salt.

Tables and curves showing the solubility of the modifications of sodium sulphite, and certain physical characteristics of the solutions, form the main portion of Hartley and Barrett's paper, but as far as photographic work is concerned it may be sufficient to give the following particulars.

Solubility of Sodium Sulphite.

The solubility of the anhydrous or true salt varies very little with the temperature, but the solubility of the crystallised (hepta-hydrate) increases rapidly as the temperature is higher. Thus a saturated solution prepared at a temperature of 37.2 Centigrade (98.9 Fahrenheit) contains 44.08 parts by weight of the true or anhydrous sulphite in association with 100 parts by weight of water. If instead of this we take a solution saturated at 18.2 Centigrade (64.7 Fahrenheit), the composition will be 25.31 of the true sulphite, and 100 of water.

As 64.7 F. may be looked upon as sufficiently near to the "ordinary temperature," we may take it that according to the determination of Hartley and Barrett a saturated solution prepared under usual conditions will contain 4 of water and 1 of true sulphite, or 3 of water and 2 of the crystallised sulphite. Is it necessary to remind the photographic reader that the really pure crystallised salt, $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$, consists of equal weights of true sodium sulphite and of water?

Ambiguity in Prescriptions when Sodium Sulphite is Ordered.

Considering the above-mentioned fact, it appears highly desirable that when sodium sulphite is ordered in a photographic prescription, it should be stated whether the true anhydrous salt is intended, or whether the crystallised (hepta-hydrate) is intended. Failure in this respect often causes uncertainty: indeed, not only uncertainty, but error in copying, as the copyist may halve or double, according to his estimate or guess of what is intended.

I much like the definite and luminous way of putting the case adopted by Mr. Boursalt:—

Metal	50 grs.
Hydroquinone	25 grs.
Sulphite of soda, anhydrous	$\frac{1}{2}$ oz.
(or crystals)	1 oz.
Water to make up to	20 ozs. (fl.)

Defects of Commercial Sodium Sulphite.

Those of importance are:—

1. Presence of sulphate. This may be due to the use of sodium carbonate containing sulphate in the original preparation of the sulphite; or it may be due to the subsequent oxidation of the sulphite, but in most cases it may be conjectured that both causes contribute to the defect. As far as my own experience goes, the very best commercial specimens of sodium sulphite contain about 3 per cent. of sulphate, while the bad specimens may contain as much as 60 per cent. Quite apart from the fact that the presence of sulphate necessarily involves a deficiency of sulphite, the sulphate itself is a disturbing factor in development, and in other uses of the salt. Sulphate of soda withdraws water from wet gelatine, and prevents dry gelatine from swelling, but it does not permanently harden the gelatine. Valuable as it may be as an addition for retarding development, its unrecognised presence is a disturbing element.

2. Deficiency in true sulphite. This fault is a necessary consequence of any impurity; but it is important to remember that the crystals may show the correct amount of sulphite on titration or volumetric testing, and yet the sample may be short of ideal, as the crystals may have been somewhat over-dried. In other words, we may have a product containing some eight per cent. of sulphate, which shows the correct amount of sulphite on titration, by reason of some of the water of crystallisation being driven off. If this is done by heat, and under certain conditions, the crystals scarcely show any trace of efflorescence. This fact may account for statements which have been made as to the almost theoretical purity of samples which proved to be unsatisfactory on subsequent examination.

3. Water in sodium sulphite sold as anhydrous. Such samples as I have examined have not been so defective in this respect as to merit reproach, two, or even three or four, per cent. of water being so small an amount as not to interfere to an important extent with the uses or keeping qualities of the compound.

The Testing of Sodium Sulphite.

Many short instructions for testing sodium sulphite have been given, but instructions sufficiently detailed to be really and fully useful to the ordinary practitioner would involve rather a long special article. It may, however, be mentioned that a careful and observant person may form a tolerably just notion of the value of a sample of sodium sulphite by dissolving a few grains in water, adding barium chloride together with a moderate excess of hydrochloric acid which has been proved to be free from sulphuric acid. Really pure sodium sulphite would give no milkiness, turbidity, or deposit under these circumstances but really pure sodium sulphite is non-existent as a commercial article, so in practice the opinion must be based on the amount of the deposit, not on its presence or absence.

An Ideal Sodium Sulphite, Fully Protected Against Oxidation.

The experiments of Messrs. Hartley and Barrett suggest the practicability of putting a really pure sodium sulphite on the market, or, if not pure, at least of constant or invariable quality. A pure or constant sulphite would be of secondary value if packed in such a way as to make deterioration a possibility, and the sealed tube method of protection, a method which has of late come into extensive use for certain pharmaceutical and other commercial products, suggests itself as safe and convenient, also as not too expensive considering the advantages. A cardboard box containing four sealed tubes, each including two ounces of the anhydrous sulphite, would be equivalent to one pound of the crystallised salt. The sealed tube now generally used for therapeutic preparations has an extended parallel neck, easily cut off by making a file scratch, and the cut-off part can be closed by a small rubber cap.

THOMAS BOLAS, F.C.S., F.I.C.

THE USE OF STENCILS IN THE DECORATION OF POSTCARDS.

[The current issue of "Das Bild," the monthly journal of photography issued by the Neue Photographische Gesellschaft, of Berlin, contains the following notes illustrating the ornamentation, by application of colour and jewelling powders, of a bromide postcard which, in its ornamented state, is presented as a supplement. In the absence of this original, we have made a wash reproduction, which will serve to show the parts to which the respective colours are applied by means of the stencils.—Eds. "B.J."]

BEFORE proceeding with the making of the stencils, by means of which colour is applied to considerable numbers of postcards,

follows that the simplest means of securing the effect should be employed in order to reduce the series of operations on the large scale to the fewest possible. A coloured original having thus been produced by hand, the next step is the cutting of the stencils, by aid of which comparatively unskilled labour will be able to produce a similar effect. The stencils themselves may be cut from the commercial semi-transparent stout tracing paper, or the latter prepared by soaking a well-sized writing-paper with linseed-oil varnish, hanging it up to dry over-night, so that the excess of varnish can drip off. The paper should be

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

employed whilst it is still somewhat tacky and transparent. If kept too long, the paper assumes an efflorescent appearance, and becomes less transparent, in which state it is obviously less suited for its purpose. A second important point in cutting the stencils is to use a sharp stencil-cutter's knife of hard steel, a sharply cut stencil being essential to the success of the process. The stencils having been cut in the manner shown in the drawings, it is well before varnishing them to make a trial on a piece of card, in order to see that they have been cut in proper register. They are then varnished with a preparation made from

a specimen should be suitably coloured by hand in order to gain an idea of the effect required. In doing this, it naturally

brown shellac dissolved in spirit. The mixture must be made up of fair consistency, otherwise several applications are necessary. Two should suffice if the varnish is properly prepared. The test-card having proved to be in correspondence with the effect desired in the decorated print, the worker is in a position to commence operations. For this purpose the stencilling brushes specially manufactured should be employed, the excellence of the results depending to a great extent on the use of the proper tools. The colours employed are the aniline dyes obtainable for the special purpose of colouring bromide prints.¹ A moderate amount of colour is taken in the stencilling brush, a stencil laid in register on the print, and the latter taken over the portion left exposed by the stencil with, as far as possible,

¹ A series of colours specially prepared for the decoration of bromide prints is made under the name of "Bertha" by the Vanguard Co.—Eds. "B.J."

a circular motion. Excess of colour in the brush has the effect that the dye runs under the stencil. Each brush should be kept for its special dye, since traces of one colour left in the brush will impair the purity of another applied with the same brush. The chief masses of colour are first applied, and then, without the aid of a stencil, the brighter red of the lips and other points of bright colour—such as flowers, etc.—applied with a finely pointed brush.

The "jewelling" of cards is a form of decoration very largely employed at the present time, and is done by means of a suitable gold or silver bronzing powder which is caused to adhere to spots on the print which are made with a pointed glass rod dipped in fish-glue solution. The jewellery powder, being immediately dusted on to the print, adheres to points thus treated.

R. HABICHT.

THE SULPHIDE TONING OF P.O.P. PRINTS.

(A Paper in the current "Journal" of the Royal Photographic Society.)

As mentioned in a previous communication, P.O.P. prints may be toned by sulphiding with compound thio-salts, such as thio-molybdates and thio-tungstates, and rich tones result. The process, as already stated, is to fix first, and then wash the prints, afterwards sulphiding them.*

Tests of Sulphide-toned P.O.P.s

I stated in my previous notes on the subject ("Photographic Journal," June, 1908), that I did not think it necessary to wash the prints before fixing, though I pointed out that it might be done as a measure of precaution, and that the soluble silver salts in the prints might be converted into haloid salts of silver by the usual methods, such as a bath of sodium chloride. I further said that I had found it difficult to trace any subsequent difference in the purity of the high-lights, in prints washed and not washed before fixing. While this is so for a considerable time, subsequent severe tests with different brands of P.O.P. papers (prolonged exposure to bright sunshine, and keeping the prints in the atmosphere of a chemical laboratory for a year) show that there is a difference, more with some papers than with others, and therefore there is room for improvement here. For preventing subsequent yellowing of the high-lights, sodium chloride gives good results; but it seems in many cases to have a not altogether desirable influence on the final tone.

I have recommended that it was a safe plan to wash the prints before placing in the sodium chloride bath, as well as giving a wash after this bath and before fixing. Whatever opinions may be held on this point, it is, I think, fortunate that further experiments have shown that a bath may be substituted for the sodium chloride, which certainly renders these two washings unnecessary; so that one eliminates the possibility of subsequent yellowing of the high-lights, owing to the first washing water not being changed as quickly as possible. Where a preliminary wash is given, if this point is not attended to, "It is then that the greater part of the mischief is done," to quote from "Photographic Printing Processes," by the late Mr. Hector Maclean.

A Preliminary Phosphate Bath.

After trying many baths, I consider that a 10 per cent. solution of ordinary sodium phosphate (Na_2HPO_4) is better than the sodium chloride bath; or a bath of 5 per cent. strength glacial phosphoric acid (crystal) may be used. These methods seem satisfactory; but in both cases a wash before fixing is necessary, which makes the process rather long; and I thought

it advisable to endeavour to find a bath into which the prints could be placed direct from the printing-frame, and then direct from this into the fixing-bath.

If the silver nitrate in the print is converted into silver phosphate by a bath of ordinary sodium phosphate, the reaction is:—

so that here (to quote from Roscoe and Schorlemmer) we have the fact of two neutral or slightly alkaline solutions, when mixed, yielding a strongly acid liquid. This renders a wash before placing in the fixing-bath necessary in order to avoid decomposing hypo in the print. To avoid this wash, I was led to try ammonium orthophosphate $(\text{NH}_4)_3\text{PO}_4$ with which (putting on one side all consideration of the organic silver compounds in the image) the reaction may be presumed to be—

Silver phosphate is to some extent soluble in aqueous ammonium nitrate. A bath of ammonium phosphate, therefore, would appear to be very suitable for treating P.O.P. prints with, direct from the printing-frame, since it combines with the free silver nitrate in the print without forming any free acid, the products of the equation being silver phosphate and ammonium nitrate, so that this first bath of ammonium phosphate not only converts the silver nitrate into a salt very easily fixed out, but probably to some extent fixes it out at the same time, though not entirely so, as, in the test tube, dilute solutions of silver nitrate and ammonium phosphate of course give a precipitate, the solvent action of the ammonium nitrate not being great enough to prevent the separation of the silver phosphate. If, however, the ammonium sulphate solution be made alkaline with ammonium hydrate, the precipitate first formed is quickly and entirely dissolved.

The Use of Ammonium Carbonate with Phosphate.

Instead of using plain ammonium hydrate to render the ammonium phosphate solution alkaline, it is advisable to go one step further, and use a solution of ammonium carbonate. The use of ammonium carbonate in this connection was first advised by Mr. J. Spiller, and Sir William Abney refers to this fact in his Treatise on "Photography" (Tenth Edition, page 205) where it is stated that ammonium carbonate dissolves out certain compound left in the whites of the print, otherwise insoluble, and which readily decomposes under atmospheric action.

The solution of ammonium carbonate that can be recommended is that commonly found on the reagent shelf, made up

* Without bleaching.—Eds. "B.J."

as directed in Clowes' "Qualitative Analysis," viz.:—400 grammes of solid ammonium carbonate is dissolved in three-fourths of a Winchester quart of cold distilled water, and when dissolved the remaining fourth part of the Winchester is filled up with .880 ammonium hydrate. Ammonium carbonate has also the further advantage of being a good solvent of silver phosphate. (A Winchester quart bottle contains about 2,400 ccs.

The presence of the ammonium carbonate does not appear to interfere with the conversion of the silver nitrate into silver phosphate, for if in a test tube one adds to a solution of silver nitrate a solution consisting of aqueous ammonium phosphate of 10 per cent. strength, to which has been added a third part of its bulk of the reagent ammonium carbonate solution, the yellow precipitate of silver phosphate at once comes down. A very little excess of the reagent, however, is required to dissolve up the precipitate to a clear solution, which augurs well for the efficient clearing out of the silver nitrate from the print. As the print after ten minutes in the ammonium phosphate and carbonate bath is, of course, quite alkaline (and one finds in the test tube, on adding hypo to a clear solution of silver phosphate in alkaline ammonium phosphate solution as above, that the solution remains perfectly clear), there would seem to be no chemical reason for washing prints that have been treated with the alkaline phosphate bath before placing them in the hypo.

Formulæ and Working Directions.

I have not yet found any difference in prints washed after this phosphate bath and those put into the hypo direct; the prints being exposed to bright sunshine, with a portion covered with black paper, so that any slight change in the purity of the high-lights or the tone may be more readily noticed. The process that can be recommended, therefore, is to put the prints straight from the frame into a bath composed of:—

Ammonium phosphate (10 per cent. solution) 3 parts.

Ammonium carbonate (reagent solution) 1 part.

This bath is allowed to act for ten minutes, and the print

is then transferred direct to the hypo bath, which is of the following composition:—

Hypo (three ounces to the pint of water) 4 parts.

Ammonium carbonate (reagent solution) 1 part.

After fixing for fifteen minutes the print is thoroughly washed for one hour, and then sulphided with the "Cubrome" thio-molybdate solution. The addition of the ammonium carbonate to the hypo makes certain of its work in dissolving the white compound, mentioned by Mr. J. Spiller, being completely carried out, and also precipitates any calcium in the tap water, with which hypo solution is usually made up, so that there is no risk of calcium phosphate being formed in the substance of the print. In making up the ammonium phosphate and carbonate bath it may be advised to dissolve the ammonium phosphate in its proportion of water and then add the carbonate solution to this. It will be noticed that the ammonium phosphate, unlike sodium phosphate, generally makes a clear solution with tap water until the ammonium carbonate solution is added. Possibly this is because any calcium phosphate formed with the calcium carbonate in the tap water is kept in solution by the by-product of the equation (ammonium carbonate), in which calcium phosphate is rather soluble.

It is true that on addition of the ammonium carbonate reagent solution the free ammonium hydrate in it causes a slight milkiness, probably owing to the separation of the calcium as hydrate; but this may be disregarded, though, of course, it may be avoided by the use of distilled water.

In making up the hypo bath, it will be noticed that the addition of the ammonium carbonate solution causes a slight milkiness; but there would appear to be no necessity whatever to filter the hypo because of this, as it is quite harmless, and generally very slight.

Even if any calcium phosphate were formed in the substance of the print, when this is placed in the hypo bath, which would seem very unlikely, it would not stop there long, calcium phosphate being very sensibly soluble in the ammonium carbonate solution.

HARRY E. SMITH, F.R.P.S.

PROCESSES OF CATATYPE PRINTING.

I.

[Although little is heard of the commercial development of the catatype process invented some eight years ago by Professor Ostwald and Dr. O. Gros, there is still evidence that these methods of preparing prints from negatives without exposure to light are engaging attention from experimenters, and, therefore, the very useful review of catatype methods, written by Dr. E. Stenger in the work recently published by Knapp, entitled "Moderne Photographische Kopiervverfahren," may be translated in an abridged form as showing the principle of the method and the difficulties encountered in bringing it to the commercial stage.—Eds. "B.J."]

PROFESSOR OSTWALD and Dr. O. Gros, of Leipsic, were the first to apply in the year 1901 (patent of November 18, 1901) the well-known phenomenon of catalysis to the making of prints from photographic negatives, calling the process itself catatype. By catalysis chemists understand the quickening of a chemical change by means of the presence of a body which remains unaltered at the end of the reaction. Ostwald and Gros took the view that light does not actually give rise to the change in photo-sensitive films, but that it acts in a certain way as a catalyser only, causing the change to take place in a short time, whilst without the action of light a much longer period would be required. Photographers will see at once that the fog which takes place in dry plates unexposed to light, the change in printing-out papers and the spontaneous insolubilisation of bichromated gelatine films are examples of this theoretical view. As already said, these changes do not take place so quickly as when the materials are exposed to light, but proceed slowly, and require time for an appreciable effect. Among the catalysing

bodies known to chemists platinum takes a prominent place, whilst the silver formed on photographic negatives behaves similarly. The catalysing action of finely divided silver in the presence of gelatine and a bichromate has already been pointed out by Howard Farmer as far back as 1893.

The Medium in a Catatype Process.

We may turn at once to the concrete case in which the silver of a negative acts as a catalyser. In this instance the silver must act with the greatest degree of speed on a body with which it is brought in contact. In those places where silver exists in the negative the body which comes in contact with the latter is altered, whilst in those in which the negative is clear glass the body will remain unaltered. If this unaltered body which forms the medium between the negative and the printing film acts chemically upon the latter, there will thus result an action in those places where a portion of it is left unaffected: that is to say, where there is little or no silver, to an extent propor-

tional to the freedom of the negative from silver. Where in the ordinary printing process the light passes unobstructed through the negative, and produces an action on the film of the printing medium, there, in the catatype process, the residue of the body is left unaffected by the negative. The body which in the catatype process plays this part is a solution of hydrogen peroxide, a substance which is closely allied to water, but possesses a larger proportion of oxygen, so that in contact with metallic silver it is decomposed into oxygen and water.

Possible Catatype Methods.

In other words, a negative, the film of which is treated with hydrogen peroxide, contains this substance in its unaltered form only in those places which are free, or almost free, from a silver deposit; that is to say, a negative so treated contains in itself an invisible positive image consisting of hydrogen peroxide. If this invisible image of hydrogen peroxide is brought in contact with the reagent capable of reacting chemically with the peroxide there must result a positive print without any action of light in a way comparable with the taking of an impression on paper from an inked plate. The production of a print in this way may be explained as follows:—The gelatine film of the printing paper may have in it a substance which under the influence of hydrogen peroxide is converted from the colourless form into a highly coloured modification. A process may also be based on the fact that a soluble dye existing in the film may become insoluble, and the production of the print may therefore be based on the removal by washing of the soluble compound. In contrast with this direct method there are others which are indirect. If the hydrogen peroxide acts on a gelatine surface containing no added bodies it diffuses into the gelatine, producing there an invisible positive image of hydrogen peroxide, which may be developed in various solutions containing such colourless or coloured salts which, in conjunction with the peroxide, give rise to insoluble coloured bodies. The invisible image of peroxide is thus converted into the coloured image at the same time that it is itself destroyed. There are thus two distinct methods of working out the catatype process; the second is that which has proved to be the most adaptable in practice, in addition to which catatype has also proved to be applicable to the making of pigment prints. In this case it requires a printing film of gelatine containing a colouring matter, with which is mixed a substance which under the influence of the peroxide penetrating the film becomes altered in such a way that it tans or hardens the gelatine; in other words, plays the part which light does in the ordinary printing process.

Without attempting a detailed review of the voluminous patent literature relating to catatype, we may attempt to show what are the scientific principles upon which a number of the improvements which have been made are based, particularly as regards the reduction of the process to a form of practical and commercial value. The early experimenters found a great many difficulties in their path. The prints were marked by unsharpness, fogging, and bad gradation, and the process was generally erratic and difficult. It was then found that glass negatives are unsuitable for the process, owing to the fact that the peroxide, when decomposed, is reduced to water and oxygen gas, and the latter in the case of a film which is fixed to an impenetrable support, such as glass, gives rise to bubbles and blisters, and causes such a disruption of the negative as to make the latter useless. A negative made on a paper support is very suitable for the process.

Silver and Platinum as Catalysing Agents.

It was also found that silver alone is of comparatively small effect as a catalyser. A. Ebert observed that a finely powdered metallic silver does not act upon hydrogen-peroxide purely as a catalyser, but is itself oxidised (Eder's "Jahrbuch," 1906, pages 514 to 523). Lüppo-Cramer has done work in this direction, and Pinnow has shown the prejudicial effect upon the catalysing

action of silver on stains, etc., in the negative. Gros recognised the necessity of converting the silver into a catalysing substance, which was more permanent under the working conditions, in order to allow of a number of prints being obtained from a single negative by the catatype method. In a patent specification Gros has given a number of recipes for converting silver into permanent catalysers (Eder's "Jahrbuch," 1907, page 526), in which simplified and improved recipes for the same purpose are given. The full particulars need not be given, as the process has not yet come into practice. From a number of sources it has been shown that a platinised paper negative is the best original from which to work in the catatype process.

Properties of Peroxide.

Hydrogen peroxide in the pure state is a water-white, syrupy liquid, which boils at a temperature of 84 to 85 deg. C. under reduced pressure (about 1-11th of an atmosphere). Hydrogen peroxide in this pure state is difficult to prepare, and decomposes very readily, frequently with explosions of considerable violence. Aqueous solutions, as sold commercially, are, however, comparatively weak, and present no danger to the user, although a solution as strong as 30 per cent. is made by Merck of Darmstadt, being supplied in vessels coated with paraffin wax so as to avoid the traces of alkali from the glass, which give rise to the decomposition of the peroxide. For the process, solutions of peroxide in ether are used, and are made by shaking up the aqueous solution of the peroxide with sulphuric ether. On standing the mixture separates into two layers, part of the peroxide being taken up by the ether. These ethereal extractions contain usually from 1 to 2 per cent. of peroxide.

The patents for the catatype process which have been taken out since the year 1903 by the Neue Photographische Gesellschaft have led to the practical usefulness of the process, most of the work having been done by Drs. Heimrod and Friedländer and Herr Hirsch.

In preparing the original for the process the following conditions require to be observed as regards the catatype negative.

1. The catalyser should be present in the finest form of division and in good gradation.
2. It should be penetrable by the peroxide and by its products of decomposition, both of which should be easily removable again from the paper.
3. It should offer sufficient resistance to mechanical wear and tear.
4. It should be as free as possible from structure.

The Paper Original for Catatype Printing

These conditions are not so very difficult to fulfil. The N.P.G. has prepared a commercial catatype negative paper which, as regards its manipulation, differs in no way from the ordinary negative paper. The photographer employing it should use a soft-working developer, which gives a fine grain silver deposit. The employment of reducing or intensifying methods such as are customarily adopted is not desirable. In the case of making catatype originals from already existing glass negatives, the usual course is to prepare the duplicate negative on paper, and to use this, a glass transparency either of the same size or enlarged being made the intermediary in this process. After development of the negative the latter is rinsed and is fixed for about twenty minutes in a special catatype fixing-bath, several negatives being fixed together so long as they are moved about so that all receive full action. The fixing-bath should exert a tanning action upon the negative in order to give it the necessary resistance to the hot platinum toning-bath to follow. After this fixing the plates are laid in a bath of half the strength for a further ten minutes, and are then washed. The second bath is a necessary precaution against small blisters. The washing occupies half an hour in running water, after which the negative is gone over with clean cotton-wool and hung up to dry.

Platinising the Silver Negative

The dry silver image may be used at once, as it is as a cotype original; but metallic silver, owing to the action of the peroxide upon it, soon loses its power, so that the prints are lacking in fine detail. If a series of prints are to be made from a silver negative, the time adopted for each must be progressively prolonged in order to obtain a uniform set. A silver negative which appears to have lost its power can be completely renewed and made usable again by replacing the silver by platinum. It is advisable to effect this process at the start. The usual platinum toning-baths act only in a very partial way on the developed silver negative; but if used warm the bath acquires much more energetic action. In the case of the bath supplied by the N.P.G. it is necessary to use a temperature of 55 deg. C. for a bath, which is diluted nine times as directed. A higher temperature than this endangers the film. At a temperature of about 45 deg. C. toning requires about thirty-five minutes; at 55 deg. C., twenty to twenty-five minutes; and at 60 deg. C., about fifteen minutes. These figures apply to a freshly prepared bath: in one which has already been used the time of toning will be about ten minutes longer. A soft negative is platinised much more rapidly than a strong one, and on this account negatives which are free from hardness, though at the same time not flat, are the best for the process. It is all the better to transfer the developed negative direct into the platinum-bath; but if it has been allowed to dry it is soaked in water for a few minutes, and after toning is given a short washing. A certain amount of silver chloride is formed in the toning process owing to the substitution of the silver by the platinum. A weak bath of ammonia is quite sufficient to remove the silver chloride without affecting the activity of the negative; although a special clearing-bath is supplied by the N.P.G. which removes also other substances which may be formed. In this clearing-bath the bluish tone of the platinised negative changes into one of yellowish tint. As soon as there is no further alteration in colour the cleared negative is washed for five or ten minutes in running water, and is then ready for use.

The making of a negative thus suitable for printing by the cotype method is, it will be seen, not exactly simple; but, on the other hand, the actual printing operations are very rapidly carried out. The platinum negative is not only superior to the original negative as regards its catalytic power, but retains the latter also for a longer time. If the toning-bath

has been used for the full time the density of the platinum negatives will be just as great as at the first, although, if the original negative was somewhat over-dense, advantage may be taken of a shorter time of toning to improve it in this respect. Over-toning of the platinum-negative may in certain cases lead to prints of too hard gradation being obtained.

Alternative Methods of Printing.

As regards the printing methods, they are divisible into two sections, namely, those in which prints are obtained consisting of a manganese compound, and those in which the final image consists of a pigment. The first requirement in the practice of the printing is that the negative should be perfectly dry. The ethereal solution of peroxide, which, as already mentioned, supplies the means of obtaining a positive from the negative, is not miscible with water, and therefore would fail to penetrate into portions of the negative which contain moisture. In treating the negative, a brush or tuft of cotton-wool is used, a few drops of the preparation of peroxide sold as "Perisol" being sprinkled upon it, and the perfectly dry negative gone over with the solution. Using more or less pressure, the "Perisol" is rubbed into the film. After a few seconds the negative becomes dry. The following are the general rules to be observed. Light rubbing of the negative gives prints tending to softness, whilst a strong application affords harder prints. If the negative be laid on the printing-paper quickly so that it is only surface-dry, the results are softer, whilst a longer interval leads to prints of harder gradation. The longer the interval before the two are put in contact the greater the decomposition of the peroxide in the negative, particularly in the after-tones, so that the gradation in these portions may be to a certain extent lost. In the case of the manganese process described below, the longer the time of contact the harder is the resulting print; but the reverse is the case when making pigment prints, increase of the time of contact leading to softer results. By suitable choice of the working conditions a good deal may be done to improve the character of the prints, negatives which are flat and fogged giving prints of considerable strength by allowing the print to dry off before putting in contact, and giving a longer time for this latter part of the process. Negatives which give hard prints are, on the other hand, treated once or twice with the solution, and kept in contact for a shorter time.

DR. F. STENGER.

(To be continued.)

MIXTURES OF DYES AS SENSITISERS OF GELATINE PLATES.

V.

[The following is an abridged translation of a thesis by Guido Daur, presented for the degree of Doctor of Philosophy at the Münster University. The experimental work was done on the suggestion of Professor Miethe, to whose colleague, Dr. E. Stenger, the author of the papers renders his thanks for much advice and assistance. The full text of the paper occupies a book of 105 pages, published by E. Grieser, Frankfurt a/M.—Eds. "B.J."]

43. *Glycin-red-pinacyanol*.—This combination (Fig. 43) gave the result not previously noticed that the two plates, after sensitising in a bath containing the two dyes, were totally different as regards the sensitiveness curve according to whether they were washed in running water or in alcohol. In Fig. 43 the times of exposure are 30, 120, and 300 seconds, given to each plate. It will be seen that the plate washed in water has the glycin-red character, whilst those bathed in alcohol resemble pinacyanol. As seen from the curves in broken lines (plates washed in water), there is a slight rise at 580, obviously due to the pinacyanol. The maximum of the latter is much more plainly seen at 630. Colour-sensitiveness has suffered, and the general sensitiveness is poor; moreover, the region of sensitising is somewhat contracted. The pinacyanol curve drops from its maximum, gradually extending with medium exposure to 680. The curve of the two dyes, however, falls much more steeply, and

extends only to 650. In the case of the plate washed in alcohol (the curves of which are shown solid), sensitiveness in the green and orange is much better, although compared with that to the blue-green it does not equal the water-washed plate, but there is a broad gap in the blue-green reaching from 510 to 560, with its deepest point at 540. From here the curve rises fairly steeply to the first maximum at 590, which is a good deal inferior to the second maximum at 630. The water and alcohol plates resemble each other in that in each case the 630 maximum of pinacyanol is greater than that at 590. Both plates showed the same amount of fog—30.

44. *Dicyanine-glycin-red*.—As in formula 43, this mixture gave different results according to the manner of washing the plate. Here also the plate washed in water (dotted curves) had the glycin-red character, whilst that bathed in alcohol (solid curves) approximated more nearly to dicyanine. In each case the general sensitive-

ness was equally poor, that for colour very different. The water plate shows some sensitiveness for the blue-green and green, but none at all for the red, whilst the alcohol plate is almost insensitive

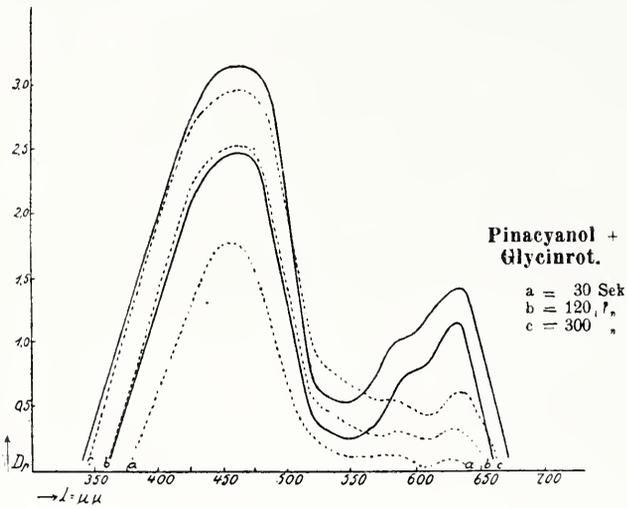

Fig. 43.

----- Bathed in water.
 ————— Bathed in alcohol.

to the blue-green and green, and commences to show sensitiveness in the orange and red. In the case of the alcohol plate, although there was no heavy fog, the plate showed light and dark bands, which interfered with the measurements, and, indeed, prevented them in many cases. In the case of the water plate, the effect of the dicyanine cannot be seen. On longer exposure (200 to 300 seconds) the glycin-red curve is prolonged about 25 to 30 μμ into the red. On

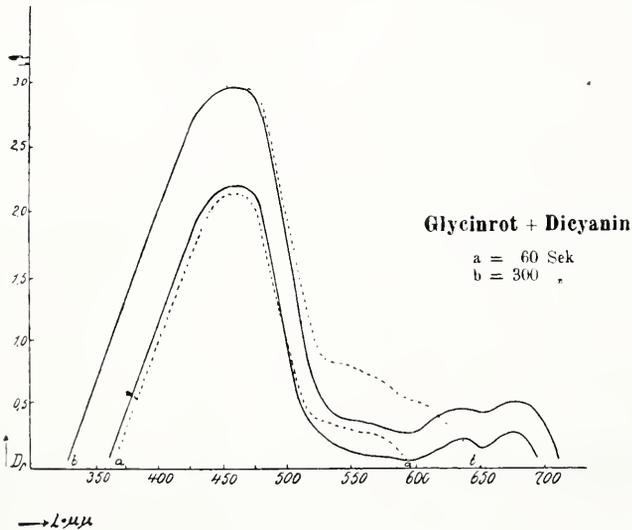

Fig. 44.

----- Bathed in water.
 ————— Bathed in alcohol.

the other hand, in the case of the alcohol plate, scarcely a sign can be seen of the glycin-red. After the steep fall of the curve to 535 the glycin-red does produce a slight influence up to 600. One notable fact is that there is no sign of any action of the dicyanine maximum of 580, which in every other combination shows itself. The 630 maximum, however, is plainly developed at 645, whilst the greatest action is effected by the dicyanine maximum of 700, which experiences a shift of 20 μμ towards the blue.

45. *Dicyanine-chinoline-red*.—Only the plate washed with alcohol could be used. It showed similarity with the glycin-red-dicyanine plate, also bathed in alcohol. The general character of the curve is that of dicyanine. The deep broad gap in the blue-green follows the same strong rise in the blue. A curve which rises from the bottom point at 520, after the manner of dicyanine, shows two rises at 560 and 590, one probably due to the chinoline-red and the other to its fellow dye. The two last dicyanine maxima show the accustomed shift, the first, 630, 10 μμ towards the red, and the second 700,

20 μμ towards the blue. Whilst the general sensitiveness leaves much to be desired, the relative sensitiveness in the orange-red compared with that in the blue is much better than with dicyanine and glycin-red.

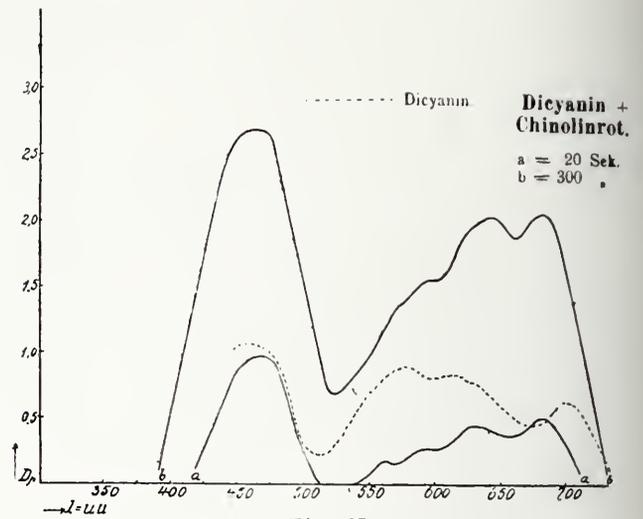

Fig. 45.

46. *Dicyanine-formyl-violet*.—Similar properties as regards sensitiveness are shown by this mixture (Fig. 46), the sensitiveness curve being almost the same. The gap in the blue-green is better. Even by longer exposure no sensitiveness is developed for the blue green rays, this showing first with 60 seconds' exposure. With this

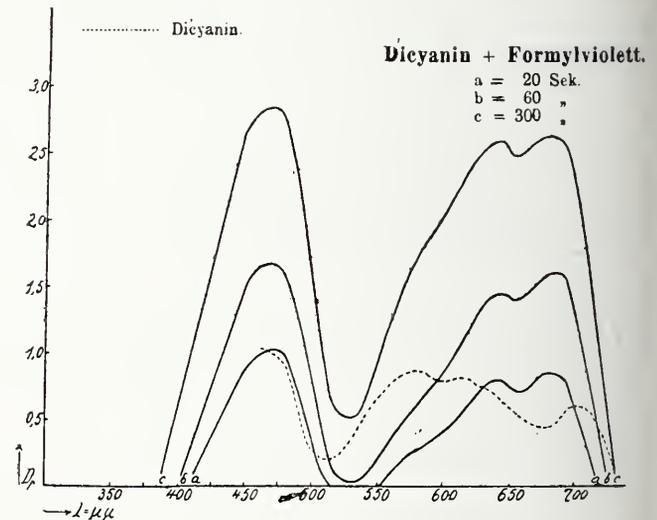

Fig. 46.

mixture of dyes also the 580 dicyanine maximum hardly appears, the maxima at 630 and 700 coming up strongly. Here again also there is the accustomed shift of these two maxima, which take their place at 640 and 680.

Summary and Results.

In order to bring together in an abridged form the facts obtained for the various mixtures of dyes, as shown in the foregoing curves the following thirteen tables have been drawn up, giving the properties of the various dyes when used in combination with others. The figure which follows the name of the dye at the head of the table indicates the position of its maximum.

I.—Aureosine 550.		
Combined with	Maximum of this sensitiser.	Maximum with mixture.
Eosine	540	550
Erythrosine	560	560
Rose-Bengal	550	560
Ethyl-red	530, 580	540, 580
Glycin-red	—	550

Aureosine (Table I.) is a weak sensitiser, which, when used with a strong sensitiser, has scarcely any effect. In admixture with ethyl

red the maximum of the latter moves from 530 to 540. With rose-Bengal the latter's maximum is shifted from 550 to 560. With eosine and erythrosine the dye improves the ratio of colour-sensitiveness compared with that in the blue.

II.—Eosine 540.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Aureosine	550	550
Rose-Bengal	550	550
Erythrosine	560	560
Ethyl-red	530, 580	540, 580
Pinacyanol	580, 630	580-590, 630-640

Eosine (Table II.) does not show its 540 maximum in the same place in any combination. In those with aureosine and erythrosine it effects a rise of the sensitiveness maximum in these dyes. When used with ethyl-red and with pinacyanol it causes a rise in the maximum of these dyes lying in the red of the spectrum.

A prejudicial effect is obtained only in the mixture of eosine and rose-Bengal.

III.—Rose-Bengal 550.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Aureosine	550	560
Eosine ..	540	550
Erythrosine	560	560
Ethyl-red	530, 580	560

Rose-Bengal (Table III.) is a sensitiser which imparts its characteristic curve in all combinations; weak sensitisers, such as eosine, in no way affect the curve; those of a somewhat stronger action produce only a shift to the maximum, about 10 $\mu\mu$ towards the red.

IV.—Erythrosine 560.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Aureosine.....	550	560
Eosine	540	560
Rose-Bengal	550	550
Pinaverdol	530, 580	530, 580
Ethyl-red	530, 580	520, 560
Pinachrome.....	550, 590	550, 595
Isocol	530, 580, 620	565, 630
Pinacyanol	580, 630	565, 635
Dicyanine	580, 610, 700	555, 630, 680
Chinoline-red	570	560
Glycin-red	—	560
Formyl-violet ..	610	560

Erythrosine (Table IV.) resembles rose-Bengal in its sensitising properties. In combination with ethyl-red, chinoline-red, glycin-red, and formyl-violet, the curve obtained is wholly, or almost wholly, that of erythrosine. On the other hand, it is weaker than pinaverdol or pinachrome, its effect being hardly marked when used with these dyes. As regards the shift of the erythrosine maximum, and that of sensitisers used with it, there is a certain rule: All maxima which lie to the left of wave-length 550 are shifted to the left, and those lying to the right are shifted to the right. The shift of maxima of greater wave-length than 550 to the right takes place only up to a certain wave-length, about 650, after which wave-lengths lying to the right thereof experience again a shift to the left. (See also dicyanine below.)

V.—Ethyl-red 530, 580.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Aureosine	550	540, 580
Eosine	540	540, 580
Rose-Bengal	550	560
Erythrosine	560	560
Pinaverdol	530, 580	530-540, 580-590
Pinachrome.....	550, 590	530-550, 580-590
Isocol	530, 580, 620	530, 580, 630
Pinacyanol	580, 630	540, 580 590, 635
Dicyanine.....	580, 610, 700	535, 580, 630, 680

Ethyl-red (Table V.) is not a strong sensitiser. In combination with eosine and erythrosine, its action is more marked than that of these two dyes. Its maximum at 580 is not shifted, though that

at 530, when the dye is used with eosine, aureosine, pinacyanol, or dicyanine, is shifted about 10 $\mu\mu$ towards the red.

VI.—Pinaverdol 530, 580.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine	560	530, 580
Ethyl-red	530, 580	530-540, 580-590
Pinachrome	550, 590	530-540, 580-590
Isocol ..	530, 580, 620	530-540, 590
Pinacyanol	580, 630	585, 640
Dicyanine.....	580, 610, 700	530, 580, 630, 685
Chinoline-red	570	530, 580
Formyl-violet	610	530, 580

Pinaverdol (Table VI.) is a dye of great action on silver bromide. Even so strong a sensitiser as erythrosine does not develop when in combination with pinaverdol its maximum at 560. In combination with erythrosine, pinachrome, chinoline-red, and formyl-violet, the curve, so far as concerns the position of the maxima, is that of pinaverdol. Sensitiveness to colour, as compared with that to the blue, is at the same time improved. Particularly good is the mixture of pinaverdol with isocol and dicyanine, whereby this ratio is particularly improved.

VII.—Pinachrome 550, 590.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine	560	550, 590-600
Pinaverdol	530, 580	530-540, 580-590
Ethyl-red	530, 580	530-550, 580-590
Isocol	530, 580, 620	540, 590, 630
Pinacyanol	580, 630	560, 590, 630
Dicyanine.....	580, 610, 700	550, 590, 680

Pinachrome (Table VII.) is the most powerful sensitiser after pinaverdol, since in all combinations, except those with pinaverdol, it produces its characteristic curve. Its maximum at 550 is frequently shifted towards blue or red, though its 590 maximum is not affected by any other dye.

VIII.—Isocol 530, 580, 620.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine	560	550-560, 630
Pinaverdol... ..	530, 580	530-540, 590
Ethyl-red	530, 580	535, 580, 640
Pinachrome.....	550, 590	540, 590, 630
Pinacyanol	580, 630	580, 630-640
Dicyanine	580, 610, 700	530, 580, 640, 670

Isocol (Table VIII.) loses its characteristic curve in all mixtures except those with dicyanine: the shift of its maximum (620) 10 to 20 $\mu\mu$ towards the red is very characteristic of it.

IX.—Pinacyanol 580, 630.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Eosine	540	585, 635
Erythrosine	560	560, 630-640
Pinaverdol	530, 580	540, 580, 640
Ethyl-red	530, 580	540, 580-590, 635
Pinachrome	550, 590	560, 590, 640
Isocol.....	530, 580, 620	580, 635
Dicyanine.....	580, 610, 700	580, 635, 680
Glycin-red	—	580-590, 630

Pinacyanol (Table IX.) is about equal as regards sensitising power to erythrosine. With almost all sensitisers used with it, there is a shift of the orange maximum about 5 to 10 $\mu\mu$ towards the red end of the spectrum.

X.—Dicyanine 580, 610, 700.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine	560	550-560, 630, 680
Pinaverdol	530, 580	530-40, 580-90, 685
Ethyl-red	530, 580	530, 580, 630, 680
Pinachrome	550, 590	550, 590, 680
Isocol	530, 580, 620	530, 580, 640, 670
Pinacyanol	580, 630	580, 630-640, 680
Chinoline-red	570	595, 630, 680
Glycin-red	—	635, 680
Formyl-violet	610	640, 680

Dicyanine (Table X.) is about comparable with pinachrome. Used in mixtures, there is a characteristic region of sensitiveness lying

near wave-length 650. Maxima lying to the left of this point are shifted to the right, those lying to the right are shifted to the left. The shifting of the maxima does not take place in the same way as in combinations with erythrosine, since here the maxima lying to the left of wave-length 530 are shifted to the right. The maxima 610 and 700 are very characteristic of combinations of dicyanine. The first is found to be shifted 20 to 30 $\mu\mu$ towards the red, the latter very regularly 20 to 30 $\mu\mu$ towards the blue.

XI.—Glycin-red.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Aureosine	550	550
Erythrosine	560	560
Pinacyanol	580, 630	585, 635
Dicyanine	580, 610, 700	635, 680
Chinoline-red	570	—
Formyl-violet	610	—

XII.—Chinoline-red 570.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine	560	560
Pinaverdol	530, 580	530, 580
Dicyanine.....	580, 610, 700	595, 630, 680
Glycin-red	—	—
Formyl-violet	610	570, 610

XIII.—Formyl-violet 610.

Combined with	Maximum of this sensitiser.	Maximum with mixture.
Erythrosine.....	560	560
Pinaverdol	530, 580	530, 580, 620
Dicyanine	580, 610, 700	580, 640, 680
Glycin-red	—	—
Chinoline-red	570	565, 610

Glycin-red, chinoline-red and formyl-violet (Tables XI., XII., and XIII.) stand as regards their dyeing properties towards bromide of silver in the order: formyl-violet, chinoline-red, glycin-red. All three are weaker sensitisers than aureosine, nevertheless all three are able to cause a shift of the maxima of dicyanine, causing it to move 20 to 30 $\mu\mu$ towards the red in the case of the 610 maximum, and 20 $\mu\mu$ towards the blue in the case of the 700 maximum.

* * * * *

The following further conclusions may be mentioned:—

I. The application of the dye to the emulsion film varies according to whether the colouring matters act together or in succession. This applies, not to the position of the maxima, which is the same in each case, but as regards the relative degrees of action in the maxima compared with each other, and with that of the mother-emulsion.

II. All dyes suitable for the sensitising of gelatino-bromide dry plates may be placed in a series, so that if they are used in mixture the one which stands first in the series decides the character of the plate. The following is such a series for the dyes mentioned in the foregoing notes:—

Pinaverdol.	Isocol.
Pinachrome.	Ethyl-red.
Dicyanine.	Aureosine.
	Eosine.
Erythrosine.	Glycin-red.
Pinacyanol.	Chinoline-red.
Rose-Bengal.	Formyl-violet.

III. A rule of general applicability as to the shifting of the maxima of two sensitisers, when used in one and the same bath, can be easily stated, although it has been found that for single dyes, combined with one stronger or weaker, a shift takes place always in the same way, and almost always to the same number of wave-lengths. In all combinations a maximum in the red will shift towards the blue, one in the orange towards the red. The maxima in the green and yellow will be irregular as regards shift.

* * * * *

As regards the differences in the action of dyes when applied together in one solution or separately as single baths, attempts were made to answer the two following questions:—

1. Is there any alteration in the position of the maxima if the emulsion before coating is dyed with a mixture of two colouring matters, or if the dyeing is done by dividing the emulsion into two parts, to

one of which one dye is added and to the other the other, the two parts being mixed before coating?

2. Is there a difference in the relative intensity of the maxima among themselves and in comparison with the maximum in the blue, according to whether sensitising is done by one or other method?

It must be said at once that exact data obtained by photometric measurements could not be obtained, as the plates had to be coated by hand, and therefore the exact adjustment of the quantity of emulsion used for a plate was not possible. Further, the emulsion was not uniform on the plate.

The second question could thus be answered only by preparing a sufficient number of plates by both methods and comparing them as regards intensity of the maxima with the eye. The emulsion was made according to Eder's formulæ, and using ethyl-red in the proportion of 3 ccs. of 1:1,000 solution per litre of emulsion. For the other two colouring matters pinaverdol and dicyanine were selected, these being applied by bathing. The pinaverdol plate gave a very good result, but the dicyanine showed heavy fog. It was concluded (1) that the position of the maxima remains the same, whether the two dyes are used together for dyeing the emulsion or whether they are added separately to two separate parts of the emulsion. (2) That the relative intensity of the different maxima varies in this case as with bathed plates. In the previous case the separately dyed and mixed emulsion gave a better result than one containing a mixture of the two sensitisers.

G. DAUR.

THE FELLOWSHIP OF THE ROYAL PHOTOGRAPHIC SOCIETY.

NEW REGULATIONS.

THE Council of the R.P.S. have made the following regulations under which the Fellowship will, in future, be awarded:—

Fellows are elected by the Council, and only members of the Society are eligible for election to the Fellowship.

Applicants for the Fellowship must be recommended by two Fellows of the Society as proposer and seconder, such recommendations being taken as expressing only the personal and social eligibility of the candidate.

The qualifications of the candidate are first considered by a Committee appointed by the Council, which consists of eighteen Fellows or Members of the Society. This Committee meets in March and October of each year and reports to the Council upon the applications received.

The Council then considers each application with the Committee's report thereon, and elections take place in May and December of each year. No candidate is elected unless two-thirds, or a greater proportion of the members of Council present, vote in favour of his election.

Each applicant must submit a statement of his qualifications under one or more of the following heads:—

- (a) Original investigations, improvements or inventions adding to photographic knowledge in either theory or practice. References to publication and application of such original work must be given.
- (b) Educational work, e.g., writing, teaching, etc.
- (c) Technical work, e.g., the application of photography in the various arts and sciences, and in record work of all kinds. Process work, methods of reproduction, etc.
- (d) Pictorial work.
- (e) Professional portraiture.
- (f) Other qualifications.

The application should be supported by as much evidence as possible, such as copies of published papers, examples of work, etc. and by particulars of any examination passed, or of any honours or awards received for work directly or indirectly connected with photography.

The two latest dates in the year for receiving this form are March 1 and October 1.

ROTHERHAM PHOTOGRAPHIC SOCIETY.—The twentieth annual exhibition of the Rotherham Photographic Society will be held October 20-23. Open section. No entrance fees, except for lantern slides. The judges are Mr. C. Barrow Keene, F.R.P.S., Derby, and Mr. T. A. Scotton, Derby. Entries close October 11. The hon secretary is Mr. H. C. Hemmingway, Tooker Road, Rotherham.

LECTURES AT THE R.P.S. EXHIBITION.

THE following is the list of lectures to be given at the New Gallery, Regent Street, during the holding of the annual Exhibition of the Royal Photographic Society. The lectures commence at 8 p.m.

Thursday, September 23.—“Through the Federated Malay States with Cycle and Camera,” by Frederick Knockner, F.Z.S.

Saturday, September 25.—“Among the Cornish Fisher Folk,” by Valter Thomas.

Monday, September 27.—“A Visit to a Marine Biological Station,” by Francis Ward, M.D.

Thursday, September 30.—“The Romance and Humour of Invention,” by A. H. Dunning, F.R.G.S.

Saturday, October 2.—“Modern Ideas about the Sun,” by T. F. Connolly, B.Sc.

Monday, October 4.—“San Marino, the Pigmy Republic,” by the Rev. T. T. Norgate, F.R.G.S.

Thursday, October 7.—“Saints, Benedictines, Goths and Vandals,” by E. W. Harvey Piper.

Saturday, October 9.—“The Photography of Sport,” by Adolphe Abrahams, B.A.

Monday, October 11.—“Holy Days and Fête Days in Spain,” by R. Falconer Jameson.

Thursday, October 14.—“Pictures from Portugal,” by George E. Thompson.

Saturday, October 16.—“London Through the Eyes of Gossip Pepys,” by A. H. Blake, M.A.

Monday, October 18.—“Wild Birds and their Ways” (Second Series), by W. Bickerton, F.Z.S.

Thursday, October 21.—“The Home Life of some familiar Wild Birds,” by W. Farren.

Saturday, October 23.—“The Romance of Plant Life,” by F. Martin-Duncan.

Monday, October 25.—“A Trip Round the World, via Ceylon, through Australia and Canada,” by C. J. Marshall, A.R.I.B.A.

Thursday, October 28.—“The Catacombs of Rome, and the Early Christian Period,” by S. J. Beckett.

Saturday, October 30.—“Westminster Abbey,” by S. G. Kimber.

Photo-Mechanical Notes.

Process at the Dresden Exhibition.

In the very comprehensive exhibition now being held at Dresden it was certain that photo-mechanical work would not be forgotten, and, in fact, a large building, the Reproduktion Halle, is devoted to it. At the outset it must be remarked that the English representation is very disappointing, for only a few firms exhibit, and these not their best work. It is to be hoped that visitors to the exhibition will not judge our capacity from a comparison of the work shown with that of other countries.

The most striking things to be seen in the exhibition are as follows: (1) The excellent half-tone reproductions of Autochromes, Messrs. Hamcock showing a very large number of these, together with the originals. Some of the reproductions are more pleasing than the Autochrome, due to the exercise of taste on the part of the fine-etcher and printer.

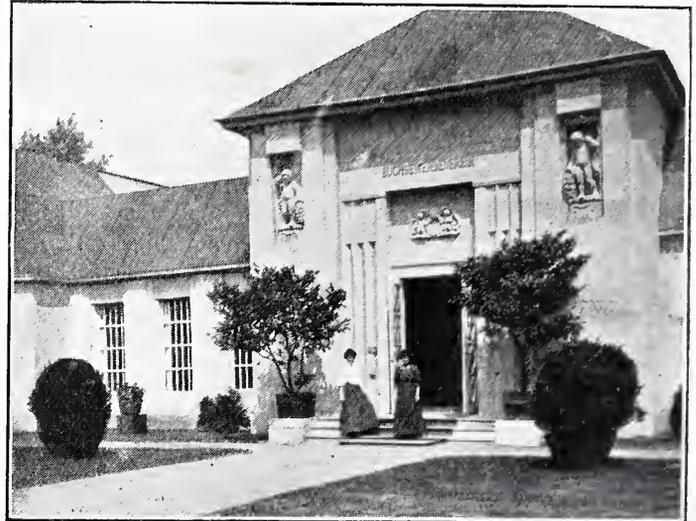

(2) The very fine coloured collotypes. Some of these are recognisable as the requisitions of a well-known London firm of print-sellers, who find they must come abroad to get satisfactory colour-collotype. Several of these coloured collotypes are in more than three colours, but some of the best of them—for example, the reproduction of old illuminated manuscripts by Albert Frisch, of Berlin—are only in three, and these are magnificently brilliant.

(3) The large number of coloured photogravures. Beside the ordinary “synchronous” method in which all the colours are dabbed on the plate and pulled in one impression, there are several printed in three colours, just like blocks, and the yellow, red, and blue proofs

are shown as well as the completed print. Messrs. Elson and Co., of New York, even show the originals and the three-colour photogravures side by side, and in some cases these are astonishingly good, though for the most part there is a want of sharpness that one feels would probably not exist in three-colour half-tone.

(4) The very large amount of combination work in which photography has aided lithography. Grained transfers, collotype transfers, half-tone, indeed, all sorts of photographic methods have been employed in conjunction with lithography, and were not the statement made, one would imagine some of the results to be all pure hand-work, as it is quite impossible to detect the photographic basis in many cases.

(5) The excellent apparatus shown. The writer was especially anxious to see this, as he had recently heard of two cases in which

The Reproduktion Halle, Dresden Exhibition.

Continental customers, formerly always purchasing their apparatus in England, were now purchasing it in Germany, not because it was cheaper (it was actually dearer), but because it was better. Their judgment must be approved; it is certain that our camera makers do not market any process camera so compact and so convenient as those of Falz and Werner or Hoh and Hahne, which are most carefully thought out in every detail. Particularly interesting is the small space occupied by the screen gear, and that at the side and not at the bottom of the camera, the lazy-tongs support for the bellows, the possibility of slightly angling the camera and copy-board when using long extension, so that less space is required and better balance maintained; and the narrow stands used, which also economise space and make for convenience in working.

Rolling Up Enamel Prints.

A reader of Messrs. Penrose's “Process Work,” writing from Christchurch, New Zealand, in answer to a querist who wanted a process for rolling up copper line jobs which have been printed in enamel, etc., describes a process he has used himself, enclosing an enamel print on zinc rolled up exactly as a litho stone is done—and just after the merest pass in the acid bath. The way it is done is to damp the plate with dissolved dextrine—British gum, not ordinary gum arabic—and roll up as usual. Use the dextrine thin and sparingly, damp with a sponge; this makes the plate slimy, but allows the roller to run freely, putting no pressure on other than its own weight. Any one who has a slight knowledge of litho work, or can do rolling up on zinc plates, will find the whole thing simple. Any good starting ink will do, but line zinc is merely rolled up with ordinary litho ink. The writer has not tried the effect on copper, but fancies that a fish glue print on the copper would take the ink in the same easy manner as the zinc. Hot water easily dissolves the dextrine to the proper consistency. Gum up in the usual way and damp as already stated.

A NUMBER of street photographers were fined at Blackpool recently for using water for other than domestic purposes.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between August 3 and August 7:—

EXHIBITING PHOTOGRAPHS.—No. 18,029. Improvements in or relating to the exhibiting of photographs, pictures, and similar artistic productions. William Wild, 7, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 18,031. Improvements in or relating to cinematographs. Vittorio Benaglia and Ubaldo Grimaldi, 111, Hatton Garden, London.

CAMERAS.—No. 18,045. Improvements relating to photographic cameras to obtain sky and cloud effects. David Kay, 37, West Nile Street, Glasgow.

APPARATUS.—No. 18,079. New or improved apparatus for use in fixing, washing, or other like operations of photography. Sidney Samuel Frank, 70, Chancery Lane, London.

CINEMATOGRAPHS.—No. 18,093. Method of and apparatus for producing cinematographic pictures. Ewald Escher and Karl Kochendorger, 345, St. John Street, London.

FLASHLIGHT.—No. 18,213. New or improved telescoping match-holder, particularly adapted for use in flashlight photography. Bettie Hill McDonald, 31, Bedford Street, Strand, London.

FILM-PACKS.—No. 18,266. Improvements in film-packs. Johann Georg Schneider, 6, Lord Street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ENLARGING APPARATUS.—No. 20,227, 1908 (September 26, 1908). The invention consists in a form of construction, according to which the stage holding the negative carrier may be adjusted at an angle

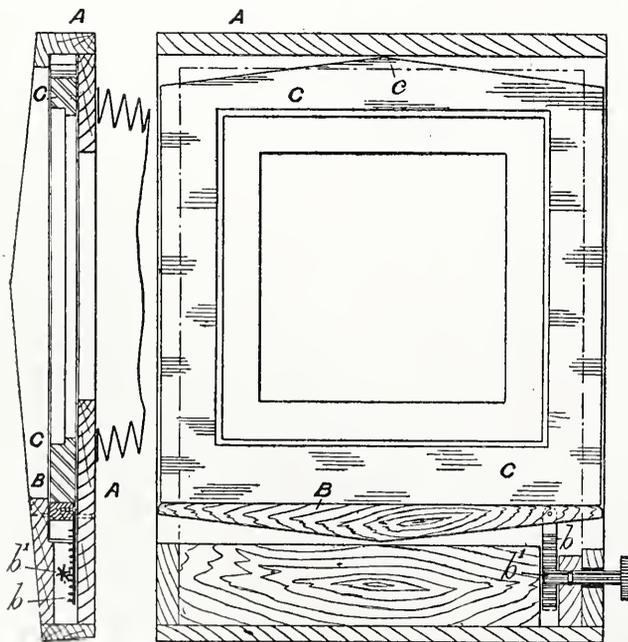

Fig. 2.

Fig. 1.

in its own plane, so as to compensate for the negative not being set straight on the negative. It consists in applying a rocking base piece to that part of the stage or negative receiver on which

the negative carrier rests, or in attaching to the bottom of the negative carrier a rocking piece, so that any distortion in the picture can readily be corrected by tilting the negative when placed in position for the enlargement.

The stage or negative receiver A is constructed of the usual rectangular form, but with a movable or rocking base piece B, by which the negative carrier C when placed thereon can be raised or lowered at one side or the other.

In the form shown in Figs. 1 and 2 the base piece B is pivoted in a suitable position at or near the centre, and provided at one end with a rack b and pinion b¹, by which it can be inclined in either direction to tilt the negative carrier resting thereon. Arthur Gray Pickard, director of the Thornton-Pickard Manufacturing Company, Ltd., of Altrincham, Cheshire.

GUM PROCESS.—No. 27,686 (December 19, 1908). The invention consists of a dry mixture, such as gum arabic 20 parts, sugar 1 part, potass bichromate 4 parts, together with pigment 20 parts, for use as a sensitising mixture for the gum-bichromate printing process. A mixture, such as the above, is dissolved in twice its weight of water to form a sensitising liquid, which is applied to paper, and the latter exposed under the negative and developed in water, just as in the gum process. The mixture is intended to be used in making three-colour prints by successive sensitising of the same piece of paper. Société Anonyme, La Photographie des Couleurs, 24, Comte rue de l'Hôpital, Antwerp; Joseph Sury, Wyneghem, Belgium; and Edmond Bastyns, 29, rue des Tanneurs, Antwerp.

PRINT TRIMMERS.—No. 4,743, 1909 (February 26, 1909). The invention consists of a form of guillotine trimmer, in which the top shear is not bent or cambered, but is straight and rigid. It has no handle and is uniform in length with the base. In use, the top shear is pushed down by simply placing the fingers upon the top edge

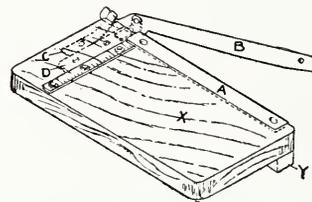

Fig. 1.

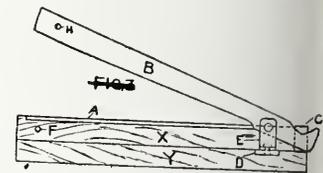

Fig. 2.

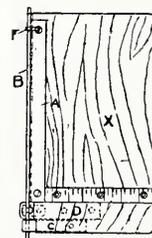

Fig. 3.

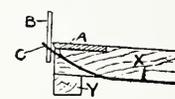

Fig. 4.

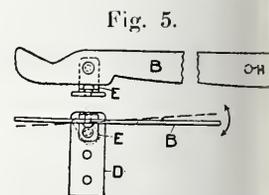

Fig. 5.

Fig. 6.

thereof. It works so freely that very little pressure is required to do this. It is fixed to the base with the usual double pivoted or turntable hinge, but is pivoted at such a distance from the end thereof as to allow a sufficient projection of the shear beyond the hinge for the spring to work upon.

It is controlled and actuated by one spring only, which is fixed to the base. When it is being pressed down to make the cut or trim, the spring keeps the top shear in proper cutting contact with the bottom shear, and on the cut being made, and the top shear released, the spring raises it, and keeps it in position for the next cut.

When the top shear is pressed down for cutting, a stop on the base prevents its going beyond the end of the cut, and when the trimmer is out of use, the top shear is pushed downwards and slightly outwards, when the stop engages in the hole in the free end of the top shear, and the same is thereby held firmly down and parallel with the bottom shear, and when pushed off the stop rises again into cutting position.

The spring and the hinge-plate are both fixed to the underside of the base. These can either be let in flush with the underside of the base or fixed thereon without letting in. In the latter case

fillet of wood (or other material) is attached to the underside of the base to protect the spring and hinge action, and this fillet has the effect of slightly elevating the trimmer at the back and so giving a desk-like slope towards the front, which is an advantage and convenience in working.

The trimmer is also provided with the usual graduated rule for measuring the size of print and obtaining a square cut; but such rule, instead of being permanently fixed in position, is fixed to the base with screws, passing through holes in the rule of such a size as to allow for adjustment, and held firm by washers under the screw-heads. In the drawings X is the base; Y, fillet attached to the base; A, bottom shear; B, top shear; C, spring; D, hinge-plate; E, hinge; F, combined stop and fastener; H, hole in top shear for stop. John Merrett, Trowbridge, Wilts.

CAL-PLANE SHUTTERS.—No. 15,548, 1908 (July 22, 1908). The invention consists of a blind shutter, for use in the focal-plane or on the lens in which the exposure is made by causing two blinds to travel in the same direction across the opening, the edge of one blind being an adjustable distance in advance of that of the other, so as to form a space between the two blinds. To effect the exposure, two of the rollers, one of each pair, and generally those situated in the lower part of casing, are connected by means of toothed wheels, while the shutter mechanism is in motion, but at all other times the rollers are capable of independent motion. To make this connection, the rollers in question have toothed wheels attached, and on a plate capable of partial rotation, about the axis of one roller, and permanently in gear with the wheel, attached to that roller, is an idle wheel, having similar teeth to those of the wheels carried by the rollers. The mechanism for releasing the shutter is connected with this swinging plate, and the whole is arranged so that the act of releasing causes the plate to be moved into such a position that the idle wheel, already in gear with one roller, meshes with the wheel attached to the other roller. This arrangement ensures the two rollers, and the blinds in connection therewith, travelling at equal velocity, or by changing the gear wheels, one blind may be made to travel at a greater or less speed than the other during the making of an exposure, but immediately afterwards, as soon as the releasing device is free, the idle wheel falls out of gear with one blind roller, and the capping blind is drawn into the aperture-closing position. Duration of exposure depends upon the distance between the two blinds when they are in motion. This distance is regulated by winding, during the process of setting, the upper blind, and a portion of its tapes upon the roller until the desired aperture is indicated by a dial provided for the purpose.

Setting the shutter is performed by a winding wheel, geared into the roller to which the blind is attached, in the upper part of the casing. Retention in the set position is ensured and release effected by a pawl, acting in conjunction with a ratchet wheel, connected with or formed by the winding wheel. For the purpose of making "bulb" exposures, the winding wheel is furnished with a stop pin or stud, designed to come into contact with a projection, fitted to, or formed on, a moving piece contained in the shutter case. Other studs are fitted to the winding wheel, which during the revolving of the wheel come into contact with the moving piece just mentioned, or projections connected therewith, and set the piece into such a position that the part intended to act as stop comes into the path of the stop pin of the winding wheel.

This moving piece is under the influence of a spring, and normally takes up such a position that it cannot obstruct the free working of the shutter mechanism. Frank Philip Whitehead and Walter Frederick Giles, trading as F. Whitehead and Co., Scientific Instrument Makers, 34, Pickets Street, Balham, London, S.W.

PHOTOMATOGRAPH MECHANISM.—No. 453, 1909 (January 7, 1909). The invention consists in apparatus for making film negatives or positives, and for projecting the latter, or to make reduced copies of the images on ordinary films. In connection with this latter, the invention also relates to the production in an improved way of the reduced image pictures from such films on to a strip, which may be in a loop form, and in which the pictures forming a single subject, or a series of subjects, following one another, lie side by side in rows either longitudinally or transversely of same, the strip being used either by reversal at the ends of same, accompanied by a lateral movement to bring the next row into position or by

a lateral movement without reversal, or when in a loop form by arranging the pictures longitudinally in a spiral or continuous line on same. The Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C.; and Ferdinand von Madalaer 11, Stowe Road, Shepherd's Bush, London, W.

Analecta.

Extracts from our weekly and monthly contemporaries.

Carrying the Camera Case.

As my canvas half-plate camera case was beginning to look shabby (writes Mr. T. W. Pallett, in the "Amateur Photographer" for August 17), catalogues and shop windows were searched for another, and, having found the usual "open at the top" pattern rather awkward when carrying an extra lens, yellow screen, and other necessary adjuncts, the search was for the unusual—something in which the camera could lie alongside the dark slides, etc., so that it would not be necessary to move one article to get another.

Attaché cases were thought of, examined, and found unsuitable in size, and, more important still, too expensive.

Finally, a bag-maker in Bermondsey was consulted, with the result that the equipment is now more easily carried in a baize-lined half-Gladstone, on opening which every article is ready to hand.

The size is 18in. by 11in. by 5in., takes six double dark slides comfortably, costs no more than the ordinary leather case, and has the further advantage that it will take a change of clothing, so making a capital week-end bag.

Phosphate Papers.

Messrs. H. G. Bailey and T. J. Ward (writing in "Photography" for August 17) have made some experiments with "Ensyna" and also with Paget "phosphate paper" regarding time of washing, and have come to the following conclusions:—

It is important that the final washing of the prints should take place in running water, as, if left to soak in a dish, even after ten minutes' washing, there is enough "hypo" remaining to destroy the image completely if left soaking for another hour or so. This we have found to be the case both with ordinary "hypo" (15 per cent.) and also with the "Ensyna Acid Hypo."

Even if the paper is properly washed for thirty minutes in running water, the hypo is not completely removed, and we find on an average from a quarter to one-third grain remaining under these circumstances in a quarter-plate print, as estimated by titration with iodine.

This small amount may have no deleterious effect on a phosphate paper print, but the fact seems to have escaped notice that they may be stored loosely in contact, or face to face in an album, with either P.O.P. or bromide prints, and then would very probably lead to stains and fading in these in course of time. We therefore recommend that these prints be washed as ordinary P.O.P., viz., for at least an hour in running water, as suggested by you.

Another point which may be of interest is that if one is uncertain regarding the exposure of a very dense negative, it is best to expose until a very faint image is produced. This on development will give a brown colour, and, by relatively decreasing or increasing the exposure, the desired tone can then be obtained.

A point on which we differ from the editor is when he states that "very little difference (except in colour) can be detected between prints on phosphate paper which have had widely different exposures." We find that with an exposure of very short duration a contrasty print is obtained having, of course, a blue tone, while with prolonged exposure the contrasts are softened immensely, thus increasing the scope of the paper.

Further, to amateurs it may be of use to know that the metal developer as given by the Paget Company for use with their "phosphate paper" may also be satisfactorily employed with "Ensyna," the only difference being that in the latter case it requires approximately twice as long to complete development.

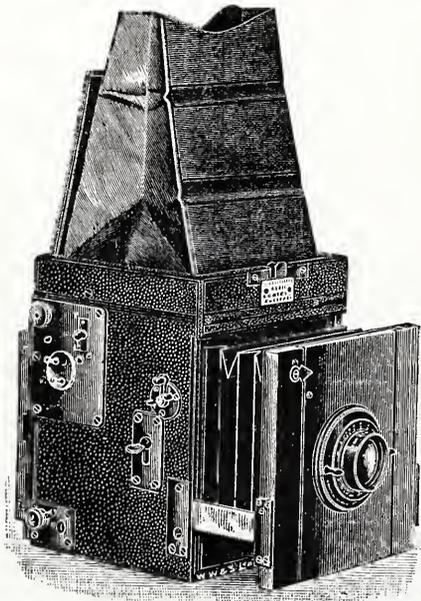

New Materials, &c.

KODAK SELF-TONING C.C. POSTCARDS.—Two grades of cards, glossy and matt, have just been introduced by the Kodak Co., the emulsion in each case being that familiar to users of the Kodak Self-toning C.C., and giving with great ease the fine range of tones obtainable with the latter paper. In a plain bath of hypo the new cards give excellent cold brown tones, about ten minutes' immersion giving a most pleasing purple brown tone. In fact, if a really warm brown tone is required it is best to wash the prints in three changes of water before placing in the hypo bath. Purple black tones are readily obtained by placing the prints first for a minute or two in a weak salt bath and then fixing as usual. The readiness with which the results are obtained and the fine tone and surface of the prints should recommend them to postcard users. They are sold in shilling packets of twelve cards.

New Apparatus, &c.

"BIRDLAND" OUTFIT.—When calling at Messrs. Sanders and Co., Shaftesbury Avenue, a day or two ago we were able to examine a complete outfit for natural history photography prepared by them and, at the time of our visit, on the point of shipment to New Zealand. The set comprised a half-plate "Birdland" reflex camera, fitted with 12in. Goerz Dagor ($f/6.8$) and Celor ($f/5.5$), with telephoto attachment for the latter. The camera was fitted with the two forms of hood, the ordinary vertical pattern and the triangular type for use when employing the camera in a higher position and focussing with a magnifier. The outfit also included a new form of the "Lodge" hiding tent, the supports for the latter being made of bamboo, and the whole tent of larger size, but yet folding when closed in a conveniently small space. The outfit altogether was certainly one every detail of which evidenced the care of the makers in consulting the wishes of nature-photographers.

THE $3\frac{1}{2} \times 2\frac{1}{2}$ "ARGUS" REFLEX.—Messrs. W. Watson and Sons, 313, High Holborn, London, W.C., have just placed on the market a $3\frac{1}{2} \times 2\frac{1}{2}$ size of their well-known and excellent "Argus" reflector camera. The camera is of the same substantial construction as the larger sizes, and measures over all about $5 \times 5\frac{1}{2} \times 6\frac{1}{2}$ inches. The

total extension is close on 8 inches, the front being very rigidly supported on a pair of metal runners. There is a rise of front of $\frac{3}{8}$ of an inch, as well as a fall of nearly half an inch, both movements being actuated by a rack and pinion. The hood is self-erecting, and folds back on its hinges, giving instant and complete access to the focussing screen. In the important matters of the shutter and mirror the makers adhere to the movements found successful and reliable in the larger patterns of "Argus," that is to say, a mirror which

falls again after exposure, and a shutter which is adjustable both by alteration of slit and tension, the latter while the shutter is set. Complete with rotating back and three solid double slides, the price of the $3\frac{1}{2} \times 2\frac{1}{2}$ "Argus" is £11 7s.; with three book-form slides the price is £12 10s.; or for the same price the camera may be obtained with a changing box for twelve plates. As a lens for the outfit Messrs. Watson supply their 5-inch Holostigmat for £6, in a suitable recessed mount. The whole forms a most excellent outfit in a size which we consider peculiarly suitable for a reflex camera on account of the great accuracy with which the subject can be arranged.

CATALOGUES AND TRADE NOTICES.

THE BOOK OF THE BROWNIES.—An altogether admirable booklet illustrating the excellent results to be obtained with such inexpensive cameras as the Brownie Kodaks has just been issued by the Kodak Co., and is sent free on application to 57, Clerkenwell Road, E.C. The reproductions include portraits and portrait studies, interiors, shipping and natural history subjects, and the letterpress accompanying them appropriately refers to the ease of Kodak-Brownie photography, and concludes by asking for an opportunity of demonstrating the fact to the reader. The booklet is one which dealers will surely benefit by distributing.

ENLARGEMENTS IN TWO COLOURS.—Messrs. H. Edmund and Co., Ezra Street, London, E., send us a circular just issued by them containing directions for toning bromide prints and enlargements in two colours by means of the "Sanzol" green toner and the "Cubrome" blue toner. The process does not present great difficulty except in certain subjects, and the directions are commendably explicit. The circular is sent free on application.

PROFESSIONAL REQUISITES.—A new list has just been issued by Messrs. O. Sichel and Co., of apparatus and materials for the use of professional photographers. It includes particulars of studio cameras, the "Sickle" studio reflex, portrait, and other lenses shutters, and other apparatus. We should mention the very convenient "Finsbury" head-rest and screen and the very nice styles in studio furniture, in mounts, and in mouldings. Particulars are given of the Morgan system of dry-mounting and embossing, and the list which is sent post free to *bonâ-fide* professional photographers, includes a list of discounts for the various items. Professional workers will certainly not lose anything by applying to 52, Bunhill Row for a copy.

CHEMICALS.—In sending their current list of prices, Messrs. Fuers Bros., 17, Philpot Lane, London, E.C., intimate that terms on certain lines have been increased, as per the inset circular. Should any of our trade readers not receive a copy in the usual course they should apply to Messrs. Fuerst, who will be pleased to furnish them with all information.

FORTHCOMING EXHIBITIONS.

September 10 to October 23.—The Photographic Salon. Latest date August 30. Sec., Reginald Craigie, 5A, Pall Mall East, London S.W.

September 23 to October 30.—1.—Royal Photographic Society Latest date (carrier) September 1, (hand) September 2. Sec J. McIntosh, 35, Russell Square, London, W.C.

THE CINEMATOGRAPH EXHIBITION.—It is announced in the "Optician" that the Optical and Photographic Exhibition which was arranged to be held at the Crystal Palace will not take place this year. As a result of the publicity given to the matter, a number of optical and photographic firms had bespoken space, and to these Mr. Bernard Brown desires to tender his thanks, and an expression of regret that his plans have been so seriously interfered with. It is explained that certain advertising—to the general public, by means of posters—which was to have been given on an extensive scale, has been withheld. Also paragraphs reflecting on the conduct of the undertaking have found their way into some of the leading continental journals; and the promoter considers that the time available is now too short for making good the mischief arising out of these circumstances.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 21.

Finning Park Co-operative Camera Club (Govan). Outing to Kilmalcolm.

MONDAY, AUGUST 23.

Southampton Camera Club. Discussion: "The Value of Record and Survey Photography." W. R. Olney.

TUESDAY, AUGUST 24.

Blackney Photographic Society. Some Novelties.

WEDNESDAY, AUGUST 25.

Southampton Camera Club. Ramble to Netley Abbey.

THURSDAY, AUGUST 26.

Blackley Photographic Society. Monthly Meeting.
Southampton Photographic Society. "Stripping Films from Glass Negatives." W. Grove.

TORONTO CAMERA CLUB.—The annual outing took place on July 1st, Dominion Day, when about forty of the members, accompanied by their wives or sweethearts, left at 7.30 a.m. by the Canadian Pacific Railway to the village of Meadowvale, which was reached by 10.30, when the members wandered at their own sweet will looking for something to snap at, strolling through leafy vales, Micawber-like looking for something to turn up. Arrangements had been made some time previously at a rural hotel for dinner and tea, to which all the members did ample justice. Stand cameras were used in numbers, whilst other members were supplied with the ever-ready Kodak, and reflex cameras, and even the "Tiny Ticker" was amongst them. There were as many makes of cameras represented as there were members of the party, each with his own fancy and liking. After a weary tramp in the sun and dust of a Canadian dusty road (which wants to be seen to be credited with the amount of dust it can kick up when disturbed), the party returned home by the 7.30 train in the evening, all expressing themselves as having had a lovely day.

Commercial & Legal Intelligence

FAILURE AT EBBW VALE.—The first meeting was held on August 11, Newport (Mon.), with regard to the failure of Wm. Henry Oleamor, photographer, residing and carrying on business at 5, Armoury Terrace, Ebbw Vale, and formerly of 11, Church Terrace, Ebbw Vale. The statement of affairs showed liabilities £156, assets £26. Debtor, who was at one time a rail-straightener at a local ironworks, commenced business as a photographer five years ago. He attributed his present position to over-buying at the commencement of his enterprise, and his expenses being in excess of the profits. The case remains in the hands of the Official Receiver.

A BIRMINGHAM BANKRUPTCY.—The creditors of Messrs. Wm. Tylar (London), Ltd., 41, High Street, Aston, photographic apparatus dealers, etc., met at Birmingham on August 11. Mr. Iliffe was voted to the chair. Accounts were submitted showing liabilities £3,665, assets £2,604, deficiency £1,060. Mr. Jagger, solicitor, examined that Mr. Wm. Tylar had successfully carried on the business for many years prior to 1907, when, in consequence of his failing health, and thinking it desirable to give his employees an interest in the concern, he converted same into a small private company. He believed some of his friends and customers would take up shares, but in this he was disappointed. 1907 showed a considerable falling-off in turnover, and the net result of the year's trading was a loss. Mr. Tylar was sanguine, however, of pulling the business through, as the net profits for the previous five years averaged £700 per annum. In consideration for the sale of the business to the company was £3,635, and Mr. Tylar was appointed managing director at £250 a year. In June last, while Mr. Tylar was in Bournemouth for his health, the person whom he left in charge absented himself, and investigations revealed defalcations to the amount of £80. The person in question was subsequently sentenced to six months' imprisonment. A meeting of the shareholders was convened, and it was decided to proceed to voluntary liquidation, Mr. E. Fisher being appointed liquidator. During the course of the discussion which followed Mr.

Jagger's explanation it was mentioned that Mr. Tylar was to receive his purchase money in 3,635 £1 shares and £2,000 in cash. He had only received the shares, and was an ordinary creditor for the £2,000. No shares were issued except to the seven signatories. Mr. Jagger pointed out that Mr. Tylar gave his employees an interest in the business, and that was part of the £3,653. Replying to questions, Mr. Tylar said the defalcations had been going on for eighteen months, and he could not say for certain what the total was. He accounted for the deficiency by bad trade, and being unable as in the past to place large orders. A motion was passed appointing Mr. A. Cripwell to act conjointly with Mr. Fisher with a committee of inspection.

LEGAL NOTICES.—The London and Provincial Electric Bioscope Theatres, Ltd., is being wound up. Mr. Harold Speer, 29B, Western Road, Brighton, is the liquidator. The creditors meet to-day (Friday) at 42, Bedford Row, W.C.

A first and final dividend of 6½d. in the £ has been declared in the bankruptcy of Henry Morton Pearce, carrying on business at 26 and 28, County Arcade, Leeds, under the style of Morton's Star Photo Company.

A dividend at the full rate of 20s. in the £ has been declared in the estate of John Harris, retired photographer, 75, Haviland Road, Boscombe, Bournemouth, Hants.

News and Notes.

THE PRINT-IN-GROUND COMPANY, 171, Jay Street, Schenectady, N.Y., have invented an ingenious device by which a rubber stamp can be used on a negative and a background printed in any position.

GUNNERY BY CINEMATOGRAPH.—Experiments have been made to apply the cinematograph to the use of gunnery instruction in the Italian fleet. During gunnery tests off Sardinia continuous photographs were taken of the work at the guns and also of the arrival of the shots at the target, and it is believed these will prove of great assistance to gunnery demonstrators. The Minister of Marine is establishing a special section of photography and cinematography, with headquarters in Rome.—"Daily Express."

SNAPSHOTS OF THE KING.—With reference to the visit of King Edward to Marienbad, the Military Governor, Prince Liechtenstein, has published a notice in the "Marienbad Tagblatt" requesting the public not to crowd round his Majesty when he appears in the Colonnade and the Park. All attempts to photograph the King are strictly forbidden. The Prince ends by expressing the hope that it will not be necessary for him to put into force any of the powers entrusted to him for the preservation of order and the desire that the orders of the police will be strictly followed.

HAMEL HALF-TONES.—On a visit to Nottingham recently a representative of the "B.J." was interested in seeing in the large, well-equipped photo-engraving works of Messrs. E. Hamel and Co. a complete Levy installation for machine etching. In other respects the Hamel Works is very completely fitted out for line, half-tone, and three-colour engraving, in addition to which this enterprising firm does its own electrotyping, and prepares originals for lithographic and other methods of reproduction. Mr. Hamel, it was interesting to find, had acquired his knowledge both in America and England, and no doubt a large factor in the success of the business has been his personal interest and supervision of every department.

THE LIVERPOOL A.P.A.—If you want a receipt for that popular mystery known to the world as—a society programme, you cannot do better than take a look at the list of fixtures which the Liverpool Amateur Photographic Association annually produces in the height of summer, and even so early not a half-programme or containing that common fixture, "To be announced later." Instonian notions of how a society should be run do not admit of this kind of thing. And there are some evidences in the list of fixtures of Instonian pressure, applied gently, but, all the same, without compunction. The result is a most skilfully blended programme, various in parts, but every feature as good of its kind as one can get, or as they may describe it in Liverpool, "a champion." At any rate, the fascination

of travel with the camera is represented by lectures on Algeria, Ireland, China, Canada, Southern France, Holland, and Cornwall, besides which a number of prominent workers contribute a variety of papers of great interest. We congratulate Liverpool on leading the way as regards society organisation, which remark we hope all readers within practicable radius of 9, Eberle Street, will take as our suggestion that they cannot afford to be non-participants in the benefits of membership of the L.A.P.A.

1,000-TIMES ENLARGEMENTS.—The "Star" of last week drew attention to a fresh variety of the free or semi-free portrait trick, which emanates from a firm at Welsbach House, calling itself the Electrophot Company. To quote our contemporary:—"The Electrophot Company have quite a new idea. They advertise that they will make '1,000 lifelike portrait enlargements' of any photograph for 'a special sample price of 1s. 3d. each.'

"The advertisement guaranteed a correct likeness, because their 'powerful apparatus will bring out every feature of the original photo.' Only 1,000 of these art treasures could be produced; and if your application was No. 1,001 your money and your application would be returned.

"A Croydon correspondent who sent 1s. 3d. received what he calls a 'smudge,' accompanied by a delightful circular.

"This explained that:

"The costly apparatus employed in this process is sufficiently powerful to ENLARGE A PHOTO UP TO 1,000 TIMES ITS OWN SIZE. You can therefore appreciate the fact that the lens searches out the smallest details in the original; and, whilst PRODUCING AN ABSOLUTELY PERFECT PORTRAIT, it also necessarily brings into undue prominence any imperfections or defects existing in the photograph, such as spots, scratches, technical flaws, strong effects of light and shade, etc., etc.

"It follows, therefore, that the Picture can be vastly improved by the removal of imperfections, the toning-down of harsh shadows, and by the building-up of imperfect lights."

"All this could be done by hand, and 'a large staff of skilled artists constantly employed in portraiture' enabled the Electrophot Company to 'convert your enlargement into a highly finished life-like picture, mounted ready for framing at the small cost of only 3s. 9d.' (extra).

"In other words, the 'lifelike portrait enlargements' mentioned in the original advertisement which were to be supplied for 1s. 3d., were in the end to cost 5s.

"We are not surprised that this cool proposal is described in the circular as an 'unprecedented offer.' Unprecedented cheek would, however, be nearer the mark.

"It is curious that the circular our correspondent sends us bears a number numerically higher than 3,000, so that No. 1,001 must have long since been passed in the anxiety of the Electrophot Company to plant their fifteenpenny 'life-like' portraits on a confiding world at 5s. each.

"In fact, at that price, there is no apparent reason why the numbers should ever stop."

TECHNICAL AND SCIENTIFIC PHOTOGRAPHY AT BIRMINGHAM.—In the hope of creating increased interest in general photography, both among members of societies and unattached photographers, and desiring to extend the good work already carried on by the Warwickshire and other photographic surveys, and by the scientific sections of various photographic societies, the Birmingham Photographic Society have decided to enlarge the scope of the annual exhibition by adopting the scheme recently brought forward by Dr. Hall-Edwards. Special plaques and certificates will therefore be offered in the classes enumerated below at the exhibition of 1910. The classification is as follows:—Section 1.—Scientific Photography: (a) Natural history photographs, illustrating the life history of bird, animal, fish, or insect; (b) natural history photographs, illustrating life history of tree or plant; (c) general natural history photography; (d) geological photographs; (e) tele-photographs; (f) radiographs (X-rays, radium or other radio-active substances); (g) photo-micrographs—general; (h) photo-micrographs—dealing with structure of metals; (i) other scientific photographs (such as lightning, electric sparks, etc.); (j) photographs dealing with the detection of crime. Section 2.—Applied Photography: (a) Photographs illustrating camp life, naval or military manœuvres, etc., suitable for recruiting pur-

poses; (b) photographs illustrating life in factory or workshop (including dairy, brewery, electric-light station, tram depot, fire station, gas works, sewage farm, railway station); (c) photographs illustrating the various processes a manufactured article passes through; (d) photographs illustrating life in the streets; (e) photographs (instantaneous) illustrating any kind of sport; (f) photographs suitable for advertising. All exhibits in these sections will be judged chiefly from the scientific standpoint, by a competent staff of specialists. Prints, transparencies, or lantern slides will be accepted in any class. It is desirable that no set of photographs should occupy a greater wall space than 4 sq. ft., and that no single print should exceed whole-plate. Entry forms and all particulars will be sent in due course. All communications should be addressed to the Secretary, Exchange Buildings, New Street, Birmingham.

Correspondence.

** We do not undertake responsibility for the opinions expressed by our correspondents.

** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

GLAZING THE STUDIO ROOF.

To the Editors.

Gentlemen,—I read with much interest your editorial note regarding the above, and as you mention the use of an imperishable putty, I cannot refrain from advising anyone who is troubled with a leaky roof to make use of Carson's Plastine putty, and also another article of theirs—Vitrolite paint. I feel sure that anyone using these two articles, and using them in the right way, will never have any more trouble through a leaky roof. By using in the right way—I mean first of all, if new work is being put in—and seeing that the sash bars are of well-seasoned stuff, and thoroughly dry before being well primed and given a coat—or a couple is so much the better—of Vitrolite, and, when this is well set, bedding the glass well into a well-pressed-in and liberal bed of the Plastine, care being taken to see that the glass goes well down, and, when set, carefully stripping off the back putty and stopping where needed. I am old-fashioned enough to advise a light top putty, and if this, when set is painted with Vitrolite, the paint being allowed to just lap over the putty on to the glass, then a thorough good job is the result.

The "Vitrolite" is an elastic paint, which, if put on to dry work will never flake off, or rub away, and the "Plastine" is a putty that never hardens or dries up like the ordinary article.

The reason for well priming and painting previous to glazing is to keep the wood from absorbing the ingredients that keep the putty always in a plastic condition. It is absolutely indispensable that the wood must be dry before painting and when glazing, or success cannot be expected.

I must apologise for the length of this communication, but the "B.J." has proved so helpful to me that I feel it but a pleasant duty to try, if possible, to help the JOURNAL and its many readers, by writing in terms of praise of what I know, and have proved to be two articles of particular service to the photographer.—Yours truly,

The Green, Feltham, Middlesex.

CHAS. WM. COLE.

MESSRS. LUMIÈRE'S DEVELOPMENT TRIALS.

To the Editors.

Gentlemen,—The elaborate trials of Messrs. Lumière and Seyewetz, given in the "B.J." of August 13, seem to me surprising not as regards the conclusions arrived at, but in the apparent neglect of the most important influence—that of time—in arranging the experiments.

The object of the trials seem to have been the means to be adopted in reducing or increasing contrasts. The experimenters seem to have ignored the well-known fact that with any given plate and any given developer, time of development is the factor which (within limits) settles the amount of contrast, and they do not in any way allude to this fact, or include time in the means they advise for modifying contrast.

They do not even appear to have adopted any uniform stand-

of time for their trials, but to have varied the time according to personal judgment at the time of the trial. The only information given on this point is that "the time of development in each case being sufficient for obtaining the maximum of detail in the shadows." If this personal judgment was exercised to merely secure full detail, irrespective of contrast, it is obvious that the trials merely express the well-known fact that the appearance of detail and the attainment of a given contrast has a widely varying ratio with different developers, or (in some cases) different compositions of the same developer.

But if, in any way, the desire to attain contrast was mixed up in the personal judgment which decided the time for each trial, it is difficult to say whether the conclusions arrived at are reliable.

Perhaps the best way to state my meaning is to say that Messrs. Lumière's conclusions are not applicable to those who develop by time methods (whether thermo-time method, or factorial-time method), but only to those who decide time of development in the same way that the experimenters have done.

The investigators have in one matter confirmed the conclusions of other experimenters, namely, "That all the developers examined, whatever their composition (with the exception only of those containing solvents of silver bromide), allow of development of faint impressions to the same degree."

Hereford,

August 14.

ALFRED WATKINS.

CARBON PHOTOGRAPHS.

To the Editors.

Gentlemen,—Photographers, at any rate, owe a debt of gratitude to Mr. S. G. Kimber, F.R.P.S., and the rather cheap sarcasms of "Q. S." in the "B.J." for August 13 will certainly not be echoed by them.

If the so-called photographers think that the public do not care one straw what a picture (?) is called, etc., then they might at least have the decency to call them something that will not harm photographers who believe the best policy is good work at good prices.—Faithfully yours,

The Esplanade Studio,

South Cliff, Scarborough.

W. FOSTER BRIGHAM.

August 17, 1909.

PHOTOGRAPHIC RECORD AND SURVEY OF SUSSEX.—An exhibition of photographs of places of interest and antiquity in various parts of Sussex is now open at the Brighton Fine Art Galleries, Church Street, Brighton, and remains open until Saturday week, August 28. The public are admitted free from 10 a.m. to 7 p.m. on week-days; 2.30 to 5 p.m. Sundays. The photographs, which are the property of the Photographic Record and Survey Association of Sussex, number about 600. The collection of photographs which the Association is making of local buildings and documents is of great value, being in many cases the only accurate record existent. It would be impossible to do more than mention a few of the photographs to be seen. A very fine set of photographs of the Pevensey Pageant of last year will be of general interest, and photographs of such places as East Maccalls, Balcombe Mill, the old "Sussex Pad" before it was burnt, Blockfields House, near East Grinstead, Horsham Manor House before restoration, Cowdray Ruins, Ditching Old House, Ewhurst Place, Rodmell Farm before restoration, Worth Church before restoration, to mention only a few, will undoubtedly attract much attention. There is a fine set of platinum photographs from drawings by Rowe in 1823-4 of various old Sussex churches, including Salehurst, Peasmarsh, Mountfield, Crowhurst, Hollington, Fairlight, Ewhurst, and several Hastings churches, a photograph of the old charter for a market at Cuckfield dated 1672, several sets of views of East Grinstead in 1864 and subsequently, and a fine collection of photographs of old Sussex fonts, brasses, sculptures, and specimens of ancient ecclesiastical architecture, including the Alfriston Clergy House, Sompting Church, Rogate Church during restoration, the very fine late Norman sculptures of the tower arch at Broadwater Church, the Saxon chancel arch at Bosham Church, and some fine examples of mural paintings at Trotton Church, Preston Old Church before the fire, Binsted Church, and at Fekes, Chid- dingly, also some fine examples of Sussex church towers.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

George Edward Clementson, Belmont, St. Anne's-on-Sea, Lancs. Photograph of Motor Car going on the North Promenade, St. Anne's-on-Sea, Lancs., containing Miss Marie Studholme.

Frank England, 23, Spring Street, Edgbaston, Birmingham. Photograph of Cycle Trade Arch, New Street, Birmingham.

Charles Edward Discow, 1A, Windmill Street, Gravesend. Two Photographs of the 1st Battalion Duke of Cornwall's Light Infantry.

Samuel Powell, 128, High Street, Rushden. Photograph of "The Tofte," Sharnbrook, taken by night.

DEVELOPING FILMS.—Could you oblige by saying the best method known for developing singly or on the stand principle the "leaf" films, postcard size? The usual stand developer holders do not suit them, and they are very troublesome to deal with one by one in the usual flat developing dishes. What do you recommend?
—J. B. G.

We should suggest the use of one of the film developing apparatuses. Personally, we find no trouble in developing in a dish. The chief drawback is the liability of the sharp corners of the films to cut into the emulsion on other films, but if the corners be rounded off by one snip of a curved nail scissors, no trouble will result from this cause.

H. LONGNEY.—We are sorry, but we are not able to identify the wrapper.

COMBINED BATH.—In using a combined toning and fixing bath I have always been in the habit of pouring the clear portion of the bath off for use, and occasionally throwing the sediment away. Do I do any harm to the bath in so doing? Any further information on this subject will be thankfully received.—L. A. F.

It is certainly right to use only the clear upper part of the solution for the prints. As regards the residue, it is possible that in some cases it may be of service to retain it, as it may check the bath from becoming too acid.

LENS FOR FLASHLIGHT.—I am in want of a lens for flashlight 15 x 12 groups, what focus would be best suited to this size plate for the work?—A. M.

It is best to use one of rather short focus on account of the depth usually required in interior work. We should select 10 to 12 inches.

J. S.—It may be due to a bath not fully matured. Do you let the toning bath stand for a few hours before using, or do you use hot water in making it up and employ it when cold? Traces of hypo in the wash-water used between fixing and toning will also give rise to this stain.

FREAK PHOTOGRAPH.—Will you be kind enough to inform me how the enclosed photograph was taken? If so, I shall be much obliged. In the first place, I saw an enlargement in bromide (15 x 12) of this, and then some smaller prints, but I did not notice much, if any, faking. If you feel by informing me it would be giving a secret away I do not wish for an explanation.—PUZZLED.

There is no secret in the matter. There are several ways of producing such pictures. One is to have a pair of flap shutters inside the camera, each covering half the plate within about the eighth of an inch; that is when both are closed there is about that

space between them. The first picture is exposed with one shutter closed. The figure then changes his position, the shutter of the exposed half closed, the other opened and the second exposure made. By having the space between the two shutters the one exposure is, as it were, vignetted into the other and does not show. You should get the little book by Richard Penlake on "Trick Photography," price 6d. It will give you other methods of producing "doubles."

GLYCIN TANK DEVELOPER.—Will you kindly inform me through the "B.J.," I want to use glycin developer for tank development, so please let me know its formula for quarter-plate, and the time to get good density at 65 degrees Fahr.—S. SHO (Tokyo, Japan).

Prepare a mixture or paste as follows:—

Boiling water	4 ozs.
Soda sulphite	2½ ozs.

When dissolved add:—

Glycin	1 oz.
--------------	-------

And then in small quantities

Potass carbonate	5 grs.
------------------------	--------

This forms a thick cream, which must be well shaken and diluted with water in the proportion of about 1 oz. to 12 or 15 ozs. of water. This developer will require about ten to fifteen minutes to give good density on a gelatine plate.

ENLARGING, ETC.—1. What is the most satisfactory illuminant for an enlarging lantern where neither gas nor electric light are available. If acetylene, is the three or four burner preferable? 2. I got a bottle of bisulphite lye some time ago. A portion of the fluid has precipitated into a solid cylindrical mass at the bottom of the bottle. How can I liquefy it? By adding distilled water?—H. F.

We should place next to gas and electric light the spirit incandescent lamps, of which there are several on the market. The light is better than that of an ordinary incandescent burner, and though some patterns do not admit of being readily turned up and down quickly when in use, that objection does not apply to a lamp of this type which we reviewed in our issue of June 11 last, page 461. It is supplied by A. J. Garrad, Southampton House, Birkbeck Building, London, E.C. 2. We doubt if the addition of water will dissolve the deposit, since it can hardly be soda bisulphite which has crystallised out. We should be inclined to try the effect of small additions of sulphurous acid liquor, first breaking up the deposit and crushing it fine in a glass mortar.

BLOCKING OUT BACKGROUNDS.—Kindly favour me with instructions for blocking out backgrounds of photographs for enlargements, and where to obtain materials for same.—WM. JOHNS.

Simply apply black varnish with a camel-hair brush to the portions to be stopped out. Or, better still, "Photopake," as supplied by the Vanguard Company, of Maidenhead. It may be had from all dealers. We do not answer queries by post.

GLAZING POSTCARDS.—Having to glaze a large number of bromide postcards, I should be glad to know whether there is any easier and quicker method than by squeegeeing to glass, ferrotype, etc. Can the cards be passed through a burnisher, hot or cold, and will this give nearly as good a finish?—ENAMMO.

There is no better or quicker way than squeegeeing on glass or ferrotype plates. This is the plan followed even when large numbers are produced. If the cards are passed through a hot burnisher with heavy pressure, a good gloss will be obtained, but not equal to that got by squeegeeing on glass.

T. A. JACKSON.—From your description the lens you have is incomplete, hence the impossibility of getting a picture with it. The back lens of a portrait lens consist of two glasses with an air space between them. Evidently in yours the concavo-convex is missing. The front lens alone, with a $f/16$ stop, will make an excellent instrument for landscape work.

BROKEN NEGATIVE.—Last week I sent a negative, half-plate, to Messrs. — to have a dozen platinotype prints made from it. After four had been got off I had a letter from them to the effect that the negative had broken in the printing frame, and very much regretted the accident had occurred, but they

would copy one of the prints, complete the order, and send me the reproduced negative. Can I proceed against the firm for damages, as the negative was a valuable one to me and I could not retake it without making a journey to Scotland?—SCOTSMAN.

We think not; as it is a custom of the trade, and is generally stated on all price lists, that those executing orders will not be responsible for accidents, but every care would be taken with negatives entrusted to them. In most instances when negatives break in the printing it is due to the unevenness of the glass, and the printers are not responsible for that.

COPYRIGHT.—I have a very fine engraving of a picture proof shown in the Academy a few years ago, for which I gave four guineas. Would it be illegal for me to copy it for post-cards and lantern slides, seeing the price I paid for it? I do not see that what I propose doing will in any way interfere with the sale of other prints?—G. ROMER.

It would certainly be illegal, as there would, of course, be a copyright in the print. You say that what you propose to do will not interfere with the sale of the prints. We think differently. The publication of post-cards and lantern slides would certainly damage the sale of the prints by vulgarising it by making the thing common.

LENS FOR GROUP.—I have a 12 x 10 group to take next week. I can borrow a 12 x 10 camera, but there is no R.R. lens with it and I am unable to borrow one for that size. A friend tells me that the focal lens of my whole-plate portrait one, if well stopped down, will do the work. I find that the focus of the front combination, by itself, is about eighteen inches. The lens is by ——. Do you think this will do the work if stopped down to $f/8$, in a good light out of doors?—FRANK J.

The front lens of a good portrait lens, stopped down, will do very well for groups out of doors. At $f/8$ it will not give critical definition to the margin of the plate, but that is not of such very great importance after all. If the lens be stopped down to $f/11$ or $f/16$, the result will be little, if any, inferior than if it were done with a R.R. working at similar apertures.

STOLEN LENS.—I had a portrait lens stolen from my place a little while ago. I have just found out that it was pledged at a pawnbroker's for twenty shillings, though it bears the name of one of our leading London makers, and cost me nearly twenty pounds last year. I have seen the pawnbroker, and after explaining the matter to him he refused to give the lens up, although I offered to pay the amount he had lent on it. Will you please tell me the best way to act, as the losing of a £20 lens is a serious matter to one who is struggling to make a living?—A. B. C.

If you can find the thief and he is convicted, we believe the magistrate has the power of ordering the lens to be given up to you without charge. However, we should advise you to see the magistrate and explain the matter to him, and he will, no doubt, enable you to recover the lens for the sum advanced upon it, or a little more, as the pawnbroker should know that when only twenty shillings was asked on a lens bearing a well known maker's London name, and costing as many pounds, it was not come by honestly.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Sulphide Toning.—Mr. Douglas Carnegie, as the outcome of a long series of experiments, has laid down certain rules to be followed in the practice of the sulphide process. The bleached print should be washed for a short time only. Freshly made sulphide solution stronger than 1 per cent. should be used. Hypo in the sulphide bath only affects the colour of the prints somewhat. (P. 664.)

The making of a trimming shape serving when large prints of various sizes have to be cut down accurately is the subject of an article on p. 663.

A modification of a recent novel method of exhibiting photographic portraits is suggested on p. 662.

Mr. H. Essenhigh Corke gives a description and illustration of a useful accessory designed by him and including in itself both a seat and a background. (P. 671.)

In selecting a diffusing screen for the arc lamp used in the studio advantage may be taken of the comparatively non-inflammable nature of engineers' tracing cloth. (P. 662.)

A note on the photographer's trade card appears on p. 662.

An editorial paragraph on p. 662 raises the question whether a lowered price is a really valuable means of drawing custom to the photographic studio.

In an article on p. 663 directions are given for the use of the carbon process in making decorative panels for insertion into articles of domestic furniture.

The plan of toning collodion prints first in the platinum bath and then in a gold combined toning and fixing bath has been recommended by a German worker. (P. 667.)

A further note on the use of thiomolybdate in the sepia toning of P.O.P. appears under "Correspondence" on p. 678.

A formula for preparing in powder form the acid diamidophenol developer is given and recommended by a French worker on p. 672.

We quote from an American contemporary the formulæ for using sulphur phosphate in the preparation of a printing paper. (P. 673.)

We hear from a German source of a daylight development process based on the use of a solution of potassium iodide as a desensitizer. (P. 661.)

The conclusion of the article describing the methods necessary in printing without light by the catatype method appears on p. 668.

A printing frame for colour photography figures among "Patents of the Week." (P. 676.)

EX CATHEDRA.

Iridescent Marks on Sulphide-toned Bromides.

A correspondent sends us a sepia-toned bromide print which, save in one respect, is a remarkably good specimen of its kind, vigorous, brilliant, and of good colour, but covered with iridescent markings, visible only when looking at the print at a certain angle. We cannot complain of any lack of information sent by our correspondent, but on the other hand the sequence of operations to which the print has been subjected increases the difficulty of laying the finger on the cause of the iridescence. The print, on "carbon-surface" bromide, was developed with acid diamidophenol, treated with "Hypono" to remove hypo, bleached in bichromate, salt and sulphuric acid, and finally toned in Edmund's thiomolybdate. We have never noticed such markings when using thiomolybdate under less complex conditions, and do not think the phenomenon can be due to it. Neither weak hydrochloric acid nor weak solution of potassium cyanide affects it, but a brisk rubbing over with an encaustic paste—we used the "Vanguard" Lustralene, which we had at hand—caused it to disappear almost immediately. We should be interested in hearing of other workers who may have noticed similar markings for which they have found a preventive or remedy.

* * *

Another Daylight Development Process.

According to a note in the current issue of the "Chemiker Zeitung," a process for the development of photographic plates in full daylight is about to be introduced upon the German market. It depends upon the use of a 4 per cent. solution of potassium iodide, into which the plate is laid (in the dark), and then at once removed into full daylight in order to watch the progress of development. The developer is one of metol and hydroquinone, made up with caustic potash and a somewhat heavy dose of bromide. Usually with processes of this kind, which are announced as about "to revolutionise photography," there are certain "ifs," and in the present instance we read that ample exposure must be given, that the developer must be mixed fresh for each plate, that the fixing solution must be frequently renewed, that a longer time must be allowed for fixing, and that the negatives obtained are of the thinner, softer character which call for a "hard" printing paper. We doubt whether the convenience of conducting part only of the dark-room operations in the open is advantageously bought on these terms. If such daylight manipulation is desired, we should expect to get better results by using a tank and developing by time than by venturing on a process of desensitising the film. The iodide solution is, however, said to have been patented, and to have been named "Aktinal." No doubt it does what is claimed for it, but we hope it will not share

the fate of other similar daylight developers which have been boomed for a month or two and have then been cast into the limbo of uncommercial schemes.

* * *

The Photographer's "Trade Card"

Just as in a play produced in London recently the hero's accession to enormous wealth in the third act is symbolised by his wearing knickerbockers, so much may be conveyed, or fail of conveyance, in the card which the photographer may have occasion to use away from his place of business. Apparently, many photographers are innocent of any ambition to be simply and severely correct in this respect, although there is a good deal to be said for the practice when dealing with people who understand these little conventions. The correct card, it is perhaps permissible to point out, is identical in size, shape, and style with the customary visiting-card, save that the name appears thereon without the prefix "Mr.," and the qualification "Photographer" is printed (or engraved on the plate) immediately below, in the same style. All kinds of departures from this style are to be found, but none can be imagined in better taste or more likely to create the impression desired among a "genteel" circle of people.

* * *

Screens for Studio Arcs.

One of the advantages of the completely enclosed arc lamp for portraiture, several patterns of which are now upon the market, is the absence of the chance of igniting the material employed as a diffusing screen. Thin silk or muslin, after being kept in the neighbourhood of an open arc, becomes so absolutely dry that the touch of a fragment of glowing carbon from the lamp is sufficient to set it in flame. It would appear not to be generally known that while engineers' tracing linen is one of the very best diffusing media, it is also the least inflammable material which can be advantageously employed for the purpose. Usually if a fragment of carbon happens to fall on a diffusing screen of tracing linen its only effect is to cause the latter to smoulder without any actual flame being produced. If fabrics are used in close proximity to an open arc lamp, or, rather, in a position where they are in danger from falling particles from the arc, one measure of prevention which ought to be taken is to soak them in a solution of alum or tungstate of soda, thereby rendering them highly non-inflammable. Arc lighting, even in quite small studios, is now recognised as being so valuable an aid to business that it deserves to have proper attention given to the necessary means of using it at full efficiency and with safety.

* * *

Does the Low Price Pull Orders?

The fact that after all is said and done a photographic portrait is a luxury does not seem to be kept before the photographer so prominently as one would imagine. It certainly deserves to be considered as a very large factor indeed when framing any inducement to the public to come and be photographed. Since it is essentially a luxury, and therefore a thing to be done without when money is short, one would not expect mere lowness of price to be a compelling power in attracting customers. We recollect not long ago having this view of the price question forced upon our notice by visiting an exhibition of arts and crafts whereat a photographer had taken a stall. Among the exhibits of his work appeared the announcement that, in the case of all visitors to the exhibition who came to his studio, he would make a reduction of 25 per cent. of his regular prices. In the absence of some convincing reason why he should choose to do this—and none

was put forward—we can hardly suppose that the difference between £1 and 15s. would induce persons to pay a visit to his establishment. To us this particular price inducement seemed meaningless, and we think, too, that in almost every case more is to be made by insisting on quality in such articles of luxury as photographs than on their cheapness.

* * *

The Enlargement of an Idea in Window Display.

The ingenious plan of illuminating prints both from the front and back adopted by the Platinotype Company at the Convention at Canterbury lends itself, as we suggested at the time, to window display of a novel kind. A variation of the same idea suggested to us by a correspondent may also be worth mentioning. In place of an actual paper print in the frame, a piece of semi-transparent paper may be inserted, and the picture projected from behind by means of an ordinary optical or enlarging lantern. The lantern itself is hidden by the back frame of the window, in which an aperture is cut corresponding in size with the internal dimensions of the picture-frame. The frame thus appears suspended in the usual way, but is shown to possess the peculiarity of enclosing a picture which changes every now and then. A suitable adjustment of the light in the lantern and of those used in the window itself should allow of the projected photograph presenting the appearance of the prints displayed in the ordinary way. We offer the idea for what it is worth to those who may care to spend some time but very little money in arranging an exhibit which would cause some curiosity among passers-by.

* * *

An Apprenticeship Question.

We are sometimes the recipient of letters asking us to decide disputes between master and apprentice, a duty which, it need hardly be said, we do not feel called upon to discharge. There are, however, certain customs which we believe are generally recognised, yet are frequently a bone of contention between those who have taken an apprentice and the latter's parents or guardians. Perhaps the chief of these, and one which is not infrequently referred to us, is as to whether the apprentice should be taught retouching. We think that if the indentures are drawn up according to the usual form, under which the master undertakes to teach his apprentice the "art, trade, or business of photography," there is not a doubt that retouching should be included in the instruction given, seeing that this branch of work is a very essential part of the portraiture business. Unless this, or any other, part of the ordinary business of the photographer is specifically mentioned as excepted from the knowledge which the master covenants to teach, it may be taken to be included in it nevertheless, our advice to parents is that they cause to be included in the terms of the indentures a list of the actual branches to be taught, obtaining advice in the matter from someone versed in photography. If this course were more generally followed, we should hear less of after-disputes.

* * *

The Non-Return of Specimens.

We hear less than we did of specimens being retained by persons or firms to whom they are submitted by those applying for situations. It will be remembered that we have on several occasions cautioned assistants against sending specimens to box numbers at our office, and no doubt the fact and Messrs. Greenwood and Co.'s refusal to insert requests for specimens in advertisements appearing under a box number have reduced the evil to small dimensions.

As in all other human affairs, there are two sides to the question, and we have had instances brought before us in which employers who had been accused of retaining specimens were doing so for want of marks on the photographs identifying them with the applicant. Some years ago we published some hints to applicants, one or two extracts from which we may with advantage repeat:—

1. Write clearly and to the point. Answer all the questions in the advertisement.
2. Enclose a stamped envelope for reply.
3. If enclosing a portrait of self, let the sender's name be upon it.
4. In sending specimens, let stamps for return invariably accompany them, with also a suitably addressed envelope for their return.
5. Let every specimen have its owner's name (and, preferably, address) written plainly upon some part of the picture or mount. If on the picture itself there is little danger of dishonest persons detaining them.

* * *

Defacing negatives wholesale. A question which sometimes arises in the practice of a professional photographer is the quickest method of treating a batch of negatives which may be passing out of his possession in such a way that no prints can afterwards be taken from them. Naturally such a course is advisable, in order that the photographer may feel assured that the negatives will never be used to the detriment of his sitters, and therefore of himself. It will be found that the scratching through each film with a blunt bradawl or similar tool is a slow procedure. A method which may be employed very rapidly and serves in the case of both varnished and unvarnished negatives is to give each negative a dab with a solution of aniline-violet dye in methylated spirit. The dye attaches itself firmly to the negative and permanently prevents any after-use being made of it. Although the law on this question is very vague, yet we think that every photographer who values his reputation should take some such means as this when getting rid of any number of old negatives.

UNIVERSAL TRIMMING SHAPE FOR LARGE PRINTS.

In a note on print trimming in our issue of August 20, we described one way of dealing with large prints when a big cutting shape is not available. It is, however, an easy matter to make a large cutting shape that will serve the same purpose more rapidly and with the same degree of accuracy. We select a sheet of fairly thick ground glass and cut it to a rectangle the size of the largest print that is to be dealt with. The cutting need not be very accurately done except in regard to one respect—one of the four angles must be a perfect right angle, while the edges meeting at this angle must be quite straight. The other edges and angles may be very irregular without in any way interfering with the use of the shape. The next proceeding is to rule parallel lines on the ground surface with a fairly hard blacklead pencil. One set must be ruled strictly parallel to one of the prepared edges, and then these lines must be crossed by another set ruled parallel to the other edge. The whole surface is thus divided up into squares, the size of which depends on the distance apart of the parallel lines. For a small shape for prints under whole-plate in size quarter-inch squares are most convenient, but for large prints half-inch or even inch squares will serve. A coat of varnish over the lines will fix the blacklead and render the ground glass sufficiently transparent for trimming purposes. In use we lay the shape down on the print, so that the square corner comes just where one corner of the print is intended to be,

and we square up the edges with the lines of the subject by the aid of the pencil lines. When properly arranged we trim two sides of the print along the prepared edges, and then turn the shape so that the right angle comes diagonally opposite its first position. Next we square up the boundaries of the print by arranging the shape so that the print edges previously cut are exactly parallel with the nearest pencil lines in the shape, and two more cuts then complete the trimming process, leaving us with a perfectly squared print. It should be noted that the accuracy of the result depends entirely on the truth of the right angle prepared in the shape. It is easier to produce one correct right angle than four of them, therefore the result produced with a shape prepared in the way described is likely to be more accurate than any that we can attain with the ordinary type of shape, in which all four sides are used as cutting edges. It is just as well to mark the one correct angle so that in use we may make no mistake in cutting along the wrong edges. The safest precaution perhaps is to cut in a wavy fashion the two edges that are not to be used.

CARBON PHOTOGRAPHS FOR DECORATIVE PURPOSES.

ONE of those old-time uses of photographic printing of which profitable use may often be made deserves to have occasional attention called to it—we refer in particular to the employment of the carbon type of photograph in the decoration of screens, panels, and other objects of the cabinet-maker's or wood-worker's craft. We are quite aware of the ease with which paper prints may be mounted on such surfaces and preserved by means of a coat of varnish, but we have now in mind the production of a much more handsome effect, namely, that in which the natural grain of the wood forms the ground of the photograph. For this purpose the carbon process stands alone in the ease and success with which it can be applied. Moreover, the pictures have the advantage that they are absolutely permanent, and, further, by the method to be given they can be dusted, washed, cleaned, and polished like ordinary furniture, without the least fear of injury, even after many years' service.

We will first say a word or two on the preparation of the panel which is to receive the picture. The wood chosen should be one of light colour, in which the grain or "figure" is not very pronounced. Some kinds of satin-wood, birch, pine, and American white-wood answer this requirement, and in each case the wood should be free from knots. The rough wood is first carefully planed up so that it shows no traces of the plane. It goes without saying that it should be well seasoned to begin with, otherwise there is a risk of its "casting" or warping after a time if subjected to great variations of temperature, or possibly during the manipulations. For this reason, also, the panel should not be too thin: what is known as half-inch "stuff," before it is planed up, is a suitable thickness, which will be about three-eighths of an inch when it is finished. The board or panel having been satisfactorily planed up, is next finely surfaced with glass-paper. A medium-grain paper, strained on a small piece of perfectly flat wood, should be used first, a finer one afterwards, then finishing off with a paper of the finest possible grade. The glass-paper should be used in one direction only—that of the grain of the wood, and never crosswise, as the fine scratches made that way are difficult to get rid of, and it is essential that none of any sort should be left. After glass-papering, the dust must be wiped off and the panel carefully examined. Any fine scratches which may

be visible must be worked out with the finest grade of glass-paper.

The surface having been satisfactorily obtained, the next thing is to fill up the pores of the wood. This is best done with insoluble gelatine similar to that used in the preparation of single transfer paper in the carbon process. A good formula is as under:—

Nelson's No. 1 gelatine	1 oz.
Water	25 oz.
Chrome alum (in 2 oz. water)	20 grs.

Both solutions should be warmed to about 180 deg. F. when they are mixed. The mixing should be done slowly, the alum solution being added a little at a time, with vigorous stirring. It should be applied hot with a soft hog-hair brush. If the wood is very porous, two, or even three, coatings may be necessary. When the coating is dry, it is well to go over the surface, as before, with the finest-grade glass-paper: this will get rid of any marks that may be formed by the brush, for it may be borne in mind that the only purpose of this coating is to fill up the pores of the wood, and nothing more. This coating, being colourless, does not hide the grain of the wood in the least.

The panel being prepared, the next thing is to make a carbon print in the usual way on flexible support. The colour of tissue should be one that will suit the tint of the wood. As a rule, cold blacks should not be selected; a warm black or dark purple is preferable in most instances. Red chalk or sepia is very suitable for some woods. With regard to the subjects best suited for this class of work, almost any will do; they may be portraits, landscapes, figure studies, etc. Subjects that will appeal to many are reproductions of paintings by old masters. Nothing special need be said about the printing, except that overprinting must certainly be avoided; in other words, the high-lights must be kept quite clear from tint. It must be kept in mind that the pictures are to appear on a basis that is not white, but more or less tinted according to the wood employed; hence it will be seen that any tinting on the highest lights must be detrimental to the picture.

A satisfactory image having been obtained on the flexible support, it is trimmed to the size and shape desired. This should be in accordance with that of the panel, leaving a suitable margin all round. This latter, however, should not be too wide, or it may to an extent overpower the picture itself. On this point a little judgment should be exercised in order to obtain the best effect. We have now to transfer the carbon print from its temporary support to the panel. To do this we require a solution of gelatine and chrome alum similar to that used for transferring the

carbon image to other rigid permanent supports. The following is a suitable preparation for our present purpose:—

Nelson's No. 1 gelatine	1 oz.
Water	20 oz.
Chrome alum (dissolved in 2 oz. water) ...	12 grs.

The temperature at the time of mixing should not be under 150deg. F. The mixing is done in the way directed for the solution for preparing the panel. The solution is then strained through a piece of "nainsook" or fine muslin into a dish warmed to about 140 to 150deg. F., and all air bubbles on the surface skimmed off with a strip of blotting paper. The panel and the picture are then put into the warm solution and allowed to soak for a couple of minutes or so. The two are then brought together, face to face, of course—taking care that no air bubbles become imprisoned between the two—and the print is arranged in its proper position on the panel. The two in contact are then gently withdrawn, squeegeed together, and placed in an upright position, that is, with regard to the grain of the wood, to dry spontaneously. Placed the other way there is the possibility of the panel losing its flatness. When the whole is perfectly dry, and not before, the temporary support is stripped off, when it will be found that the image is so firmly fixed to the wood as to seem part of it. Should any trace of the waxing compound of the flexible support be seen on the picture it may be cleaned off with a pledget of cotton wool moistened with benzole.

In its present state the image is analogous to one on paper, and is equally as liable to suffer from abrasion, and as a consequence, it would be of little use for our present purpose. It is therefore varnished either with mastic varnish, such as is used for painting, or with pale copal varnish. The latter is preferable, as it is best suited to wood, is more durable, and bears more rough usage than does the mastic. It is applied with a soft hog-hair varnish brush. Two coatings of the varnish may be given to enhance the brilliancy of the surface—the second after the first has become thoroughly dry and hard. French polishing, however, is preferable to varnishing, as it gives the picture a more refined appearance. For our present purpose white polish should be used. This is made with bleached lac in place of the ordinary button or orange lac. It may be obtained of any of the large polish and varnish manufacturers. If the photographer is not *au fait* with french polishing, he had better hand over this part of the work to a professional polisher, supplying him with the polish, because, as a rule, french polishers have little or no use for white polish. It need not be said that these photographs can be coloured either with oil or water colours before they are polished or varnished, as these operations will not disturb the colouring in either case.

THE CHEMISTRY OF SULPHIDE TONING.

The frequent failure of the sulphide toning process is a subject of such perennial correspondence and inquiry that an examination into the nature of the degraded tones so often obtained, together with a quantitative investigation of the deterioration of sulphide solutions, seemed to be desirable.

The Sulphuretted Solution and the Bleach.

The sodium sulphide used in this investigation was the colourless crystalline variety of commerce. The crystals proved on analysis to be the hydrate $\text{Na}_2\text{S}\cdot 9\text{H}_2\text{O}$ with 2.4 per cent. of adhering water of deliquescence. The solution used was obtained by dissolving 10 grammes (roughly weighed) of these crystals in one litre of water. On titration with decinormal iodine, the solution so prepared was found to contain exactly

.3 per cent. of anhydrous Na_2S . This is rather a dilute solution, but the dilution was purposeful, the decomposition of strong solutions being so exceedingly slow. It follows from the results of the above-mentioned titration that some $33\frac{1}{2}$ grammes of the crystalline sulphide must be dissolved in a litre of water to furnish a true 1 per cent. solution of Na_2S , and my experiences lead me to advise that nothing very much more dilute than a true 1 per cent. solution of Na_2S should be used in practice.

The bleaching solution used had the following composition—

Potass. ferricyanide	34.8 gms.
Ammonium bromide	10.8 gms.
Water	1,000 ccs.

I have before pointed out that the recipe for the bleach given

in the "B.J. Almanac" contains more bromide than is necessary for the reaction involved, and that this superfluity of bromide is not only prodigal, but dangerous. For the sub-bromide of silver constituting the material of the bleached image is soluble in ammonium bromide, and any excess thereof is apt on occasions of prolonged bleaching to discharge delicate detail from the picture. The above specified bleaching solution, if kept in a well-stoppered bottle in the dark, may be used over and over again to complete exhaustion. It has been said that the solution deteriorates on frequent use by the development in it of potassium cyanide as a decomposition product. I can find no support for such a statement. A bleaching solution which has been in repeated use since last September did not contain a trace of cyanide, and, moreover, gave tones indistinguishable from those given by a freshly made up solution. In testing the bleach for cyanide, it was acidulated with tartaric acid, the acidified solution extracted with ether, the ethereal solution extracted with caustic soda solution, and this latter solution tested for cyanide by means of the Prussian blue reaction. No Prussian blue was formed, although it was formed in a control experiment conducted concurrently in which a trace of cyanide was purposely added to the bleach.

And here I may mention a matter of some importance in the practice of sulphide toning that seems hitherto to have been overlooked. It has reference to the duration of the washing after bleaching. There appears to be a prevalent idea that, in general, washing cannot be overdone. This is by no means always true. Long washing after bleaching leads, at any rate when weak sulphuretted solutions are in vogue, to poor tones. Indeed, so degrading an effect on the final tone has a protracted washing after bleaching that a great number of comparative toning trials made before I recognised the deteriorating effects of long washing had to be repeated, the time of washing being kept constant, and not protracted at that. Excellent warm tones are, in fact, obtained when the merely rinsed bleached print is plunged directly into the sulphide bath. The only objection to such procedure is that the sulphide solution must be thrown away after use. Several other instances might be adduced of the heresy that washing is universally a virtuous operation which cannot be over-indulged in to detriment. Attention has recently been drawn in these columns to the injurious effects of protracted washing in the chromium intensification process. I, and probably others, have noted the same baneful influence in the case of mercurial intensification, and hundreds of the lantern slides of my salad days came to untimely ends in the lantern—the pock-marked victims of supererogatory ablutions.

It is to be noted that the injurious effects of long washing are in evidence only when using dilute sulphuretted solutions whose sulphide content has fallen to about $\frac{1}{4}$ per cent. If the 1 per cent. solutions of sulphide are employed, the duration of the wash has no influence on the tone finally obtained. If only dilute (e.g., .04 per cent.) solutions of sulphide are in use, then, again, the duration of the washing is immaterial, for with these extremely attenuated solutions the tones are in any case poor.

This peculiar and unexpected result (viz., that the duration of the wash following bleaching is of importance only in the case of sulphide solutions of intermediate strengths) was confirmed by repeated trials. Since a short washing is never injurious, and since under certain conditions a long washing is injurious, the recommendation to habitually curtail the washing should be acted on both on the score of economy in time and of certainty of satisfactory issue.

Throughout the investigation comparative toning tests were made on machine-printed bromides of the same subject. These prints were of such uniformity as to render comparisons unequivocal. For an unlimited supply of these prints I must ex-

press my indebtedness to Messrs. Butcher, Curnow, and Co., of Blackheath.

The Products of Decomposition of Dilute Sulphide Solutions.

The possible products of decomposition of sodium sulphide solutions are sodium salts of thiosulphuric and the thionic acids, caustic soda, sulphur, and polysulphides of sodium.

In solutions of sodium sulphide kept bottled in the dark and of such concentrations as this investigation concerns itself with, the equation of decomposition would seem to be a very simple one. The only decomposition products formed under these conditions are sodium thiosulphate ("hypo") and caustic soda. The decomposition is quantitatively expressed in the equation

A certain proportion of the caustic soda resulting from this primary reaction is, however, transformed into sodium carbonate by the carbon dioxide in the air. When decomposition is complete there is no residue insoluble in acids, as would be the case if free sulphur were formed; nor is the solution at any phase of its decomposition coloured greenish-yellow, as would be the case if polysulphides of sodium were formed.

A full account of the analytical details and the calculations founded thereon which established the above equation of decomposition would be out of place in the pages of a photographic journal. Let it suffice here merely to state, broadly and comfortably, the scheme of analysis adopted. The combined amounts of undecomposed sulphide and of hypo present at any time was determined by acidifying a measured volume of the solution with acetic acid and titrating with deci-normal iodine solution. The sulphide was removed from another measured volume of the solution by shaking vigorously with repeated additions of bright copper turnings till the filtrate showed no change of colour with lead hydroxide dissolved in soda—by far the most delicate of all the tests for the presence of soluble sulphide. A measured volume of the sulphide-free filtrate thus obtained was titrated with acid; the result gave the Na_2O present as NaOH , Na_2CO_3 and Na_2S . Another measured portion of the sulphide-free filtrate was boiled with barium chloride solution, made up to a definite volume, and the precipitate of barium carbonate allowed to settle. An aliquot portion of the supernatant clear liquid titrated with standard acid gave the alkali present as caustic soda and sodium sulphide, so that this titration taken in conjunction with the results of the previous acid titration permitted of the calculation of the alkali present as carbonate. The neutral solution thus obtained was titrated with deci-normal iodine, so as to arrive at the amount of hypo present. Seeing that the amount of hypo and sodium sulphide was furnished by the first iodine titration, the amount of sulphide still remaining undecomposed as well as the caustic soda resulting from the sulphide decomposed could be found by subtraction.

It is quite clear that if the decomposition proceeds in accordance with the equation given, then the disappearance of every two molecular weights in grammes of sodium sulphide (156 grammes) must involve the appearance of one molecular weight in grammes of hypo (158 grammes) and two molecular weights in grammes of alkali, reckoned as caustic soda (80 grammes). This relationship or proportionality was established by the analyses just outlined.

Analyses of solutions of sulphide which had been exposed to bright light or had been aerated (see *post*) showed, as would naturally be anticipated, a defalcation in the amount of hypo demanded by the equation—the hypo itself having suffered a decomposition due to the insolation or aeration. Furthermore, in the insolated and aerated solutions magnesium sulphate gives no precipitate till the solution is boiled, thus proving that in these cases the alkali is no longer present in

the form of caustic soda and the normal carbonate, but in the form of sodium bicarbonate.

The Rate of Decomposition of Sulphide Solutions Under Varied Conditions.

A .3 per cent. sulphide solution was divided into three portions. One portion, A, contained in an uncovered glass cylinder was exposed out of doors during a run of exceptionally bright sunny weather. Another portion, B, which was protected from light, had air aspirated through it by a filter pump. The third portion, C, was kept in a bottle—thickly swathed in brown paper—in a cupboard. Toning tests of the three portions were made daily, and analyses of the solutions were made when the results of the toning tests seemed to demand them.

When 15 days old the tones given by A showed manifest signs of degradation, the warm purplish sepia of normal sulphide toning giving place to a cold sepia very similar in hue to the pigment made from beech-wood and known to water colourists as "bistre." A day later the bistre tones gave place to raw yellow browns. At this stage the solution contained .047 per cent. sodium sulphide and .158 per cent. hypo. When 18 days old A ceased to tone altogether; the substance of the bleached image was first dissolved out of the gelatine by the hypo now present to the extent of .174 per cent., and then thrown down as a reddish brown precipitate by the remaining traces of still undecomposed sulphide, which amounted to .016 per cent. A faint indication of the original picture, however, still remained on the paper, and there is little doubt but that this residual image is none other than the so-called residual image of primary development. It is identical in strength and appearance with the image which remains when the silver of primary development is dissolved from an untuned bromide print by persulphate, also with the image which survives when a bleached bromide print is treated with hypo.

The aerated solution B began to show manifest signs of its deterioration on the 11th day; the tones given from the 11th to the 14th day being bistre instead of a warm purplish sepia. On the 15th day, when the solution contained .016 per cent. sulphide and .1 per cent. hypo, there was a partial solution of the bleached image, and the final tone was khaki coloured in the shadows and dirty yellow in the high-lights. On the 16th day the last trace of sulphide had disappeared and the bleached image dissolved away in the hypo (now present to the extent of .11 per cent.), leaving only the residual image of development.

The bottled solution C retained good toning power for weeks after the solution A and B had completely decomposed.

It would appear then from these observations, as I think would generally be anticipated, that both aeration and exposure to light greatly accelerate the rate of decomposition of sulphide solutions; aeration, however, being a more powerful accelerator than insolation. Another set of observations proved that the instability of sulphide solutions increases with the temperature. The solution A, as we have seen, took 18 days to decompose; another solution of slightly greater concentration and exposed during a run of much hotter weather had completely decomposed in 8 days.

It will be convenient and conducive to brevity, if we here make a classification of the successive phases of tonal degradation as follows:—

- (1) The bistre phase—the toned image becoming progressively colder and rawer.
- (2) The ochreous phase—the image getting progressively lighter and often showing metallic glance in the shadows.
- (3) The phase of incipient solution of the bleached image with re-precipitation in the sulphuretting solution, a faint yellow image remaining in the gelatine.
- (4) The phase of complete solution of the bleached image, leaving only the residual image of development in the gelatine.

The question now presented itself:—Is the ratio hypo : sulphide, necessary to bring about any specified one of the phases, constant; or is the ratio a function of the particular concentration of the sulphide solution used?

A long series of experiments, involving sulphide solutions all concentrations from 2.5 per cent. to .05 per cent., prove that the ratio is not constant but rises in value with the strength of the sulphide. A few illustrative instances are quoted at random from my notes. The ratio hypo : sulphide which must be reached to bring on phase (1) is about 8 : 5 for 1.5 per cent. sulphide, but only 2 : 5 for 1 per cent. sulphide. Again, the ratio for phase (3) was 8 : 1 in the case of a 1 per cent. sulphide solution, and only 4 : 1 for a solution of .05 per cent. concentration. With the 2.5 per cent. sulphide, phase (3) was never realised, although the ratio hypo-sulphide was made very large. In all these experiments hypo of known strength was added freshly prepared sulphide solutions—the mixtures, of course simulating stale sulphide solutions.

A very curious, and to me inscrutable, fact was noticed when working with the 2.5 per cent. sulphide solution. Such a solution (which, be it said, is far too concentrated for general use in toning) gives poor brown tones, not to mention blisters. The curious fact is that the addition of hypo to such strong sulphide solutions up to a certain limit, instead of degrading the tone, improves it, rendering it warmer and more purple. The limit of betterment is reached when the ratio hypo : sulphide is about 1 : 1½; if this limit be exceeded there is progressive but slow degradation. Though the observation has no significance for the practice of sulphide-toning, yet it seems desirable to put on record a case where contamination with that *bête noire* of the dark-room, hypo, is found to be not only not baneful but positively beneficent.

Attempted Explanation of the Vagaries of Sulphide-Toning.

The fact that such different sulphuretting agents as sodium sulphide, sodium sulphhydrate, and sulphuretted hydrogen furnish identity of tone under comparable conditions at once suggests the application of the theory of ionic dissociation to the problem. There is, too, another very important fact that challenges attention in this connection—the fact that very dilute solutions of sodium sulphide, even when quite fresh and therefore hypo-free, give cold bistre tones in strong contrast with the warm sepias of normal toning.

If a bleached print is placed in, say, a .002 per cent. sulphide solution it tones very slowly to a light brown. Toning in such a dilute solution may demand hours instead of seconds for completion, and a large volume of solution may be used to ensure that the absolute quantity of sulphide present is more than sufficient to sulphurise the bleached image. Furthermore, and this is a most important point, the tone of a print so obtained is not improved by subsequently treating it with a strong sulphide solution—indeed, it is not changed in the slightest degree by such treatment.

Sodium sulphide in solution dissociates into Na⁺ and S²⁻ ions. But the S²⁻ ions interact with water producing SH⁻ and OH⁻ ions, thus

so that solutions of sodium sulphide (as also sodium sulphhydrate and sulphuretted hydrogen) present us with complex equilibria implicating in all three cases the ions of Na, S, SH, and OH. Though the S²⁻ ions are probably present only in very small quantity, yet the characteristic reactions of the substance named, used in solutions of ordinary laboratory strength, are due entirely to the S²⁻ ions. For immediately any S²⁻ ions are removed from the equilibrium by the chemical change in progress, the SH⁻ and OH⁻ interact to produce a fresh supply. May we not plausibly assume that in very dilute solutions of sulphide the stable SH⁻ ions alone persist—practically all the

stable S'' ions having been hydrolysed? In accordance with this assumption we would attribute to the action of S'' ions the purplish sepia tones given by fresh sulphide solutions of moderate concentration, while the colder brown tones given by very dilute solutions would be attributable to the interaction of the H' ion with the bleached image, the compound formed being unstable as to resist any subsequent change from the S'' ions when placed in stronger sulphide solutions.

The rôle played by the hypo of decomposition in stale sulphide solutions would seem to be somewhat as follows.

When present in relatively small proportions the hypo influences the ionic equilibrium system in such a way as to diminish the concentration of the S'' ions relatively to that of the SH' ions—thus producing tones indistinguishable from those obtained by the use of very dilute but uncontaminated sulphide. As the proportion of hypo to sulphide increases, a race ensues between two rival reactions. In virtue of its concentration the hypo now diffuses into the gelatine film more quickly than the sulphide; the bleached image is dissolved by the hypo before the S'' or SH' ions have had time to reach and directly attack

By the time the S'' and SH' ions have penetrated the film they find the film occupied, not by a solid sub-bromide of silver, but by a solution of $Na Ag S_2 O_3$, and its ions Na^+ , $Ag S_2 O_3'$. The product of the interaction of the S'' and SH' ions with the complex ion $Ag S_2 O_3'$ in the presence of a colloid such as gelatine is a colloidal solution, which stains the gelatine yellow. Hence the so-called ochreous phase. If, *in vitro*, dilute sulphide ($\frac{1}{8}$ per cent.) be added to a solution of silver bromide in hypo—the hypo : sulphide ratio being adjusted to about 7 : 1—a yellow solution is first formed, but this soon becomes colourless, depositing a brown precipitate. If, however, gelatine is present, the yellow solution is permanent.

When, owing to prolonged decomposition, the proportion of hypo present rises still higher, it diffuses into the film, dissolves the bromide of silver and the solution of $Na Ag S_2 O_3$ diffuses out again before the attenuated sulphide has had time to come into action. When the sulphide does react it is with the $Ag S_2 O_3$, which has emerged from the film; away from the restraining influence of the gelatine it is precipitated by the sulphide as a reddish brown precipitate, which appears, as it were, to effloresce up out of the image if the dish is kept steady. It is at once disseminated through the liquid when the dish is shaken, or the surface of the print wiped with cotton wool. The only remnant in the gelatine of the original image is now the faint residual image of primary development.

There is one other peculiarity of the toning produced by stale

sulphide that deserves mention. It consists in the fact that the degradation of tone is very generally confined to the heavier shadows while the high-lights still continue to tone normally. This double-toning can, I believe, be attributed to purely physical causes involving relative rates of diffusion and the relative velocities of the two reactions between the bleached image and the sulphide on the one hand and the bleached image and the hypo on the other. If we may be permitted to assume that the hypo diffuses more rapidly than the sulphide, and that the velocity of the sulphide reaction is greater than that of the hypo reaction, then double-toning of just such a character as is in evidence must result.

Summary of Results Affecting Practice.

1. The bleaching solution—which should be kept low in bromide—can be used to exhaustion without affecting tonal values.
2. The wash after bleaching should be of short duration.
3. The sulphide solution should not have a much lower concentration than 1 per cent. anhydrous sulphide. (About 33 grammes of the hydrated crystals per litre of water will give an approximately 1 per cent. solution.) Though the decomposition of solutions of this strength is very slow when they are kept well corked and in darkness, yet if absolute constancy of tone is essential it is necessary to use freshly made solution.
5. The presence of hypo in the bleaching bath (the limiting amount depending on the percentage of sodium sulphide present) is, of course, fatal. A considerable amount of hypo may be present in the sulphuretting bath, with either no effect at all on the resulting tone, or no more disastrous effect than the production of cold brown tones in the place of warm purplish sepia ones.
6. The polysulphides of sodium (made by boiling sodium sulphide solution with sulphur) give colder tones than the monosulphide, and the solutions deteriorate very rapidly. Yellow "sulphide of ammonium," so-called, also gives colder tones than sulphide of sodium.
7. There seems to be no satisfactory method of bettering a sulphide-toning failure by any process of re-bleaching and re-sulphuretting. The only procedure with a failure is ruthlessly to scrap it, and begin *de novo* using a freshly made sulphide solution.
8. For bringing out blocked up detail in the heavy shadows of toned prints I have met with no better specific than "lustraline." It is advisable to heat the print before a gas fire after waxing it.

DOUGLAS CARNEGIE.

A SIMPLIFIED METHOD OF TONING C.C. PRINTS WITH GOLD AND PLATINUM.

[In the following article, which appears in a recent issue of "Photographische Rundschau," the writer recommends the use of first a platinum toning bath, followed by brief gold toning in a combined bath. It is claimed for this form of gold-platinum toning that the gold bath may be used repeatedly, whilst the process is quite equal to the usual method as regards giving fine prints of black tone.]

In making prints of black tone on matt collodion paper it is necessary after the first thorough washing to tone in a bath of gold and borax, then in a platinum bath, and, finally, after a series of further washings to fix the prints in a bath of hypo. This combined gold and platinum toning is a necessity, since the gold bath alone will give only bluish tones, whilst platinum alone gives only prints of brownish colour. A pure black tone in any case is largely dependent upon the skill of the operator. The two baths must each be allowed to act for a given time, and too long immersion of the prints in the gold bath will lead to a cold tone, whilst too short an immersion has the opposite effect.

Although the combined gold and platinum toning is universally used by professional photographers, amateurs almost entirely neglect it, the cause no doubt being the somewhat difficult manipulation and the fact that the gold bath must be specially prepared, and is, therefore, not suitable for treating only a few prints at a time.

Platinum- followed by Gold-toning.

In a recent number of the "Wiener Mitteilungen," 1909, p. 73, there is a note by Alois Ulrich recommending the use of a platinum toning bath with self-toning collodion paper. But the writer there records his experience that this method does not

lead to any new variety of tone, whilst it does not simplify or facilitate the production of familiar tones. Attention may, therefore, be asked for the following description of a method in which the prints after the preliminary washing are toned first in a platinum bath, then washed, and then gold-toned in a bath of the combined type. In order to obtain a pure black tone the ordinary combined bath should not be used. Although in the case of many a short immersion in the bath will give a very good tone, this latter, on longer immersion, will often pass into a disagreeable tone of bluish-grey. If the prints are removed immediately after the desired tone has been reached, it frequently happens that they require to be placed in a fixing bath, since immersion in the toning bath has not been long enough to complete also this part of the process. If, however, a separate toning has to be employed the advantage of the process compared with the usual one ceases to be appreciable, since it consists only in the fact that the combined bath possesses better keeping properties than that made up with borax.

A Slow-toning Combined Bath.

In compounding the combined toning and fixing bath it is necessary to ensure comparative slow toning, and at the same time to exclude the possibility of any sulphur toning taking place. As the present writer has previously ascertained by a considerable number of trials that the well-known gold fixing salts of the Bayer Co. give rise to no sulphur toning whatever, or, at any rate, to an amount quite inappreciable, and as he has further found that prints toned in the Bayer combined bath have proved highly permanent, this brand of toning bath was used for the gold toning now used in the method described. The contents of a small carton of the Bayer toning and fixing salt (50 gms.) were mixed with 50 gms. of hypo, and the mixture dissolved in 750 ccs. of water. In this bath the prints which had been platinum toned underwent gold toning sufficiently slowly to allow of their being thoroughly fixed as well as toned. The whole process, therefore, may be set forth in the following operations:—

1. The collodion prints are made a little deeper than usual. The degree of over-printing varies with the different brands,

but is soon found with some little practice. The film side of the paper should never be touched with the fingers, since the least impression will show as a marking on the print.

2. The prints are placed separately, film side down, in a dish containing pure water. From this they are taken out separately and placed in a second dish of water, and changed over and over in this way for at least six times within eight to ten minutes.

3. After well washing in this way they are transferred to the platinum toning bath composed as follows:—

Potass chloroplatinite	1 gm.
Phosphoric acid	10 gm.
Water, distilled	1,000 ccs.

Here they are kept in movement until they have reached dark brown colour, only perfectly clean glass or porcelain dishes being used in the process.

4. After removal from the platinum bath the prints are again well washed by the method already described under 2, at least five changes being given.

5. The prints are now placed in the combined gold toning and fixing bath, made up as follows:—

Gold toning and fixing salt, Bayer	50 gms.
Hypo	50 gms.
Water	750 ccs.

In this bath they remain for at least eight minutes, during which time they attain a pure black tone.

6. The prints are given a washing of at least one hour, changing over into clean water at least ten times, or they are placed in running water to wash for a couple of hours.

The pure black tone depends chiefly on the time of use of the platinum and combined bath, and the exact point at which to remove prints is soon learnt. It is advisable to adhere to a given brand of paper, since commercial varieties of collodion paper differ somewhat in their properties. Compared with the customary method of toning with gold and platinum, the process has the advantage that one bath less is necessary, and that the gold solution does not need to be thrown away as soon as it has been used.

DR. G. HAUBERRISSER.

PROCESSES OF CATATYPE PRINTING.

II.

[Although little is heard of the commercial development of the catatype process invented some eight years ago by Professor Ostwald and Dr. O. Gros, there is still evidence that these methods of preparing prints from negatives without exposure to light are engaging attention from experimenters, and, therefore, the very useful review of catatype methods, written by Dr. E. Stenger in the work recently published by Knapp, entitled "Moderne Photographische Kopierverfahren," may be translated in an abridged form as showing the principle of the method and the difficulties encountered in bringing it to the commercial stage.—Eds. "B.J."]

In preparing prints by the manganese process the active agent is the invisible image consisting of "Perisol" in the paper of the negative. This positive image of hydrogen peroxide formed by treatment of the negative is transferred to the specially prepared "manganese" positive paper manufactured by the N.P.G. This paper is laid film to film in a printing frame with the paper negative, and pressed for one or two minutes between a glass plate and the back of the frame. The positive paper is then given an immersion in a bath of special preparation, the image appearing at once. The developer in this case is the hydrogen peroxide, which has diffused into the positive paper and has converted the soluble manganese salt into a soluble compound of a higher degree of oxidation. This body is precipitated as a brown manganese picture. The paper is then freed as rapidly and uniformly as possible from the manganese solution.

If the time of contact between the negative and positive paper

has been correct, the development will be finished within a minute. During development it is well to go over the paper with a tuft of cotton wool in order to remove particles of dust and airbells. Dr. Gros, in his English patent of June 22, 1898 (Eder's "Jahrbuch," 1905, page 453), gave the following solution as suitable for the development of manganese catatype prints:—

Manganese sulphite solution, 25 per cent.	1 part
Ammonium chloride, saturated solution	3 parts
Ammonia, concentrated	1 part

The prepared salt, made up by the N.P.G., and requiring only the addition of ammonia, proves better in practice than that prepared as above. Development is continued until sufficient vigour is obtained, and the print is then transferred to a clearing bath, where it remains until the reddish-brown color has become completely yellowish-brown. The clearing solution instantly checks development. It is made by addition of 6

ces. strong acetic acid to 1,000 ces. of water. The print is when well gone over with cotton wool under a stream of water, washed for a short time and dried. If the tone is thought to be not satisfactory, a toning process can be applied.

Reducing the Activity of the Platinum Negative.

So far the preparation of manganese prints has been described as following an almost automatic process, but it frequently happens that the platinised negative will not immediately give a satisfactory print, but requires a certain amount of restraint or better "gradation" in its manipulation. In other words, the catalysing power of the platinum may be so great that it must be reduced, otherwise the prints obtained will be of excessively hard character. This excess of activity in the platinum image may be diminished by means of suitable substances, a mixture of which is prepared by the N.P.G. as a so-called "gradating" bath. The decomposition of the hydrogen peroxide in the negative film then takes place more slowly, so that time is given for undecomposed "Perisol" to transfer itself from the negative to the positive. At the same time the scale of the gradation is prolonged; in other words, a softer print is produced. The special preparation is intended for negatives of extra vigour. For soft negatives the "gradating" solution is mixed with an equal bulk of 50 per cent. alcohol. Not only the character of the negative, but also the kind of print required must be taken into consideration in using the "gradating" mixture. If in development the print appears in weak outline it is necessary to employ the undiluted "gradator." If the print, however, appears too hard the solution is diluted as above directed with alcohol. In this bath the platinum negative remains until it is seen, by holding it up to the light, that the solution has completely penetrated it. It is then hung up to dry without rinsing or pressing out the liquid. The dry negative then supplies prints of the desired character, it being necessary, as a rule, to keep it in contact with the printing paper for from one to two minutes.

Variations of the Manganese Process.

As already stated, the result of this process of treatment with manganese salt and ammonia is to give an image consisting of manganèse peroxidé, but this does not end the possibility of the process, since manganese peroxide is a substance which gives rise to a series of different colours, and has on this account received the name of "mineral chameleon." This arises from the fact that manganese peroxide can behave both as a weak acid and as a weak base. It would lead us too far to detail the different chemical processes which can be based on this property, but among the most important is that in which salts of cobalt are used. The range of colours obtained by treating the manganese image with cobalt compound is the subject of a patent (Eder's "Jahrbuch," 1907, p. 525). The cobalt preparation is put up in carton and tablet form, and allows of black, greenish-black, brown, photographic purple, and other tints, such as red, green, blue, and violet being obtained. In this, as in all catatype processes, the greatest cleanliness is necessary, and in dealing with the manganese prints a thorough toning action is necessary. The desired colour having been obtained, the prints are rinsed, cleared in an alum bath (in which the high-lights lose their yellowish colour) and are finally again washed and dried. As the colours obtained by the cobalt process are sensitive to acids and alkalis, the finished prints require on this account to be treated with more than ordinary care. This point requires to be kept specially in mind in mounting the prints, since an acid mountant will affect the film; they are best attached by the dry mounting process. The manganese bath on being allowed to stand some time in the air forms a kind of skin on its surface. This can be re-

moved with a bit of tissue paper. The deposit which settles on the inside of the dish is easily removed by a weak solution of oxalic acid.

Pigment Prints by the Catatype Process.

So far we have dealt with the making of prints on the catatype principle using a manganese salt. We must now turn to the variation of the process in which a pigment print is obtained. The making of this variety of a catatype print is a much simpler operation. There are no toning processes, and comparing catatype pigment with the ordinary carbon process the advantage as regards readiness of manipulation lies with the catatype. There is no printing in the light, no sensitising with the bichromate bath, and all the operations may be done in full daylight. Also the process has the flexibility which is necessary in dealing with negatives of widely different character. In this connection it should be said that in the catatype pigment process the print is softer (not harder, as in the manganese process), the longer the time of contact. This arises from the quite different action of the peroxide. In the film of the manganese print the longer the time of contact the less the amount of "Perisol" which remains over, and gives the precipitate of manganese peroxide in the developing bath. In the case of the pigment paper the action of the hydrogen peroxide is to harden the gelatine, the peroxide diffusing from the negative into the positive. As the result of a short time of contact the peroxide passes over chiefly from the portions of the negative most fully impregnated with "Perisol"—therefore, hard prints—whilst with longer contact parts of the negative containing lesser proportions of "Perisol" also give out the peroxide and a softer print of full detail is the result.

The film of the catatype paper consists of gelatine, colouring matter, and a substance which, under the influence of the hydrogen peroxide becomes so altered that it acts as a hardening agent on the gelatine. It behaves in this way in proportion to the amount of "Perisol" contained in the pigment film, the action being exactly similar to that caused by light on gelatine containing potassium bichromate. Thus it will be seen that the "Perisol" not affected by the catalytic action of the negative transfers itself as a positive print into the pigment paper, there forming an image in hardened gelatine. This it does owing to its action upon a metallic salt (*e.g.*, a salt of cobalt) contained in the gelatine film. The pigment is held fast by the hardened gelatine, so that pigment treatment with warm water gives rise to a print just as in the ordinary carbon process.

Making a Catatype Carbon Print.

In working the process the catatype original (the platinised negative) is treated evenly with a small proportion of "Perisol," and after it has dried is laid film to film in the printing frame with a piece of catatype pigment paper and the two put under pressure for about two minutes. The pigment paper is then placed in cold water, and air bubbles removed by a soft sponge; after a few minutes it will be seen that the gelatine film has swollen up into relief. The remaining part of the process is exactly as practised by carbon printers. The print is squeezed under water to transfer paper, left under pressure for three to five minutes, and then developed in water at 95 to 105 deg. F., although, if necessary, development may be done at 86 deg. F. or as high as 110 deg. F. Obviously this process gives rise to a print which is reversed as regards right and left. If a print is required correct in this respect a double transfer method is used, the print being allowed to dry before the second transfer.

Precautions in Using Catatype Materials.

Some concluding remarks must be given of one or two features of the catatype pigment process. It goes without saying that the paper must be protected from vapour of hydrogen peroxide

as well as from ammonia. The air of a workroom containing vapours of peroxide will act injuriously upon unused paper, whilst "Perisol" remaining undecomposed in the different prints will also affect the unused paper. A patent has been taken out by the N.P.G. (Eder's "Jahrbuch," 1907, p. 524), under which paper, etc., is protected from vapour of "Perisol" by a wrapping impregnated with a solution of potass permanganate and soda. A further hint is not to allow the catatype pigment paper to become absolutely dry, otherwise the absorption of the "Perisol" is obstructed. Paper which has been allowed to dry should be moistened before use by being allowed to remain for an instant exposed to steam in order that it may take up a little moisture without becoming tacky. Storage for a short time in a damp place or between sheets of moist filter-paper may also be used. It is advisable to keep pigment tissue wrapped in oiled paper or stored in a metal case in order to prevent it becoming dry. Under proper conditions the paper will keep in a fit state for use for months.

Want of strength in a print which has been given an ample time of contact shows that the pigment paper was too dry, and that the "Perisol" could not penetrate it in sufficient quantity. If, on the other hand, the print is lacking in strength and at the same time tends to hardness, it is probable that the negative contained too little "Perisol," in which case a further

application is necessary, the negative and print should be brought immediately into contact and a longer pressure given. If the negative contains an over-dose of hydrogen peroxide the print will be too strong, and it will be difficult to develop the pigment film. In this case a longer time of contact will give softer prints. Prints with a certain amount of veil over them are the result of placing in contact too soon by giving too short a contact. In such cases one should wait for one to ten minutes, and give an equal time under pressure. The occasions on which the use of a "gradating" bath on the platinum negative are necessary are about the same as in making the manganese prints.

It may be not uninteresting to note that the N.P.G. have devised a different method for the making of pigment prints on the catatype principle. According to a patent of 1903 (Eder's "Jahrbuch," 1906, p. 552), a pigment print is taken from a catalysed negative and the catalysing substance incorporated in it. Starting from this positive transparency a negative pigment print is developed and the gelatine of the print then saturated with silver nitrate, a brief surface rinsing given, and the silver then reduced to the metallic state with a developer, thus giving a catatype original. Other metallic salts may in a similar manner be prepared in the gelatine film for catatype processes.

DR. E. STENGER.

MISCONCEPTIONS CONCERNING "MAGNIFIERS"

THE single supplementary lenses commonly known as "magnifiers" are not so much employed as, from their undoubted utility, they deserve to be. This is partly due to their properties and advantages not being well understood, and perhaps also because they are often expected to perform impossibilities, and are discarded when they fail, without fair inquiry into the cause of failure. As there are many fallacies and popular misconceptions on this subject, an attempt to clear the air from some of these may not be without its value.

It is difficult to explain why a positive supplementary lens should be called a magnifier, for it certainly does not enlarge the image given by the camera lens, but, on the contrary, reduces it. Probably the name was originally given from the fact that a single convex lens when held in front of any object acts as a simple microscope, or magnifying glass. This, of course, has nothing whatever to do with the photographic use of such a lens, where it acts in quite a different way. Curiously enough, the negative supplementary lens, which might justly claim a right to the name of magnifier, is seldom so designated.

There has been a good deal of very vague explanation as to the actual effect produced by a positive supplementary lens when placed in front of a photographic objective. We recollect reading recently the statement that a magnifier practically lengthens the camera extension, so that near objects which could not otherwise be brought into focus, either through lack of the necessary extension or the camera being a fixed-focus one, may successfully be photographed. There is great saving virtue in the adverb "practically," but even when this is allowed full force the foregoing explanation is radically wrong. A convex supplementary lens reduces the focus of any objective to which it is added, and, of course, correspondingly shortens the extension necessary for the work in hand. The extent to which the focal length is shortened may readily be calculated by the well-

known formula:— $\frac{f_1 \times f_2}{f_1 + f_2 - s}$, in which f_1 and f_2 = the respective focal lengths of the objective and the supplementary lens, and s = the separation. By separation is understood the distance between the optical centres of the two lenses, not,

as is often apparently imagined, the distance between the outer adjacent surfaces. This being so, absolute contact between the lenses is in most cases impossible. As an example of the use of the above formula, two lenses of the same focus—say 8 in.—will, ignoring the separation, yield a combination of 4 in. focus, thus:—

$$\frac{8 \times 8}{8 + 8} = \frac{64}{16} = 4$$

It is an extraordinary but, nevertheless, common fallacy that a supplementary lens used for copying will necessarily include the whole of the copy in the negative, provided the size of the copy does not exceed that of the plate. It almost needs an apology to mention so elementary a misconception, but it is a fact that many workers have expressed chagrin and wonder when a newly purchased "copying magnifier" has failed in this respect; or when, although giving the entire copy, has not fully covered the negative. Fortunately, there is a useful and not generally known coincidence, that will serve greatly to simplify comprehension of the law on which depends the size of image given by a supplementary lens. If the camera lens is set to its principal focus, the supplementary lens being in contact and at its own principal focus from the object copy, then the size of the image may be calculated by dividing the focal length of one lens into the other. Thus, suppose we have a camera with a 12 in. lens, and a supplementary lens of 6 in. focus. If the camera lens is set to its principal focus (12 in.) and the copy is 6 in. distant from the supplementary lens, then the image will be $\frac{12}{6}$, = twice the linear size of the

copy. Or, if we were to use a 6 in. lens in the camera, and a 12 in. supplementary lens, thus reversing the previous state of affairs, the ratio between object and image would still be the same, but a reduction instead of an enlargement would result. Strictly speaking, the foregoing figures are not quite correct in practice, since they ignore the separation; but, if the lenses are placed as close together as possible, the result is not much affected.

The reason for this coincidence is that when two lenses are co-

lined in contact, one being at its principal focus from the plate, and the other at its principal focus from the object, the image and object are respectively at conjugate foci of the combined lens; and these conjugate foci are such as to give an enlargement or reduction in the same ratio as that which exists between the focal lengths of the two separate lenses. For example, take an objective of 15in. focus, and a supplementary lens of 5in. focus. These in combination produce a lens of $3\frac{3}{4}$ in. focus. Now, as any table of enlargements will show, 15in. and 5in. are the conjugate foci necessary for a three-times enlargement or reduction with a lens of $3\frac{3}{4}$ in. focus. If, therefore, the plate is at the principal focus (15in.) from the camera lens, and the object or copy is at the principal focus (5in.) from the supplementary lens, it is evident that a negative three times the size of the copy will be secured, or somewhat smaller when separation is allowed for. In some cases a slight focal adjustment may be necessary.

There would seem to be some strangely chaotic reasoning as regards the exposure required with a positive supplementary lens. It has been stated that practically no difference is made by using the latter, but that the same time should be given as if it were not being employed. This advice must be received with caution, for, obviously, if the focal length of the lens is shortened, while the aperture remains unaltered, the f values will be automatically reduced—*i.e.*, the lens becomes more rapid. In all exposure calculations, the rapidity of the lens should first be considered, any allowance for stopping-down or for abnormal extension, as in copying or enlarging, being made afterwards.

A convex supplementary lens is often of great assistance for temporary wide-angle purposes. This is worth while remem-

bering by any worker who finds himself in pressing need of a wide-angle objective when far from home. The nearest optician or spectacle-maker will be able to supply a suitable glass, which, if no better means of attachment is available, may be secured in front of the camera lens by sealing-wax or strips of gummed paper. For more permanent use, a cardboard, leather, or metal cap to fit on the lens hood, and having a circular hole in the centre against which the supplementary lens is glued, may be employed. If closer contact is desired, the hood may be removed, if this is possible, and the cap made to fit the lens tube.

So far, we have spoken only of the positive supplementary lens. The negative or concave variety will now be briefly alluded to. This lengthens the focus of the camera lens, and gives an image on a larger scale. The alteration in focus with a given negative lens may be estimated by the formula previously quoted, but care must be taken not to omit the *minus* and *plus* signs in making the calculation, or very misleading figures will be obtained. The multiplication, addition, and division of mixed *minus* and *plus* quantities is different from the ordinary arithmetical procedure that suffices when dealing only with positive lenses, and the worker who feels doubtful of his knowledge in this respect should consult the first chapters of a simple primer on algebra.

It is desirable that a supplementary lens should be achromatic. Although uncorrected glasses of the spectacle type are capable of very fair work, if the alteration of focus is not extreme, and attention is paid to stopping-down, they cannot be expected to give such good results as corrected lenses. The latter are not unduly expensive, and an assortment of different foci, both positive and negative, is an invaluable addition to the photographer's outfit.

A. LOCKETT.

BACKGROUND AND SEAT IN ONE—A USEFUL ACCESSORY FOR THE STUDIO.

Most professionals who cater for a good-class clientèle have by this time banished from their studios the many distinctly property articles, such as stone walls, balustrades, and stone steps leading to nowhere, and have replaced these with more modern studio furniture, of such a character as would usually be found in their clients' own homes. This outcast of all papier-maché accessories and introduction in its place of good solid furniture, such as oak chairs and chests, combined with a wonderful change in backgrounds from the old-fashioned conservatory, generally well stocked with ornamental palms and artistically (?) draped curtains, is perhaps the most pronounced change which has taken place in the better-class studios during the past few years. Certainly the advantage thus gained does tell upon the increase of business, and also upon the increase of better-class styles and prices which the alert worker can obtain, but at the same time it all costs money, and a good number of those who would like to introduce new styles and new accessories from time to time are often detained from so doing because of the necessary outlay. And even those who do manage to find the spare cash to purchase new accessories feel at times that they are getting more or less into a groove in their style. They have just a few stock poses suitable for various clients, and know that such and such a chair or table will be the best suited for such a subject, while another chair or table will suit the same client in a different position. To the man who is really trying to improve his work this state of things is rather depressing, and try as he may he finds often that it is really impossible for him to make fresh-looking poses, etc. Give him a new chair

or table quite a different shape to the ones he has already got, and he will at once find he has scope for several with the new accessory.

True, although the furniture seems always the same to the photographer, yet in most cases it is quite new to one's clients, and it is improbable they will ever be photographed in the same pose and with the same accessory again, because every live worker will naturally avoid purposely using that chair or table upon a given client the second time, but will select some position enabling him to use a different accessory. And in some cases even it is desirable to knowingly use it for a friend of the first client, who when arranging the sitting particularly states, "I liked the portrait you made of Miss So-and-so in that old armchair" (or whatever it may be), "and would like mine similar to that."

However, a change is good at times, and I know one or two workers who make a practice of periodically exchanging accessories and backgrounds, and in cases where each worker is about upon the same standpoint as far as the class of work goes, and also when they are far enough apart as not to clash with each other in competition, this is a really excellent plan to adopt. Another professional of my acquaintance has an arrangement with the local furniture man whereby by a small yearly payment he may borrow for periods of a month or so several different pieces of furniture, and change them at stated intervals. In return for this privilege, he displays a neat notice in his dressing-rooms to the effect that his "studio furniture is supplied by Mr. So-and-so," similar to the printed line seen upon theatre programmes.

In cases where it is impossible to do this, the worker must use his ingenuity as best he can to prevent his work looking

“sameish.” The window-seat shown in the illustration is an accessory which I have made in my own studio recently, and

have found exceptionally useful, as it forms at once an accessory and a background, besides at the same time improving the appearance of the room itself and adding to the appearance of the studio more the look of a comfortable room than a rather barn-like place. It has the advantage of being easily made and costing very little money, and also it can soon be cleared altogether when I am tired of it. The side of my studio is composed of the quite ordinary long sash-bars, glazed with ground glass, as the outlook is ungainly; but in cases where the outlook is pleasant, plain glass, through which the background (which will be out of focus) will show, would be better still. The indication of foliage in my case was an afterthought, and obtained by painting upon the outside of the glass.

To make the old leaded-light effect several sheets of brown paper were cut into narrow strips and carefully pasted upon the glass, and although this is getting dangerously close to the old style of pure imitation, yet it looks so real with the strong light behind it that never once have I heard a client pass any remark upon the fraud. The window-ledge will then have to be built up, and unless one is a practical carpenter it is best to place this part in the hands of a good carpenter to do; and often the photographer may know a man who will be pleased to do this in his spare time. It consists of plain deal wood, afterwards painted a pale cream colour, as does also the upright piece in my case, which was necessary to hide the pulley-ropes of my backgrounds, which fix to the wall just behind them. The total cost of my fitting was about 15s., and I am sure it has more than paid for itself over and over again during the past few months.

Some very pretty effects of lighting can be obtained with this accessory, but as the average client wishes for a likeness as well as an artistic portrait, it is advisable to open the blinds in the studio, and allow a good deal of light to fall upon the shadow side of the sitter. In working thus against the light it is advisable to use backed plates and give a generous exposure. In conclusion, I am sure that if photographers seriously look around their own studios they will find that several little things like this could be made, and when made they will prove a very real advantage.

H. ESSENHIGH CORKE, F.R.P.S.

DIAMIDOPHENOL DEVELOPER FOR LANTERN-SLIDES AND CLOUD NEGATIVES.

[To the current issue of the “Photo Revue” M. G. Underberg contributes a further note on the use of the acid diamidophenol developer according to the formulæ already given in two recent issues of the “B.J.” The author adds a formula for the developer when a powder is to be made up for preparation of the developer merely by addition of water.—Eds. “B.J.”]

ACID diamidophenol is without a rival as a developer of transparencies, owing to the beautifully soft results given by it, and to the fact that the image is formed through the thickness of the emulsion film, not on the surface only. This property of the developer is particularly valuable in making stereoscopic transparencies, the “snowy” effect often seen in these latter being avoided. Using the two-dish method already described, the results obtained are characterised by both softness and brilliancy.

Acid Diamidophenol for Cloud Negatives.

A branch of work on which many questions are often put is that of cloud photography, or, rather, of securing clouds and landscape on the one plate. The chief difficulty lies in the over-exposure which the sky receives, the clouds being buried in density and failing to put in an appearance in the print. The remedy is in the use of a yellow screen or a sky-shade, in conjunction with a developer which does not choke up the dense parts of the negative. In this respect no developer is better than acid diamidophenol, for even when a high degree of density results the deposit is very transparent, and moreover, owing to the flexibility of the developer any degree of softness may be obtained and hardness avoided by sufficient immer-

sion in the B solution. Since the present seems a convenient occasion, a word may be said on the practical means to be taken when using light-filters in obtaining clouds and landscape on the one plate. If the sky is cloudy, but somewhat feebly lighted, a dull sky, it is well to use a Monpillard screen of aesculine* which does not prolong the time of exposure. This screen serves the purpose of cutting off the ultra-violet rays, which form the chief proportion of the direct light from the sky. In the case of a somewhat brighter sky, a yellow 2-times screen will suffice. Lastly, for very bright skies (white clouds) a special screen is used, composed of thin yellow films, such as that contained in the boxes of the Chromo-Isolar plates. A bit of this film is cut in the shape of a semi-circular section, the straight side (diameter) of the complete circle being cut saw-tooth fashion and fixed to the lens so as to shield that part of the plate on which the image of the sky falls. Usually the sky will occupy two-thirds of the whole plate. Means for holding this portable screen in position can be easily extemporised. The sky thus receives much less exposure than the landscape. It may be said that the sharpness of the outlines will suffer owing to the interposi-

* Messrs. Wratten supply aesculine screens.—Eds. “B.J.”

tion of the film screen, but even though this is the case in some instances, there is actually no objection to it in the case of the clouds, as the only result is to enhance their vaporous and airy appearance.

A Dry Diamidophenol Developer.

We know that metabisulphite of soda can replace the bisulphite liquor in the acid diamidophenol developer. Although the bisulphite is preferable, the metabisulphite may be useful, for example, in preparing a dry powder mixture for use on tour.

The following is the normal formula for a preparation to be dissolved in 1,000 ccs. (35 ozs.) of water:—

Soda sulphite anhydrous.....	1 oz.	30 gms.
Diamidophenol	80 grs.	5 gms.
Soda metabisulphite cryst.....	1 1/2 ozs,	50 gms.
Potass bromide	45 grs.	3 gms.

These substances are pounded together with mortar and pestle until a fine powder is produced, and the mixture is stored in well-closed tubes. It is, in the writer's experience, the best dry developer to be found.
G. UNDERBERG.

A MODIFIED PHOSPHATE-LAC PROCESS.

[In a recent issue of our Philadelphia contemporary, the "Bulletin of Photography," are given details of a modification in the process in which silver phosphate held in suspension in shellac was employed. The addition of gelatine is recommended for obtaining prints of richer tone and greater delicacy.—Eds. "B.J."]

Most of the old silver printing processes have been superseded and are now worked only by a few experiment-loving amateurs. Of these long forgotten worthies of the youth of photography, the most distinguished is Taylor's white-lac process.

The process is based on reactions which differ toto caelo from those in common use. In the original method the two following stock solutions were made up:—

1.	Water	10 ozs.
	Borax	180 grs.
	White-lac	360 grs.
2.	Water	10 ozs.
	Phosphate of soda	180 grs.
	White-lac	220 grs.

The lac is finely pulverised and then well shaken up in a flask containing pure water to remove any easily soluble substances in the lac. It is then filtered and dissolved in the given quantity of water, which is placed in an enamelled iron kettle and slightly warmed. The lac is then introduced and the water kept at the boiling point for two hours, replacing the portion lost by evaporation.

The mixture is then allowed to settle, and the clear portion is decanted into the filter.

The borax and the phosphate are dissolved before the lac is introduced.

The two stock solutions are used alone or mixed, according to the tone desired and the strength of the negative. A mixture of five parts of the borax solution to three parts of the phosphate seems to give the best results.

Plain paper is immersed for twenty seconds in this mixture, and hung up to dry. It is then sensitised by floating from three to four minutes, on a forty to fifty grain silver bath, and when dry, again immersed in the lac solution.

Paper prepared in this way will keep good for a long time and the prints will need no preliminary washing; and a good tone, ranging

from a dark purplish-brown to a beautiful sepia, may be obtained without the use of the toning bath.

The prints should be printed deep, and are placed without washing in a 1 to 10 solution of sulphocyanide of ammonium, in which they are allowed to remain five minutes, when they are transferred to a 1 to 4 hyposulphite of soda solution, and fixed. The usual washing for elimination of the hypo follows as a matter of course.

Prints on paper prepared with the phosphate solution alone, or with a large proportion of this salt, will strike a good tone without the sulphocyanide bath.

The appearance of the prints will be greatly improved by varnishing the backs with a 10 per cent. alcoholic solution of white-lac, which softens the image and increases its resemblance to sepia work.

The above is a description of the original process. The modification consists in adding gelatine to each of the stock solutions, and the use of a salting bath of chloride of ammonium and lactate of magnesium. One hundred grains of swelled gelatine are dissolved in each of the stock solutions, and the paper is immersed as before. When dry, it is immersed or floated for two minutes on the following solution:—

Chloride of ammonium	10 grs.
Lactate of magnesium	10 grs.
Water	1 oz.

and when dried sensitised on a sixty grain silver bath, and treated as before.

Paper prepared according to the modification gives prints of a richer tone and greater delicacy than the original method, owing to the presence of gelatine. The use of the salting bath is not indispensable.

For large prints either the original or the modified process gives wonderful results of great artistic merit, far surpassing prints on albumenised paper.

Air bubbles must be removed from the paper while in the solution, and the silver bath should be filtered each time it is used.

AT THE MAKING OF A "FAKE" CINEMATOGRAPH FILM.

[Under the title of "Hunting African Lions in the City of Chicago," "The Chicago Tribune" prints the description of a day alleged to have been spent with a firm of cinematograph film producers at the time of their preparing the negatives for a series of pictures, representing Mr. Roosevelt shooting lions in Mombassa. While the public is content to accept the artificial for the real, the issue of a film such as this cannot, we suppose, be penalised as fraud, but in the interests of the cinematograph trade as a whole it is to be hoped that such fake films will meet with no encouragement from the public.—Eds. "B.J."]

How to shoot a lion in the jungle near Mombassa, Africa, without going any further than Western Avenue and Irving Boulevard.

First—Get your lion. Almost any old sort of lion will do so long as he has four legs, a waving tail, and a fierce expression.

Second—Make your jungle out of 5 cent bamboo fishing poles, artificial palms, and several weeks' work on the part of stage carpenters and scenic artists.

Third—Engage a gang of native beaters from South State Street, including one giant with magnificent torso development, who looks good in the near-altogether.

Turn your lion loose in your encaged jungle. prod him in the ribs with poles and other annoying things, and then—

Let him have it with three polyscope cameras, a .305 high-power rifle, and develop your films and sell them around the country to moving picture exhibitors for a total of something like \$15,000.

That's the way to shoot a lion in the wilds of Africa on Western Avenue, according to the theory and practice of the Selig Polyscope Company, who put Roosevelt through his Smithsonian Institution stunt long before the doughty ex-President ever filled a rifle magazine on African ground.

They didn't call him Roosevelt. Professional courtesy prevailed, and the nearest they came to it was to label the baggage unloaded at Mombassa with the significant letters, "T. R." But it was Teddy, all right. Look at the photographs, note the flashing teeth, the "dee-lighted" expression, the strenuous life postures, and see if you don't recognise Theodore, or the nearest thing to him that can be materialised in Chicago at the present date.

It all happened one bright April day in the big enclosed yard on the wild prairies on the north-west side. It was a queer place to go to kill a lion. You take the North-Western L part of the way, and then change to a street car—but there are advantages to this sort of hunting. In the first place, you can get back home in time for a home-cooked dinner, you don't have to get seasick making the trip, and the nearest thing to a jungle fly that fell to the lot of the intrepid Nimrods was a specimen of the common house variety, that rode on the lion's back when they put him into the ca—native jungle.

But don't fancy for a minute that even lion hunting, à la moving picture plant, is free from danger. On the contrary, it is just about as exciting a proposition as ever came off anywhere. Each and every man, woman, and child who took part in the hunt is willing to testify to this fact, and two moving picture men and one certain newspaper photographer swear to this day they owe their lives to the fact that in an emergency they can make Sig. Dorando look like a hitching-post for speed in a sprint. This proves the truth of the old adage, "Once a lion, always a lion," even in a moving picture.

Eight-thirty a.m. saw the hunting party assembled at the time-clock, whence the start for the jungle was begun. It took some time to cross the Atlantic—the big yard—and it was well on toward noon when "the American party" arrived at "Mombassa." The coming of the famous party was heralded by several dozens of shivering coloured persons, who scurried up the landing stage—right in the eye of the camera—bearing on their glistening backs the famous baggage marked "T. R." A large, white person in the khaki uniform and pith helmet that all good African huntsmen wear, superintended the movements of the dusky crew, and then—

There was a kneeling and bowing on the part of the black population, and, lo and behold, the celebrated American party—teeth, glasses, Kermit, and all, hove into focus. Even if he hadn't worn the teeth or glasses you would have known him by the energy in his movements. He stepped around like a man living up to a strenuous reputation. He chased the coloured gen'men to their respective duties, shook hands, smiled, and posed with a speed that taxed the cameras to capture. It was Teddy, sure enough, and every time he got out of the scene he took the world-famous teeth out of his mouth and said:

"Whew! These things are hard to wear. It must be fierce to have 'em growing on you."

"Roosevelt leaves for the jungle," called the producer. There was a hurrying and scurrying of horses. The party was mounted, and, to the tune of native African cheers and frantic gestures of delight on the part of the assembled populace, the party rode out of view, Roosevelt waving his rifle above his head to show what was going to happen to poor Leo when he met him face to face.

The scene shifted. It was the jungle now—a cage about sixty feet long by twenty wide, with the best jungle scenery to be purchased or manufactured in the city. A fine spring breeze agitated the bamboo and palms, and no one could be blamed for feeling like a real hunter when he faced the scene with a rifle in his hand. It was real enough to satisfy everybody, even unto the critical producer, who insisted on getting the last touch of atmosphere into every scene.

"You've got to have the real colour in a moving picture show as well as in a stage production," said he. "We come as near to doing the real thing here as it can be done. Get ready for the hunt!"

From the vantage point of the camera men, who stood on a platform erected twelve feet above the ground, in order to be above the bars that formed the side of the cage, one could make out the jungle king as, slowly and suspiciously, he trod his way out of the wheeled cage and slipped through the gate into his native atmosphere. The gate was shut behind him, and he was trapped.

He didn't like it at all. Being a regular lion, he gazed around at the African foliage waving about him and shivered. Never had he seen anything like this. The jungle frightened him. He felt lost, and yearned for the comforting bars he had known since his happy child-

hood days, and he began the wildest sort of a race through the intricate jungle paths. Looking for some nice, safe cage where he could lie down in peace and comfort.

From the camera platform it was the most realistic thing in the world. King Leo first picked out a path that led straight towards the film operators. His head rocked from side to side, and his tail waved in a way that made even an inexperienced lion killer apprehensive. Right in front of the picture men he changed his mind, decided to forego an attempt at leaping the bars, and drove back into the brush that hid him from view.

But he had left his track in the soft earth of the path. His doom was sealed from the moment he took that little stroll. Only a few seconds elapsed before there came creeping out upon his trail the chief of the native hunters, the great African tracker, who had come all the way from his south side home to see that the hunt was well supplied with the proper colour. On all fours, his sharp eyes scanning the ground, the tracker crept forward. At the sight of Leo's broad tracks he stopped, bent close to the ground, then leapt straight up in the air and waved frantically to the rest of the party.

They came forward on the run, Teddy, Kermit, and the great English hunter whose guests they were. The great man got down to examine the tracks, made sure it was a lion, then he, too, waved his arms in frantic delight. His teeth gleamed some more, and native tracker and ex-President shook hands, and Teddy said, right out loud, "Dee-lighted!"

The hunt was on in real earnest now. The white members of the party retired for the nonce, and to the fore came a crew of native beaters, stripped to the waist, and armed with everything that might be expected to scare a lion out into an open spot, where Teddy might have a chance to bring him down.

The beaters disappeared, and again King Leo held the centre of the stage. He was getting excited now. Animal instinct told him that he was being followed, and possibly he had read the "Jungle News" and knew that Theodore the Mighty was on his trail. At all events, his movements became wilder and more natural.

Who knows—perhaps poor old King Leo knew that while the hunt was artificial in some respects, for him it was going to end like the real thing? Who knows but that his animal instinct told him he was to be butchered to make a moving picture film? Who knows but Leo saw his finish?

Certainly, he could have been no wilder under any circumstances. He was raving now. His body dropped close to the ground, like a cat stalking his prey, and he eyed the human beings in sight with the malevolent gaze of an animal picking out the choicest morsel in a herd. Nearer and nearer drew the beaters, and wilder and wilder grew the lion, until at last he dashed back into the jungle like a flash of tawny light, and hid himself in the impenetrable tangle of brush.

From here he would not stir. The shouts of the beaters were of no avail. Leo clung to his cover. There was but one thing to do. Desperate action was needed. Roosevelt must dash into the jungle and beard the lion where he lived.

Everybody took a long breath and braced himself for the shock. The crucial moment was at hand. Hitherto it had been something like play; now it was getting to be the real thing. The camera men up on their lofty platform looked down and estimated their chances in a sudden leap for life. The producer bit his upper lip.

"Are you ready?" he called.

"Ready," replied everybody concerned.

There was a puff of smoke and the sharp crack of a rifle back in the jungle. The next instant there was a roar, such as no lion ever turned loose in a cage, and Leo, his lower jaw broken by the bullet that went too low, burst out into the open, straight for the men on the high platform.

The vertical bars that enclosed the jungle were twelve feet high. Twelve feet is a good healthy leap even for a wounded lion, but Leo went into the air as if he was going to clear it with something to spare. Then it was that the two Polyscope men, Tom Nash and Charley Turner, and the staff photographer, broke the world's amateur record for high jumping and quick sprints. They took one last, lingering look at Leo's gleaming jaws. Then they jumped. Recovering their footing, they sprinted, Nash in the lead, Turner a good second, and the staff photographer working his short legs like pistons to bring up a fair third.

Back in the jungle Leo hit the bars about eight feet from the ground, fell back, and retreated, bleeding, to the jungle.

The camera men went back to their positions. Again the stage smoke puffed in the jungle, again the real rifle spat out its smokeless charge. No bungle this time. There were two shots. One hit Leo in the right eye, the other went an inch above. Leo never stirred. He was killed as dead as anything that Teddy ever brought down in real life. Down on the home-made jungle ground he sank at full length, and then and there he passed from the world of moving pictures into that happy hunting ground of wild animals, where hunters do not exist, or, if they do, it is the animals who have the guns.

"Get him!" cried the huntsman, by this time worked up to a state of real excitement.

The big native tracker, always on the job, burst through the underbrush and found the slain monarch. Again he raised his war-club, and again the party came hurrying up. The great English hunter took the lion by the tail and dragged him out into the open. Then came Teddy, his teeth gleaming as they never gleamed since the charge at San Juan Hill, his neckcloth fairly dancing with excitement, his whole appearance shouting the triumph of the successful hunter.

They picked Leo up and looked him over. They counted the bullet holes and shook each other by the hands, Teddy and the black tracker almost falling over themselves in their mutual joy. Then everybody did a war dance around the corpse, and Kermit wound up the scene by scaring the wits out of the "natives" with his camera.

But the realism didn't cease here. They tied the game to a long pole and carried him back to camp. Here he was hung up and skinned. It was night now, in the jungle, and the glow of the camp fire reflected from the dark bodies and from Teddy's teeth made a picture never to be forgotten so long as the film remains in use. Altogether the hunt was voted a success, and everybody punched the time-clock and went home, well satisfied with the first presidential day in the jungle.

"Only one thing about it that I don't like," sighed the wild animal man.

"What's that?"

"Well, there's a perfectly good lion, costing \$300, that we can't use again."

And when you see the films you may agree with him that it's too bad. At the same time you will appreciate the realism of the hunt. One part—the most thrilling perhaps—you will miss. The picture men refused to contribute their high jumping specialty to completing the truly exciting picture of *How to Shoot a Lion Without Leaving Home*.

CELLULOID MANUFACTURE.—In a year when most items of imported reductions it is interesting to note (writes the "Chemist and Druggist") that the purchases of celluloid by Japan in 1908 increased from £32,000 to £68,000. Germany was the chief source, the United Kingdom's share being not more than £12,000. This business, however, is not likely to flourish for long, as work has been progressing rapidly at the two large Japanese celluloid factories, and they will probably be in a position to start manufacturing some time this year. One is situated at Sakai and the other at Aboshi, and they are controlled respectively by the wealthy Mitsui and Iwasaki (Mitsubishi) families.

THE SOUTHAMPTON EXHIBITION.—This exhibition will be held from November 23-26, at the Southampton Art Gallery, Mr. Furley Lewis acting as judge. Arrangements have been made with the Hackney Society (who will collect exhibits free from the Royal and Salon) for exhibits to be forwarded carriage free from Hackney to the Southampton Exhibition. The Southampton awards are in a new and attractive form, being Royal Doulton bowls. In addition to the classes which include technical as well as pictorial photography, there is a separate class for colour work, with a substantial award which should ensure a good entry. Lantern slides, instead of being judged in sets, are to be judged individually. Entry forms are now ready, and can be obtained from Mr. S. G. Kimber, Oakdene, Highfield, Southampton.

Photo-Mechanical Notes.

Apparatus at the Dresden Exhibition.

It seems to be fully recognised here [in Germany] that the enclosed arc lamp is not suitable for coloured originals, and consequently there is on offer a very convenient arrangement of open arcs, consisting of two on each stand. These are very easily adjustable, sliding up and down a single iron upright and remaining wherever placed. These single upright stands (which are also supplied for the enclosed arc lamps) are also great economisers of space. The open arcs burn the carbons at right angles to each other, and the four properly arranged give a very powerful and satisfactorily even lighting. To those who want something even better, there is shown a search-light, on a much more convenient stand than those formerly supplied and with bigger wheels, so that it is very easily movable. One of these, with a reflector at the opposite side, will evenly illuminate very large copy. The use of electric light for illumination seems to be as universal as in London, although daylight is better and space more freely used.

For the printing-room there is offered a novel whirler. It is similar to the old Levy pattern, but automatically locks the plate in the centre wherever it is placed. There is also shown a small printing frame on a turntable, and others, with one end cut away, to facilitate the placing of the negative and plate in the frame.

Ready-built collotype ovens are also shown with the front dropping in order to allow of heavy plates being easily put in and taken out. The oven is heated by gas and fitted with automatic regulation of temperature.

The latest model of the Holmström etching machine is shown by Falz and Werner. It is entirely made of porcelain. The plate is placed in vertically, there being only one paddle wheel as against two in the earlier patterns of "Axel" machines. This machine appears to have a very wide use on the Continent, and etchers speak very favourably of it.

Truth in Reproduction.

One of the most remarkable exhibits at Dresden is that arranged by the Leipsic School to illustrate the differences in rendering of different reproductions of the same original. One of the originals selected is the famous "Sistine Madonna" in the picture gallery in Dresden, a work of art which probably has been more often reproduced than any other picture. Good and bad ordinary photographs are shown, all sorts of monochrome engravings, and, finally, all sorts of coloured reproductions. The wide variation of these latter is simply astonishing; those entirely produced by hand are often wrong also in drawing as well as colour, but the photo-mechanical reproductions, although superior in truth of drawing, are frequently untrue in regard to colour. It would seem that the Autochrome plate should here play a useful rôle in affording some indication of the original colours. The practice now, when reproducing pictures in galleries, is for a photographic enlargement to be made, and then this to be carefully coloured by hand with the picture in front of the artist. If this is properly done it is probably better than an Autochrome would be, but judging from the observed errors in the final reproduction, it does not seem as though a good Autochrome could be a worse guide, if any guide at all has been followed.

Register with Hand-made Papers.

It is sometimes necessary to print an edition of coloured prints on hand-made sheets, in which the edges are quite irregular. It is therefore not possible to obtain register as easily as with paper cut square at the edges: sometimes the hand-made paper is cut square on two edges, in order to obtain a regular feed, but, of course, this will not do for the customer, who wants to see his sheet with the deckle edge all round. In this case it is desirable to paste two small pieces of card on the back of the paper, extending beyond for about $\frac{1}{8}$ inch on two sides; the paper is then fed up so that these pieces of card form the points of contact. After the prints are finished the pieces of card are cut away with a knife. The sheet so made looks well, and register is perfect.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between August 9 and 14:—

MOVING-PICTURE MACHINES.—No. 18,340. Improvements in moving-picture machines and in the films used therewith. Edward Charles Robert Marks, 57, Lincoln's Inn Fields, London.

PHOTO-TELEGRAPHY.—No. 18,366. Improvements in or relating to photo-telegraphy. Thomas Thorne Baker, 7, Southampton Buildings, London.

PHOTOGRAPHIC APPLIANCES.—No. 18,472. Improvement in photographic appliances. Charles Foster, 24, Castlemaine Terrace, The Grove, Hammersmith.

PHOTOGRAPHIC PRINTING.—No. 18,532. Improvements in and connected with photographic printing. (Compagnie Générale de Phonographs Cinématographes et Appareils de Précision, France.) Reginald William James, 1, Queen Victoria Street, London.

MULTICOLOUR PHOTOGRAPHY.—No. 18,553. Improvements in and relating to multicolour photography. Robert Krayn, 33, Cannon Street, London.

PHOTOGRAPHIC SHUTTERS.—No. 18,574. Means for regulating the speed of photographic shutters. Wilfred Hunt, 121, West George Street, Glasgow.

CINEMATOPHONS, MAGIC LANTERNS.—No. 18,673. Improvements in and relating to cinematophons, magic lanterns, and similar apparatus. Percy Branel Milsom and Elver Clement Milsom, 70, Chancery Lane, London.

AUTOMATIC PHOTOGRAPHIC APPARATUS.—No. 18,699. Harry Aston Wolff, 33, Cannon Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINTING-FRAMES FOR COLOUR PHOTOGRAPHY.—No. 15,937 (July 27, 1907). In copying colour screen plates upon bleach-out paper difficulties are met which are not found in copying "glacier" prints and other coloured transparencies.

Owing to two-thirds of the white light falling upon a colour screen plate being absorbed by the colour screen, and further on account of the translucent nature of the starch granules employed in the Autochrome plate, the time occupied in copying such screen plate is naturally correspondingly prolonged. In addition to this it must be borne in mind that when the whites of the photograph have been copied so far as to reproduce the screen colours, which, of course, leave grey areas upon the bleach-out paper, a further copying for the purpose of producing pure white is exceedingly difficult, and, as a matter of fact, is opposed to the principle of the bleach-out process.

In ordinary diffused light this difficulty is obviated to some extent by the action of the lateral beams of light, which, by diffusing the light between the screen and the print, partially destroy the screen image in the whites. The weakness of the light and the prolonged time of copying associated therewith are, however, so detrimental that they render copying by ordinary light practically useless.

With a view to rendering the advantages obtained by the use of diffused light available for sources of intense light, the apparatus described below has been constructed.

Around the printing-frame mirrors are arranged in conical or pyramidal form, and the frame is placed so that the sun's rays fall perpendicularly thereon. The light is thus partially reflected from the mirrors and thrown at a corresponding angle on to the positive, so that, in addition to the direct perpendicular rays of sunlight,

an abundance of lateral light is received, and by this diffusion of light between the screen and the print the whites are bleached out with sufficient rapidity.

In this manner finished copies can be produced in from one-half to one hour in strong sunlight and turned out much better than in double the time without such apparatus.

In order to exclude the print from the great heat which is developed by the concentration of the beams of light, a water trough or alum trough can be inserted in the same way that such troughs are employed for shutting off the heat rays in connection with cinematographs.

In the case of copying from lined colour screen plates the mirrors crossing the path of the screen lines (i.e., those which would, if produced, cut the screen lines at a right angle) are naturally omitted, as they do not produce the desired effect. The mirrors placed parallel to the screen lines diffuse the coloured light of one line underneath the adjacent lines of different colour, whereas mirrors placed at right angles to the direction of the screen lines would only intensify the colours of the individual lines and thus rather hinder than assist in the production of a white ground.

By conical and pyramidal forms of mirrors are to be understood all kinds of mirror arrangements diverging outwards from the printing-frame.

Dr. John Henry Smith, 60, Rue de la Côte. St. Thibault, Paris, France, and Dr. Waldemar Merckens, 1, Schwarwald-Platz, Mülhausen, Alsace, Germany.

CINEMATOGRAPH CAMERA.—No. 20,191, 1908 (September 25, 1908). The invention relates to photographic apparatus for taking a series of negatives on a band film, and consists of a process for carrying out the same, by means of which it is rendered possible to make uniformly exposed negatives even when the mechanism actuating the photographic film is operated with a non-uniform velocity.

Hitherto the duration of the exposure for the various negatives has been directly dependent on the velocity at which the feed mechanism of the band film has been driven. In consequence of the variations of the velocity of the driving mechanism, while the photographs are being taken, over-exposed or under-exposed negatives are produced which diminish the value of the series of photographs.

This defect is done away with by means of the present invention, according to which the duration of the exposures which occur between the intermittent movements of the band film is regulated independently of the velocity at which the feed mechanism is driven. Alfred Duskes, 46, Friedrichstrasse, Berlin, Director, and Duskes Kinematographen und Film-Fabriken Gesellschaft m. b. H., 46, Friedrichstrasse, Berlin, Germany.

The following complete specification is open to inspection before acceptance:—

CINEMATOPHONS.—No. 16,441, 1909. Cinematograph apparatus for the continuous exposure and projection of photographic plates. Robin.

New Trade Names:

KLTD (DESIGN).—No. 314,212. Photographic chemicals. Kodak, Ltd., 57-61, Clerkenwell Road, E.C. June 23, 1909.

PROTAL.—No. 314,494. Chemical substances used in manufactures, photography, and philosophical research. Casein, Ltd., Calvert Works, Sheepcote Lane, Battersea, London, S.W.

EURELLA.—No. 314,614. Chemical substances used in manufactures, photography, and philosophical research. Alexander Fletcher Knox, trading as Clayton Jones and Knox, 15, Victoria Street, Liverpool. July 8, 1909.

ANTALO.—No. 313,677. Photographic apparatus included in Class 8. Albert Thornley, 35, Mountain View, Cockermouth. June 3, 1909.

SKETCHO.—No. 314,059. A camera attachment for the purpose of allowing more than one exposure to be made on the same plate. John Currie, 68, Kelvingrove Street, Glasgow, and "Rockside," Core, Dumbartonshire, Scotland. June 17, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Chiffon as a Substitute for Bolting Silk in Making Soft Enlargements.

Some eighteen months ago, writes Mr. Herbert Mills in the "Amateur Photographer" for August 24, after experimenting with a piece of bolting silk, it struck me that there might possibly be other materials quite as suitable, and possibly cheaper. The first material I used, and which I have exclusively used ever since, was chiffon—a soft, diaphanous material, not too closely woven, and obtainable in various colours.

The piece that was given to me was heliotrope. I held the chiffon immediately in front of the lens, and examined the effect on the screen, upon which the image was focussed sharply. A delicate softening of the picture was the result.

I then folded the material, and again noted the effect of the two thicknesses. The image, as was to be expected, was still more subdued, but quite different from that given by the bolting silk.

Then three thicknesses were placed before the lens, but in this case the result was rather *outré*, although for a big enlargement from a strong negative it would be particularly effective with subjects of suitable character.

Test exposures were then made to ascertain the necessary increase in exposure when using one and when using two thicknesses of the chiffon. In the first instance about half as long again was found to be about the correct exposure, and twice the normal exposure in the second.

Comparing the prices of chiffon and bolting silk, the advantage lies decidedly with the former, as a piece about 7in. by 3in. (that is sufficiently large to cover the lens when folded) would cost—nothing, if one possesses a wife or sister; whilst in the case of bolting silk (which must be sufficiently large to cover the sheet of bromide paper upon which the enlargement is being made) a piece about 12in. by 10in. would cost about 1s. 6d.

The chiffon, it should be mentioned, is attached to the lens by means of a cardboard ring, which fits the lens hood—the frame of an old lens cap would answer.

Those who have used bolting silk will know that its softening effect on the enlargement is really a slight blurring of the outlines, whereas chiffon, as I have just mentioned, preserves the sharp outline, providing the image is focussed sharply. In other words, chiffon does not destroy either definition or detail.

The Diaphragm to Use in Night Photography.

Writing in "Photography" for August 24, Mr. H. Wild describes the methods employed in making a series of excellent night photographs of Tunbridge Wells. As regards the choice of stop to be used in such work he says: "Apart from the question of rapidity, I fancy the larger aperture gives a better rendering. From practical experience I am inclined to think that the rendering of the actual lights depends on the time the plate is exposed without very much reference to the aperture.

"For instance, suppose we find that an exposure of ten minutes is as much as we dare give to a street lamp at $f/11$ without getting reversal, calculating in the ordinary way one would expect to be able to give five minutes at $f/8$ or twenty minutes at $f/16$, but in practice it will be found that nearly ten minutes could be given at $f/8$ and very little more than that at $f/16$.

"This apparent suspension of an accepted law is a most providential one for the night photographer, for it means that, to obtain detail in both shadows and lights, it is only necessary to use a lens of such rapidity that the darker parts of the subject are sufficiently exposed before the high-lights are reversed."

FORTHCOMING EXHIBITIONS.

September 10 to October 23.—The Photographic Salon. Latest date, August 30. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 23 to October 30.—1.—Royal Photographic Society. Latest date (carrier), September 1 (hand) September 2. Sec., J. McIntosh, 35, Russell Square, London, W.C.

New Books.

BEAUTY SPOTS OF THE CONWAY VALLEY.—A book of over a hundred excellent half-tone reproductions of photographs of the scenery between Llandudno and Bettws-y-Coed has just been issued by Mr. John M. Clark, 12, Pearson's Row, Liverpool, at the price of 7½d. It is obtainable from bookstalls and booksellers at 6d. net, and provides a most pleasing souvenir of a visit to the beautiful valley of the Conway river, as also a useful demonstration of the variety of scenery—sea, forest, and mountain—to be found between the mouth of the river and the even more picturesque surroundings of Bettws. The photographs are all from the camera of Mr. T. Lee Lloyd, of 361, Park Road, Liverpool, who has provided some brief letter-press, and there is also a map of the district.

New Apparatus, &c.

THE PILOT ARC LAMP.—A new self-regulating arc lamp for studio use is just being placed on the market at a very moderate price by the Pilot Arc Lamp Manufacturing Company, Limited, 21, Imperial Buildings, Ludgate Circus, London, E.C. The lamp is of the completely enclosed type and is supplied complete with resistance, plugs, leads, globe, and case, for £6 in pattern to take 110-volt continuous current; to work on an alternating current of this voltage the price is £6 18s., whilst a third pattern of the lamp (the "Universal"), adaptable to either continuous or alternating current, is sold at £7 18s. The great portability of the lamp is one important point in its favour, whilst another is the absence of any adjustment. All that is necessary is to connect the plug to any domestic supply, switch on the current, and the light is at once obtained. An illustrated circular showing the design of the lamp is obtainable post free on application to the Pilot Company, at whose offices, 21, Imperial Buildings, Ludgate Circus, the lamp can be seen. We believe that professional photographers desiring a lamp of moderate power for studio use will find it worth while to investigate the claims of the Pilot lamp, of which we hope to write further, after having had it in practical use for a while.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 28.

Hackney Photographic Society. River Trip.
Southend-on-Sea Photographic Society. Excursion to Herongate.

TUESDAY, AUGUST 31.

Hackney Photographic Society. Suggestions for the Annual Exhibition.
Kinning Park Co-operative Camera Club (Govan). Club Meeting.

WEDNESDAY, SEPTEMBER 1.

United Stereoscopic Society. Paper: "Separation and Exaggeration."

Commercial & Legal Intelligence.

DISSOLUTION OF PARTNERSHIP.—The partnership between Messrs. Albert Flint and John Robert Jeffs Pearson, photographers and frame makers, 68, Church Street, Camberwell (trading as Albert Flint and Co.), has been dissolved. The business is to be carried on by Mr. Pearson, who will pay and receive all debts due by, or owing to, the late firm.

Mr. Robert Nevins Allen, Cotham Hill, Bristol, collotype printer and photographer (trading as Senior and Co.), has transferred his business to Mr. Charles Lott Brass, Chelfham Bridge, Barnstaple, who will carry on same and receive and pay all debts due to and from the firm.

News and Notes.

THE EPSOM RURAL DISTRICT COUNCIL have approved of a set of plans by Mr. Drinkwater Butt, F.R.P.S., for a house and studio, to be erected at the corner of Anyards and Freelands Roads, Cobham, Surrey, for Mr. Hugh Weet of that place, who will transfer his photographic business thereto on completion.

PHOTOGRAPHERS IN NEWCASTLE PARKS.—At a meeting of the Town Moor and Parks Committee of Newcastle Corporation, held last week, the Town Clerk submitted a report with respect to photographers in Jesmond Dene and other parks in the city, and it was decided that immediate steps should be taken to put a stop to photographers carrying on business in the parks.

PHOTOGRAPHY UP-TO-DATE.—For the nominal price of 2s. (says a Washington correspondent of the "St. James's Gazette") you can go down to posterity on a piece of pasteboard, clasping hands with the American President. Over an obscure little photographer's shop in a street near the White House floats a flag with the inscription, "Come in and have your picture taken with President Taft." The photo is taken by the simple method of imposing the customer's figure beside the stock plates of President Taft with outstretched hand, as if in greeting, or in a friendly arm-in-arm pose. The illusion, however, is very good, and the photographer has been making a lot of money. The White House looms in the background of the picture.

PHOTOGRAPHS OF CHINA.—On Tuesday, August 31, at the ordinary fortnightly meeting of the Royal Horticultural Society, Vincent Square, S.W., there will be exhibited, on behalf of Professor Sargent and the President and Fellows of Harvard University, Cambridge, Mass., U.S.A., a selection of photographs illustrating the flora, fauna, and scenery of Central and Western China. These photographs are from the large collection taken by Mr. E. H. Wilson during his last (third) journey to China. It is thought that this exhibit will be of interest and value to those keen on the recent new plant introductions from China. It is also hoped that from its varied character the selection made will appeal to a wider circle. The photographs are whole-plate size (8½ in. by 6½ in.), with liberal mounts for herbarium purposes, and all are duly labelled. The work of developing and printing has been done by the well-known expert in floral photography, Mr. E. J. Wallis, Kew, S.W.

THE SCOTTISH SALON.—The following gentlemen have accepted the invitation of the Scottish Photographic Federation to act on the Board of Selection for the Seventh Scottish National Photographic Salon, to be held in Dundee, January, 1910:—Messrs. J. Craig Annan, Archibald Cochrane, and W. B. Lamond, R.B.A.

SULPHIDE TONING OF P.O.P.

To the Editors.

Gentlemen,—Referring to your reprint of my note on the sulphide toning of P.O.P. last week, perhaps the following particulars of the way I prepare the tribasic ammonium phosphate may interest some of your readers, particularly as the salt generally bought as ammonium phosphate is the hydrogen di-ammonium phosphate $H(NH_4)_2PO_4$, and any of your readers wishing to try their "Cubrome" thiomolybdate "B" solution on P.O.P. prints may be rather at a loss to obtain the salt that I recommended, as it appears in very few lists.

I dissolve the ordinary ammonium phosphate in cold distilled water nearly to saturation, and then add excess of .880 ammonia. After standing a short time, the contents of the flask, after being shaken up, is thrown on a Buchner funnel, when the precipitated salt is dried as far as possible by suction with the filter pump. The salt in this state (a somewhat pasty crystalline mass) I do not attempt

to recrystallise, but dissolve it (1-10) in distilled water. To every three parts of this solution, one part of the ammonium carbonate solution is added to make the alkaline phosphate bath.

Better crystals of the tribasic salt may be obtained by Sestini's method of dissolving the acid in an excess of strong ammonia and evaporating in a desiccator over quick-lime; but though no doubt a purer salt is obtained, the crystals take some time to form, and for this use it is, I am sure, unnecessary to go to this trouble.

Since I consider the ammonium carbonate solution a necessity in the phosphate bath, it might be thought that as the free ammonia in the carbonate solution would neutralise any nitric acid formed on converting the silver nitrate into phosphate, ordinary ammonium phosphate or di-hydrogen ammonium phosphate, or ordinary sodium phosphate (or, better, the tribasic sodium phosphate) might be used. But I prefer not to use the sodium salts, as it seems a mistake to mix the bases unless there is some necessity for it; and I think that the use of the tribasic ammonium salt undoubtedly yields the best tones.

The tribasic ammonium phosphate can be supplied to any one who cares to apply to me at this address (c.o. Edmund and Co.).—Yours truly,

H. E. SMITH.

Ezra Street, Columbia Road, London, E.

August 23, 1909.

Answers to Correspondents.

. All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

John Sutherland Jenkins, 2, Anworth Villas, Corstorphine, Midlothian. Photograph of Lauriston Cottage, Cramond Beach, Davidson's Mains, Midlothian.
Frederick Danby, Church Street, Radcliffe. Photograph of Child in Bath.
Arthur E. McKinney, 28, Waring Street, Belfast. Three Photographs of Irish Girl Embroidering Lace.

E. D. P.—1. Reliable pieces of apparatus are sold by all the large dealers. They are of different forms, and all are good. Apply to Messrs. Sinclair and Co., 54, Haymarket, London, S.W. 2. Yes, if used according to the directions.

INSURANCE.—Some months ago I saw something in the "British Journal of Photography" with reference to insurance of photographic apparatus, etc., and a gentleman's name was mentioned who would supply forms to those who wished to insure. Will you kindly give me his name and address, please?—INSURANCE.

You are doubtless thinking of what was said some time ago about the advantages that members of the Professional Photographers Association enjoy with regard to fire insurance and reduced premiums. These advantages are confined to the members of the Association only. If you are a member, the Hon. Secretary, Mr. A. Mackie, 89, Albany Street, N.W., will send you a form. If you are not, he will send you a prospectus of the Association and particulars of membership.

MIRIAM.—From the fact that the edges of the stains are straight lines, it looks as if the cause was overlaying of the prints on each other in the fixing-bath.

PHOTOGRAPH FOR DAMP PLACE.—I have recently been asked to make a portrait or enlargement, to be hung in the vestry of a church which I know is exceedingly damp. Which would be the better one of the two, carbon or platinotype, and what would be the best

course to follow in preserving it as long as possible—I mean in the way of framing same? Could I do better than do it in carbon (or platinotype)? Would cardboard be the best support for it?—**VESTRY.**

You cannot do better than carbon or platinotype. We would suggest that the picture be mounted by the dry method, as the medium used is highly waterproof. The glass should be secured in the frame by strips of good paper, and the backboard firmly bradded in and papered round. When dry, the back may be given a coat of ordinary wainscot varnish. The thing is, make the frame damp-proof as far as possible. Take care that the print and mount are thoroughly dry before they are put into the frame, or they may become mouldy in time.

FLORIDE OF GOLD.—Could you, through your correspondent's column in "B.J.," inform me the way to dissolve a gold coin so as to make a gold solution for toning bath?—**N. E.**

Dissolve the coin in the following mixture (in a glass flask):—Nitric acid 1 part, hydrochloric acid 5 parts, water 6 parts. Digest by gentle heat. When all is dissolved, dilute with distilled water and precipitate the gold with a filtered solution of sulphate of iron. Well wash the precipitate with distilled water, and redissolve it in the above, then crystallise it in an evaporating dish over a sand bath. It is well to crystallise it a second time so as to get rid of all the acid possible.

SEPIA TONING OF P.O.P.—In this week's issue of the "B. J." there is a paper (page 646) on getting rich sepia prints on P.O.P. without gold toning. I can understand the formula, as far as the ammonium phosphate and ammonium carbonate are concerned, but when I come to the "Cubrome" thiomolybdate solution, I find myself at a loss. Can the compound be purchased, or can it be prepared? also what proportion of water is used? If you would kindly answer these questions I should be greatly obliged.—**THIOMOLYBDATES.**

A special preparation of thiomolybdate is sold for the purpose by Messrs. Edmund and Co., Ezra Street, Columbia Road, E. See also a letter from Mr. H. E. Smith under "Correspondence" on another page.

CHEMICAL CONGRESS.—I shall esteem your kindness in replying as to where I may obtain pamphlet reporting the deliberations of the International Congress of Applied Chemistry, the meetings of which was reported in your valuable edition of May 28 last.—**COHEN.**

The Congress issues a report of its proceedings, but publication may not be expected for several months, and even then it is doubtful if all the papers and discussions will be given in full. If your inquiry relates to a photographic paper, your best course, we think, would be to apply direct to the author of the paper.

SPRINT.—Seven inches is a rather short focus for a half-plate reflex. We frequently use an $f/4.5$ lens of this focal length on a quarter-plate reflex. We think that in many instances you would find a lens of 9in. to 15in. focal length necessary with your half-plate reflex. We hope you realise that a half-plate reflex is rather a big affair to take about long distances. The two cameras are very similar. If your lens could be fitted to a 5 x 4 reflex of the best maker you name in your letter we should consider that the best use was being made of it as regards the outdoor work you speak of. It is rarely that exposures shorter than $1/50$ or $1/100$ require to be given. We advise you to use pyro-metol (Ilford formula) for such work, or one of the single-solution developers—sodal, certinal, or victrol. As regards the choice of reflex cameras, an issue of the "Photo-Miniature" (Dawbarn and Ward, limited, 6d.) has just been published on this subject.

STEREO SUBJECTS.—I have about 150 really good stereo negatives without prints, and about 5,000 prints of other views without corresponding negatives; these 5,000 comprise about 200 separate views, with varying quantities of each. I wish to dispose of them. Will you kindly tell me what is a reasonable price to ask, as follows: (1) Price of stereo negatives per dozen; (2) ditto per 100; (3) price of stereo prints per dozen; (4) ditto per 100; (5) ditto per 1,000 or lot; (6) price of stereos for reproduction?—**ETLAW.**

Impossible for us to say, as we have no idea of the interest of the subjects. The prints will be of practically no value unless the right to copy them goes with them—that is, is yours to sell.

CINEMATOGRAPHY.—I am desirous of obtaining all the information I can on cinematographs, and shall be very much obliged if you will favour me with the dates of any issues of your journal containing articles on the subject. The information I require is of a practical nature, dealing with the construction of cameras and projection apparatus.—**T. H. W.**

We have not dealt at all fully with cinematograph work. The best periodical of this branch in the "Kinematograph Journal" (1d. weekly), in which you will find a good deal of practical information.

HOT WEATHER TROUBLE.—I should be greatly obliged to you if you would kindly give me your opinion on the enclosed prints. The print marked X is on glossy bromide. You will notice the markings in the paper, which has the appearance of a print which is melted. They are dried overnight (not by the fire) so that melting is out of the question. The other print is matt bromide developed in the same bath and dried on the same slab. The makers say that there is nothing wrong with the paper. I think it is faulty in emulsion, or stale.—**E. WALTON.**

We cannot trace any fault in the paper. The appearance is evidently due to the recent hot weather. The gelatine has softened during the manipulations owing to the solutions being too warm. Probably you will not get it now that the weather is cooler even with the same paper.

DEFECTIVE NEGATIVE.—I should feel very grateful to you if you could help me out of my difficulty in your journal. I am constantly getting the effect on enclosed print. I may say the camera and slides are quite light-tight. When exposing the enclosed I took the precaution to shield the lens with umbrella, the sun on the point of setting and well on the left of camera. The lens used was a Wray, 15 x 12, rect., comparatively new, except that the iris diaphragm has become a little bright through the friction of usage. If I coated the inside of lens mount and diaphragm with Bates's dead black would that, do you think, help me? I made two exposures. The fellow plate to the enclosed from the same holder is only slightly fogged, but I used a larger stop.—**J. W. RICHARDS.**

It is clear that the corner of the plate has been light-struck, either in the dark-room or the camera. You say that the dark slides are light-tight. That we are inclined, by the appearance of the print, to doubt, but the camera itself may possibly admit a faint beam of light at the corner corresponding with the fogging of the negative. If the inside of the lens mount has become bright it will be well to re-black it. But the brightness of it will not account for the fogging of one corner of the plate only.

CHARGES FOR RETOUCHING.—Having been apprenticed at a good class photographer's for three years, have now obtained some retouching to do at home for another photographer, but am at a loss to know what to charge, so I am writing this to know if you could tell me the usual charge in such a case for imperial cabinets, C.D.V.'s, and also whether I ought to charge according to the number of people on negative. If you could kindly tell me I should be much obliged.—**H. RICHARDS.**

There is no fixed charge for the work. Every retoucher makes his own charges, and they depend upon the quality of his work. We have not seen any of yours, so can give no opinion on it, and what it is worth. We should advise you to consult the advertisements in our columns headed "Miscellaneous Trades." From that you will gather what other retouchers charge. Of course, an extra charge is made when there are several figures in the picture.

OWNERSHIP OF NEGATIVES.—A gardener in the employ of a gentleman in this vicinity called on me at my studio and said he had instructions from his employer to get a photographer to come and take several views of his house and grounds. He fixed a day on which it would be convenient for me to attend. On arriving at the house I was given a definite order by the gardener to take nineteen positions, 12 x 10 size. I took twelve that afternoon, and the remainder the next morning. I did not see the owner of the house, as he was in town for three or four days, so nothing was said about the price until I sent the proofs, when I quoted my usual terms—viz., 2s. for first negative and 5s. 6d. per negative after (this is my charge for taking negatives), then prints from negatives 5s. 6d. each

in silver. He replied, grumbling about the price, but ordered thirteen copies, which I finished and sent off next day, enclosing my account. I received an acknowledgment from him to-day, asking me to send the negatives charged for and he will settle the account in full, otherwise he will only pay for the prints supplied. I have written saying that I have not charged for the negatives, but for taking them, and quoted part of the copyright law about the copyright of negatives being vested in him, but the custody of them being given to me. If he will not pay what is my best course?—X. Y. Z.

The negatives are your property. Do not give them up. If the man will not pay you must summon him in the county court, when you will get the money. It is a little unwise to make a definite charge for taking the negatives. It is better always to charge only for photographs.

VARIOUS.—Some months ago an advertisement appeared in your journal for prints (various) for publication. I sent a batch, from which they marked four, saying they had enough at present, but would be glad of them in the near future. Fully three weeks ago I sent them again with stamped address for return, if not wanted, and can get no reply whatever. As the prints were double-printed they were valuable to me. (1) What can I do further in the matter? Their address was, The ——— Co. (2) Would 10s. 6d. (sole right) and 3s. 6d. (not sole right) a print be a fair charge for prints cabinet size? (3) I have seen carbon prints done with an oval border round the portrait; does not show the slightest join anywhere. Can this be done single printing, or is a large border screen used in front of sitter and photographed thus? (4) A customer has a lot of negatives reproduced by means of transparencies. Who has right to transparencies, customer or man who executes order?—AN OLD READER.

(1) The only thing you can do is to sue the parties in the county court for the price of the pictures they have kept. (2) The price is very moderate indeed. (3) Without seeing an example we are unable to say how the prints are done, but probably they are by double printing. (4) The transparencies are the property of the photographer who executes the order.

COPYRIGHT.—Would you kindly answer me the following question in the "Journal"? I (A) take views for B and sell B the negatives and postcards. B makes a smash and is sold out. C buys stock at auction sale. Can A stop C from selling them, or how can A get his money? Does A have any claim on the copyright if he copyrights them, being the author of the work?—OLD READER.

A has no title in the copyright, inasmuch as he was engaged by B for doing the work. That is vested in B. C has no copyright in the negatives unless it was assigned to him at the time of the sale. But A has no voice in the matter. All he can do is to look to the trustees for payment of his account according to the dividend declared.

COPYRIGHT.—I take a number of views for publication by myself, and do not register them at the time. Afterwards I find that some of them have been pirated. I register them and then take proceedings against the reproducer, or those selling the copies. Where then, may I ask, is the good of spending money on the registration of the pictures, until one finds that they have been copied? If one registers, say, a dozen, perhaps only one or two are copied, and the money paid for the other ten is simply wasted.—SUSSEX.

The advantage of registering in the first instance is that proceedings can at once be commenced for the recovery of penalties, damages, injunction, etc., for all that has been done from the time of registration. Whereas if the registration has been delayed until the copyright is infringed nothing can be recovered for what has been done before that. All that can be done is to sue for damages, and an injunction from the time of registration.

FOUSSING MAGNIFIER.—Unfortunately, I am not so young as I was and have had to take to spectacles. With these I can see very well, but I have a difficulty in focussing in them. Somehow or other I cannot get sharp negatives, although, with the spectacles, the image seems sharp on the ground glass. Will you please help me out of my difficulty by telling me the best kind of

focussing magnifier to use, as I see so many different ones advertised?—TOO OLD AT FORTY.

The best to our mind is the Ramsden form of eyepiece, consists of two plano-convex lenses mounted in a tube, which adjustable by a screw in an outer jacket. The tube is adjusted to the sight of the user to a pencil mark made on the focussing screen and then clamped tight by a screw nut, so that the distance is fixed once for all. These instruments are sold by all large dealers at from six or seven shillings upward.

M. C. J.—We are afraid you will not be able to obtain any compensation now. If broken glass could be heard in the box when delivered by the railway man it should have been opened in his presence, or else his book for signature should be marked "received damaged," or have been refused altogether. Signing a book without remark implies that the parcel was received in good condition.

A. T. Cox.—The picture sent is but moderately good. It is possible, however, that it might be awarded a medal if exhibited at some of the minor societies.

F. J.—You have either been quite misinformed or, possibly, confused the two things. A mirror for obtaining reversed negative which is placed at an angle of 45 deg. in front of the lens, may be optically worked and have an absolutely plane surface, and be silvered on the front. A mirror placed outside a window when enlarging by daylight may be of common sheet glass silvered on the back, like an ordinary looking-glass. Its only purpose is to reflect light through the negative. It has nothing to do with the formation of the enlarged image.

MIXING ALBUMEN WITH GELATINE.—Is it possible to make a mixture of albumen and gelatine that will keep, and if so, how?—FIDOS

Yes; the best way is to beat up the albumen into a perfect froth. Let it rest for a day or so and then pour off the clear albumen. Next dissolve the gelatine in the usual way, but at a temperature at the time of mixing must not exceed about 120 deg. Fahr., or there would be a danger of the albumen coagulating. Then add a few drops of carbolic acid. The mixture will require warming each time it is used, but the temperature should not exceed that given above for the reason stated.

A LECTURE ON DEVON AND CORNWALL.—Among the transactions to which we referred last week in making mention of the Liverpool Association's syllabus was that on Cornwall. It may be said that, according to a circular which has just reached us, the author of the lecture, Mr. Chas. R. Rowe, is prepared to deliver in person before other societies without fee. Good Devonian times he is, Mr. Rowe knows the West Country most intimately, and what he has to say on the beauties and traditions of Devon and Cornwall comes from a first-hand acquaintance with places and people. Gifted with a ready way of entertaining as well as instructing, Mr. Rowe will surely be welcomed as a lecturer by photographic societies. Those interested are advised to send a stamped addressed envelope to 83, Edith Avenue, Plymouth, for particulars.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

"Free" Portraits and Sunlight Soap.—At Huddersfield last week to canvassers from Scotland received six months' hard labour on a charge of representing themselves as connected with Messrs. Lever Bros., soap manufacturers. The case is reported on page 687, and we comment on this new variety of the "free" portrait dodge on page 681.

Trade printers will probably confirm our opinion that the average portrait negative has dropped off in quality during the last year or two. Apparently a negative is thought to be good enough if it will make a decent print on gaslight paper. We endeavour to give some technical reasons for this, apart from a possible lower standard of work in development. (P. 682.)

Pirie Macdonald, when in London last week, was entertained at supper and discoursed on copyright and fraternity. (P. 688.) On page 683 we give a short account of the proposals of a Bill for the regulation of the hours of shop assistants.

The method of preparing mechanically-etched wood blocks from photographic reliefs is described on page 688, under "Photo-mechanical Notes."

The intentions of the Government with reference to cinematograph exhibitions are reported on page 694.

In our recent paper on the present condition of sensitometry, by Dr. C. E. K. Mees, gives a fairly popular account of this little-studied subject. (P. 685.)

The colour screen-plate of quite novel pattern figures with the daylight loading of plates under "Patents of the Week." (P. 689.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Reports on the "Thames" combined plate take the form of some editorial notes on page 66, and an article by Mr. H. E. Corke, on page 65.

M. A. A. Personnaz, in a contribution on page 67, dissents from the views of painters as to the pictorial quality of Autochromes recently quoted by M. Demachy.

M. Lumière have drawn up a table as a guide to the use of the single-solution metoquinone developer when correcting mistakes of exposure of Autochrome plates. They adopt a modification of the Fabrial method. (P. 67.)

In our recent paper by Mr. Howard Farmer on the copying of Autochromes is given on page 71.

Colonel Houdaille has recently published a paper aiming to provide a basis for the exposure of Autochrome plates. (P. 69.)

Professor Namias has suggested a modification of the Traube "Autochrome" process for the making of three-colour prints and transparencies. Lead sulphate or lead oxide is used as the mordant instead of silver iodide. (P. 68.)

EX CATHEDRA.

A New Bogus Portrait Game. "You know the game, the free portrait business, is played out, and we have to tell them some sort of a tale to get them to have one."

So said one of two canvassers at Huddersfield last week on being charged with representing themselves as agents of Messrs. Lever Bros., Limited, soap manufacturers. To this ingenious purveyor of photographs truth is no doubt stranger than fiction, but in this instance there is reason to suppose that he proclaims a fact. The press up and down the country must chiefly be thanked for the enlightenment of the public as to the fraudulent nature of the business of canvassing for photographs, inasmuch that the two gentlemen who are just entering upon a six months' term of hard labour found it necessary to bait their line with something less open to suspicion than a "free photograph." They declared to the magistrate that "when calling upon people the mere mention of the word photograph was enough to have the door closed against them." Unenviable as is the fate of photography to be thus associated with the most barefaced kind of deception, there is some consolation in knowing that the public—or a large portion of it—clearly recognises that these practices are not those of established photographers, and are condemned by them more vehemently, because with greater reason, than by anyone. At the same time, unfortunately, the malpractices of the canvassers prevent the photographer from taking measures to extend his business which, but for the bad name of door-to-door solicitation, might be adopted in a respectable, if not very dignified, way.

* * *

The Chemistry of Sulphide Toning.

The paper on this subject by Mr. Douglas Carnegie which we published last week marks another important step in advance in our knowledge of the mechanism of photographic processes. It is a curious fact that very few processes have been submitted to an exhaustive examination, and sulphide toning is only one of many that are carried out frequently, and quite successfully, by numerous workers without any knowledge of how or why the results are attained. This paper does not exhaust the subject by any means. The exact nature of the toned deposit is not determined, but several very common causes of failure are quite successfully demonstrated, and this alone is a very valuable feature. It will be seen that the results very nearly confirm the suggestions we made in a leader published on January 29 last in regard to the effects obtained with exhausted and partially exhausted sulphide solutions. A point brought out in the article is the lax fashion in which some previous writers have described the strength of the sulphide solution used.

The water of crystallisation, to say nothing of that of deliquescence, is generally disregarded, with the result that the solutions used are often much weaker than they should be.

* * *

The Fixing-Bath for Bromide Prints

It is often advised to employ a bath of the acid type—such as one made with hypo and potass. metabisulphite—for the fixation of bromide prints. While there is no theoretical objection to such a bath—in fact, the non-staining properties of the solution are in theory an advantage—there is, however, a practical drawback to the use of a fixing-bath which does not become coloured in use when it is being used on a commercial scale. Inasmuch as there is no certain means of telling when a bromide print is completely fixed, the use of a bath which does not give any signs of its progress towards a state of exhaustion is actually a danger when the work of fixing is relegated, as it usually must be, to somewhat inexperienced hands. The very fact that the dark colour of the solution indicates that a great number of prints have been passed through the bath is a strong reason for selecting a plain solution of hypo only. Many of the bromide prints which are sent to us for our explanation of various yellow and brown stains are stated by their makers to have been treated in an acid bath, the careless use of which, and nothing else, is, we believe, the most common cause of these defects.

* * *

The Two Exhibitions.

A final reminder may be given to those who, in paying a visit to London in September, do so with the object of visiting the Photographic Salon and the exhibition of the Royal Photographic Society. The private view of the Salon is on Thursday, September 9, the exhibition opening to the public on September 10. In the case of the Royal Photographic Society, the date of the private view and conversazione is September 22, the first day on which the New Gallery is open to the public being September 23. We hope to give a first impression of the Salon in our issue of the 10th inst., and shall deal with the sections of the Royal Photographic Society's show as soon as possible after the opening.

* * *

Novel Photographs as Christmas Gifts.

Photographers anxious to make the most of the present-buying season which commences a week or two before Christmas are none too early in starting to make their preparations now. Mount manufacturers who supply goods specially applicable to the Christmas season are already busily engaged in offering their wares, and a great variety of effects are obtainable by taking advantage of the multitude of commercial designs. There are also other directions in which photography may be advantageously applied in producing gifts other than the conventional type of mounted portrait. If we remember rightly, we referred last year to a novelty introduced to its customers by a studio in the West-end of London. It took the form of a doll of the "Teddy bear" type, the fabric face of which had impressed upon it the portrait of one or other of the parents of the child on whom the gift was intended to be bestowed. A present of this kind, on account of the fun to be obtained from it, is pretty sure of a good sale, and it may be to the advantage of those in search of opportunities of increasing the volume of their Christmas business to think over other varieties of presents in which a photograph could be embodied. We believe that there are many directions in which the customary processes of photography might be profitably applied.

THE QUALITY OF NEGATIVES

THOSE firms engaged in making prints from negatives sent to them for that purpose have the opportunity of seeing such a large number of negatives that they are able to note very accurately the progress that photographers generally are making as regards quality of results, and we have recently been informed by such a firm that the most striking characteristic of the average modern negative is its badness. It is usually quite unsuited to either carbon or platinum printing, or indeed to first-rate results by other processes. The proportion of good negatives received is much smaller than it used to be, and the reasons for this falling off in quality are well worth consideration. The main fault appears to be undue flatness, the result being that gaslight paper is the only one that will yield a passable print. Possibly the popularity of gaslight paper has something to do with the prevalence of such negatives, but it occurs to us that there may be several other contributing factors, chief among which is, perhaps, the modern tendency to omit bromide in the developer.

Given "correct" exposure, bromide is, of course unnecessary with the majority of modern plates and films but given a little over-exposure, then with some developer the omission of the bromide invariably leads to a foggy result. If the time of development is cut down to keep the fog at a minimum, a thin and flat negative is produced while if we develop up to full density a heavily fogged image that is barely printable on any paper is obtained. The majority of negatives to-day are no doubt produced on fast plates, and the modern lens is so very efficient, that over-exposure is a much more common defect than it used to be. In earlier days, under-exposure and hard negative were the prevailing *bête-noir*, while nowadays over-exposure and thin, foggy negatives are the source of the printer's troubles.

Possibly another contributing factor is the idea held by many workers that different classes of negatives are desirable with different kinds of printing paper, exceptional pluck and vigour being required for carbon or platinum printing, and exceptional thinness for bromide enlarging and gaslight paper. This is, of course, a great mistake for a really good negative will yield a good print by any process. Negatives that will only print well by one or two special processes cannot be classed as "good" specimens, the fact that their use is limited being itself an obvious indication of faultiness. Some excuse the badness of their negatives on the ground that they will yield the results wanted on some special paper; but a good negative will do the same thing, and also yield good prints on other varieties.

Perhaps the majority of photographers have the same fault as the too enthusiastic patient who doses himself vigorously for one complaint as to bring on a different variety of trouble. Very fast lenses and extremely rapid plates are invaluable on some occasions, but not at all desirable on each and every occasion. Extremely fast plates are very prone to fog if a little over-exposed, and one of the commonest blunders is the use of plates that develop much faster than really needed.

Another reason for the prevalence of fogged negatives is probably the frequent use of tank development with unrestrained diluted developer. It may be taken as a general axiom that bromide is always required when development is prolonged, yet many seem to think that dilution of the developer renders the use of bromide unnecessary, and therefore they omit its use altogether. Further than this, when a number of exposures are developed together some invariably will show more fog than others, and very few trouble to apply the necessary reducer to clear them. A weak Farmer's reducer will

make a marked improvement in such cases, and its use involves a minimum of trouble and risk if the negatives are plunged straight into it on leaving the fixing-bath. Clearing-baths of all kinds are somewhat out of fashion nowadays, but there are very few negatives that are not the better for clearing, though all do not require reduction.

PROPOSED CHANGES IN THE REGULATION OF THE HOURS OF SHOP ASSISTANTS.

A BILL "to consolidate, amend, and extend the Shops' Regulation Acts, 1892—1902" has been introduced into the House of Commons by Mr. Gladstone, the Minister in charge, and though the Government do not propose to proceed further with the measure during the present session, it will probably serve as a basis for legislation in the near future. Photographers, in common with several other classes of the community, will be interested to know how the Bill affects the conduct of business, and the following outline of the Government's proposals will, we think, show clearly that the respectable trader has nothing to fear from the operation of the principles embodied in Mr. Gladstone's Bill.

The main features of the measure may be grouped under our heads, thus:—

(1) Compulsory closing on Sundays, subject to modification in the case of Jewish quarters and established street markets.

(2) A weekly half-holiday.

The local authority is given a wide discretion in this matter, but the principle must be observed, and if the local authority do not appoint a particular day, then the occupier of the shop must select one, and place a notice to that effect in his shop.

(3) Early closing at the option of the local authority, which in the case of London will no longer be the metropolitan borough, but the London County Council.

We may note in passing that the relatively small area of the borough has done much to render the present Acts operative, and the Government are evidently alive to this fact.

(4) No shop assistant may be employed for more than sixty hours per week, exclusive of meals. There must be no employment after 8 p.m. on more than three days per week.

The occupier is to fix the times at which work begins and ends within the above limits. He must in a notice affixed in the shop specify the "spells" of work, and also the "meal-times," which last must be in accordance with the prescribed scale. Provision is made for "overtime" to the extent of two hours a day for not more than thirty days in the year. The Bill contains special provisions dealing with holiday resorts and public holidays, and as it applies to "outside" trading, there need be no fear of unfair competition from hawkers and street traders gener-

ally. Part 3 of the new measure deals with the provision of seating accommodation, proper ventilation, and sanitary conveniences.

In part 4 particulars are given as to the powers and duties of the local authority. This section also specifies the penalties for various offences under the Act, and deals with business carried on in bazaars, fairs, and exhibitions.

In the event of any local authority failing to enforce the regulations of the Bill, the Secretary of State may, after inquiry, appoint an inspector to report breaches of the law.

Mr. Gladstone informed the House of Commons that the introduction of the Bill in the present session had been decided upon with a view to promote discussion, and in the hope of attaining something like unanimous support. He added that about one million assistants and half that number of employers would be affected by the passing of the Act. Conditions in some of the larger shops were not unsatisfactory, but on the other hand there were cases of assistants who worked from eighty to ninety hours per week, and who had no means of shortening their toil. In Mr. Gladstone's opinion (and we venture to predict many will agree with him hereon), the main cause of the evil is the wasteful and mischievous system of competition which is unhappily so prevalent in the mercantile community of to-day. It appears that all the business done might be transacted in 75 per cent. of the time now devoted to it, and if this be so, the public certainly need to be taught reasonable consideration for those who serve them in the shops. Finally, it should be noted that the legislation proposed will not tend to divert the flow of trade from home to foreign channels.

It is worthy of note that the first reading of the Bill took place with the approval of all the members present except Mr. Bottomley. Even he, while characterising the measure as "undemocratic" and the product of "parental" government, approved of a reduction in the hours worked by shop assistants. This practically unanimous approval of the House does not, of course, imply that the measure as it now stands will become law without modification in any respect, but it seems to show that the principle of the measure will command the support of members on both sides of the House. This being so, we expect to see legislation on the lines of the Bill in the near future.

Signs are not wanting that the old policy of *laissez faire* which has been so long a dictum of the utilitarian school is losing ground before the combined forces of humane feeling and common sense. Something may fairly be said in favour of leaving capital and strongly organised labour to adjust their differences with the minimum of interference on the part of the State. Where, however, the workers from any cause or combination of causes are unable to protect themselves from obviously harsh and oppressive conditions, it becomes the duty of the Government to intervene on their behalf. This does not necessarily mean that the masters will suffer. The ultimate employer is the purchasing public, who must learn to pay a fair price for what they buy, and in the act of purchase to extend reasonable consideration to the man in the shop.

DAMAGE OF PHOTOGRAPHS.—Extraordinary conduct was alleged against a well-known Reading dentist in the local police-court last week, when Neville Walsh, of Blagrove Street, was summoned by Messrs. Walton, Adams, and Sons, photographers, for wilfully damaging several of their pictures. Defendant occupies rooms over Messrs. Adams' business premises, it was stated, and for some time past there had been unpleasantness between the parties. On Messrs. Adams visiting their show-rooms in the morning they have found sundry photographs and pictures damaged by a darkish liquid. Holes had been bored through the ceiling, through which liquid, which looked like ink, had apparently been squirted, it was alleged. A

witness living opposite the studio said she had seen defendant in a crouching position, as though examining the floors over the studio. In reply to one letter from Messrs. Adams, defendant said he was frequently kept awake until daylight, being suspicious that something wrong was going on in the studio. Messrs. Adams added that even since the summons had been served on defendant they had had further pictures damaged by what looked like ink. Defendant said: "I don't confess, and I don't deny it. If I did do it, I plead justification." The chairman of the Bench told defendant he had been guilty of most wilful and malicious damage. An inclusive fine of 11 guineas was imposed, or in default five weeks' imprisonment.

AMERICAN NOTES.

THE Dresden Exhibition has been very much in the minds of the Americans—amateurs, professionals, and especially manufacturers. Two of the greatest manufacturing firms, in discussing it at some length, have expressed the hope that it might form a precedent, and be the first of a series of really great and really international exhibitions. The idea seems to be that in 1911 there should be one in London or in an American city (Buffalo and Chicago have been suggested), followed by Paris, and then by Melbourne or Sydney. American eyes are turning more and more towards trade with the British Colonies—especially Australia—largely as the result of the great world-trip of the U.S. battleships.

Our Great Colony.

In discussing exhibition sites there is quite an inclination to consider Toronto or Montreal, for the men of the United States are greatly impressed with the enormous and immediate promise of our great Dominion—even if many Britons are not so fully alive to it as they ought to be. In the near future Canada will see the greatest commercial contest the world has ever known. At present there is a very strong general prejudice in favour of British goods in the photographic line; but the Americans are next door, they are alert, and they will leave no stone unturned to capture the great trade that is growing daily. The homeland has the preferred products, in quality and design, in almost every line. In most lines we can compete fully on prices and terms, and the field is ours if we can only keep in touch with the development of the new cities and districts, cultivating them directly or through responsible agents by a ceaseless appeal of tactful advertising, fresh stock, and suitable packing.

Ambassadors of Commerce.

When I landed in the States last winter Lord Northcliffe was there in the interests of the Harmsworth publications. A week later, in Toronto, I found Mr. W. E. M. Goode in that city, in the interests of "The Standard of Empire." "The Times" has opened a fully equipped Canadian office, as well as one in New York, in addition to strengthening its staff in Washington; and "The Standard" aims to represent Canadian matters as no other paper can attempt to do.

British Trade in the U.S.

On this head I will say little at the moment; but there are some notable facts. First: I am assured that the sale of British plates is growing steadily—the Ilford, Imperial, Wellington, and Mawson lantern-plates being especially mentioned. Second: The sale of British lenses is said to be growing. Old favourite high-class makes are believed to be more than holding their own in competition with the American and the German makes; and one lens in particular, which has recently been specially modified to suit certain American cameras, is expected to make a sale such as no imported lens has ever attained, and it is not a "cheap" lens, either. Third: The Ensign film appears to be making a place for itself with a rapidity and success that must be most gratifying to Austin Edwards and Houghtons Limited.

A New Studio Camera.

A camera which is new in almost every detail, and not merely a slight variant of old patterns, has been devised by the Century Camera Company (branch of the Eastman Kodak Company), and

though it will doubtless be illustrated and described in the "B.J." as soon as it is absolutely ready for the market, some details may be of interest now. The stand is a metal pedestal of circular section, more like the binnacle-box of a steamer than like an ordinary camera-stand. A pedal raises the camera gently and steadily by air-pump pressure, while another lowers it just as gently by letting the air escape. The ostensible lens is a big dummy, and the image is thrown by a mirror to a ground-glass in the side (not the back) of the camera, which has a most convenient focussing hood, rendering a focussing cloth unnecessary. In photographing children or nervous persons the operator looks as if he was working with the dummy lens, and can pose and manipulate the mother or an assistant while keeping observation on the real sitter. For children on the ground the camera drops very low, as the pedestal is telescopic, and the operator then turns his mirror to throw the image on a focussing-screen in the top of the camera. Many other details—as the reversing back, an entirely new lens-hood device, etc., etc.—are individual and interesting.

Record and Laboratory Camera.

Cameras of this type are amongst the latest products of the Century Company. The record outfit is prepared especially for use in insurance, surveyors' and architects' offices, and consists primarily of a large square cabinet, at one end of which the front-board with lens and reversing prism is fixed, while the camera back moves horizontally along the top, and the copy-holder moves vertically up and down the end of the cabinet, beneath the lens and prism.

The laboratory outfit is not so new in principle, though it has many ingenious and useful details, and seems an ideal machine for photo-micro, copying, and lantern-slide work.

Through College with a Camera.

While in the office of the Century Camera Company, I happened to see the opening of a parcel, which was interestingly typical of certain conditions in America. It was a set of prints from a young student in one of the Middle-States universities, who is working his way through college by his earnings as a semi-amateur. A working man, with no money to pay for an advanced education, he saved enough to buy a 7 by 5 field camera, and learned enough to give confidence that he could earn a living. Then he boldly took the entrance-examination and started a course of study and photography combined. Since he has "made good," and feels grateful to those who supplied the camera and have given many useful hints, he sent them a parcel of prints culled from his work, with a query as to whether they could make use of them in any way. The prints were excellent, from charming out-door portraits and groups, mainly of children.

This method of working one's way through college is not at all unusual in the United States; in fact, many of the smaller universities, with a long session through the winter and a very long vacation in summer, have a number of students who take work in summer as waiters, farm-hands, boatmen, etc., to earn enough to pay for their tuition in winter. No prejudice or stigma attaches to these students, and their determination to secure the best possible education indicates the power which forces so many Americans to the front in commerce, and in other walks of life to which they devote themselves.

H. SNOWDEN WARD.

A REPORT ON THE PRESENT CONDITION OF SENSITOMETRY.

[The following paper, by Dr. C. E. Kenneth Mees, F.C.S., read before the recent International Kongress für Angewandte Photographie at Dresden, discusses a subject of considerable importance to dry-plate manufacturers, and indirectly also to all users of plates, seeing that a large section of it deals with the thorny question of the value to be taken as the measure of the speed of a plate.—Eds. "B.J."]

THE sensitometry of photographic dry-plates is somewhat peculiar, in that while it is a subject of considerable magnitude and difficulty, it is the study of but few persons, and is almost unknown to the professional scientific worker. It has been developed by a few photographic enthusiasts, and to a small extent in technical works; but while the number of workers on the subject has been few, their enthusiasm has been great, and many papers have been published on the subject.

There is no text-book which deals adequately with the subject as a whole. The only papers and books present the conclusions obtained and the methods adopted by the writer himself, rarely referring at any length to previous publications. In the text-books of photography the subject is almost entirely neglected, the writers, where they refer to it, being those who have themselves developed methods, and confining their attention almost entirely to their own methods.

Branches of Sensitometry.

Sensitometry can be divided into three main sections:—

1. Sensitometry proper, or the measurement of the sensitiveness of plates.
2. The measurement of the rate of development of plates.
3. Colour sensitometry, being the measurement of the distribution of colour-sensitiveness in plates.

Besides these three branches, the application of plates in measurement, and the special factors required to be known for quantitative measurement of phenomena by means of their effect upon plates, forms a fourth division of the subject.

It will be clear that methods of sensitometry can be considered from two different aspects analogous to those from which we can consider an analytical method. First, from the point of view of accuracy and of convenience in scientific investigation. For this purpose the great requisite is accuracy, all other considerations being subsidiary to this. Complicated and delicate apparatus, and the necessity for great skill in use, are not disadvantages. But just as an analytical method requiring great skill and complicated apparatus is not suitable for the use of a manufacturer, who requires to know the purity of his products, so methods suitable for research in sensitometry are not necessarily suitable for use in a dry-plate factory. As a general rule, however, the difficulty of getting accuracy is so great, and the need for it is so much felt, that accuracy must be the first desideratum in the factory as in the laboratory.

It may be well to remark here that the photographic manufacturers are rather unenviably distinguished for their lack of scientific method, both on the Continent and in England. Manufacture is largely in the hands of skilled practical men who have but a small amount of scientific training and prefer rule-of-thumb methods to measurement. This fact is due, no doubt, to the very difficult nature of the work, emulsion work, like cookery, being dependent more on the skill of the operator and his experience than on his scientific knowledge.

A Suggested Definition of Plate-Speed.

The great difficulty in designing a system of sensitometry has always been the definition as to what is meant by the sensitiveness of the plate. On reading over the discussions which have taken place on this subject it seems to me that many who have taken part in those discussions have been so concerned with the difficulties of the definition that they have failed to observe the necessity of having some definition, even if that definition

be insufficient. I would suggest as a practical definition one that agrees with ordinary practice, viz., "The relative sensitiveness of two plates is the relation between the exposures required to produce a deposit transmitting 1-10th of the incident light when the plate is developed so that the density differences for the 'straight line' portion of the characteristic curve are equal to the differences of the logarithms of the exposures received, the light source being daylight, and the total exposure for that density not exceeding two minutes nor being less than five seconds." This definition, it will be observed, defines the colour of the light, and also avoids difficulties with regard to the failures of the reciprocity law.

It is quite true that the ratio of sensitiveness may not be unaltered—

1. For other regions of the characteristic curve,
2. For much more or less intense light sources.
3. For differently coloured light sources;

but I think it better to define these variations, of which 1 is comparatively small; 2 is very small indeed; and 3 very small, except for colour-sensitive plates which are separately measured, independently of the normal sensitiveness measurement for practical purposes. Apart from colour-sensitive plates, the errors introduced in practical photography by 1, 2, and 3 are probably much smaller than the errors occurring in many other directions.

Sensitometry Proper.

For a considerable period investigators have been concerned in attempting to measure the sensitiveness of photographic plates. In the very early days of dry-plates, plates were stated to be 10, 20, etc., times as fast as wet-plates, but before long the need for a more accurate method of measurement was felt. This need was to a certain extent met by the "Warnerke" sensitometer, which consists of a piece of glass covered with squares of pigmented gelatine, each square having an opaque number printed on it, and transmitting for each square $\frac{1}{3}$ rd less light than the preceding square. Other instruments giving intensity scales of the same sort were used by Spurge and Dr. Vogel. In the "Warnerke" instrument the plate is exposed to a graduated series of intensities, and its sensitiveness is measured as the least degree of intensity which it can register. A recent and convenient application of this method is the "plate-tester" devised by Mr. Chapman Jones.

This method has been developed in Germany by Eder, who used the sector wheel designed by Scheiner. In the Scheiner wheel there are in the big model 23 angular apertures, each of which is larger than the preceding one by 1.27. This is rotated in front of the plate, and exposure is made either, as proposed by Scheiner, to a benzine standard lamp, or to a Hefner-Alteneck amyl-acetate standard. After development, which is for a definite time (a method which, as will be explained below, leads to inaccurate results), the plate is placed face downwards on a sheet of white paper. The exposure corresponding to the lowest densities which can be observed is termed "schwollenwert," or "threshold value," of the plate. This method has been largely adopted in Germany, especially in consequence of the advocacy of it by Professor Eder; but it appears to be being now slightly displaced by the Hurter and Driffield system, which was, at any rate nominally, adopted in England rather more than ten years ago.

The Congress of Photography in Paris (1889) suggested another method of finding the sensitiveness of a plate, but no one seems to have adopted their suggestions in practice. They suggested that the amount of light which was required to produce a density which would transmit half the light should be taken as the standard. They do not seem to have stated anything concerning development, which is, of course, the vital point of this definition. If the definition were that the sensitiveness should be taken as that exposure which would produce a density which was equal to the steepness of the characteristic curve—that is, a density of 1, with a development factor of 1—there seems to be no objection to it, and in practice it would come close to the recommendations of Hurter and Driffield.

Abney found the sensitiveness of plates by plotting the transparency against the logarithmic exposure, calculating the sensitiveness from the point at which the tangent to the inertia point met a parallel to the exposure axis. In this method the sensitiveness found is the point of least light-action, and is dependent on the lower portion of the characteristic curve. And in 1890 Hurter and Driffield read before the Liverpool section of the Society of Chemical Industry a paper which they entitled "Photo-Chemical Investigations." They gave a number of experiments in which they had exposed plates to varying extents, and had then measured the optical density, which they showed to be proportional to the mass of silver developed in the plate. They then plotted the density against the logarithm of exposure, obtaining what they call the "characteristic curve of the plate." They found that the central portion of this curve was very close to a straight line, and that, if they prolonged the central position, the point at which it cut the exposure axis was not affected by the time of development. They consequently considered the point at which this straight line cuts this axis to be proportional to the insensitiveness of the plate, and they termed it the "inertia" point. In spite of much criticism and of certain practical disadvantages, this method has been, and is being, steadily adopted as the best practical method of finding the sensitiveness of a plate. Unfortunately, there is much confusion as to light standards, and obviously the choice of a light standard greatly affects the results.

Hurter and Driffield used a British standard candle. Shepard and Mees, when repeating a great portion of their work, standardised acetylene burners by means of the present standard pentane burner. This standard and the candle standard give practically identical results. Hurter and Driffield defined their sensitiveness as 34 divided by the "inertia," and this was what was meant by the Hurter and Driffield (H. and D.) speed. The H. and D. speed published by some commercial houses must lead one to conclude either that the standards used are inaccurate, or that the numbers are intended simply to serve as trade marks without any actual reference to the speed of that particular box of plates. Inasmuch as the Hurter and Driffield "Actinograph," for which the H. and D. speed was intended, is very little used—having been supplanted, in England at any rate, by the Watkins and Wynne meters—it would appear better to give sensitiveness in numbers suitable for these instruments. After some correspondence with Mr. Watkins I have come to the conclusion that the nearest approximation to his numbers can be got by dividing the "inertia" into 50, which makes them about 50 per cent. greater than the Hurter and Driffield numbers. The Wynne numbers are got by multiplying the square root of the Watkins number by 6.4.

A few words should be said concerning the apparatus required for carrying out sensitometry. For the purpose of finding speed, two instruments only are essential. First an exposure instrument with a standard light source, either a primary source such as the pentane standard, or a secondary standard, and of a method of graduating the light so as to obtain a series of intensities. The best method of accomplishing this latter object seems to be to use the sector wheel suggested by Dr.

Hurter, from which nine angular sectors are cut out, the angles being 180 degrees, 90, 45, etc., each one giving half the exposure of the next one. The wheel can be rotated by an electric motor or a small hot-air engine, or, if not often used, by hand. Secondly, an instrument for measuring the density of the silver deposit is required. Abney used a Rumford photometer, Hurter and Driffield a Bunsen bench photometer; but these earlier instruments have largely been replaced by the smaller and more convenient, as well as more accurate, polarisation photometers. A very convenient polarisation instrument is the Martens pattern made for the purpose by Schmidt and Haensch, which is largely used. A photo-chemical laboratory will require a spectrophotometer for other purposes, and this will form a very perfect instrument for the measurement of densities.

I may refer here to an important paper by A. Callier on "Scatter in Photography" (Phot. Journ., April, 1909).

If work on development is to be done, apparatus for keeping the developer at a constant temperature will also be necessary. A complete discussion of the apparatus used in carrying out the H. and D. system will be found in a paper in the "Photographic Journal" for July, 1904, entitled "On Instruments for Sensitometric Investigation."

Measurement of the Development Constant of Plates.

If a plate be given an exposure, and then cut up so that different portions of the plate can be developed for different times, it will be found on measuring the density and plotting the curve of the density against the time of development, that the density rises with the time of development rapidly at first, and then more slowly, finally arriving at a limiting value which is dependent upon the exposure which the plate has received. The equation connecting the density with the time of development is given by the law that the velocity of development is proportional to the difference between the final density which can be attained, and the density which has been already attained, that is:

$$V_{(D)} = \frac{dD}{dt} = K(D_{\infty} - D_t)$$

which on integrating gives:

$$K = \frac{1}{t} \log_e \left(\frac{D_{\infty}}{D_{\infty} - D_t} \right)$$

It will be seen from this that if we differentiate so as to get the initial velocity, the initial velocity is equal to $K D_{\infty}$.

Now since the density for a given exposure is proportional to the slope of the characteristic curve, that is to $\tan \theta$ for the straight portion, which was termed by Hurter and Driffield γ , we can write γ for D in this velocity equation, getting:

$$K \frac{1}{t} \log_e \left(\frac{\gamma_{\infty}}{\gamma_{\infty} - \gamma_t} \right)$$

and for the initial velocity $K \gamma_{\infty}$. In order then to know the developing properties of a plate, we require to find K and γ_{∞} . These two constants are found by developing two plates, one for twice the time of the other, and solving the simple simultaneous exponential equations thus obtained. Tables have been published to facilitate the after-calculation, but a good deal of practical work has convinced me that it is safer to find out how long a given plate will take to develop, and develop to a high density, and then to develop for so much longer that the plate will be completely developed, and take the γ reading as γ_{∞} . K can be calculated from another plate, developed for a fixed time in a standard developer at a standard temperature. A useful application of the two constants thus found is to calculate from the time of development for that particular batch of plates. For normal purposes, γ_{∞} is a very important sensitometric constant indeed, it settles the density-giving power of the plate and is one of the chief controlling factors in emulsion making. It is a very variable factor, which is easily altered by small alterations in making emulsions. The velocity constant

development "K" is even more variable, varying from time to time in different batches without apparent cause. It is dependent upon the rate of drying of the plates.

Colour Sensitometry.

If the determination of the sensitiveness of plates is in a somewhat unsatisfactory condition, the determination of colour-sensitiveness may be said not to have commenced. There are two methods which are usually practised, but the great difficulty with all methods of colour-sensitometry is the amount of time which they consume. The two methods are:—

1. The measurement of the density curve of the plate when exposed in the spectroscope.

2. The measurement of the sensitiveness of the plate by a "Schellenwert" or Hurter and Driffield method, when exposed under given sets of broad-banded filters.

The first method has been greatly developed by R. J. Wallace ("Astrophysical Journal" XXV., No. 2, March, 1907). Wallace uses daylight, employing a standard plate in order to find the intensity of the daylight, and exposes the plate in a spectroscope of his own design, measuring the density in a Brace spectrophotometer. The plates are developed to a γ of 1, and the spectrum curve plotted. Mr. Wallace suggests a coating of the density readings found in this manner for six or seven points in the spectrum.

The second method, using pigments as well as filters, has been much developed by Abney, who also designed a "colour-sensitometer" transmitting narrow spectral regions of the same visual intensity, so that for a properly corrected plate they should produce deposits of equal density.

In my own practice I have found the relative sensitiveness under a yellow and a blue filter as suggested by Eder, the blue filter transmitting the portion of the spectrum below 5,000, and the yellow filter the portion of the spectrum above 5,000; or else, in my later work, under a set of tri-colour filters, taking the tri-colour ratio as a measure of the relative sensitiveness of the plate.

Mr. Wallace rightly objects to this method, that a plate may give, for instance, a high reading under the red filter without having even sensitiveness in the red, owing to great sensitiveness in the orange, and I find it, therefore, convenient to control the quantitative numerical statement of sensitiveness as given by the tri-colour filters by a qualitative investigation in the spectrum.

In order to avoid the trouble of making a series of exposures, or of measuring density curves, I employ a black glass wedge in front of the slit, which produces a graduation of intensity from 1 to 1,000 in the length of the slit, and in this manner obtain what I usually term "wedge spectra," a combination of which spectra with a three-colour ratio for a definite set of filters appears to me to be satisfactory.

I should here make reference to a paper at present appearing in the "Zeitschrift für wissenschaftliche Photographie" by Leimbach, entitled "The Sensitiveness to Radiation of Gelatine Dry Plates." Leimbach has measured the intensity of his radiation in a spectroscope, by means of a radiometer, and has measured the density of his plates in a Hartmann micro-photometer. The chief point of novelty appears to be that he expresses the intensity of light in absolute energy units for each portion of the spectrum.

In closing this review of sensitometry, I must refer to the application of photographic plates for the measurement of intensities. It is not uncommon in scientific work to find photographic plates used for the measurement of intensities without a sufficient understanding of the conditions under which they must be used. It is not sufficient, for instance, to take densities, even if accurately measured, as a measure of light action, unless they are first interpolated on the characteristic curve of the plate. It is not sufficient in sensitometry to take

plates developed for the same time as being developed to the same extent. If plates are to be developed to the same extent so that densities can be taken as proportional to sensitiveness, they must be developed to the same γ , and two plates developed for the same time are very unlikely to be developed to the same γ .

It is also advisable, if scientific workers use photographic plates, that instead of attempting to discover the whole of the properties of photographic plates for themselves, they should refer to the photographic literature on the subject. I have recently, for instance, read several papers where the authors had completed a laborious piece of investigation upon some particular property of a photographic plate in blissful ignorance of the fact that the whole of that work had been done, and been done much better, some fifteen years before.

The complicated nature of the subject, and the scattered character of its literature, is no doubt responsible for such mischances.

C. E. KENNETH MEES.

A NEW BOGUS PORTRAIT DODGE.

At Huddersfield Police Court last week Tom Duncan, 21, canvasser, Glasgow, and James Houston, 20, canvasser, Edinburgh, were charged with having obtained 3s. 6d. from Mary Wood, Prospect Street; 3s. 3d. from Harriet Shakeshaft, Outcote Bank; and attempting to obtain money from Emily Schorah, Spring Street, all by false pretences. On a fourth count, prisoners were charged with having obtained food by false pretences from Mary Ann Berry, Albion Street. Defendants pleaded not guilty.

Mr. Frank Sykes appeared on behalf of Messrs. Lever Brothers, Ltd., soap manufacturers, of Port Sunlight, and said that for a considerable time past there had been a gang of men, including prisoners, going up and down the country defrauding the public by making use of Messrs. Lever Brothers' name. They called upon persons and asked whether they were users of Lever Brothers' soap, and if they found they were, they said Lever Brothers had ceased giving presents in connection with wrappers, and they had decided to present an oil painting to the users once a year. Generally, they obtained portraits from such people, and then made arrangements with them for supplying frames, for which they made charges. They carried that out at Glasgow, Edinburgh, Leeds, Manchester, Liverpool, Londonderry, and various other places, including Huddersfield. Owing to the smartness of Detective-sergeant Whitehead, of the Huddersfield Police, two men were suspected, and subsequently identified as having used this deception on the public.

The evidence showed that on August 3 the prisoners called at the house of Harriet Shakeshaft, at Bank Terrace, Outcote Bank, and asked if she used Sunlight soap. Receiving a reply in the affirmative, they said they represented Messrs. Lever Brothers, who had commenced to give enlarged photographs in oil once a year to all users of Sunlight soap. Believing the men, she gave them a small photograph of her son for enlargement, and they went away. They called again on August 10, and showed her samples of picture frames. They offered her one for framing the enlarged picture for 3s. 3d., which they said would also cover the cost of carriage. Witness paid them 3s. 3d., and they gave her a receipt for the money, signed A. Duncan and T. Smith.

In the case of Mrs. Mary Wood, prosecutrix said defendants called upon her on the 3rd inst., and made similar representations. She paid them 3s. 6d. to have a portrait enlargement framed. She did not, however, receive the picture.

According to the evidence of Mrs. Emily Schorah, the methods adopted by the prisoners in her case were similar to the others. She gave them for enlargement by Messrs. Lever Brothers a photograph of her daughter, and the prisoners, showing her some picture frames, said the cost of the different samples would be 5s. 6d., 3s. 9d., and 3s. 6d. Prisoners added that the charges would include the cost of carriage from Port Sunlight. Witness said she would not pay any money until her husband came home, and the prisoners left, taking the photograph with them. Her husband subsequently communicated with Messrs. Lever Brothers.

Detective-sergeant Whitehead gave evidence of apprehending the prisoners on August 15. When charged, Duncan said:—

"No, we don't represent Lever Brothers. We only tell the people that we want our firm to be as well known as Sunlight soap. You

know the game, the free photograph business, is played out, and we have to tell them some sort of a tale to get them to have one."

Robert Morris Lister, confidential clerk to the secretary of Messrs. Lever Brothers, Port Sunlight, said the prisoners had no authority to represent the firm.

On the charge against the prisoners for obtaining food by false pretences from Mrs. Mary Ann Berry, the latter stated that the prisoners had boarded and lodged at her house from August 9 to 13. They said they represented the Empire Art Company, Gordon Street, Glasgow. They stated that the firm would wire a deposit, as they would stay three weeks. A few days afterwards, becoming suspicious of the prisoners, she gave information to the police. The food they had consumed was valued at 10s. 3d.

Addressing the magistrates, Duncan said the reason that Messrs. Lever Brothers' name was used was that it was "a little business fact" to get an introduction to a house. When calling upon people the mere mention of the word "photographs" was enough to have the door closed against them. They mentioned the name of Sunlight soap and said they were a firm trying to build up a business on these lines. They never said they represented Messrs. Lever Brothers.

Prisoners were committed for six weeks' hard labour in each case—six months each in all.

A TALK ON COPYRIGHT AND FRATERNITY BY
PIRIE MACDONALD.

On Thursday, August 26, Mr. Pirie Macdonald, of New York, was entertained at supper, at Gow's Restaurant, Strand, London, by an impromptu party of a few London photographers. Present were:—Mr. Lang Sims, President of the Professional Photographers' Association, in the chair; Mr. Alfred Ellis, in the vice-chair; and Messrs. Ernest Elliott (Elliott and Fry), S. H. Fry, E. O. Hoppé, Alexander Mackie, Richard Speaight, H. Snowden Ward, and Arthur Weston. Others who expressed regret at inability to be present, owing to the very short notice which alone was possible, were Messrs. H. Walter Barnett, F. A. Bridge, George E. Brown, Furley Lewis, Louis Langfier, Reinhold, Thiele, and R. Fellows Wilson.

After the usual loyal toasts, the chairman briefly and heartily welcomed the guest of the evening, and proposed his health. In reply, Mr. Pirie Macdonald said that he felt his capacity to be representative rather than personal—representative of the Professional Photographers' Society of New York, and of a number of men who were in every sense the brothers of his hosts. In America it had been realised more fully than in this country that the best friends for a photographer were photographers; that the best companion for any man was a man who had similar experiences, aims, tastes, and difficulties. In the P.P.S. of N.Y. it was found that men attended the informal social meetings with pleasure and zest, because they could always gain something, but most of them went with greatest pleasure to a meeting when they had something to give to others. They had absolutely broken down the old bad secretiveness and jealousy that existed for too long, and had realised that the best way to cure competition and price-cutting was by raising the price-cutter to a higher level, helping him to do better work, encouraging his confidence and pride in his work; for they found as an actual fact, that as soon as a man felt sure that his work was as good as another man's who was getting better prices, he wanted better prices too. There was still some pettiness and still some unfair competition in New York, but the average photographer was in a more firmly established commercial position, especially the middle-class photographer, and his position was the basis of the American good prices and good profits. Even the low-priced man was in a sound position, as a rule; and he was respected by his neighbours because his work did not interfere with theirs, but appealed to a distinct class of custom which they could not reach. The result was that the three-dollars-a-dozen man met the kings of the craft at the Society's meetings, asked them freely for any information or assistance that he wanted—and got it.

During the past four years many of the American photographers had been at work influencing the new copyright legislation which had just been passed. The bulk of the work had fallen upon Mr. B. J. Falk, one of the greatest and most unselfish men in the craft, a magnificent organiser and a giant for detail. Mr. Falk had asked him (Mr. Macdonald) to represent photography at the actual sessions of the committee that dealt with the four different bills and a host

of amendments and modifications, so that in addition to their long work on details, they had forty days on the floor of the committee-room, debating, opposing, supporting, and influencing point after point—forty days of strenuous work that became absolute agony.

They found that photography was not seriously recognised in any of the draft bills, and that many of the representatives of writers, painters, etc., wished to give no copyright to the work of the photographer. The photographers refused to consider any position of privilege or of inferiority, so that under the new law they stand on all fours with all American authors. The old law was an agglomeration of enactments and rulings, puzzling, inconsistent, and sometimes flatly contradictory of itself. The new law was clear and logical. The old law had come to a deadlock because the penalty for infringement often could not be collected. In the new law the maximum penalty was greatly reduced, but there was little doubt about its being recoverable.

The "manufacturing clause" was a most important one. Under the old law copyright could only be had in books, photographs, etc., if they were printed from type set, negatives made, etc., in the United States. This clause remained in the new law for all forms of art work except photography. Photographers had insisted on the removal of the word "negative." Therefore, under the new law, a British or other foreign subject can obtain copyright in his photographs on exactly the same terms as an American subject. This (said Mr. Macdonald) was a real expression of the feeling of brotherhood, a free-will offering to the photographers of the world, without any bargaining, terms, or conditions; and if authors in other lines still felt that the "manufacturing clause" was a grievance, he hoped photographers would feel that their brothers in America had tried to be generous. Reciprocity would be appreciated; he felt sure that, in influencing the copyright law that would soon be under consideration in Britain, the British photographers would guard the Americans' interests as far as possible.

The fraternal feeling of the American for the Briton was not confined to photographers, but was a strong, deep, national sentiment, and whatever might be the actions of governments or of diplomats in the future, the hearts of the people would always be with the people of Britain.

The conversation then became general, and questions of copyright, international co-operation, price-cutting, and the Professional Photographers' Association were discussed until a late hour.

Photo-Mechanical Notes.

Mechanically Etched Wood Blocks from
Photographic Reliefs.

ACCORDING to a recent invention of Messrs. A. E. and W. A. Say, 2, Whitefriars Street, London, E.C., an apparatus has been devised for engraving on wood by a mechanical or automatic method, the device being attached to a wood-engravers' ruling machine. The patent specification (No. 21,752, 1908) gives the following descrip-

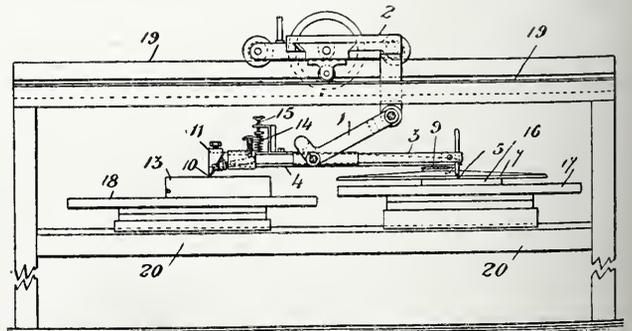

Fig. 1.

tion:—The frame, 1, is constructed and suspended from the usual travelling tool carrier 2 of a wood-engraver's or like ruling machine. To this frame 1, are connected two levers 3, 4, arranged side by side and pivoted on separate pivots in or to the frame 1, with the pivots in the same axial line, as will be understood from fig. 3.

To one end of one lever 3, termed a graver lever, is attached

tracer point 5, and the corresponding end of the other lever 4, termed a guide lever, an ordinary point or pin 6 or other means for connection of a plate 7. A pin 6 is placed at an angle as shown, and enters an angled hole 8 in the plate 7 and is held to the plate 7 by a spring 9 as in fig. 2.

On the other corresponding ends is attached to the graver lever 3, a graver or cutting tool 10, and to the guide lever 4 an adjustable screw or socket 11, having a smooth end 12, or a disc attached thereto, so that it rests upon the block or plate 13 to be engraved without injuring the surface.

On the guide lever 4 is fixed a spring 14, and on the graver lever 3 a screw rod 15 is connected which has action on the spring 14 on the guide lever 4 to prevent the cutting tool 10 digging too far into the surface of the block 13 to be engraved whilst at work.

The strip or plate 7, having a smooth surface, rides over the surface of the relief or mould 16, and in such a manner as not to injure its surface, the lever 4 and plate 7 adjusting themselves to any angle with regard to each other.

The mould 16 is fixed to the table 17 of the machine, and immediately under the tracer point of graver lever 3 with the plate 7 of

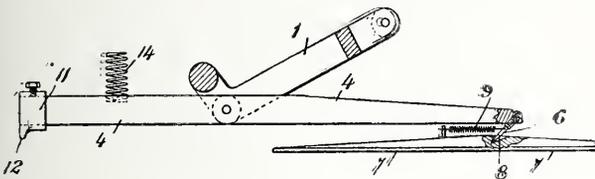

Fig. 2.

the guide lever 4 laying upon its surface. The wood block, metal plate, or other body 13, to be engraved is fixed to the table 18 of the machine immediately under the graver tool 10 of the graver lever 3.

The tracer 5 is then positioned to commence the work at one side corner of the prepared surface on the mould 16, and the graver 10 in corresponding position on the surface 13 to be engraved. The adjusting screw 15 on the lever 3 is then positioned for the tracer 5 to touch the mould 16, and the graver tool 10 is positioned to be within cutting distance of the engraving surface, i.e., to just touch the surface to be engraved, when the tracer 5 is at the lowest depth on the mould or relief 16.

Now by reciprocating the frame 1 and its carrier 2 along the usual rack 19 of the machine, the graver 10 will cut into the surface 13 in accordance with the movements of the tracer 5 over the mould or negative 16, the depth being varied in accordance with the surface

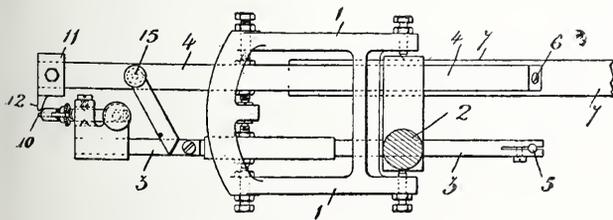

Fig. 3.

of the mould or negative 16, and during this reciprocating of the frame 1 and its carrier 2 the usual ratchet or other wheel is operated to move the frame sideways, so that at each movement forward, or in some cases forward and backwards, the surface is engraved or cut with one line, as is well known with engravers' ruling machines, the degree of side movements depending upon the amount of relief.

The mould or negative 16 and the block 13 to be engraved may be fixed to revolving plates 17, 18 in the bed 20, so that they can be positioned to allow of line engraving of any direction.

The positions of the pivots on the levers 3, 4, can be varied with ease in the frame 1 to suit the depth of cut required in the surface of the block 13 or the amount of relief—that is to say, the pivots, though always in axial line, may be adjusted as to distances from the ends of the levers.

The tracer 5, in moving over the mould surface 16, rocks the graver lever 3 about its pivots, and the graver or cutting tool 10 is caused to vary its depth in the surface whilst cutting, and the cutting point of V shape will remove a narrow or wider strip, and consequently will leave lines of the desired width, according to the depth

of the cut and angle of the V tool; thus if the tracer 5 is moving over a higher position of the surface of the mould which represents a white or light tone surface on the picture, the graver 10 enters deeper into the surface 13 and cuts a broad groove, and in some cases will leave no lines for printing, and when the tracer 5 is moving over a deeper surface of the mould 16 the graver 10 will only lightly cut

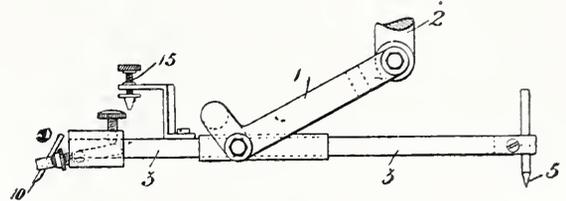

Fig. 4.

into the surface of the block 13, and in some cases effect no cut at all, so that we have the heavy lines or black portions of the pictures, the lines being varied according to the movement of the tracer 5.

To produce pictures or engravings from a relief where the lighter tones are represented by the greater depth of the relief, the positions of graver or cutting tool 10 and adjustable screw socket 11, and screw rod 15 and spring 14 respectively, are reversed, so that there is the same movement with the graver as with the tracer instead of the reverse, as in the previous case. In cases where the cutting takes place on both the forward and backward movement of the frame, a graver or cutter is used, having a specially shaped or a double cutting edge, or it may be two gravers.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for the following patents have been received from August 16 to 21 :—

PRINTING APPARATUS.—No. 18,907. Resiliently cushioned printing frame for photo-printing cabinets. James Frank Ware, 52, Chancery Lane, London, W.C.

SHUTTER RELEASES.—No. 19,021. Improved method and means of releasing photographic shutters. Katharina Baser, née Verini, 7, Southampton Buildings, London, W.C.

CINEMATOGRAPHY.—No. 19,028. Improvements in the manufacture of opaque cinematograph images for projection by reflected light. Charles Dupuis, 31, Bedford Street, Strand, London, W.C.

CINEMATOGRAPHS.—No. 19,097. Improvements in or relating to cinematographs. Vittorio Benaglia and Ubaldo Grimaldi, 111, Hatton Garden, London, E.C.

SHARPENING RETOUCHING PENCILS.—No. 19,125. Strop for sharpening pencils used by photographic retouchers and others. William Aristides Verel and Charles Frederick Wiggins, 100, Wellington Street, Glasgow.

CINEMATOGRAPHS.—No. 19,275. Improvements in cinematographs. William Speirs Simpson, 173, Fleet Street, London, E.C.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR SCREEN-PLATES.—No. 17,509, 1908 (August 18, 1908). The first two claims in regard to the invention are :—

1. A colour screen-plate, which consists of a glass plate covered over with a screen coating composed of a graduated continuation of colour rings of equal or varying widths, the corners of these plates or other support being segments of these circle rings.

2. A colour screen-plate as claimed in Claim 1, composed of a graduated continuation of coloured rings of equal or varying widths, each circle ring consisting of a number of coloured squares or points.

That is to say, the glass plate is covered entirely with a mass of graduated colour circles, joining each other, but not overlapping, which upon the surface have the appearance of a grey tint, but upon being viewed against bright light have no colour at all as the optically correct primary colours in their proper proportions form white light. The method of taking a picture with these screen-plates is practically the same as when using the Lumière "Autochrome" plates, except that positives which are transparent can be printed direct by contact with the negatives, which are also transparent, the registration being accurate, for the reason that the positive plates are made in exactly, the same manner, and from the same printing blocks, and are therefore self-registering; or the negative can be turned into a positive by various well-known means if desired.

A method suggested for the manufacture of the plates is as follows:—

For a film or such-like transparent support a set of three or more wood or metal blocks can be made by machine-ruling or engine-dividing and the various sets of the required colour rings printed from these blocks direct, or from blocks made partly by hand and by various well-known photo-mechanical processes, a set of three blocks, supposing three colours only are being used, covering the plate entirely with these colour rings of graduated

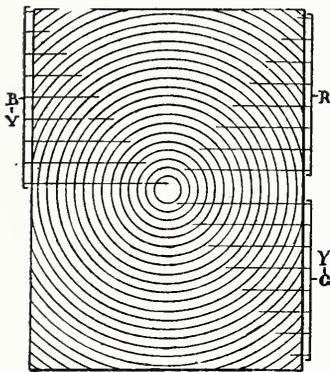

Fig. 1.

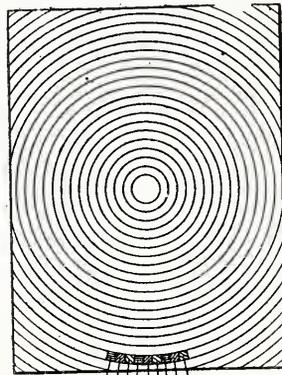

Fig. 2.

sizes fitting into each other and leaving no spaces between. Or the colours may be partly printed in, or partly stained in, or printed in inks that will repel each other, and by this means any overlapping is avoided.

The designs may also be printed upon the prepared glass plate direct by three or more colour-printing, rubber-faced blocks using ceramic colours and process of firing, as claimed in Patent No. 22,228, 1907 ("B.J.," November 13, 1908).

In printing in ceramic ink much the same method is adopted as above, except that the rubber printing faces are made direct from the engraved blocks or stereotypes causing the parts intended to accept these substances to be inverted as upon an engraved copper plate.

The glass plates or other supports (except those printed in ceramic inks and fired) are varnished preferably with a thick celluloid varnish before being coated with colour-sensitive emulsion, and are then ready for use.

As regards the use of the screen-plate with a cinematograph camera or projecting machine, a device may be used in front of the ribbon film attached to the gate and with suitable adjustment for proper registering with the colour records on the positive film, which have registered themselves from the negative-taking film. Through this screen and film combined the pictures are shown in their natural colours. Or a revolving colour-shutter may be used in close proximity to the film, or the ribbon film may be printed upon direct in colour in the manner previously described. The circle lines of the rings of colour for this purpose are about 1,200 to the linear inch, and at the same time being circular are evenly distributed over the picture, and are invisible in the enlarged projection upon the screen. When the screen surface is required upon paper or similar material upon which printed impressions may be made the same printing blocks can be employed, printing with the necessary coloured inks in succession

in proper register with each other, until the whole of the surface is covered with these graduated circles or point circles of colour and having no spaces or overlapping; the paper is then varnished if required, and super-coated with a printing-out emulsion and used in the ordinary way with such papers; the coloured positive or negative plate or film being used for the printing the colours will then be shaded down, more or less, with blacks or browns according to the emulsion or toning solution used, but through the clear parts the colours remain unchanged, and lights and shades are toned down according to the graduated depths and shades of the printing plate. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London, W.C.

DAYLIGHT LOADING OF PLATES.—No. 16,732, 1908 (August 8, 1908). The invention consists of a special form of wrapper or covering for a sensitive plate, which latter thus encased is inserted in a dark slide, such as that described in Patent No. 7,319, 1905 ("B.J.," February 16, 1906, p. 132), by means of which it is exposed and, if necessary, developed without resource to a dark-room.

The envelope in which the film or plate is packed is made preferably of black paper. It embodies in one arrangement (shown in Figs. 1 and 3) three parts—namely: 1. An inner sheath for the back of the plate folded over it at the two side edges Ax of the plate B, and at the two ends A¹ thereof, so that the whole plate is enclosed, except the sensitised surface B, and permanently fastened to the plate by some adhesive material. The sheath is provided with a small flap, C, at the upper end. 2. A sliding

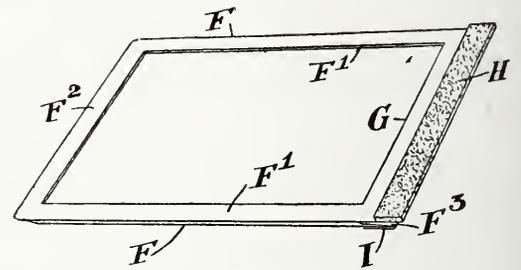

Fig. 1.

cover or blind, D, which is made of such a size as to be of rather greater length than the combined length of the back and front of the plate B. This blind is passed down the back of the plate outside the inner sheath, leaving a flap piece, D¹, projecting at the top, then up the front or sensitised face B of the plate, so as to entirely cover it. This blind, D, at front of plate is equal to the width of the plate. At the back it may be narrower if desired, as shown by the dotted lines, so long as it forms a sufficiently strong connection between the tab or flap, D¹, and the front portion, D. E is an auxiliary blind fastened at e to the main cover or blind, D. 3. An outer cover or sheath, F, which is closed at the two sides F¹ and at one end F², but is open at

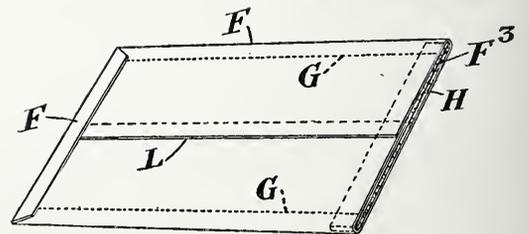

Fig. 2.

other end F³ to receive the plate or film B with its inner sheath together with its intermediate case or blind D. This outer sheath cover F has an opening, G, at the front, and is made of such a size that it can be slid into the dark slide, and then when the opaque shutter of the dark slide is slid over it into position the plate B, with its three coverings, is entirely enclosed therein, a light-trap consisting preferably of a piece of velvet, H, being fastened on the top edge of the outer covering, F, so as to make a light-tight joint against the opaque shutter. A small rib at the top of the dark slide on the inside engages the outer cover, and prevents it being accidentally withdrawn. I is a piece of stiffening fastened at the mouth of the outer covering, F.

The manufacturer inserts the plate, B, with its inner cover in the intermediate blind, D, and then with the flap, C, of the inner cover folded completely down, inserts the plate with the two covers in the outer sheath, F. The small flap, C, of the inner cover projects slightly through the opening, G, in the front of the outer sheath, F. This is then folded back over the edge of the opening, G, in the outer sheath and fastened by an adhesive. In this condition the plate, B, with its inner sheath, is firmly secured to the outer sheath, F, while the intermediate blind, D, is left absolutely free. The plates are now ready to be sold to the consumer. In use a plate with its light-tight envelope is placed by the consumer in the dark slide, the opaque shutter inserted outside the front of the sheath, and the intermediate blind, D, drawn out by taking hold of the tab, D¹, and pulling it. This removes the blind, D, from the sensitised side of the plate, B, and

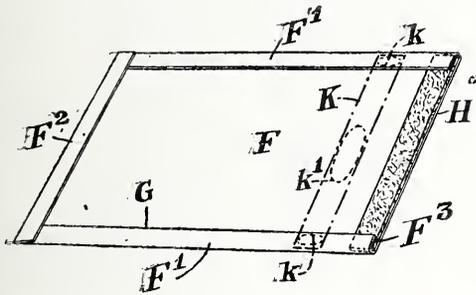

Fig. 3.

leaves the sensitised surface ready for exposure immediately the opaque shutter is withdrawn. The blind so withdrawn is discarded.

To take a photograph, therefore, all that is necessary is to remove the opaque shutter and take the photograph in the usual way, then replace the opaque shutter again before removing the dark slide from the camera. A box or container, such as described in Patent No. 7,319, of 1905, is then taken, and the dark slide and the parts 1 and 3 of the envelope enclosing the plate placed in this box. The developer is now introduced through an aperture in the box, and permitted to flood the photographic plate contained within the envelope and dark slide. When this has been continued for the desired length of time the solution is run out of the aperture. The subsequent operations of washing the plate and fixing it are accomplished in a similar way by running in the requisite amount of water and fixing solution in succession. Thus the various operations of developing, washing, and fixing are gone through without the use of a dark-room. Of course, the box or container could first be filled with the developing agent and the plate-carrier with its enveloped plate then inserted, and the shutter removed. In either case both the washing and fixing might take place subsequently in a second and similar box. George Edward Hawkes Rawlins, Low Skelgill, Windermere.

The following complete specification is open to public inspection before acceptance:—

LOUR PHOTOGRAPHY.—No. 18,553, 1909. Multi-colour photography, Krayn.

New Trade Dames.

WALTURDAW (DESIGN).—No. 314,397. Bioscope apparatus and all accessories therefor, including films, included in Class 8. Walturaw Company, Limited, 6 to 10, Dane Street, High Holborn, London, W.C. June 30, 1909.

FORTHCOMING EXHIBITIONS.

1909.

September 10 to October 23.—The Photographic Salon. Latest date, August 30. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 23 to October 30.—1.—Royal Photographic Society. Latest date (carrier), September 1 (hand) September 2. Sec., J. McIntosh, 35, Russell Square, London, W.C.

1910.

April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 114, Parade Chambers, Sheffield.

Analecta.

Extracts from our weekly and monthly contemporaries.

Hypo on Tap.

The following method (writes Mr. Ernest Collins in "The Amateur Photographer and Photographic News" for August 31) will be found easy, economical, and decidedly convenient. A great point about it, too, is that from first to last there is no need to handle the hypo at all, a consideration devoutly to be desired, should we find that the fixing bath has run out just when we are toning or after developing. The expense is trifling, and, with care, a permanent piece of apparatus is added to our stock. Procure from your chemist a magnesia bottle—these are of a deep blue colour, stand about two feet high, and very firmly, especially when full of solution, and hold over 200 ounces. Then have made, out of a piece of butter muslin, a narrow bag, in the shape of a stocking. This should be about two feet long and about four inches wide. Also provide yourself with a small elastic band or two, these latter small enough to tightly close round the top of the bottle. The bag is just slightly wetted at the closed end, and dropped into the mouth of the bottle to about half-way down.

The protruding piece is turned back over the lip of same, and securely fastened by the elastic band. The hypo—one or two pounds—may now be poured in, in the proportion of four pints of water to the pound. It is surprising how quickly the hypo dissolves, and in five minutes an ample quantity of full strength, that is, plate-strength, hypo solution is ready—in fact, over a gallon. Withdraw muslin bag carefully, rinse same, dry and put away for future use. A syphon of thick glass tube can easily be fitted, and a tap of good black rubber tube, clipped with a burette, is a handy contrivance to draw off same. This can stand upon a high shelf in the dark-room, and a desideratum to all photographers is achieved, viz., the hypo laid on.

New Books.

TRAVEL AND EXPLORATION.—Since the whole civilised world is watching with interest the efforts of the Persian nation to rise to the rank of constitutionally governed nations, it is appropriate that the principal article in the September number of "Travel and Exploration" should describe that country. The author of the article, Major Sykes, C.M.G. (Gold Medallist of the Royal Geographical Society; British Consul-General and Agent of the Government of India in Khorasan), describes "A Pilgrimage to the Tomb of Omar Khayyam," and besides throwing new light on the life and thought of the Persian philosopher-poet, draws a vivid picture of Persia of to-day. Colonel C. E. de la Poer Beresford writes of an official mission to Bokhara, in which he has much to say in praise of Russian administration in that part of Central Asia; Miss Mary Bridson gives an account of an eight months' visit to Nyasaland, and Miss Agnes B. Warburg describes Dalecarlia, a part of Sweden little visited by tourists. How a steamer was carried in sections overland to a lake in the Andes over mountains and across waterless deserts is told by Mr. W. F. Nixon, who undertook and successfully accomplished the work.

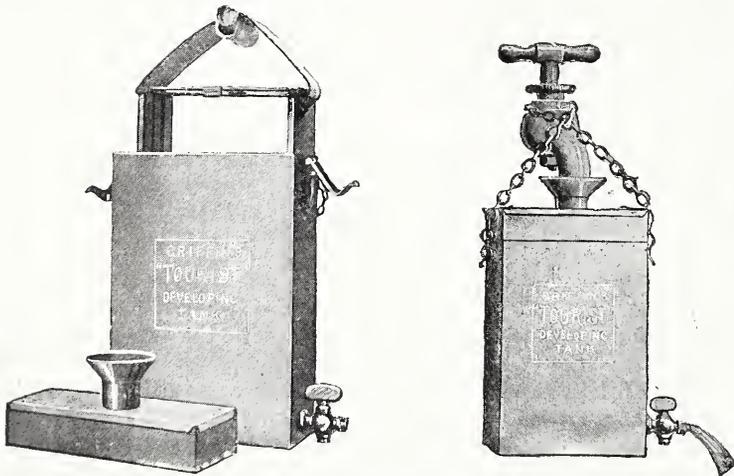

New Materials, &c.

GRIFFIN'S SATIN BROMIDE PAPER.—Messrs. J. J. Griffin and Sons send us a very pleasing window card, taking the form of a sepia-toned print, upon their Satin surface bromide paper, which they are issuing free to dealers, together with a private circular, giving particulars connected with the sepia toning of the paper. These embody the results of recent experiments by Messrs. Griffin, and should be of value to the dealer, who is frequently made the recipient of inquiries by customers who have found difficulty with this method. The circular and the mounted print are obtainable free on application to Messrs. John J. Griffin and Sons, Kingsway, London, W.C.

New Apparatus, &c.

The "Tourist" Daylight Developing Tank. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

Still another piece of apparatus for the use of photographers employing a tank method of development has just been placed on the market by Messrs. Griffin under this name. It is especially intended for the service of those who may choose, on occasion, to develop and finish plates while on tour, its qualifications in this respect being that it may be used not only as a developing and fixing tank, but also as a washer and a drying rack. This result is achieved by making the rack loose and providing the tank with an outer tap at the base and a chain so that it can be hung on to any tap, as shown in the second illustration, when washing the plates. Apart from this the tank has one or two other special features which deserve to be mentioned. The lid is very efficiently light-capped by a double rebate, and the same remark applies to the upper aperture by which the developer is passed into the tank. Also the developing solution is caused to travel down the ends of the tank and thus is prevented from acting irregularly upon the plates, which, as is the custom with tanks of this description, may be placed in it in a changing bag and the charged tank then removed into daylight before the developing operations are commenced. Development being done it is necessary simply to draw off the developer by the tap, place the plates to wash for a minute or two, and then having turned off the tap to pour in the fixing solution. The rack is made open at each end, the plates being inserted in pairs back to back in the three grooves

available at each end. This allows of the rack being filled with plates without any chance of damage owing to their touching each other when the rack is being lowered.

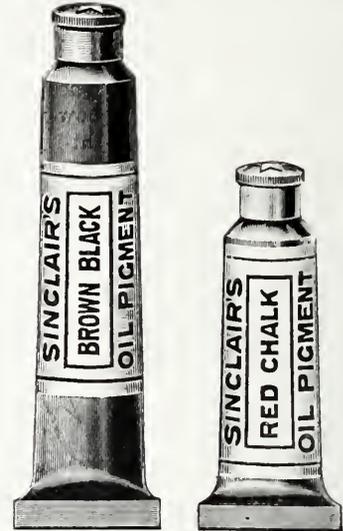

For use with the tank Messrs. Griffin supply a series of "Tanka" developers in packets, each containing sufficient (16 ozs.) to fill the tank and allowing of development being complete in twenty minutes. The packet of six developing powders is sold for one shilling, whilst there is also provided a series of "Tanka" fixing salts, each also to be dissolved in 16 ozs. of water, and serving, of course, for use over and over again. The box of six, making in all 96 ozs. of fixing solution, is sold at 1s. 6d.

The price of the tank itself in quarter-plate size is 7s. 6d., in 5 x 4 10s. 6d., in postcard (5½ x 3½) 10s. 6d., and for half-plate 12s. 6d., in each case serving for the development of six plates.

OIL AND BROMOIL REQUISITES.—Messrs. James A. Sinclair and Co., Ltd., 54, Haymarket, London, S.W., send us their new list of apparatus and materials for oil processes, which runs to eight pages, and lists the inks, brushes, paper, cleaning fluids, pigmenting trays, etc., supplied for the use of workers in the oil pigment processes. Messrs. Sinclair have been to the front with the highest class of articles for oil printing since the inception of the process, and their new list forms as useful a reference as can be had of the facilities which are at disposal. They also supply selected materials in the way of gums, printing frames, etc., for the gum-bichromate process.

The inks for oil printing supplied by Messrs. Sinclair, of the brand used by M. Demachy and other well-known French workers, in pots, have now been supplemented by a series of somewhat softer

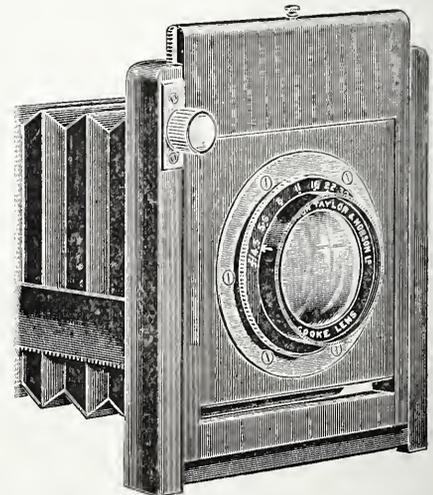

tube colours—that is to say, the inks in this form are ready for use and do not require any thinning as in the case of the pot inks. Many workers will esteem this convenience, although we quite agree with the vendors that in cases where a very great degree of depth and strength is required in the print the pot ink, on account

of its greater consistency, will be found somewhat preferable. The tube colours are supplied in ten different varieties, ranging from standard black to red-chalk, at a price of 1s. per tube.

Reference is made in another column to the competition for oil and bromoil prints organised by Messrs. Sinclair.

COOKE LENSES IN SUNK MOUNTS.—Messrs. Taylor, Taylor, and Hobson have just issued special series of the renowned Cooke lenses in sunk mounts of the form specially useful in reflex and other hand cameras. The focal lengths listed in this form are 5, 5½, 6, 8, and 10½ inches, whilst the series of lenses in which these are obtainable are the *f*/4.5 Series II., *f*/6.5 Series III., *f*/5.6 Series IV., and *f*/8 Series V. We have had an opportunity of examining a lens of the Series IV. of 6.2 inches focal length intended for a 5 x 4 camera and are bound to express our admiration of the beauty of the mechanical work—there is no need to repeat encomiums of the optical quality of the Cooke lenses. The lens in question projects into the camera about 1¼ inches from the back of the flange, the front and rear combinations being very quickly detached and refitted owing to the special form of thread adopted by Messrs. Taylor, Taylor, and

Hobson. A circular giving the prices of the lenses in this form of mount has just been published, and is obtainable from Messrs. Taylor, Taylor, and Hobson, Stoughton Street, Leicester.

CATALOGUES AND TRADE NOTICES

"FALLOWFIELD'S COURIER."—The August issue of this little publication deals with the most recent introductions in apparatus and materials which have appeared on the photographic market. The list of chemicals which Messrs. Fallowfield now supply at a reduced price to professionals and dealers should be of interest to those concerned.

LEGAL NOTICES.—Wm. Tiddy, photographer, 60, Tontine Street, Folkestone, has been adjudicated bankrupt. The receiving order was made on the debtor's petition.—On Saturday the first meeting of creditors will be held in the matter of Percy Hague Marsden, photographer, etc., High Street, Pateley Bridge, Yorks. The public examination of the debtor is fixed for Monday, at Northallerton.

NEW COMPANIES

COUNTY STUDIOS, LTD.—Capital, £200 in £1 shares. To take over the business of a photographer carried on by L. Mason. The first subscribers are:—L. Mason, 120, Clapham Road, Lowestoft; and A. H. Mitchell, 70, York Road, Great Yarmouth. Private company. The first directors are:—L. Mason and A. H. Mitchell. Registered office:—Nelson Chambers, London Road, Lowestoft.

GRAHAME, ELLERBY, AND COMPANY, LTD.—Capital, £2,000 in £1 shares. To acquire the business now carried on at 17, Farringdon Avenue, E.C., and to carry on the business of photographers, manufacturers of and dealers in cameras, lenses, etc. The first subscribers are: R. Grahame, The Grange, Keynsham, Bristol; and J. W. Ellerby, 17, Farringdon Avenue, E.C. Private company. The number of directors is not to be less than two nor more than seven; the first are R. Grahame and J. W. Ellerby. Registered office: 17, Farringdon Avenue, E.C.

News and Notes.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The seventh annual exhibition will be held from April 5 to 9, 1910, in the Montgomery Hall, Sheffield, when Mr. Arthur Marshall will judge the exhibits. Entry forms will be issued in due course, and these, together with full particulars, may be obtained from the hon. secs., Messrs. J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

LECTURES FOR PHOTOGRAPHIC SOCIETIES.—Mr. H. Essenhigh Corke, who last year blossomed out as a lecturer and proved eminently successful in his new rôle chiefly because he spoke at first hand of what he had worked out himself, advises us that he is able to allocate a few further dates to his lantern lecture on "Novel Portrait Effects by Day and Artificial Light." Though a professional photographer, Mr. Corke has quite the amateur spirit, and his lecture is a very free and frank account of methods which

are the outcome of his own ingenuity. He has also an illustrated lantern lecture in preparation on colour photography with the various screen-plates on the market. Secretaries of societies will be doing themselves a good turn by putting themselves in communication with Mr. Corke at the Studio, Sevenoaks.

AN OIL AND BROMOIL COMPETITION.—Prizes to the total value of £25 are being offered by Messrs. James A. Sinclair and Co., Ltd., 54, Haymarket, London, S.W., for oil and bromoil prints made with the Sinclair permanent pigments. Entries must be made on the coupon which accompanies each tube or pot of the Sinclair inks, and must be received before October 31 next. Prints should be mounted, but must not be framed, and should be marked with a *nom de plume* of the exhibitor, the name being entered upon the entry form. The prints will be judged by Messrs. E. T. Holding, Furley Lewis, and J. C. S. Mummery, and the prints obtaining the first three prizes of £10, £5, and £3 will become the property of the organisers of the competition, who further reserve to themselves the right of reproducing any picture to which an award is made, and also of exhibiting for a short time any picture thought suitable for that purpose.

CELLULOID MANUFACTURE.—In a recent issue of the "Chemist and Druggist" was indicated briefly the progress of the celluloid industry in Japan. A recently issued Kobe Consular Report states that the imports of celluloid in its various forms during the past four years have been as follows:—

	1905.	1906.	1907.	1908.
	Yen.	Yen.	Yen.	Yen.
Total imports	496,865	818,122	320,696	668,315
From Germany	446,542	636,597	265,912	530,513
From Great Britain	47,775	157,791	47,585	119,909

The general duty on celluloid is 25.60 yen per 60 kilos., and on celluloid goods the duty is 40 per cent. *ad val.*, the imports of the latter in 1907 being valued at 15,800 yen, and in 1908 at 32,600 yen. Of the raw material required to manufacture celluloid (cellulose, camphor, and sulphuric acid), the two latter are obtained in Japan and are very cheap. It is this fact, in combination with the growing demand in East Asia, which has suggested the establishment of celluloid factories to be worked with Japanese capital. The Japanese Celluloid and Artificial Silk Factory is the principal concern. It has a nominal capital of from one to two million yen, one-quarter of which has been paid up, and one-tenth of the capital is in German hands. The company will commence to manufacture celluloid, and later, as the business prospers, it will take up the manufacture of artificial silk and the chemicals necessary for the production of both articles. The technical manager (Dr. Green) is in England purchasing the necessary machinery for the manufacture of celluloid, while the machinery for the production of artificial silk will be bought in Germany. The factory will be erected at Aboshi, near Himeji, the workmen's quarters and the business premises being already completed. Two years is expected to elapse before the factory gets to work. Another concern, the Sakai Celluloid Company, is building a celluloid factory at the town of Sakai. This company has a capital of 2,000,000 yen, of which 1,125,000 yen is in the hands of the founders. The buildings are expected to be completed by the beginning of 1910. The company has an American manager, and the daily production is expected to amount to several thousand kin. Judging by figures published in regard to anticipated output, there is going to be a large over-production in Japan, for which an outlet will be sought in other parts of East Asia.

SEEING BY TELEGRAPH.—Writing in the August number of "Knowledge," Dr. Alfred Gradenwitz gives a short but interesting account of an instrument just invented by Mr. Ernest Ruhmer, of Berlin, which is the first actual solution of the problem known by the name of "tele-vision." Dr. Gradenwitz had an opportunity of inspecting the machine before it was sent to Brussels for demonstration before the promoters of the Universal Exhibition which is to be held there next year, and of which a complete tele-vision apparatus, costing the sum of £250,000, will be the principal feature. The demonstration apparatus has been produced at a cost of £250, and owing to its more elementary construction only lends itself to the reproduction of simple patterns, consisting of squares arranged in different combinations. A projection apparatus throws the pattern on a screen hung up on the wall. The screen is a

square divided into twenty-five square sections. "Behind each of these sections," writes Dr. Gradenwitz, "is arranged a highly sensitive selenium cell in which, by a novel process, inertia has been absolutely eliminated. It thus responds instantaneously to any variation in lighting it is exposed to. At the receiving station is arranged a similar screen, divided into the same number of sections, each of which communicates with the corresponding section on the transmitting screen. While the actual system used in transmission is kept secret, this much may be stated, that a highly sensitive mirror galvanometer reconverts the fluctuations of current produced by fluctuations in luminous intensity on the transmitting screen into corresponding light variations. To the right of the receiving screen is seen the accumulator battery, supplying the current to the tele-vision circuits. As soon as a perforated pattern is inserted into the projector, a telegraphic reproduction of the picture is seen to appear at the very moment it is thrown on the transmitting screen. The sluggishness of the cells has been compensated to such a degree that the telegraphic picture will respond practically instantaneously to any motion. In fact, a reproduction obtained at most in a few minutes with the photo-telegraphic apparatus so far constructed is here achieved in a fraction of a second, so that several phases of a motion can be reproduced within a second. It is hard to realise what sum of laborious work had to be expended in constructing even this relatively simple apparatus. In fact, each section, with its selenium cell and mirror galvanometer device, is an apparatus of precision in itself, while the definite apparatus will be composed of 10,000 elements of the same kind. Each selenium cell will have to be wound personally by the inventor, who never entrusts his work to anybody else."

DEFINITIONS OF SOLUBILITY.—In a recent paper read before an American pharmaceutical conference the suggestion is made that some indication of quantity should be attached to the terms "soluble," "very soluble," etc., commonly used in reference to chemicals. It is pointed out that for pharmaceutical purposes—and we may add, in photography also—the exact figures for solubility given in tables are usually unnecessary. The following scheme is put forward in their place:—

- Articles that are soluble in less than—
- 1 part of solvent=very soluble.
- From 1 to 10 parts of solvent=freely soluble.
- From 10 to 100 parts of solvent=soluble.
- From 100 to 1,000 parts of solvent=slightly soluble.
- From 1,000 to 10,000 parts of solvent=very slightly soluble.
- From 10,000 to 100,000 parts of solvent=nearly insoluble.
- More than + 100,000 parts of solvent=practically insoluble.
- The same definition might be stated in another form, thus: 100 ccs. of solvent will dissolve
- 100 Gm. or more of a "very soluble" substance.
- 10. to 100 Gm. of a "freely soluble" substance.
- 1 to 10 Gm. of a "soluble" substance.
- 0.1 to 1 Gm. of a "slightly soluble" substance.
- 0.01 to 0.10 Gm. of a "very slightly soluble" substance.
- 0.001 to 0.01 Gm. of a "nearly insoluble" substance.
- Less than 0.001 Gm. of a "practically insoluble" substance.

PHOTOGRAPHER BURNT OUT.—Considerable excitement was occasioned in Beer, Devon, during the early hours of Friday morning, August 20, by an outbreak of fire, which involved the total destruction of a large photographic studio (occupied by Mr. A. C. T. Wild) situated a few yards to the rear of the parish church. The fire was first noticed by a gentleman visitor, who was returning from Seaton in his motor-car between two and three o'clock in the morning. He immediately raised an alarm, and ere long the fire brigade and a large crowd of visitors and residents were on the spot. By this time the fire had got a strong hold on the wooden structure and also its contents, some of which were of an inflammable character, and it was seen that the whole was doomed to fall a prey to the flames. However, the brigade, assisted by a willing band of helpers, were able to prevent the fire spreading to the surrounding houses. Within an hour from the time that the alarm was made the structure was reduced to a heap of smouldering debris. The fire is supposed to have originated from some sparks or live soot from a chimney fire (which happened the previous evening about fifteen yards from

the studio), alighting on the building and smouldering for hours before the fire broke out. Mr. Wild's total loss is about £265, including valuable plant of seven cameras and lenses, and 31,000 negatives. There was absolutely nothing saved from the fire. The larger portion of the £265 becomes a dead loss, only a small part being covered by insurance. Mr. Wild had practically the whole of his money invested in the business, and now his means of living has been destroyed, he is endeavouring (with what help he can obtain) to make another start, and if any fellow photographers have any surplus stock or odd apparatus they could contribute to help Mr. Wild to get a living, he would be deeply grateful and pleased to pay the carriage.

THE CINEMATOGRAPH BILL.—Owing to the late hour at which the Cinematograph Bill was brought up in the House of Commons on August 25 very little mention appeared in the daily papers of the measure.

On Clause I. (provision against cinematograph exhibitions except in licensed premises) Mr. Walter Guinness moved the omission of the words "for the purpose of which inflammable films are used." He explained his object was to extend the restriction in the Bill, for it stood at present it would be perfectly possible for anyone who wished to give an unlicensed cinematograph exhibition to say the films were not inflammable. It would be impossible for the local authority to challenge this statement. The exhibitions are continually changing, and so are the films used, and the fact that they were not inflammable one week would by no means ensure that those used the next week were not extremely dangerous. The shows aimed at being topical, and in that way the changes were frequent.

Mr. Gladstone said he would accept the amendment.

Mr. E. H. Carlisle considered the scope of the Bill sufficient large as it stood. Without the amendment anyone using inflammable films, however much they might describe them as non-inflammable would be liable to a penalty of £20. The Bill was experimental character, and this should be borne in mind.

Mr. John Mooney desired to point out that if the amendment were carried the Bill would apply to any instrument used for the exhibition of pictures, such as a magic lantern or any instrument for throwing pictures on a screen.

On a point of order, the Chairman ruled that the Bill was sufficiently wide to cover its object, even if the words in question were taken out.

Mr. T. M. Healy said he thought the British Parliament was intended for some better purpose than passing fancy Bills of this character. The real truth was that the minds of members had been so absorbed with greater subjects that they had not had time to look into this proposal. It was only when there was a Liberal Government in power that these wretchedly small things were brought up in the House; they were promoted by some clerk who desired to get a C.B.-ship.

Mr. Gladstone, in reply, said that it was to be remembered that crowded audiences go to see these exhibitions, the number of which was increasing. He had had the strongest representations made to him by the local authorities, which showed plainly that there were demands for such legislation. Quite recently there had been very bad accidents through films flaring, which in some cases had entailed loss of life. There was an accident in Mexico, at which 300 lives were lost.

Mr. T. M. Healy: Does this Bill apply to Mexico?

Mr. Gladstone: No; but we want to prevent such accidents happening in this country. Continuing, he said that there would have to be regulations, but they would be very simple, and the whole object of them would be to stop danger where it exists.

Mr. Walter Guinness said the real danger did not come from the films. There was a case at Newmarket where three people were killed, not from the burning of films, but from the escape of compressed gas. The illuminants were of far greater danger than the films. The hon. Member went on to argue that the carrying of an amendment would not prevent magic lantern exhibitions at schools.

Mr. T. M. Healy said the title of the Bill was "To make better provision for securing safety at cinematograph and other exhibitions. That might include the dry shampoo case which happened the other day. If there was all this danger with regard to these exhibitions why did the Home Department not punish the owners as they were

seeking to punish the people who used something on a lady's head? Personally, he had no reason to oppose the Home Secretary, but he thought this Bill was the acme of absurdity.

Mr. Mooney desired to point out that the Member who moved the amendment said the danger arose from the illuminant used. The light of a magic lantern was produced under pressure, and there had been several cases of explosion. He contended that a magic lantern exhibition would be brought under the Bill if the amendment was carried.

Mr. Carlisle said anyone who knew anything about magic lanterns was aware that some of the best pictures were moving ones. The gases used for magic lanterns at village entertainments were the same as those used for the cinematograph. It had been admitted by Mr. Guinness, who represented the London County Council in this matter, that the danger did not attach to the films. The real danger arose from alarms of fire and the rush of the audience to the doors.

In the course of the debate which ensued, Mr. Gladstone said the object of the Government was to prevent dangerous exhibitions, and if the amendment did not widen the scope of the Bill it certainly would not widen the scope of the regulations.

In the result Mr. Gladstone suggested that if the London County Council desired the Bill to pass the amendment would, in face of the feeling of the Committee, be withdrawn.

The amendment was then by leave withdrawn.

Clause 8 ran as follows:—"The Secretary of State may by order extend the provisions of this Act to other exhibitions involving the use of any apparatus which may be declared by the order to be dangerous." Upon the motion of Mr. Gladstone the clause was struck out.

Clause 10 (Application to Ireland) was amended by limiting the expenses to be incurred under the Act by Town Councils to not more than 1d. in the £.

The whole of the other clauses were agreed to without debate and the Bill was reported.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

PERSULPHATE IN HOT WEATHER.

To the Editors.

Gentlemen,—A rather curious occurrence which happened during the recent hot weather in the writer's atelier may interest some of your readers and point a moral. A two-ounce bottle containing one ounce of ammonium persulphate burst with considerable force, the contents of the room being covered with a film of the salt, and all fragments of the bottle being scattered in all directions. The next bottle had its side smashed, and several others were dislodged, the shelf above being bruised by the impact of the stopper and broken. The persulphate may have been damp when placed in its bottle, the heat no doubt causing decomposition. Look to your bottles occasionally.—Yours truly,

SIDNEY L. YOUNG.

2, Hazelbank Road, Hither Green, S.E.,

August 25, 1909.

THE CHEMISTRY OF SULPHIDE TONING.

To the Editors.

Gentlemen,—Kindly permit me to correct a transposition which has been made in setting up the article on sulphide toning ("B.J.," August 27, 1909), and which might lead to misconception. Heading No. 5 in the summary of results affecting practice, p. 667, should read as follows:—"The presence of hypo in the bleaching solution is, of course, fatal. A considerable amount of hypo (the limiting amount depending on the percentage of sodium sulphide present) may be present in the sulphuretted bath," etc.—Yours truly,

DOUGLAS CARNEGIE.

Stonhaven, N.B.

August 31, 1909.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- Jakeman & Carver, The County Studio, Hereford. Photograph of the Right Rev. the Lord Bishop of Hereford and General Booth, the Bishop standing and the General sitting, with the Bishop's Chaplain, the Rev. H. Probyn, standing at back, and an Officer in attendance on the General. Taken in front of the Palace. Photograph of the Right Rev. the Lord Bishop of Hereford shaking hands with General Booth, who is seated in Motor Car. Taken in Palace Grounds.
- J. E. Reeves, 48 and 50, Hermit Road, Canning Town, E. Photograph of the West Ham United Football Team, Season 1909-1910.
- G. Keppie, 38, Howard Street, Millport, Cumbrae, Scotland. Photograph, Sand-Building, Kilehurn Castle, taken on August 19, at Millport.
- S. H. Greenway, 27, Abington Street, Northampton. Photograph of Northampton Town Football Club, Season 1909-1910.
- C. St. J. Vaughan, Victoria House, Muswell Hill Road, Muswell Hill, N. Photograph of Drawing from Life of Charles Dickens, signed by him. Two Photographs of Colours and Colour Party, 6th Battalion P.W. Own West Yorkshire Regiment.

CHROMIUM INTENSIFIER.—I noted with interest your remarks in last week's "B.J." re the use of the chromium intensifier for strengthening weak bromide prints. I looked up the formula in the "B.J. Almanac," in which a solution of hydrochloric acid sp. gr. 1.160 is to be used. How is that to be made? No one seems able to tell me.—BROMIDE PRINTER.

Any chemist can supply you with hydrochloric acid of this strength. It is a recognised commercial acid, but if you use the acid sold as "commercial pure concentrated" you will not be wrong.

SULPHOCYANIDE AND GOLD.—I have had an experience that puzzles me, and as I cannot explain it, I, as usual when in difficulty, apply to you for a solution of it. I started to make up a toning solution on the Kodak formula (p. 850 of this year's "Almanac"). I dissolved 150gr. of sulphocyanide of ammonium, but used 15oz. of water instead of 30, as I have not a 30-oz. bottle. When the sulphocyanide was dissolved I broke a 15-gr. tube of gold chloride into it, but the gold would not dissolve. It made a brick-red flocculent deposit, and in spite of agitating by pouring from one measure to another several times, it remains in that condition. What is the reason? I have since dissolved the two ingredients separately, the sulphocyanide in 10oz. and the tube of gold in 5oz. of water. They both dissolved easily, but on pouring the gold solution into the other a deposit was formed at once. Can it be that the sulphocyanide is impure?—J. E. G.

The error lies in adding the gold or the gold solution suddenly into the sulphocyanide. It is necessary to add slowly, i.e., with constant stirring. You will see a note to this effect on p. 800 of the "Almanac," and most text-books and articles on toning P.O.P. emphasise the point.

DIAMIDOPHENOL.—Can you give me in your next issue the formula for making the B.B. solution for using with G. Underberg's diamidophenol developer? I could not understand it from the article, and so had to send to my London dealer. It is the best paper developer of my experience.—THIRTY YEARS' SUBSCRIBER.

The B.B. solution is: Potass bromide 10 per cent. solution 2 oz., bisulphite liquor (commercial pure) 4oz.

SPOTS ON PRINTS.—Could you tell me the cause of the spots on prints I enclose? I fancy there are some loose chemicals (crystals) in the vicinity of the printing-room, but up to now have not discovered anything. It happens on all brands of paper, but feel assured it is not the paper to blame.—WORRIED.

The spots are clearly due to chemicals, but what, of course, we cannot say. They do not seem to be caused by crystals of anything, but rather by something splashed upon them. One shows decided

traces of some solution having been so splashed. There is certainly no fault with the paper. You will have to look to the manipulation for the cause of the trouble.

WEDDING GROUPS.—Will you kindly inform me in your "Answers to Correspondents" column whether it is absolutely necessary in a wedding group to have the bride on the left of bridegroom, and oblige.—**CONSTANT READER.**

So far as we are aware, there is no "absolute necessity" in the matter, if the parties concerned prefer a different arrangement. Usually the bride is posed on the left of the bridegroom.

LENS QUERY.—Will you kindly let me know whether I will have to have one or three lenses for whole-plate cabinets and C.D.V. full lengths in each, using studio 22ft. by 8ft. If three or one, kindly say what focal length is best to get.—**W. H. F.**

For convenience in working in so short a studio you will require three lenses if you wish to take full-length figures. One of 6in. focus will do for C.D.V. and smaller. One of about 10½in. will serve for cabinets; and one of about 13in. for whole-plate.

YELLOWED BROMIDES.—I enclose two bromide prints for your inspection. I should feel obliged if you can tell me the cause of yellowness. When mounted they appear white, but after a time go yellow. The time varies. Sometimes it is in a few days, other times it is weeks or months, but eventually they go yellow. The fixing bath is the hypo alum, glacial acetic acid, and sulphite of soda, as recommended in the "Almanac."—**FINE ART.**

We think the most likely cause is an exhausted overworked fixing bath. Why do you use a bath which remains clear during use? By doing so you forgo the advantage of gathering a hint as to the degree of deterioration in it. We think if you use a plain hypo bath of 4 oz. per pint and throw it away as soon as it becomes discoloured you will not have cause to complain of yellowed prints—that is, if you exercise care in freely exposing prints to the solution.

FLAME ARCS.—I should be glad of your knowledge and assistance in the following:—I have two large flame arc electric lamps, which I should like to install into lighting for studio use. These can be made to use the ordinary blue light carbons; they have been used to burning the red arc. Do you think they would answer the purpose for which I want them, and do you think that one would be sufficient to get quick photographs of, say, children, as I do not want to fix up two to burn unnecessary current, if one will do? I might say it is a small studio, about 20ft. by 13ft. I think I can make all other necessary reflectors myself and fitting for lamps. Would you advise using these without the white globe on and using a reflected light or a direct light? Any information you may tender will be greatly appreciated.—**ARC LIGHT.**

Certainly, you can use the lamp, and if it is a good flame-arc lamp it will consume less current than an enclosed arc of equal candle power, but we doubt if it will be actually more efficient photographically. No doubt one lamp will suffice for single heads, or three-quarter lengths, or full lengths of children. We should think a single diffusing screen, used in conjunction with a reflector on the far side of the sitter, will be better than working by the reflected light of the lamp.

J. W. AND CO.—We can only refer you to the list of exhibitions held in London and the provinces during the course of the year, which you will find (under "Exhibitions") in the Index to the annual volume of the "B.J." At most, there is a trade section in which goods may be exhibited at a moderate charge. We should not describe the use of the exhibitions, however, as "the most effective and rapid" method of bringing an article before the photographic public. We shall be much interested in seeing the article.

COLOURING LANTERN SLIDES.—I should take it as a favour if you would kindly inform me if there is to be obtained a plain and explicit, practical and not expensive, book showing how to colour slides for use in the lantern. If you would kindly say the price and where purchasable I should be greatly obliged.—**A. C. (Alexandria, Egypt).**

The best information we know is contained in the chapters on the subject in "The Book of the Lantern," by T. C. Hepworth, which, we believe, is no longer in print. You could probably easily obtain a copy through a small advertisement. We may add that, though oil and water-colouring are still used by trade workers, the tinting of slides by aniline dyes is largely done now by amateurs, and requires very little experience. Special dye solutions are

supplied for the purpose, and are obtainable from any large London photographic house at a price of 3s. to 4s.

K. R. EDDY (Sault Ste. Marie, Mich.).—About the best practical work is by Cecil M. Hepworth, mentioned in the "Almanac." It is published by Messrs. Hazell, Watson, Viney, and Co., Ltd., Long Acre, London, W.C., to whom we have passed on your letter.

RETLAW.—Presuming that the copyrights have been properly transferred to you—a list of the subjects made and embodied in the transfer—the prints may be offered, we should say at about 5s. each, to stereoscopic or other publishers. But if no such transfer has been carried the copyright has become void, and in that event we fear the prints will not command much of a price, as anyone will be at liberty to copy them. Much depends upon the exact use which a purchaser may have in mind.

C. ROWNEY.—You do not say from which formula your chemist has worked, but you will notice that his figures agree pretty closely with those given, in reply to a reader, on page 619 of our issue of August 6. We suggest your chemist follows this latter.

TINTOMETER.—(1) I note in the "Handbook of Photography in Colours" (Bolas, etc., published by Marion), page 238, note at foot, a tintometer is recommended as a standard to work the dyes to. Where can such be obtained? (2) Also suitable dyes for filters in small quantities (Penrose's list I have, but want smaller quotations).—**SYDNEY H. CARR.**

(1) The Tintometer, Ltd., Salisbury. (2) Try Fuerst Bros., 17, Philpot Lane, E.C.; or Mawson and Swan, Mosley Street, Newcastle-on-Tyne.

G. W. WEST AND SON.—Jonathan Fallowfield, 146, Charing Cross Road, London, W.

MARKS ON C.C. PRINTS.—I should be glad if you would tell me in the "Journal," as soon as possible, if you can suggest any cause for the spots and marks on C.C. prints enclosed. We have used — and occasionally other brands of C.C. paper for about six years, and have never had any difficulty excepting stains some times, but these are easily seen in the toning bath, and, by rubbing a little platinum on, are easily got rid of. The marks, however, that are worrying us at the present time cannot be seen at all in the toning bath, and, moreover, they are only on prints that have been single toned—that is, brown prints toned in gold bath only. We used to use a weak solution of salt before and after toning, but I thought perhaps that had caused the film to harden and so prevent thorough fixation, so we toned without salt; we have tried no salt, salt scalded, and used, without sediment, and entirely new toning gold bath, and everything we can think of, but we still have the spots or marks. Sometimes only a few in a batch are marked, at other times all prints are marked. I have sent prints to the — people, but they have not been able to trace them. We use — gold in solution and borax; the latter is not borax, which is well washed before being dissolved.—**COLLOID CHLORIDE.**

It is not uncommon to find these markings when gold only used for toning. We advise you to try the double-bath (gold and platinum) method. We could take many other suggestions, but you might turn with advantage to the articles on C.C. paper in the "B.J. Almanac," 1907, p. 786 to 789.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

A first impression of the Photographic Salon, which opens to-day at 5a, Pall Mall East, appears on page 699. Portraits of members of the selecting committee appear on page 700.

Mr. A. Lockett in an article on the "Dixio" or Pigeon stereoscope points out that by a very simple modification the apparatus may be used with the two stereoscopic prints lying flat on the table. (P. 701.)

Economy of labour in cleaning glass, a novel source of air supply or the "Aerograph," fallacies of newspaper process plants, with other topics, appear under "Photo-Mechanical Notes." (P. 707.)

A writer in "Camera Craft" gives the directions found advisable in transferring films from glass negatives to flexible supports. (P. 704.)

We draw attention in some editorial notes to the method of preparing chloride of gold from gold coins or scrap metal, mentioning that the process is likely to be economical only when very considerable quantities are thus converted. (P. 698.)

The Ozobrome Company has just issued a new booklet describing a simplified method of Bromoil and the procedure to be adopted in working the "ozobrome-oil" or transfer method of oil printing. (P. 706.)

Some comments on a recent editorial article on the quality of negatives appear under "Correspondence" on page 714.

A folding reflex camera and new formulæ for slow burning flash-powders appear under "Patent News." (P. 709.)

Professor Namias has drawn attention to the use of lactic and oxalic acids in gold-toning baths made up with thiocarbamide. (P. 703.)

A delicate method of registering the level of the camera in two directions has been described in a recent paper before the French Photographic Society. (P. 702.)

Formulæ for developing P.O.P., by which a variety of tones may be produced, are given on page 707.

A contributor to "The Photographic Monthly" has recently advised the use of a factorial method in reducing with persulphate. (P. 697.)

EX CATHEDRA.

Controlling Reduction by Time.

The Watkins system of controlling development by time with the aid of "factors" has been applied, as described in a paper in this issue, to the production of warm-toned lantern-slides, and the current "Photographic Monthly" records yet another suggested application of the same principle. If we use a fresh solution of ammonium persulphate, containing 12 grains of persulphate and 2 drops of sulphuric acid in every ounce, and allow it to act for four times as long as the period which elapses between the first application of the solution and the first appearance of the milkiness that is the characteristic sign of the beginning of reduction, then an average amount of reduction will be effected. This suggestion is made by Mr. R. B. Hughes, and it seems to be one of considerable value. It is pointed out that the negative should be soaked in water for fifteen minutes before reduction, and that the dish should be rocked continually throughout the reducing process. Of course, the operator is free to vary the factor if he pleases, but as it is suggested that two successive reductions conducted in this way are as much as any negative will stand, it would appear that the factor of 4 should be a generally useful one. The factorial method of control is now so generally known in its application to development, that the possibilities of its use in other photographic operations are of considerable interest. If it could be made use of in the process of gold toning it would be an advantage to many workers, and perhaps some one will yet work out a toning method with which it will be applicable.

* * *

American Lantern Slides.

A set of slides brought together by the American Lantern Slide Interchange, an organisation of many years' standing of which the hon. secretary is Mr. F. C. Beach, has just been received by "The British Journal of Photography" for circulation among photographic societies in the United Kingdom. The set includes 100 slides, which, both in respect of subject and technical quality, represent a very considerable variety. The set is received in exchange for one which is now circulating in America, and composed chiefly of slides contributed by members of the Liverpool A.P.A., the Manchester A.P.S., and several of the Yorkshire societies. These include examples of the work of well-known slide-makers, such as Messrs. James Shaw, S. L. Coulthurst, Godfrey Bingley, C. Thurstan Holland, and R. Williamson, in addition to which there are slides by exhibitors in other parts of the country, such as Messrs. Graystone Bird, S. G. Kimber, Fred Judge, Ellis Kelsey, and H. T. and R. A. Malby. Mr. Beach advises us of the safe receipt of these 117 slides in New York, and of the interest which he anticipates they will create in their

itinerary round American societies. Secretaries of societies who may wish to take advantage of the American set should address their inquiries to the Editors of "The British Journal of Photography," who will be in a position within the next few days to allocate dates. On this account a selection of dates which will be convenient to a given society should preferably be stated.

* * *

The Autumn Show.

A few days ago we were passing a suburban establishment, the showcases of which contained a selection of sound and interesting portraiture, plus a selection, quite as varied, of unsound blue-bottles! Our readers have, we hope, had a good summer season, and no doubt there is still a very considerable aftermath of work to be cleared off before the autumn and Christmas rush comes along. But we would strongly urge that the showcase receive the attention it not only deserves, but demands. Not only must those defunct flies, together with the dust of the summer, be removed, but faded prints or discoloured mounts need replacing, and the styles which are attractive in the summer become repellent in the chilly autumn days. Why not remove the lawn tennis groups and the prints of the summer girl in her dainty muslins, and replace them with prints in sepia or brown, and mounted on warm-toned mounts? One or two football groups will attract attention as the football season commences, and a few portraits of hockey players, sportsmen with guns, huntsmen, and pictures of sporting dogs, all have a topical interest, and serve to show that one is wide awake and prepared to accept commissions for work of all kinds. Of course, these suggestions are more particularly applicable to the business in provincial towns where specialisation in portraiture, and even in one kind of portraiture, is not possible, as it is in the metropolis.

* * *

Foggy Negatives.

Another autumn trouble which a little intelligent anticipation will ameliorate, if it does not entirely remove, is the hazy or fogged-looking negative. Assuming that this foggy appearance is due neither to under-exposure followed by forced development on the one hand, nor to over-exposure on the other, we may assume the cause to be haze in the studio, dust or moisture on the lens, or internal reflection in the lens or camera. Haze in the studio is difficult to get rid of, and perhaps the best way is to keep the apartment comfortably warm, and thus at the same time dry. In hazy weather it often becomes necessary to avoid, whenever possible, the use of long-focus lenses, so that the distance from lens to sitter is as short as may be, and the intervening atmosphere of less extent. The glasses of the lens may be carefully screwed apart, taking care to notice their position so that they may be correctly replaced. They should be cleaned with a piece of well washed and dried cambric or soft silk, moistened, perhaps, with a little alcohol. While the glasses are out of the mount the interior of the latter may be dusted, and if at all grey, a coat of dead black may be applied. This will rapidly dry, when the glasses can be replaced. The same black should be applied to the interior of the camera. A large hood of thin wood or stout cardboard, lined with black velvet and placed over the lens, is also excellent as a means of lessening the risk of getting veiled negatives.

* * *

Recording the Level of the Camera.

On another page we give a translation of a paper by M. Emile Wenz, in which a very ingenious method of recording the exact degree of tilt of the camera is described. As we understand it, the appliance is only intended for use in

a surveying camera, or photo-theodolite, in which the lens is fixed always at right-angles to the plate. For survey work very exact levelling is, of course, essential, but such a delicate appliance would be quite out of place in any other kind of camera. It will be seen on inspecting the diagram that, however much the camera is tilted, the tops of the four vertical columns of mercury must all be on the same level. The height of two of these columns is recorded on the plate by the shadows they cast, the other two columns being simply reservoirs of mercury that supply the extra quantity required by the two columns next the plate when the camera is tilted upwards, and taking up the overflow when the camera is tilted downwards. When the camera is absolutely level the columns of mercury touch a datum line that is marked permanently in some way not described by the inventor. If the camera is tilted upwards, the mercury rises above the datum, while a downwards tilt brings it below the datum. A sideways tilt, of course, brings the tops of the two columns to different positions above or below the datum, and by using a proper scale to measure the positions of the two columns in regard to the datum, it is easy to determine the exact degree of tilt in either direction by following the rules given by M. Wenz. The device is clearly sound in principle, and it strikes us as likely to be as reliable as any method that can well be devised. It is evident, however, that very exact adjustment of the datum is necessary in the first instance.

HOME-MADE CHLORIDE OF GOLD.

SEVERAL times of late we have replied to correspondents with reference to the making of chloride of gold for toning purposes. We are quite aware that some photographers prefer to make their own chloride, generally using gold coin for the purpose. Strictly speaking, it is illegal to destroy current coin of the realm, but it is frequently done by jewellers as well as by photographers, and we have never heard of anyone being proceeded against for this quite technical breach of the law. Whether it is worth the while of the photographer who is in a small way of business to make his own chloride of gold may be a question, seeing that at the present time it is to be had from reputable houses with the guarantee that each fifteen-grain tube contains seven and a half grains of metallic gold, the intrinsic value of which is, to be precise, 15 15-16 pence. It must be kept in mind that in making the chloride some little waste must be entailed in the operations, however careful the maker may be, unless he be an expert in chemical manipulations. This waste, in the hands of a novice, is practically as much in making a small quantity as a large one; therefore, while it may pay the large user to make it himself, to do so may mean a loss to the small consumer, unless he is an exceptionally neat worker.

Since the standard of gold coins in this country is an alloy of eleven parts of pure gold with one part of copper, in order to obtain a pure chloride of gold the base metal has to be got rid of. Some say that this is not necessary, as it does not materially interfere with the toning; but in any case, if the chloride be made from coins it is best to use Australian ones, as they are usually alloyed with silver, and that will be separated as an insoluble chloride when the coin is dissolved, and may then be simply filtered out.

Without going further into the question as to whether it is, or is not, worth the while of a photographer in a small way of business to make his own chloride, there is no question that it is—in some circumstances. For example, if he has some worn-out trinkets—watch-chains or the like—it will pay him better to convert them into

chloride of gold for use than to sell them to those who purchase old gold and silver, such as pawnbrokers and the like. They, as a rule, give but a small sum for it in comparison with the content of the gold. We here propose to explain the way by which the gold in such articles can be converted into chloride which is in every way as good as that to be purchased.

In the first place, the trinkets should be broken up, and such parts of base metal as can be separated thrown away. It may as well be said that some disappointment may at times be felt at the small amount of chloride obtained in the end; but this will be due to the poorness of the gold often used in jewellery. Some is not more than eight carats fine, some twelve. The first-mentioned only contains one-third pure gold to three parts of alloy. The twelve carat is half and half. Eighteen carat gold is three-quarters gold and one-quarter alloy. Thus it will be seen that the quantity of chloride that is obtainable from such trinkets depends entirely upon the actual amount of pure gold in them.

The broken-up metal is put into a Florence flask, which, with the arrangement for heating it, should be out of doors, or where all fumes will pass off into the outer air. The following mixture is then made in a stoppered bottle:—

Nitric acid (pure)	2 oz.
Hydrochloric acid (pure)	5 oz.
Distilled water	6 oz.

Some of this, according to the weight of metal to be dealt with, is poured into the flask. Not much should be added at first, as sometimes, when there is much base metal present, a violent effervescence takes place. After digesting for a time, the flask may be gently heated over a spirit lamp to assist the solution. When the acids cease to act, if the metal is not all dissolved, a little more should be added, and so on by degrees until the metal is wholly dissolved. Any great excess of acid should be avoided. The solution will be blue or green, according to the alloy, which must now be got rid of. This is done as follows:—The solution is filtered into a clean bottle of good size. Some distilled water is then passed through the filter into the bottle, to free it from gold, and thus avoid waste. We now make and filter a solution of pure sulphate of iron. When filtered, it is a good plan to add to it a few drops of sulphuric acid. A little at a time of this acid solution is then added to the impure gold solution until no further

precipitate is thrown down. This precipitate is pure gold in a fine state of division, and settles down quickly on account of its weight. The supernatant liquid is then carefully decanted without disturbing the gold, the bottle filled up with water, and well shaken. When the precipitated gold has again settled down, the water is poured closely off. It is well, at this stage, to add a little hydrochloric acid, to remove any traces of the iron or copper which may remain. The precipitate is then washed in several changes of water, the last being distilled water, to get rid of all traces of the acid.

The gold is now put back in the flask and a little of the mixed acids poured in to dissolve the gold. In this operation no more acid should be used than is absolutely necessary to get the metal into solution, because it must be kept in mind that any excess has to be driven off in the crystallisation of the chloride. The solution is then put into a Berlin evaporating dish, on a sand bath, and crystallised. Too much heat in this process should be avoided. When the crystals seem dry, they should be dissolved in pure distilled water, and re-crystallised, so as to free the chloride as much as possible from acid. As the chloride of gold is a very deliquescent salt, it is well to put it into *small* bottles, well corked, or seal it up in glass tubes as it is met with in commerce; or it may be dissolved at once in distilled water and kept in solution.

An alternative way of dealing with the precipitated gold that will appeal to many photographers, inasmuch as it avoids the trouble of crystallising, is as follows:—After the precipitate has been thoroughly washed, it is dried and carefully weighed. It is then put into the flask and dissolved as before, taking the precaution that no more acid is used than is absolutely required. The solution is then diluted with distilled water in quantity according to the weight of gold—say, making the bulk up equal to one grain of the pure gold to each two drams of solution. This will give us a solution equal to one grain of the chloride to one dram of water. Bicarbonate of soda is then added, a little at a time, as it will produce violent effervescence, until the free acid is just neutralised. Lastly, a drop or two of hydrochloric acid is added. This may now be kept as a stock solution of chloride of gold of the strength of one grain to the dram of water. The addition of the hydrochloric acid is to prevent the spontaneous precipitation of the gold, which might take place if the solution were neutral, or slightly alkaline.

AN IMPRESSION OF THE SALON.

Having been brought by sundry rumours and "editorials" to a pitch of panting expectancy, we entered the R. W. S. gallery in an impressionable and highly receptive state of mind, prepared for—anything. Our first glance showed us a neat and orderly exhibition free from the intermural structures and the gauzy arrangements of earlier years. Already one felt that there was air and light and that the Linked Ring had, as it were, dusted and shaken themselves into a free and wholesome condition. Surprise culminated when we read the forewords of the catalogue, and we reflected, with some amusement, that it has taken this society some years to endorse such a sentiment as "All work which lives is without eccentricity."

This society is to be congratulated upon its recovery from a state of nearness to death caused by the malady eccentricity. We hope and believe that it is now going to be good and careful of its health, having sown its wild oats.

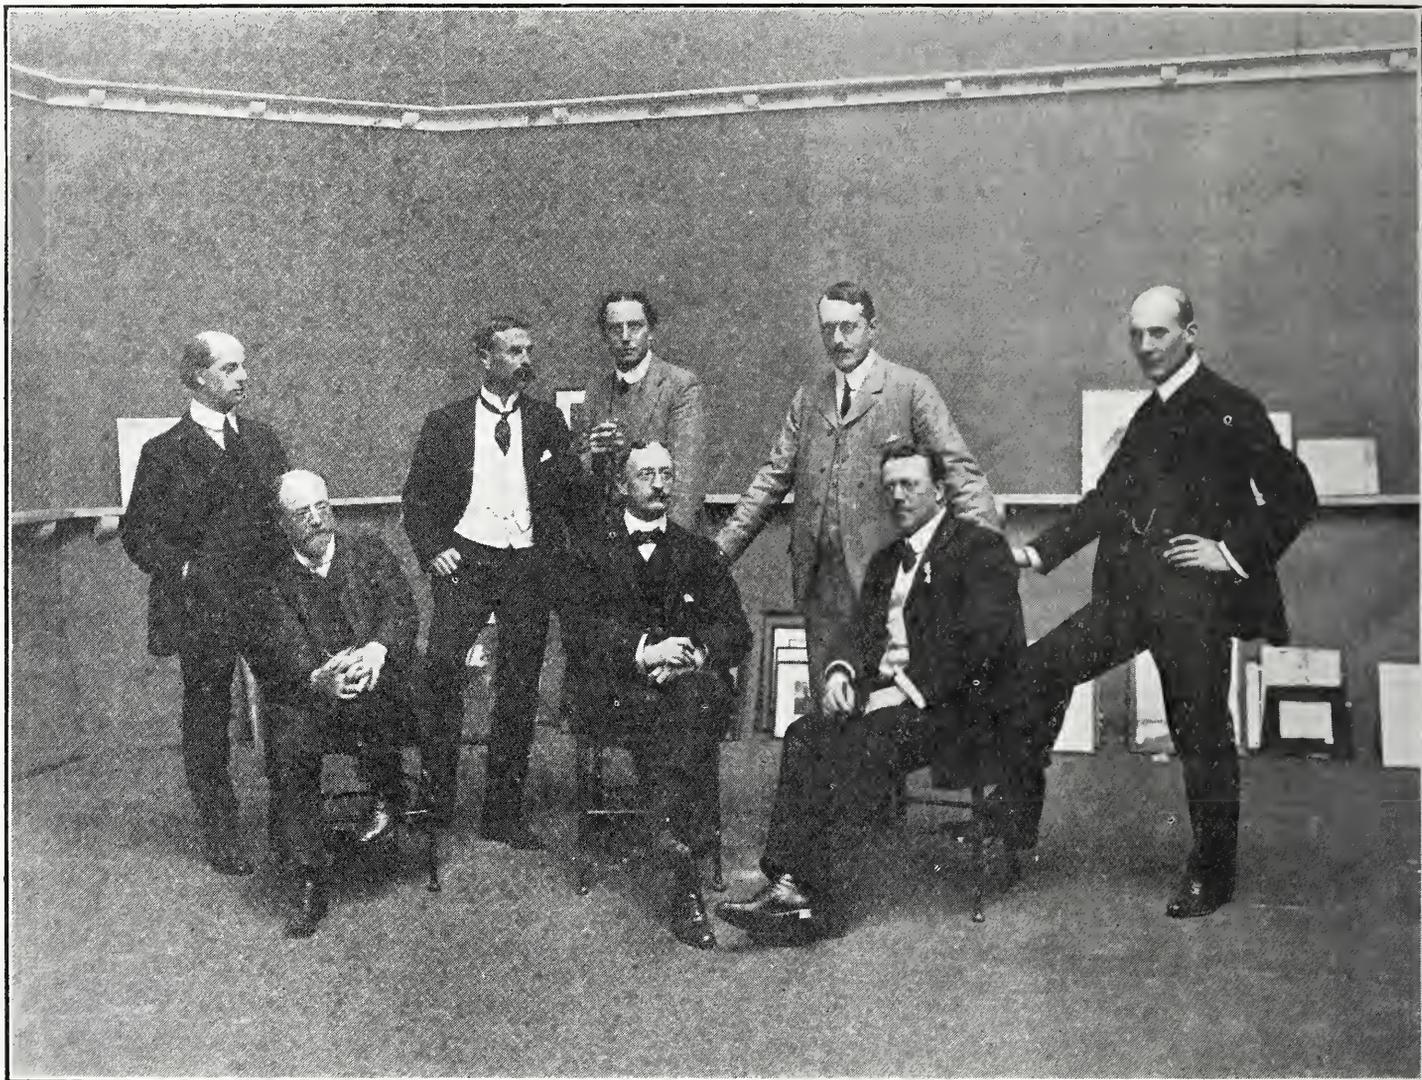

Let it not be thought that its present show is in any way lacking in go and verve because it is sane. On the contrary, it is full of good things, though perhaps not so overwhelmingly fine as people have told us it would be.

It is very fairly representative, containing the works of forty-six exhibitors, only one of whom shows as many as a dozen pictures. Many have but one work, and that a good one, which, to our minds, is much better for everybody than the display of several of differing merit by one man. M. Demachy's oil print, St. Pol de Léon, is certainly one of the finest of his prints we have seen; and something similar may be said of Mr. Furley Lewis's single portrait of Pirie MacDonald, Esq. Mr. Arbuthnot shows one or two things that are astounding, particularly the childish portrait of A. J. V. Chodyko, Esq., but he has others that fortunately save his reputation. J. Dudley Johnstone scores, and so does

J. Craig Annan with a fine series of portraits and a highly romantic "Ruined Castle." From F. J. Mortimer we have some excellent oil prints, the best being, perhaps, "Lambeth Bridge" and "The Mill on the Dyke." Of E. O. Hoppé's portraits, which are certainly above his average work, we must demur to his inharmonious mounts. Frederick H.

Porterfield's "Italian Woodland" is also promising of good things to come.

Altogether the exhibition is sterling in merit; but without transatlantic excitements. We only hope that the charm of lawlessness which fascinates so many will not be missed by the public to their displeasure. It is something to say that

Photograph by

THE SELECTING COMMITTEE OF THE PHOTOGRAPHIC SALON.

Hana Studios, Limited.

Reading from left to right the names are as follows: Walter Benington, Frederick H. Evans, George Davison, Malcolm Arbuthnot, Reginald Craigie (seated), J. Dudley Johnstone, F. J. Mortimer, J. Craig Annan.

Evans gives us a strong selection of landscape, architecture, and portraiture, the best being his "Hubert Bland" and "Night on the Hills." David Blount has but one print, but that a strong piece of work. We welcome the work of Harry Wild, who evidently understands the art of selection of subject, and we hope great things of him in the romantic vein. W. H.

this is a British show, and although we should be the last to deny that the work of other nations should not find a welcome exposition here, we feel that something has been achieved in the formation of a show of pictures of which it can be said that it represents a show of English work in England—not a show which relies upon importations for its attractiveness.

DEMONSTRATIONS OF "ENSYNA."—Messrs. Houghtons Ltd. announce that they are prepared to give demonstrations of "Ensyna" before photographic societies during the coming winter session. Secretaries who have not completed their programmes should write to Messrs. Houghtons Ltd., 88 and 89, High Holborn, W.C., and mention what dates they have vacant.

AT THE WOMEN'S EXHIBITION, now open at Olympia, photography is less prominently represented than one would suppose from all that is written on the prospects open to ladies engaging in this occupation. As we have often said, the qualification for success is the somewhat rare combination of business ability and natural aptitude for studio work, and therefore girls advised to "take up

photography" are seriously counselled to consider the probability of their being able to command more than a decent wage as receptionist-retouchers. At Olympia a very attractive display of work is made by Miss Lena Connell from her study in Grove End Road, St. John's Wood, N.W. A collection of about 50 prints is very daintily shown on a stall which looks all the better for having been cut in half. In such little details as the booklet offered to visitors, and the "Remarks by a Client" contained in it, Miss Connell shows a nice regard for the proprieties of a photographic business, whilst her work, largely of men, and including not a few celebrities, grows in strength and character. A selection of portraiture is also shown by Miss Kate Pragnell, of Brompton Square, S.W.

A NEGLECTED MODIFICATION OF THE "DIXIO" STEREOSCOPE.

In view of the signs of renewed interest in stereoscopy, it is somewhat remarkable that the old-fashioned lenticular stereoscope still holds the field, although the single-mirror arrangement devised by Professor Léon Pigeon, of Dijon, and known as the "Dixio" stereoscope, is simpler in construction, and, moreover, permits the examination of pictures of any size.

This is, no doubt, partly owing to the fact that its advantages are not sufficiently well known on our side of the Channel. Of a dozen persons interested in stereoscopy recently spoken to, only one had the "Dixio" stereoscope in use. Six of the others

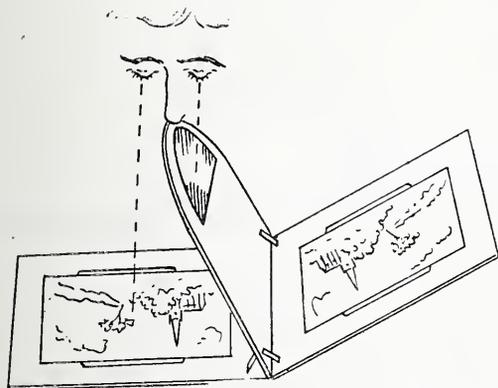

Fig. 1.

had never heard of it, while the remaining five seemed to consider it a disadvantage that the pictures had to be examined at a definite angle, and that one of them had to be reversed, thus involving special preparations in taking the negatives, or else a troublesome stripping operation.

These trifling objections cannot fairly be considered as drawbacks sufficient to weigh in the scale against the numerous advantages of the "Dixio" system, if only we first disabuse our minds of a prejudiced allegiance to the old conditions governing the production of stereoscopic "slides," of a circumscribed size and shape. The ease with which the "Dixio" system lends itself to magazine and book illustrations of any size, and allows the pictures to be viewed *in situ* without removal from the book, is an immense gain, worth sacrificing something for.

The mirror stereoscope would, in all probability, be much more appreciated if the method of use were simplified. The assumed necessity for the pictures being held at a given angle is a point that does not appeal to the easy-going public, who would prefer a means by which the prints can be viewed in some ordinary position, without any special adjustment. Also, as far as books and magazines are concerned, a loose mirror, which could be held to any page as required, would please the popular fancy more than one permanently fixed in a portfolio or holder, into which the pictures have to be inserted.

Fortunately, as will be shown, it is *not* necessary that the two pictures to be viewed by the "Dixio" method should be inclined to each other at a given angle. The stereographs may be inspected with every satisfaction and comfort when both halves are on the same level; as is the case if they are mounted side by side on a card, printed on a single page of a book, or even with the two pictures on opposite leaves, providing these are kept flat. The mirror, of course, instead of being inclined, has in this case to be held in a perpendicular position between the two pictures. It is rather surprising that the possibility of doing this has attracted so little attention. Professor Pigeon himself, in his able and comprehensive "Etude sur la Stéréo-

scopie," mentions such an arrangement in definite terms, as "intéressante par sa simplicité," but appears to consider it only suitable for small prints, and passes it briefly by. Presumably he tried the experiment with the usual small mirror set in the upper portion of a dividing panel, as supplied with the ordinary pattern of "Dixio" stereoscope, and also had the two pictures rather close together. With such a mirror, when perpendicular, only small prints can be inspected, although this difficulty is overcome to some extent by increasing the separation between the prints. If, however, the perpendicular mirror is prolonged to the bottom of the panel, quite large pictures can be viewed; while there is no reasonable limit to the size that can be inspected if the mirror is held in the same position but further away from the pictures.

To explain more clearly the method suggested above, reference may be made to the accompanying illustrations. Fig. 1 shows the ordinary type of "Dixio" stereoscope, in which the two prints are inserted in guides in a portfolio, the sides of which are adjusted to an angle of 140 deg. One half of the stereograph is seen with one eye, by reflection in the small mirror attached to the bisecting panel, while the second half is viewed direct by the other eye. Since the reflected image seems to occupy the same place as that inspected direct, the two views coalesce, and stereoscopic relief accordingly results.

Fig. 2 shows the more convenient, and what would doubtless prove the more popular plan, of having both views level and placing the mirror perpendicular to them. The principle of the upright mirror is easily understood from what has been previously said. It must be admitted that, for sundry reasons, this arrangement is not so ideal in theory as the inclined mirror; but from the purely utilitarian and practical point of view it is much to be preferred.

If a loose mirror, surface-silvered and of good quality, could be obtained at a moderate price, and if the editors of pictorial magazines and publishers generally could be impressed with the ease and cheapness with which stereoscopic illustrations could be produced, there should surely be a pronounced revival

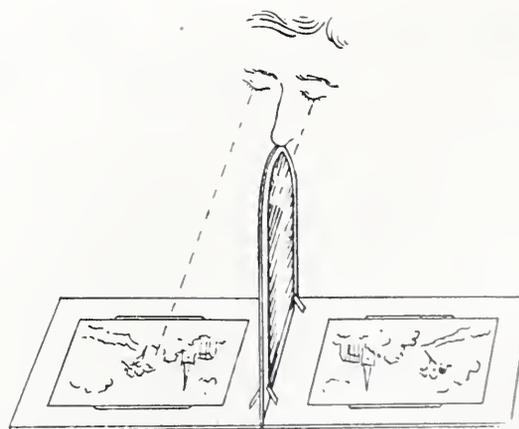

Fig. 2.

of public enthusiasm for what is undeniably a most instructive, entertaining, and useful branch of photographic work.

Fig. 3 may be of interest, as showing how readily a pair of mutually reversed stereographs may be obtained without any special preparations whatever. The two pictures represent the result of a successful accident. A couple of exposures were made with an ordinary quarter-plate magazine hand camera, moving it $2\frac{3}{4}$ in. sideways between the two exposures. On

coming to develop the plates, it was found that one of them had carelessly been inserted in the sheath glass side to the lens. However, probably owing to the fact that the lens was of short focus and that a fairly small stop was used, there was

seem to offer a hopeful means of making reversed stereograms for those who only need an occasional exposure; while for those who view the thickness of a glass plate with a suspicion more scientific than practical, the use of thin flat films offers a simple

Fig. 3.

no appreciable unsharpness. The two prints give excellent stereoscopic relief, as may be tested by holding a mirror in a perpendicular position to the page, centrally between the pictures, and viewing them as before explained. This would

alternative. It may be stated, in conclusion, that there is no need to mount the prints so close together as in the example given; it is sometimes advantageous to place them further apart. A. LOCKETT.

A METHOD OF REGISTERING THE LEVEL OF THE CAMERA IN TWO DIRECTIONS.

A Paper read before the Société Française de Photographie.

[The following article by M. Emile Wenz describes an interesting method of recording on the plate itself during exposure the exact level of the camera, its degree of tilt either forwards or sideways being recorded simultaneously.—Eds. "B.J."]

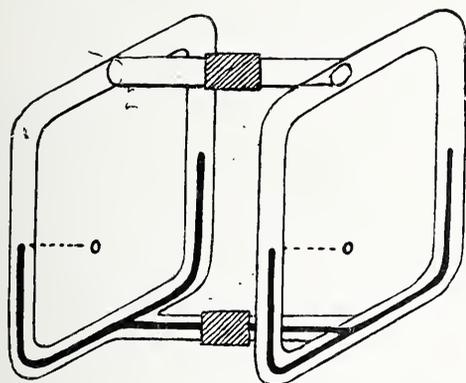

THE first plan which was adopted to record the sideways inclination of a photographic plate was by means of a tube of glass half filled with an opaque liquid and throwing a shadow around the edges of the sensitive plate, forming, as it were, a frame. About 1895 M. Batut had experimented with this method, using alcohol in the tube. This liquid he found unsuitable for the purpose owing to its lack of stability. M. Jardinet devised a similar kind of level, but he employed mercury in the tube, which latter he filled with a gas having no oxydising effect on the mercury. He employed a flat tube on account of the easier passage of the light compared with one of round section. If it is desired to record also the inclination of the optical axis a similar level must be included, but one placed perpendicularly to the plate, and having only one side touching the sensitive surface.

It occurred to the present writer that it would be possible to register by means of two tubes only the inclination of the

camera in two directions. For this purpose a plate of 13 by 18 cm. was provided with two tubes, each forming a rectangular space measuring 14 by 17.5 cm. To the centre of each of the long sides of each tube a small perpendicular branch was affixed, of the same diameter, and about 85 mm. ($3\frac{1}{4}$ in. long), and open at the end. The two open ends were joined by means of a short piece of rubber tube, the whole apparatus having been previously half filled with mercury. This forms a system of communicating vessels, the mercury occupying the lower part and the air the upper part. The apparatus is fixed in the camera so that the short side of each element of the tubes comes against the coated side of the plate. The camera having been levelled in all directions the levels of the mercury in the tube are recorded once and for all, the two data fixing the zero points 0 in the diagram.

We have now to consider the conclusion to be drawn from the

positions of the shadows of the two meniscus surfaces recorded on the plate, in reference to the zero point O, which, as already indicated, represents the position of the meniscus surfaces when the camera is absolutely level in both directions. By means of a scale specially constructed for each apparatus, an observation is made of the degrees of inclination on the right and left,

with also their directions, which are reckoned as *plus* above the zero point and as *minus* below the zero.

The half of the sum of these two figures will give the angle of inclination of the optical axis: the half of the difference of these two figures will give the side tilt of the camera.

We may assume that the movement of the liquid in the two levels is independent, and we may distinguish the readings as follows:—

A indicates side tilt of camera only.

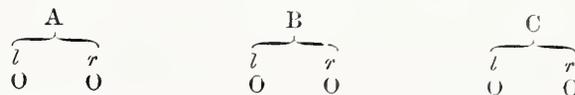

B indicates inclination of the lens axis only.

C indicates the effect of the double tilt.

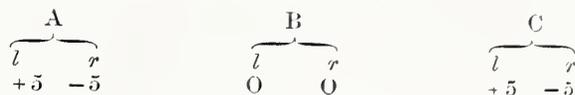

The letter *r* indicates right-hand and *l* left-hand.

We then have

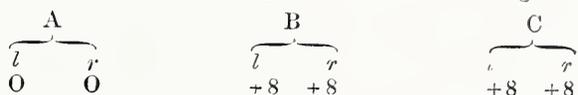

Case I. Camera horizontal in all directions.

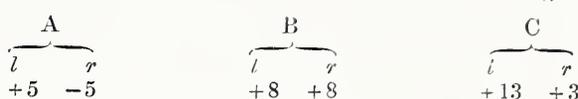

Case 2. Side tilt of camera 5deg. Optic axis horizontal.

Case 3. Side tilt 0 deg. Optic axis inclined 8 deg.

Case 4. Side tilt 5deg., and optic axis inclined 8deg.

Reading on C. + 13 to the left and + 3 to the right, we obtain as half difference of these two figures 5, giving us a side tilt of 5deg.

Half the sum (= 8) similarly gives us 8deg. as the inclination of the optic axis to the horizontal.

It should be added in conclusion that in order that the reading with the scale shall be accurate, it is important that the four vertical tubes should be at a uniform distance from each other.

EMILE WENZ.

NOTES ON THE USE OF THIOCARBAMIDE GOLD-TONING BATHS.

[The text of a paper contributed by Professor R. Namias to the Congress of Applied Chemistry, recently held in London, is given in the current issue of "Photographische Chronik." From the following translation it is seen that Professor Namias favours lactic acid as the most advantageous substance for use in conjunction with thiocarbamide in a gold-toning bath. He also insists on the necessity of a proportion of salt being used in such a bath on account of the considerable quantities of organic salts of silver present in printing-out papers.—Eds. "B.J."]

GOLD-TONING baths made up with thiocarbamide were the subject of my experiments as far back as the year 1893, and have during the last few years been further studied by many photographic workers, although they have not come very much into practice. It may, therefore, be well to direct some further attention to the properties and advantages of these toning baths, giving the results of some of the recent observations which have been made in regard to them. It should first be noted that the two most common substances of the carbamide class, namely, thiocarbamide and allyl-thiocarbamide (commonly known as thiosinamine) behave similarly as regards their action in the toning bath, and it is therefore a matter of indifference which is used for the purpose. In any case the quantity present must be very small. If the proportion is not sufficiently reduced the substance exerts a solvent action upon the silver salts, in many cases quite altering the character of the bath and preventing the production of the best tones.

The presence of acid, even if it is not necessary, is at any rate advantageous, as it gives a greater degree of permanency to the bath. In order to ascertain whether the various organic acids differ in this respect I have employed not only the citric and tartaric acids usually adopted, but have made experiments with the addition of lactic and oxalic acids. The difference between these two latter is very slight. If the bath is used

immediately after making up it will be noticed that the lactic acid exerts a more favourable action on the toning properties.

It is interesting to note that oxalic acid, which ordinarily functions as a reducing agent of gold chloride solutions somewhat rapidly, does not exert this property if a minute quantity of thiocarbamide is present. If more than the requisite quantity of acid is added to the bath the toning process is more or less retarded, although the final tone obtained is the same. There is practically no appreciable difference between prints treated in baths made up with the different acids.

The addition of sodium chloride (common salt) is indispensable, but it is not to be assumed that it is more necessary in the case of baths made up with thiocarbamide than with those prepared with sodium acetate and sodium phosphate, as also with borax. This fact has been emphasised by myself since 1905, and is one which must not be overlooked. The print-out papers at the present time contain less silver chloride but much more organic salt of silver, particularly silver citrate, tartrate and oxalate. Therefore, if there is not a sufficient quantity of sodium chloride in the toning bath the organic salts of silver undergo decomposition at the expense of the gold chloride, and the excessive decomposition of the gold in the bath is not in any ratio to the brown compound of which the image consists. There, therefore, results a greater or less loss of gold whilst

the toning process takes place very irregularly, and in many instances gives rise to markings.

The most notable advantage of the toning baths containing thiocarbamide is very great stability, that is to say, they keep well. Whilst it is well known that baths made up with acetate, phosphate, or borate of soda are liable to deposit the gold gradually within the space of a few hours, the thiocarbamide bath, on the other hand, will keep in good working conditions for weeks at a time. A bath made according to the formula given below has been kept in stock for over six weeks without depositing the slightest trace of metallic gold.

The great permanency of the baths is of particular advantage inasmuch as there is no waste of gold and the regularity of the toning action may be depended upon. Whilst gold toning baths prepared with alkaline salts must stand for at least half an hour before being used, that is until the complete conversion of the gold from the auric into the aurous state, in the case of thiocarbamide the bath is ready for use as soon as made.

It has been recommended to add a very small quantity (about $\frac{1}{4}$ -gm. per 1,000 ccs.) of sodium sulphite to the bath, which

addition ensures the instantaneous conversion of the auric salt of gold, but, however, it is found that even if the quantity of sulphite remaining in excess be extremely small the bath works very badly, so that users of the method are strongly advised not to make use of the sulphite.

The following is the formula of a bath which works excellently:—

Sodium chloride (common salt)	10 gms.
Lactic acid (sp. gr. 1.2)5 gm.
Gold chloride (10 per cent. solution)	25 ccs.
Thiocarbamide solution	2 per cent., sufficient to redissolve the precipitate formed by the first addition.

Finally, it may be noted that the sulphocyanide baths, so largely used at the present time, may also be employed with the addition of lactic acid. If this be added to an ordinary sulphocyanide bath in the proportion of $\frac{1}{2}$ gm. per 1,000 ccs., toning takes place with great uniformity, and the keeping properties of the bath are greatly improved.

R. NAMIAS.

STRIPPING AND PRESERVING FILMS.

[In the following article, from the current issue of "Camera Craft," the writer gives very explicit directions for several alternative methods of stripping the film from glass negatives. Although he does not appear to be acquainted with the non-distortion method of stripping with hydrofluoric acid worked out by Middleton and Holcroft, and given among the standard formulæ in the "B.J. Almanac," the various procedures recommended are evidently of great practical value. Still, it is doubtful if any will compare in speed and certainty with the Middleton-Holcroft method, in the practice of which there is no occasion for the fingers to come at all in contact with the hydrofluoric acid solution.—Eds. "B.J."]

EVERY photographer, amateur or professional, has very early in his photographic experience come face to face with the problem of removing the gelatine film from glass negatives. Perhaps my own experience is that of nearly all others, when wishing to use the glass from a worthless negative for other purposes, I found that the gelatine film, wet, slimy, and tacky, baffled all of my early attempts to effectually remove it, and when dry it appeared to present a still more hopeless problem. Then later on I spent a number of years in the teaching profession, which necessitated repeated transportation of my negatives, and it was seldom, even after the most careful packing, that I unpacked the negatives without finding a few broken or at least cracked. Then came the problem of saving the cracked negatives and the more important problem of preventing such accidents in the future. This article is written in the hope that it will reach others who have been perplexed by the same problems, and in the further hope that it will offer the solution of those problems for them.

A number of formulæ for stripping negatives have been published in various photographic books and magazines, but most of these omit the most important step in the process, and the individual who is so unfortunate or foolish as to try his best negatives on the first experiments soon comes to grief. By far the best process which I have seen published is one which appeared in "Camera Craft" several years ago. The process is simple and easy, and with reasonable care is sure to give good results. But, like all other processes, it is susceptible of improvement. Keeping in mind the fact that simplicity and certainty of result are both of primary importance, my own efforts have been directed to the search for methods which have greater latitude than any heretofore published. One worker may wish simply to clean the glass, while with another the glass has no value, but the film with its silver image is important. Owing to the variety of uses to which the stripped film is put, a number

of stripping processes will be given and their applications will be discussed later.

First method: Use either formula given below:—

Potassium carbonate (saturated solution)...	2 parts
Formaldehyde	1 part
Glycerine	1 part
Water	40 parts

Or:

Sodium carbonate (saturated solution)	1 part
Formaldehyde	4 parts
Water	40 parts

In my own work I prefer the first, but either of these formulæ may be used. The carbonates of potassium and sodium in solution may be used alone, but the addition of the glycerine or formaldehyde, or both, makes the formulæ more reliable in their action. While the formulæ admit of wide variation in the proportion of the constituents, it is advisable in the first attempts to adhere strictly to the proportions given. In any case, the solution should be allowed to settle, and the clear liquid should be poured off. The dry negatives are placed in the clear solution for about thirty minutes and then drained and placed on the drying rack. The drying takes several hours. The length of time of immersion of the negatives in the solution, while averaging thirty minutes, really varies a trifle with the make of plates and the density of the image in the negative. Insufficient immersion fails to loosen the film, while too long immersion makes the film brittle and liable to crack. A little experience will enable the operator to judge the degree of hardening of the film by means of the finger nail. After the negative has been dried, a sharp knife is used to cut the film as near as possible to the edge of the plate on at least two adjacent edges. The corner is then gently lifted and the film is withdrawn. If it sticks in spots, a silk thread should be inserted.

Second method: A weak solution, about five per cent. of

hydrofluoric acid, will remove the film from a negative. Identically the same result may be secured by first immersing the wet negative for about fifteen to twenty minutes in :—

Sodium fluoride 2 parts (weight)
Water 98 parts

and then, without rinsing, immersing it in :—

Sulphuric acid (concentrated) 2 parts
Water 98 parts

Hydrofluoric acid is generated and quickly lifts the film.

Third method: The negatives should first be soaked for from fifteen to twenty minutes in either of the solutions given in the first method, then superficially washed, and finally, without drying, it should be treated by the second method.

The effects of these methods are strikingly different. In the first method we get the film off in a dry condition, while in the second and third it comes off wet. In the second method, the film expands and results in considerable enlargement. The first and third methods do not affect the size of the film. In the third method, the film comes off with chemicals which are more easily removed by washing than the first.

Mention should be made of some of the reagents employed. Formaldehyde and the carbonates of potassium and sodium produce an effect on gelatine similar to tanning. Either of these two carbonates also acts slightly on glass, thereby reducing the adhesion between the glass and the gelatine. Hydrofluoric acid readily dissolves glass, and this action of a dilute solution, while slight, removes the film. Formaldehyde is a gas which is readily soluble in water, and the commercial form is a forty per cent. solution in water. The hydrofluoric acid is also a gas, sold like the formaldehyde in aqueous solution. This acid is, however, one of the nastiest and most disagreeable chemicals. Since it attacks glass and many other common substances, it must be kept in wax or lead bottles, and even then the escaping fumes are apt to corrode nearly everything in the same room. Great care must also be exercised in handling this dangerous reagent, as the sores produced by fairly strong solutions may be followed by serious results, and the fumes are very irritating to the air passages. Solutions of hydrofluoric acid, as well as formaldehyde solutions, should be kept in a cool place and tightly stoppered. In my own experience, I have found the solutions of sodium fluoride and sulphuric acid, as given above, just as effective as and much less disagreeable than the hydrofluoric acid.

The most perplexing problems arise after the film is stripped, and unfortunately these are almost entirely ignored in most of the published methods. They should cause no difficulty, however. I give below directions for the after-treatment of the stripped film, depending on the purpose which the worker has in view.

To preserve the gelatine film unmounted: Strip by the first method, place in water, and wash. The washing will not take long, as both surfaces of the film are exposed to the water. Then slip a piece of waxed paper into the water and under the film, and withdraw both film and paper together. Drain, and then with a lintless blotter take up all surface moisture. Then place the film between two dry pieces of lintless blotting paper and dry under light pressure. The pressure should be just great enough to prevent the film from wrinkling. A dozen or two of glass negatives are sufficient as a weight. This last step may seem surprising, but a gelatine film soaked in formaldehyde and an alkaline carbonate loses all adhesive properties, and there is not the slightest danger of the film sticking to clean blotting paper.

The second stripping method may be employed and the film after washing may be squeegeed on to a clean ferrotype plate; but the method is treacherous and uncertain and is not to be recommended for sizes larger than 3¼ by 4¼.

It may be desired to preserve these films without any further treatment, but the edges at least should be protected in some way. Perhaps the simplest way is to take a piece of paper of good quality and of a size a trifle larger than the film. Cut a mask from this paper, making the opening a little smaller than the stripped film. With a brush, run a line of gelatine around the edge of the opening, and fasten the film at its edges to this. Where a large number of stripped films are to be preserved in this way, it is best to use sheets of paper of a uniform size, and to leave the margin wide enough for data and notes such as are usually placed on negative envelopes. The opening may be of such a size and shape that the support will act also as a mask. The photographer in possession of such stripped films should remember also that the carbon process is made much simpler when one can print from the reverse side of the film and employ the single transfer method.

Mounting the Film on Celluloid

Old celluloid film negatives are very useful for this purpose. If it is desired to mount the film direct on the celluloid, remove the film entirely and thoroughly wash the celluloid. Then strip the desired negative by the first method, wash, and dry between blotters as above described. When thoroughly dry, soak in pure grain alcohol and mount directly on a sheet of clean, dry celluloid. The alcohol softens the surface of the celluloid sufficiently to make the film adhere, but the addition of a little amyl acetate to the alcohol is even better. The curling is slight, but the danger of bubbles is great. If it is desired to use the gelatine film on the celluloid negative as an adhesive, reduce the image and wash the negative. The stripped film (which may be stripped by any method) is floated in water, the celluloid is pushed under, and both are withdrawn together. The surplus water should be squeegeed out, and the film should be dried as celluloid films are dried. The curling is exceedingly troublesome when films are mounted in this way. If the celluloid negative had been treated with a hardening agent like alum, and if the stripped film had been removed by the first method, then considerable trouble may be experienced in making the film stick.

Enlarging Negatives.

The negatives to be enlarged should be somewhat denser than the normal, as a reduction in density occurs when the film swells. An old plate or negative should be used for a mount. If a plate is used, treat with hypo; if a discarded negative, treat with the reducer. When the gelatine film of the mount is perfectly clear, wash thoroughly. The negative to be enlarged is stripped by the second method. Wash, and when the desired enlargement has taken place, slip the glass as above prepared under the film and withdraw both together. Roll out all surplus water and allow the enlarged film to dry on the gelatine-coated glass. The enlargement of the film increases slowly while in the water, but may be hastened by adding glycerine to the water. Should it be found afterward that the enlargement of the film has been too great, the film should be transferred to dilute alcohol, about thirty per cent., and then placed in succession in alcohols of about fifty, seventy-five, and ninety-five per cent., allowing about five to ten minutes between changes. In this way the film might be restored to its original size, if desired.

If the negative before stripping is treated for about ten minutes in a solution of:

Formaldehyde 2 parts
Water 98 parts

the film becomes a trifle tough and the swelling is limited to about ten per cent. in its dimensions, so that a 4 x 5 negative gives a 4½ x 5½ stripped film. By varying the strength of the formaldehyde bath and the length of time of immersion, the amount of swelling of the film may be definitely regulated.

Films treated with formaldehyde are much easier to handle than those not so treated, as they are much firmer and tougher.

There is one very important caution, however. Never use anything but a discarded negative until you have mastered the method. All methods are easy after they have been mastered, and all are difficult (in varying degrees) before they are mastered. When the film comes off so easily in the hydrofluoric acid bath,

and seems so tough and firm in the water, there is a temptation to strip half a dozen good negatives "just for luck." But unless you fiercely resist the temptation your joy will be turned to bitter disappointment when you see them hopelessly ruined on their new support. Use fogged plates or spoiled negatives until you are sure of yourself, and do it with every new method you try.

E. F. LANGE.

BROMOIL PRINTS BY A SIMPLIFIED METHOD AND BY A TRANSFER PROCESS.

[The results of recent investigations by the Ozobrome Co., proprietors of the patent in the "Ozobrome" solution, are described in a booklet just issued under the title of "Oil-Ozobrome," by which name the company allude to an oil print prepared by a transfer process. The major portion of the booklet is quoted in the following paragraphs, which form the working instructions for both the simplified form of the Bromoil process and for a mode of working "Bromoil" prints which corresponds with the No. 2 method in the Ozobrome process. The full booklet contains the prices, etc., of the materials required by the worker. It is obtainable on application to Messrs. Ozobrome, Ltd., 122, Allcroft Road, Kentish Town, London, N.W.—Eds. "B.J."]

Method No. 1 (Bromoil Simplified).

In this method a bromide print is treated in such a manner that the altered image will retain greasy ink while the unchanged portions will repel it. The result is a picture in oil-pigment taking the place of the black silver image. As the ink is put on with a brush, almost unlimited control can be exercised in expressing personal artistic feeling.

Make up a stock solution of 1 per cent. hydrochloric acid, thus:

Water	25 oz., 1,000 c.c.
Hydrochloric acid, pure	2 fluid drachms, 10 c.c.

This solution will keep indefinitely.

BLEACHING BATH.

"Ozobrome" Concentrated Pigmenting Solution as sold	1 part
Water	4 parts
Stock one per cent. solution of hydrochloric acid as above	5 parts

or The "Ozobrome Working Bath" (made by adding 4 parts of water to 1 part of Concentrated Ozobrome Pigmenting Solution)

1 part	
Stock solution of hydrochloric acid as above.....	1 part

or "Tabloid" Ozobrome Pigmenting Compound, 1 "tabloid" product dissolved in each ounce of water

1 part	
Stock solution of hydrochloric acid	1 part

Immerse the bromide print in any one of the above bleaching baths until thoroughly bleached to a faint yellow brown colour, which will take one to three minutes according to the hardness of the bromide emulsion.

The bleached print is then transferred without washing to a bath consisting of:

Water	20 oz.
Hypo	2 oz.
Liq. ammonia	60 minims

where it should remain from two to six minutes according to the original hardness of the bromide emulsion. The hardness of the emulsion can be roughly gauged by the time the image takes to bleach.

If the bleaching is complete in one minute or less it is an indication that the gelatine is fairly soft, and two or three minutes in the fixing bath would be sufficient, but if the time occupied in bleaching is two or three minutes or longer, the print should remain in the hypo. from five to six minutes.

Finally wash three to five minutes in running water. After removal of the superfluous moisture the print is ready to ink up, or, if convenient, the print may be allowed to dry, in which case it

will require to be soaked in water at a temperature of 60 deg. 65 deg. F. for about twenty to thirty minutes.

Method No. 2 (The Transfer Process).

The initial difficulties experienced in working out this process have been overcome by the introduction of a special transfer paper prepared by Ozobrome Limited.

The rationale of the process is:—A piece of specially prepared transfer paper is immersed in a bleaching bath and placed upon a glass slab, the bromide print (previously soaked in water of weak solution of salt) is brought into contact with it and the two papers squeegeed together. The silver of the bromide image in conjunction with the bleaching solution held by the transfer paper produces a tanned gelatine image (reversed as regards right and left) upon the transfer paper. After washing and drying, the image is ready to ink up. The image of the bromide paper is also tanned, and after fixing can be used for bromoil. The salt accelerates the bleaching.

In this method an ordinary bromide print will produce an image reversed with regard to right and left, but of course in enlarging this can be easily rectified.

The bleaching bath described under Method No. 1 is used. 1. Immerse the bromide print in a salt bath, thus:—

Water	20 oz.
Common table salt	1 oz.

where it may remain while the following operation is being carried out.

2. Immerse the special oil-ozobrome transfer paper in the bleaching bath (prepared as in Method No. 1) until it is saturated, which will take about two to three minutes in summer or four to six minutes in winter.

3. Remove the soaked transfer paper from the bleaching bath and place it, gelatine side upwards, upon a sheet of glass.

4. Take the bromide print from the salt bath and lay it, image side downwards, upon the soaked transfer paper resting on the glass, avoiding airbells or any lateral movement. Then, without losing time, squeegee the papers gently into contact with a rubber squeegee (a flat squeegee removes too much of the solution) and place them, transfer paper uppermost, on another piece of glass. The bleaching action takes place fairly rapidly (from five to fifteen minutes) and the process of the bleaching can be distinctly followed by looking through the adhering papers in front of a fairly strong light.

5. When the image is completely bleached, separate the two papers (under water by preference), leaving them in the water, which should be changed several times, until all yellow coloration has disappeared, which will take from seven to fifteen minutes according to the temperature.

The impressed transfer paper is not in a condition to ink up

until it has been dried and re-soaked in water for five to ten minutes.

The bromide print, after washing, may be re-developed for further transfer, or, after separation from the transfer paper, it may be placed at once in the hypo and ammonia bath mentioned in Method 1, washed, left to dry, and re-soaked for a few minutes, when it can be inked up as a bromoil print.

Note.—Experiment shows that when two gelatine surfaces have been pressed together and separated by force, they are not in a condition for pigmenting until the pores of the gelatine have been closed by drying, when quite a short re-soaking in water is sufficient.

Keeping Properties.

The "Ozobrome" solution as sold will keep indefinitely, but the bleaching bath should be freshly prepared. It may be used for quite a number of prints at one sitting, but should not be kept till the next day. The hypo bath should be renewed after about six prints have been treated.

Inking.

It is almost impossible to give precise instructions for the inking up of the print, as nearly every worker has his own ideas upon the subject, and no two persons handle a brush in exactly the same way. Hopping, dabbing, and sweeping motions all have their uses, and the amount of force to be used depends both upon the hardness of the surface of the print and the degree of contrast required. It is, however, a safe rule never to use force unless you have first tried every possible kind of gentle persuasion, as sometimes just a slightly different touch will produce the required effect.

The soaked print should be placed upon a pad consisting of several thicknesses of damp blotting-paper (the fluffless photographic variety for preference), resting upon a glass or metal support, and the superfluous moisture should be removed from the surface of the print with a clean soft handkerchief or a piece of butter muslin.

A little ink about the size of a pea should be dabbed upon a sheet of glass and spread down evenly with a palette knife. A very small amount of medium may be added if the ink is very stiff and difficult to spread. The tip of a special brush is very lightly charged with pigment by dabbing first on the patch of ink and then on plain glass and is then applied to the print.

With regard to the brushes used they may be made either of Lyons hog-hair or fitch, and the shape generally preferred is that of a hart's foot. It is a great convenience to have a number of these brushes in various sizes, as a clean one is often required.

Brushes may be cleaned by rubbing the hairs upon a piece of rag moistened with turpentine, or the pigment may first be loosened by dipping the brush in turpentine and subsequently washing with soap and water. In any case it is essential that the brush should be perfectly dry before being used again.

DEVELOPING P.O.P.

With the advent of the new phosphate papers, on which results practically indistinguishable from those on P.O.P. are obtained by gaslight exposures, less importance attaches to the methods of developing ordinary print-out papers. On occasion, however, such procedure is useful where a more rapid paper is not at hand, or where, on grounds of economy, it is thought advisable to take off proofs on developed P.O.P. We may, therefore, quote the directions given in the current issue of the "Bulletin de la Société Havraise de Photographie," where M. Schweitzer gives the following formulæ and directions for the use of a pyro developer for P.O.P. Unless we are mistaken, a solution of very similar composition was sold years ago as a secret preparation capable of giving a variety of warm tones on faintly printed P.O.P. The following stock solutions are prepared:—

A. Potass. bichromate	10 gms.	1 oz.
Water	100 ccs.	10 ozs.
B. Citric acid	20 gms.	2 ozs.
Water	100 ccs.	10 ozs.
C. Pyrogalllic acid	1.5 gm.	13 grs.
Water	1,000 ccs.	20 ozs.

Solutions A and B will keep indefinitely, but solution C should be made at the time of developing a batch of prints. The precise

tone obtained is largely dependent on the character of the negative, the degree of printing-out, and the composition of the developing bath. The bath itself should be made up at the moment of use by means of the above solutions, the quantities given in the formulæ cited below being sufficient for the development of one quarter-plate print.

For green tones—

A	3 drops	3 drops.
Water.....	25 ccs.	7 drms.

A different shade of green is given by—

A	3 drops	3 drops.
B	8 drops	8 drops.
Water	25 ccs.	7 drms.

For cherry-red tones—

A	1 drop.	1 drop.
B	3 ccs.	50 mms.
Water	25 ccs.	7 drms.

For reddish brown tones—

A	1 drop.	1 drop.
B	1 cc.	16 mms.
Water	25 ccs.	7 drms.

For blue-black tones—

A	2 drops	2 drops.
B	5 drops	5 drops.
Water.....	25 ccs.	7 drms.

The depth of the tones obtained increases the slighter the printing in the first instance; on the contrary, if very warm tones are desired it is better to go on printing until a fair amount of detail is visible. The best results are obtained in this process by the use of fairly contrasty negatives.

Having decided the kind of tone that is preferred the solution corresponding to it among the above formulæ is made up and the prints immersed in it for about five seconds, and then placed, without washing, directly into the C solution. Here development is completed, the print then placed for a moment in water, and then transferred to a 10 per cent. solution of sodium sulphite, which clears the print from any silver stain due to the potassium bichromate. It is then washed, fixed, and again washed in the usual way. The process is very simple, and gives a considerable variety of results from a paper of the P.O.P. type.

Photo-Mechanical Notes.

Plates for Embossing by a Photographic Process.

A mixture of rubber and asphaltum is used as a sensitive material in a process patented by John Hartnett, Jun., No. 1,550, I Street, N.W., Washington, U.S.A., for preparing relief plates for embossing, etc. According to the specification, No. 6,795, 1909, a solution is prepared, consisting of pure crude rubber dissolved in any suitable solvent of rubber, as benzole, benzine, acetone, etc., and to this solution is added a small percentage of asphaltum or coal tar.

A plate is coated with one or more films of the above solution according to the amount of relief desired, the films being thoroughly dried before subjecting them to use. It is found that by thoroughly drying the films they are rendered more sensitive. The effect of light, either natural or artificial, upon a plate prepared as above is to render the exposed parts of the film more or less insoluble, depending upon the amount of light and thickness of the film.

A transparency is made of the object to be reproduced in relief. This transparency may be a photographic negative or positive on glass, or any similar translucent representation of the object, a photographic negative being usually preferred. This transparency is placed face to face with the film of the sensitised plate, the two being clamped together in a frame as in the ordinary method of printing photographs. The transparency is then exposed to light, either natural or artificial, for a suitable time, depending upon the intensity of the

light, the density of the negative, and the thickness of the film. The light will render the parts of the film exposed to it more or less insoluble, depending upon the amount of light passing through the transparency. The film exposed to clear portions of the transparency will be quite insoluble, while the film exposed to shaded portions will be more or less soluble according to the amount of light received through them.

After sufficient exposure the plates are separated, and the sensitized plate is placed in a bath of any suitable solvent of rubber, as benzole, benzine, acetone, etc., and subjected to the bath until the parts which were shaded by the transparency have swelled to the desired relief. The amount of swelling or relief at any particular point will depend upon the thickness of the film, the amount of light to which it has been subjected, and the length of time the developing process has continued.

When the desired relief has been secured the plate is removed from the bath and a plaster cast made from it, which cast will be found to have the outline and more or less of the relief of the subject from which the negative was made. If it be desired to make an electrotype, this plaster cast is dipped in boiling oil (such as linseed oil or paraffin) to fill the pores, and then coated with graphite, after which an electrotype may be made in the usual manner and stereotype plates may also be made.

Stereotype plates, positive and negative, made as above described, may be used for embossing. For light embossing, such as is required to bring out the features of photographs, the plaster cast above described, together with a negative made from the positive, may be used as a pair of embossing dies. Such dies will exactly register with the features of a photograph produced from the original negative, and they may be used to emboss pictures printed from the negative.

Newspaper Process Plant.

The object of installing a process department in a newspaper office must be to enable illustrations to be conveniently produced in regard to time, for it is improbable that blocks can be produced any cheaper by the newspaper's department than they could be purchased at the present low prices of blocks. Now the attainment of this objective of speed is frequently stultified by an inadequate knowledge of process work or exaggerated expectations of its possibilities. The utmost speed can only be attained by division of labour, each worker becoming extremely expert on his particular point in the work. Yet we constantly hear of departments being started with only one man to do everything. It takes a very clever man to be able to do everything necessary in the making of a block, and if he does it well then he cannot do it quickly. The same with regard to plant; it is of no use installing a second-hand camera of obsolete pattern, arc lamps only suitable for street lighting, and lens and prism of the slowest type. This, however, is what is sometimes done, with consequent disappointment. For a newspaper process department to be thoroughly successful it must have an adequate staff, not one man only, and plant selected in every respect with regard to its capability in turning out work quickly. Such apparatus is not always the most expensive.

The Air Supply of the Aerograph.

The "Aerograph," without which no process studio is complete, has gone through quite an evolution as regards its air supply. At first a skate foot pump, or even a bicycle pump, was used to compress the air, then the little hot air engine was introduced, then the electric motor. Some firms used their ordinary power engine to compress the air, others, using the monotype casting machine, availed themselves of its compressed air, and now we find a firm in Austria using for the purpose, with every satisfaction, cylinders of carbonic acid gas, the same as are used in the beerhouses there. We suppose liquid air is not yet cheap enough for the purpose, but no doubt, when it becomes so, it will be used.

The Cleaning of Glass.

One of the most troublesome operations in connection with wet collodion work is the thorough cleaning of the glass plates, and probably more waste arises from negatives useless on account of dirty glass than from any other cause.

The usual plan is, first, to soak the glass in a bath of strong nitric acid or a mixture of bichromate of potash and sulphuric acid. Whether this is effective or not, of course, depends entirely on the way in

which the soaking is allowed to take place. If the glasses are simply laid horizontally on top of each other without any division, naturally the acid cannot freely attack the surfaces. In order to accomplish this it is better that the plates be stood in the bath vertically, and to this end lead-lined grooved troughs are sold. These, however, are very expensive; the same end may be obtained by the use of a deep porcelain trough, fitted with two pieces of wood in which narrow grooves have been cut. These grooved pieces are cheap and easy to make out of quartering, and can therefore be replaced as soon as the acid disintegrates the wood.

After the soaking in acid the plates are usually scrubbed with a brush and some fine powder, such as tripoli. It is here also that thorough work is necessary, and generally much dissatisfaction is expressed with the boy who has this job to do.

To overcome this difficulty one large establishment has installed a machine similar to a stone-grinding machine. This is fitted with a soft pad and supplied with rouge, the glass laid on a slab, and the boy then goes thoroughly over it with the machine, which is pushed about just like the radial arm router. Since this means of cleaning the glass has been used there has been no complaint of dirt, and great has been the relief of the operators.

The Finish of Zinc Blocks.

Now that zinc is becoming increasingly used in England it is somewhat surprising that the Continental method of nickelling the plate is not adopted. This has several advantages—viz., the zinc plate is protected from corrosion, inks do not affect it, it wears very much longer on the printing press, and, finally, its appearance is improved. The operation takes no time to speak of; certainly, it can be completed in three minutes, including the cleaning of the plate, the preliminary brass facing, and then the nickel facing. It is true the material and plant for reducing the voltage of the electric current is a somewhat heavy first expense, but this is all, and is only incurred once.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

COLOUR PRINTING.—No. 19,665.—Improvements in the manufacture of blocks for colour printing. Oliver Samuel Dawson and Clare Livingstone Finlay, 254A, High Holborn, London.

The following specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

ENGRAVING AND PRINTING.—No. 18,338.—Engraving and printing process. Valentin and Zerreiss.

FORTHCOMING EXHIBITIONS.

1909.

September 10 to October 23.—The Photographic Salon. Sec. Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 23 to October 30.—1.—Royal Photographic Society Sec., J. McIntosh, 35, Russell Square, London, W.C.

October 21 to 23.—Rotherham Photographic Society. Entries close October 11. Secs. H. C. Hemingway, Tooker Road, Rotherham and F. Sargeant, 17, Aldred Street, Rotherham.

November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber Oakdene, Highfield, Southampton.

1910.

April 5 to 9.—Sheffield Photographic Society. Secs., J. A. Georg and J. R. Wigfull, 14, Parade Chambers, Sheffield.

THE RANKS OF LADY PHOTOGRAPHERS in London are being augmented in the opening of a business by Miss Florence C. Vandamm at 26, Victoria Street, Westminster. Miss Vandamm, in common with many other lady photographers, has been trained at the Polytechnic School of Photography, Regent Street, W., where she has been a student for three years. She holds the student's medal for portraiture, and in addition to other awards gained a plaque for portraiture at the last Cripplegate Exhibition, and had accepted portrait in the pictorial section of the 1908 R.P.S. Exhibition.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

Applications for the following patents have been received from August 23 to 28 :—

CAMERAS.—No. 19,342. Improvements in and relating to photographic cameras. Otto Halbach, 53, Chancery Lane, London.

REFLEX CAMERAS.—No. 19,432. Improvements in and relating to folding and other forms of reflector photographic cameras. Frank Philip Whitehead, 34, Pickets Street, Balham, London.

PHOTO-TELEGRAPHY.—No. 19,516. Process and apparatus for electro-mechanical transmission to a distance of half-tone illustrations, portrait, and other photographs, engravings, manuscripts, typograms, and the like. Henri Carboneille, 111, Hatton Garden, London.

TELE-OBJECTIVES.—No. 19,580. Improvements in photographic tele-objectives.—Carl Zeiss, 29, Margaret Street, Regent Street, London.

CINEMATOGRAPHY.—No. 19,669. Improvements in or relating to stereoscopic cinematography. Alfred Barnett, 3, New Oxford Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOLDING REFLEX CAMERA.—No. 28,448, 1908 (January 7, 1908). According to the invention, the frame which carries the ground glass and is pivoted on the axis of rotation of the mirror is not connected directly to the mount of the objective. This mount is carried by a separate frame jointed to the rear frame of the camera on a pivotal axis, which is not that of the mirror. In this manner the height of the ground glass is no longer limited, and, moreover, as it may be situated at a distance from the mirror, the pivotal axis of the latter need no longer be necessarily placed against the shutter, and the rollers of the shutter may be placed inside, thus allowing of the use of a reversible frame and of plate-holders or magazines of all kinds.

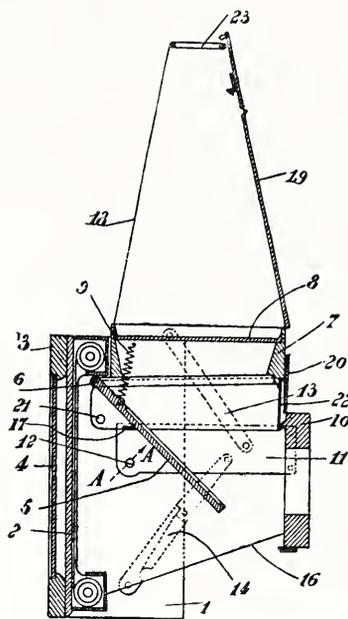

The rear frame, 1, of the camera comprises two bearings or recesses for the rollers of the shutter, 2, behind which there is arranged the reversible frame, 3, containing the sensitised plate.

The mirror, 5, of the finder is pivoted on an axle, 6, on which is also pivoted the frame, 7, carrying the ground glass, 8. A spring, 9, fixed to the frame 7, and to the mirror, 5, has a tendency to pull the latter against the lower face of the frame, 7. The mount, 10, of the objective is attached to two side plates, 11, pivoted on two axles, 12, fixed to the rear frame, 1. These plates, 11, are connected at one end to the frame of the finder, 7, by means of rods, 13, and at the other end to the frame, 1, by means of jointed levers, 14. An intermediate frame, composed of two side plates, 15, and a transverse plate, 22, designed to close the space between the frame, 7, and the plates, 11, is adapted to pivot on axles, 21, fixed to the rear frame, 1. The longitudinal edges of the plates are turned in to form hooks for engaging similar hooks formed by turning in the adjacent edges of the plates and the side faces of the frames when the apparatus is folded. The lower part of the camera is closed by a leather flange, 16, one of the bottom edges of which is screwed to the spring of the lower roller of the shutter and the other to the mount, 10, of the objective, its side edges being fastened to the plates, 11.

For focussing the mirror is held down in a position of 45 deg. against stops, 17, fixed to the plates, 15, by an oscillating arm, 24, the free end of which is formed with a projection engaging with the end of an arm, 25, the other end of which is fastened to the axle, 6, of the mirror. On lowering the actuating knob, 26, the

bell crank lever, 27, disengages the arm, 24, from the arm, 25, and allows the spring, 9, to raise the mirror and with it the arm, 25, which strikes the ratchet, 28, and disengages it from the teeth of the wheel, 29, to allow the shutter to move down. For moving down the mirror the knob, 30, secured to the arm, 25, is pulled down in the slot, 31, until the end of the arm, 25, has passed the projection of the arm, 24, which engages it when the knob, 30, is released.

This arrangement allows of constructing apparatus having cameras of different lengths when unfolded, although the size is the

same when folded. For this purpose it is sufficient to shift or change the position of the pivotal axis, 12, along a line A—A at 45 degrees. The dimensions of the ground glass may be larger than in the arrangement hitherto in use, because its height is no longer limited by the front part of the frame in which it is mounted. It may even be made in the shape of a square having a side equal to the longest side of the photographic plate. Jules Frennet, 113, Rue de l'Arbre, Bénit, Brussels.

POCKET CAMERAS.—No. 27,866, 1908 (December 22, 1908). The object of the invention is to provide a pocket camera which shall combine with the smallest practical size and weight a sufficient stability and firmness for the proper working of the apparatus.

For this purpose the casing is formed along its edges in the shape of a pointed arch with rounded top and rounded corners, thus facilitating the handling and holding of the apparatus during operations, while also imparting to such apparatus the most suitable shape required for pocket camera which should have neither sharp corners nor sharp or square edges.

Furthermore, the guides which retain the four corners of the lens-carrier or movable front-plate in the usual manner are adjustably mounted on the inner side of a twofold or divided cover for the collapsed camera, while the divided cover is controlled by springs tending to open the same and thereby project the lens-carrier sufficiently outwards, when released, so as to permit of the latter being readily withdrawn with the fingers alone. Armand Boreux, 31, Petersgraben, Basle, Switzerland.

ENDLESS CINEMATOGRAPH FILM.—No. 9,262, 1909 (January 7, 1909). This invention relates to films or strips for moving-picture machines, and has for its object to provide a flexible film or strip of small dimensions containing a very long series of pictures. Such a film or strip is compact, portable, easily handled, convenient for use with the machines for which it is intended, and is little liable to injury: moreover, it is a convenient article for sale and delivery, and for storage either by the dealer or by the customer.

According to the invention, the flexible film or flexible strip has the pictures following one another arranged in rows or columns forming either a continuous spiral line or a number of

parallel lines, longitudinally, and such flexible film or strip may either be in the form of an endless band or loop or flexible cylinder, or it may be two-ended.

The pictures, which may be taken either from an ordinary cinematograph or like film or from the moving subject, are reduced on to the improved film or strip to as small a size as is convenient. The Rotary Photographic Company, Limited, 12, New Union Street, Moorfields, London, E.C., and Ferdinand Von Madaler, 11, Stowe Road, Shepherd's Bush, London, W.

CINEMATOGRAPH MECHANISM.—No. 10,292, 1909 (April 30, 1909).

The invention relates to apparatus for projecting series of luminous pictures and the like, and its object is to provide for this purpose apparatus which is entirely automatic, requiring no supervision of any kind, both the changing of the pictures and the control of the driving mechanism and illuminating means being automatically performed.

The apparatus essentially comprises a spring motor, a circular rotatable picture disk which is connected to the motor, a lamp of known type, and a governor which intermittently locks the mechanism by which the disk is rotated. Georg Mewes, 61, Mühlendamm, Hamburg, Germany.

SLOW FLASH POWDERS.—No. 16,448, 1908 (August 4, 1908).

According to the invention a slow-burning mixture is obtained by mixing an oxygen-containing compound of a rare earth metal or its equivalent with a quantity of magnesium equal at least to three times the chemical equivalent of the content of oxygen in the compound of the rare earth or other easily combustible metal. With such a time-light there is a repeated reduction and re-combustion of the oxide or compound of the rare earth metal or easily combustible metal. An example will illustrate this action. In the case of a mixture of magnesium and cerium oxide the action is as follows:

The cerium and magnesium again burn in the air and the CeO_2 thus produced is again reduced by the magnesium, and the pure metallic cerium again burns in the air. It is by this repeated reduction and reaction that the prolongation of the light is obtained. In this way the actinic power of the light is not reduced, while the desired time-light is obtained. The excess of magnesium given in the above equation may, of course, be greatly increased.

The oxygen-containing compounds of the easily combustible metal employed may be oxides of the rare earth metals, oxides of the alkaline earth metals, manganese and the like. It is known that as the equivalents of magnesium, aluminium, calcium, barium, or strontium may be employed. In deciding which compound to take with any of these equivalents of magnesium, regard must be had to the fact that the magnesium or its equivalent must be capable of reducing the compound. Of course, the oxides of the rare earth metals may be used with any of the equivalents of magnesium, and in the specification the oxide of the rare earth metal with magnesium is taken as the typical example of the invention.

As can be understood from the equation and explanation given above, the function of the oxide of the rare earth metal is to act as an oxygen carrier. Taking the example above, the cerium oxide is reduced by the combustion of the magnesium. The reduced metal is now ignited, and again burns in the air to cerium oxide. Owing to the excess of magnesium this oxide is again reduced by the combustion of the magnesium, and this reduction and re-combustion proceeds until the excess of magnesium is exhausted. The result of this is that the temperature of the combustion rises, and as the cerium also gives a high actinic light on combustion, a strong light is maintained. It will be understood that the reduced metal of the compound employed should be lower on the electro-positive scale than the magnesium or its equivalent.

In order to produce light of exceedingly uniform intensity, compounds of vanadium in small proportions may, with advantage, be added as a further oxygen-carrying agent.

The patentee refers to the suggestion in Patent No. 3,794, 1904, to mix nitrates of the rare earths with an excess of magnesium; to Patent No. 27,267, 1904, where it is proposed to mix a sulphate of a rare earth with an excess of magnesium, and to add an alka-

line earth to produce a time light; and to other proposals, such as mixing an excess of magnesium with an oxide, carbonate, or phosphate of a heavy metal.

The mixtures, according to the present invention, are characterized by their quiet burning, whilst their brilliancy is also increased. A mixture of an oxide of a rare earth metal with magnesium in excess equal to double the chemical equivalent of the oxygen of the oxide burns comparatively quickly, but when an excess of magnesium equal to at least three times the chemical equivalent of the oxygen is taken, the time is considerably lengthened. The following are some numerical examples of the mixtures employed. An excess of magnesium may be anything up to, say, 10 times the equivalent of the oxygen present in the compound:—

- I.—250 parts magnesium powder. 150 parts cerium oxide.
- II.—250 parts magnesium powder. 150 parts cerium oxide. 50 parts vanadic acid.
- III.—250 parts magnesium powder. 100 parts oxalate of cerium.
- IV.—250 parts magnesium powder. 75 parts calcium hydroxide.
- V.—250 parts magnesium powder. 50 parts cerium oxide. 50 parts calcium hydroxide.
- VI.—250 parts magnesium powder. 50 parts oxide of manganese.
- VII.—250 parts magnesium powder. 50 parts cerium oxide. 25 parts oxide of manganese.

2 to 3 gms. of the above mixtures will burn on the average for thirty seconds; greater quantities, of course, will burn for longer periods. Carl Bethge, 18, Schlesische Strasse, Berlin.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

PHOTO-RELIEFS.—No. 12,302. Process for obtaining photo-reliefs. Baese.

CINEMATOGRAPHS.—No. 19,097. Cinematographs. Benaglia and Grimaldi.

New Trade Names.

CINÉMA ECLAIR PARIS (DESIGN)—No. 312,924. Cinematograph and cinematograph films bearing finished pictures for use thereon. Société Française des Films et Cinématographes "Eclair," 27, Rue Taitbout, Paris, manufacturers. May 8, 1909.

LION.—No. 314,216. Photographic sensitised paper. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, manufacturers of photographic materials. June 24, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Mounting Enlargements.

One of the difficulties which I encountered on taking up the question of enlarging on thick rough surface bromide papers (writes Moore in "Photography and Focus" for September 7) was that of getting the enlargement to adhere to the card on which I mounted it. Starch paste, which had answered well enough for mounting P.O.P. and bromide prints of the ordinary thin paper kind, did not seem to possess sufficient adhesiveness, and the enlargements, after drying came right off the card. Glue I knew would stick, but the glue is impure. Gelatine, however, a purified glue, is not subject to the same objection.

The method of using it is much the same as if it were glue. The sheet of gelatine, which is sold at most oil shops, is allowed to soak for an hour or two in cold water, and, when it is perfectly limp, is taken out, squeezed in the hands, and put into a jar, which is stood over a saucepan of hot water. The saucepan should be put on a gas stove until the water is brought to the boil, and the gelatine should then be liquid and very hot, is applied to the back of the enlargement with a stiff brush.

The brush should be worked round and round all over the back of the enlargement, until it seems to be covered with a fine

oth. Particular attention should be given to the edges. When the hole of the enlargement has thus been covered with adhesive, a fresh supply should be taken on the brush, quickly brushed all over the back, and then the enlargement, being held face upwards in the hands by the middle of two opposite sides, hanging down in a loop between them, it should be lowered on to the mount so that the first touches it along a line at the middle of the picture. It is then quickly brought into contact all over, smoothed down with the fingers, always rubbing from the centre outwards, and put under slight pressure to dry.

New Books.

"La Photo-Sculpture Pour Tous." By T. Tranchant. Paris: Charles Mendel. Price 60c.

In this manual of 32 pages the author has described the methods of preparing reliefs, medallions, etc., by photographic methods. Among these are (1) the "carbon" method of producing a relief by washing out the soluble gelatine from a bichromated film after exposure to light, and (2) the swelled gelatine process. The details of preparing reversed negatives, of obtaining gelatine reliefs of the requisite depth, and of preparing casts from these latter are clearly explained by the author, who writes the results of his own lengthy practical experience on these processes.

MAKING LANTERN SLIDES.—A second edition of Herr Paul Hanke's "Herstellung von Diapositiven" has just been issued from the press of Gustav Schmidt, Berlin. It forms volume 20 of the well-known library series of photographic text-books, and in the new edition the author has given directions for the making of colour transparencies on screen-plates and by the three-colour separate methods such as the Sanger-Shepherd. Additional formulæ are also given for the making of warm-toned slides, whilst as regards the staple portion of the volume, the bromide and chloro-bromide processes, albumen, carbon, and collodion-emulsion, and wet collodion methods are, as before, the subjects of clearly written chapters.

New Materials, &c.

Bromoil and Oil-Ozobrome Materials. Supplied by Ozobrome, Ltd., 122, Allcroft Road, Kentish Town, N.W.

Ozobrome, Ltd., of 122, Allcroft Road, Kentish Town, N.W., are now issuing a special form of transfer paper for the production of bromoil prints by the oil-ozobrome process, and also they are issuing their special ozobrome "pigmenting" compound in the very convenient "tabloid" form prepared by Messrs. Burroughs, Wellcome and Co. The "tabloids" can be used in place of the ordinary ozobrome pigmenting solution, and they are equally suitable for the bromoil, bromoil or oil-ozobrome processes. The bleaching solution for either of the oil processes is made by dissolving one of the "tabloids" in one ounce of water and adding an equal quantity of 1 per cent. hydrochloric acid. For bromoil, the bromide print is simply bleached in this solution and then fixed, without washing, in a 10 per cent. hypo-bath rendered alkaline with ammonia. The special acid bath ordinarily used is dispensed with and the preparatory process is thus shortened, the final result being a faint brown instead of a green image. It is stated that after 3 to 5 minutes' washing pigmenting can be proceeded with, while as an alternative the bromoil print may be dried again and brought into condition for pigmenting by about 20 minutes' soaking in water. We tried both ways of working and obtained excellent results in both cases. The dried bromoil print, however, showed by far the greater contrast, and we should be inclined to recommend drying when a flat result is to be avoided. For the oil-ozobrome process the bromide print is soaked in 5 per cent. salt solution, while the special transfer paper is soaked in the bleaching bath. After a suitable time of immersion the two are

squeegeed in contact and left until the bromide image is bleached. They are then separated, and the transfer image is washed, dried, and then resoaked and pigmented, while the bleached bromide image is either washed and redeveloped, or at once fixed, washed, dried, resoaked, and pigmented as a bromoil print. Our test here gave an excellent bromoil print, while the oil-ozobrome was very promising. It, however, failed to pigment in the light half-tones, and possibly a better result would have been obtained if a little pressure had been applied to the squeegeed papers. Nothing, however, is said about this in the instructions. The loss of detail in the lights has always been a source of trouble with the oil-ozobrome process, and it would be an advantage if the cause of this trouble were specifically dealt with in the instructions. The new tabloid preparation is highly convenient and very effective for the bromoil process, and its introduction should be greatly appreciated. One statement on the first page of the instruction booklet we fail to understand altogether. It is stated that "none of the published formulæ for bromoil will work with this process." It is, however, a matter of common knowledge that some of them work excellently with bromoil, and also very effectively with oil-ozobrome, or ozo-oil, as it has also been called. Possibly, however, it is intended to say that none of the published formulæ will work with the ozobrome pigmenting solution or tabloids as now prepared. If this is so, it is very desirable that the fact should be more clearly stated, otherwise the workers who keep to the old methods will meet with considerable trouble. Certainly the introduction of tabloid "pigmenting" compound is a very great advantage, and this improvement will no doubt be highly appreciated by all workers of the bromoil process. The tabloids certainly give quite as effective results as the old preparation, while their convenience is far greater.

The Barnet "Super Speed" Plate. Made by Elliott and Sons, Ltd., Park Road, Barnet, Herts.

In the new Barnet plate which Messrs. Elliott and Sons, Ltd., have just placed upon the market, the aim has been at the combination of, first, great general speed, and second, a high degree of colour-sensitiveness. Such a conjunction of properties as this obviously must have the very greatest importance in the eyes of all classes of photographers. In studio work a great amount of advice has been given to the photographer of late years in the way of instilling into him the desirability of using a colour-sensitive plate. His reply has usually been that when employing a plate of the orthochromatic variety with the screen which is usually necessary for it, the exposure became protracted beyond what is feasible in commercial portraiture, or, if exposures of the usual time be given, the remedy for false tones and textures proves worse than the disease. Similarly, the great numbers of workers, most of whose photography is done with a hand camera have reason to appreciate the value of a plate which will allow them to give even slow instantaneous exposures when using a fair aperture of lens and a compensating light-filter. Therefore, in offering a plate, and one which is sold at the "popular" price of 1s. per dozen quarter-plates, giving both very high speed and a very considerable degree of colour-sensitiveness, Messrs. Elliott are assured beforehand of the interest of the photographic public.

In making some trials of the new introduction we had to be content with exposures made within a few yards of the offices of "The British Journal of Photography," and under atmospheric conditions which were not by any means the most favourable. In a light which required about 20 secs. to bring the paper of the Wynne meter to the standard tint we proposed to ourselves the test of an exposure of 1-10 sec. at $f/6$ through a filter which we had found by previous use might be taken with fair accuracy as being one of five times. If, under these conditions, we got negatives as fully exposed as are usually obtained when giving, say, 1-25 to 1-50 of a sec. at $f/6$ without a screen, we should be justified in describing the combination as one capable of the very widest use in hand-camera and studio photography. The negatives made in this way, which lie before us, show all the detail and other characteristics of a fully exposed plate, in addition to which the orthochromatic qualities of the emulsion are evidenced by the good rendering of foliage and that of a blue sky with clouds. While experts in sensitometry are still at variance as to what constitutes the speed of a colour-sensitive emulsion, we may be content with such a practical test as this, which will be sufficient to tell the photographer the capabilities of the plate as regards brief exposures through a filter. Although we gave 1-10

sec. we should say that a considerably shorter exposure would have been sufficient, the negatives attaining full density in ten minutes' development, despite the great speed of the emulsion. We found also that the plates fixed with considerable speed, and as regards their range of gradation and cleanness of working these are what one would expect of an orthochromatic emulsion of high quality. We have said enough to show that the new plate marks a notable step forward on the part of the makers of Barnet plates, and we are sure that among those practising both studio and outdoor photography a trial will show that in the Barnet "Super Speed" Messrs. Elliott have provided them with an important new power in all branches of photography. We would add that Messrs. Elliott are offering to send samples of the plate at 2s. 3d. per dozen half-plate, 1s. quarter-plate.

Paget Prize Phosphate Lantern Plates. Made by The Paget Prize Plate Co., Ltd., Watford, Herts.

Since reviewing recently the new phosphate paper manufactured by the Paget Prize Plate Co., we have received a small supply of lantern plates coated with the phosphate emulsion and placed on the market for the making of lantern slides and transparencies by precisely the same process as that employed with the phosphate paper. These phosphate plates thus allow the lantern-slide maker to produce a series of tones on transparencies by contact which are something quite distinct from those ordinarily obtained on gelatino-bromide and chloride plates. With the exception that the Paget Company advises the use of a somewhat stronger developer than that for the paper, namely, one made by diluting the stock solution with nine parts instead of with nineteen parts of water, the procedure is precisely the same as for the paper. In making some slides we found that, as with the paper, an increase in the exposure (which, we would interpose, is best given to daylight) gave us both warmer tone and softer character, so that the hardness or softness of a negative may be to a considerable extent remedied in the transparency made on the phosphate plate. The plates themselves are almost transparent, quite different in appearance from the ordinary gelatino-bromide lantern plate and resembling more nearly a collodion emulsion plate. The most convenient method, perhaps, of developing is to use a dish with a glass bottom held over a piece of white paper. The image is then seen to increase gradually in strength, and development can be most readily stopped at the right point simply by pouring off the solution and flooding the plate with water for an instant before putting it into the fixing bath. The opalescent appearance of the plates here disappears completely, it being just as easy to tell when the phosphate plate has been fixed as in the case of the semi-opaque bromide or chloride emulsion. The great transparency, however, of the phosphate plate is a point which the beginner in lantern-slide making will appreciate, as it renders the precise depth to which to take the plate in the developer more easy of judgment. For contact work, and particularly for obtaining a series of different tones with the greatest ease without altering the composition of the developer, the new plates certainly occupy a field of their own. The results show great transparency in the shadows, more nearly akin to a stain than to a granular silver deposit. They are marketed by the Paget Company at the customary price for transparency plates, namely, 1s. per dozen, $3\frac{1}{4}$ by $3\frac{1}{4}$ size.

Since the appearance of our first notice of Paget Phosphate paper, the following additional directions giving the revised formula for a developer for red tones and greater contrast have been published. The best and simplest light for developing is an ordinary candle. This light is sufficiently yellow not to do any harm even when the dish is held quite close to it.

For exposing, a white light is necessary; daylight, magnesium wire, and incandescent gas are all good, ordinary flat flame gas, lamps or candles are too yellow, electric light varies with the strength of current—when full current is on so that the light is white it is all right.

When we say that the tone depends on the exposure and not on the developer, this, of course, means so long as the same developer is used.

The addition of tartaric acid to the developer gives much redder tones when full exposures are given. It also gives greater contrast.

Tartaric acid	$\frac{1}{4}$ oz.
Water to make	20 ozs.

For use with ordinary negatives, take one part of above solution one part of the metal stock solution, and 18 parts of water. (For weak negatives reduce the water, even down to only eight parts.) We do not recommend the addition of the tartaric acid for cold tones, as it is more liable to fog with short exposures.

If, owing to under-exposure, forced development or the use of too strong light in developing, the whites of a print should be slightly fogged, the print may be cleaned by the reducing solution, diluted with three to six times its bulk of water, applied only as long as necessary and quickly washed off.

Phosphate prints may be toned if desired, after fixing and washing in any of the ordinary combined toning baths. In this way a further variety of colour is available.

"VICTORIA" AND "GROSVENOR" ART MOUNTS AND MOUNTING PAPERS.—Under these names Messrs. Houghtons Ltd., 88 and 89 High Holborn, London, W.C., have just issued two further series of mounting materials supplementing their excellent "Ruskin" mounts and "Ensign" art papers which we reviewed some time ago. The former, it will be remembered, are art mounts, each with a centimetre pasted-on tint of colour harmonising with the outside border, and also with prints of various tones, whilst the "Ensign" art boards, which are the materials forming the "Ruskin" mounts, are supplied in a series of eighteen different tints and textures, all of them free from pronounced colour, and therefore serving admirably for photographic purposes. In the "Victoria" Royal Art boards they have issued a further series of mounting papers in sheets 20 by 25 inches at a somewhat lower price, namely, 18s. per gross (thin) and 30s. per gross (thick). The series includes a very nice variety of colours, including a stone or buff, Nos. 62 and 72 (thin and thick respectively), a light brown, Nos. 64 and 74, a dark brownish-grey, Nos. 67 and 77, and slate-grey, Nos. 68 and 78. Though not possessing quite the character of surface of the "Ensign" art boards, the "Victoria" series, nevertheless, provides for the very tasteful mounting of prints both black and sepia. The "Grosvenor" mounts are selected from both "Ensign" and "Victoria" boards, and are put up in packets, each selling at 6d., and containing either 13 pieces, 8 by 6; 9, 10 by 6, 12 by 10. These boards represent a very convenient form in which to buy plain mounts for prints, and should be appreciated by the many who prefer an uncommercial looking mount or go through the trouble of multiple mounting in a small way.

PRINTING FOR PROFESSIONAL PHOTOGRAPHERS.—A booklet, specially issued to help the photographer in securing winter and Christmas trade, has just been prepared by Messrs. Walter Pearce and Co., St. George's Press, Brentford, W., of whose previous designs and booklets and similar literature we have had occasion to write appreciatively in the past. The present issue is a daintily printed 16-page leaflet, enclosed in a cover of linen-surface paper, very nicely embossed, and tied with ribbon, and providing a space for a photograph about 2in. by 2½in. This may be an actual photographic print or a half-tone reproduction, according to the photographer's desire. The text of the booklet bears the title, "Friend to Friend," and a few appropriate words makes a recommendation as to the suitability of a photograph as a Christmas or other gift. The wording may be varied somewhat to meet particular photographers' requirements. The booklet, which is issued at a moderate price by Messrs. Pearce, is supplied by them only to one firm in a given district.

Messrs. Pearce also send us a specimen book of the St. George's series of private Christmas card mounts, representing a very choice variety of mounts on linen surface and other papers, most of them in folders, providing a space for an oval, panel, or square print. Among them are also a series of very daintily produced calendars, and with space for the reception of an oval, circle, or rectangular print. There is nothing loud or garish about the colours, lettering, or ornament, and not a single card in the series would be considered out of place in the show-case of a photographer who prided himself on his tasteful work. Particulars of prices of the cards and of the small extra charge for alterations in the wording are obtainable on application to Messrs. Pearce, at St. George's Press, Brentford.

Hove Town Council have approved plans submitted on behalf of Miss Leeney for a photographic studio at 158, Church Road.

CATALOGUES AND TRADE NOTICES.

MESSRS. SINCLAIR'S CATALOGUE.—The new list of photographic articles supplied by Messrs. James A. Sinclair and Co., Ltd., 54, Market, London, S.W., has just been issued, and is sent post free on receipt of 6d. in stamps. This is a small sum for a cloth-bound list, which is not only a compilation of prices and descriptions, but also represents the personal recommendations in the way of apparatus and materials of Mr. James A. Sinclair, which is something of a good deal more than 6d. The first few pages of the list give the special designs in cameras and accessories obtainable only from Messrs. Sinclair, following which the remainder of the list is arranged alphabetically. Messrs. Sinclair's business has proved so successful in adopting the method of supplying only the best, that our readers, and particularly those in foreign countries, will find to their advantage to possess themselves of this latest catalogue, which is issued, we would remark, without the articles on photographic topics which accompanied the previous issue. These are now published separately, under the name of the "Sinclair Book of Photography," and represent the candid advice of a number of practical workers on current photographic processes. The book is obtainable, price 1s. post free, with or without the catalogue.

BALEAINS AT SLOANE SQUARE.—A bargain list of second-hand apparatus, just issued by the Sloane Square branch of the City Sale Exchange, 26 and 28, King's Road, London, W., reaches our hands, and contains, we find, a special closely printed four-page supplement, devoted to studio and field cameras and other professional photographic accessories, in the supply of which, new and second-hand, the Sloane Square branch of the City Sale have made a special feature of their establishment. The list also contains particulars of a large number of hand cameras, lenses, and other apparatus, and in which those about to purchase may be advised to get, without a view of paying a personal visit to the firm. The list, which is the general catalogue of the City Sale, is sent free on address-card to 26 and 28, King's Road.

CINEMATOGRAPH APPARATUS.—The season's list of bioscopes, lanterns, and lantern apparatus has just been issued by the well-known firm of R. R. Beard, 10, Trafalgar Road, Old Kent Road, London, S.E., and contains a description of the latest patterns of apparatus in lanterns and carriers, and the jets, arc-lamps, and the recently used Beard oxygen regulator. Mr. Beard's long connection with the lantern trade as an actual manufacturer entitles him to be named as a leading maker of apparatus, and the present list shows that his models are kept quite up-to-date.

SCHOOL OF PHOTOGRAPHY.—We are in receipt of the syllabus of a course in art and photography, held at the Studio, Compton Road, London, by Mrs. Mather, Miss Woolnoth, and J. Mather, M.A. In addition to classes in portrait painting, sketching from nature, etc., the curriculum includes instruction in portraiture in the studio, developing, enlarging, and mounting, working-up in black and white and colours, and miniature painting. The fees and other particulars are given in the syllabus.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, SEPTEMBER 11.

London Photographic Society. Outing to Battlesbridge.
Sociological Society. Outing: Kingston to Hampton Court.
Sociological Society. Excursion to Sutton Park.

Commercial & Legal Intelligence

LEGAL NOTICES.—The partnership between Messrs. Walter Holmes and Joseph Geldard, carrying on business as camera bag makers, etc., at 90 and 92, Woodhouse Lane, Leeds, under the style of Holmes and Geldard, has been dissolved. All debts due to and owing by the firm will be received and paid by Mr. Holmes.

An application will be made at Leeds on October 18 for the discharge in bankruptcy of Mr. Henry Morton Pearce, lately carrying on business under the style of Morton's Star Photo. Co., at 26 and 28, County Arcade, Leeds.

News and Notes.

ELECTROPHOT ENLARGEMENTS.—Since commenting in our issue of August 20 upon the business methods of the Electrophot Company, of Welsbach House, Gray's Inn Road, W.C., we have been the recipients of a letter from the company, in which they point out the misleading, incorrect, and consequently damaging nature of our remarks. Whilst stating this they gave us the opportunity of investigating their business and reporting on the methods adopted by them in supplying the public with enlarged portraits from photographs. Of this opportunity we gladly availed ourselves and have pleasure in stating that our visit proved to us that the company carry on a satisfactory and *bonâ-fide* business. So many fraudulent methods being practised in the so-called "free-enlargement" trade it is right that we state that our visit of investigation, paid at a few minutes' notice, showed that the Electrophot Company is not to be classed with firms practising the various forms of the "free-portrait" trick, and we regret that we should have fallen into the error of attributing a character of this kind to the company. We inspected a large number of the 18 by 14 enlargements which the firm is at present offering for the sum of 1s. 3d. They represented a very creditable standard of enlarged portraits of this size made from a "copy" negative. We were allowed to inspect their files, and found hundreds of unsolicited testimonials respecting portraits supplied, and saw for ourselves that expressions of satisfaction were forthcoming from many classes of purchasers. We also inspected the studios and workrooms of the company, and saw that the technical part of the business was efficiently carried out on their own premises by their own staff.

THE CINEMATOGRAPH BILL.—This Bill was again brought up in the House of Commons on September 1. On Clause 7, "Application of Act to special premises," Mr. Cooper moved an amendment to Sub-section 2, which as drafted was to the effect that where premises were used only occasionally for cinematograph displays and on not more than two days in any one year, it shall not be necessary to obtain a licence if the occupier gives notice to the County Council seven days before the exhibition and complies with the various regulations. The alteration suggested was that premises connected with churches, chapels, mission halls, or schools, should be exempt from licensing under similar conditions if not used more than one evening weekly from October 1 to March 31. Mr. Gladstone, on behalf of the Government, said he could not accept the amendment. He pointed out that the licensing fee of £1 was a small matter. No representations had been made to him on behalf of religious bodies that they feared the drastic regulations of the County Councils. On the other hand, however, the London County Council and fourteen of the metropolitan boroughs had made most urgent representations to the Home Department on account of the danger of these performances. He (Mr. Gladstone) did not deny that when a cinematograph exhibition was properly regulated it was not a dangerous thing in itself, and though a film may take fire, there is no danger of the fire spreading. But there is no existing power to enforce the using of an iron box. It was also to be pointed out that there was a danger apart from fire, for a film may flare up and cause a panic. It was not in the least the intention of the Department to insist upon unreasonable or unnecessary regulations. Sir Daniel Goddard urged that the number of casual performances might be increased from two

per year. He had used a cinematograph himself, and he knew what accidents can happen from it. In his own town (Ipswich) the local authority had made regulations and insisted on iron boxes being provided. Therefore he did not understand what Mr. Gladstone meant by saying there were no regulations. He (the speaker) knew a place where a children's party was given once a month throughout the winter, and it was a common form of entertainment to have a cinematograph. Under the Bill these could no longer be given. Mr. Jeremiah MacVeagh said that the Bill began at the wrong end altogether, because it was not the building which should be licensed but the operator. The danger did not come from the building at all, but from incompetent operators. If the Home Secretary would confer with the cinematograph firms throughout the country, he would find that they themselves, for their own protection and for the advance of the industry, decided to hold examinations for operators with the view to the issue of certificates to those persons who were found to be competent. The manufacturers were obliged to reject 50 per cent. of those who came forward to be examined, and the very men who were rejected are giving demonstrations in the working of the cinematograph practically every night in the year. He (Mr. MacVeagh) thought that this was a strong point as showing that the danger does not come from the buildings, but from incompetent operators. He knew that the Home Secretary did not see his way to make arrangements for the granting of such certificates, as there were difficulties in the way; but surely with the large staff of factory inspectors in connection with the Department it would be possible to devise some scheme under which certificates could be given to operators who were found to have some scientific knowledge, and to exclude men who have no scientific training and no knowledge of the work in which they engage. In conclusion, he asked the Home Secretary to confer with the law officers on the Bill. Mr. Gladstone agreed with Sir D. Goddard that two performances in a year was rather small. After further debate the Sub-section was amended so as to make the number of unlicensed performances which could be given in a year six instead of two. On Clause 11, "Short title and commencement," upon the motion of Mr. Gladstone, an amendment was passed to the effect that the Act come into operation on January 1 next instead of August 1, 1909, as originally proposed. The Bill was read a third time and passed.

THE QUALITY OF NEGATIVES.

To the Editors.

Gentlemen,—I have read with considerable interest the article on above subject in No. 2,574, and, as a professional photographer of some fifteen years' experience, perhaps I may be allowed to make a few suggestions as to the causes why the majority of present-day negatives are wanting in "quality," "pluck," "correct density," and "freedom from fog" understood.

Firstly, I have found a great tendency at the present time to "rush" development, also I find, as a general rule, development of the day's exposures takes place "after hours"—i.e., when the studio is closed for sitters. Now if the operation is left to assistants to perform they know that the sooner the last plate leaves the wash the sooner they are free; consequently all are developed side by side, as many as can be packed in one big dish, a certain quantity of developer poured over, an occasional rock, then taken out as soon as they appear dark enough and fixed.

The evils of this method are that those that are over-exposed, the under-exposed ones, and the few—very few—that may be correct are all treated exactly alike. The developer is, as a rule, a normal one, generally very active, and contains little, if any, bromide. The consequence is that every batch yields a crop of indifferent negatives, most of which are flat and lifeless, due to

over-exposure; or else hard and contrasty, without half-tones, due being under-exposed. Recourse has then to be taken to intensifying, reducing, and other after-treatments in order to secure passable print; and, by the way, there are too many "passable results" nowadays.

On the other hand, if each plate was developed carefully negatives would be the rule. I suppose it would be considered absurd to suggest that all plates exposed in a busy studio should be developed separately, so I suggest an idea which I find practicable. The changing-room should contain three negative boxes, one for plates known to be under-exposed, for instance, child subjects and the like, which necessitate quick exposures; one for those judged as correct; and one for long exposures or those known to be over-exposed. Then when developing-time comes, by modifying developer for each batch I feel sure better results would be achieved.

Another reason which I think accounts for poor-quality negatives is the use at the present day of new "fancy" developers, of equally fictitious names. They are advertised as economical labour and time savers, "simply dilute with water and ready for immediate use," "can be used over and over again"—in short, "the lazy man's friend." Good old pyro seems to be gradually being pushed further and further into the background, and may in days to come, will be written in photographic history as one of the fearful concoctions used by the ancient pioneers of the craft (art if you like), with its disagreeable habit of staining of fingers and an occasional negative or two. Needless to say, it is by far the best developer science can produce for the development of photographic dry or wet plates, and as for its staining proclivities, well, they are easily avoided.

Now if I have any doubts about an exposure I develop purposely to get a stain, for I find a yellow-stained plate almost as good as intensifying. It may take a few minutes longer to print, but the odds are that I get a much better result than if I intensify and afterwards intensify. Thus the stain minimises labour. Moreover, there is a possibility in more than one direction of ruining that plate if one commences to doctor it up.

Another reason. Our grandfathers used to get very fine negatives—aye, negatives that will compare with the best obtained to-day; negatives that will print in any known process, one and all from the same plate. I can submit negatives taken forty years ago that cannot be bettered to-day by any photographer. What was the reason of their success? Their secret lies in the fact that they used "slow" plates, and to-day the tendency is for the fastest that can be made.

Consult the advertisements in the "B.J.": "S. and So.'s plates, the fastest in the world, 550 H. and D., reduces exposure to a minimum." That they do, but the trouble I have experienced with plates of phenomenal rapidity is that they refuse to develop up into bright, crisp, sparkling negatives. Unless they develop they are no use to me. I exposed six absolutely correct actinometer in the studio a short time ago; afterwards spent a half hour tinkering with them in the dark-room in order to get a "passable result." Is it any wonder, I ask, that present-day negatives are of poor quality?

If photographers generally would begin to use plates about 200 H. and D., and develop them with a recognised pyro and ammonia developer, I feel sure they would soon find a distinct improvement in their results, with a smaller percentage of flat, foggy negatives.—Yours truly,

TURB.
Crown Studio, Esplanade, Scarborough.

MR. W. TULLEY, photographer, of Glastonbury, has just published a photographic souvenir of the Royal visit to Glastonbury on June 22. The souvenir, which is very tastefully designed, contains a complete set of photographs of the ceremonials. An excellent frontispiece is made by a photograph of the Royal group, including their royal Highnesses and the Archbishop of Canterbury, the Bishop of Bath and Wells, the Marquis of Bath, etc. The souvenir is rendered complete by the story of the Abbey's history, told in an interesting manner, and also an account of the Royal visit, while the portraits are included of those local gentlemen who took an active part in the proceedings.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

1. Brookes, Castle Studio, Northwich. Photograph of Herbert Broomfield, Secretary, Football Players Union.
- A. Moore, 21, Sidwell Street, Exeter. Photograph of the Exeter City Association Football Team, Season 1909-1910.

SODA BISULPHITE.—I am afraid my query re diamidophenol developer was not explicit. I wanted the formula for bisulphite liquor, as I sent to chemists for same and they could not supply. Can you give the formula.—M. and SON.

As stated in M. Underberg's article, 2 grs. of soda sulphite cryst. dissolved in the minimum quantity of water, and with addition of 5 drops sulphuric acid is equal to 2 ccs. of commercial bisulphite solution of 40 per cent. strength.

GUILBERT.—The most likely cause we can suggest, supposing that the treatment of the prints in the acid baths has been properly done, is insufficient sizing of the paper in the first instance, or possibly the use of a paper of insufficient purity.

A. B.—Messrs. J. H. Dallmeyer, Ltd., 83, Denzil Road, Neasden, N.W.

COPYRIGHT.—A certain shopkeeper asked a photographer to photograph several views and make post-cards for him to sell in his shops. The picture side of the card has shopkeeper's name printed on the address side of card, the photographer's name, "—series." After some time the shopkeeper hears of another photographer, and for certain reasons wrote him and sent him one each of these post-cards, asking him to copy them and make post-cards, of course keeping the shopkeeper's name on the front of card. Of course, neither photographer has the right to sell them. They belong entirely to the shopkeeper. Is it right for him to copy them?—**QUERY.**

Certainly, the shopkeeper having paid for the taking of the photographs in the first instance can have them copied as he pleases and by whom he pleases.

FINISHING BROMIDES.—Is there any method whereby a bromide print can be worked up by separate washes in the same manner as a platinotype? If not, what is the recognised professional method?—**MAGDA.**

There is no universally "recognised professional method." Bromide pictures can be worked up in the same manner as platinotypes are, whether by washes of colour or otherwise. There are many different surfaces of bromide papers, and some may require a different method of working than others.

STEREOSCOPIC CURIOSITY.—I enclose herewith a print which was copied a good many years ago from an illustrated paper, but apparently the original was an engraving. The enclosed print when looked at through a stereoscope shows strong relief. Could you oblige me by saying how this result is obtained?—**J. F. DUTHIE.**

The relief is due to the fact that the print is a stereoscopic slide. The inscription states that it was "Stereographed, by permission, from the 'Illustrated London News,'" and you could find the original by searching the files for the period of the Crimean War. It may be a reproduction for a stereoscopic photograph, or

it may have been drawn stereoscopically. In the latter case it is a very clever piece of work. From the nature of the subject and the grouping we should say that it owes more to the draughtsmen than to the camera.

CLOUDS IN LANTERN SLIDES.—I shall feel much obliged if you will kindly advise me how to "print in" clouds in carbon lantern slides.—**H. WINGRAVE.**

The printing in of clouds by double printing in carbon lantern slides is by no means an easy matter. The simplest and the best way is to print the clouds on the cover glass. By this method very successful pictures may be secured with a minimum of trouble.

OZOTYPE, ETC.—I intend to try the ozotype process as described in Sir W. Abney's tenth edition, and procured the necessary chemicals for making the sensitising solution, as the manganous chloride and sulphate are very deliquescent, especially the former, I find it very troublesome to weigh a part without spoiling the rest. If I dilute each salt into its volume of distilled or boiled water (and then measure the required quantity), will it decompose? as I know not their stability or instability in diluted state, and am rather confused how to proceed. 2. Which is the best acid fixing bath for bromide papers that does not give sulphur fumes and that may be kept in stock solution, added to the hypo at time of use? 3. What material shall I use for making a tank to try development of negatives by the stand method? Will zinc do, and is it necessary to be coated to prevent corrosion of the metal?—**CIVIS.**

We think each salt might be dissolved separately in distilled water in quantity and the solution prepared from these stock solutions. We suppose you are aware that the process is patented and the property of Messrs. Ozobrome, Ltd., 122, Allcroft Road, Kentish Town, London, N.W. 2. Potass metabisulphite is the best acidifying agent. Add, say, $\frac{1}{2}$ oz. to a bath containing 4 ozs. of hypo per 20 ozs. of water. 3. Zinc rapidly corrodes in an alkaline developing solution. The best material is enamelled steel.

HALF-TONE POSTCARDS.—Would you kindly forward me the following information? I wish to produce a good enamel on half-tone post-cards. I have tried by floating prints on gelatine solution and then squeegeeing on glass, but have great trouble in them sticking, though I never had trouble with ordinary gaslight paper sticking. Is there any machine on the market for turning out quantities quickly? Would it make any difference if a hard gelatine was used?—**ALLEDALE (Auckland, N.Z.).**

By half-tone we surmise you mean prints made from half-tone blocks in printers' ink. We should say that the simplest way would be to coat them with a hard gelatine, allow that to well set, and then squeegee the prints on glass that has previously been soaped or rubbed over with French chalk. There is no machine for doing this class of work.

E. WELCHMAN.—The specimen you send is done by lithographic printing, such work being usually obtainable through the trade from German printing houses. We should say any litho printer could do a small job for you, but it would probably be somewhat costly. If we are not mistaken, the Autotype Company supply a similar article made by the carbon process.

ENQUIRER.—(1) From Messrs. Wratten and Wainwright. (2) From most ironmongers. The makers are Cementum Patent Company, Ltd., Tanner Street, Bermondsey, S.E. (3) On the score of convenience we think the advantage is certainly with the petrol lamp. As regards light, there is not much to choose between the two. (4) The titles are not written on the negative, but are applied by the method given on page 791 of the "Almanac," and frequently given in this column.

ROUGH PROOFS.—Will you be so good as to inform me, through the "Journal," if there is any way of preventing rough proofs from toning?—**PYRO.**

So far as we are aware, there is no method by which rough prints can be rendered "toning proof" without impairing their appearance before they are submitted to the customer.

LENS.—We do not appraise the value of second-hand apparatus. Your best way of getting an idea of the value of what you have to dispose of is by consulting our advertisement columns, and seeing what the dealers in second-hand apparatus quote for such things as you wish to sell. You say that one of the lenses has "Dall-

meyer's name on it." If you are in any doubt as to its genuineness, and send, or take, it to Dallmeyer's, they will tell you whether it is their make or not.

OLD LENS.—Could you tell me through the "B. J." if the following lens is of any value, and what kind and size of work it could be used for? The lens is marked "Lerebours et Segretan, à Paris." It is about 12 in. focus, with 3 in. diameter lens. Stops in front of lens. The front and back lenses are of the same size, but differ in "composition."—LYNN.

From the description, we should say that the lens is a portrait lens of early construction. From the fact that the stops are fitted in the front, we judge that it was made fifty, or perhaps more, years ago. If it is 12 in. back focus, it is what was called a whole-plate lens. At the present time it has practically no market value; probably not more than a few shillings. Still, it may be a useful tool. Better try it by taking a negative or two, and see what it will do.

H. J. G.—If you have advertised, or publicly stated, that your competitor has infringed your copyright, while from what you say you cannot possibly have any copyright in the pictures, you must not be surprised that he threatens legal proceedings. The best thing we can advise you to do is publicly to apologise for the wrong you have done; that will, possibly, save legal proceedings being taken.

UNSCREWING LENS.—Will you please tell me how to get a lens out of its mount? It seems to be screwed in so tightly that it defies all my strength to unscrew it. The lens is about two inches in diameter.—FIXED.

Run a little paraffin oil round the thread of the screw and let it rest till next day. It will then generally be found that the lens will unscrew easily. If it does not, gently tap round the outside of the mount evenly all round with a piece of wood. That treatment seldom fails.

RENOVATING LENS MOUNT.—My studio lens by long use had become in a very shabby condition. To improve it, as I thought, I thoroughly cleaned it with emery-cloth. I got the metal bright enough, but it really looks worse now than it did before, though the brass is quite bright, but shows scratches. How can I mend matters.—A. S. CONSTANTINE.

In the use of the emery-cloth you have removed the lacquer. The only thing now to be done is to have the mount relacquered by an optician, or a good brass finisher. You may, however, greatly improve the appearance of the mount in the following way:—Get some flour emery-cloth, the finest grade, and with it work out the scratches already made. That done, get some fine emery-paper, known as "blue back," and use that to get rid of the fine scratches left by the flour emery-cloth. In all the work the polishing medium must be used in one direction, and that only, namely, round the tubes. When a fine polish, free from all traces of scratches, has been obtained, the tubes must be lacquered. At most of the shops that make a specialty of varnishes a cold lacquer is sold. This is much easier for a novice to use than the ordinary, which requires heat, while the result is nearly as good.

DIFFICULTY IN MOUNTING WITH GELATINE.—Can you enlighten me in the following:—I want to mount some large (12 by 10) prints specially with gelatine, but I cannot get on with it. My difficulty is that when I have coated the whole of the back of the print the gelatine has set and will not hold to the mount. I have tried with three of the most expensive sorts in the market and they seem to all behave the same, so that it cannot be any fault with the gelatine. I have used the solutions both thick and thin, but that seems to make but little difference.—T. J. BRIDGOOD.

Your trouble is due to the use of an unsuitable gelatine. It has been of too good a quality. The gelatine best for the purpose is one of low quality as a gelatine. What is required is of the kind known as soup gelatine, or such as Nelson's "No. 2 soluble." With such as these you will have no difficulty with a moderately thin solution in coating the back of 12 by 10 pictures before any portion gelatinises.

NOVICE.—To copy a photograph the same size as the original with a lens of nine inches focus, the camera must be capable of exten-

sion to eighteen inches. It matters not what size the original may be, whether quarter-plate, cabinet, or whole-plate, the same conditions obtain. To copy any size picture the same size as the original the camera extension must be double the focal length of the lens employed. That holds good in all cases. For convenience in working it is well to have the camera an inch or two longer than is actually necessary.

D.O.N.E.—As the canvasser worked on commission only, with no salary, he was in law not a servant. He was only acting as your agent. That being the case you cannot proceed criminally against him. All you can do is to sue him in the county court for any sums that may be due from him to you. If he had been in receipt of a salary the case would be different.

CUTTING GLASS.—Will you please tell me how to cut down negatives, say from half-plate to quarters? I have bought two or three of the wheel cutters sold for the purpose. Sometimes I succeed all right, but more often than not I break the negative. They seem to lose their cutting powers after they have been used two or three times. Glazier's diamonds are so very expensive.—C. R. JOHNSON.

Some of these wheel cutters are usable for a time, but they are not to be depended upon. When they were first introduced, now many years ago, they seemed to be of a better quality than now, but they were of a higher price than at present. We remember having one in use for a year or two which was very useful. Nothing is so good for cutting negatives as a glazier's diamond.

GUTTA PERCHA.—The thin gutta percha in sheets, such as you refer to, may be had at most shops that supply indiarubber goods. It may also be obtained at many chemists' shops, as it is sometimes used for keeping bandages in a moist condition.

INDIARUBBER SOLUTION.—Will you please tell me how to make an indiarubber solution, such as you mentioned a few years ago, for producing carbon prints on Japanese papers? I have got some rubber ("bottle rubber"), cut it up into shreds, and put it into a bottle with some pure benzol. After digesting for days it does not dissolve. It merely swells up like gelatine does when soaked in cold water. Can you assist me?—RUBBER.

Some kinds of rubber behave in this way. What you had better use is what is known as "masticated rubber," or, better still, buy a tin of rubber solution and thin that down with benzol. This, and the masticated rubber, may be had from Hancock's, Goswell Road, E.C.

PROPOSED VISIT TO THE EARL'S COURT EXHIBITION.—We are informed that arrangements have been made for photographers to pay a visit to the Earl's Court Exhibition on Saturday, September 18, on payment of 1s. 6d., which includes admission, permission to photograph, and tea in the Quadrant Restaurant, and entrance to a meeting which is to be held in the evening at 8 o'clock under the presidency of the Rev. F. C. Lambert, M.A. Arrangements for this visit to the "Golden West" Exhibition have been made by Mr. Ernest Human, in conjunction with the London and Provincial Photographers' Association. Application for tickets should be made on or before September 15.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Messrs. Wratten and Wainwright have issued a booklet on lantern slides which contains the results of some important investigations. We reprint part of the booklet (p. 726), and comment on the subject in an article. (P. 719.)

An interesting article on "The Comparison and Measurement of Density and Contrast," by Dr. G. H. Bryan, F.R.S., describes a very simple form of photometer. (P. 723.)

The Salon is very fully reviewed. (P. 720.)

We describe a simple method of estimating the proportions of enlargements. (P. 719.)

We point out some advantages of film negatives for the single transfer carbon process. (P. 717.)

Some precautions advisable at this time in view of the rapidly falling light are suggested. (P. 718.)

Under "Patent News" this week will be found a new method of making a three-colour screen-plate. (P. 730.) A clockwork developing table is also described, and a one-solution sensitizer for ceramic work. (P. 731.)

In "Analecta" a new method of obtaining green tones on bromide prints is described. (P. 732.)

Another case of photographic canvassers being fined for failing to make out pedlars' licences is reported. (P. 734.)

A correspondent suggests smearing untuned proofs with celluloid varnish to prevent any subsequent toning being effected. (P. 735.)

EX CATHEDRA.

Films for Carbon Workers.

Given a good average negative of reasonable strength there is no print so easily made as a single transfer carbon print, and no other process gives anything like the same possibilities of securing varied results. The colour may be anything from red chalk, through an infinite range of warm and cool browns, to engraving black. The surface, as rough or as smooth as any other printing process will yield, and the colour of the support, white or tinted, bring still further variations. The one drawback is that single transfer prints are reversed laterally, and if the double transfer process is employed for occasional work the perfect simplicity of the process is to some extent lost. Not that double transfer is in itself difficult. At the same time the risk of failure is increased with each additional operation, and blistering is more apt to occur on the temporary support than on a single transfer paper of ordinary character. When an occasional order is taken for carbons we would suggest the negatives be taken on a film, and the Kodoid plate forms a very handy method of doing this without the need of any special appliance for holding the film. This plate may be used in the ordinary dark slide, placing behind it an old negative if the pressure spring be at all strong, to prevent any bulging of the cardboard and film surface. Negatives on films may be printed from the back, and the single transfer carbon print is then non-reversed, while the film is always available for any of the ordinary printing processes.

Show Room Specimens.

A remarkably effective method of exhibiting specimens in the show room is to have a slightly sloping shelf fixed along one side of the room, just the width of the length of the mounts in use. Along the front edge of this shelf a bead of wood is firmly attached, both bead and shelf being stained a neutral shade of brown. Cut to fit this shelf are a number of sheets of stout glass, and under the glass the specimen prints are laid. Card mounts should not be used, unless the prints are dry mounted or merely attached by the two top corners, for the cockling of a card mount will prevent the glass from lying flat. Of course, the ideal thing is a sheet of plate glass, possibly three feet long, and with polished edges, but if economy must be studied carefully selected stout window glass may be used, the sharp edges being taken off with a fine flat file, used *wet*. The shelf should be fixed along a wall at right angles to the window or windows, so that the specimens may be in a good light, for the idea is to show them through the glass, which protects them at once from the dust and from the wear and tear of handling. The expense of frames is avoided and it is a simple matter to change a dozen speci-

mens displayed in this way, the time taken being less than that required to remove one print from a bradded-up frame and substitute a fresh one.

* * *

Exposure in Early Autumn.

During the next few weeks the professional worker will have to face two changed conditions which have an adverse effect on his work. The light is failing—failing rapidly too, and under-exposure will frequently be found on development unless this changing character of the light is borne in mind. Not only does the declining altitude of the sun make the light actually weaker, but the autumn mists, particularly in the morning and late afternoon, filter out a good deal of the actinic rays, and so render the light less strong than it would appear to be from a visual inspection. Few professionals ever think of testing the strength of the light in the studio occasionally, yet an actinometer is so inexpensive an instrument and the test so easily and quickly made that there is really no excuse for the neglect of so obvious a precaution. As a rule most of the studio work is done with one stop and with plates of the same brand and rapidity, and if the strength of the light is taken at, say, 10 o'clock, 12.0 and 3.0 on two or three days each week a ready method of checking exposures is at hand without any calculation, for the camera exposures will be proportional to the meter-times. It goes without saying that the studio worker who is making sixty or eighty exposures per day becomes so accustomed to light variation, especially if the plates are being developed by an assistant immediately after exposure, that the actinometer is almost superfluous, but the operator whose connection is less extensive, and who, perhaps, has three or four sitters a day, as is the case in many small businesses, would find the meter a great help in light of a fluctuating character.

* * *

Temperature and Development.

The other condition to which we alluded in the previous paragraph as now rapidly changing is the temperature. In cold weather development is always much slower. All experienced workers know that during the dog days it is almost imperative to add bromide of potassium to the developer to prevent chemical fog, and do add it, though under temperate conditions they may prefer to omit it. Just as heat accelerates development cold retards it, and with the approach of colder weather the time of development must be increased and harshness must be guarded against. Much depends on the water supply, however. If the supply in the dark room comes direct from the mains it will generally be found that well into the autumn the water temperature will be high in comparison to the air temperature. Sea bathers know that the temperature of the sea is higher relatively to that of the air in late autumn than in early summer. If, however, water is stored in a cistern in the roof or other somewhat exposed position the temperature will not be so equable. Again, where the water supply does not come from large reservoirs and through great lengths of water mains, greater variations in the temperature will exist, and some spring supplies are very cold even in summer weather. As no general rule is possible we can only suggest that each worker should look into the matter for himself, for it is by attention to these variables that working conditions can be standardised and the failures or defective results lessened in number.

* * *

Halley's Comet.

The reappearance of this historic comet has been announced by Prof. Wolf, of Heidelberg, and his discovery has been confirmed by the examination of some photographs made at Greenwich a

few days previously. For the next two or three months it will be visible to the camera alone, and not till the end of January next will it be observable in small-size telescopes, while the unaided vision will not be able to see very much of it until April, 1910. Indeed, photography has succeeded in detecting its approach about seven months before it will be visible to the eye of the average person, which fact is a somewhat startling example of the enormous value that photography is to the astronomer. It may be noted that Halley's comet is of special interest to Englishmen, as it is the one that appeared just before the Norman Conquest. It was taken as a good omen by the invaders, while it terrified the English, and in record of this fact it was represented in the Bayeux tapestry. Photographers, however, need not expect their photographs to resemble the tapestry version, for, apart from the fact that this owed a good deal to the imagination, it seems that the brilliance of the comet has decreased considerably since those early days.

More Spirit Photography.

From a letter published in "Light" we learn that a Mr. Wyllie, who appears to be a producer of psychic photographs, is on his way to this country, if he has not already arrived, for the purpose of giving sittings. The writer of the letter suggests to the secretaries of the leading societies that at least one society in each district should form a sub-committee to arrange sittings, including test sittings "conducted by persons of ability and repute—and especially by well-known spiritualists." It is suggested that "this would be much better than for self-appointed and irresponsible individuals and amateur photographers, who know six or sixty ways of producing sham spirit photographs, but no single way of producing a genuine one, from harassing our invited visitor with their insulting absurdities." We presume that spiritualistic societies, and not photographic ones, are referred to in this letter, as the latter would hardly be likely to respond to such a courteous invitation. We note that if no "extras" appear on Mr. Wyllie's plates he is to be held blameless, while if they do appear the extras are guaranteed to be genuine. It appears that the first sittings are to be held at Rothesay, and at these amateur photographers who wish to photograph the sitter while Mr. Wyllie is doing his work are to be excluded. Why, is not very clear, because it would seem that two or more photographs made simultaneously by different people would afford good evidence in favour of the genuineness of the extras in question. Past experience, however, shows that genuine psychic "extras" never do appear in the presence of photographers who do not happen to be believers in spiritualism. "Reputable photographers will be allowed to assist, but "gentlemen who are dominated with a fixed idea of fraud" will not. This will, we fear, exclude many "reputable" photographers who have "assisted" at similar demonstrations before.

The R.P.S. Exhibition.

This exhibition opens to the public next Thursday, at the New Gallery, Regent Street, and will remain open till October 3. A certain amount of special interest attaches to the Pictorial Section this year owing to the fact that the selecting committee is almost a new one, including but only of the last year's members. Whether the change will be in any way reflected in the pictures on the wall remains to be seen. The private view takes place on Wednesday from 11 a.m. to 4 p.m. and will be followed in the evening by the annual soirée. The list of lantern lectures to be given in the evenings upon which the exhibition is open appeared in our issue of August 20.

ADVANCES IN THE MAKING OF WARM-TONED LANTERN-SLIDES.

THE article by Messrs. Wratten which we publish in this issue not only gives very full and complete details of the various methods of utilising Wratten lantern plates for making warm-toned slides, but also adds very considerably to our knowledge of the scientific principles that govern the production of warm tones. Hitherto the cause of the tones given by modifying exposure and development has been largely a matter of speculation. Various theories have been propounded, but very little experimental work has been devoted to investigating the matter, and as a consequence the results have sometimes been looked upon as of doubtful permanency. As it has now been demonstrated that the images consist practically of silver only, and that the colour does not depend upon the residual salts of silver left in the film, these doubts are dissipated. It must, however, be remembered that the tests described refer only to the Wratten plates, which are bromide plates, and that the conditions which prevail in bromide emulsions need not necessarily be exactly the same in the case of chloride plates. Further experimental work on similar lines with the latter plates would be very desirable in the interests of scientific knowledge.

Up to the present, many workers have shirked the development method of producing warm tones because they found the final result to be one of considerable uncertainty. The ultimate colour was often either warmer or colder than desired, and the conditions governing the exact tone were too vaguely understood to enable one to hit any desired colour, besides which, the colour could not be judged by inspection, as it changed considerably in the course of drying. A further trouble was the fact that the density of the slide could not easily be judged. These difficulties were not imaginary, but very real ones, for it is next to impossible to foretell the final result by merely examining the wet slide. The time system now introduced has, however, got over these troubles completely, and from practical experience we can say that it is perfectly easy to attain just the right final tone, if in the first instance we ascertain accurately the right exposure for a black-toned slide. A little care is necessary here, for such slow emulsions have considerable latitude, and very good results can be produced from slides that are exposed for a longer time than that really necessary. The unit of exposure should be the shortest one that will give a good black tone with the normal developer, and when this is once ascertained all the other tones can be attained with certainty by merely modifying exposure and development in the way shown by the tables.

At times complaints have been made that red tones produced by development methods are liable to change, or are, in fact, impermanent. We have noticed such changes ourselves in the case of chloride plates, but not with the Wratten bromide plates, for which the system of development described has been worked out. These changes may be due to the existence of a larger residual image of silver salts in the chloride plates than exists with the bromide plates, but, also, they may be occasioned by varying degrees of moisture in the films. If a warm-toned slide is wetted, a very remarkable change of colour at once takes place, and it appears quite likely that the colour normally varies, perhaps to only a very slight extent, with the amount of moisture present in the gelatine. The best preventive of such changes is to varnish the thoroughly dried slide with some reliable waterproof varnish, such as celluloid, which, indeed, is a precaution that should be taken with all slides. Still, even with chloride plates we have only noticed a marked change of tone in the case of pure red or pink tones, which are in general such undesir-

able tones that it does not matter much whether they are permanent or not. We have submitted toned images on bromide plates to fairly severe tests in strong, hot sunlight, and found no visible change, hence when it occurs with chloride plates the most probable explanation seems to be the darkening of the residual chloride image.

An interesting point is raised by the statement in the paper that the residual images found in both fast and slow lantern plates were completely soluble in a fixing-bath. It may be remembered that Messrs. Piper and Carnegie in their investigation of the action of the chromium intensifier found similar residual images in negative plates which were quite untouched by a fixing-bath, while in chloride lantern plates a similar image of remarkable strength and density was found. It would seem that these insoluble images are worth further investigation, for no satisfactory explanation of their existence or of their composition is at present available.

RELATIVE PROPORTIONS OF ENLARGEMENTS TO THE ORIGINALS AND HOW TO FIND THEM.

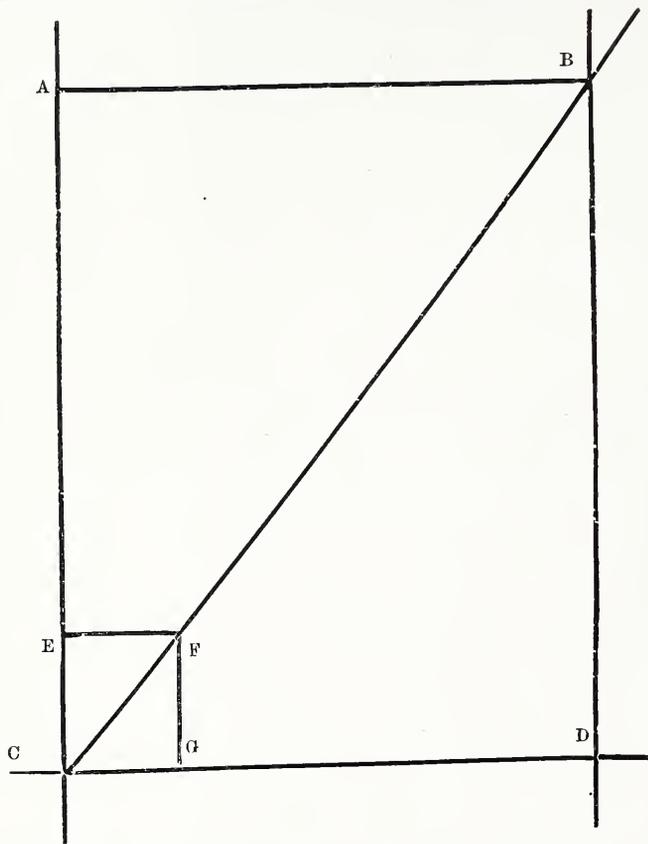

THE pictorial side of photographic picture making is without question receiving more attention on the part of photographers, both in portraiture and landscape work, than it has hitherto done. Greater attention is now paid to the trimming and mounting of the work, and it is fully recognised that the artistic merit of a picture in great measure depends upon quite small things—such as the cutting away of the subject included in the negative in one or other direction, or, possibly, both. This applies equally to portraits, landscapes, and figure studies. Very much frequently depends upon the judicious use of the trimming knife. A half or a quarter of an inch off the subject top or bottom, or off one side or the other, may make all the difference between an artistic production, and the reverse. As this applies to the effect in small pictures it is obvious that it applies in an amplified degree to the case of enlargements made from them.

Those who do their own enlargements are able to see by the enlarged image on the focussing screen how much, or how little, of the subject it is desirable to include in the finished picture and act accordingly. But not a few, both professionals and amateurs, do not make their own enlargements; they send their negatives to professional enlargers with instructions to make the enlargement of a certain size. Now enlargers have their regular set sizes as shown in their price lists. But in very many instances they are not of the same relative proportions as those of the original negatives that have to be dealt with. Therefore if the negative is sent to have an enlargement made of a given size, as per price list, it may happen that if the whole of the subject in one direction—say, the length—is made the full size, then the width of the paper is more than sufficient to include the subject in the other direction. On the other hand, if the width be made the full size it is manifest that something must be sacrificed in the length, and if that is done the picture may be considerably marred by the angle of view being curtailed.

Few of the set sizes as given in price lists are in unison with those of negatives. There are, however, one or two exceptions—the 5 x 4 and the 20 x 16 for example—they are in exact proportion. With the picture postcard size (5½ x 3½) obviously they are not, so that it is impossible to make a 20 x 16 enlargement from that size original which will fill the whole of the plate, or paper, as the case may be. If the full amount of the subject is included in the longest dimension it is clear that there must be a large amount of blank space the other way. On the other hand if the narrowest dimension be filled out then a considerable

proportion of the length must necessarily be left out. This fact is often overlooked, and we have heard from professional enlargers that when pictures have been sent home customers have complained that the enlargements have not been the full size ordered—as per price list.

The above trouble could, of course, be avoided were the

photographer to send with the negative a print trimmed according to what he thinks the best proportions, with instructions to make an enlargement so that it will include that portion of the negative on a given size paper. If this were always done there could be no disappointment and much trouble would be saved, particularly when the enlargement has been expensively finished to the order of the photographer.

It is easy by the rule of proportion, which we were all

taught at school, for the photographer to arrive at the actual size each way that the enlargement will be from any size negative—or any portion of the subject, that has to be included in the picture. But there are many who do not like figures, especially when fractions of an inch are concerned. There is, however, a very simple method of arriving at what the amplified proportions of one dimension will be to another without any arithmetical calculations at all. It is as follows:—Let us imagine that we have a negative, say of the half-plate size, to enlarge, and we wish to have a certain dimension of the subject in one direction of a given length and want to know what will be that of the other.

We take a sheet of paper somewhat larger than the enlargement is to be, a newspaper will answer the purpose quite well; indeed it will be very convenient for the purpose, inasmuch as the margins are always true and the lines of printed matter will serve as a guide for parallelism in the diagram we have to draw. The newspaper we will suppose is represented by A B C D. In one corner we set out the size of the small already trimmed picture represented by E F C G, or better still secure it in that position. We then rule a long line, diagonally, through the points C F to B. This done we have only to mark on the line A C the length the picture is to be and then from that mark rule a line at right angles across the paper. The distance from the mark on the edge of the paper to where the line intersects the diagonal one gives us the correct width the enlarged picture will be. If, on the other hand, we desire to know what the length will be from a given width we measure that on C D, mark it and then rule a line at right angles from that point to where it intersects the diagonal and that will give us the length the enlargement will come.

It need scarcely be mentioned that by proceeding in the reverse direction it is as easy to arrive at what will be the dimensions—each way—of a small picture when reduced from a larger one. This is often convenient to know when a small copy has to be made from, say, a larger painting. In this case, of course, ruling lines of the picture is out of the question, but the matter is still simple enough; all that has to be done is to stretch a fine cord or thread diagonally across the painting and treat that as the diagonal line in the diagram, the bottom or side of the picture serving for the lines A C, C D.

THE SALON.

THERE are two innovations in the exhibition of The Linked Ring in Pall Mall. The first is the absence of the usual American work, with the exception of ten pictures sent by half a dozen people; the second innovation is the presence of a loan collection (the first of a series, we are told) of photographs bearing an interest apart from the rest of the exhibits. This collection is a sort of "Old Masters" or "Deceased Masters" show in the manner of the winter displays at Burlington House. It is comprised of originals and reproductions of the masterly work of D. O. Hill, who practised photography in its infant days when present pictorialists were for the most part neither born nor thought of. That his subject matter should be good is not surprising when it is remembered that he was a talented painter—a member of the Scottish Academy; and that he succeeded so well technically only proves him to have been a man of skill and resource as well as an artist. Had he been a clerk or a counterman we could better understand the note of wonderment and adulation sounded in his praise in the catalogue. If his works here shown do indeed put to shame the modern man working with modern advantages the obvious conclusion is

to the detriment of the modern man. It is not salutary that Hill should be regarded as an abnormally shining light in artistic photography. We imagine that few pictorial photographers would care to acknowledge themselves as lacking artistic vision and technical skill; yet this contrast between old work and new must be accounted for somehow. One or the other is off the normal line. "Oh," say the moderns, "let Hill be above the line, otherwise we shall be said to drop below it."

To come now to the moderns. Miss Warburg leads off with "Portrait" (1). It is fine in its way; the forehead and hands are full of beautiful modelling; but what of the whole thing? Why this quasi old German style, and the flatness of the body and its clothes? It is not sufficient to supply modelling in the face, which may yet be flat, like a bas-relief. Hill's heads are round things, and his figures have action and animation. In the "Portrait Study of a Young Girl" (6) Mrs. Käsebier comes up to Hill's mark. To look from that end wall to her young girl is to suffer no shock, no disappointing drop. But in the next but one, "Le Roy Beaulieu" (9), she falls back again to the photographer's ideal of superficiality. This gentleman,

esting as he undoubtedly is, and frail also, no doubt, has the form and texture of a flower that has been pressed for years in a book. Between these extremes comes her third, an exquisite piece of sentiment, entitled "When the Sands Are Running Low" (7), and representing two ladies, one of middle age, who clasps the head of an aged friend or relative. Here again everything is sacrificed to the faces, the modelling of which is almost monotonous in its wealth and delicacy. No one can but admire the beauty of the idea and the design of the work; but it sounds the prevalent note of photography of this class—truth that is falsely given: microscopic modelling that misses the truth: analysis at the expense of synthesis.

Furley Lewis's well-known formula is exemplified in his "Mirie Macdonald, Esq." (3) and a safe one it is artistically, though likely to land him into mannerism. At any rate, he gets design and evidence of life in his sitters. In this respect he ranks with F. H. Evans, whose portraits are models of taste and accuracy. The forceful "Hubert Bland" (32) is perfectly arranged with the characteristics of the handsome sitter in view. And when we come to that "A. J. V. Chodyko, Esq." (36) of Malcolm Guthrie, and we ask ourselves what is the use of that display of historical models of portraiture on the end wall? Is Mr. Guthrie not absolutely and entirely without any vestige of ideas to design, composition, posing, modelling, tonality, that he should suffer this thing to occupy valuable space in his name? If it is not, then why does he suffer it, and why do his brother photographers suffer it? O! for Steichens, Stieglitzs, Coburns, and Hoppers again if this is what creeps in in their absence! E. O. Hoppé has made great advances. "Jerome K. Jerome" (54) and "David C. Murray" (55)—the latter might have been given the initials "R.A."—are two good things, especially the Jerome. Like Mr. Hoppé's series of German gentlemen will help his reputation. They are all fine subjects, handled with keen appreciation of their merits. In his treatment Mr. Hoppé has become tedious. Why do photographers think that a print stained to a deep amber is better than one in its natural scale of light and dark? What are they supposed to be emulating? Is it the staining of antiquity in museum examples? because that is a thing which would all gladly obviate. When Mr. Hoppé puts his "copper-tinted divinities" upon harsh light-grey mounts the total effect sets one's teeth on edge.

J. Craig Annan has better traditions. His "William Strang, Esq., A.R.A., LL.D." (72) is a perfect portrait managed with rare skill and taste in the lighting and background. "Grant Richards, Esq." (70) is less good, being a little unfortunately placed on the paper, and suffering from the impression that the sitter is sitting upon something uncomfortable in his coat-tail pocket. "Eustace Calland, Esq." (64) is a portrait of a different order, smaller in scale and in light silvery tones. Here the figure—what there is of him—is merely accessory, being overwhelmed by the dining-room effects. Three ghostly heads of figures come from Augustus Thibaudeau, but they do not interest us much. There appears nothing clever or happy in mere faces that can only be seen properly from the opposite wall. Any enlargement can boast that effect. A "Portrait" (84) by Francis Bruguiere is much nicer, being a choice piece of modelling relieved at one side by a bright window curtain, and a very effective "Portrait of a Young Girl" (91), said to be by Gustav Courant—we always thought the gentleman's name was Courant—is a captivating picture of a damsel in fancy costume. The print is charming, in spite of a curious stripey treatment in the background. Mrs. Anny Heimann's two intimate profile profiles, called "Geschwister" (92) are worth attention. There is, indeed, Reginald Craigie's beautiful "Young Brunette" (95), so rich and varied in tones. Mr. Craigie has always been himself, and has not inconsistently run after every dodge that the fashion introduces. We are delighted also with Mrs. Courant's strong and skilful "Walter Nevelle, Esq." (100) which is modelling "in the round," not "in the flat." We fear, on

the other hand, that Eustace Calland's "Portrait Study" (103) can never be regarded as more than a piece cut out of a larger print, so aimless are its lines and masses. Will Cadby has three of his delicate child studies which are, in our opinion, much better than anything else he has done in the same way. The best is certainly the little boy busy eating and drinking, which is called "Important Business" (111). In this we do not miss essential qualities as we used to do in earlier studies. Though a light key is employed the thing is "all there," as the phrase goes. H. Mortimer Lamb's "Portrait" (112) is of a lady so lugubrious as to spoil our pleasure in it.

That finishes the portraits as far as we are concerned. Of the landscapes we are pleased to note that they are, on the whole, a distinct advance upon those in recent shows, though many of them belie those noble sentiments embodied in the catalogue's Forewords. Starting at the commencement again we come to "The Harbour at Low Tide" (2), by J. C. Warburg. It puzzles us. Under what natural conditions, we may fairly ask, does a view appear at all points, far and near, of equal strength and equal distinctness? This has the look of a faint stencil. We know Mr. Warburg to be a man of taste and discernment, and that he can talk with sustained eloquence upon matters of pictorial art. We are astonished, therefore, that he should out-Cadby nature in this way, and we hope he will immediately quit the anæmic school and return to robustness. Charles Job's "Seascape" (4) has the smack of nature, and is therefore more comforting. We could only wish that he had kept his foreground stretch of sand and flat water more equable in lighting. The only reason for a variation of lighting over these planes is the reflection of a light patch in the sky; but that need not have spoiled the sensation of flatness in the sand nor have entailed the conventional photographic dark corners. F. H. Cliffe, in his "A pillared shade, high overarched" (5), walks too obviously in the footsteps of Mr. Evans. There are other ways of treating church interiors. A gratuitous challenge of comparisons serves no good purpose. Let him do something better than Mr. Evans and we shall highly commend him. The Salon would not be complete without the annual miniature from Charles H. L. Emanuel, and here it is as pretty as ever: "The Fishmonger's Shop" (8). His "Paris Courtyard" (22) is of larger scale, but it suffers from hanging immediately over the Demachy, the quality of which it cannot boast, though it is quite good in other respects. John H. Anderson grows year by year towards a finer sense of style, and his work this year proves that his hand is equal to grasping the nettle of oil-printing. "A Windmill" (10) is within an ace of being the picture of the Salon; but a little falling short in natural truth debars it that distinction. He has here a fine composition and splendid pictorial material; moreover he has invested his print with an etching quality that is highly attractive. It fails, nevertheless, on account of a general flatness and an unconvincing sky. The natural lighting of the objects has been suppressed, and the tell-tale remains of this original lighting look ridiculously out of place under the clouds born of the brush. The sky also is very granular, which would not matter so much if it were only less granular than the solid and earthly things of the picture. Mr. Anderson should make a pilgrimage to South Kensington, or the British Museum, and study Rembrandt's etchings. His "Off Yarmouth" (11) is really better, though not so attractive. It has fine movement, and the water has a real washy swish about it. This also applies to the water in "Fishing Boats making Yarmouth Harbour" (18). Here we can almost hear the splash at the cutwaters. The sails and the shadowed parts of the hulls are, however, the ruination of all by reason of their unrelieved blackness. "A Harbour, Evening" (16) is nice in feeling and broad in style; but we should think some little glitter of light might have shown to advantage in the dark right-hand bank. Another etching-like print is the house-front elevation in the manner of Dutch art of the print shops. This Mr. Anderson

calls "Old Home Dortrecht" (23). Mr. Eustace Calland's "At the Seaside" (12) is frankly modern in style, subject, and sentiment, and possesses a deal of charm and sparkle.

In the four examples by Archibald Cochrane we have the true old Salon flavour of art beyond the comprehension of common folk—something so precious as to be naturally caviare to the general. Again we think of those Forewords, and wonder whether the misfortune of the artistic temperament is not sitting rather hardly upon this thoroughgoing Link. His least temperamental picture is by far the best, for it has a sky of tenderness with a touch of nature. This is "The Viaduct" (17), but the others do not appear to us to have that sincerity of motive that would entitle them to serious criticism. "The Ferry Boat" (20) of W. C. S. Fergusson is a little over soft and woolly. D. Giuseppe Tesio shows a really true effect of moonlight in his delightful subject of picturesque Italian houses. It is well named "Plenilunio" (24).

F. J. Mortimer, F.R.P.S., is well to the fore this year. Oil printing has done much for his artistic reputation. His "Bruges" (25) is highly successful, especially in its suggestion of vaporeous light across the canal and on the wall beyond. "Waterloo Bridge" (27) is perhaps the best of his works. The composition is first rate, and the picture is full of feeling and subtlety. We demur once more to the eternal dark corners, without which few photographs seem to exist. In "The Harvest Moon" (38) the impression is given that the moon itself is not so bright as its reflection. We feel, too, that in "The Mill on the Dyke" (76) the trees on the right are too dark; but we like the sky. "Tara Bridge" (77) had better have been omitted. Its composition is unpleasantly angular and its tones hard. "Lambeth Bridge" (78) is a much better thing. We admire the delicate way in which Mr. Mortimer has lighted up the lamps. Bertram Park essays a landscape, rather too heavily handled in oil, which he calls "Willow Pattern" (26). The title, however, must not be allowed as an excuse for a very formal and unpictorial view of horizontal bank and vertical trees. There is an appreciable feeling after effect here; but true landscape feeling does not appear. In a print of the straightest variety F. H. Evans shows what feeling may lie to hand in a natural view uncontrolled. "Dirge in Woods" (28), to which the catalogue supplies a Meredith excerpt, exhibits the solemnity that pine trees always seem to possess. The stately view well illustrates the poem. It is pure unsophisticated photography, free from dark corners and other defects. There is a nearer approach to control in "Spilt Sunshine" (29), though we do not suppose that control here went beyond a certain easiness of focus. It shows a woodland scene with a picturesque tree in front, and a middle distance where the sunshine is spilt in an effective streak. "Night on the Hills" (31) is a little gem of the utmost breadth. The great gable mountain towers up into the evening sky—all detail lost in the failing light. But such light as there is constitutes the picture. Seldom does one see so deep and luminous a sky in photography. We confess that the vertical lines of the pillars in "Bourges Cathedral" (30) are too much a series of upright lines for our enjoyment, though we believe Mr. Evans considers this the crowning charm of the collection. If only a charwoman had been there to shake a mat and fill this void with some softening dust motes there would have been less monotony in the length of these verticals. The interest of "Free Seats" (99) lies in the carved stall ends of the bare forms which accommodate impetuous worshippers.

Arthur Marshall gives us a repetition of an old success in his misty view of public buildings in "Dublin" (35). The magnificent pile of architecture and the sky are both fine; but they sadly need the set-off that the near boat should give them, which it does not do because it is too faint in tone. Mr. Marshall's other contribution is an attempt at realism in colour by the oil process. As such it is a highly creditable achievement, but as

a picture considered upon its own merits we must admit that it is somewhat sodden, and lacking in the breezy vigour that a sea piece, called "Away to the West" (107) would be expected to show. "Limehouse Hole" (37) is by Walter Benington, whom we regret to say, does not surpass his earlier efforts in pictorial photography. This absolutely unpictorial elevation of ugly houses is without any interest to our minds, and the lights in a window childishly picked out, have not saved the situation. "The Cab Rank" (39) is more ambitious and more successful and should have been a really good thing had Mr. Benington possessed more observed facts of the effect he portrays. The subject is a crowd of cabs in a railway terminus, beyond which the brighter light of day can be seen through the semi-circular roof—a fine subject, the beauties of which are missed. Mr. Benington stops his light hard and fast at the entrance of the station. He appears to be ignorant of the fact that the light would creep into the covered parts, flashing and glinting in less and less strength upon every available surface until all but lost in the foreground. Such an effect should be the soul of the picture. All his cab roofs are nevertheless innocent of the slightest stray ray, being uniformly dark from front to back where the light suddenly drops across the opening like a porch. The woolly "Gates of Fairyland" (45) is a park-like scene, including a small domestic group, but somehow it has no message for us. There is good design and open air in "Toile of the Field" (40), by R. S. Kauffman. We now come to a group of landscapes by Malcolm Arbuthnot, of which it is pleasurable to be able to say that they are far in advance of his figure work. Our old familiar branch across the picture—that never-failing resource of photographers—comes in well in his "Decorative Landscape" (41). Its lines are carried on in the meadow bay or whatever it is beneath, skirting which are two little figures in black and white, happily placed. "Water Sports" (42) is an interesting and animated scene of nice quality; but "La Laveuse" (43) is more smug and sophisticated. Better style and feeling exist in "Château Galliard" (44), where a castle on a mountain height is finely rendered with due realism. The trees upon the left, however, are formal, and lack pictorial qualities. By far the best of this series is "A Thames Wharf" (53). This is a most happy selection, which composes excellently, and has a good tone pattern. A charming little print called "On the Lagoons" (46), is the best work sent by J. Dudley Johnston. This little boat with set sail catches the light in a captivating way. The whole print is scintillating with light, and is full of subtle differences of tone that proclaim the proper spirit for work of this kind. But photographers are the most unrequited people in the world, and appear to be devoid of self-criticism. Mr. Johnston's next work, "A Venetian Impression" (47), has no sensation of light at all, although we can see the sun shadows that exist in the original negative. Why this hard indigo-drab record should be called an impression passes our comprehension. In "The Valley of the Dragon" (48) there is more mood. It represents a craggy valley, behind a peak of which a blazing sun peeps out, with that eating away of the contour of the rock which the strong rays would naturally cause. It is one of the most striking landscapes in the gallery; but for our own part we think the one strong beam that shines diagonally from the orb across the front of the hill is unexplained, for there is no apparent reason why the rays should show more just there than anywhere else. We have already spoken of "In Memoriam" (49), Mr. Johnston's last picture. We might add that the sculptured figures, seen in silhouette against the fog, are effective in the highest degree, and reflect credit upon the designer of the memorial as well as upon the present photographer. Another fine subject is David Blouin's "Tyne Bridges" (52). Unfortunately it is tame in effect, being in want of some sort of treatment that should imbue it with some of the sparkle and variety of the busy life it depicts.

We have now to speak of the landscapes of J. Craig Annand.

some of them he adopts an old-fashioned style of presentment, which harmonises with the calotypes of Hill. Indeed, in the case of "The Cooperage" (56) it is easy to believe that the old style of premises, the funny little shop, and the top-hatted gentleman have suggested to Mr. Annan a treatment in imitation of photographic prints of half a century ago. As a subject, "A Genoa Harbour" (57) is finer, though it has a treatment similar to "The Cooperage." Here horses and boats and the distant shore buildings combine into splendid subject matter. "Bolney Backwater" (58) we think a little too contrasted in tone, and its water too light in tone, for judging by the effect the sky which is reflected would be considerably darker than that which is seen, yet the water is lightest of all. "The White House" (59) and "The Water Garden" (63) are not so interesting as "The Ruined Castle" (68), hard and forbidding as it is and should be. "Man Sketching" (69) is in reality a close view of some rocky cleft. It is very impressive, and would be of greater success if Mr. Annan had come again some day when the man was not sketching. "Sloe Blossom" (71) is a hark back to the "æsthetic" manners of the early eighties, and shows an "utter" lady in profile contemplating a sprig of sloe in a sparkling glass.

Mrs. Minna Keene shows to good advantage here. Her two pleasant women, one plucking a goose and thus "Preparing for Christmas" (60), and the other "Combing Flax" (62), are both unusually good character pieces in rich bright prints. Her "Basuto Girl" (61) is only less good because of some emptiness in the shadows. Frank H. Read is not a well-known name, but deservedly will become so, for its owner evinces good landscape feeling. "The Bay" (65) shows us our old friend the pine ranch, beyond which a nebulous sort of landscape retires into a misty distance. The Bay itself looks not a little as though it owed some of its existence to the "putty rubber" of the painter. Some figures in a rowing boat under willows is the subject of "A Silhouette" (67), so called because they are in shade against the light. It is a most effective and charming little design, though we think the foreground is too long and the reflections of the trees too dark. When will photographers learn that reflections can never be so dark or so light as the objects that cause them? Mr. Read's "Outdoor Portrait Group" (66) is all good but the near back view of the man's figure, which is out of scale and generally awkward. Not every snapshot will bear enlargement just as it stands, and this is one that would not. Very depressing, but yet touching in a way, is J. Huysen's "Sickness and Poverty" (79), which shows a Dutch peasant ill in a panel bed and an old woman sitting by. It is a fine piece of work. More idyllic is H. Mortimer Lamb's little "Girl in the Rushes" (86), a tastefully treated figure.

Alexander Keighley adheres to his old methods, which are,

by comparison with those now in vogue, somewhat flat and tame. His subjects are worthy ones, full of fine pictorial possibilities; but they miss success because of the shortness of their tonal range. In "An Italian Courtyard" (93), for example, what shadows might lurk under the arches! And what fine effect of chiaroscuro could be given by the oil process! The same reflections are prompted by "The Rest Is Silence" (94) and "The City on the Hill" (96). The landscapes that please us as much as any here are those of Harry Wild, whose name we do not appear to have met before. His two mountain pieces are as full of feeling and romance as anything could be. "The Crucifix" (97) depicts a plateau or shelf half-way up the vertical side of a crag, and upon this, in the solitary fastnesses where the level ground is out of view, stands a solitary crucifix looking towards the soft and level sunlight. Not the least of the beauties of this view is the light that comes across the chasm to strike upon the sacred image. "Montsalvat" (98) purports to be the castle in which is guarded the Holy Grail, and here our imagination is stirred and helped by Mr. Wild's choice of view. The castle stands upon an inaccessible height towering and solitary with guardian peaks around it. Both prints show subtlety of mind and delicacy of workmanship. John M. Whitehead gives us once more his gentle fearsomeness of nature in a castled crag at the margin of the sea at sunset, with the title "Sic transit gloria mundi" (101). "Twilight" (102), by A. R. F. Evershed, is a gloomy woodland scene where the effect of light in the trees is suggestive; but there should have been a little more light on the path, for artistic and natural reasons. In the spirit of German landscape W. H. Porterfield gives us "Italian Woodland, Evening" (105). It has what the Germans call "stimmung," which might be translated as "a message," or "something to say." Without this romantic landscape is futile. Mr. Porterfield's picture does not rely upon deep blacks and indefinite depths. It is tender and full of light, and it makes an appeal that is absent in the similar subjects of Dr. Evershed and Mr. Park. An excellent colour-gum is submitted by George Hilderley, called "Light and Shadow" (106), and representing a bend in a narrow street. We have only to complain of the sky, which is too opaque and granular. But the sky of "Jan's Return" (108) is too awful for words. Another colour attempt, with a Dutch figure cut out against Dutch flats and an unpleasant sky, is by Arthur W. Ward. We have now arrived at the last picture, a pretty photograph of a "Cobweb" bedecked with dew. This, needless to say, is by Carine Cadby, and is distinctly more picturesque than some of her flower pieces, culled and without any apparent means of support. This spider's web is stretched across the points of some weedy growth—we forget the variety—but it is in its natural conditions, and is interesting from a point of view of natural history as well as of art.

THE COMPARISON AND MEASUREMENT OF DENSITY AND CONTRAST.

THE handbooks of instructions which commonly find their way into the hands of the photographic beginner generally contain but scanty information, if any, as to the precise meaning of density and contrast of negatives and the proper ways of measuring them. It is pointed out that, in developing, correct contrast is to be aimed at rather than uniformity of density, and that this end is secured by calculating the time of development according to certain rules, increasing the time if it is desired to increase the contrast, and *vice versa*. But in applying the rules mistakes are very easily made, and hence, when a number of negatives have to be developed, it is of importance to have a ready means of testing the contrast of the first batch without waiting till they have been dried and prints made

from them. Very often negatives which look very pretty when held up to the light do not give bright prints, while others which look as if they were hopeless yield excellent prints.

The measurement of density is equally important in calculating the exposures required for making lantern slides, bromide enlargements, or prints on any of the "gaslight" or other papers which blacken by development, and not by exposure to light. The necessity of some preliminary test became evident as soon as I commenced to enlarge a long series of snapshots taken on a summer holiday. Had it been necessary to make a preliminary trial for each separate negative on the test pieces, the series would never have got enlarged. What is needed is to compare the exposures required with negatives of

widely varying density in order that several can be printed off in succession when the proper allowances for the intensity of the light and speed of paper have been determined by means of one or more exposures on the test pieces.

At the time when I began experimenting in this direction I had not succeeded in obtaining definite information regarding the densitometer and the test box which have been patented for the purpose of calculating exposures in enlarging, otherwise I should probably have purchased one of these apparatus. It thus became necessary to devise and rig up some simple home-made arrangement which might possibly answer the purpose. When this was done it soon became evident that the device was even more useful for testing the contrast of negatives than for calculating their relative exposures in enlarging.

The simplest device that can be constructed for the purpose, and perhaps the best for those who work with artificial light, is the photometer shown in Fig. 1. It consists of a box open at both ends—a cardboard box would do, or a small table might be substituted—containing an opening in the top sufficiently large to allow of two negatives being examined side by side. Underneath the middle of the opening is fixed an isosceles prism, or double inclined plane of white cardboard, with the faces sloping up at an angle of 45 deg. or thereabouts. The two faces are to be illuminated by equal sources of light—say candles placed on opposite sides of the box. Now let two negatives be taken, and suppose in the first instance that they have the same *contrast*, but are of different *density*. Place them above the two faces of the cardboard prism. Then if the two lights are at the same distance from the faces of the prism,

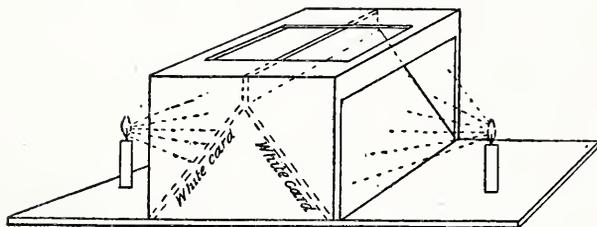

Fig. 1.

the denser negative will appear to be the darker. Now move the lights until the two negatives appear to be of the same density, and measure the distances of the lights from the two faces respectively. The illuminations on the two faces will be, by the well-known law of optics, inversely proportional to the squares of their distances from the sources of light, and their ratio will give the ratio of the total quantities of light required to produce similar prints from the two negatives, under similar conditions. If, for example, the distances are as 4 to 1, the quantity of light required to print the denser negative will be sixteen times the quantity of light required for the thinner negative. In order to make the time of exposure the same it would be necessary to expose the denser negative to a light sixteen times as strong as that required for the thinner negative. If, on the other hand, the intensity of illumination was the same for both, then, according to all ordinary assumptions, the denser negative would have to be exposed for sixteen times as long as the thinner one. I am not sure that it is always mathematically true that a certain intensity of light acting on a sensitised film for sixteen seconds will produce exactly the same effect as a light of sixteen times the intensity acting for one second, but this law is always assumed in comparing exposures with different stops, and it is sufficiently approximate for ordinary purposes. If the distances of the lights from the faces are as 3 to 4, the exposures will be as 16 to 9, or approximately 2 to 1.

Practically, it rarely happens that two negatives have exactly the same contrast. If the distances of the lights be adjusted so that the transparent parts appear equally bright, the opaque parts will appear darker in the negative which has the stronger

contrast. If, on the other hand, the opaque parts are made to look equally dark, the transparent parts will appear brighter in the negative having the greater contrast. We thus have an easy way of testing the contrast of negatives. A negative which gives exceptionally good prints should be taken as a standard. When the first one or more of a batch of fresh negatives have been developed and fixed, they may be compared with this standard, and it will be at once evident if they possess excessive or defective contrast. In such cases the necessary modifications of treatment may be decided on before proceeding with the remainder of the series. The photographer who has been misled by the appearance of his negatives when held up to the light will be at once disillusioned when he makes this simple test. Moreover, when he comes across an exceptionally weak negative he will not waste his paper and lose his temper over trying to get a print from it without previously taking some steps to remedy or overcome the defect.

If it is desired to test negatives while still wet, a preliminary test should be made by taking a negative that is of no use and soaking one half of it in water. On placing the dry and wet halves over the two faces of the prism, the effects of drying can be examined and allowed for in future observations. In comparing yellow negatives, such as those developed with pyro, with black negatives, such as those developed with hydroquinone, it is necessary to look at the two through a piece of blue glass.

An apparatus of this kind is very suitable in connection with

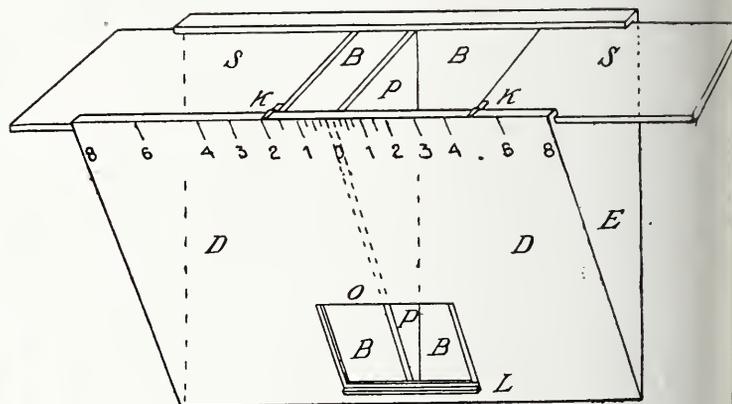

Fig. 2.

contact printing with artificial light. The simplest plan is to keep the time of exposure always the same, and to vary the distance of the printing-frame from the source of light, making it in every case proportional to the corresponding distance of the source of light in the photometer. The objection to the method is the trouble of always providing a pair of candles of the proper height. There is also the necessity of measuring the distances of the candles, though this difficulty can be got over by the use of suitably graduated scales.

For these reasons, and also because my principal object is to test negatives with a view to daylight enlarging, I use the "contrast gauge," of which Fig. 2 is an attempt at a representation, looking down on the apparatus from above, so as to see the front and back in one diagram. This very handy piece of apparatus consists of a large box of triangular shape or desk, closed at both ends and open at the back. The base B, is covered with white paper, and the whole of the interior should also be covered with white, not black, paper, so as to give as uniformly diffused illumination as possible. The interior is divided into two parts by a triangular partition, P, like the partition in a stereoscope, but also covered with white paper. Near the bottom edge of the desk is an opening, large enough to allow of the greater parts of two quarter-plate negatives to be viewed side by side on opposite sides of the partition, and the dark line, L, represents a ledge against which the negatives can rest. At the back are two shutters,

which can be slid in and out horizontally in grooves, and these carry pointers, K, whose positions can be read off on the graduated scale shown on the top edge of the disc.

The apparatus is placed with its back close up to a window which is exposed to uniformly diffused daylight. The two negatives to be compared are placed over the opening on opposite sides of the partition, and the light, falling on the parts of the base underneath them, is adjusted by drawing out the shutters. When these have been adjusted so that the two negatives appear equally dense, the readings of the pointers will give the ratio of the exposures.

The "contrast gauge," from its construction, is not mathematically accurate, but it gives results well within the limits of accuracy obtainable in calculating exposures. The deviation from mathematical accuracy lies in the fact that the illumination on either half of the base is not quite uniform even over the area underneath the opening. This defect can be remedied by making the apparatus large. In mine, which is suitable for quarter-plate negatives, the desk only measures 12 in. by 3 in., but a larger size would be better in this respect. If this should be found unwieldy, it might be easily made to fold flat when not in use. A further precaution is, where possible to compare those parts of the negatives which are near the partition and towards the bottom, for which purpose the negatives should be turned round into various positions, to enable different parts to be critically compared. Moreover, the observer should stand well over the gauge, so as to look down from above on the back parts of the base, which are most nearly uniformly illuminated. In adjusting the shutters they should be moved to and fro till the right adjustment is obtained, as, if they are left long in any position but the right one, it is very easy for the eye to make a misleading comparison.

In my gauge the full opening is marked 8, and there are graduations at the points representing $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{2}$, 2, 3, 4, 6. The range covered by this scale is sufficient for many purposes, and if two negatives are of such unequal density as not to fall within the range in question, the comparisons may be effected most easily by using negatives of intermediate density. On the other hand, the range of the instrument may readily be increased fourfold by fixing across the back on one side of the partition a grating of horizontal bars, the spaces between which are one-third of the width of the bars, so that only one-quarter of the light passes through them. Instead of this I use a piece of perforated zinc, the holes in which form about a quarter of the whole area. When placed in position on one side of the partition, the two halves of the base were found to be equally illuminated when the apertures of the shutters were as 4:1, thus testing the effect of the screen. For greater ranges of density a screen with a factor of 16 or more can easily be substituted.

In comparing the exposures of well-contrasted or over-contrasted negatives, the object is to bring out the details without sacrificing the high-lights. For this purpose the comparison must be effected between the denser portions. With an under-contrasted negative, the exposure must be sufficient to blacken up the shadows. Even with no negative at all, or with one in which the transparent parts are perfectly clear and glassy, a certain minimum exposure is needed for this; consequently, attention must be paid to the transparent parts in calculating the exposure. For daylight enlargements from weakly contrasted negatives I use a slow gaslight paper, with which, roughly speaking, hours have to be given in place of the minutes required by the fast bromide papers, minutes taking the place of seconds. An experimental test made by exposing the same negative on the two kinds of paper shows a very much stronger contrast on the slow paper, and in this way bright prints can be obtained from negatives otherwise hopeless.

In photographing a bright landscape with the sun high up

in the sky the well-known trouble crops up of the chalky foreground and leaden sky. The best cure, after the negative has been developed, is to estimate separately the exposures for the two parts and make the necessary differences with a moving screen. Sometimes the light reflected from the sky is stronger near the horizon than high up, so that by turning the daylight enlarger in a suitable direction the effect can be cured more simply. For P.O.P. prints I place the frames in sunshine in a place where the shadow of the edge of a window will slowly move across the frame as the sun changes its position; this is a very useful dodge, but the frame requires constant watching and moving.

If the testing is carefully done, two negatives with calculated exposures in the ratio of 100 to 1, or even 300 to 1, may be enlarged in succession, and the prints when developed together in the same bath will reach the stage of complete development almost simultaneously.

The contrast gauge makes a very convenient desk for retouching and spotting negatives.

I should strongly recommend every amateur photographer who wants to avoid failures to adopt some method of testing his negatives equivalent to the methods described above. Even for P.O.P. printing it is an advantage to recognise badly contrasted negatives, instead of making futile attempts at getting good prints from them. The remainder of this article is intended to give a simple account of some of the theoretical considerations underlying the measurement of density and contrast.

By placing a negative on one side of the gauge, or photometer, and no negative on the other, an absolute measure of the density of any part of the negative can be calculated. It is only necessary to reduce the illumination on the uncovered side till that side appears of the same darkness as the portion of the negative under observation. If then the ratio of the illuminations on the covered and uncovered sides is as 3:1, the photographic film only transmits one-third of the light falling on it, and we may say that its *density factor* is 3. For these comparisons it is useful to cover up the opening of the gauge with a card perforated with two holes, through which the part of the negative under examination and the uncovered base on the opposite side of the partition can be seen. Without such arrangement the eye is apt to be misled by the parts of the negative not under examination.

The ratio of the density factors of the thickest and thinnest parts of a negative may be called its contrast ratio. If the thickest part has a density factor of 48 and the thinnest a density factor of 3, the contrast ratio is 16. If we have another negative in which the corresponding greatest and least density factors are 24 and $1\frac{1}{2}$, this will also have a contrast ratio of 16, and if the second negative be given half the exposure as the first, the two prints will have the same contrast, provided the other conditions remain the same. Thus, if the ratio in question is the same for two different negatives, they possess the same amount of contrast. It does not follow that they will give equally artistic or picturesque prints, for a pretty photograph depends not only on the actual contrasts, but also on the way in which these are distributed over the various parts of the picture. So far as my experience is worth anything, a negative that is to yield good prints on self-toning paper or good enlargements on rapid bromide paper ought to have a contrast ratio of not less than 16. Yet I have a very transparent negative whose contrast ratio is less than 3 (tested with the aid of blue glass), and I have a rather good enlargement from it on gaslight paper, obtained by a prolonged "soaking" in very dull, cloudy weather, with care in directing the thinner parts of the negative towards the brighter parts of the sky.

Let us now apply the "Index Method" previously described in this journal by the present writer in an article reproduced from "Knowledge." Suppose that we have a film which trans-

mits half the light falling on it, and whose density factor is therefore 2, the index of this in the system proposed is 1. Let two such films be placed one above the other. Then each transmits only half the light falling on it, with the result that only one quarter of the original light gets through the combination, and the index is 2. According to this method, the density index of any film is measured by the number of films of unit index required to produce the equivalent density. If, then, we have several films of different thickness, but alike in every other respect, the density index of each film will be proportionate to its thickness.

This view of the matter may be easily tested by a simple experiment. Messrs. Marion, some time ago, issued a cheap set of three orthochromatic films giving 2, 4, and 8 times exposure. On placing the 2 and 4 times films in contact, and holding them up to the light, they will be seen to be identical in appearance with the 8 times film. And no better example can be given of England's neglect of mathematics than the fact that, to my knowledge, a firm some time ago advertised for sale a 3 and 5 times colour screen, and stated that by using them together an 8 times screen would be obtained! Of course, the real result would be a 15 times screen, and I can imagine many failures resulted which were not attributed by the users to the mistakes made by the manufacturers.

Next, suppose that we have an over-exposed negative, and suppose that the upper layer down to a certain depth is of uniform density throughout, so that the variations which produce contrast are all below this depth. Let the upper layer be removed by ferricyanide of potassium without touching the lower layer. Then the density will be reduced, but the contrast will be unaltered. It is only if the upper layer shows reversal that its removal will increase contrast. If there is any direct contrast in it, the contrast of the negative will be reduced instead of being increased by its removal.

Let us, in conclusion, ask the question why it is that a thin, under-contrasted negative looks so pretty when laid film downwards in contact with a sheet of white paper? The light which reaches the eye has to go through the negative to the paper and to come back again through the negative. If the contrast ratio of the negative is 8, then the paper receives 8 times as much light through the thin as through the thick parts and the proportion of the light so falling on and reflected by the paper, which, passing through the film on the return journey, is again 8 times as great in the thin as in the thick parts, consequently the contrast ratio appears to be 64 instead of 8; and it is easy to see that in all such cases the contrast ratio appears to be squared. It is not doubled; its index is doubled. The effect is practically the same as if two films, each similar to that of the negative, were placed one above the other.

The whole of the ideas in this paper have been worked out quite independently of anything which may have previously been written on the same subject. Whatever may be the result of future investigation as to the extent to which they have been already anticipated, it is hoped that there may be some interest in a paper written by one who has to get the results he requires by working things out mathematically, and who has neither the time nor the inclination to aim at attaining the same objects by compounding chemical formulæ.

NOTE.—The method of making transparencies of different density look equally bright by varying the illumination is practised by every lanternist when he tries to make the best of the lecturer's over-exposed failures by turning up the light. According to the present suggestions, the experiment should be tried with the negatives, and allowances made for variations of density when the positives are being printed. This would often save an explosion of gas on the part of the lantern, followed by an explosion of temper on the part of the lecturer.

G. H. BRYAN, Sc.D., F.R.S.

NEW METHODS IN LANTERN-SLIDE MAKING ON THE WRATTEN PLATE.

[Since the introduction some months ago of the new bromide lantern-plate by Messrs. Wratten and Wainwright, that firm has been investigating in its research laboratory the conditions under which warm tones are produced on the plate by direct development. The results are embodied in a booklet just published under the title of "Lantern Slides," and obtainable free on application. From the extracts made below and our comments on the results on another page it will be seen that the makers of the new "Wratten" plate have provided slide-makers with still further means of obtaining the widest range of tones with, at the same time, a full scale of gradation. The very succinct instructions in which Messrs. Wratten have embodied the results of their experiments certainly deserve to be regarded as a most important contribution to the practice of making warm-toned transparencies.—Eds. "B.J."]

Lantern Slides.

It is generally acknowledged that a really good lantern slide forms one of the finest prints which can be obtained from a negative. A good lantern slide should render the gradation of the negative from clear glass to full black with an almost perfect accuracy of range, and, while there should be very little clear glass in the slide, it is essential that there should be no trace of veil upon what clear glass there is. The first essential, therefore, of a satisfactory lantern plate is that it should work with perfect cleanliness and should resist fog, even under severe trial.

Not less important than cleanliness is the necessity for accurately rendering gradation. Plates of the "gaslight" type tend to give too great a jump between clear glass and the next tone, so that slides made on those plates seem to have an appearance of baldness in the high-lights; the delicate gradations of the sky, which are so well rendered in a negative taken on a panchromatic plate, may be lost in the making of the slide. These gradations are best obtained upon faster plates, and the Wratten "Ordinary" plates will give most exact rendering of gradation. Unfortunately, however, such plates will not give the slides of warm tone which are most in favour, and in order to get the pleasing sepias and browns which are required, most slides have hitherto been made upon plates containing more or less chloride of silver.

As a result of a series of investigations we succeeded in obtaining

an emulsion from pure bromide of silver, in which the bromide is so fine a state of sub-division that warm tones can be obtained easily as upon chloride plates.

Bromide of silver is very much more resistant, both to development fog and to climatic effect, than chloride of silver, so that the emulsion will withstand development to a greater degree than an lantern slide emulsion previously prepared, and the plates may all be relied upon to keep under the most trying conditions of climate. Moreover, the use of bromide of silver ensures that the gradation shall be satisfactory, and especially that the finer gradations in the high-lights are retained unimpaired. A bromide of silver emulsion is therefore in every way preferable to one containing chloride.

The Development of Warm Tones upon Lantern Plates.

While lantern plates which have been developed to a black tone can be changed in colour by an after toning bath, this not only involves a separate operation, but it is the opinion of expert workers that slides prepared in this manner are rarely so satisfactory, either in tone or gradation, as those in which the warm tones are obtained during development.

The cause of the warm tones obtained by developing lantern plates with a solvent of silver (usually ammonium carbonate) present in the developer has been a subject of considerable discussion without

very definite results based on experimental evidence having been arrived at.

The general opinion seems to have been that the image developed in this manner does not consist of pure silver, but of a mixture of silver with more or less silver bromide, which, owing to its close association with the silver, is not dissolved out by the fixing bath, and, on this view, the warmer the tone the greater would be the amount of bromide present.

In order to investigate the matter we took a fast plate, developed to a black image, and also a slow lantern plate, developed by the aid of ammonium carbonate to a bright red image; the two plates were then treated with an acid permanganate solution (which removed the silver), and, after washing with a solution of sodium sulphite to remove the brown stain from the manganese di-oxide, both plates then proved to have a very faint trace of image remaining, which trace could be completely removed by a fixing bath, or could be considerably strengthened by a developer, showing that it almost certainly consisted of silver bromide. We see, therefore, that, while it is true that small amounts of silver bromide are associated with the silver in developed plates so completely that they cannot be removed by a fixing bath, yet the warm tone plate developed with ammonium carbonate had no more of the silver bromide than the black tone plate, and the warm tone cannot therefore be due to silver bromide.

Inasmuch as it is well known that silver can be produced, especially in solutions containing gum or gelatine which is so finely divided that it will not settle, and that this silver is frequently brightly coloured, it seemed to us desirable to try to find out whether the warm-toned images differed from the black toned images simply in the fineness of division of the silver constituting them. This we found to be the case; whereas an image developed in the ordinary way on the "Wratten" lantern plate has grain which is just visible under the highest power of the microscope, if the image is developed to a warm tone the grain is no longer visible at all under the microscope. In order to see it we therefore had to adopt an ultra-microscopic method of examination. In this method, which is of comparatively recent introduction, the plate is illuminated, not by light coming through from underneath, but by strongly convergent light entering the film *sideways*.

If there is nothing in the film the field under the microscope remains black, but if there are any particles there, even if they be too small to be seen by the microscope in the ordinary way, they will reflect the light and appear as small bright points of light, just as the dust floating in a room, which is quite invisible to the eye, shines out clearly when a sun-ray falls in the room, the little particles of dust reflecting the light and catching the eye.

On examining warm-toned plates in this manner we found that the grains were indeed very fine, and we were able to observe that the warmer the tone the finer the grain. At the commencement of development a warm-toned slide has the finest possible grain, and if dried appears of yellow colour. This is succeeded, as development progresses, by reds, browns, and sepias, the grains growing larger all the while, so that the image always consists of pure silver, the colour of it being determined by the size of the grain which is produced. It may be noted that the warmest tones of all are indeed identical with what is known as green fog or dichroic fog, except that they do not cover the whole surface, and they are indeed strongly dichroic, the red images appearing green by reflected light. The theory of the production of warm tones will therefore be the same as that of the production of dichroic fog. These finely divided forms of silver are produced by using a developer which contains an active solvent of silver bromide, so that a considerable quantity of silver bromide can be dissolved in the developer, and be ready for deposition as finely divided silver. There is no more certain cause of dichroic fog, for example, than the presence of hypo in the developer, while the usual cause for it is the use of ammoniacal developers, ammonia being a strong solvent of silver bromide.

In order that satisfactory warm tones should be obtained upon a lantern plate, it is therefore necessary to use solvents of silver, and since silver chloride is very much more easily soluble than silver bromide the best warm tones have hitherto been obtained upon chloride plates. Just as it is easier, however, to dissolve a solid which has been powdered, so a substance always dissolves more rapidly the finer the state of its division, and for "Wratten" lantern plates we have succeeded in getting the silver bromide into so fine

a state of division that it will dissolve as easily as silver chloride in chloride plates.

It has already been pointed out that the conditions which favour the production of warm tones upon lantern plates also favour the production of dichroic fog. Dichroic fog will not appear as general fog unless the unexposed salt becomes slightly developable. Silver chloride, however, is always subject to this trouble, and consequently the great difficulty in getting warm tones on chloride plates has been that if development were sufficiently prolonged to get a satisfactory tone the plate was very liable to general fog. This difficulty does not apply in the case of a bromide plate, and consequently very strong solvents of silver, far stronger than can be used in the case of a chloride plate, can be used with the Wratten lantern plate. Such powerful solvents as hypo and thiocarbamide, which would produce heavy fog with a chloride plate, can be used to produce excellent tones with perfectly clear high-lights on the new plates.

The Exposure of Wratten Lantern Plates.

The best dark-room light for handling these plates is a bright yellow light. A suitable "Wratten" "safe-light" is the Series OO.

The exposure of any plate behind a normal negative may be calculated in the following manner:—The unit of light is one British standard candle, which is near enough to ordinary wax candles for practical purposes. The unit of light intensity is that given by one candle at one metre (39 inches) distance. The unit of exposure is therefore that given by exposing a plate for one second to a candle distant one metre. *This unit is known as the candle-metre-second (C.M.S.).*

Since the intensity of light varies inversely with the *square* of the distance from the source, if we expose a plate for one second to a candle at half metre distance, we shall give it $\frac{1}{4}$ C.M.S. exposure. If at one-third metre (13 inches) $\frac{9}{16}$ C.M.S., and so forth.

Now, the exposure behind a normal negative (a landscape developed for the time given by us with a non-staining developer) to get a good positive may be taken as 1,000 candle-metre-seconds, divided by the Watkins speed of the plate. Thus, on the Wratten speed plate (300 Watkins) the exposure will be 1,000-300 C.M.S., or $3\frac{1}{3}$ seconds at 1 metre to 1 candle.

On the Wratten Ordinary plate (12 Watkins) the exposure will be 1,000-12 C.M.S., or 83 C.M.S.

(This calculation will, of course, not apply to colour-sensitive plates, whose speeds, measured to daylight, are not comparable when candle light is used.)

The Wratten lantern plate averages $1\frac{1}{2}$ Watkins in speed, and therefore requires 750 C.M.S. exposure.

Thus, if a 10 candle-power batwing burner is used at 1 metre, 74 seconds' exposure will be required.

Similarly, an incandescent C burner (40 c.p.) will require 18 seconds' exposure. An equivalent exposure will be found to be one inch of magnesium ribbon at $1\frac{1}{2}$ metres (about 5 feet).

If magnesium ribbon is used, the following table may be of use:—

Black tones (unit exposure)	1 in. ribbon at 60 in.
Exposure factor 2	1 " " 43 "
" 4	1 " " 30 "
" 8	1 " " 22 "
" 16	1 " " 15 "
" 64	2 " " 11 "

Development of Wratten Lantern Plates for Black Tones.

To get a black-toned slide all that is necessary is to expose the plate for the unit exposure, as described in the previous section, and then to develop the plate in any developer which does not contain too much bromide. Too much bromide in the developer will give greenish or brownish blacks, the latter tone being pleasing and the former the reverse.

A suitable formula without bromide is that given as "A" for warm tone development, without any addition of "B." Really dead, blue-grey, or grey-blacks, however, are most easily got by development with thiocarbamide.

If the contrast of a negative is to be increased, the slide should be under-exposed and development lengthened; if the reverse, the

slide should receive full exposure and short development. If greater contrast is required, the following developer should be used:—

A. Hydroquinone	25 gms.	$\frac{1}{4}$ oz.
Potass. metabisulphite	25 "	$\frac{1}{4}$ "
Potass. bromide	25 "	$\frac{1}{4}$ "
Water.....	1,000 ccs.	10 "
B. Caustic potash (pure, in sticks) ...	50 gms.	$\frac{1}{2}$ "
Water.....	1,000 ccs.	10 "

For use, take equal parts "A" and "B." This developer is prone to give yellow stain, especially if development is forced with it in warm weather.

Development of Warm Tones on Wratten Lantern Slides.

We have already explained:—

- (1) That the production of warm tones depends upon the presence in the developer of a solvent of silver bromide.
- (2) That as development proceeds the tone darkens and becomes colder.

It must also be remembered that in all development the contrast increases with the prolongation of development, and that range of contrast is entirely governed by the duration of development. So that while warm tones may be obtained from the same developer by varying the time of development, that is, by varying the exposure so as to produce sufficient density in various times, yet only one time of development will give correct gradation.

Consequently the time of development for a given constitution of the developer should be regarded as a fixed quantity. If a different tone is required the developer must be varied as well as the exposure.

Many of the muddy and blocked-up warm-toned slides, which are too often seen, are due to non-observance of this rule. They have been over-exposed, and development has been stopped far too early, with the result that, while the density is correct, yet the gradation is entirely wrong.

The tone, then, is to be regarded as fixed by the constitution of the developer.

The exposure is similarly fixed, since it is that exposure which will be necessary to produce sufficient density in the given time of development.

The Time of Development.

It is well known that it is extremely difficult to judge the density of a warm-toned lantern slide during development. Fortunately, however, there is no need at all to attempt to judge the density. The best way of developing slides is undoubtedly by time. When developing negatives by time, the objection which is sometimes urged that variations in exposure may necessitate variations in development may have some force. It is true that most people are liable to make those compensating variations in the wrong direction, though sometimes a skilful worker may improve a negative by departing from the fixed time of development. (Anyhow, even a skilful worker will probably be helped by knowing how long the fixed time of development is.)

But in the case of lantern slides, when wrong exposure merely means making another, this objection has no force whatever. If the exposure is wrong, then alteration of the time of development may save the slide as regards density, but gradation will suffer, and the slide will be inferior. It is a poor lantern slide maker who is content to use a slide in the making of which a mistake has been made.

The best method of dealing with wrongly exposed slides is to put them for a few minutes in nearly boiling water. When carefully cleaned they make excellent cover-glasses.

The time of development naturally increases as the developer is more restrained and warmer tones are obtained, but at the same time the "Wratten" lantern plates do not require the very prolonged developments which were formerly necessary to produce warm tones.

The time of development for each constitution of the developer is given in the following table, but, inasmuch as the time of development is very greatly influenced by the temperature it is probably better to use Mr. Watkins' "factorial" method. The time is observed from the pouring on of the developer to the first appearance of the image, and this time (known as the "time of appearance") is multiplied by a fixed "factor" to get the time of development. For all warm tones the factor for our developer is 8; for black tones, 6.

These factors give slides of density suitable for ordinary lime-light lanterns. If the slides produced by them are considered too thin, the factor should be increased; if too dense, the factor should be diminished; but once the factor has been settled it should be adhered to, and if the resulting slide is incorrect, then a new exposure should be tried.

Exposure.

As the developer is more restrained the exposure must be increased, and must be increased far more rapidly than the time of development. While the time of development increases arithmetically, the exposure increases geometrically.

The unit of exposure is taken as the exposure necessary to get a black-toned slide with an unrestrained developer, and will depend upon the negative in the manner described in the section dealing with exposure. The times of exposure in the table are given simply as multiples of that unit exposure.

It may be mentioned again that intensity of illumination, and consequently exposure, varies inversely as the square of the distance between the source of light and the printing frame. One inch of magnesium at one foot, for instance, gives nine times as much exposure as one inch at three feet.

TABLE OF DEVELOPERS, EXPOSURE, AND TIME OF DEVELOPMENT FOR WARM-TONED SLIDES AT 60° F.

Normal Developer.			
A. Metol	44 grs. or	10 gms.	
Hydroquinone	22 " "	5 "	
Soda sulphite	1 oz. "	100 "	
Soda carbonate.....	1 " "	100 "	
Water.....	20 ozs. "	2,000 ccs.	
Restraining Solutions.			
B. Ammonium carbonate	1 oz. or	50 gms.	
Ammonium bromide ...	1 " "	50 "	
Water.....	10 ozs. "	500 ccs.	
C. Sodium thiosulphate (Hypo)	1 oz. "	50 gms.	
Water	10 ozs. "	500 ccs.	

Tone.	Developer (1 oz. contains)	Exposure Multiple. (in mins)	Develop- ment time
Warm black	$7\frac{1}{2}$ drms. A, $\frac{1}{2}$ dr. B	... 2 ...	2 $\frac{1}{2}$
Cool sepia ...	7 " A, 1 " B	... 3 ...	4
Warm sepia	$6\frac{1}{2}$ " A, $1\frac{1}{2}$ " B	... 3 $\frac{1}{2}$...	8
Sepia brown	6 " A, 2 " B	... 6 ...	10
Brown	$6\frac{1}{2}$ " A, $1\frac{1}{2}$ " B, 1 dr. C	... 3 ...	5
Brown purple	6 " A, 1 " B, 1 " C	... 5 ...	10
Purple	$5\frac{1}{2}$ " A, 2 " B, $\frac{1}{2}$ " C	... 10 ...	12
Carmine	$4\frac{1}{2}$ " A, 3 " B, $\frac{1}{2}$ " C	... 48 ...	20

The Production of Warm Tones on Faster Plates.

When lantern slides have to be made by means of reduction, owing to the size of the negative, it is not always convenient to use so slow a plate as the "lantern" plate. In this case first-rate slides can be made on the Wratten "Ordinary" plates, but such slides are necessarily of a cold tone unless they are afterwards toned in some way.

Results identical with those obtained by the restrained development of slow plates can, however, be obtained by the following method, which was recently published by Mr. Welborne Piper.

A rather thin black-tone slide on the Wratten "Ordinary" plate is prepared, and this is bleached in a solution consisting of:—

Potassium bichromate	$\frac{1}{4}$ oz.	2 $\frac{1}{2}$ gms.
Hydrochloric acid	$\frac{1}{2}$ "	5 "
Water.....	10 "	100 ccs.

After bleaching the slide is well washed.

We have now a slide in which the image consists of silver chloride and this can be developed by any formula for the production of warm tones.

The warmer the tone the denser the final slide will be, so that the warmer tones we must either use a very thin black slide or must stop development in the restrained developer before completing fixing out the undeveloped silver chloride.

The Chemical After-Toning of Lantern Slides

Black-toned lantern slides can be changed in colour by any of the usual toning baths.

Sepia toning, either by bleaching and sulphiding, or by the hy-

alum bath, gives satisfactory results, probably more satisfactory than those obtained by means of copper, uranium, etc.

As a general rule, after-toning produces the brighter and less often required colours, while restrained development is used for the warm blacks and sepias, which are most in favour.

The extreme tones (violets, carmines, and reds) produced by restrained development are of very little use, and are more easily obtained by toning with copper or uranium; but the sepias and blue-blacks, produced by ammonium carbonate or thiocarbamide, are not easily produced by after-toning.

Chemical toning always gives an appearance of "double-toning," unless it is allowed to complete its work, when bright colours are produced, and it is for this reason that restrained development is so much more satisfactory for most purposes.

Blue, Blue-Black, and Violet-Blue Tones by Development.

It was mentioned in the introduction that the "Wratten" lantern plates, owing to the way in which they resist fog, enable use to be made of other solvents of silver bromide than those which can generally be employed.

One of the chief of these silver solvents is thiocarbamide. If thiocarbamide is used for ordinary negative plates it will be found that, after development has proceeded for a short time, the *unexposed* silver bromide begins to develop rapidly with a brownish deposit, while the exposed silver bromide remains clear in proportion to the intensity of the exposure, so that a *reversed* negative—i.e., a positive—is produced, the highest light being represented by a light deposit of black silver. This action was first described by Major-General J. Waterhouse.

The rationale of this reversing action of thiocarbamide seems to be as follows:—Thiocarbamide is a powerful solvent of silver bromide, and induces a general deposition of fine-grained silver similar to the dichroic fog produced by hypo in the developer (which also shows this reversing action). The solution of silver bromide and consequent precipitation of silver is, however, greatly retarded by the presence of traces of soluble bromide. Now when a developer containing thiocarbamide is poured on to a plate it first begins to develop the ordinary exposed image. In doing this it impregnates the film *wherever the image is developed* with the soluble bromide formed as one of the products of development.

Consequently, when the general deposition of silver, caused by the thiocarbamide, begins, the places where this bromide exists—i.e., where the greatest exposure was received—will develop last, and we shall obtain a positive. The truth of this explanation is borne out by the fact that the positive image is always a little indistinct in outline, and that there is always a tendency for such objects as a church spire projecting into the sky, which should appear dark, to fail to develop owing to the diffusion of the soluble bromide sideways in the film.

This strong solvent action possessed by thiocarbamide suggested that if suitably restrained with bromide it might be found to give a different group of tones in development, and this was found to be the case, the tones varying from a blue-black to blues and violets, and even finally carmines, according to the amount of ammonium bromide and carbonate which is added.

The thiocarbamide is used in the form of a 1 per cent. solution of tetra-thiocarbamide ammonium bromide.

This solution is taken by dissolving 33 grains of thiocarbamide and 1 grain of ammonium bromide in 10 ounces of water. We may term this solution T.

The following table gives the exposure and developing factors for the production of blue tones with thiocarbamide:—

Tone.	Developer.			Exposure Multiple.
	drms.	drms.	drms.	
Dead black (neutral)	7 A +	$\frac{1}{2}$ B +	$\frac{1}{2}$ T	2
Blue black	6 A +	$\frac{1}{2}$ B +	$\frac{1}{2}$ T	4
Blue	$5\frac{1}{2}$ A +	2 B +	$\frac{1}{2}$ T	8
Violet	5 A +	$2\frac{1}{2}$ B +	$\frac{1}{2}$ T	16

The time of development with thiocarbamide depends so greatly on the temperature that visual inspection is necessary. Neither time or factorial methods are of any use.

"Physical" Development of Lantern Plates.

In the wet collodion process the image is received upon a surface of silver iodide, and is then developed by means of an *acid* reducing

solution, which does not change the silver iodide, but which precipitates silver from the free silver nitrate solution contained in the film.

This is generally referred to as "physical" development, as opposed to the "chemical" development, in which the silver bromide of a dry-plate is dissolved and precipitated as metallic silver by means of an *alkaline* reducer.

A physical developer is, therefore, distinguished as containing free silver nitrate, and also as being acid. Physical developers are best known to modern photographers, unacquainted with wet collodion, because they are sometimes used as "silver" intensifiers, where they deposit silver on the developed image of a dry-plate in order to produce greater density.

Dr. Lüppo-Cramer has shown that slow chloride plates can be developed by means of physical developers, and he gives the following formula as being the best:—

Metol	2 gms.	88 grs.
Citric acid	10 "	1 oz.
Water.....	100 ccs.	10 ozs.

To which add 1/10 volume of 10 per cent. silver nitrate solution.

We have found that this formula is quite satisfactory with the "Wratten" lantern plates, and gives very beautiful pictures of a bluish tone and of great delicacy and transparency. For seascapes and mountain scenery the results obtained in this way are magnificent, but the process is not an easy one to work.

The plates used for physical development must be quite fresh; plates which will give perfect results with ordinary development may give fog with acid silver.

The exposure required is about four times that required for ordinary black tones.

The dish used for development must be very clean; it is usually better to wash out the dish, measures, etc., with nitric acid or acid permanganate solution, to get rid of any traces of deposited silver.

The exposed plate is then put into the dish, the given amount of silver nitrate solution (not more) added to the developer, and the developer poured over the plate, which is then rocked for four minutes.

The silver may deposit over the whole face of the plate, on the dish, and on the fingers of the operator, from which acid permanganate will remove it.

The developer is then poured off, the plate rinsed, and then the whole surface of the film scrubbed fairly hard with a pledget of cotton wool.

The general deposit of silver will be found to rub right off, leaving the image unaffected.

If the density attained is not considered sufficient on looking through the plate, the dish is cleaned, as before, the back of the plate scrubbed with cotton wool, and the plate is placed in a fresh lot of developer until sufficient density is attained. The plate is then fixed and washed as usual.

FORTHCOMING EXHIBITIONS.

VIVE CAMERA COMPANY, LIMITED.—A correspondent asks for the London and American addresses of the above-mentioned company. Possibly some of our readers may be able to supply the information required.

Photo-Mechanical Notes.

Exposures in Screen Negative Making.

In the September number of "Le Procédé" L. Villemaire gives a table of exposures for wet collodion in screen negative making, which is the most practical and thorough of any yet published, inasmuch as it takes account of the varying screens in general use, the varying reductions, and also has columns for the two different sorts of originals—namely, black and white and warm toned. Moreover, the author is aware that collodions vary, so he has given the formula of the collodion he uses himself, and a correction factor for a commercial collodion that is commonly used in Paris. With regard to the lighting, he gives a description of the lamps he uses, and also the time they take to darken a Wynne actinometer, thus enabling a further correction factor to be worked out for any different set of lamps. With such a table properly used, it would seem difficult for the veriest beginner to go far wrong in exposure when making a screen negative on wet collodion.

Collodion Emulsion.

We are invited by an American correspondent to make some remarks about collodion emulsion for three-colour negative making, which, he says, is only slowly winning its way in America. He complains of "spots" and asks for recommendations as to emulsion. If he wants to make up his own emulsion he cannot do better than refer to the formulæ given in the "Almanac," the emulsion of Hübl being expressly designed for process work. If, however, he wishes to buy the emulsion, then Dr. Albert's, or that of Sillib and Bruckmann enjoy great favour, and both sell the emulsion in powder form, and issue instructions in English. One precaution is very necessary—namely, pure ether must be used.

With regard to "spots," such spots as are caused by airbells are, of course, due to sheer carelessness; but many spots in collodion emulsion seem to come, in spite of the most painstaking care. Naturally, they are more frequent when every precaution is not taken. The utmost cleanliness is requisite everywhere, the glass must be perfectly cleaned, the substratum used must be filtered over and over again, all the rooms must be free from dust, the same slide that is used for wet plate must not be used for emulsion, and, finally, the temperature must be low and the air sufficiently moist. If all these precautions are carefully attended to, and plenty of regular work is done, the troubles with emulsion will be greatly minimised, and it will be found an economical medium; but if the work is intermittent and the conditions are anything short of what we postulate above, then we strongly recommend the use of colour sensitive dry plates, instead of emulsion, for, although their cost is apparently greater, they will really be cheaper in the longer run, considering that there will not be the waste with them that there inevitably is with collodion emulsion, unless it is worked under almost ideal conditions.

PHOTO-MECHANICAL PATENTS ACCEPTED.

HALF-TONE NEGATIVES FOR RELIEF-BLOCKS.—No. 17,215, August 15, 1908. This invention relates to a method of making half-tone negatives for producing so-called half-tone relief printing blocks, in different patterns, whereby the desired relief effect and the desired patterning effect are simultaneously produced. The original is photographed on an ordinary dry plate, which is intensified so as to obtain a rather dense negative semi-opaque in the shades, and from this negative a diapositive is made. These plates are placed slightly out of register, and a suitably figured or patterned glass plate, which may also be ground or semi-opaque, is interposed between them. Upon photographing by transmitted light through such three superposed plates, a picture is obtained which, in addition to the relief effect due to the said negative and diapositive plates, will also contain the patterning or figuring effect due to the interposed plate, and upon the thus produced plate being photographed through a screen, a picture is obtained reproducing the relief and pattern in a state ready for etching.

By figuring or patterning the interposed plate in different

manners different effects and varied grounds may be obtained more readily than according to the customary method.—Niels Bendixen, 1, Mariendalsvej, Copenhagen, Denmark.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for the following patents have been received from August 30 to September 4:—

REFLEX CAMERAS.—No. 19,803. Improvements in reflex cameras. Walter Dockree, Herbert Holmes, and Houghtons Limited, 88, High Holborn, London.

DEVELOPMENT.—No. 19,809. Improved contrivance for developing photographic negatives. Charles Edwin Layton, 22, Southampton Buildings, London.

ARTIFICIAL LIGHTING.—No. 19,838. Means for artificially lighting halls or other places in which cinematographic or magic-lantern pictures are exhibited, or photographic operations and the like are carried on. Ernest Grenier, 47, Lincoln's Inn Fields, London.

PAPER.—No. 20,046. Improvements in photographic paper for grained photographs and in the process of manufacture of same. August Albert, 57, Lincoln's Inn Fields, London.

PRINTING APPARATUS.—No. 20,049. Improvements in photographic printing apparatus. William Lowthier Cole, 37, Chancery Lane, London.

LENS ATTACHMENTS.—No. 20,088. Improvements in devices for fitting supplementary lenses or other attachments to lens hoods of varying dimensions. George Leonard McAlpine and John J. Griffin and Sons, Ltd., Kemble Street, Kingsway, London.

CAMERAS.—No. 20,103. Improvements in photographic cameras and the like. Samuel Newsome Player, 18, Hertford Street, Coventry.

REFLEX CAMERAS.—No. 20,147. Improvements in or relating to photographic cameras of the type known as reflecting or reflex cameras. Arthur Lewis Adams, 24, Charing Cross Road, London.

ACETYL CELLULOSE.—No. 20,195. Improvements in or relating to the manufacture of acetyl cellulose. Kodak, Ltd., Chancery Lane Station Chambers, High Holborn, London, for David E. Reid, United States.

PLATE RACK.—No. 20,204. Improved folding portable plate or drainage rack. Ernest George Marshall, 17, Sterndale Road, Hammersmith, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR SCREEN-PLATES.—No. 11,147, 1909 (May 11, 1909). The invention is an improvement on the process of patent No. 3,252, 1908 ('B.J.," Oct. 16, 1908, p. 796), of preparing a three-colour screen-plate by attaching coloured grains of celluloid or glass to a transparent tacky plate.

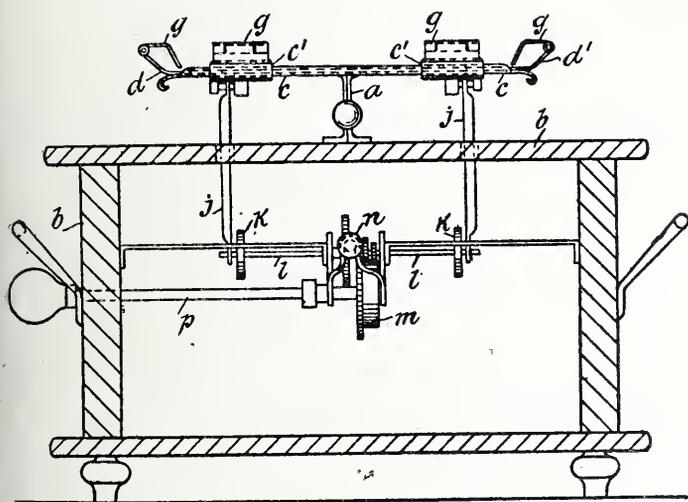

In the improved process the tacky substratum is itself stained yellow, red, or green, or a combination of two or more colours in various proportions adjusted to the light by which the photograph has to be made whether by daylight or by artificial light. A special compensating light-filter is thus unnecessary: the necessary correction is made in the colour-screen itself.

A solution of gum gamboge is made by boiling the gum turpentine spirit. A small portion of red dye may be added such as that obtained from alkanet root. In this is dissolved sufficient pale gum copal to make a solution of suitable consistency for coating the supporting plate. A suitable quantity bleached linseed oil is added to retard the drying of the subst

tum for a sufficient length of time to form the screen, but any other suitable absorbing dyes may be used, or any substratum giving a tacky surface.

The coloured grains having been spread in one layer in close contact with each other over the tacky stained surface are, after the substratum has become sufficiently dry, then rolled under heavy pressure down to the surface of the carrying sheet. The grains are thus flattened out, and at the same time most of the stained substratum is pressed from underneath, and is forced up and between each coloured grain, thus forming an exceedingly fine ring of transparent yellow round each grain. This acts as an efficient stop to white light being transmitted by the screen, and adds the desirable portion of fixed yellow. The small residue of stained substratum left underneath the grains forms the necessary correction to the light passing through the blue and green grains without having any absorbing action on the red grains, thus giving in the finished photograph a correct colour reproduction. John Bamber, 56, Lansdowne Road, South Lambeth, London, S.E.

CLOCKWORK DEVELOPING TABLE.—No. 1,196, 1909 (Jan. 18, 1909). A bracket, *a*, is fitted on stand, the bracket being capable of rocking from side to side. An elongated clip, *c*, is fitted on the top of each end of the brackets, and a like clip, *c*¹, is fitted on the slips at a right-angle thereto at an equal distance from the centre

of the stand. Two flat bars, *d* and *d*¹, are placed in each of these clips with their inner ends meeting at the centre of each clip when closed, and capable of sliding therein, but prevented from being entirely withdrawn therefrom by a small projection, *e*¹, engaging in a slot, *e*, along the centre line of the clips: each of the sliding bars has a hinged clip *g* at its outer end. The elongated clips and sliding bars are caused to rock by being connected by a rod, *j*, under each of the clips *c*¹ to an eccentric, *k*, on each end of a rod, *l*, on which a tooth wheel is fitted that gears into a wheel connected to a coil spring, which gives motion to a train of wheels; a plate, *m*, or an equivalent, is fitted on the spindle of one of the wheels, and a stop rod, *n*, is fitted in proximity, so as to engage with or be released from the plate.

When a plate requires to be developed, a tray or dish of corresponding size is placed on the flat bars *d* and *d*¹, which are withdrawn to the extent required, and the hinged clips *g* at their outer ends are turned over the edges of the dish by which it is retained in position. The clockwork mechanism is then wound up by the rod *p*, and the stop rod *n* withdrawn from the plate *m* on the spindle of one of the geared wheels in the mechanism, when the tray or dish will be caused to rock, either until the mechanism has run down, or, if required to stop sooner, the stop rod *n* is pushed in, thereby engaging with the regulating plate *m* and stopping the mechanism. Thomas Anthony Bowers, "Woodlands," Walton Road, Stockton Heath, and James Stanley, Craik, "Greenbank," 276, Manchester Road, Warrington.

CERAMIC PHOTOGRAPHS.—No. 17,432, 1908 (August 19, 1908). The invention relates to the use of a ground or roughened glass surface in making enamel photographs with a one-solution sensitiser such as that described in Patent No. 24,214, 1907 ("B.J.," May 15,

1908, p. 382). The rough surface obviates the use of nitro-cellulose in the sensitiser. The following are suitable sensitisers:—

Lithium bichromate	2 gms.
Honey, invert sugar, or other carbohydrate ...	4 gms.
Ethyl alcohol or wood spirit	100 ccs.
Calcium or strontium bichromate	2 gms.
Honey, invert sugar, or other carbohydrate ...	4 gms.
Ethyl alcohol or wood spirit	100 ccs.
Sodium bichromate	2 gms.
Honey, invert sugar, or other carbohydrate ...	4 gms.
Ethyl alcohol or wood spirit	100 ccs.

Some precautions are necessary during the washing process, when the plate is first placed in the water, to prevent the film dissolving away underneath the pigment, and the image being thereby distorted.

The invention may be applied to surfaces of ground glass, glass etched with hydrofluoric acid, or roughened by any other means. It may, in fact, be applied to a roughened surface of any material whatsoever, provided the latter be not absorbent.

It is possible to apply the process to absorbent rough surfaces provided they be rendered non-absorbent by first coating them with a suitable material.

In cases where the invention is applied to ground glass or other vitreous surfaces and it is desired to remove the rough appearance, the glass, etc., may be subjected to sufficient heat to vitrify or fuse the surface sufficiently to attain the object desired. Arthur Robert Ling and Theodore Rendle, 74, Great Tower Street, London, E.C., and Ernest William Colbrook, 65, London Wall, London, E.C.

CERAMIC PHOTOGRAPHS.—No. 17,433, 1908 (August 19, 1908). The invention consists of a one-solution sensitiser (free from water) for enamel or ceramic work. This solution does not involve the addition of water as does that described in Patent No. 24,214, 1907 ("B.J.," May 15, 1908, p. 382). It consists of a bichromate and a suitable carbohydrate dissolved in a solvent of both.

Chromic acid itself cannot be used in presence of carbohydrates since it rapidly oxidises the latter, undergoing reduction itself. This oxidising action may be restrained (*a*) by the addition of a certain amount of a base (less than is necessary to form the bichromate), or (*b*) by substituting a more resistant hygroscopic substance, such as glycerine, for the carbohydrate. It follows from (*a*) that the polychromates are available for the process, but they are not so satisfactory as the bichromates, owing to their liability to be reduced in the sensitising solution.

When glycerine is used in place of the carbohydrates, a lower proportion is necessary, but the exposure has to be considerably lengthened to overcome the tendency of the pigment to adhere generally to the plate, and the pigment is not retained so firmly on the exposed surface, so that greater care has to be exercised in washing.

Either the commercial or the anhydrous solvents, bichromates or polychromates may be employed, although in practice the commercial substances will be used.

A convenient proportion of bichromate to use is about 1gm. per 100 ccs., but any proportion of bichromate can be used up to its limit of solubility in the solvent or solvent mixture.

The two following examples will serve to illustrate the practical application of the invention:—

Lithium bichromate	1 gm.
Honey, invert sugar, or other carbohydrate	2 gms.
Ethyl alcohol or wood spirit mixed with ether or ethyl acetate	100 ccs.
A nitro-cellulose soluble in the solvents used ...	0.4 gm.
Sodium bichromate	1 gm.
Honey, invert sugar, or other carbohydrate	2 gms.
Ethyl alcohol or wood spirit mixed with ether or ethyl acetate	100 ccs.
A nitro-cellulose soluble in the solvents used ...	0.4 gm.

With chromic acid:—

Chromic acid	0.5 gm.
Glycerine	1 gm.
Ethyl alcohol or wood spirit mixed with ether or ethyl acetate	100 ccs.
A nitro-cellulose soluble in the solvents used ...	0.4 gm.

In all the above examples the carbohydrate, where specified,

may be substituted wholly or partly by glycerine. The quantity of glycerine used would be, for example, about half that of the carbohydrate replaced. Arthur Robert Ling and Theodore Rendle, 74, Great Tower Street, London, E.C., and Ernest William Colbrook, 65, London Wall, London, E.C.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

CINEMATOGRAPHS.—No. 19,028. Manufacture of opaque cinematographic images for projection by reflected light. Dupuis.

TELE-OBJECTIVES.—Photographic tele-objectives. Zeiss.

New Trade Names.

ASTARID.—No. 315,040. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Blagden, Waugh, and Co., 50 and 51, Lime Street, London, E.C., chemical manufacturers. July 22, 1909.

ISTARAS.—No. 315,041. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Blagden, Waugh, and Co., 50 and 51, Lime Street, London, E.C., chemical manufacturers. July 22, 1909.

SPIROGRAPH.—No. 315,436. Cinematographic apparatus and photographic films bearing finished pictures for use therewith. Charles Urban, Urbanora House, 89-91, Wardour Street, London, manufacturer. August 7, 1909.

GEVAERT PERFECT PICTURES (DESIGN).—No. 315,310. Photographic printing-out, bromide, gaslight, collodio-chloride, papers and postcards. Gevaert, Ltd., 26 and 27, Farringdon Street, London, E.C., manufacturers. August 3, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Green Tones on Bromide Paper.

There are reliable and simple processes (writes Mr. M. Kugler, in "The Amateur Photographer and Photographic News" for September 14) for toning bromides blue, sepia, and shades of red and red-brown, but those for green are not so satisfactory. After trying several of these with indifferent success, I worked out the simple process described below, and found it to work smoothly in every instance. Three solutions are required. They are:—

A	Potassium ferricyanide	5 gms. or 77 grs.
	Ammonia.....	5 drops or 7 drops.
	Water	100 ccs. or 3½ ozs.
B	Concentrated ferric chloride ...	5 ccs. or 80 minims.
	Water	100 ccs. or 3½ ozs.

Or if ferric chloride is not at hand, one can use:—

	Ferric ammonium citrate	2 gms. or 33 grs.
	Hydrochloric acid.....	5 ccs. or 80 minims.
	Water	100 ccs. or 3 ozs.

C	Sodium sulphide	1 gm. or 15.5 gr.
	Water	100 ccs. or 3½ ozs.
	Then add hydrochloric acid ...	5 ccs. or 80 minims.

This solution may become turbid, but no attention need be paid to that.

Having made up the solutions, one sets to work as follows:—The washed bromide print is placed in solution A until bleached through to a light brown. This usually takes from two to three minutes. The solution is now poured back into the bottle, and the print washed until the whites are free from the yellow colour of the ferricyanide. Upon the thoroughness of this washing the ultimate purity of the whites depends. Having washed the print, it is placed in solution B for five minutes, then rinsed once or twice, and transferred to solution C for five minutes. A short washing completes the process.

The chemical reactions involved are as follows:—When the bromide print is placed in the ferricyanide the silver reduces it with forma-

tion of silver ferrocyanide. When this is treated with the ferric chloride solution, the iron combines with the ferrocyanide radical to form Prussian blue, while the chlorine unites with the silver, giving white silver chloride. At this stage the print is a bright blue. On now treating it with the acidified sulphide solution the silver chloride is converted into yellow silver sulphide, which, together with the Prussian blue previously formed, gives the green of the finished print.

An Opaque Non-Cracking Screen.

It is by no means a difficult matter for one to prepare his own screen occasionally, when occasion arises (writes B. W. Adams in the "Kinematograph"). The materials, etc., required are: Convenience to wash the sheet or screen, four pounds of whiting, four pounds of good size, a couple of ounces of boiled linseed oil, half an ounce of alum, a brush, about an ounce of soft soap, and a pinch of ultramarine blue.

First mix the materials by soaking for an hour or more the whiting in sufficient water, after which time the surplus water may be poured away. Mix the ultramarine blue in a small quantity of water, and pour slowly into the whiting, meantime stirring it well. Melt the size, and add to it the boiled oil, then pour this in, also stirring well. Next dissolve the soft soap in boiling water and add this, and finally dissolve the alum in boiling water and pour that in. It must then be well stirred, and although at first the mixture will foam up it will soon settle down again.

Having washed the screen and well rinsed it in clear water it should be stretched on, say, a wall, and the mixture well brushed on with even strokes. It is necessary that this coating be done whilst the sheet is very slightly damp. When the screen thus prepared is dry, it will be found to be coated with a fine opaque surface, which will be sufficiently pliable to prevent cracking even when folded up.

New Books.

"Elementary Photo-Micrography," by Walter Bagshaw. Second Edition, 1909. 2s. 6d. net. (Iliffe and Sons, Limited, London.)

This very useful little work should be welcomed by those numerous amateurs who are desirous of attempting the production of photo-micrographs, either with the aid of a well-equipped microscope stand or without the aid of any stand at all. The author describes the use of the microscope as a magic lantern, to which purpose many never think of applying it. He also describes the method of fitting up a very simple photo-micrographic outfit before proceeding to deal with the use of the microscope proper. In describing the essentials of the microscope, he mentions as desirable features rackwork draw-tube, centring sub-stage with rack and pinion, and mechanical stage, all of which are no doubt desirable though we should hesitate to describe them as essentials except for very high-power work. They add considerably to the cost of the stand, and much good work can be done without them with moderate-power objectives. We think also that the author might have dealt more in detail with methods of obtaining good definition with ordinary objectives not corrected for photographic purposes. Compensating oculars are mentioned, but there are various simple expedients, such as the use of colour-screens, which the amateur would find useful when limited to the ordinary optical systems. We are glad to see that the writer recommends the use of an eyepiece. Most amateurs come to grief in their first attempts at photo-micrography through attempting to work without it, but it use greatly simplifies matters, especially in the hands of the beginner. The book is very clearly written, and contains numerous practical hints and a glossary that should be of considerable aid to the beginner.

AMATEUR PHOTOGRAPHIC COMPETITION.—The "Graphic" announces another of its amateur photographic competitions, which have met with great success and attracted much interest among amateur photographers the world over. The prizes offered are: First prize, £21; second prize, £10 10s.; and third prize, £5 5s. The competition closes on February 28, 1910.

CATALOGUES AND TRADE NOTICES.

BARGAINS AT LIME STREET.—The City Sale and Exchange, 54, Lime Street, London, E.C., have issued a list of second-hand and shop-soiled apparatus, which they are offering at greatly reduced prices. The items include a large number of hand, stand, and reflex cameras, enlarging lanterns and field glasses, all by well-known makers whose names are sufficient guarantee as to the reliability of the goods. The firm also state that any goods will be supplied either for cash or on the deferred payment system, and that customers' apparatus may be taken in exchange as part or full payment. Copies of the list can be obtained by sending a postcard to the City Sale and Exchange at the above address.

Meetings of Societies.**MEETINGS OF SOCIETIES FOR NEXT WEEK.**

SATURDAY, SEPTEMBER 18.

Borough Polytechnic Photographic Society. Outing to St Paul's Cray.
South London Photographic Society. Excursion to Hampstead Heath.
Kinning Park Co-operative Camera Club (Govan). Outing to Houston.
South Suburban Photographic Society. Excursion to London.

SUNDAY, SEPTEMBER 19.

United Stereoscopic Society. Outing to Surrey.

MONDAY, SEPTEMBER 20.

South London Photographic Society. "Models I have Photographed." P. R. Salmon, F.R.P.S.
Southampton Camera Club. Judging, by Members' Votes, of the Slides Produced in the Previous Competition and Projections of other Slides.

TUESDAY, SEPTEMBER 21.

Jackney Photographic Society. "Our Easter Trip." A. J. Linford. "Sports Day Pictures." Alec. Akerman.

WEDNESDAY, SEPTEMBER 22.

South Suburban Photographic Society. The Affiliation Prints (with Illustrated Lecture).

THURSDAY, SEPTEMBER 23.

Wandsworth Photographic Society. "Ensyna and Phosphate Printing Papers." J. Gough and A. A. Major.

THE ROYAL PHOTOGRAPHIC SOCIETY.

ORDINARY meeting held Tuesday, September 14. Though this was simply a meeting held for the election of new members, yet it had a special interest, owing to the fact that it was the first business meeting of the Society held in the new premises at 35, Russell Square. The President, Mr. J. C. S. Mummery, took the chair, and in a short speech informally bid the members welcome to their new abode. The formal opening of the new premises will, however, come later. During the evening some Autochrome slides were shown upon the screen by Messrs. Marriage, McIntosh, and others, while Mr. H. Armitage Sanders exhibited portraits of Dr. Cook and Commander Peary, of North Pole fame.

Commercial & Legal Intelligence.

A PHOTOGRAPHER'S "SIDE-LINE."—Louis Baga, photographer, Berne Bay, was charged at Canterbury, on September 11, for, on August 3, selling to another person the return half of a ticket to and from London, such ticket not being transferable, contrary to the by-laws of the South-Eastern and Chatham Railway Company. Defendant: I must plead guilty, not knowing I was doing wrong, as I thought I could get a few ha'pence. Mr. H. H. Groves, who appeared to prosecute, said this was a prosecution by the Railway Company under By-law VI., according to which defendant was liable for a first offence to a fine of £2, and for a second offence to a penalty not exceeding £5. The by-law in question was framed with a view to meeting circumstances prevalent in the case, which were that the defendant approached a lady and asked her if she was in want of a ticket to go to London. She was going to London, and purchased a ticket from defendant for 6d., being the return half not required by some passenger who had come down. In this instance the railway authorities learnt of the fact, and the lady was not allowed to travel with the ticket. It

was through her that they learnt about the defendant. At the instigation of the railway authorities, she purchased another ticket from the defendant, and they found that he was doing a regular trade in this sort of way. Defendant told the lady when he sold her the first ticket to London that he was able to obtain handfuls of them, and that if she did not purchase from him she would have to pay 5s. Therefore, contrary to what he stated, he was thoroughly conversant with what he was doing, and the railway company was being defrauded.

Defendant: This lady is a customer of mine. I had taken her photograph, and I happened to find the ticket on the beach. When I took her photograph she told me her husband was coming down. After finding the ticket I met her with her husband, and she said her husband was going back that day. I said "I have got a ticket," and I did not ask for any money. She gave me a shilling, and after going to the station she came back and gave me another 2d.

Did you give her the photographs in exchange for it?—Defendant: No.

The Chairman (Mr. F. H. Wilbee): Do you say that was the only transaction you have had with tickets?—Defendant: No, sir. I admit another transaction with the same lady.

The Chairman: Those are the only two?—Defendant: Three, your worship. This lady has said a handful of them, and I cannot help people coming to me. I have boat tickets (producing some), and others I find on the beach. People open their purses and lose their tickets. I have a sick wife and four children at home, your worships, and I have been fairly trapped into this.

The Chairman: Well, Baga, you have pleaded guilty to this charge, and some of the magistrates are rather afraid you have been in the habit of carrying on this trade for some time. As this is the first time you have been here, however, they will let you off with a nominal fine of 5s. and the costs, which are 18s. The money was paid by a friend of defendant's who was in Court.

A BOGUS CAMERA.—At the Westminster Police Court, on September 11, William Henry Robertson, 31, described as a chef, was charged, on remand, with obtaining money by false pretences.

At the first hearing three women, the wives of Chelsea workingmen, deposed to paying the prisoner small sums on deposit for photographs which he apparently took of members of their families or themselves. He called upon them with what purported to be a camera, and pretended to be able to take photographs of the inmates of the house while the machine was outside. He made a speciality of producing copies of photographs of aged persons taken many years ago, and also of babies. The prisoner did considerable business in Chelsea, but never delivered any photographs. A few days ago one of his victims accidentally encountered him at Fulham, and called a policeman.

A further charge of obtaining 13s. from Mr. Robert Sawyer, a Putney laundryman, had been preferred while the prisoner was under remand.

Amusing evidence was given by the prosecutor. He said that the prisoner called upon him at his laundry, where were employed some forty-five girls. He had what looked like a camera, and as he was "down at heel" and apparently anxious to earn a little commission, the witness showed him over the premises, and allowed him to take photographs. He ranged up the girls, and the prisoner walked up and down among them. The witness noticed that the prisoner did not take the cloth off his camera, and when he spoke to the prisoner about it, he said the camera got so hot that he could not remove the covering. He frequently turned a handle. As he said that prepayment would enable him to draw his commission at once, the witness gave him a cheque for 13s., and this was passed through the bank in due course. He (prosecutor) had reason to remember this cheque. When he drew it he wrote out another for £25 for Messrs. Lever Bros., of Port Sunlight, and did not fill in either counterfoil. Later, information reached him which induced him to stop the cheque he had given the prisoner, but instead of doing that he gave the number of the cheque drawn in favour of Lever Bros. (Laughter.) The prisoner gave him the address of a firm in Shaftesbury Avenue, and he (prosecutor) wasted four hours one afternoon trying to find it.

When arrested by Detective-Sergeant Davey at Wormwood Scrubbs Prison, the accused said others were in the affair besides himself, but he expected they would clear out now.

It was also stated by Mr. Sawyer that the prisoner obtained 7d. from a boy earning 5s. a week, by promising to send him some photographs on postcards. The prisoner, who had been previously convicted, asked to be dealt with, and was sentenced to twelve months' hard labour.

A SHARP SENTENCE.—At the Marlborough Street Police Court, on Friday last, Ralph Edgar Pavey, 19, a porter, living in Mercers Road, Tufnell Park, was charged with stealing, in November, two cameras, of the value of £6, belonging to his employers, Messrs Marion and Co., Soho Square.

The prisoner pleaded guilty, remarking that it was his first offence, and that he did not like his life spoilt by being sent to prison.

Mr. Mead (to the accused).—It is spoilt by committing a theft I regret to say that these offences by young persons are very frequent. It seems to be a general idea that the first offence can be met by an expression of sorrow. I cannot deal with this under the Probation of Offenders Act, because, if I did, instead of being a benefit, the Act would be most mischievous, because it would raise the presumption in the minds of persons like you that they could steal with impunity. You must go to prison for four months in the second division.

THE AFFAIRS OF A FOLKESTONE PHOTOGRAPHER.—The first meeting under the failure of William Tiddy, 60, Tontine Street, Folkestone, photographer, was held at Canterbury. The statement of affairs showed total unsecured liabilities £172 19s. 5d. and net assets £26 5s. 11d. Creditors of £10 and upwards were scheduled as follows: Brown, E., 112, Snargate Street, Dover, £15; Houghtons Ltd., 89, High Holborn, W.C., wholesale photographers, £10; Moodie, Thos., Bassenthwaite Lake, near Cockermonth, £12 3s. 2d.; Philp, Mrs., 30, Allendale Street, Folkestone, £10; Watts, Arthur Edward, 51, Guildhall Street, Folkestone, solicitor, £29 7s. 9d. It was decided to leave the matter in the hands of the Official Receiver.

At the public examination which followed the debtor stated that he started business as a photographer at Folkestone about eighteen years ago with a borrowed capital of £100. He carried on the business successfully until 1900, and repaid the loan. He kept books, but never made up a balance-sheet. Three years ago he found the business was going down, and he began to think he was insolvent, but he kept on in the hope of better times. He had been paying premiums on four life policies, the total amount he had paid being £500. He deposited the policies at the bank to secure an overdraft. The surrender value of the policies was £345; they would have turned out a good investment if he had been able to keep up the premiums. The furniture belonged to his wife under a deed of gift. He gave it to her when he was perfectly solvent. The examination was closed.

PEDLARS' LICENCES FOR PHOTOGRAPHIC CANVASSERS.—Two well-dressed men, named William Harvey Stringer and James William Johnson, hailing from Liverpool, were charged at the Northwich Police Court last week with acting as pedlars without having certificates.

P.C. Lodge stated that in consequence of complaints received from several tradespeople, himself and Sergeant Robinson kept the prisoners under observation. They followed them to several of the houses they had been to and found they had been selling frames and photographs at 4d. each. They asked them had they got certificates and they said: "No; they were not aware they wanted one."

The Magistrates' Clerk (Mr. C. E. Newell).—They do not require a licence to take photographs, but in this case they have been offering the frames for sale as well.

P.S. Robinson corroborated, and remarked that the photographers from whom they received complaints considered it very unfair competition. One photographer in the town did the photographs (produced) at 3d. a dozen, whilst the prisoners charged 4d. each with a small frame. The local photographers thought it an injustice that they should pay rates and taxes and then the prisoners come in opposition to them without paying for a licence.

Stringer said they were under the impression when they bought the camera last May that no licence was required. They had travelled about twenty large towns and had never been asked for a licence before. The frames they sold were necessary for the photographs.

Johnson said he was a married man with five children in Liverpool, and was it reasonable to think he would run the risk of being shut up for forty hours as he had been for the sake of a 5s. licence? He did not know one was required. He was working in Warrington Road for three hours on Saturday afternoon and took 19s., so he must have been pleasing the people.

The Clerk said a licence was required, but it would not be necessary if they took the photographs home to develop.

The Chairman said the prisoners had committed a breach of the Pedlars' Act, and they would be fined 5s. each.

Johnson: I assure you I will take a licence out as soon as I get back to Liverpool.

THE first meeting of creditors in the failure of Alfred Churcher, photographer, 41, Dorset Road, Clapham Road, S.E., and late of 252, Lambeth Road, Stockwell, will take place on the 21st inst. in the Bankruptcy Buildings, Carey Street, W.C. The public examination is fixed for the 27th prox. in the same place.

DISSOLUTION OF PARTNERSHIP.—The partnership between Mr. Frank Wilkins and Mr. S. G. Holyoake, photographers, of 2, Sydenham Road, Sydenham, trading as Wilkins and Holyoake, was dissolved on September 1. All debts due to and owing by the firm will be received and paid by S. G. Holyoake, who continues the business.

News and Notes.

THE MANCHESTER SCHOOL OF TECHNOLOGY.—The Photography and Printing Crafts Department of this school, under the able direction of Mr. C. W. Gamble, commences its work on Monday, September 20, and will continue until July 22, 1910, with vacations of two weeks at Christmas and one week each at Easter and Whitsuntide.

PHOTOGRAPHIC AWARDS AT THE WHITE CITY.—The following is the list: Professional and Commercial Section: Grand prize, Ca Hentschel, Langfier, Ltd.; diploma of honour, Mattype, Maya, John Swan, New Zealand Government: Gold medal, Miss Agnes Jennings, Miss Ellen Macnaghten, Wakefield, André and Sleight, Pa Laib. Club exhibits: Grand prize, Postal Camera Club, Wearside Photographic Circle; diploma of honour, Photographic Society Ireland, Glasgow and West Scotland Amateur Association, Bow Park Photographic Society; gold medal, Oxford Camera Club, South London Photographic Society, Society of Night Photographers.

PORTSMOUTH CAMERA CLUB.—The twenty-second annual exhibition of the Portsmouth Camera Club (formerly known as the Southsea Photographic Society) will be held at the South Parade Municipal Pier, Southsea, from October 6 to 13, inclusive. In the classes nine bronze plaques will be placed at the disposal of the judge, Mr. F. J. Mortimer, for award, together with a special prize of a silver vase for the exhibitor showing the best picture in class A—framed prints, any subject. Entry forms are now ready, and may be obtained, with full rules and conditions of entry, from the hon. secretary, Mr. James C. Thompson, 23, Elm Grove, Southsea.

MR. CHERRY KEARTON IN EAST AFRICA.—An interesting letter in the "Daily Graphic" of September 8 from Mr. Cherry Kearton shows that this well-known nature photographer is having some exciting experiences in the East African bush while photographing the numerous wild beasts at home. He has once been treed by a rhino whom he unwittingly disturbed in the middle of a nap, and one night immediately the flash-light went off a lion took a leap of twenty-five or thirty feet straight at the camera, and went off with the camera cover, the photographer himself fortunately being in a tree at the time. By dint of spending many weary nights in the purpose of manipulating the flash-light, Mr. Kearton succeeded in securing some fine pictures of the larger animals in the bush, but he describes it as work that is extremely fatiguing mentally and physically. We may expect some very valuable results from the enterprise of Mr. Kearton, whose skill in nature photography has been so fully proved in less adventurous fields.

Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE QUALITY OF NEGATIVES.

To the Editors.

Gentlemen,—In reply to Mr. Turner's attack on fast plates, I am a special friend of the high speed which seizes opportunity, and I had a Norman knight to represent me. Speed of plate H. and D. backed, developed with sodinal, no bromide, and no weighing and measuring and bother about time and temperature; simply development. It enlarges up to about four times in height quite well smooth bromide, and is an absolutely ideal negative. I am an artist, as well as a member of the P.P. Association, caring little for means, but a great deal for the results.—Yours faithfully,
SYDNEY A. DRIVER.
September 13, 1909.

SEASIDE LIGHT.

To the Editors.

Gentlemen,—In "Photographic Scraps," No. 241, p. 72, it is stated by the writer that "the actinic value of seaside light is not likely to vary to any appreciable degree." Why "seaside" light should not be subject to the usual variations of the other brands of that commodity I am at a loss to understand. The matter may, perhaps, interest the makers of exposure meters.—Yours faithfully,
R. W. WICKS.
Brighton, September 9, 1909.

AN AUTOCHROME EXPERIENCE.

To the Editors.

Gentlemen,—I shall be glad if you will publish the following in the correspondence column of your next issue:—Can you explain the cause of the disappearance of the colour from the most perfect Autochrome portrait after it had been finished in the usual way, without any variation from Messrs. Lumière's instructions? It was developed with quinomet and reversed with acid potassium permanganate, and subsequently intensified with Messrs. Lumière's intensifier, fixed, washed, dried and varnished with vitriol varnish—a cover glass was attached with adhesive strips fixed with a hot iron. Shortly afterwards it was discovered the colours had entirely disappeared from the whole of the plate, with the exception of a very small portion adjacent to two edges; it looked exactly like an ordinary cold grey monochrome positive without the slightest indication of colour. On examination with a microscope, it was found that the starch grains were in no way injured, their colours being as brilliant as ever. The only visible change was that the background, which was dark green velvet, had a slightly brownish appearance. Another plate which was developed and completed at the same time has so far shown no sign of the same defect.—Yours faithfully,
WALTER BOURKE.
September 9, 1909.

We have never experienced any effect of the kind described, but possibly some of our readers have done so, and may be able to offer suggestions.—Eds. "B. J."]

TONING ROUGH PROOFS.

To the Editors.

Gentlemen,—I note in the column of "Answers to Correspondents" of September 10 a query by "Pyro" respecting the toning of rough proofs submitted to customers. I would make the suggestion that if "Pyro" would use a trace of celluloid varnish on the rough proofs before sending out, toning is prevented. My procedure is as follows: I give a touch with cork from varnish and smear over the face, etc., with the finger, the varnish being noticeable. Should toning then be tried a most disagreeable effect will be the result. It is an undoubted fact that a great number of rough proofs are returned by customers and taken to other photographers to tone.

In my own experience well-to-do people have brought me proofs by leading West End firms with the intimation that I should tone and finish them.—Yours truly,
GEO. MOSS.

Christchurch, Hants.

September 20, 1909.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- W. H. Warburton, Harris Promenade, Douglas, Isle-of-Man. Two Photographs of Mr. Hall Caine.
- S. B. Reynolds, 8, Victoria Road, Brentwood, Essex. Two Photographs of the Fire at the Great Eastern Stores, Brentwood.
- W. Berry, 8, Row 100, South Quay, Great Yarmouth, Norfolk. Photograph of the Winterton No. 2 Life Boat and Crew, "Eleanor Brown." Photograph of the Ceremony on the Winterton Life Boat, "Eleanor Brown."
- A. Dungey, 100, Cambridge Road, Mile End, London, E. Photograph of Group taken at the Foresters Music Hall, September 9, 1909, consisting of Young Josephs, Sam Ives, Harry Chamberlain and Officials.

DRAWING REGISTERED:—

- G. Guthrie, 26, Panmure St., Brechin, N.B. Drawing adapted from old seal of the Duke of Montrose and Earl of Crawford in 1488 (while he held both titles).

TERRY HUNT.—If the man who gave you the order to take the photographs was the authorised agent of the firm you can sue it in the County Court of your district for any money that may remain due to you for work done. You are quite under a misapprehension with regard to the copyright in the pictures. That is vested in the firm whose agent gave the order to you to take the pictures. If it does not pay for them, it makes no difference, inasmuch as a debt for them has been incurred which is recoverable in a court of law.

MERCURY IODIDE INTENSIFIER.—I have some negatives that I intensified some two or three years ago with mercuric iodide. I followed the instructions, and after intensification gave them five to ten minutes in a developer. The light deposits on the negative have gone a yellowish green, rather similar to the colour obtained by toning a slide with iodide. The denser deposits do not appear much affected. I am told by a chemist that there is not much hope of putting them right now. I should be much obliged if you could let me know: first, the reason for the change; secondly, if there is any remedy.—D. H. HALL.

We cannot give the reason for the change, as the conditions of the image are so very complex. Neither can we suggest a remedy which will be certain. We should, however, be inclined to attempt the removal of all mercury compounds with a strong bath of potassium bichromate and hydrochloric acid, and after washing follow with a strong hydroquinone and caustic soda developer. Exposure to sunlight or to magnesium will probably be necessary to make this act. As an alternative, the effect of the developer might be tried first. If it fails, then try the bleaching and redevelopment process.

SOCIETY FOR PHOTOGRAPHIC ASSISTANTS.—A short time ago I thought I would join the National Union of Shop Assistants, Warehousemen, and Clerks, and with that object I applied to the local secretary, who, after my filling in a form, gave me a membership card, and I paid two separate fortnightly sums, viz. 1s. I then heard that the local secretary had heard from the head office re my application, but same must stand over until their organiser came into this district. He has now been, and during a chat

with him he told me I was not eligible; I was not engaged in the "distributive" trade, but employed by a "manufacturer" (a photographer). Of course, I could do no other than return my card, and they are going to return my contributions. It was rather a surprise to me. I should be obliged if you would tell me, through the columns of the "B. J.," if there is a society open to photographers' assistants (a "benefit" society, I mean). If so, could you give me address of same?—O. R.

We are not aware what the rules are of the society you mention, but it seems clear, for the reasons stated by the organiser, that you are ineligible for membership. It is clear that a photographic assistant is not really connected with a distributive trade—a shop assistant. There is no benefit society at the present time connected with photography. There was one once, but it died through its not being supported by those it was intended to benefit.

DISPUTED ACCOUNT.—I took six different positions of a motor-car for a gentleman ($\frac{1}{2}$ plates), and developed and finished all, and submitted them to my customer, who then ordered nine dozen all told, which I sent along when ready, enclosing my account at 6s. per dozen, in all £2 14s. I now have what I consider a rude reply from him, to the effect that my price is "silly," stating he will not pay such a price, and even suggesting the return of photos. I feel my price is very reasonable, and have replied to this effect, that I shall accept no rebate, as these were produced to his specific requirements, and are of no use to me in the ordinary way of trade. I should be obliged if you will kindly answer in your journal what I can best do with him, and your general opinion as to price.—WHITTLESEY.

What you will have to do is simply to sue the gentleman in the County Court for the sum due. The price you have charged is very moderate indeed. Many photographers would have charged him much more.

VARIOUS QUERIES.—Will you kindly give me a little help through the "B.J."? Last week an annual show was held at —, not far from here. I asked at the booking office, if I went in the grounds, could I take a few snapshots? As soon as I got in I came in touch with a party that were catering for refreshments. They wanted me to take their photograph. Seeing the secretary close by, I asked him if he had any objection. He threatened to turn me out of the grounds if I put my camera up. Of course, I did not earn sixpence all the day. About 1,500 people there, and no photographs taken. Was not that a public place after I paid my shilling? I call it fraud. 2. Can you tell me where I can get in touch with the following firms: Cinematograph film makers, Christmas postcards and designs? 3. What speed shutter, lens, and plates for taking a horse water-jumping? What kind of camera (hand) for same? 4. If I supply a man with a photograph, is he at liberty to take it to the local press? The Territorials had a field day, and I took a photograph of officers. I do not want it in the press, as it stops me selling them direct.—XIX.

In most such functions photography is not allowed unless permission is previously obtained, and then usually only by payment of a certain fee for the privilege. There is no fraud in the matter, as the place was not a public one. 2. Only by applying to the publishers of such subjects. 3. A reflex camera best for such work. The speed of the shutter must, of course, depend upon the light at the time. 4. Yes, certainly, unless you have registered the copyright in the pictures.

COLLOTYPE PROCESS.—I should be glad if you would kindly answer the following questions through your paper: 1. The names of one or two firms who make the machinery for colotype work. 2. Are there any books published dealing with the work? If so, please give names.—COLLOTYPE.

1. Try Penrose and Co., 109, Farringdon Road, E.C., or Griffin and Son, Kingsway, W.C. 2. There are many such books. Possibly "Practical Colotype," by W. W. Fithian, or "Photo-Mechanical Processes," by W. T. Wilkinson, will serve your purpose.

X-RAYS.—Having taken in your "B.J.P." for eight years and read it, will you kindly give me a little idea how to go about taking photographs with the aid of X-rays? A doctor of my acquaintance has all the ray apparatus and has invited me to make a

series of photographs for him. Will you let me know what to take in the way of plates and lenses?—BROOKLYN.

No lens is required at all. You had better obtain some special X-ray plates, but we fear you will not get much in the way of results at your first attempts. You had better study "Practical Radiography," by A. W. Isenthal and H. Snowden Ward for details of working.

WAGES IN LIEU OF NOTICE.—Will you kindly inform me in your next issue if an assistant can give his master a week's wages (as he is paid weekly) in lieu of a week's notice to leave?—DEVONSHIRE.

Yes, if he was engaged as weekly servant. But if he was engaged for a given term he cannot, though he may be paid weekly.

P.O.P.—Will you kindly let me know of a place in London where I can learn to mix emulsions, coat, and finish printing out paper, known as P.O.P., as used by photographers, and much obliged?—J. J. FORSYTH.

There is no such place in London that we are aware of. Manufacturers of the commercial papers naturally keep their formulae and methods of working to themselves. However, if you refer to page 799 of the "Almanac" you will find formulæ for P.O.P. if you wish to make your own, though we fancy you will find it more economical to buy it than to make it. We do not refer to correspondents by post.

THE AFFILIATION.—The annual gathering of members of affiliated societies will take place at the New Gallery, 121, Regent Street, W. (by the courtesy of the Royal Photographic Society), Friday evening, September 24, at 7 p.m. The chairman of the Executive Committee (Mr. P. Bale Rider) will give a brief address on the work of the affiliation at 8 o'clock, in the North Room, and will present the plaques and certificates awarded in the recent slide competition. The 1909 set of competition slides will be shown during the evening. Admission to the New Gallery will be granted on presentation of the "Red Book," and the half-price tickets contained therein will be available for members' friends.

HACKNEY PHOTOGRAPHIC SOCIETY.—The annual exhibition of the society will be held at the King's Hall, Hackney Baths, from November 10 to 13, inclusive. There are five open classes, one of which is specially devoted to colour photography—prints or transparencies by any photographic process—and in all of these the awards take the form of silver and bronze medals, with a special award of a gold medal for the best picture sent in. The judges will be in the hands of Mr. F. J. Mortimer. Entry forms, together with the necessary entrance fees, must reach the hon. sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E., on or before October 12, and exhibits must be delivered, carriage paid to the Hackney Baths between November 5 and 8. It is stated that exhibits will be collected from the R.P.S. and Salon exhibitions without additional charge on receipt of the signed official receipt, and free carriage is also offered for exhibits entered for the Southampton exhibition (November 23 to 26). Further particulars together with entry forms, may be obtained on application to Walter Selfe, 24, Pembury Road, Clapton, N.E.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Royal Photographic Society's Exhibition.—In the pictorial section the artistic level of the work is higher than it has yet been, a condition which naturally prevents any particular work from standing out pre-eminently. Amongst the prints in colour, however, there is one, an oil print, which marks the highest achievement so far in the direction of pure realism. As a whole the exhibition may safely be said to have benefited by the impetus given to pictorial photography by the oil and bromoil printing processes. The hanging of the works is this year more upon the lines of decorative spacing and balancing, the walls being divided into groups and panels which assist materially in localising and memorising the position of prints. Light frames and passe-partout mounting are very generally adopted, the walls gaining in lightness and attractiveness by the absence of the sombre wooden frames of past days. Picture sales commenced at the private view, at which the general consensus of opinion was that the show surpassed those of recent years in interest. (P. 738.)

An analysis of the printing processes used in the pictorial section shows that oil and bromoil are in a considerable majority. (P. 745.)

Photographs of the selecting and hanging committees in the pictorial, technical, and colour sections are given. (Pages 739, 740, and 741.)

Velarium. (P. 754.)

In the technical section the chief support has been obtained from many photographers of natural history subjects, including a collection exhibit by members of the Zoological Club. Among the general scientific exhibits spectroscopy, radiography, astronomy, and photographic work are very adequately represented. (P. 746.)

Colour photography on paper shows up very badly. The Autochrome section contains a good deal of very interesting work, including one Autochrome of an express train taken in 1-25th of a second. (P. 747.)

The fine work of Crooke dominates the professional photography section, which is this year of greater interest than usual. One notable point is the oil print pigmented for professional purposes. (P. 748.)

Among the process exhibits the first example to be shown of the dry-plate method of photographing direct on to the metal plate will be found in the north gallery. These include proof of a half-tone portrait made direct from life on to the block. (P. 747.)

The trade exhibits include the apparatus and materials of a considerable number of leading firms. (P. 749.)

Some lectures which will NOT be delivered at the New Gallery during the present exhibition are published without admission of responsibility. (P. 753.)

The announcement is made in several of our German contemporaries of the combination of the chief camera manufacturing firms in Germany. (Page 737.)

Some of the points which require to be borne in mind in making spectroscopic photographs of near objects are mentioned in an editorial article. (P. 738.)

owing to great pressure upon our space many articles, reviews, and paragraphs are held over.

EX CATHEDRA.

An Amalgamation of German Camera Makers.—The announcement is made in several of our German contemporaries of the amalgamation of the largest camera manufacturing firms in Germany which has just been concluded. Those who have just entered into this combination are the firms of Hüttig and Sohn, of Heinrich Ernemann, and of Emil Wünsche and Co., all of Dresden, the firm of Dr. R. Krügener, of Frankfort, and the camera department of Carl Zeiss, Jena. In the new form which this combination of interests will take, the business will be conducted with a capital of 4,000,000 marks. It is anticipated that a step of this kind, in which the largest camera makers are brought into intimate association with one of the most eminent optical houses, is certain to be of great importance, not only to the home market, but still more in the maintenance and expansion of German trade in photographic apparatus in foreign markets. The step is one which is evidently taken with the object of meeting foreign competition.

* * *

Removing Prints from their Mounts.—A writer in the *Evening Standard and St. James's Gazette* suggests a method of removing prints from their mounts which is, to say the least, risky. Briefly, the instructions are to first soak in very hot water, then bend back the card until it leaves the print. The latter is then pressed between blotting paper until nearly dry, when it is cleaned from all traces of gum or mucilage. After this, it is again pressed and left between the blotting boards until quite dry. No doubt this method would work well with albumen or collodion prints, but with gelatine the results would certainly be disastrous, unless the film had previously been rendered insoluble by treatment with formalin. This hardening process could not, however, very well be conducted on the mounted print without affecting the mountant, and if this happened to be gelatine or gum, then the mountant would become as insoluble as the film. Our experience is that it is no easy matter to unmount a print on a gelatine paper, but the most promising method is to soak well in cold water, then lay print face down on a piece of glass and rub away the mount from the print with the finger-tips. Much care and patience is needed, and the print generally requires frequent re-soakings.

* * *

Photography at the North Pole.—The controversy raging over the discovery of the North Pole has drawn attention to the difficulty of any explorer proving that he has actually visited it. Some, who have evidently not given much thought to the problem, have suggested that the only convincing proof would be a photograph of the stars as seen in a camera placed with the lens pointing vertically upwards. No doubt such a photo-

graph would be very convincing, but it is not likely to be forthcoming, for the simple reason that the stars are invisible even to the camera at mid-day in the summer time, which is the period during which both explorers claim to have reached the Pole. If photographic evidence is produced at all, it will most likely consist of photographs of the sun, but even these will probably not be of much value unless they have been produced in a photo-theodolite which will record the horizon at the same time.

STEREOSCOPY WITH NEAR OBJECTS.

SOME writers in our contemporary, the "Photo Revue," are discussing the old question of the advantages and disadvantages of using converging lenses when making stereoscopic negatives of near objects. Nearly all the earlier workers used this method, and they usually employed a single camera, which was traversed from one position to the other on an arc of a circle, the centre of which was situated at the subject. Their object was the centring of each view on its own plate, but they omitted to note, as do many modern advocates of the same method, that as the swinging of the camera round the arc set the two plates at an angle with each other, it was therefore essential that the two views of the finished stereoscopic slide should also be set at an angle. If the two prints are to be mounted on one plane slide, as is usual, it is absolutely necessary that the plates upon which the negatives are made should also be in one plane.

There is, however, another point to note. It is in most cases quite correct and very advisable to carefully centre the views on each plate, and when using the ordinary single plate camera the adjustable front is employed for this very purpose, but this centring process makes no difference in the ultimate mounting separation or in the trimming required when the object is very near. It does make a difference in the trimming in the case of distant objects, for with these we can use a wide mounting separation and utilise every portion of the negative, but with very near objects we can never in any case utilise the whole of the negative because the mounting separation is too small to allow of it. Subjects such as flower studies are generally taken so near that the mounting separation for a prismatic stereoscope, if worked out by the rules given in the "Almanac," often comes to two and a quarter

inches or less. That is, it is an inch less than that required in the case of more ordinary subjects, and therefore the prints have to be an inch less in width. It will be smaller than this if the lens separation in the camera is much over two inches, and if we remember this point it is obvious that the converging lens idea has no merits whatever. The old workers used it because, with its aid, they could work at a very wide lens separation. They did not, however, understand that this involved a very small mounting separation, and as a consequence their slides often show most alarming distortion. The old daguerre type slides were often made in a single camera, moved so as to keep the lens axis directly on the object, and it was often moved so far as to render the correct mounting separation very minute. We have tried to remount some of these old slides correctly, and have found it quite impossible, as in some cases the two pictures should occupy the same position (or be mounted with a zero separation) to get rid of the distortion.

There is yet another fallacy with regard to the convergence of the lens axes. It has been argued that as the eye axes converge on to the subject the lens axes ought to do so as well, even in a single plate camera, but whether they do or not the images will be exactly the same, and the final slides will not differ in any way. This should be obvious to anyone acquainted with the elementary optics of lenses, and it is surprising to see the fallacy with regard to convergence so often repeated.

We fear that modern workers are just as loth to consider the matter of mounting separation as were their ancestors. Anyone who doubts the importance of correct mounting should make the following experiment: Select some small object of such a nature as to readily reveal any distortion of form. Make a stereoscopic negative of it on a scale of nearly full size, then mount one pair of prints with a separation of about $3\frac{1}{4}$ inches, and another pair with the correct calculated separation. Comparison of the two slides in the stereoscope will at once show the defects peculiar to wrong mounting separation. We may point out that as the correct separation may work out to only two inches an object must be selected that is less than two inches in width, otherwise some of the images may have to be cut away in trimming. Stereoscopy, being largely used at the present time for the photographing of near objects, but we regret to say that correctly mounted slides are extremely rare, and as a consequence correct representations of the near objects are rare also.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

WITH the opening of the Royal Photographic Society's exhibition yesterday the selecting committees may rest from their labours and congratulate themselves that in every section, with the exception, perhaps, of that of the colour prints, there has been brought together a remarkably fine collection. The pictorial section is quite distinctly an advance upon last year's, whilst the fostering care which has been given to the technical section has borne fruit in the greater interest of the exhibits. Process, too, particularly in the case of the method of making half-tones direct on the metal plate by the process of Mr. Arthur Payne, once again takes a prominent place in the exhibition, whilst progress in photographic manufacture is very fully

represented in the trade sections. Professional photography, as in previous years, gains somewhat scant representation in the New Gallery.

In reviewing the exhibition we shall, as in previous years, arrange our notices in the order in which the visitor most usually makes a tour of the New Gallery.

Pictorial section, West Room.

Technical and colour section, Gallery and North Room.

Process Exhibits.

Professional work, South Room.

Trade exhibits, Court and North Room.

THE PICTORIAL SECTION.

It will be generally agreed that this is an extraordinarily good display of pictures. This fact, in conjunction with the

other fact that its selecting committee was composed of men, with two exceptions, will not unnaturally lead to the con-

lusion that the altered conditions of selection have resulted in the better show. Prima facie this is sound argument enough; but it is not necessarily the whole explanation of affairs. It must not be forgotten that the standard and style of work at the R.P.S. has been rising and developing steadily for many years past. It is to-day quite an international show, and no longer a kind of pick from the work of the London and provincial photographic clubs. For our own part, we have not a jot more confidence in the artistic judgment of the present committee than we had in the last, a little less if anything; and we are convinced that, by reason of the still further development of printing processes, the spreading interests of the society, the increased number of works submitted, and the smaller amount

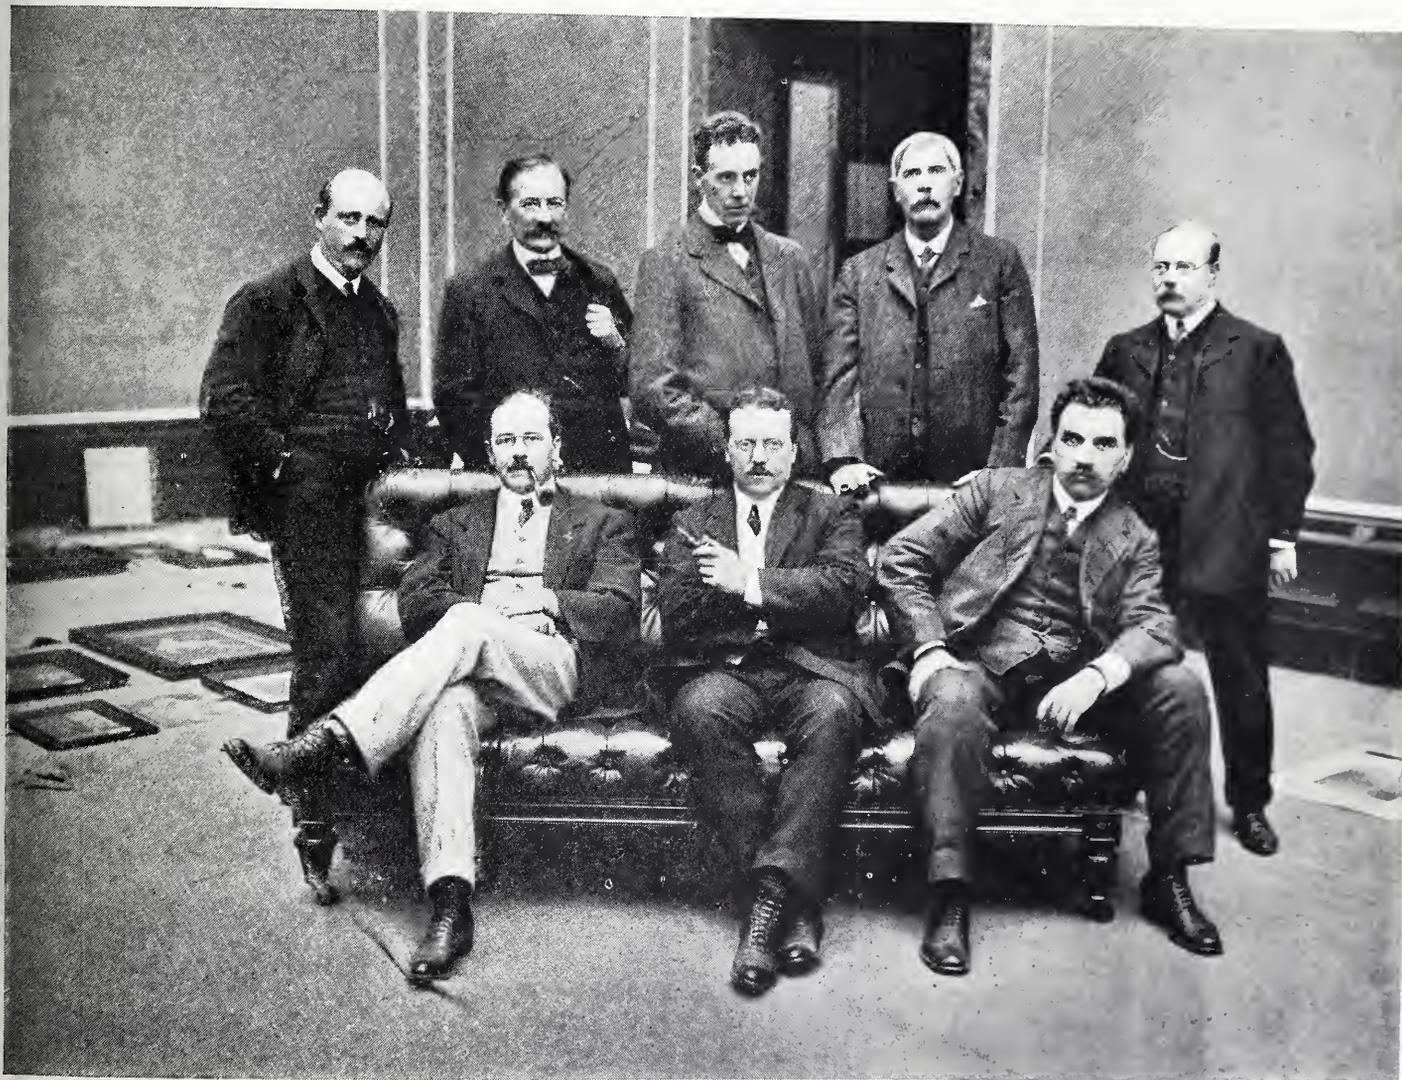

room, and has a distinctly depressing effect by reason of its curtailment of space, light, and air.

Amongst the pictures, oil prints and bromoils figure very largely, and there can be no doubt that this fascinating process is proving a fresh incentive to good pictorial work.

In order that our readers may locate the prints to which we are referring we shall paragraph this notice in accordance with the panelling of the walls, as we did in our review last year.

East Wall, Right-Hand Division.

No. 1 is called "A man of cheerful yesterdays and confident to-morrows." The title is suggested and borne out by a good-humoured expression in the face of the sitter, but such parts

THE PICTORIAL SELECTING COMMITTEE OF THE ROYAL PHOTOGRAPHIC SOCIETY.

[Hana Studios, Ltd.]

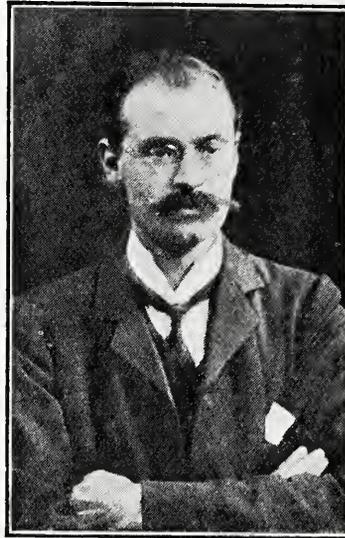

Reading from left to right the names are as follows: (standing) E. T. Holding, A. H. Blake, F. T. Hollyer, Harold Holcroft, J. McIntosh (Secretary); (seated) Arthur Marshall, F. J. Mortimer, C. F. Inston.

an usual selected, it is unlikely that an even less capable committee could have made a selection much different from the one we are about to review. Where the new committee have particularly asserted themselves is in the matter of gallery decoration, and here it is quite a question as to whether their alterations are improvements or not. Their white tape is a good deal more staring than the old "styles" which broke the walls into panels, and the velarium is a luxury which we feel ought to enjoy, though we cannot precisely see its advantages, as here arranged. The velarium of a picture gallery is designed to shade the spectator's eyes effectually whilst it concentrates light upon the pictures; but this complete roofing of the web does but diminish the illumination of the gallery without affording a rest to the eye by extra shade in the middle of the room. Moreover, it dwarfs the noble proportions of the

of the print as are not black have an unpleasant stony texture. The collar is particularly bad in this respect. The print is by John Moffat, who, we think, ought to have more regard for the general roundness of a sitter's head. C. H. Hewitt is one of the few control-printers who are not too proud to preserve detail, which in the interesting picture of "Bickleigh Bridge, Devon" (2) is one of the chief delights of a fine print. Another bridge at closer quarters is shown in "An Ancient Waterway" (3), by J. C. Nunn. This, too, is a print of excellent quality and great pictorial interest. A bromide print called "In the City" (4), by Peter Orr, gives an extremely dignified view of a street in a large town. The centre house of white stone introduces a light passage among the dark houses, and connects with the sky in a happy way, and the classic portal on the right comes in with good design. "Peonies" (5) is a superb

flower piece, by M. A. Smart, combining the utmost realism with decorative effect. Louis Fleckenstein sends a photograph of "The Life Class" (6). There appears to be a small attendance. Only two students are visible, and one of them is in the foreground, whilst the model, as though she and Mr. Fleckenstein himself were both ashamed of the whole proceedings, is far removed into a distant corner. The most uninteresting elements of this view are those which are given in largest scale and greatest force of tone. We think Mr. Fleckenstein has missed a good opportunity. A Thibaudeau

a boat drawn up on a beach and some boys, not free from self-consciousness, and all at a back view, employed variously in what are supposed to be repairs. The print has a good design, but errs a little on the side of all-overishness. It is by T. Carter. The mediæval cut of the hair of a "Choir Boy" (10) gives the picture of a little fellow in a surplice and holding a book a decided extra interest. The lighting is charming. Dr. E. G. Booia has, we think, let his pretty picture of a girl talking to a bird on her wrist suffer from too much laxity of focus in the distance. The figure seems to be lost amongst the

SELECTING COMMITTEE IN THE TECHNICAL AND SCIENTIFIC SECTIONS.

Upper Row—C. Thurstan Holland, F. Cheshire, Douglas English, and W. Farren.
Lower Row—C. E. Kenneth Mees, A. J. Newton, and Major General Waterhouse.

shows a large head of a handsome, robust girl, named "Cleo" (7), which is very flat in treatment and almost in a single tone, but yet gains solidity and rotundity at a little distance.

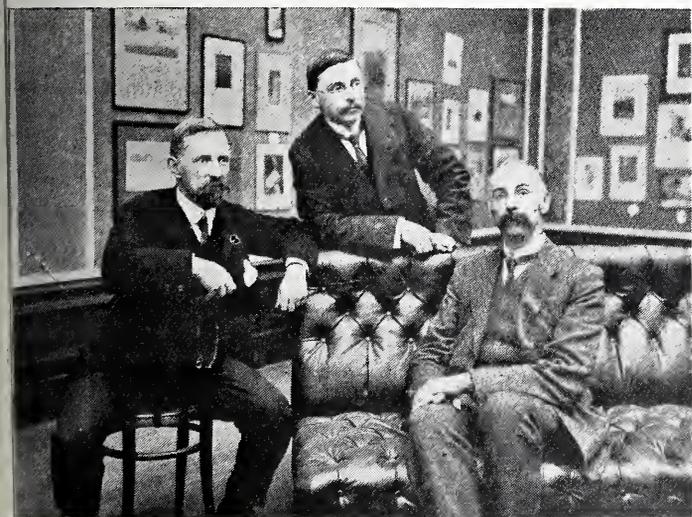

We suppose that W. L. F. Wastell quite knew what he was about when he placed his Trafalgar Square fountain in the centre of his print. There are certain interests of light on the extreme right and left hand sides which he perhaps did not wish to sacrifice. He has very successfully secured an effect which must have charmed us all at different times, namely, the light in the spray and its reflection in the water below, backed against what is, by contrast, a misty darkness. He calls it "Ripples and Spray" (8). "Repairs" (9) depicts

blur of disquieting surroundings, but there is fine quality in his picture of "My Neighbour's Pergola" (11). Another missed opportunity shows in "The White Swan" (12) by H. W. Batley. The glory of a swan is largely its whiteness, but in this print the very full middle tones discount that particular charm, although the spread of the wing and the grace of the neck could scarcely be better. The water is characterless—that that matters much—but another choice of view might have helped matters of contrast. We do not like to see the water go out at the top of the picture without a finish. There is a deal of dignity and splendid composition in "The Pillars of St. Mark" (13), by John M. Knapp. The two loafing figures

the right-hand side are an excellent foil in the sentiment as well as in the making of the picture.

South Wall, Left Panel.

In "The Viaduct" (14) Harry Wild gives us another of his effective mountainous landscapes. The viaduct itself is a good motive, but we miss the more romantic theme of crucifix or castle, such as particularise his subjects at the Salon. William Davenport has chosen his view of "St. Nicholas, Amsterdam" (15) with most precise ideas as to symmetry. The effect is not bad when one recognises it, but at first glance it is a little wearying to find commonplace objects ranging themselves in such symmetry. We think the sky should have been lighter behind the dome and tower, and we believe he has overstepped the mark when he makes clouds take a pair of dome shapes on each side of the central architectural dome. G. P. Higgins gives us two nice orderly portraits, showing nothing out of the way, of "William Roberts, Esq." (16) and "Miss Cochran" (17): There are also a pair of John M. Whitehead's effective landscapes, "Lown Waters" (17) and "In the Lough Hills" (18). They are both quite different in mood and above his

SELECTING COMMITTEE IN THE COLOUR PHOTOGRAPHY SECTION. From right to left—James A. Sinclair, F. Martin-Duncan, and Ernest Marriage.

average, which is saying a good deal, and it is difficult to make a preference. "The Cornfield" (18), by Gideon Clark, is fine in its tones, and we cannot say we admire its composition. Neither is there much composition to boast of in W. C. S. Egusson's "Holly Tree" (19). H. Essenhigh Corke shows the extremely attractive head and shoulders of "Miss E. W. S." (20). His print is very low in tone. In "The Silent Pool" (21) we have the never-failing attraction to photographers of reflections of trees shown at great length and with more regard than the originals which cause them. Such a print as this may be thought to be decorative in a certain way by some people, but it is curious landscape art after all.

South Wall, Central Panel.

John Dunlop very dramatically presents a "Thames Tug" (22) under the most awful conditions of weather due to "contrast" of some sort or another. When we come to George W. Mer's "Wood Magic" (25) we are face to face with an old-fashioned subject, singled out by old-fashioned ideas, of what is beautiful in nature and art without any obtrusive "decorative" quality or without unduly forced effect of lighting or colour. This is simply an honest selection by a man who has his own innate ideas of what he likes, and in our opinion it is one of the nicest landscapes in this exhibition. It depicts a trees and bracken with a misty distance—commonplace

subject enough, and photographed thousands of times; but it does not pall as do Dutch canals, Dutch bridges, reflections of things we cannot see, and other photographic resources of that kind. "St. James Street, Lincoln" (26) is a rather hot bromoil print by Bertram Cox. Judging from the way the light falls on the tower and on the road, the full-faced lighting of the chief object has been falsified in the pigmenting. There is no harm in enhancing an effect when printing with control, but we think one should keep a consistency in the natural phenomenon of a view. As it is, Mr. Cox might have given a little less light to the gable and a little more to the tower. "The Old Jetty" (27), a toned bromide, is unwarrantably low in tone, although the subject is one of brilliant sunshine. It is a very picturesque selection where some dark figures give the necessary accent. "A Gleam of Sunshine" (29) falls upon pillars and a curtain wall in a cathedral in a most effective print by S. G. Kimber. Mrs. Hester Perry has been highly successful in the rolling mists that come down a valley in "The Kingdom of Kerry" (31). The tone values, lighting, recession of planes, and general feeling are all excellent in this successful print. F. J. Mortimer, F.R.P.S., who is always on the look-out for new ideas, has done extremely well in his "Landscape in Holland" (32), where a low horizon, unbroken except by a distant elm, yet justifies an upright picture by an inclusion of two almost branchless tree trunks and of a fine big cumulus cloud. We think this is the success of Mr. Mortimer's year. An ox cart, which is being loaded by a man and a woman, both extremely well posed, is the subject of the "Hillside Harvest" (33), by Alex. Keighley. If only this picture had more force and more effect it would be a work of high order. Sydney J. Tayler sends a very good mountainous scene called "Above Wastwater" (35), where the clouds have their relative brightness correctly given. This is a bromide. Next it hangs a bromoil. The difference in process is obvious without reference to the catalogue, for in "The Church in the Vale" (36), by C. David Kay, we find the proper relative tones of things all gone to pieces in the printing control. In other respects this is a picture which has good pictorial parts. We fear Mr. Kay has a little to learn in portraiture also, since in his portrait of "Miss G." (38) he has not shown his sitter off to the best advantage by making a pictorial motive of her sterno-mastoid muscles, while her face is turned away in darkness, and has an irritating passage of light in the background against its dark contour. We have a fault to find with Dr. E. G. Boon for allowing his very pretty little photograph of girls "Arranging the Flowers" (37) to share the absolute stony quality of the steps upon which they sit and the balustrade beside them. Louis Fleckenstein's "Mother and Babe" (39) is very much a reminiscence of similar subjects of recent exhibition, particularly those of Dührkoop, and we do not think he gains anything by the "rottenness" in the texture of his print. A very successfully worked bromide print is "The Cathedral of St. Ouen" (40), by T. Arnold Bennett. It is highly picturesque in subject and the pavement is right in tone, a rare occurrence. "Summer" (41), by E. T. Holding, gives us a charming damsel with her hand upon the latch of a door as she enters a cottage. The dimly reflected light from the walls near her is beautifully rendered. So are the objects upon the table to the left, only we think these are redundant in the picture, and we should prefer the doorway and the piece of wall to stand, all sufficiently, by themselves, letting the window and the table loaded with objects go by the board.

South Wall, Right Panel.

"Water Lilies" (42), by A. B. Webb, is a quite legitimately decorative piece in the Japanese style. The dainty arrangement of the single blossom is highly effective. There is more strength than usual in J. M. Whitehead's "Moorland Mist"

(43). The white clothed figures of T. Lee Syms appear again in "Her Great Grandmama" (44) with good effect. We really prefer this picture to most of those that he has given us on previous occasions. It is a highly effective group of mother and daughter, the child making beautiful lines. As an example of what pictorial qualities may be gained from a snapshot, the "Pedlar Woman" (45), by R. S. Kauffman, is highly interesting. She is full of character, even to her left foot with its toe turned in in the physical effort of the ascent of a hill. The trees on the left come well. A. K. Dannatt's "Portrait Study" (46) depicts a lady at a spinet. The poise of the head and the artistic management of the hands are its chief charms. "Heimkehr" (47) is a group of fishing boats returning at evening. The relative tones of water, sky, and boats has been most jealously preserved, with the result that the simple little motive makes an excellent picture, the work of Rudolf Kölmen. "Peter" (48) is a little chap of about two years old sitting by himself on a stony bank. The little figure is beautifully lit, and we congratulate Miss G. Back upon his appearance in this collection. "Stephen" (49) is an older boy in a large hat. This is by G. W. Miller, and is a little more ordinary, though effective enough. A. B. Webb has struck a new idea in his delicately toned three-quarter figure of a lady in sunlight, which he calls "A Summer Fantasia" (50). He has secured an excellent effect in his background, which consists of a wall on which tree shadows are playing. In "A Flower" (51) Bertram Park has far surpassed his other efforts. We think the left hand is unfortunately posed, but the print as a whole has richness and quality.

West Wall, First Panel.

Sky and sea are too dull in W. L. Crossley's "A Corner of the Harbour" (52), which wants more effect. In contrast with this we may look ahead to Mr. Mortimer's shipping subject, "Look out for Squalls" (63). If Mr. Crossley will glance at this he will see that the whole pictorial success of the subject lies in the breadth of light obtained by a cumulus cloud, which relieves the rigging and figures. Another "effect" of a different nature can be seen in John Moffat's "Proclamation at the Mercat Cross" (67), where a shaft of light coming diagonally across the picture is the making of an otherwise very gloomy view, crowded with figures and full of incident and interest; but its dignified breadth is due entirely to the massing of simple light and shade. Going back to 53, "Old House, Dinant," we see that George Hilderley is also wanting in effect in company with Mr. Crossley. Old houses by themselves will not make a picture, even with the introduction of a figure, especially if this figure is a rather uninteresting back view devoid of detail. Mr. Hilderley's darks are all of equal density wherever they occur. In F. E. Huson's "Oatfield" (54) there is a much more artistic counterchange of dark and light objects, one against the other. A dark stack to the right and some light standing grain to the left have been of the utmost service in picture-making in this instance. "The Sower" (55), by A. W. Hill, recalls a class of subject made popular by Millet's great picture of that name, but it is a pity that Mr. Hill did not take more lessons from Millet's masterpiece. He would then have given more importance to the head of his figure and not lost the lower part against a field too dark in tone.

"The Trail of the Frost" (56) is still another of those intensely photographic subjects which are all foreground and no sky. Still, we cannot quarrel with a picture so delicate and silvery in its contrasted tones. The photographer is Walter A. Scott. "An Awakening" (57) is by Miss E. L. Willis. Why she entitles it thus we cannot conceive. It represents a very fuzzy woodland scene through which the sun rays slant. It calls for no special remark. There is almost too much material in W. C. S. Fergusson's "Morning Shadows" (58), and for a morning view we feel that his sky is much too

dark near the top of the picture. The head of a lady who is holding a circular mirror close to her face so as to reflect her profile, is called "The Moon Goddess" (59), by Miss Emily Pitchford. We fail to see how she can be identified with Diana, but it is a fine head well placed in the picture, and the circular mirror is a novelty, and that is a desideratum in photographic work in these days. Dr. A. R. F. Evershed has sent better things here than he has to the Salon. In "The Edge of the Wood" (62) he has secured a fine quality. Even better still is the quality of the print he calls "The White Hull" (76), which shows the prow of a vessel lying in still water and dark wharves beyond. A dress of the sixties is the subject of C. D. Kay's "Costume Portrait" (64); the head is rather hard in treatment. There are two little girl subject hanging side by side which are of interest. The first is "Miss Mischief" (65), by Mrs. K. Haenel. Here the little girl with bare legs sits upon a chair and appears to be suffering from maternal repression. In the next a little girl stands reading a book which supplies the title "A Fairy Tale" (66). In this Miss W. H. Prout has achieved a decorative effect by obliterating the background and providing a slight shade for the figure to stand upon. The few shadows that remain suggest the effect of bas-relief rather than that the child is standing in free air.

"Flowers for the House" (68) gives us again the steps and balustrade which Dr. Boon used with better effect in the picture we have already dealt with. In the present case there is but one girl upon the steps. This print has the same defect as the other—a want of differing textures. We do not care much for B. F. Eilers's "In Restless Water" (69). The subject is not subject enough in it for a picture, and the oil process has not in this case imparted any extra interest. A small nude figure is used with a good deal of success in a rocky view entitled "By the Waterfall" (71), by C. O. Freytag. It suffers a little from want of simplification. Anybody in ignorance of the meaning of the term "Strubley Head" (70) may perhaps get an explanation by studying W. D. Brodhun's head and shoulders of a child under this curious title. The treatment of the hair is highly successful, and the child's profile is sweet and engaging. "At the Stile" (73) is a village idyll, by C. Plenderleith, with an uninteresting foreground. O. E. Wilms sends a head and shoulders of a dark woman, which he calls "Minneha'ha" (74). We think the line of shoulder and arm that runs down to the right-hand corner is a little regrettable. A. H. Lisett has procured from somewhere a most curious head-dress for his figure entitled "The Pendant" (75). This alone is sufficient warrant for a safe entry into a photographic exhibition. He still further gains on the side of peculiarity making his sitter hold up two fingers from which are stretched the pendant and chain. The whole thing is as queer as it can be, but it is quite good from a technical point of view and unusually nice in quality.

West Wall, Second Panel.

Mrs. K. Haenel has two views of a pleasing model, which she calls respectively "In Granny's Time" (78) and "Roses" (80). We prefer the former, which is prettily posed. A very choice piece of still life comes from W. A. Stewart, comprising some roses in an antique glass, which are reflected in "The White Mirror" (79). The centre of this panel is occupied by what is called "A Japanese Landscape" (80). So far as we can see through the reflections of the velarium in the glass and the flat, faint, stencil forms of the print, it represents a bridge going in one direction and a branch in another. We believe the Japs have better ideas of composition than this, and we do not feel that the result is either decorative or pictorial in the proper sense of the words. The bugbear of decorative arrangement is carried to the utmost point in Dr. Boon's "Pot-pourri" (81). He has placed his figure in the middle

f a couch which faces us in horizontal lines. The lady's dress is fanned out in a purely symmetrical way. We are only surprised that the head has been allowed to turn out of the straightforward aspect.

West Wall, Third Panel.

"Homeward at Evening" (85), by T. B. Blow, stands out as a picture, in which the true sunlight effect has been allowed full play in a practically straight print. This light envelops the landscape and falls with excellent pictorial effect upon the figures of two native women, the left-hand one of which is perfectly classic in her grace of pose, her handsome face, and her picturesque clothing. We can only wish that a little of the print had been trimmed off on the left-hand side, as the figures, as they stand, are not quite pleasantly placed on the paper. There is a little stodginess in the dark tones of Mary Taylor's pretty subject, "The Gold Fish" (86). Those of our readers who have ever suffered at the hands of the critic, C. Tilney, may now indulge in recriminations, since he appears this year as a photographer, stepping into the arena with two costume subjects. The first is "His Eminence" (88), a figure with an eye to pierce plots, and the "Painter's Model" (89), who represents a man-at-arms in the time of Maximilian. The model has the brutal type proper to this class of man, and is furnished with fire tongs in lieu of a sword. Such an extemporised weapon would unfortunately be useless in the case of a photographer's model. "Helen" (89), by H. W. Finns, is a charming little print of a little girl, whose innocence and wistfulness are quite captivating. We now come to a pair of portraits by Furley Lewis, which we think surpass anything that he has in his own show in the professional room. That of "Childe Poccock, Esq." (90) has splendid animation and movement, whilst "Horace Mummery, Esq." (91) gives the man to the life with his somewhat troubled abstraction. Another pair a little further on are equally striking and realistic. They are "Mons. Wassili Safonoff" (102) and "Pirie Macdonald, Esq." (103).

"Young Holland" (92), near at hand, is a group of Dutch children at play, photographed by F. J. Mortimer, R.P.S. The action of the children is capital, but the print is too sodden for our taste. "In Amsterdam" (101) is, from the point of view of tones, a more satisfactory print, and in motive is very like the Bruges subject at the Salon. "Mother and Child" (93) and "Sussie" (99) are two splendid enlargements by G. A. Amy. "Sussie" is particularly happy, being a portrait of a little girl seated upon the floor and illuminated by reflected sunlight. The figure in D. A. Davis's "Contentment" (94) appears by her pose and action more apprehensive than content. We do not like the way she is placed in the middle of the floor in quite an unusual manner, and we think the print may be described as dirty, but we admit that it possesses that elusive charm, quality. The same background is used in the curious grandfather's clock subject which he calls "Forever-Never; Never-Forever!" (100), a title which we confess is beyond us. In this picture the figure is not free from stiffness. James A. Sinclair sends a view of "Antraigues" (105), a city on a hill in a mountainous district. We feel disposed to criticise the management of the distant mountains, which are distinctly edgy. Three platinum prints from Miss Schönberg do not interest us very much. We think the best is "A Study" (98). This is a head, larger in scale than the others, and shown in profile. "Sunshine," by W. H. House (105) is the portrait of the head and shoulders of a boy in a large brimmed hat. The boy's face is puckered up as a defence against the strong light. It is a piece of realism, but that is all one can say. We like better his "Joan" (107) which hangs next. In this pretty little girl's head there is less of realism. "Portrait of My Wife" (108), by H. Essenligh Corke, is a light-toned head and shoulders of sharp definition.

West Wall, Fourth Panel.

A fairly successful outdoor nude subject is treated in "Hesitation" (109), by Arthur Smith, who shows two boys stripped at the edge of a river. They are not happily placed for composition, and their bodies are a little porcelain-like. When we come to "A Sunlit Court" (110) we have reached what is, in our opinion, one of the choicest gems of the collection. This court is seen through a sort of covered way. A strong light falls on the floor, and the figures of an old woman and a little girl stand in the rays. The great beauty of this print lies in its general harmony and quality. With the exception of the sunlight on the ground, which is a thought chalky, all the tones are perfectly given; the distance is well thrown back, and the effect both realistic and pictorial. This very pleasing work is by T. Arnold Bennett. R. T. Dooner has missed any such qualities in his head and shoulders of a girl whom he calls "Ceres" (111), rather strainedly placed in a lunette-shape. We get more quality again in J. C. S. Mummery's "Barn Door" (113), which all have seen before, and which we need not describe further. E. T. Holding's large and imposing print, "The Magazine" (112) is, we feel, too harsh in its contrasts. Particularly, we think the lady's face need not have been so dark. The figure is happily posed, but on the whole we much prefer his smaller work "Summer" before referred to. Bertram Park's dramatic semi-nude, "The Watcher" (115), is not happy in its lines, but it is full of good qualities and promises better things in the future. The hardness and unsympathetic management of "Chateau Dieppe" (116), by H. Jacob, may be against it in some way, and its flatness of tone is no doubt a drawback. Nevertheless there is a grandeur about the simplicity of its effect and the romance of its solitary and forbidding aspect. The effect of light above and behind it is highly advantageous.

West Wall, Fifth Panel.

A beautiful sea piece comes from G. P. Jordan. He calls it "Ancient and Modern" (117). A sailing vessel is opposed to a not very modern steamboat, the smoke from which has been turned to fine account. Another eminently pleasing work is "The Summit of the Pass" (118), in which William Rawlings has given with great realism a gloomy and stormy effect upon snow-covered heights. Both these works are unusually good. "The Trespasser" (119), by W. C. S. Fergusson, is a cow or calf which has found its way into an orchard. We think this print suffers from unnecessary lowness of tone. "Last Year's Leaves" (120) is better, because here Ward Muir has given a proper contrast between the near tree trunks and the distant brightness of the wood. At a street corner, where a large ornamental lamp hangs at the entry of a passage, "A Gleam of Sunshine" (121) shoots down into the desolate and grimy locality with startling effect. This style of thing is not new, but it is always welcome when it is well done, as in this instance. A very pretty little child, engagingly posed, plays with "Buttercups and Daisies" (123) in H. W. Rennie's print, the quality of which is good enough to be that of a good oil print, which we believe it is. F. A. Lidbury has caught some of the modern spirit of German landscape in his picture "A Winter Landscape" (124). It is more quaint than beautiful, but one cannot deny its attractiveness. It is curious that three thin tree stems far apart on the snow-covered flat banks of a river should, by means of artistic treatment, afford such a pictorial subject. "When the Evening Lamp is Lighted" (129), "In Maiden Meditation" (122), and "Con Amore" (125) are three pictures by G. A. Davis. They are figure interiors which do not call for special remark. Tom Crabtree is a name not familiar to us, but we are glad to meet it since it subscribes such an excellent bromide enlargement as the view of St. Paul's seen through shipping. Its title is "In the Grey of Dawn" (126). The whole thing is excellently managed and

full of good feeling. A village street in a state of flood, and showing nothing but doorways and a few windows, with no distance to speak of and never a figure, has yet some pictorial claim on account of the surface of the swampy road, which is quite in the manner of Fritz Thaulau. This is by C. D. Kay, and is called "After Rain" (128). Arthur Smith contributes a landscape very large in style and quite according to tradition in the picture "A Yorkshire Valley" (130). Though quite a modest print, this is one of the good things of the Gallery. "The Haunted Room" (131) is another version of the two figures in the picture by Mr. Syms we have referred to before. "A Profile" (133) is likewise almost a replica of the print which Miss Warburg has at Pall Mall, but the present version strikes us as being preferable in roundness and realisation to the other. A quite impossible moon spoils A. B. Webb's "The Dawn of Night" (134). Another river and St. Paul's view comes from Arthur Norman under the title "Domine Dirige Nos" (135). This boasts a good effect. "Burgtor, Rothenburg" (136), is a highly successful view of the entrance to the old German castle by John H. Gear. Needless to say this is an oil print controlled with great skill.

North Wall, Left Panel.

"The Man with the Hoe" (137) comes from James A. Sinclair. A rapid exposure has seized the figure at a point when one foot is off the ground, resulting in a pose which is a little unusual. Mlle. Laguarde gives us a beautiful oil print, controlled with the utmost delicacy and clever management in "L'Été" (138). One of the finest pictures that Mr. Holding has recently done is the mother and child laughing together over what he calls "A Good Story" (141). The figures are placed close against the wall, and the shadows help to bind the composition together, and this shows much clever resource. The pattern is highly successful, and the quality of the print is all that can be desired. A winter view by Leonard Misonne, "Village de Campine" (142), is beautiful in composition, but we cannot quite account for the lighting of the ground and the distant gables. "A Street in Chartres" (143), by Mrs. M. E. A. Powles, lacks pictorial interest. R. T. Dooner's allegory "Dawn" (154) appears to be a little far-fetched, and, to our mind, unsuccessful. Much more interesting is the fine study of the young man in antique garb, called "The Cigarette" (145). Here we have animation of pose and a lively expression, to say nothing of the charm of the blacks and whites in the print.

North Wall, Centre Panel.

"Summer" (147) is a very charming woodland scene by P. Bale Rider of wild flowers under willow trees. A fine effect of light under arches is shown in the very lively "Market Place, Lucerne" (148), by W. A. I. Hensler. J. C. Warburg has sent a picture which we consider to be the finest we have ever seen from his hands. Having written somewhat disparagingly of his faint effort at the Salon, we are all the more pleased to be able to record our great admiration for the very stately landscape entitled "Cypress Shadows" (149). It has composition and dignity, and the light in the sky gives it a culminating glory. We are unable to tell in Mrs. R. Dunlop's "Winter" (150) whether the distance is backed by mountains or clouds. There is also a curious give-and-take of light all over the snow in the front, a mottled appearance which we never remember to have seen in nature. "The Night Cometh" (151) is an extremely effective view upon the Thames, with a cluster of four shafts belching smoke, while the sun is setting at their feet. It is by Frederick Humpherson, whose works we hope to meet again in this Gallery. We now come to a picture which has been the subject of some differing opinions. It is a colonial work by Nelson Stedman, and it depicts an old horse straining at the traces. We have referred to it before

in another exhibition, and it is only necessary now to repeat that we consider its black background does it more harm than good. A capital snow scene, beautifully rendered and very tender in effect, is presented by Thomas Wright under the title "In Winter's Cold Grip" (154). In "Bruges" (155) we have at last the much bephotographed town under a new aspect. As a matter of fact Bruges itself is non-evident, being crowded out by an ecclesiastical procession and the onlooking crowds. The picture is very lively. We feel the want of some accent of simplicity in W. R. Bland's charming woodland scene called "A Glen" (157). If some of its sparkle could be infused into James Gale's windmill scene, "Nature's Garden" (158), which is too flat and fuzzy, and some of the restfulness in this transferred to Mr. Bland's glen, the exchange would be advantageous. Peter Orr preserves with fixed determination the different planes of his scenic subject "Gilmorehill—Evening" (159), and a good pictorial effect has been achieved by Alex. Keighley in his "Eastern Gate" (160). This is a print of great charm, the gradation in the sky being particularly noteworthy. It looks like a book illustration of old times more than a modern photograph. Mrs. Barton, who, we are glad to find, has taken a fresh lease of artistic life, gives us a "Boy with Apple" (161), which is quite like an old master in its richness of strength of design. This and her portrait at the Salon show her to have overcome the slight falling off which we felt in her recent work. "Reverie" (162) and "Storm" (163) are two good subjects by James Cawwood, but they both suffer from over-darkness. Even the storm is more gloom than it need be.

North Wall, Right-hand Panel.

Rather a forced effect of light and shade, but pleasing in its play amongst architectural features characterises the motif of F. H. Cliffe's "Where Light and Shade Repose" (165). We like it as well as anything he shows this year. Sunlight in trees has rarely been better rendered than in W. G. Meredith's "The Bridesmaids" (167). The subject is a procession of little girls, presumably bridesmaids of the church. The sunlight glints upon their white dresses and casts shadows before them on the shining pavement. The air above is full of dusty light and the effect as a whole is highly pleasing. "The Quay, Boulogne" (168), is another effective oil print by J. A. Sinclair where we think he has perhaps gone too far in repressing the distance and accentuating the near figures. "Verschneit Waldweg" (169), by R. Kölmen, is one of the most beautiful snow scenes we have ever seen. The light upon the snow-covered ruts of the road is quite captivating, and the infinite delicacy and tracery of the trees have not resulted in the slightest loss of breadth. So true are the tones that one can almost imagine the complementary colours of the blue in the shadows and the warm tints in the lights. Next to it has another excellent view. This is "Marée Casse" (170), by Leonard Misonne. Here the effect is of wet sand, which lights in ripples and culminates in a bright spot underneath the stones. Several figures and a bathing-machine are silhouetted against the sky. It is to be noted that both these excellent things come from abroad. We think J. B. Johnston has lost much by a mixing up of near and distant planes in his otherwise picturesque view "On the Esk, Midlothian" (172). B. W. Thompson sends a photograph of a rainbow under the title "A Token of a Covenant" (173). We think this is one of his best works. There is a deal of truth in it, particularly in such rarely observed phenomena as the slightly brighter light in the sky within the arc compared with the sky outside it. It is a pity that the whole picture is so low in tone.

East Wall, Left-hand Division.

Of two pictures by Mrs. M. Ralli hanging together, "Shadows and Sunlight" (174) is not quite so good in effect as "S-

chine" (175), although the latter is only a little girl in a road, and the former is a much more ambitious subject of a market square, dark archway, and brilliant distance. "A Morning Walk" (176) is almost professional in its studious attention to details of costume and general presentment. It shows a lady prettily posed, holding a parasol, and walking away from us towards an avenue in the distance. It is low in tone and nice in general effect. In a magnificent and harmonious frame W. Crooke presents one of his inimitable mezzotint-like portraits. This is a likeness of the late Lord Robertson (177) in his legal robes, and is exactly in the spirit of the best work of this class of a past century. "Richard Langford Speaight and his Mother" (178) will be recognised as one of the chief attractions of Mr. R. N. Speaight's own show in Bond Street. We have dealt with it before in these columns, and need do no more now than recommend it again to our readers. Another picture by Mrs. Ralli of three peasants standing on a quay has far better qualities and effect than the two we have just mentioned. The title is "A Gossip" (179). Frederick Hollyer sends his well-known portrait of "George Meredith" (180). We suppose that in the minds of the poet's admirers this presentment of George Meredith will be most easily remembered. It lacks the feminacy which some other portraits have given to the subject, and is more full of character and strength. Ernest Carriage contributes a group of spectators "At The Bull Fight" (181), in which he has contrived, by the use of the seat backs, to weld unpromising material into an effective composition.

East Wall, Middle Division, First Panel.

"By the River's Brim" (182) recalls the steel engravings of old-time in its method and manner. It is by Henry Bond, and is pictorially quite successful. We wish we could say as much for Peter Orr's "Decorative Portrait" (183), a class of work with which we feel out of sympathy. It is much more healthy photographic art which produces "At the Horse Fair" (186), by Mr. Evershed. This is a good group on the turf, quite natural and of the times. We only regret that it is so needlessly dark. We might say almost the same of "The Smith" (184) by Harry R. Hill, where the chief defect, if there is one, is the hardness and "edginess" of the chief figure. Miss E. Pitchard's picture, "Mother and Child" (188) and A. J. Craston's "Simple Life" (191) are also quite unaccountably dark in tone. We wish we could see the advantage of this method of darkening prints so that they are neither decorative nor naturalistic. It is a pleasant relief to turn to Mlle. Laguarde's "Paysage" (189), which has something like a full gamut of tones, and is, in consequence, much more decorative than the would-be decorative somy prints. "In an Essex Creek" (190) is Mr. S. E. Wall's

only contribution, but it stands apart from many by observing the sound traditions of picture-making in the matters of scale, composition, arrangement, and tonal value. We think this delightful picture one of the best we have ever seen from his hand.

East Wall, Central Division, Centre Panel.

This section is almost entirely composed of prints in colour. They mark a distinct advance on the similar attempts of last year. One in particular must be regarded as a tour de force in oil printing. It certainly has never been approached for realism, and the full effect of a painted picture. It is called "Writing to Her Sweetheart" (199), and comes from Ramiro Lorenzale of Barcelona. We fear, however, that it is not entirely innocent of paint locally applied independently of the action of the gelatine. The same worker sends two colour gum prints, which show a great falling away from the high standard of the oil. They are quite arbitrary in the localisation of the various tints, which seem to wander about in defiance of the photographic forms. Miss Hildegard sends a print, mostly blue, but evidently in two printings, called "Einsamkeit" (192), a truly lonely-looking group of trees in a landscape of much feeling. It is a pity that Geo. Hilderley made such a sodden print of his fine group of "Women on the Beach, Cancale" (194). His two views of Volendam, "Evening" (198) and "Early Morning" (200), are in full colour; but we feel that, highly creditable as these results are, they fall between the realistic and decorative ideals. Dark tree trunks and a watery road make the subject of N. H. György's powerful "February" (195). The same clever worker is seen to even better advantage in "Village in Winter" (204). Here the houses in the village street are brilliantly lit by a pinkish sunlight. A fine effect of artificial lighting is given by Fred Judge in his "Embankment at Night" (196). Leonard Misonne's "Verdure" (201) is the one of his which has been chosen for illustration in the catalogue, though in our opinion it is by no means the most worthy of this distinction amongst his contributions.

East Wall, Central Division, Right Panel.

Upon this wall are a group of portraits that are, on the whole, below the level of the rest of the exhibition. The most ambitious is the large back view of a nude figure, of rather contorted pose, which Miss M. Schönberg sends under the title of "Dreaming" (210). Of the rest the best is a girl's head with a sweet expression. This is "Elona" (211), by Augustus Thibaudeau.

Here we leave an exhibition of which it must be said that a better has never been produced by the Royal Photographic Society.

PROCESSES AND PICTURES

AT THE NEW GALLERY.

In the pictorial section the catalogue states the process used in the case of 119 pictures out of 214. Of the remaining 95 are by a worker who is well known to always use platinum, while two other pictures are known to be oil prints. We have added these extra numbers to those gathered from the catalogue, and the results are as follows:—

Coloured oil prints and gum colour pictures are included in above figures. Eighty-nine prints are unaccounted for in the table, but even though the figures only represent a part of the total, nevertheless the two oil processes account for nearly 20 per cent. of the whole, which is a goodly proportion. The figures for carbon and gum would probably have been considerably increased if all exhibitors had responded to the invitation to state the process, while we may be certain that the figures for the bromide and platinum processes are much too low. The popularity of the oil methods is, however, very evident, and it will be seen that honours are about equally divided between the original oil and the bromoil processes. The total number of pictures is very much reduced compared with last year, when they amounted to 309, or 85 more than the present number. This reduction in numbers greatly improves the appearance of the walls, which were much overcrowded last year.

SCIENTIFIC AND TECHNICAL SECTIONS.

These sections show a marked advance over last year in point of both numbers and scientific value. As is usual, zoology is a very important feature of the exhibition, but though this section is even bigger than usual, yet less than half the frames are devoted to it.

"Fur and Feather."

Fifty of these frames are contributed by members of the Zoological Club, and are hung on the south wall of the gallery; the numbering of the frames, however, commences on the west wall with the general zoological exhibits. Among these W. Bickerton is prominent with frames 301, 302, and 303, the first representing the Stone Curlew and the others the Arctic Tern. Frame 302 should be specially noted for the sake of the beautiful wing plumage shown. O. G. Pike shows a fine enlargement representing the Raven (304), and also has some very interesting studies of the Buzzard (308-9), which are, unfortunately, toned to a very unpleasant colour. He also has a good photograph of a Sedge Warbler in 313. An exhibitor whose name is new to us is Kathe Hecht, who in frames 305-6, 335-6, shows some very clever and humorous animal and bird studies, some of which are very delicately tinted. A curiosity is 314, by Alf. E. Tonge, which illustrates the Marbled Green Moth asleep on a brick wall. Attention is directed in the catalogue to the protective resemblance of the moth, and this is so effective that we failed to discover the insect at all after a prolonged search. E. J. Bedford's Young Long-eared Owls (316) will no doubt attract notice on account of the quaint expressions of the sitters; his Young Common Sandpiper (319) is also interesting. No. 317 is a very lifelike photograph of a Fox, by F. Martin-Duncan, and George A. Booth's 325, 328, and 329 are of special interest, as they represent probably the first application of the oil process to zoological photography. These are very good indeed, and show very fine and careful pigmentation, though it is obvious that this would be a somewhat risky process for scientific record work in the hands of an inexperienced worker.

The next things to specially note in this part of the gallery are some frames containing series of photographs, the finest of which are perhaps Dr. Gray Duncanson's set (330) illustrating the metamorphosis of the Dragon-fly. Another good set is J. A. Lovegrove's (332-4) showing Sea Spiders, while Philip J. Barraud also has a very interesting frame (324) showing the Six-spotted Burnet Moth at six different stages of its emergence from the pupa.

We now turn to the exhibit of the members of the Zoological Photograph Club, Nos. 447 to 497. Some good, well-exposed, and rather humorous pictures of Guillemots are shown by C. J. King (447), and Mrs. L. J. Veley has some fine studies of Dogs in Nos. 451, 457, and 459. Her Swan (452) is an equally good specimen of photography. R. and V. G. L. van Someren show some good photographic work in 455, in which the White-throat at nest is shown in three enlargements, which leave nothing to be desired in the way of clearness.

We then come to some series of great scientific value. Dr. Francis Ward shows the life history of the Plaice in frame 466, while Alfred Taylor has two most interesting series showing the life of the Merlin (469) and that of the Cuckoo (470). The one fault of the second frame is that the Cuckoo has evidently been taken from the nest and set in somewhat unnatural surroundings. Wm. Farren also has some sets in frames, 471 to 474, which are quite up to the usual high standard of his work. Riley Fortune shows a good set of pictures of a Gull in frames 476 to 480, all of which are well worth close study. Miss E. L. Turner has a number of frames, all showing her usual excellent work. No. 481, entitled "Water-rail: A Hatching-out Day," is especially interesting, the unceremonious manner in

which the mother-bird breaks the shells and lugs out the youngsters being quite amusing. R. B. Lodge shows some fine photographs of a Golden Eagle (483-5), while Douglas English contributes some of his familiar studies of insects, which for delicacy of treatment can hardly be surpassed. Studies of British Lepidoptera, in frame 493, show some of the most beautiful examples of his work. He also has four frames of larger animal studies, of which the Fox Cub (497) is perhaps the best.

The zoological exhibits are completed by a set of thirteen large prints, collected for exhibition by R. Voigtländer, of Leipsic. These are all good, but special attention may be directed to 505, Red Deer, which is quite pictorial in its treatment, to 507, a Fox Cub, and to 511 and 517, which respectively show an Æsculapian Snake and a Green Lizard.

General Scientific Work.

These are very varied, and much good work is shown. A little print by J. Howden Wilkie (338) is worth notice, because it simply illustrates a distant rain-storm, a familiar phenomenon which many would pass by as too trivial to notice. Some fine snow studies by E. Igel (344, 5) should not be overlooked, while the balloon photographs of Oscar Halldin (351-6) are sure to compel attention. As a rule photographs of this class are foggy and disappointing productions, but these are as clear as could be wished, and show wonderful map-like views of the town and country underneath. No. 352 should be specially noticed, for it shows with remarkable clearness the wave-formations in the water below. We next come to a very interesting series of photographs by R. H. Yapp (357-362), showing mangroves and various other growths in damp tropical regions. Dr. Vaughan Cornish again illustrates his favourite subject, waves, but this year the particular waves dealt with are those produced by sledges when travelling over snow or loose gravel, and they represent the result of an investigation into the cause of the formation of these waves. Close by there are two frames (374, 5), containing very fine and very valuable sets of photographs, illustrating in one case, "A bit of good feeding turf analysed," and in the other "Clovers, and some of their Impurities." These are by D. Finlayson, F.L.S. Various frames of photo-micrographs are distributed among the other exhibits, and prominent among these is one (327) by Alf. E. Tonge, showing the egg of British butterflies and moths. These objects are themselves often very beautiful, and their representation here is as perfect as possible. Dr. Rodman has some photo-micrographs of diatoms (378) and F. Martin-Duncan a frame (379) showing Tripanosomes, all of which are worth careful study.

Dr. Charles Lester Leonard has several radiographs (380-388) illustrating subjects of medical interest, and we once more see some of Dr. Rodman's beautiful radiographs of Mollusc Shells (383), with one example of a similar subject in pseudorelief (384). Two frames here, by Professor P. Zeeman (388 a, b), illustrate the magnetic resolution of spectral lines, and should be studied in connection with his transparencies, which we refer later. A photograph of the extreme red end of the solar spectrum, by Dr. C. E. Kenneth Mees and E. Kenne Hunter, shows remarkable resolution and much detail, the space between the A and B lines being $8\frac{1}{2}$ inches. Other spectrum photographs are shown by A. Fowler and Prof. H. Kayser, and by C. H. Fabry and H. Buisson, the latter (392-4) giving interesting examples of interference spectra.

Dr. Max Wolf has a very fine series of astronomical photographs (399-410), in which many beautiful nebulae are shown in fine detail. The comet Morehouse is also included in the series, while it again appears in the set of frames (443-446) sent by the Astronomer Royal. This second set of frames also shows the satellites of Jupiter and Saturn. Frames 412 to 417 ill-

trate the results of an important investigation undertaken by Dr. C. E. K. Mees and E. Kenneth Hunter into the questions of resolution and irradiation in photographic plates. These can be understood by reference to the detailed description given in the catalogue. A frame of photo-micrographs (418), by J. H. Pledge, shows the various screen-plates at a common magnification of 150 diameters. These will be of interest to those who use the plates, who will probably be struck by the fineness of the units of the Autochrome screen as compared with the others. H. J. Channon has an interesting set of prints showing the intensifying or continuing action of yellow or red light on partially printed silver images. No. 420 is a "Photographic Slide Rule," by Mr. A. Lockett.

The technical section also includes a set of Japanese prints, lent by J. Orange, 3, Gray's Inn Square, W.C. These are interesting examples of Japanese photography, and worth attention. They are all by Japanese workers, and were exhibited at the exhibition of the Japan Photographic Society in 1903.

Colour Photography.

This year, while the transparencies are rather a strong feature, the colour prints are undoubtedly a weak one, none of them showing any particular merit or any advance. No three-colour carbons are exhibited at all.

Miss Acland has two prints, of which we like best 434, Study of Crimson Bougainvillea. Samuel Manners has seven, of which the simplest, 441, Roses, is, as a whole, perhaps the most satisfactory. In most of the others the colour details are remarkably well rendered, notably in 436, Grapes and Apricots, but too often the subject is spoilt by an unsuitable background. One print by the Sanger-Shepherd process (442) is contributed by Owen M. Bartlett, and the collection of colour prints is completed by a set of six pinatypes by Dr. E. König, of which set we like 500 and 501 best.

Autochromes

The Autochromes are exhibited in the same way as last year, that is, they are placed in sloping frames and viewed by reflection in mirrors placed underneath. This method works very well, and gets over in a convenient manner the difficulty of exhibiting a number of Autochromes at once, but it has the drawback that double reflections sometimes confuse the image. It is, however, difficult to get over this trouble, which is only apparent in some cases, not in all. Dr. Drake-Brockman has two good, large specimens in 637 and 638, the latter of which,

representing "A Casting of Pig-iron," is of special interest, as he applied John Sterry's bichromate method of treatment to avoid undue contrast, the result being very successful. The same exhibitor has some more good slides in Nos. 735-9, which are natural history subjects, and in 743-745, of which we like 744, a portrait, best. No. 641, "Sunshine," by Ellis Kelsey, has a very good sunny effect, and 646, "La Ménagère," by Jean Occhipinte, is a good specimen of a figure subject. Mr. Kelsey has many good Autochromes in the exhibition; 693, "Eastbourne Illuminations," repays close study, while 695, "Reaping," and 696, "Sunlight and Shadow," are both very pleasing little pictures. The same worker again scores a success in 740, "The London Express," which is an excellent example, though the exposure was only 1.25 second at $f/2.5$ with a Grün lens. J. C. Warburg has several good things; 654, "Notre Dame de Vie," being a striking example. "The Land's End," 655, is also a very pleasing picture, even though the sea is, perhaps, too blue. He has also secured a beautiful grey effect in 657, "Across the River Bed, Hayle." Nos. 709, 710, and 711 are also Mr. Warburg's work, "Jack and Jill" and "The Butcher's Shop" being notable examples. Some technically fine results are shown by W. J. Russell and O. F. Bloch in Nos. 660-662, and D. H. Illingworth and Thomas B. Blow show some excellent pictures in Nos. 663 and 664. A fine representation of a stained glass window is shown by Dr. G. Lindsay Johnson in No. 671, while a similar subject is treated with equal success by H. W. Fincham in Nos. 746, 747. H. C. Knowles has also very successfully used the Autochrome plate upon wild animals in captivity (678-9), which work must have involved fairly short exposures. Walter V. Westlake shows two good specimens of Thames plate transparencies in Nos. 683-4, and the same plate has been used by Colin N. Bennett with not quite so much success in No. 699. Urwick Jones, who was very successful last year, again contributes four excellent pictures in Nos. 689-692, of which 692 is quite a charming water scene. T. D. Ralli has two very pleasing figure studies in Nos. 705, 706, while H. C. Knowles has a good portrait in No. 707. No. 708 is a fine study of a Rose, by Sydney A. Pitcher, there being very few flower studies in the exhibition. E. J. Bedford again shows a number of transparencies of natural history subjects, which well illustrate the great advantages of the plate for such work. Another series by Dr. C. E. K. Mees and J. H. Pledge show the effect of superimposing various screen plates so as to obtain a moiré effect, and No. 717 is really quite striking. It is interesting to note that Dr. Mees also appears as a pictorialist in "A Meadow under the Hill," No. 712.

PROCESS AT THE R.P.S. EXHIBITION.

By far the most important exhibit so far as process work is concerned is the frame sent by Arthur Payne, showing the stages of the Paynetype process (North Gallery). This method of producing blocks direct in the camera (that is, photographing a sensitized metal plate instead of first on to an intermediate glass negative) has already been described at length in these pages. It is, however, of the highest interest to see the actual stages of the manipulation of the new material up to the point of the etching, which is then exactly the same as in the ordinary process of blockmaking. A line block is also shown by Mr. Payne, in which the acid resist has been formed of deposited copper, and also a print from a half-tone portrait made direct from life, the first ever done. We presume it will not be long now before the sensitized metal for this valuable process can be purchased and used by any photo-engraver.

Adjoining this exhibit are a couple of frames sent by the L.C.C. School of Photo-engraving, showing comparative photo-micrographs of sections of plates etched by the various etching machines and in hand-rocked etching baths; also showing photo-micrographs of original etching and stereotype made from

the same plate. The series demonstrates the very unsatisfactory results that may be produced from good etchings if the stereotyping is not efficiently performed.

Messrs. Wratten and Wainwright have collected in the North Room a large number of three- and four-colour prints from various block-making firms who have used their plates to make the negatives. The most striking of these are, perhaps, the reproductions of marble. One (by Marshall and Co.) is shown framed up together with the original marble, and the accuracy of the reproduction is simply astonishing. This firm also show a reproduction of a piece of coloured embroidery, in which the effect of relief is excellent. Some of the other reproductions are of a large size, and all are extremely good. Walter Bourke, in his show of reproductions (South Room), includes four three-colour prints of pictures in Hampton Court Palace, which are very attractive in contrast to the monochrome reproductions all round.

Generally in the Technical section there is a good deal to be learnt by the observant process-worker. The enlargement of a point-image due to increasing exposures will convince him

of the enormous differences in truth of reproduction which exposure must make, also the exhibits showing the resolving power of plates and the effect of irradiation will explain phenomena

PROFESSIONAL PHOTOGRAPHY

The Professional section in the North Room is, in many respects, a great improvement on the last two or three years. It embraces a considerable variety of styles, so that any of our professional friends who visit it will find matter of interest. The room is comfortably filled, yet on the whole not overcrowded, and the walls have been so arranged that one class of work does not clash with another.

A very notable departure may be observed in the exhibition of oil prints by F. C. Tilney. Here, for the first time, so far as we are aware, in the history of professional photography, a photographer has produced the negatives, and the printing in this particularly responsive medium, the oil process, has been done by a man who is a trained artist and has devoted his life to the pursuit of art. We have carefully examined these oil prints, particularly those in colour, and they are *oil prints*, and not oil paintings on the photographic basis. By this we mean that the picture is in every case the result of pigmentation in the recognised way, the drawing being that of the lens, the colour and depth of it being determined by the pigmenter. It is, perhaps, fairly easy for an artist accustomed to brush handling to take a weak oil print and immensely improve it by *painting* on it. Mr. Tilney has not done this, but has been true to his medium, and his results lose nothing in quality or effect, and gain everything in purity of technique.

The prints demonstrate in a very convincing way the facility which stands at the disposal of the pigmenter in the way of imparting a particular kind of character to his work. The two oval prints on either side of the panel have the quality of a stipple engraving, whilst the portraits in the lowermost row approach nearly to the effect of the mezzotint. In every case, however, we think it will be admitted that the pigmenter has retained the photographic virtue of his material, particularly the likeness and expression of the sitters, and that we submit is a point which is of no little importance in the professional use which it would seem may be made of the oil process. Of the monochrome portraits, we admire extremely those of the Dowager Lady Gifford (5) and Sir Henry Parkes (7), from negatives by Gabell and H. Walter Barnett respectively.

Of the four in colour we prefer No. 11, a dainty and very attractive portrait of Mlle. Adela Atucha, the same lady who appears in the very charming monochrome portrait, No. 13. No. 10, Mlle. Josephine Atucha, is almost equally good. No. 3 is also a most attractive portrait, but possibly it would be improved by a little stronger colouring in the shoulder wrap. The face and head is perfect, but the picture seems a little weak in the lower part. Mr. Tilney is to be congratulated on his very successful essays in oil printing, and his set of pictures should be valuable to photographers as examples of the way in which a trained artist considers their materials should be employed.

Immediately on the left on entering the room we have the characteristic work of Furley Lewis. We think some of these prints would have gained had they been on a toned instead of a white mount. Several of them show the Furley Lewis mannerism—one might almost say they have been done according to the recognised Lewis formula—but we are glad to see that the portrait of A. H. Blake, M.A., is not one of these.

LANTERN SLIDES AND TRANSPARENCIES.

The greater number of these exhibits will be found in the base of the lantern stand in the North Room, but a set of fifty stereoscopic slides by A. E. Smith in a table stereoscope are in the gallery, and these may be dealt with first. They are all photomicrographs, and form a set of great scientific value, but many of

with which all process workers are familiar. These last are the work of Dr. C. E. Kenneth Mees and E. Kenneth Hunter.

It strikes a somewhat new note as to treatment, and is an eminently happy likeness, giving the characteristic impulsiveness and geniality of the sitter. Another work we specially like is the group portrait of Humphrey and Miles Tomalin. In "Patrick," an otherwise fine study, we dislike the reflected light in the right eye, and we think the portrait of Mrs. Parkinson rather heavy. We must not omit to mention the fine portrait of Dr. C. E. Kenneth Mees, fine as a characterisation of Dr. Mees, and fine as a typical Lewis portrait. The sitter looks a trifle self-conscious, but then

Of the Mattype work we can say little, except that it is not up to last year's in quality, and that the colouring is distinctly feeble in one or two instances.

Harold Moore's work is good, but possibly a little too conventional in pose and lighting. A very rich effect is obtained by the use of the carbon transparency backed up with various kinds of paper, and a portrait of a lady, in which the transparency, backed with silk, is quite dainty.

The series of reproductions of work in His Majesty's collections at Windsor and in the Bridgewater collection by Walter Bourke are interesting, technically very sound, and sympathetically produced. We particularly like the colour reproduction of the portrait of the Countess of Grammont.

One wall is entirely occupied with the magnificent platinotype enlargements of William Crooke. Commencing from the left-hand side the fifth and sixth—in each case a portrait of a lady—appeal to us as being works lacking nothing in strength of treatment and full richness of quality, yet essentially feminine and graceful in character. The masterly composition of the Irving portrait compels attention and admiration—no better or sounder piece of work is to be seen either at the Salon or in the pictorial section of the R.P.S., and the contrast between this and some of the puerilities shown at the former show, to which we referred in our notice last week, is very marked. It is in such works as this portrait of the great actor that photography comes into its own.

The display by F. A. Swaine, of New Bond Street, is one which will interest the professional worker, for every type of studio pose and lighting is to be seen. Some of these portraits have been done in the studio, and others are home portraits. Quite a number have a topical interest, as, for instance, those of the Rt. Hon. Herbert Samuel, M.P., and Mrs. Samuel. Some clever colour work is shown, among the best being Baby Adler, Mrs. Walsh, and portraits of Miss F. M. Craig and Miss N. Craig. The sketch portraits are interesting, being platinotype prints from negatives taken with a light background, a suggestion of landscape or interior being worked in afterwards on the print with lead pencil.

Fredk. Hollyer shows a group of reproductions of Holbein's work, of which we need only say that it is quite equal to the Hollyer reproduction work we have seen in previous years.

The sincere portrait worker will find much to interest and instruct in this room—a few, a very few, things which will show him what to avoid—and the exhibits, as a whole, should be distinctly stimulating.

them are also objects that will be of interest to the non-scientific visitor, who will doubtless be struck by the beautiful forms revealed by the aid of microscope and stereoscope in conjunction. The first four (numbered 586 to 589 in the catalogue, and 1 to 4 in the slides) show the eggs of various insects, and many will doubt

less be surprised at the beautiful structures revealed in many of them. Nos. 595 and 599 (10 and 14) are similarly attractive, while 620 (35), the Brittle Starfish, 625 (40), showing sponge spicules, and 629 (44), crystalline sand, are all objects of great interest.

Under the lantern stand in the North Room we find eleven more stereo slides by members of the United Stereoscopic Society. These are all well selected subjects of an ordinary kind, landscapes, portraiture, architecture, etc. All are good, but 583, by S. W. Shore, may be specially mentioned on account of the novelty of the subject, which consists of two profile portraits, one behind the other. In the same stand we find the rest of the transparencies, the first being a valuable set (518-522) by Professor Zeeman, illustrating the magnetic resolution of various spectral lines. With these we should study the enlargements of the same subjects (388A and 388B) in the gallery upstairs. Richard Hancock shows a fine series of lantern slides illustrating spiders and fungi, while natural history is also represented in slides contributed by Arthur Frost and Mewburn and Jackson. Perhaps the most valuable series of slides

is one by Walter Plomer Young, F.R.M.S., illustrating Old London doorways. The series (563-574) is well arranged, and selected to illustrate the various periods and developments, but technically the slides are of somewhat unequal merit. Some are, however, very fine, notably the one showing the elaborate doorway at No. 26, Queen Anne's Gate, Westminster. We are obliged to say that the transparency section is a very disappointing one. It seems to dwindle down each year, and this year there are very few exhibitors. Lantern slides are too small to show to advantage, and their proper place is in the lantern. Good transparencies of half- or whole-plate size are very delightful things to study, but there are none of them to be seen outside the trade stalls, so it hardly seems worth while to have a transparency section at all. Stereoscopic transparencies are, of course, very desirable exhibits, and we should like to see a much larger number, but their proper place is in a stereoscope. We feel inclined to suggest that another year a stereoscopic section for both transparencies and prints might well take the place of the present general transparency section, and we think such a section would be well supported.

THE TRADE EXHIBITS.

Wellington and Ward.

The familiar and tasteful kiosk of the Elstree firm occupies the accustomed place on the left of the entrance to the Fountain Court, where, as in previous years, Messrs. Wellington show prints and enlargements on their bromide, gaslight, and print-out papers. The

Wellington EXPOSURE DISC

exhibit contains a great deal of bromide photography of the highest order, and quite adequately represents the perfection of the Wellington products. The transparencies show the results obtainable on the Wellington "Speedy," "Press," and "Ortho" plates, whilst Messrs. Wellington this year make a small exhibit of the light-filter which

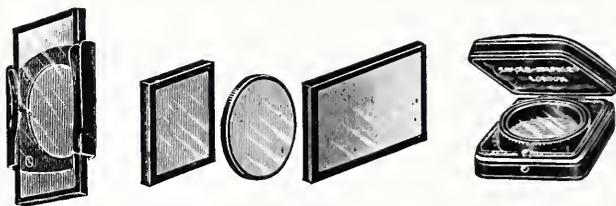

is now issued for use with their plates, and also of the very convenient exposure-disc which is prepared by them as a ready means of giving correct exposure to their own series of plates.

Sanger-Shepherd and Co.

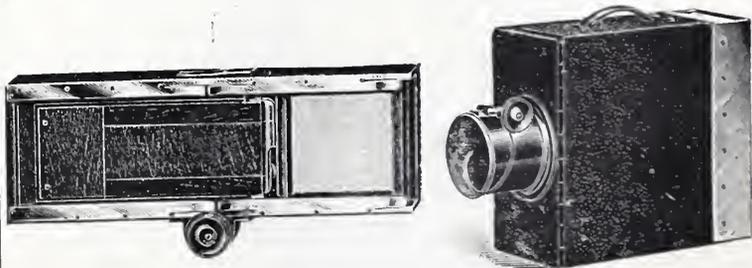

Technical advances in the making of photographic apparatus for expert work and in colour photography may usually be recorded in the case of Messrs. Sanger-Shepherd's exhibits. At this year's stall there is one print which very clearly emphasises the merits of the firm's graduated light-filter. It is from a negative by H. G. Ponting, representing a party in the Alps. A paired set of graduated light-filters has been used in order to secure both full exposure of the climbers and rocks which are close to the camera, and at the same time to render properly the sunlight and shade in the thunderstorm in the distance. Other examples testify to the very great advantage which can be taken of the graduated filter by the wide-awake landscape photographer. Messrs. Sanger-Shepherd now make a "snapshot" series, in which the part of the filter covering the foreground

of the picture is clear glass, and thus no increase in the exposure is called for.

A new piece of apparatus is a stereoscopic camera, specially designed on account of its great compactness and portability for the use of motorists, yachtsmen, and others. It carries a magazine taking twelve thin plates about 5in. by 2½in., the front of the camera being fitted with a pair of Zeiss "Tessar" lenses in focussing mounts. By a single momentary pressure one of the lenses may be brought

into the centre of the plate in order to make a wide-angle picture, the stereoscopic partition being at the same time withdrawn by an ingenious movement. In colour photography apparatus Messrs. Sanger-Shepherd show their new light model repeating-back, beautifully finished in black morocco leather, with a new rapid series of filters and an improved device for quickly changing the dark slide. With this form of back three seconds may be usually taken as the time for the three exposures, whilst from the resulting negative the photographer is able to produce a very brilliant and transparent Sanger-Shepherd lantern slide. There is also shown a new one-exposure camera of very small size and weight, also finished in black morocco, and calling for no more attention in use than an ordinary hand camera, the development of the negatives and the making of the colour transparencies being undertaken by Messrs. Sanger-Shepherd's staff.

Examples of photographs are also shown, transmitted over ordinary telephone and telegraph wires by means of various phototelegraphic instruments manufactured by Messrs. Sanger-Shepherd during the last three years. It is interesting to compare the early examples obtained in the "toy stage" of photography by wire, with those now secured with the greatest regularity and certainty, under all conditions of line, by the present machine. These results are largely due to the encouragement, in the face of much difficulty,

afforded by the proprietors of the "Daily Mirror," and to the untiring persistency of the head of the department, Mr. T. Thorne Baker.

J. H. Dallmeyer, Ltd.

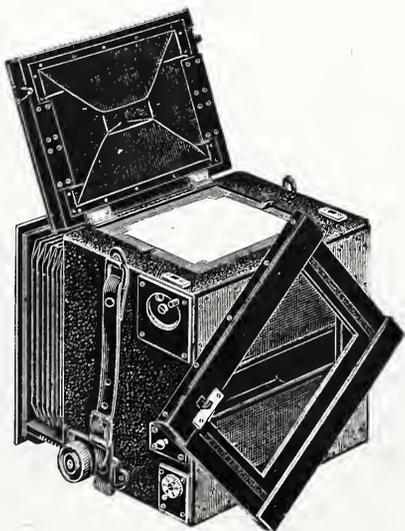

A new form of the "Adon" lens is the item of novelty at Messrs. Dallmeyer's stall. The loose black lengthening tube behind the front lens has been dispensed with, and a sliding tube substituted. This makes the lens more portable, and in other ways more convenient in working. The power of the negative lens has been

slightly increased, and the definition at full aperture has been improved. The new "Adon" will not be on sale until the New Year. This old-established firm of opticians and camera makers shows models of cameras, such as the "Correspondent" and "Naturalist," which have proved their value in past years; whilst they also exhibit specimens of the patent portrait lens in the mount now adopted, which allows of soft or sharp definition being obtained at will. The convenient pocket telephoto calculator, recently noticed in our columns, will also be found at Messrs. Dallmeyer's stall.

O. Sichel and Co.

The Morgan method of dry-mounting, plate-marking, and die-stamping at a single operation occupies the lion's share of Messrs. Sichel's exhibit. The installation, as those who visited it during the few days at the house of the BRITISH JOURNAL will know, introduces a simplified and more rapid method of mounting to the photographer, whilst, at the same time, the process particularly lends itself to the individual selection of mounts and provides the means of turning out photographs on boards, even of uncommon size and shape, with considerable economy in both time and material. It is pointed out that while the special Morgan

Sichel "Press" Reflex.

mounting press can, if desired, be employed with commercial tissue, it is primarily intended for use with sensitive photographic papers bearing the special adhesive. Particulars as to the varieties of this obtainable may be ascertained at the exhibition.

Messrs. Sichel also show a new model of the "Sickle" reflex camera—namely, one designed specially for Press photography. As

will be seen from the illustrations, the apparatus is provided with long extension reversing back and instantly accessible ground glass. The camera is made in the half-plate size at a price, including three slides but no lens, of £12 10s.

C. P. Goerz Optical Works, Ltd.

Goerz lenses and cameras occupy their accustomed place immediately facing the entrance to the Court. Here, as in previous years, the firm shows the anastigmat lenses of their manufacture, such as "Pantar," the Goerz "Celor," of $f/4.5$ to $f/5.5$ aperture, the Goerz double anastigmat or "Dagor," of $f/6.8$ rapidity, and the later and cheaper "Syntor," also of $f/6.8$ aperture. The excellent definition and covering power given by these lenses is well shown in the series of enlargements which cover the stall, whilst there are also shown the well-known models of Goerz-Anschütz cameras, the Goerz pocket "Tenax" and vest-pocket "Tenax," and, lastly, the Goerz folding reflex.

Burroughs, Wellcome and Co.

"Tabloid" chemicals and the results obtained with them make up a very attractive exhibit at Messrs. Burroughs, Wellcome's stall. The result of development, intensification, toning, etc., are shown by a series of transparencies, among which will be noticed the pleasing, warm tones obtained on an ordinary slow lantern plate by an increase

of exposure and the use of "Rytol" developer. A useful card, giving time for the development of plates and films at various temperatures when employing "tabloid" developers, is obtainable free on request. Messrs. Burroughs, Wellcome also show the striking results obtainable with their "Soloid" dyes applied to prints and transparencies

Wratten and Wainwright, Ltd.

As in previous years, Messrs. Wratten and Wainwright, in the show-case standing in the Fountain Court, treat their visitors to a species of scientific legerdemain, providing at the same time a spectacle to which one can only apply the phrase beloved of reviewers of Alhambra ballets, "a veritable feast of colour." By means of a very ingeniously contrived apparatus, they allow of spectrum being viewed through light-filters of various colours,

that the observer sees the relation which exists between a given colour and its absorption of the spectrum. Thus a green colour is seen to correspond with an absorption of the red and blue of the spectrum, whilst the other colours with which experiments can be made at Messrs. Wratten's exhibit illustrate the application of light absorption to three-colour photography and photo block-making. Some simple results obtained in portraiture and in photographing furniture with panchromatic plates are also shown, and

we were interested to see the astounding improvement obtained by using a screened panchromatic plate for photographing a scratched dark slide. Messrs. Wratten show the original to those interested. Another almost equally astonishing example of panchromatism is the pair of reproductions of an advertisement by Messrs. Lever Bros.

Naturally, the great range of results obtained on the new Wratten lantern plates are prominently shown, and the lantern-slide worker will have the opportunity of seeing for himself the very fine blue and warm tones obtainable on these new plates. Some few light-

filters of the 77 which Messrs. Wratten now manufacture are exhibited, as are also some of the special filters, including one for eliminating lines from the spectrum of mercury vapour, thus obtaining a powerful source of monochromatic (green) light. Adjoining their stand, Messrs. Wratten also show in the North Room a large collection of three-colour prints made on their Panchromatic and Process-panchromatic plates, or with their three-colour filters. These include a fine selection of work by André and Sleigh, Ltd., Anglé-Engraving Co., Ltd., Carl Hentschel, Ltd., Marshall Engrav-

ing Co., Press Etching Co., Ltd., Ruysdale and Co., and John Swain and Co., Ltd.

Johnson and Sons, Ltd.

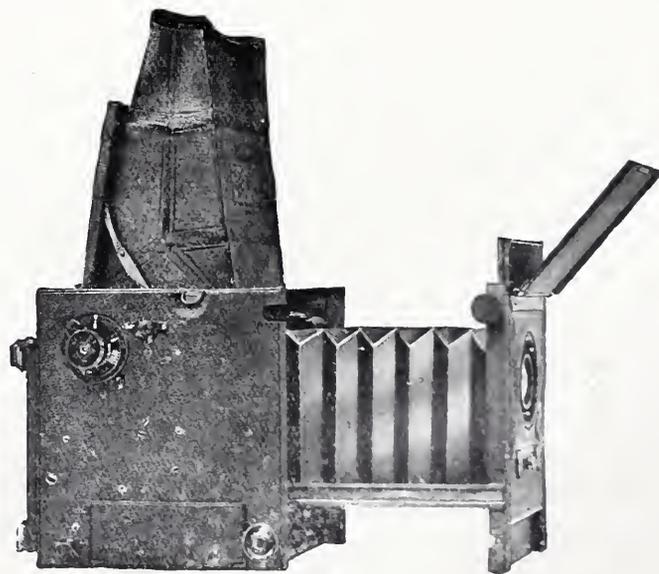

The display of gold chloride, silver nitrate, and potassium chloroplatinite at the stall of Messrs. Johnson and Sons to the total value of £1,100 is a reminder of the output of this old-established and well-known firm in the way of chemicals and chemical preparations for photographers. Apart, however, from salts of the precious metals, Messrs. Johnson have long specialised in developing chemicals, and their "Scaloid" series of photographic tablets and cartridges are appropriately given a prominent place in the exhibit. The single-solution "Azol" developer and the indispensable "Crushmeter," or combined pestle and mortar and graduate, are shown, whilst the latest introduction of the firm, a set of photo-

tints, is included. These consist of a series of concentrated solutions of nine different tints, the set being conveniently packed in such a way that the tints may be used without taking the bottles from the box. This new introduction should help further to popularise the hand-colouring of lantern slides and bromide and gaslight prints.

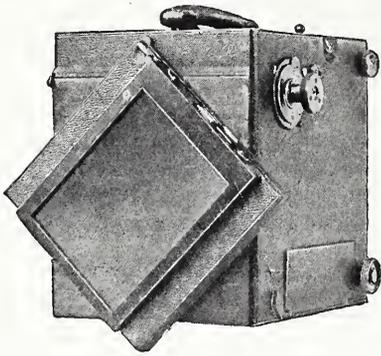

Adams and Co.

An opportunity which offers a special inducement to visit the New Gallery is the exhibition of the new Adams reflex camera, the "Minex," an instrument which we cannot adequately describe in the space now at our disposal. Sufficient to say that in the new design of instrument the maker has achieved a triumph of porta-

bility and range of movements which would seem to be the final word in this type of camera. The focal-plane shutter is of the self-capping type, and the act of re-setting the shutter automatically places the mirror in the position for re-focussing. In this matter, as in other features of the camera, the gain is all to the user in the way of rapidity of action, as also in the ability of the camera to serve its purpose in the case of the greatest variety of different

subjects. In addition to the new reflex—the details of which we hope to review in an early issue—the new models of the highly compact “Vesta” camera and of the “Idento” hand camera are

also shown, in addition to the variety of stand cameras, changing boxes, finders, and enlarging lanterns, as manufacturers of which Messrs. Adams and Co. have long enjoyed an enviable reputation.

The Platinotype Company.

Professional photographers will be interested in examining the method of illumination from both back and front which the Platinotype Company adopt at their stall in the way already described in our columns when it was shown at the Photographic Convention. The prints are placed in frames which are backed up with plain glass instead of a backing-board, an aperture of suitable shape being cut in the back of the stall behind each frame. The use of the light behind the picture gives a certain luminosity to the print when used in conjunction with a front illumination, whilst, when illumined solely from behind, the effect of the prints seen as transparencies is very pleasing. For the rest it may be said that in their exhibited portraits on Platinotype and Platinotype-Japine papers, the Company sustain their reputation for making only the best, and for placing in the hands of photographers a product which for nearly thirty years they have manufactured to an extremely high standard. Demonstrations of the process are given every afternoon and on each evening on which the Gallery is open.

Kodak, Limited.

The stall of the Kodak Company on the right of the entrance contains the latest models of the firm in the way of cameras and apparatus for the development of roll film, plates, and film-packs exposures. These include a new Kodak, the No. 4A “Speed” for pictures $6\frac{1}{2}$ in. x $4\frac{1}{4}$ in. on either films or plates. This is a focal-plane camera, allowing of exposures from 1-5th to 1-1,000 of a second, as well as time. In addition to the ordinary finder there is a direct-vision finder for vertical and horizontal pictures, as well as other movements which a high-class focal-plane camera should possess.

In the North Room the Kodak Company have a further and very tasteful exhibit of results upon papers of their manufacture, chief among which is to be noticed the exquisite black and white results on “Velox” paper, together with a few sepia prints by the sulphide method on “Velox,” which are sufficient to show the suitability of this gaslight paper for sulphide toning. The variety of the results and the technical perfection of all of them admirably bears out the motto on the panel, “There is a Velox for every Negative.” Examples of the “Velvet” surface of paper, which is issued by the Kodak Company with the Solio P.O.P., bromide, and Dekko emulsions, occupy another panel, whilst two others are filled with results on the Kodak bromide papers, including some particularly choice enlargements done, on white and cream “Royal” bromide paper, with, in one or two instances, the assistance of bolting-silk. The whole design and scheme of tones and colours in this display of the Kodak Company deserve special commendation.

Ilford, Limited.

The central space in the Fountain Court is occupied by Messrs. Ilford, Limited. The panels forming the base of the stall contain a series of most excellent enlargements on the various brands of Ilford bromide paper—namely, the “P.M.S.,” “Rough Rapid,” “Carbon Surface,” “Glossy,” “Very Rough,” and “Cream Bromona.” The series well demonstrates the extremely beautiful results obtained with these Ilford products. On the table will be

found a set of five stereoscopes, each containing fifty stereoscopic transparencies on “Alpha” plates of the recent aviation manoeuvres at Rheims. These are from negatives taken in the Richard “Verascope” camera, and lent by the firm of M. Jules Richard. The Ilford X-ray plates (a new booklet relating to which may be obtained at the stall) are represented by a very fine series of radiographs, both negatives and prints. The Ilford plate in astronomical work is represented by a positive transparency (made on an Ilford “Special” lantern plate) of one of the negatives (No. 168) made by Mr. J. Franklin-Adams for a chart of the heavens. These negatives are on Ilford “Monarch” plates. Transparencies in the Ilford “Alpha,” “Special” and “Gaslight” lantern plates are further shown, and among the numerous specimen prints from negatives on Ilford plates we may call special attention to the beautiful example of instantaneous photography, consisting of a boy doing the high jump, which is taken in 1-900 of a second on an Ilford “Special Rapid” plate, and is a capital example of full exposure and gradation.

In the way of apparatus a new introduction is shown by the Ilford Company in their light-filters for Ilford plates, ingeniously designed for attachment either over or inside a lens-hood or barrel. This form of construction gives a margin of a quarter of an inch or more in using a filter on several lenses.

Paget Prize Plate Company, Limited.

The Paget Company confine themselves solely to specimens of printing on their newly introduced phosphate paper, of which they show a large number of prints of portrait and landscape subjects, chiefly in demonstration of the excellent tones resembling those of P.O.P. obtainable on the paper. Many of these illustrate the good warm tones of which the phosphate paper is capable.

Ozobrome, Limited.

Enlargements and prints by the ozobrome method form part of the exhibit of Mr. Thomas Manly’s firm, in regard to which incidental mention may be made of the pleasing colours of some of the tissues exhibited, such as the warm black, blue-black, and Italian green. There are also shown examples of ozobrome transferred to wood, and also of oil and bromoil prints, produced by the newly recommended methods of the Ozobrome Company recently given in our pages.

Leto Photo Materials Company, Ltd.

As in previous years, the whole of the end wall of the North Room is occupied by the large and effective exhibit of the Leto Company, who here show the fine technical qualities of “Seltona” paper—antique, cream and matte—and also of the pleasing effects obtained on “Seltona” and other “Boardoid,” or extra stout papers, by means of plate-marking and shaded border printing. “Seltona” having been one of the earliest of the self-toning papers to come upon the market, it is satisfactory to see that it continues to maintain its supremacy as one of the most admirable varieties of this type of material. Further prints are shown on other Leto papers, such as “Platino,” “Tintona,” and “Gaslight,” whilst this year the Leto exhibit is reinforced by results on the Edwards’ plates, among which those on the isochromatic negative plates and on the “Kristal” lantern plates are specially worthy of notice. As on previous occasions, the Leto Company make a special feature of exhibits of interest to the professional photographer, and their representative is specially deputed to discuss matters of professional interest with visitors to the exhibition.

The Autotype Co.

In the large space which it occupies in the North Room, the Autotype Co. exhibits a great variety of its special manufactures in the way of permanent photographic prints. Naturally, the carbon process claims the chief share of the space. The specimens shown illustrate, in a very striking way, the refinement in colour of tissue and transfer paper which is now available. In this respect we think the carbon process as worked in England shows up to the best possible advantage. The garish tissues which are largely favoured by Continental workers always look to us as too full of colour and far inferior in effect to the cooler and more neutral shades of which the Autotype Co. manufacture a very considerable variety. In the matter of technical quality, one of the most striking prints is a telephotograph of “Rock Peak” (No. 5), by Dr. W. Hunter Workman and Mrs. Bullock Workman. The great contrasts of Alpin subjects obtain a perfection of rendering in a carbon print which is perhaps theirs by no other method, and a subject such as “

Race for the Summit of Mont Blanc" (No. 28), by Edward Whymper, is a most effective example of superb technical photography produced by carbon printing. Portraiture figures to a considerable extent in the Autotype exhibit, and attention will centre on the groups of Royal children by Richard N. Speaight; No. 21 represents T.R.H. the Princess Wilhelm and Ferdinand of Prussia, taken at the Marmor Palace, Potsdam. It is a pleasure to see photographic portraits of such quality as these carbon prints, and one may hope that professional photographers visiting the exhibition will make a mental note of the technical, and we might add commercial, qualities of carbons.

Some excellent coloured miniatures on ivory are also shown by the Autotype Co., as also the copper enamels which are supplied by them to the photographic profession. There are also displayed one or two specimens of the "stained drawings"—a form of picture which should command a good price among a suitable clientèle and represents a very skilful combination of photography and hand drawing.

EVENING LECTURES.

The following are the lectures to be delivered during the next fortnight:—

Saturday, September 25.—"Among the Cornish Fisher Folk," by Walter Thomas.

Monday, September 27.—"A Visit to a Marine Biological Station," by Francis Ward, M.D.

Thursday, September 30.—"The Romance and Humour of Invention," by A. H. Dunning, F.R.G.S.

SOME LECTURES WHICH WILL NOT BE DELIVERED AT THE NEW GALLERY DURING THE PRESENT EXHIBITION.

THE FUTILITARIANISM OF ART.

BY H. A. MOLMONDERY.

LADIES AND GENTLEMEN,—What I am going to say to you to-night you have all heard before many times. Still, you will be no worse off for hearing it again. What I say is always worth hearing—you have heard *that* before. You will hear it again, no doubt.

The things hung around these walls are very beautiful, but one feels that there are too many of them and too many people to see them. It would be nice to have one room with nothing and nobody in it at all, where one might kiss a sandwich. Art is a great thing, but Appetite is a greater. It is better to satisfy the latter than to hunger for the former, for, as Horace says, "Vacuus belli cantabit ervus, hunc metum et jam in corpore magnum bonum est."

Yes, Art is long and Nature stands in its way. When we walk broad in search of the picturesque we forget art and are overwhelmed by nature—unless we are photographers, in which case we probably shall have forgotten the lens and become overwhelmed with *human* nature. After all, it is at such moments that we reach the highest point of our art careers. We make the best pictures when we are without the wherewithal to spoil them. Seated in the dayside hostelry communing with oneself—having failed with the serving maid—the visions and pictures that have possessed one's ringing heart during the day pass before the mind in their fullest beauty. They are our own. Why should we ruin them by trying to paint or gum or oil them? They are better as they are—spiritual, not corporeal. They give pleasure to *one* person at least, which is better than their being reviled by many. A one-man show on these lines pays, because it costs nothing beyond the refreshments supplied to the critic.

My friends, let us not paint or photograph. Let us burn our easels and paints and oils and brushes, whether the latter be flat round, straight-cut, or pied de biche. Let us burn them all, even Cortez burnt his ships. There will then be no going back, except to the hostelry, where alone is peace without effort. I shall say all this again in my next lecture.

A TOUCH AND GO AT TURKEY.

BY W. L. F. WASSAIL.

LADIES AND GENTLEMEN,—Amongst the many commodities for which Turkey is famous I must mention, first and foremost, its "delight." That is paramount. I know, because I've had some. In fact, it is the keen desire in my innocent breast to experience the joys of that led me to undertake this Oriental pilgrimage. But there are other things also which are not to be sneezed at or into. The

Lastly, we must not omit to draw attention to the examples of oil prints made on the Autotype oil papers. No. 30, a cottage subject by C. H. Hewitt, is a striking example of the fine surface texture obtainable on the Autotype oil tissue, though No. 32 is perhaps the best example of Mr. Hewitt's work. No. 31, a portrait from a negative by Messrs. Lafayette, owes a great deal of its quality to its pigmenting by F. C. Tilney, and is a most excellent example of the apparently incoming application of oil in professional portraiture. The finely formed head has been treated in a most delicate manner, and the effect is very striking and attractive.

The Sciopticon Company.

Emerging from the North Room on the left the visitor will see a frame of lantern slides, by the Woodbury process, made and shown by the Sciopticon Company, and well representing the fine technical quality of slides produced by this most perfect of photo-mechanical methods.

Saturday, October 2.—"Modern Ideas About the Sun," by T. F. Connolly, B.Sc.

Monday, October 4.—"San Marino, the Pigmy Republic," by the Rev. T. T. Norgate, F.R.G.S.

Thursday, October 7.—"Saints, Benedictines, Goths and Vandals," by E. W. Harvey Piper.

Saturday, October 9.—"The Photography of Sport," by Adolph Abrahams, B.A.

baths, for instance, where you stew in your own juice, and will feel all the horror and shame of a dirty life if you do not first have a common or garden sixpenny "men's private" at the local urban council's shop. This suggests another of the special gifts of Turkey to civilisation—namely, sponges for outward application, not to mention rhubarb for inner. You see on the screen all the two-penny bundles of the latter waiting for shipment to England. In textiles Turkey sends us the indispensable "twill," which we use for impossible ruby lamps and the blinds of country pubs. There are also its tobacco, its cigarettes, and its carpets; and we must not forget its sultanas, its sultans (ladies first), its harems, and its "unrest," which is a thing the papers talk of, though I cannot describe it. Finally there is the magnificent bird to which the country gives its name—the terror of childhood—a succulent biped, which we fatten all the year that it may fatten us at Yuletide.

The Turks themselves are a gentle and amiable people, who are terrible only when they are annoyed. According to tradition and to pictures, the men wear skirts and the women trousers. Out of doors the ladies wear cloths over their faces, with little eyeholes, through which they ogle you. But beware how you answer back, for if you are detected passing the time of day with a Turkess you are hauled by the hair into some secret place, where your head is laboriously hacked off with a scimitar. The next ninety-seven slides are pictures of Turkish ladies. I may say that I escaped the butchery alluded to merely by threatening my assailants with the camera. The turban as a head-dress has given way in modern times before the fez, which is in reality an inverted flower-pot, with a tassel to stop up the hole. Perhaps a flower-pot is, after all, no worse than our own chimney-pot, several examples of which filled me with home-sickness in the bazaars of Constantinople. Now, ladies and gentlemen, having touched at Turkey, we will "go," and this, our last picture, is the P. and O. boat which is to bring us back from the dreams of the East to Western nightmares of hard hats and no "delight."

WALKS IN LONDON.

BY AUGUSTUS HARE BLAKE.

How few of us, ladies and gentlemen, know our London as we should. We know the stopping-places of the omnibuses, the houses of refreshment which are still the centres of so much of the life of the town, but how many of us who pass the Redcliffe or the Horse-shoe, if ever we do pass them, recall the days when Oliver Goldsmith used to stroll from his poor rooms in the Temple across Lincoln's Inn Fields, which really were fields then, and out at the

Little Turnstile into the road called Hole-Born, which you will perhaps remember got its name from that poor lad who came to London at the end of the sixteenth century wearing a suit of clothes so old and ragged that when he tried for work he was jeered at even by the ragamuffins of those days, those little gamins whom Hogarth has caricatured in the idle and industrious apprentices, one of whom, after a sad career of idleness and dissipation, we here see on his way to Tyburn Tree standing by the Tye-Burne, Bourne, or Borne (hence the phrase tith-barn, a corruption of the same word), not far from the present store of Selfridge, which very likely by this time you are tired of looking at, but I put it first on the screen because it is such a perfect example of the Early North-German-Lloyd period of decorative architecture. . . . I suppose few of us ever turn away from St. Paul's and pass again towards the West End of London without pausing for a while before this noble church and thinking of the days which poor Sir Thomas Moore spent here in the humble rectory, of how his devoted daughter led him by the hand along the streets and through all his troubles and persecutions in those disturbed days, until at last his cruel execution put an end to their life of mutual devotion, and her father's head was left for forty days outside Newgate Prison, until by bribing one of the officials it was given a decent burial—a sad story of disappointment and ill-requited service for this country which so moves me even now when I relate it that I have forgotten to tell you what the name of the church is, but never mind, it is just as likely as not you will see it some day for yourselves, or "The Amateur Photographer" may reproduce it in illustration of an article on how to photograph a fountain, or the Earl's Court Exhibition, or something of that kind.

OUR DISAPPEARING DICKIES.

BY ALLONER BYKE.

LADIES AND GENTLEMEN,—I must ask your kind indulgence for anything that may be uninteresting in my lecture to-night. I know that many people do not find much pleasure in hearing about birds, but if you will give me your kind attention to-night I hope that some words or some of the pictures may enlist your sympathies on behalf of the poor winged, harmless creatures that are so often wantonly killed in thoughtlessness or in sport. Many noble birds that used to adorn our woods and fields are now almost extinct, and one has to travel far and endure many hardships in order to secure them for the table or the show-case. Take, for instance, the case of the great lesser spotted double-breasted night-cap warbler. It is doubtful if one exists to-day. I show you a picture of one. This specimen was photographed on the wing on a string. Then there is the spotted paper fly-catcher, which is now rarely seen; his haunts have been over-run by the Mather fly paper catcher, which is more merciful to the flies that form its prey. The note of the "paper fly-catcher" used to be quite common a few years ago in the hot summer days, but I am sorry to say that the familiar cry that sounded so much like "Catch 'em alive O" is now heard very rarely, if at all. The Mather goes about its work silently. Here are pictures of the two birds. Note the spots on the head of the "spotted paper fly-catcher," from which it derives its name. The Mather is one of the waders, and is powerless if taken from the water.

I shall now show you a series of remarkable birds which are found exclusively in St. James's Park. These are mostly of the duck tribe, and are jealously guarded. I have a friend who, though only a poultier by trade, is very much interested in these birds, and though I have often tried to procure him some specimens of them, I have never succeeded, for their haunts are most carefully watched, and those in authority put the most difficult obstacles in the way of acquiring these birds or even their eggs. If we journey as far as the Embankment at Blackfriars, however, we can more easily get at another class of bird, which poetry and the sea has endeared to all Englishmen. I allude to the bird now upon the screen. This is known by the name of "Mother Seagull's Sickups." They can be induced to come quite near by the sight of a penny bag of sprats, which are sold on the adjacent kerbstone. If a sprat be thrown into the air, the gull will very cleverly dart at it, miss it, and then pounce upon it as it lies side uppermost upon the surface of the water. Here is a picture of one of the sprats lying on the water after the bird has missed it and then lost sight of it.

Now to vary the entertainment I will show you, if you will allow me, a series of pictures in a lighter vein. I call this the story of the curate's egg. In the first picture you see the curate tapping at the egg. In the second a little hole is made and a little beak appears. Note the curate's action. In the third the curate has upset the egg and the egg-cup and has risen from the table, while the chick, now fully emerged, dances upon the edge of the plate. I have written the following lines to accompany these little pictures:—

Sing a song of sick-wince,
A shockin' awful smell!
Poor and pretty dick-bird
Boiled in a shell.
When the egg was opened
The bird began to hum.
Wasn't that a dainty dish
To knock the curate dumb?

And now, ladies and gentlemen, I thank you for your kind attention, and hope my efforts have not been altogether unprofitable.

VELARIUM.

By A. LONG, F.R.P.S.

The shades of night were falling fast
As round the show the artist passed;
Or so he thought, till 'mid the gloom
A whisper struggled round the room,
"Velarium!"

Not knowing what this word implied,
He struck a match and vainly tried,
By means of its poor, feeble rays,
To find something to fit the phrase
"Velarium."

"Look up on high," the whisper said.
He looked, and just above his head
He saw a cheap and flimsy tent,
But never thought that that was meant.
"Velarium!?"

"This is a most artistic show,"
The whisper said. "And Art, you know,
Cannot endure the vulgar light.
We therefore shut it out from sight."
"Velarium!!!"

His brow grew sad; his eye beneath
Flashed like a falchion from its sheath.
The outraged artist softly swore,
Then jumped and ripped, and clutched and tore
Velarium.

He seized that ghastly ceiling cloth,
And with it fled the coming wrath.
And now he's stocked with dusters fine,
Each duster with the strange design,
"Velarium."

In consequence of the space devoted to the notices of the Exhibition of the Royal Photographic Society, a large number of "Answers to Correspondents," "Reviews of New Apparatus," etc. are held over.

GRIFFIN'S "SATIN" BROMIDE.—As announced elsewhere in the issue, Messrs. Griffin are now making a special offer to professional photographers in the shape of a free sample of this bromide paper two prints—one in black and white, and the other showing the excellent sepia tone obtained by acting on Messrs. Griffin's instructions which latter are also specially placed in the hands of applicants. The print before us is certainly an altogether admirable example of the toning process, and we think many of our professional readers will be glad to avail themselves of the information as to the process, which, we learn from Messrs. Griffin, has been engaging their attention for some considerable time past.

Photo-Mechanical Notes.

Classes at the Bolt Court School.

The forthcoming session of the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., opened on September 20, and the prospectus can now be obtained by intending students. The school, which is under the direction of Mr. A. J. Newton, is open only to those who are engaged in business in some branch of the photo-mechanical, photographic, designing, lithographic, engraving, printing; and illustration crafts, no provision whatever being made for amateurs. The school is well equipped with the necessary appliances for study and practical work. It contains a photographic studio, with four cameras and powerful electric light installation of modern pattern, including a large electric searchlight and mercury-vapour lamps, dark-rooms, sensitising-room, glass-cleaning and intensifying-rooms, tri-colour dark-rooms, extensive etching and printing-rooms—complete with electric light and modern appliances, including two types of power-driven etching machines—machine-room containing the latest power machinery for mounting, cutter, beveller, saw, etc., block proving-room, with electric motor-driven platen machine, colliotype preparation and printing-rooms, with presses and necessary equipment, a photogravure-room, a reading-room, and museum of specimens and examples. There are also two large rooms for lithographic drawing and a press-room, as well as separate studios for design, antique, and life and costume drawing. The school thus provides every advantage and facility for those who wish to improve their knowledge of their business and their dexterity as workmen, and the art section should be of special service to those artists engaged upon work for reproduction, as students in these classes will have the privilege of having selected work reproduced, and every opportunity will be afforded them to obtain a knowledge of the various processes and their limitations.

Both day and evening classes are provided at the Bolt Court School, the fees (payable in advance) being £9 per session for the day classes, and certain courses of instruction may be taken at a fee of £1 1s. for twelve lessons of one hour each for students not desiring to enter the whole curriculum. In the evening classes persons are admitted to all or any of the classes which they are eligible to join on payment of fees at the following rates:—If earning over 30s. a week, 1s. the session; if earning 30s. or less a week, 4s. 6d. the session, which begins on September 20, 1909, and ends on June 30, 1910.

Among the various courses of lecture demonstrations and practical workmanship instruction, mention should be made of those in the making of line and continuous-tone negatives, three-colour block-printing in the various printing processes, for half-tone and zinc work by the albumen and enamel processes, and other processes of half-tone reproduction, all of which are in the hands of special instructors.

There appears to be a strenuous endeavour to attract students to the theoretical side of the work, and to this end numerous lectures have been arranged, those on the "Chemistry and Physics of Photo-engraving" being divided into a number of short courses, complete in themselves, dealing with the different branches of the work. There are also courses of lectures on "Technical Photography" (by Mr. H. W. Bennett), on "Further Developments in Theory of Photographic Processes" (by Dr. S. E. Sheppard), also on "Paper-making and Stationery Manufacture," besides the usual Thursday evening lectures by individual experts of eminence. We imagine that something can be learned from the school even by those who consider themselves most proficient. We have heard that many journeymen refrain from attending because they think the work is elementary. We believe this to be quite a mistake, and, although the instruction must be elementary for those who are beginners, it can be picked up at any stage, and advanced work, or even research, undertaken. The energetic principal seems resolved to keep the school as thoroughly efficient and up-to-date as possible. We understand he has to this end spent his summer vacation in making an extended tour throughout Europe to visit some of the principal establishments in Holland, Germany, and Austria. We feel sure that there is none engaged in the craft that cannot reap advantage from attendance in some department or other at Bolt Court. We have not space to enumerate all the activities of the school, but a copy of the prospectus, with time-table and full particulars, may be obtained free on application to 6, Bolt Court, Fleet Street, E.C.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- S. B. Reynolds, 8, Victoria Road, Brentwood, Essex. Photograph of Wax Bats in Shop Window after a Fire; Title: "As I looked at Wilson's Fire I did feel Waxey; I never had such a close Shave."
 J. W. Powell, 13, Rutland Street, Swansea. Photograph of Two Persons and a Donkey in Act of Telephoning, &c., on Porthcawl Beach, entitled "Old Friends at Play. On the Telephone at Porthcawl."
 M. Lutenberg, 56, Waterloo Road, Widnes. Photograph of a Bird's-eye View of Widnes.

DRAWING REGISTERED:—

- Edith Trantom, 31, Islington, Liverpool. Drawing (pastel) entitled, "A Simple Child that lightly Draws its Breath."

ARTHUR ADDINGTON.—It seems to us that the copyright belongs to you unless the other man employed you to take the pictures. But what use is the copyright to you now that the negatives are no longer yours to print from? If you give the firm the sole right it will be of no use to them unless you assign the copyright in each picture separately.

PHOTOGRAPH OF SHIP ON FIRE.—Where could I get a photograph or picture of a ship on fire, with history to same? What I really want to get is a photograph or picture of a ship that sank at sea while burning.—E. W.

We are unable to tell you. Perhaps one of our readers who has such a photograph may be able to supply you, in which case we will forward any letter.

ARTIFICIAL LIGHT.—Will you kindly let me know, through your valuable paper, the best book to purchase for the electric artificial and daylight lighting (illustrated), and from whom we can obtain same?—A. R.

There is no such book published.

LENS COMPARISONS.—(1) What is the loss of light from a lens with ten air-spaces compared to an R.R. with only four? I have read that there is a 5 per cent. loss from each air surface, but this means 50 per cent. with the above, and surely cannot be correct, as an $f/6$ lens would be no quicker actually than $f/8$. (2) Is an air-space lens slower than the F. No., or is the loss only due to milkiness? (3) What loss is there with an anastigmat composed of cemented components (say, three or four to each cell)? (4) Does a lens composed of thin cemented components show much difference to one composed of thicker cemented components?—E. C. FLETCHER.

None of your questions admit of very definite answers. The loss does not depend on air-spaces alone; there is also a loss due to absorption by the glass itself, and, assuming the lens with the greater number of air-spaces to have more transparent glasses than the other, the total loss in the two may be about equal. One cannot estimate the loss by a formula such as the one you quote, but in a ten air-space lens the loss would probably not be much under 50 per cent. We believe it has been found that the average loss in doublets is about 50 per cent., while in single thin cemented lenses, such as landscape lenses, it is less.

SPOILT FILMS.—Would you be good enough to enlighten me on the following? I took six films to a firm to be developed, with results as enclosed specimen. (1) Can you account for the state they are in? (2) If fault of firm, can I claim cost of films as well as developing charge? (3) Can it be remedied in any way?—G. B.

(1) The image appears to be reversed, but we cannot explain the reason of its being so, as reversal can be effected in many ways.

(2) You must first prove that it is the fault of the firm. Gross over-exposure of the film may have contributed to the effect, in which case they can hardly be blamed. You should apply to them for an explanation, and see what they have to say about it. In any case, it is not worth while making a great fuss over the loss of only six quarter-plate films. (3) We can only suggest bleaching and redevelopment. Try the chromium intensifier formula C given on p. 784 of the "Almanac." If this fails we fear the case is hopeless.

T. L. FULLER.—Photographs of Moscow have been taken by Beckett and Sons, The Grove, Hackney, N.E.; Photochrom Co., Hosier Lane, E.C.; W. H. Rau, 1,324, Chestnut Street, Philadelphia, U.S.A.; Lewis Medland, Kimberley, North Finchley, London, N.; and Soule Photographic, 338, Washington Street, Boston, Mass., U.S.A. We advise you to apply to one or other of the above, who may be able to grant you rights to reproduce as postcards.

H. WRIGHT.—We do not know the composition of the stop-out medium. Obviously one which is used in an air-brush has to be extremely fine, and the makers naturally keep its composition a secret.

CURRENT.—1. It is not so largely used as arc light, which on the whole is, we think, preferable. 2. Continuous only. 3. You will find a variety of arc lamps announced in our advertisement pages.

G. BONNAND.—We think the firm you refer to is the Taber Relief Co., 115, Newgate Street, E.C.

REDUCING PLATINUM PRINTS.—I should be glad if you can inform me of any good method of reducing platinotype prints (black and sepia) that have been printed too dark.—PLATINUM.

The best means, but not a very certain one, is to use a weak solution of chlorine water (from a large firm of chemists). An extract of bleaching powder made acid with hydrochloric acid will serve the same purpose. See the "Almanac," p. 816, under "Restoring Yellowed Prints." The addition of more acid, giving a stronger-smelling liquid, will reduce the prints somewhat, but the process is not to be recommended for general use.

ARMY PHOTOGRAPHS.—Can you give me any information in your next issue of "B.J." who most likely would buy some negatives of the present Army manœuvres, as I have some for sale?—H. E. W. UPSHER.

Apart from the illustrated papers, try Gale and Polden, Aldershot.

ACID FIXING BATHS.—As old subscribers of your Journal, we would esteem it a favour if you will kindly let us know if it is practical to use alum, hypo, and acid in one fixing bath for the keeping of prints, or would same turn yellow in a short time, as we are informed by a young man in the trade that this would be the case.—M. KELLY.

Such a fixing bath (see formulæ in "Almanac") is very commonly used for bromide and gaslight prints, but its advisability in the case of P.O.P. is doubtful. For the latter an alkaline fixing bath is generally advised. See our note on page 682, "B. J.," September 3, with reference to use of acid fixers with bromide prints.

MOUNTANT.—We do not know the recipe, which, we may further tell you, is protected by patent.

INTERIOR WORK.—I should esteem it a great favour if you could inform me of a good method of developing negatives of interior work showing great contrasts of light and shade. I have of necessity to over-expose the lighter parts to get sufficient detail in the darker shades. Is it possible to equalise matters in the developing so that I could retain full detail in the lighter parts and prevent flatness, while still having good density and detail in the shadow portions of good printing value? Any hints, most suitable developer, etc., which would help me to overcome my difficulty, would be greatly appreciated. I have taken the usual precaution of using backed plates.—A. R. GRAY.

More depends on the exposure than on the development in work of this kind. Regulate your exposure for the darkest parts of the subject, and disregard the lighter ones. They will not readily show any signs of over-exposure, because the scale of light intensities is really much shorter than in ordinary outdoor work. From your letter we should say that you are under-exposing; it is a difficult matter to over-expose on an average interior. Given enough exposure you will find no difficulty in developing with almost any developer. Aim at a soft result. Use only just enough

bromide to prevent fog, and do not use a highly concentrated developer. Any developer is equally suitable, with the possible exception of plain hydroquinone.

GASLIGHT PRINTING.—Will you please tell me: 1. The best way of vignetting in gaslight work? 2. Also the best way of introducing clouds in the same process? 3. Is the fixing bath given on page 582 of current "Almanac" suitable for prints as well as for negatives? If not, perhaps you will kindly give me a simple formula for prints that will harden and fix together. It is intended for use with Velox papers.—CHROMO.

1 and 2. You can use precisely the same methods as with P.O.P. There is no special difficulty with gaslight paper that we are aware of. Use a diffusing screen of muslin over the vignetting mask. 3. There is no objection to a bath of this composition, but it is rather strong for print work, and we should double the quantity of water.

COPYRIGHT.—I have in my possession a set of twelve photographs which I have taken of the germination of the broad bean. As I wish to copyright them, would it be necessary to copyright each one separately, or is it possible to copyright them as a set, and would the fee be as one photograph? 2. I have already an application from a journal for a set for publication. If I charge, say 10s. 6d. for a set, with right to reproduce, could they claim the right to publish them in more than one issue?—A. Z.

1. We think it will be necessary to register each print separately if there is a really appreciable difference between them. Legally each exposure should be separately registered. 2. Certainly the fee should be for reproduction in one issue only. You should make this clear in your letter to the editor and in signing any receipt for the money.

ULTRA-VIOLET LIGHT-FILTER.—1. Where can I obtain nitrosocyanide methylaniline? 2. How is it used to make a light-filter to pass ultra-violet only?—ULTRA.

1. From E. Merck, 16, Jewry Street, E.C. 2. We believe it can be dissolved in gelatine solution and coated in the usual way. A screen is supplied ready made by Messrs. Wratten.

COPYRIGHT QUERY.—Kindly inform me in "B.J." re copyright photographs given away by me prior to registration. Are they unprotected also as well as being sold? I have sold none. All does change of address make any difference to the registration afterwards?—J. W. P.

Until the copyright in the pictures has been registered they are unprotected. After that they are protected, but no action can be taken for anything that was done prior to the registration. Change of address makes no difference.

PROCESS.—The directions and materials for the process are supplied by A. W. Penrose and Co., 109, Farringdon Road, London, E.C. We think you will be unwise to attempt to work the process yourself with a view to rapid production, that is, in considerable quantities. Far better arrange for getting blocks made quickly and have prints done from them.

E. D.—The phrase is not in common use. We should take it to refer to finishing prints; certainly not to backgrounds, unless they are specially mentioned.

ALEX. COUTTS.—Apply to Wolf and Co., 245, Tottenham Court Road, London, W. But you will not get actual colour photographs unless you want to pay a guinea or so each for prints about 8in. by 6in.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The "B.J." Almanac. Our publishers would remind intending advertisers that only fifteen days more remain before the pages of the 1910 Almanac must be closed for the press.

In an editorial article on page 758 attention is directed to the conditions under which commerce is likely to be carried on in the far future within the region of the Persian Gulf.

Mr. A. Lockett describes the construction and use of a photographic slide-rule now being shown in the Royal Photographic Society's Exhibition. (P. 759.)

The awards in the Dresden Exhibition have been made. We give the list of English-speaking persons and firms who have received diplomas. (P. 760.)

"Rapid proofing and drying of negatives," "Removing prints from mounts," "A curious case of fading colours," appear with other technical and trade topics under "Correspondence." (P. 769.)

Holders for plates which are being backed, daylight development apparatus, etc., figure under "Patent News." (P. 762.)

Under "Photo-Mechanical Notes" (page 761) is given the text of a recent patent of Dr. Albert for a cold-enamel process for photo-graved plates.

Formulæ for obtaining high relief in gelatine are given in reply to a correspondent on page 761.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Dr. H. G. Drake-Brockman, in an article on page 73, describes the process which he has made of the Sterry method of obtaining reduced contrasts in making Autochromes of subjects of exceptional difficulty. Drake-Brockman's results are included in the present R.P.S. Exhibition.

Baron von Hübl, in a lengthy article which appears in a German contemporary, has described the *modus operandi* involved in testing dichromatic filters by means of colour test charts. The luminosities of the colour patches used in making the test charts are first measured with the Abney sector-disc apparatus and each colour patch then mounted on a neutral grey paper of equal luminosity. (P. 74.)

The translation of a recent article in "La Photographie des Couleurs" in which some suggestions are made as to the reproduction of screen-plate transparencies on paper appears on page 78.

The official formulæ for use with the various filter dyes made by Messrs. Lucius and Brüning are given on page 79.

The causes of the complete disappearance of colour from an Autochrome are the subject of several letters from correspondents on page 80.

EX CATHEDRA.

The "B.J. Almanac," 1910.

On behalf of our publishers we would draw special attention to the fact that the "make-up" of the forthcoming "British Journal Almanac" is almost complete for the press. Almost the whole of the anticipated advertisements are arranged, and therefore those who have not yet decided as to their advertising in the 1910 issue are requested to note that *only fifteen days more* remain before the pages must be finally closed—on Friday, October 15. The large size (over 1,000 pages) and edition (25,000 copies) of the "Almanac" coupled with the making of the "Index to Goods Advertised" inserted in the volume as a guide to its contents, leave the publishers no option as to the date of going to press. The text also must be closed at practically the same time, and we would therefore ask any secretary who has not yet acceded to our requests for information to do so without further delay.

* * *

Oil and Bromoil in Portraiture.

In our notice of the Professional Section of the R.P.S. Exhibition, we referred very fully to the portraits in the oil pigment process which have been made from photographers' negatives by Mr. F. C. Tilney, the well-known critic and Royal Academy exhibitor. It is, we believe, no secret that Mr. Tilney is open to accept commissions for making oil prints, and many of our readers who see the admirable results in the Exhibition may realise the desirability of moving with the times and having, at all events, one or two examples of this class of work at hand to show to clients who would be likely to appreciate it. The Autotype Company, who manufacture some excellent papers for the oil process, are also prepared to produce oil prints from photographers' own negatives. Those photographers, however, who wish to become *au fait* with the process will be interested to note that classes are being arranged at the Regent Street Polytechnic on Thursday evenings in both oil and bromoil. The classes are conducted by Mr. C. H. Hewitt, whose work in these processes is well known, and as we see from an advance prospectus the fees are little more than nominal, we advise our readers who are interested and within reach of the Polytechnic to apply to the Director of Education for a prospectus of the evening instruction.

* * *

The Preservation of Scenery.

Every photographer is surely in sympathy with any body which seeks to curtail the disfigurement of rural scenery and of specially picturesque spots in this country by unsightly advertisements, but probably few photographers are aware of the very valuable work to this end accomplished by the "Society for Checking the Abuses of Public Advertising." The "occasional journal" of this organisation is entitled "The Beautiful World," and the current

issue bearing the date September, 1909, is a volume of 230 closely written pages dealing with the many abuses of public advertising and pointing to the practical measures by which this plague of disfigurement can be stayed. The subscription to the society is only half-a-crown per annum, and we feel sure that the honorary secretary, Mr. Richardson Evans, The Keir, Wimbledon Common, will be glad to enrol new members as well as grateful for any contributions, for future issues of the journal, assisting the very excellent cause which the society has espoused.

* * *

Electric Lighting for Portraiture.

We usually call attention at this time of the year to the fact that in another month the quality of the daylight will be only moderate, and that the quantity will be very limited. The proportion of really bright days in November and December is small, and no degree of certainty exists that the appointments booked will be satisfactorily dealt with. This is, of course, a strong argument for the photographer's placing himself beyond the mercy of the weather, yet time and again we hear of workers who neglect even the consideration of an electric light installation until they find that they are losing money through the failure to take sitters, and through the inferior quality of their work which is done in a poor light. This is not the place for a recommendation of any particular system of lighting, and many are advertised in our columns set apart for the purpose. We are always glad to answer specific inquiries and to take into consideration the special requirements in the direction of prime cost and space available. We would suggest to inquirers that they send us one or two photographs of their studio, with measurements to eaves and ridge, the width and length of the room, and so on. Such particulars enable us to suggest the most suitable type of lamp, for what will work well in one studio may be quite unsuitable in another. At all events, we would urge once more the importance of prompt attention to the matter, for the Christmas rush is now not far off.

* * *

Exposure in Pictorial Work.

A writer in "Camera Craft" discusses the matters of so-called "correct" exposure and pictorial effect, and claims that correct exposure is destructive of all feeling and necessarily produces a mere record. He assumes the case of a woodland scene on a bright summer morning, and points out that an exposure that is somewhat shorter than the correct one will prevent shadow detail and give detail in the high-lights and so give a bright effect, while over-exposure will give the shadow detail, soften the high-lights, and give a sombre effect. We fear that too many pictorial workers do actually rely on under-exposure for their effects, but surely it is a wrong idea to suppose that detailless shadows have any pictorial merit. Want of detail in the shadows is perhaps one of the most prominent pictorial faults in photographic exhibitions. In nature such shadows never exist, and when they appear in pictures their unnaturalness is very evident. There is no reason that we know of why brightness cannot be rendered evident without destroying shadow details, and it is a pity to suggest that such an obvious fault can by any possibility be considered a picture. On the other hand, we fear that full exposure is not always the method adopted for introducing sombreness. Very often such efforts present the appearance of under-exposed negatives badly over-printed, for in them again want of shadow detail is generally apparent. We believe that the best pictorialists appreciate the necessity of correct exposure in their work just as fully as do the mere "record" makers, and that the majority of them effect such variations or produce such emphasis as they want during the printing process.

TRADE IN THE PERSIAN GULF.

For some years German business men have been concentrating their attention on the Orient and the Near East, and as a result of their increasing activities, they have succeeded in building up a very considerable trade in that part of the world. There are numerous reasons why Germany is so persistently challenging British prestige in that quarter. With the phenomenal growth of German commerce and industry within the last decade or so, has arisen the evil of over-production. Encouraged by their success, manufacturers went on producing until now they are suffering seriously from the effects of this policy, for they are finding that their markets have not kept increasing in anything like the same proportion to their products. Hence they are confronted with the problem, where they may turn to find new outlets for these goods. They have exploited Europe, America, and all the Western countries so thoroughly, that now there is little prospect of further conquests for them; at least, not in anything like the proportion of their past accomplishments. Necessity has driven them to change their methods, and to turn eastward, in which direction their future path lies. They are now following closely on the heels of British traders, and, as we have said, are challenging those markets in which the British have been the undisputed masters for many generations.

What makes the situation still more critical is the fact that Americans are beginning to direct their attention to these districts, and, as one of their representatives said to us, they intend "to make things hum." As a result of all this competition business methods and customs in the Near East must necessarily undergo some very important changes in the near future. What these changes are likely to be is patent to all who are interested in the subject, and it behoves the British manufacturer to keep a sharp eye on his business out there if he is to retain his prestige under the new conditions. It is for this reason and with the object of helping the latter all we can, that we constantly report in these columns the various activities of foreign manufacturers, and the conditions of the markets as new phases become apparent in it.

Since Germany financed the building of the Bagdad Railway, she has made great efforts to increase her sphere of influence within the Persian Gulf, both politically and commercially. Much German money has been invested in the districts surrounding the Gulf of late, a fact which may be taken as an earnest of their confidence in the future prospects in these districts. Consequently it is only natural that they should stir themselves to gain from their investments the most satisfactory returns possible. The share which photographers may expect to have of the spoils is shown in a lengthy article recently published in a German contemporary, which urges German manufacturers of photographic materials, and professional photographers, and those engaged in the manufacture of picture postcards, to take much more advantage of the opportunities afforded them in these regions than they have been in the habit of doing in the past. The author calls attention to the fact that as soon as the Bagdad Railway is finally completed, the trading monopoly which England has held in the Persian Gulf, and those districts lying within reach of it, will be entirely a thing of the past. Though Bagdad will still retain its position as the chief commercial centre, it is practically certain that at least one-third of the goods imported into it for re-distribution throughout the surrounding country will find its way through the western part of Persia, along the route of the new railway. This means a great economic change, for, besides causing a great reduction in the price

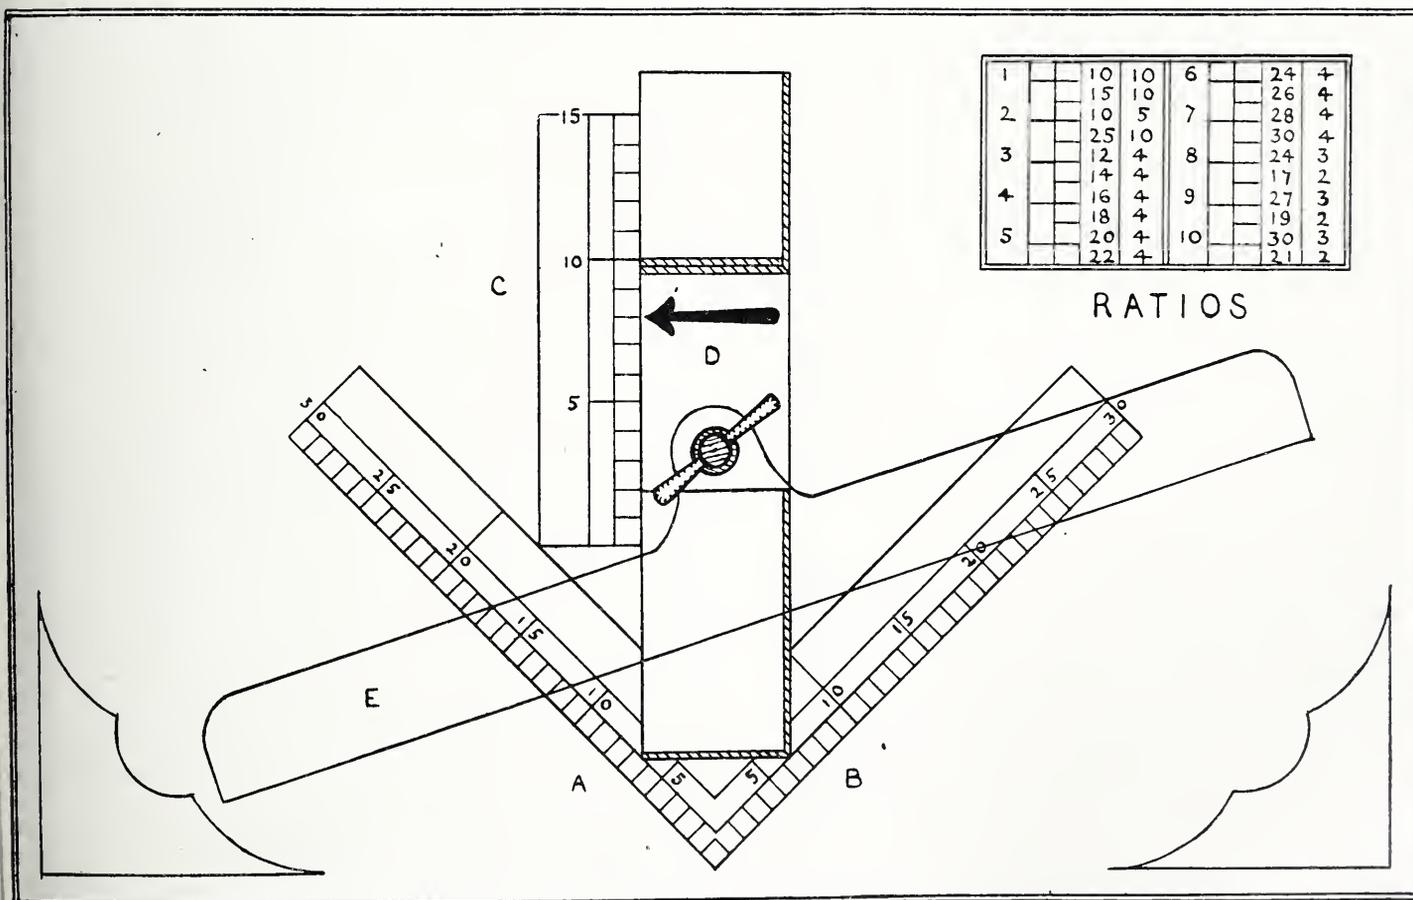

f. carriage, it will also shorten very considerably the time occupied in transit. As a consequence of this, other nations, principally Germany, will have cheaper and more ready access to the markets, and will therefore be able to compete more favourably with England. At the same time, the writer warns German manufacturers of the dangers of delay. They are not to wait in idleness until the railway is completed, but to canvass the markets at once, and have everything in thorough working order, so that the advent of the railway may find them on the ground.

The turnover in cameras, plates, and films, and photographic goods of all kinds, shows a very considerable yearly increase. The greater freedom enjoyed by the Turks, and the influence which Western ideas is having upon them, are both helping to broaden their interests and encouraging them to spend their money in many ways hitherto undreamt of. Even Turkish ladies may now be seen diligently snapshotting in their gardens, and the enthusiasm for amateur photography is fast becoming as keen as it was with us a few years ago.

A PHOTOGRAPHIC SLIDE RULE.

THE photographic slide rule, a cardboard model of which is shown in the Scientific and Technical Section of the Royal Photographic Society's Exhibition, is intended to facilitate optical and other calculations, enabling results to be arrived at automatically. It consists, as will be seen by the accompanying illustration, of two diagonal scales A and B, joining at a right

arrow pointer on the slide D, the lower edge of the ruler E is set against 10 on both the diagonal scales. In this position of the ruler the arrow should be pointing to 5 on the vertical scale. A mark is therefore made against 5 on the slide and the arrow drawn and inked in, after which it will register accurately for any position of the ruler.

...le, and a vertical scale C against which a slide D carrying an arrow pointer moves freely in a slot. To the side D is pivoted a movable ruler E by means of a winged nut. The ruler E may be of any material, but transparent bone or celluloid is preferable, as the whole of the graduations are then readily seen during adjustment. The two diagonal scales are graduated in tenths of an inch, the zero point of each coinciding at the angle. Fifty divisions, as shown, are sufficient for most ordinary purposes, but there is no necessary limit. The divisions on the vertical scale are each equal to the diagonal of a square whose side measure one-tenth of an inch, and in number may be half those on the diagonal scales, in the present case fifteen. The slot in which the slide D moves must bisect the right angle formed by the two diagonal scales, and is arranged so as not to cut off any of the graduations, the shape of the ruler being designed with this object in view. To insert correctly the

Such problems as ascertaining the focal length of a lens, finding the focal length that results from combining two lenses, ascertaining the necessary length for a studio with a given lens, estimating the distance required for a lantern screen under any specified conditions, obtaining original measurements from photographs, and so on, are quickly and accurately solved by this appliance. In addition, it is useful for the solution of many other optical, arithmetical, and mathematical problems, of both a photographic and a non-photographic nature.

A few typical examples of its use may be given, these being chosen for their practical character and their application to everyday work, although many of a more complex and experimental kind might be quoted.

Finding Focal Length of Combined Lenses.

What will be the focal length obtained by placing a supple-

mentary positive lens of 12in. focus in contact with a photographic objective of 24in. focus?

The illustration shows the solution of this problem. Set the ruler against 12 and 24 respectively on the diagonal scales. The arrow will then indicate the resulting focal length on the vertical scale—*i.e.*, 8in.

Finding Distance for Lantern Screen.

What distance must the screen be from the lantern to obtain a picture 6ft. in diameter, the objective being of 7in. focus?

Set the ruler against 3 (the lantern slide opening being 3in. square) and 7 respectively on the diagonal scales, and clamp the winged nut. Then shift the ruler from 3 to 6, and at its other end will be read the required distance in feet—*i.e.*, 14ft.

Finding Necessary Focus for Lantern Objective.

What focus lantern objective must be used to obtain a picture 15ft. in diameter, with the lantern 30ft. from the screen?

Set the ruler against 15 and 30 respectively and clamp the winged nut. Then shift it from 15 to 3 (the lantern slide opening being 3in. square), and at the other end will be read the required focus of the objective—*i.e.*, 6in.

Finding Distances for Enlarging or Reduction.

It is desired to enlarge from quarter-plate to whole-plate with a 7in. focus lens. What must be the distances between easel and lens and negative and lens?

This is an enlargement of two diameters. Against 2 in the table of ratios will be found the numbers 10 and 5. Set the ruler against 10 and 5 respectively on the diagonal scales, and clamp the winged nut. Then shift the ruler until the arrow on the slide comes against 7 (the focus of the lens) on the vertical scale. The required distances will then be indicated by the ruler on the diagonal scales—*i.e.*, 21in. and 10½in. Exactly the same procedure is used for reduction, only the distances are reversed, the shorter one being between the lens and sensitive paper, or plate. The table of ratios provides the necessary figures for any degree of enlargement or reduction up to 10½ diameters; other ratios may be obtained by selecting two numbers in the required proportions.

Finding Length of Studio.

What length of studio is necessary for a full-length cabinet portrait with a 12in. focus lens, assuming the sitter's height to be 6ft. and the desired height of the image in the photograph to be 4½in.?

Set the ruler against 4½ and 12 respectively on the diagonal scales and clamp the winged nut. Then move the ruler from 4½ to 6, and at the other end will be read the distance from lens to sitter in feet—*i.e.*, 16ft. To this must be added a reasonable allowance of space for the camera, operator, and background—say another 6ft.—making a minimum length of 22ft. for the studio.

Ascertaining Measurements from Photographs.

A statue in a photograph is 3in. high; the distance from the lens is known to have been 15ft., and the focal length of the lens 9in. What was the real height of the statue?

Set the ruler against 3 and 9 respectively on the diagonal scales and clamp the winged nut. Then shift it from 9 to 15, and at the other end will be read the required height in feet—*i.e.*, 5ft.

Finding Principal Focus of Lens.

Set up the camera and focus sharply on any near object at full aperture. When the object is in focus (the size of the image being immaterial) measure the distances from object to lens centre and from lens centre to focussing screen. It is sufficiently accurate, with a doublet lens, to measure from the diaphragm. Set the ruler at these distances on the diagonal scales, and the arrow will then indicate the principal focus length of

the lens on the vertical scale. Example: A cabinet photograph is focussed, and the two distances (conjugate foci) are found to be 30in. and 7½in. respectively. On setting the ruler to 30 and 7½ on the diagonal scales the arrow will point to 6 on the vertical scale. The lens, therefore, is of 6in. focus.

Possibly enough has been said to show the many possible applications of the photographic slide rule. Besides its use for simplifying calculations it is obviously of value for checking the accuracy of the same when the usual arithmetical methods are preferred.

In conclusion, it may not have been noticed that the appliance forms a universal multiplication table, since if the ruler is set against the multiplicand and 1 respectively, and clamped, it will indicate the product when shifted from 1 to the multiplier, whatever the numbers may be. Division is also possible, in an inverse manner, by setting the ruler on the dividend and divisor respectively, clamping it, and shifting it to 1, when the other end will indicate the quotient.

A. LOCKETT.

THE DRESDEN EXHIBITION.

The following awards have been made by an international committee of judges at the Dresden exhibition. We are unable to give the full list of persons and firms to whom awards have been made, but the following list includes English-speaking exhibitors, together with some other firms known through the sale of their goods in this country.

SCIENTIFIC PHOTOGRAPHY.—The following have received honourable mention in this section:—Harvard College Observatory, Cambridge; P. Lowell, Flagstaff, U.S.A.; Solar Physics Observatory, London; R. W. Wood, Baltimore; Mr. Mattingley, Melbourne; Professor Hartley, Dublin; Professor A. M. Worthington, London.

PHOTOGRAPHIC LITERATURE.—Plaques have been awarded to Henry Greenwood and Co., London; A. W. Penrose and Co., Ltd., London; The Inland Printer Co., Chicago.

PROFESSIONAL PHOTOGRAPHY.—A "Stadt" medal has been awarded to Frank Eugène Smith, Munich, and diplomas for gold medals to F. A. Bradley, New York; Frank Scott Clark, Detroit; E. B. Core, New York; Pirie MacDonald, New York; E. E. Doty, Belding; Elias Goldensky, Philadelphia; Eugène Hutchinson, Chicago; Mrs. Käsebier, New York; J. C. Strauss, St. Louis. Diplomas for silver medals in this class have been awarded to A. L. Bowersox, Dayton, Ohio; R. T. Dooner, Philadelphia; George Edmondson, Cleveland; J. Mitchell Elliot, Germantown; William Ellis, Shewell, Philadelphia; J. H. Caro, Boston; Dudley Hoyt, New York; Meredith Janvier, Baltimore; J. E. Mock, Rochester; Henry Havelock Pierce, Boston; Ryland W. Philipps, Philadelphia; A. T. Proctor, Huntington; Hermann Schervée, Worcester; Simon Stein, Milwaukee.

AMATEUR PHOTOGRAPHY.—In this section plaques have been awarded to Alex. Keighley, Steeton; Walter Benington, London; Archibald Cochrane, Glasgow; E. O. Hoppé, London; J. Dudley Johnston, Liverpool; A. H. Blake, London; Dr. E. G. Boon, Alassio; Will Cadby, Borough Green; Reginald Craigie, London; Frederick H. Evans, London; Cavendish Morton, London; Miss Agnes H. Warburg, London; Charles Job, Hove; J. C. S. Mummery, London; J. Cruwys Richards, Bournville; H. J. Simmons, Camberley; J. Warburg, London; F. J. Mortimer, London; Henry Berger, jun., Portland; J. N. Field, Berlin, U.S.A.; Edwin E. Keller, Buffalo; F. Lindburg, Buffalo; Gertrude A. Man, Minneapolis; W. H. Poetsch, Buffalo; Edward B. Sides, Buffalo; R. L. Sleeth, jun., Wilkirk; Augustus Thibandau, Buffalo.

PROCESS WORK.—The following awards were made in this section: Hon. mention: N. S. Amstutz, Valparaiso. Diploma for gold medal: Bemrose and Sons, Derby and London; Carl Hentschel and Co., Ltd., London; A. W. Elson, Boston. Diploma for silver medal: Republican Publishing Co., Hamilton; Taylor Bros., Leeds; Vaus and Crompton, London; Western Morning News Co., Plymouth; Deane and Co., Ltd., London; Press Etching Co., London; Binner Weir Co., Chicago; Eclipse Electro and Engraving Co., Cleveland.

PHOTOGRAPHIC TRADE SECTION.—Hon. mention: A. Lumière et Fils, Lyons; Heinrich Ernemann A.-G., Dresden; C. P. Goerz A.-G., Berlin-Friedenau; Voigtländer and Sohn A.-G., Brunswick; Meisner

Lucius and Brüning, Hoechst a/M.; General Paper Co., Brussels; Felix Schoeller, jun., Gretsche bei Osnabrück. "Staats" medal: Emil Busch A.-G., Rathenow; R. Guilleminot Boespflug and Co., Paris; Emil Wünsche A.-G., Reick bei Dresden; Dr. C. Schleussner A.-G., Frankfurt. "Stadt" medal: Chemische Fabrik auf Aktien vorm. E. Schering, Charlottenburg; R. Lechner (Wilh. Müller), Vienna; Gustav Heyde, Dresden; Trapp and Münch, G.m.b.H., Friedberg i. Hessen. Diploma for gold medal: J. H. Dallmeyer, Ltd., London; Ford Limited, London; Autotype Co., London; Neue Photographische Gesellschaft A.-G., Berlin; Regina Bogenlampenfabrik, G.m.b.H., Cologne-Sülz; Friedrich Schroeder, Brandenburg.

EXHIBITORS "NOT FOR COMPETITION."—International Union of Art Photographers; Gevaert, Ltd., Berlin-Vienna; Kodak, G.m.b.H., Berlin; Carl Zeiss, Jena; English School for Technical and Scientific Photography, London.

Photo-Mechanical Notes.

Cold Enamel for Photo-Etched Zinc Plates.

According to a recent patent specification (No. 25,934, 1908) of Mr. Eugen Albert, 55, Schwabingerland, Gasse, Munich, the plate to be photo-engraved is first covered with an etching ground of a resinous substance and then coated with a bichromate film. The plate, after photographic treatment, is then subjected to the action of a solvent of the resinous etching ground of considerable consistency or viscosity and readily miscible with water. In such a process as this, which is designed to avoid the burning-in process, it is first of all necessary to prevent the solvent from soaking through the bichromate film, which is of course very thin, as otherwise the etching ground would also be dissolved at places where it should be protected from the solvent by the bichromate coating. This condition can only be fulfilled by a solvent of considerable consistency or viscosity, so that it will not penetrate the bichromate film before the etching ground has been dissolved in the exposed places; ethereal oils will not give this result, as they are of low consistency. On the other hand, the capacity of a mixture of turpentine oil and olive oil to act as a solvent is so small that the dissolving process must be assisted by rubbing with cotton-wool, which manual operation requires personal skill and entails sources of error, like the bichromate-albumen process, the avoidance of which is the very object of the process.

It is also necessary that when the etching ground has been dissolved on the places not protected by the bichromate film, it should be possible to wash the dissolving liquid or mixture from the plate speedily and thoroughly, as of course, in spite of the consistency of the solvent, in the course of a considerable period of time the solvent would penetrate the bichromate film.

The conditions essential for attaining a successful result can only be obtained when bodies are selected for the etching ground which dissolve readily in liquids of considerable consistency, and which are readily miscible with water. Owing to their resistance to acids, resins are most suitable bodies, as they readily dissolve in alcoholic liquids. In general these liquids mix readily with water in all proportions, and, for reasons of economy, water alone is also used for removing the solvent from the plate as speedily as possible. Alcoholic liquids can also be very readily thickened with bodies which are soluble both in alcohol and in water, and which, such as tannic acid, for example, even tend to harden the bichromate skin. Alcohol also mixes in all proportions with glycerine, which is a liquid of considerable consistency and which, again, is soluble in water in all proportions; if ethereal oils be selected all these favourable factors are excluded completely.

Broadly, the invention consists in using alcoholic solutions of high consistency and high solvent power, so that the etching ground readily dissolves if they are merely poured over the plate, and if it be immersed therein, before the solvent has filtered through the bichromate skin, and in quickly interrupting the dissolving process by bringing the plate at the proper moment beneath a water pipe, preferably provided with a distributing rose. The particular steps of the process and the materials preferred are as follows:—

First the plate is covered with resin to form an etching ground, next a bichromate film is deposited over the whole of the plate, and the copy formed by exposing the plate to light and dissolving the soluble bichromate in water; the plate is then immersed in a liquid consisting of alcohol which has been thickened by the addition of tannic acid or glycerine, or both, to strengthen its dissolving power. This readily dissolves the resin from the exposed parts of the plate, the other parts being protected by the bichromate film, and as soon as that is accomplished the dissolving process is instantaneously stopped and the plate cleansed by bringing it at the proper moment beneath a water-pipe, provided with a distributing spray, the plate being then ready for the etching bath.

By this means it is possible to make an impression from the plate after the preliminary etching, to free the plate from the residue of ink adhering to it by means of benzine or turpentine and drying it with sawdust, and then for the retouching process to be carried out and the final etching undergone without rolling in fresh ink, dusting with resin powder, and subjecting to heat as has been necessary in processes employed hitherto, which frequently gave rise to error and loss of time.

Besides economising time, the results are more certain, since the positive printing elements are still covered with the original etching film when the plate is operated on by the retoucher, who is therefore certain that the desired effects will be obtained in the final etching.

If plates instead of being etched are gummed, they can be used as lithographic plates.

An important advantage obtained by using resinous substances for the etching ground is found in the fact that there are a number of alcoholic resins to choose from which do not dissolve in ethereal oils. For instance, sandarac is insoluble in benzine or turpentine.

A plate on cheap metal can be obtained by this process, giving results equal in quality to those of a copper plate.

That this process is granted a patent in England will perhaps surprise a good many people, because the method appears to have been well known for some time and frequently used, although Albert's original date of application abroad for patent protection would appear to precede any actual publication of the method here. Early last year we had the Enamo Copying Process Company, of Monument Station Buildings, selling just such a method as this, as a secret process, whereupon one man in a firm to whom it was offered stated he had worked a similar method for the past ten years. Messrs. Penrose also announce in their "Process Work," of April-May, 1908, a new cold enamel process, which described exactly the method. Subsequently we had Mr. Arthur Payne's process for photographing direct on metal, which also uses the same means for obtaining the acid resist. Herr Van Beek described a similar process in the "Photo-engravers' Monthly" for May, 1909, using bitumen as a resist. Finally, we have the American "Inland Printer" of the present month recommending this method for rapidly obtaining prints in bitumen.

Gelatine Reliefs.

A correspondent writes:—On October 30, 1908 (page 828), you issued a short article on the gelatine relief process, which I have been attempting. The utmost relief I have got up to the present is not more than 1-32in., using letters cut out of black paper stuck down on clean glass, and then exposing the sensitised gelatine to daylight, first week in September, three hours, six hours, and twelve hours in three experiments. The purpose I desire to utilise this process for is to get letters in as deep a relief as ever possible. The letters usually are about ½in. high, and I had hoped to get about ¼in. or even ⅓in. relief. I should be glad if you will tell me what is the utmost I can possibly get by this process, when I will so arrange matters that the light will only be exposed to the sensitised gelatine through *clean glass*, all parts not exposed being black ink on paper; these latter portions, of course, will be the ones to swell. Is the published formula the best for the purpose, do you think? Or is there another process that will give this result? Also, is there any text-book on the subject? Your answer to these questions would be much valued.

In reply to your inquiry, we are not sure that you will get a very

much higher relief than you have already obtained, and we doubt if $\frac{1}{4}$ in. is possible.

Here are three formulæ that are recommended by former users of swelled gelatine process:—

1. Soak $2\frac{1}{2}$ ozs. Nelson's amber gelatine in 10 ozs. water; dissolve and add 150 grs. bichromate of potassium; coat glass at the rate of 6 ozs. to 12 by 10 plate.

2. Nelson's No. 2 gelatine	2 ounces.
Nelson's No. 1 gelatine	$\frac{1}{2}$ ounce.
Water	30 ounces.
Sat. solution of chrome alum	10 minims.
Potassium bichromate	150 grains.
3. Nelson's sheet gelatine	4 ounces.
Sugar	$\frac{1}{4}$ ounce.
Glycerine	100 grains.
Phenol	2 minims.
Potassium bichromate	200 grains.
Water	14 ounces.

You might try if either of these formulæ give you a higher relief.

FORTHCOMING EXHIBITIONS.

1909.

- September 10 to October 23.—The Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.
- September 23 to October 30.—Royal Photographic Society. Sec., J. McIntosh, 35, Russell Square, London, W.C.
- October 6 to 13.—Portsmouth Camera Club. Sec., James C. Thompson, 23, Elm Grove, Southsea.
- October 21 to 23.—Rotherham Photographic Society. Entries close October 11. Secs., H. C. Hemingway, Tooker Road, Rotherham, and F. Sargeant, 17, Aldred Street, Rotherham.
- October 27 to 28.—Watford Camera Club. Entries close October 21. Sec., W. J. Edmonds, 3, The Parade, Watford.
- November 10 to 13.—Hackney Photographic Society. Entries close October 12. Sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E.
- November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138 Glasgow Road, Wishaw, N.B.

1910.

- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for the following patents have been received from September 6 to 18:—

- COLOUR SCREENS.—No. 20,513. Improvements in the mechanical production of colour screens for cinematography in natural colours. William Norman Lascelles Davidson, "Ranmore," Cross Roads, Southwick, Sussex.
- PRINTS.—No. 20,585. Improved method of making photographic prints and devices for same. Giuseppe Silvestre Barberis, 31, Bedford Street, Strand, London.
- CLIPS.—No. 20,769. Improved clips for use in printing photographs. Giuseppe Silvestro Barberis, 31, Bedford Street, Strand, London.
- FILMS.—No. 20,770. Improvements relating to films for animated photography. Edmund Seal Donisthorpe, 189, Hammersmith Road, London.
- RAIN ALARM.—No. 20,772. Apparatus for warning photographic printers of commencement of rain in order to enable them to cover or remove printing frames. Albert Day, Strand Photographic Studio, Southchurch.
- OPTICAL INSTRUMENTS.—No. 20,888. Improvements in and relating to periscopes, poleoscopes, and like optical instruments. Job

Thomas Niblett and Thomas Bolas, 11, Victoria Street, Westminster, London.

PAPER.—No. 20,891. Improvements in the preparation of paper for photographic purposes. Thomas Whitehair Vigers, 24, Grove Road, Denmark Hill, London.

RECORDING APPARATUS.—No. 20,922. Improvements in photographic-recording apparatus for galvanometers, oscillographs, and the like. Philip Middleton Justice, 55, Chancery Lane, London, for Kunesch and Jaeger, G.m.b.H., Germany.

FILMS.—No. 21,099. Apparatus for the continuous drying of perforated cinematographic films. Reginald William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes, Cinematographes, et Appareils de Precision, France.

PRINTING IN COLOURS.—No. 21,281. Photographic printing in colours with the bichromate-gelatine process. Joseph Sury and Edmond Bastyns, 27, Chancery Lane, London.

STORAGE BOX.—No. 21,347. Improved storage box for the transmission of photographic plates, lantern slides, and the like. John Wilkinson and Alfred Wilkinson, 4, St. Ann's Square, Manchester.

CAMERAS.—No. 21,389. Improvements in cameras. Otto Halbach, 53, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH-PHONOGRAPH.—No. 10,396, 1908 (May 18, 1907). The invention consists of arrangement for synchronising the movement of a cinematograph and one or more talking machines actuated by separate source of energy, and in such a manner that the talking machine always tends to rotate more rapidly than the cinematograph. The synchronous working is then obtained by means of an automatically and continuously acting electro-magnetic brake, consisting of a rotary part fitted to the shaft of the talking machine and of a fixed ring fed with electrical current from an independent source through at least three separate windings connected up the corresponding sections of a distributor, mounted on or positively geared to the obturating shaft of the cinematograph, the brake serving to check the acceleration of the movement of the talking machine on that of the cinematograph. Dr. Pietro Pieri, 224, Via Cavour, Rome, Italy.

HOLDERS FOR PLATES DURING BACKING.—No. 26,803, 1908 (December 10, 1908). The device consists of a frame having a bottom piece and a raised rim extending completely around the bottom provided at each corner just outside the inner corner of the rim with small rectangular raised corner pieces which receive the plate to be backed. To facilitate the removal and handling of the backed plate there is first placed on the frame a carrier, consisting of a piece of or other dark paper, having projections or lugs extending beyond the ends of the plate. The plate is held by the raised corner pieces in position and is supported on the frame only at the extreme edges with the film side down. When in position the adhesive backing material is applied rapidly by a brush to the back of the plate. After removal both plate and carrier are placed at one side of the frame required, leaving the frame ready for the second plate, the operation being rapidly repeated until all the plates required are backed. Albert Thornley, 35, Mountain View, Cokermonth.

DAYLIGHT DEVELOPMENT.—No. 19,218, 1908 (September 12, 1908). The invention relates to developing photographic plates, the object being to provide an apparatus, wherein the plate, contained in the usual plate-holder, is inserted into a suitable sheath, preferably at the top of the apparatus. After withdrawing the slice of the plate-holder inserted into the sheath, the plate will be disengaged from the plate-holder, preferably by the action of a finger arranged inside the apparatus and adapted to be actuated from outside. The plate, disengaged from its plate-holder, is held by gravity upon two grippers, adapted to engage and hold the edges of the plate and to impart rectilinear and rotating movements to it within a dark chamber, containing the usual developing and washing liquids.

The grippers are preferably carried by a shaft, adapted to be

moved longitudinally on a suitable support and rotated on the same from outside. The dark chamber is preferably provided with an opening, equipped with a lens and shutter, and arranged in front of a window, provided in the opposite wall of the dark chamber, so that the operator is enabled to follow the development of the plate. The plate being developed and washed within the latter, the grippers are moved longitudinally above a chute, and at the same time release the plate by the action of a suitable cam, so that the plate is allowed to drop vertically into a suitable rack, arranged within a fixing bath contained in a compartment below the dark chamber. The fixing bath is arranged on a suitable carriage, adapted to be moved and adjusted from outside the apparatus.

The latter has furthermore an independent folding dark chamber, made of cloth with sleeves, and normally contained in a second compartment below the first-mentioned development chamber. This folding chamber is used for inserting fresh sensitised plates in the plate-holder for taking further photographs. Xavier de le Croix, 88, Avenue de la Bretagne, Canteleu, near Lille, France.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901.

ARTIFICIAL LIGHTING.—No. 19,838. Means for artificially lighting halls or other places in which cinematographic or magic-lantern pictures are exhibited, or photographic operations and the like are carried on. Grenier.

PRINTING.—No. 20,585. Method of making photographic prints and devices for same. Barberis.

New Trade Names.

ALLEGRAVURE.—No. 315,546. Pictures, prints, and engravings. Allen and Co. (London), Ltd., 107, Clifton Street, Finsbury, London, E.C., photo-engravers and printers. August 12, 1909.

RADIUM.—No. 315,725. Photographic paper. Isidore Bernard Davidson, Marlborough House, Basterfield Street, Golden Lane, London, E.C., fine art publisher. August 20, 1909.

ANISOL.—No. 314,176. Photographic chemicals. White Band Manufacturing Company, Ltd., Progress Works, Selsdon Road, South Croydon, Surrey, manufacturing chemists. June 22, 1909.

RED BALL BRAND.—No. 315,441. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including white lead and not including any goods of a like kind to white lead. Stevenson and Howell, Ltd., Standard Works, 95A, Southwark Street, London, manufacturing chemists. August 9, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

A Suggestion for Next Year's R.P.S. Exhibition.

In "Photography and Focus" for September 28 "R. C. B." suggests an improvement which might be made in the technical section of the catalogue of future R.P.S. exhibitions. He says:

At present it has evidently been left to each exhibitor to say much or little about his own exhibit, just as he felt inclined. The result is that some of the prints which hardly need it are described almost minutely, and others have nothing more than mere names. There are experts in the society who would no doubt be very willing to remedy this, if their co-operation were secured.

"The catalogue could then contain a brief sketch of the points of interest in the zoological, or botanical, or spectroscopic exhibits in due proportion, pointing out why each print is exhibited and the nature of the evidence which it yields. It would not increase the bulk of the catalogue much, if it did at all, and would vastly enhance the interest of these sections.

"We do not suggest that the secretary should do it, but that each piece should be dealt with by one expert. If we go further and say that the exhibits which none of the experts considered were of

sufficient interest to show in his own section should be excluded altogether, we should get rid of a good many prints which at present dilute the scientific section without any justification whatever."

"Working-up" Bromide Enlargements in Oils.

Writing on this subject in "The Amateur Photographer and Photographic News" for September 28, Mr. M. Lewin gives the following hints: "When using platino-matt paper, either rough or smooth, oil-colour diluted with turpentine allows of any degree of 'working-up.' Gelatine is not soluble in turps. and, in consequence, does not swell when a wash of the latter is applied to it, so that the colour thus diluted may be brushed with the greatest possible evenness over any part of the print we wish to darken. Not only this, but it may be used of any required intensity from pure black to the lightest tinge of grey, and when it has dried not the slightest difference of surface or texture will be found between those parts that have been treated and those which have not. For spotting and toning down small areas it is best to use the brush nearly dry, but for larger spaces the equivalent of 'sunning-down' in a P.O.P. print—the mixture may be washed on.

"It should be understood that in no case must the colour be used as a painter in 'oils' would use it, but always diluted with turps till it can be employed as water-colours are. If, in consequence of this, the brush is too wet, it can be partly dried on a spare piece of paper before being used. The right condition for use is easily ascertained by experiment.

"Finally, if the work done is not satisfactory, the whole may be washed off, without danger to the print, by means of pure turpentine. The colour sets with just sufficient tenacity not to rub off with ordinary usage, but not so firmly that it cannot be softened in tone by means of rubbing, preferably with a pad of cotton-wool; and if it is desired to remove the colour in any particular place, ordinary indiarubber will do so effectively, giving us thus the means of 'picking-out' a high light if we want to.

"Blue-black and lamp-black, either alone or mixed with one another, will be found the most suitable shades for an untuned bromide, according to the developer that has been used, while black mixed with Vandyke-brown or Venetian-red will match sulphide or copper tones."

New Books.

"The Photographer's Note-Book on Lenses." By Conrad Beck. London: R. and J. Beck, Limited.

In this little book of nearly 100 pages Mr. Conrad Beck has provided a most useful account of those properties of lenses which are of importance in practical work. It is not a dry-as-dust treatise, there is scarcely a formula to be found from first to last, but nevertheless—or perhaps we should say by reason of this fact—the photographer will find the many points which puzzle him in lens matters very clearly set forth. Mr. Beck, who writes in a way which is delightfully lucid, keeps to such matters as aperture, wide and narrow angle, covering power, distortion, etc., and shows what these mean, and when and with what purpose one may at times be sacrificed for another. We particularly recommend to our readers Chapter VI., on the selection of a lens for a hand-camera in which the very various requirements imposed by the reflex, hand, or hand-stand type of camera are very clearly gone into. The book also contains a useful epitome of optical rules and tables, among which are those giving the lengths of studios for full-length figures, with various lenses.

The author frankly declares his interest in the "Isostigmat" and other lenses of his firm. Writing (on page 49) of the Isostigmat anastigmat, he adds: "There are of course other good anastigmat lenses, and the description applies more or less to these other optical instruments. Naturally the writer thinks it a mistake to buy anything but the Isostigmat, but quite recognises that his competitors may perhaps not share his opinion." But quite apart from all partiality for Beck manufactures, the volume contains so much information on the photographic lens expressed in few words that our advice is emphatically to embrace Messrs. Beck's offer to send the "Note-Book" free on application.

CARBON ENLARGEMENTS.—M. E. Trutat has written a short manual on the making of carbon enlargements under the title "Les Agrandissements sur Papiers à Couches Pigmentaires." In this volume, which is intended for the amateur worker, the methods of preparing the enlarged paper negative for the orthodox process of making large carbon prints are described. The so-called "Carbograph" is also the subject of several pages of notes, but there is no mention of the Ozobrome process of preparing a carbon enlargement direct. The little book is published by M. Charles Mendel at 60 cents.

"T. Q.," No. 7.—The "Telephoto Quarterly," just published, continues to pursue the admirable course of making itself indispensable to photographers desirous of help in telephoto work, or of seeing in the excellent reproductions what a telephoto lens can do. We are not surprised to hear that Captain Owen Wheeler's publishers, Messrs. Gale and Polden, of 2, Amen Corner, London, E.C., continue to receive numerous "two-shillingers," each the price of "T.Q." for one year. We read in the current number of facilities to be offered, *via* the enterprising Messrs. Raines, for obtaining first-rate photographic enlargements or prints of telephoto subjects. The contents also includes "The Telephoto Lens as a Help to Getting Pictures of Stone Carvings," by Miss F. J. Erskine; "Orthochromatic Telephotography," by E. A. Biermann; "The Editor's Holiday"; and reviews of new apparatus for telephoto work.

"TRAVEL AND EXPLORATION."—The October number of "Travel and Exploration" (the first under new editorship) covers a fairly wide field, ranging from the Far North to the Far East. Especially noteworthy are the narratives of two of the greatest explorers of the day in their respective fields—Dr. M. Aurel Stein and Knud Rasmussen. Dr. Stein describes a remarkable journey through the arid wastes of Chinese Turkestan, across the "Sea of Sand" (the picturesque native sobriquet for the Taklamakan Desert). Knud Rasmussen, the greatest living authority on the Esquimes, writes a brilliant little impressionist sketch describing a long journey on ski with a Lapp caravan. Readable accounts of travel and experiences in Palestine and Cyprus are furnished by Mr. F. G. Affalo and Mr. Justice Bertram. The latter is apparently as enamoured of the Island of Venus Anadyomene as the author of "An Enchanted Island." Finally, Mr. Elliot Stock describes a dangerous climb of the Great Gable "chimney" in the English Alps region—an article which will appeal to mountaineers in general and rock-climbers in particular.

New Materials, &c.

Christmas and Calendar Mounts. Made by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

Messrs. Marion's 16-page list of the great variety of photographic mounts bearing Christmas greetings contains, as in previous years, a very full specification of each style of mount. The price in each instance is quoted at per thousand, per hundred, and per dozen, and the photographer or dealer ordering from the list will appreciate such full particulars as regards colour, inscription, and the suitability of the mount for upright or landscape photographs. This is done throughout, even in respect to midget and carte-de-visite mounts, but the list also includes quarter-plate, postcard, cabinet, and half-plate mounts, both paste-on and slip-in, as well as a considerable variety of mounts for circle and oval prints, also paste-on and slip-in. While it would be impossible to make particular mention of the many varieties of these souvenir mounts we may perhaps single out one or two which impress us as particularly nice in design. R. 14 is a card in white board throughout with cover in wood-grain, bearing a heavily embossed circle centre, with the inscription "Best Wishes." Inside is a double folder of card, with very neat embossed reeded border for the print. The inner and cover folder are tied together with a tasselled cord. The price is 2s. 6d. per dozen, 15s. 8d. per hundred, and 141s. per thousand, the mount taking a print 3in. x 1½in., upright only. Another very tasteful card, also in white, with a gilt inscription "With Best Wishes" on the cover of it is R. 11, which also takes a print (upright only) 3in. x 1½in., and is sold at 1s. 10d. per dozen and 11s. 4d. per hundred. In R. 112 the print is inserted in a slip-in mount, with opening 3½in. x 2½in. The cover is a very fine chequer design, with deckelled edge and gold blocked, with the inscription "A Happy Christmas and a Bright New Year." This

folder mount is sold at 2s. per dozen, 12s. per hundred, and 108s. per thousand.

Messrs. Marion are also introducing a series of postcard calendar mounts, made with wood-veneer surface, in two colours, and allowing of the photograph being slipped in between the two. The price, complete with calendar and cord, is 5s. per dozen, or 30s. per hundred, and the calendars are obtainable in three patterns—namely, upright rectangle, oval, and horizontal rectangle. They are also sold in size for carte-de-visite—both square and oval—at a price of 4s. 4d. per dozen and 26s. 4d. per hundred.

We should also refer to the stickyback adhesive mottoes for attaching to any photographic mount with the object of converting it into one particularly suitable for a Christmas greeting. Messrs. Marion issue these mottoes in various styles and wordings, one very neat design being R. 142, a centre red lettering on a black ground, and bearing the words "Christmas Wishes."

The "Holdinslide" Mount. Made by J. Wright and Co., 4, Station Parade, Kew Gardens, London, S.W.

A novel type of slip-in mount is just introduced under this name, its chief feature being that the print can be very easily inserted at either end of the opening and as easily removed; also the fact that the edges of the opening are not cut in making the mount, but are turned over, and gives a pleasing bevelled surround to the print without a disturbing line of another colour, which is frequently unavoidable in making a cut-out mount of the ordinary pattern. Apart from these differences, the mounts are made in two styles—the "Singleton," for holding one print only, and the "Compactum," providing space for about a dozen prints. The mounts are made in a number of standard sizes and in a variety of tints, the retail prices, for example, of a mount of outside dimensions, 6½in. x 4½in., to accommodate quarter-plate prints, being 1s. per dozen in the "Singleton" pattern or 2s. 6d. in the "Compactum." The mounts are made in sizes up to 20in. x 17in., taking 15in. x 12in. prints, and from the samples which we have seen will certainly please those who esteem the convenience of the slip-in pattern of mount, but desire something more tasteful and harmonious in appearance.

"Academy" Greeting Calendars and Christmas Mounts. Sold by Bartons', 36, Cornwall Street, Birmingham.

The most unobtrusive and pleasing colours and designs of this series of greeting cards will appeal to those who aim at the utmost simplicity, not only in the get-up of the greeting which they may send to their friends, but also in the wording on it. The folders in which the mounts proper are enclosed bear the words "To Greet You," surrounded by a design of holly and ribbon. The colours are mostly delicate grey, cool brown, greens, and creams, all of linen surface mounting paper. In some cases the print is mounted on to the centre-piece of the triple folder, but in most a loose mount or calendar mount is provided. The calendars are corded for hanging and bear a set of monthly tear-offs. We have seen nothing more artistically produced for the forthcoming Christmas season than these mounts of Messrs. Bartons', which are made for C.D.V. and cabinet, as well as for midget prints of oval or circle shape, and are issued at prices which range from 2s. 6d. per dozen, 16s. per hundred to 5s. 6d. and 32s. 6d. respectively. On receipt of a postal order for 1s. the firm sends a very nice selection of the mounts, and allow for the cost of this sample packet on receipt of an order to the value of 10s. and upwards. Customers who so wish it may have their own designs placed on the mounts, or can obtain mounts of colour and texture other than those listed.

Gevaert P.O.P. Made by Gevaert, Ltd., 26 and 27, Farringdon Street, London, E.C.

Of the various descriptions of printing paper which Messrs. Gevaert are introducing upon the English market the first to reach us for mention is the gelatine printing-out paper or Gevaert P.O.P. the very decorative violet and grey label of which should ere long have attracted the eye in dealers' windows. P.O.P. as a photographic product cannot be expected to inspire comments as to novelty or necessity: we have discharged our duty to the maker and to our readers when we report our experience in making trial of the new brand of this familiar type of printing paper. Let it be said therefore that the Gevaert P.O.P. is one which we found to give exceedingly bright prints. It is evidently manufactured with

regard to the fact that the majority of the negatives which nowadays fall to be printed in P.O.P. do not by any means err in the direction of excess of pluck or brilliancy; that, on the other hand, they are many of them deplorably deficient in this characteristic of a good negative, and therefore the maker of a printing paper must do what he can to remedy matters. This, we find, has been done in the case of the Gevaert paper by providing an emulsion which gives a very good print from a negative which is none too plucky, but at the same time does not produce prints of excessive contrast from a really vigorous negative.

In speed of printing the paper is excellent. In the sulphocyanide-gold bath it tones quickly to a very rich purplish tone—quite the P.O.P. tone—whilst it gives a very good slightly warmer tone in the combined bath.

For really warm tones the following bath is recommended by the makers, and gives in our experience a very effective carmine tone.

Printing is done only slightly deeper than the finished print is required to be. The prints are given three five-minute soaks in water and toned in:—

Ammonium sulphocyanide	45 grs.	5 gms.
Potass. iodide	10 grs.	1 gm.
Gold chloride solution		
(15 grs. in 2 ozs.)	2½ drms.	15 c.c.
Water	20 ozs.	1,000 c.c.

In this bath toning must be continued until the deepest shadows, on holding the prints up to the light and looking through them, show the carmine tone; this will take about half an hour. Until the toning has begun the prints should be kept constantly on the move, but they can then be left to themselves, except for the movement they get as each is picked out for examination at intervals. The toning bath should be used only once, and it should be noted that the prints gain a little in drying.

The paper is issued in three surfaces—glossy, matt, and semi-glossy or “carbon” surface. The glossy is made in mauve, white, and pink; the matt and semi-glossy in white only. All three varieties are obtainable in thick and thin qualities, the former serving very conveniently for photographs which are printed with a border and are not to be mounted. While the surface of the glossy brand calls for no special remark, we would say in regard to the two other varieties that they are nicely adjusted to a matt and half-matt of a kind very acceptable for portrait work. In this as in other respects, the Gevaert P.O.P. shows itself to be a material of the highest degree of manufacture.

“CHALLENGE” CHRISTMAS POSTCARDS.—The Christmas greeting postcards, issued by the Challenge Photographic Works, Macclesfield, are supplied with the P.O.P., self-toning, gaslight, and bromide emulsions of this firm, the designs being appropriate emblematical drawings expressing seasonable greetings. The Challenge Works offer to provide imprint of name free in the case of orders of sufficient quantity.

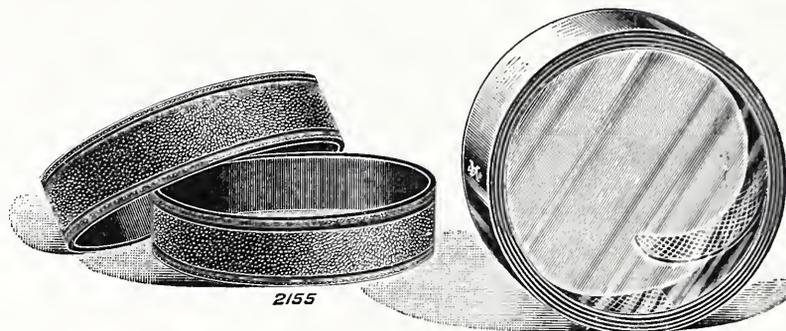

CRITERION CHRISTMAS POSTCARDS.—Postcards bearing the well-known emulsions of the Birmingham Photographic Company, Stechford, near Birmingham, are being issued as usual this year with designs suitable for the Christmas season, occupying one-half of the front side. The drawings are a new series, specially drawn for the Birmingham Photographic Company, and are certainly among the most tasteful and pleasing embellishments of the Christmas postcard which we have seen. The cards are sold at the usual prices, either P.O.P., bromide, or gaslight.

“DILOS” FRAMES.—Under this name Messrs. J. Epstein and Co., Rupert Street, Bristol, have placed on the market a series of frames to take pictures measuring 20in. by 16in., and specially designed to meet the requirements of the professional photographer, and which, from our own inspection of them, we should pronounce to be very good value for money. The frames are of handsome appearance, made of oak, and are obtainable in various patterns, either plain or ornamented, the mouldings ranging in width from 2in. to 5in., at prices from 15s. 6d. to 48s. per dozen. Messrs. Epstein are also offering a special line of these frames 2in. wide in a special design for the exceedingly low price of 12s. 6d. per dozen. All frames are complete with glass and backboard. Messrs. Epstein offer to send their illustrated price list of these and the numerous other lines for which the firm is noted, post free on receipt of six penny stamps.

New Apparatus, &c.

The Ensign C Isochromatic Screen. Sold by Houghtons Ltd., 88-89, High Holborn, W.C.

The series of Ensign isochromatic screens is now supplemented by a “C” screen, made in two grades, one requiring four times and one eight times the exposure necessary without a screen. The screens are made of specially worked glasses, between which is cemented stained gelatine, the whole being mounted in a neat brass cell fitted with spring to clip the lens. The leather case in which the screens are sent out is made to fit so closely that it will serve as a lens-cap when the screen is in use. We find that these C screens are designed to fulfil all the requirements of a perfect filter screen according to

the most modern theories—that is to say, they cut down the violet and blue-violet rays without interfering with the rest of the spectrum. The spectroscope shows that the absorption of the screen stops in the blue-green, and that the green, yellow, and blue pass unaffected; as a result good correction can be obtained without an inconvenient prolongation of exposure. The screens are made in three sizes, to fit lens hoods from lin. to 2½in. diameter, and the respective prices are 3s., 3s. 6d., and 5s. The good quality of the screens and their low price should render this series very popular.

The 4A “Speed” (Focal-Plane) Kodak. Made by Kodak, Limited, 57 to 61, Clerkenwell Road, London, E.C.

Despite the great variety of Kodak cameras, which owe their ingenuity and workmanlike qualities to the mechanics of the Rochester factories, there has not been placed upon the market hitherto a Kodak provided with a focal-plane shutter—that is to say, if we except the “Premo” and “Graflex” reflex cameras, which, though Eastman productions, are not properly Kodaks. This is no

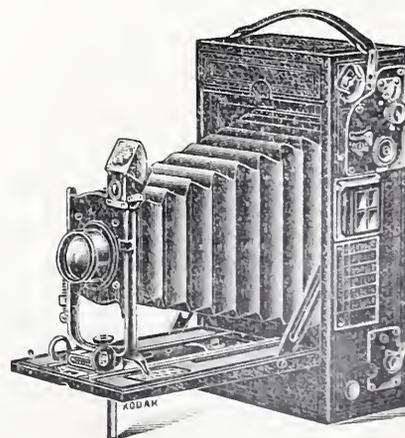

Fig. 1.

doubt accounted for by the fact that in all their cameras the Kodak Co. have set before themselves the ideal of great simplicity and portability, a conjunction of properties which certainly militates against the adoption of a focal-plane shutter. However, the development of the Kodak as an instrument for the most serious type of photographer has doubtless been responsible for the introduction of an instrument of the focal-plane type, the first pattern of which

has now been placed on the market as the No. 4A "Speed" Kodak. The instrument produces a picture 6½ in. by 4¼ in.—that is to say, it takes the 4¼ in. Kodak daylight-loading spool of six or four exposures. To sum up in a word the result which has been achieved as regards portability, it may be said that the total outside bulk of the camera encloses both the roll-holder and the focal-plane shutter, but is very little bigger than would be either of these articles separate. Folded for carrying the camera measures under 12 by 7 by 3½ in. Extended it allows of the lens panel being placed about 11½ in. from the sensitive film. It will thus be seen that much success has attended the endeavour of the makers to provide a camera suitable for the most rapid exposures within comparatively small bulk.

As regards the shutter itself it is naturally of the self-capping type—any other would be useless for a film camera—with a single slit, the width of which is very readily altered. An adjustable scale is provided with a pointer on the side of the camera. The pointer has only to be moved from one graduation into the next—it snaps at each point—to give a series of slit widths of $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, 1½, and 3 in., in addition to a much longer aperture the full height of the picture, or 6½ in., which is available only for time exposures. While the alteration in the width of slit is best made before the shutter is set, the other factor in obtaining the full range of speeds, *i.e.*, the spring tension of the shutter, may be altered whilst the instrument is held ready for exposure with the shutter set. A complete turn of the winding-key in the second illustration increases the tension one number, whilst two pressures on the lower lever relax the tension to the same amount. The latter movement

is an especially neat and convenient method of releasing the tension, far superior to that in the generality of shutters where one has to press the release with one finger and let down the tension-key with the thumb and finger of the other hand. The clutch release in the "Speed" Kodak allows of all this being conveniently done with one finger. The milled key provides a rapid wind of the shutter, whilst release is made by raising the plate fitted with a small milled knob, which is provided with a spring so that it must be intentionally raised to release the shutter. The adjustment for both time and instantaneous exposures are thus most conveniently made, whilst the conjunction of spring tension and slit width allows of a series being given from 1-5 to 1-1,000 sec., whilst with one single slit width—say, 1½ in.—a series of exposures from 1-10 to 1-70 may be given by altering only the tension. One point which we think is worthy of special mention is the closeness with

which the blind of the shutter works to the plate or film. The distance in the case of the roll-film must be less than ¼ in., a point which deserves to be emphasised since it is not unusual to find the efficiency of focal-plane shutters depreciated owing to their being mounted at some quite considerable distance from the true focal-plane.

In the way of other movements the camera is very well provided. It is fitted with direct-vision finder for pictures landscape way, the sighting point and lens of the finder both folding back by one movement flat with its metal carrier. The lens front also carries a reversible brilliant finder, and is itself provided with screw rise-of-front movement. The front of the camera is brought forward and fixed in any point by the clamps seen in the first illustration, a fine focussing movement then serving for the adjustment of the pointer on the scale. Mention should also be made of the light-tight air-vent provided in the front of the bellows, by means of which drawing in of the blind of the shutter or of the bellows is entirely obviated. Externally free from projections, except the one or two very solidly made keys on the left-hand side, the camera is eminently fitted for the tourist, whilst its workmanship throughout is of a high mechanical quality worthy of the Kodak reputation. The price of the No. 4a "Speed," without lens, is £10 10s. To it

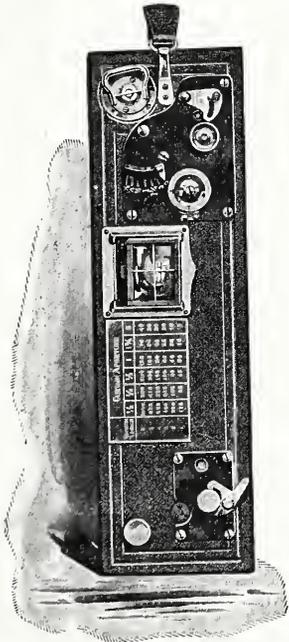

Fig. 2.

can be fitted any one of a number of high-class anastigmats of focus about 200 mm. (about 8 in.). These include the Zeiss "Tessar," the Beck "Isostigmat," the Goerz Series III. and Goerz "Celor," *f*/4.8. The camera can also be fitted with a plate adapter, focussing screen, and one double plate-holder at a cost of £1 10s.

The "Busch" Reflex Camera. Made by the Emil Busch Optical Company, 35, Charles Street, Hatton Garden, London, E.C.

To the large series of hand cameras included among the manufactures of the Emil Busch Optical Company must now be added an instrument of the reflex type, which we have had an opportunity of closely examining during the past few days. In its general construction the "Busch" reflex resembles the type of instrument which has been evolved during the last year or two—namely, one to which most of the cameras on the market more or less closely conform. It has, however, one or two special features. In the first place, the panel carrying the lens is of unusual size—namely, 3½ inches square—and therefore able to carry lenses of the largest aperture, or even a lens of the portrait type. The panel is made so that it may be reversed in its setting, and the front of the camera has considerable rise and fall movement, a total range of over an inch in the 3½ by 2½ size, which is distributed partly as rise and partly as fall. It is evident that the carrying of a large lens is particularly kept in view by the makers, since the extension struts of the camera are four in number, very rigidly made, and hold the lens front very firmly. The focussing pinion is placed on the left-hand side of the camera, whilst on the right a clamping head is provided, so that, if necessary, the camera may be fixed at a focus for any given distance.

The hood is built square, and gives a perfectly unobstructed view of the corners of the plate. The frame to which it is fixed is hinged on the front side, and is instantly turned back, giving access to the ground glass, which latter can also be turned up to allow of the mirror being dusted. The mirror itself is depressed by pressure on the lever seen in the top right-hand corner of the camera in the drawing, but is protected by a guard (not shown in the illustration), serving to prevent accidental release. The shutter release is actuated by a similar lever on the right-hand side of the camera, the release of the mirror and shutter being extremely free from vibration. The focal-plane shutter has separate adjustments for width of slit and spring tension, the latter being made whilst the shutter remains set, and providing for a considerable range of movements. The width of the slit, which must be altered whilst the blind is in view, is very rapidly done, simply by winding the slit to the top of the plate, depressing a small knob on the left-hand side of the camera, and then turning a milled head on the right to either open or contract the blind aperture. A novel feature in connection with the shutter is a brake serving for slowing down the speed and thus allowing some what longer time than the minimum which would otherwise be attainable. When we have finally said that the camera is provided with a rotating back clamped in either position it will be seen that it possesses practically all the attributes of a high-class reflex instrument. In workmanship it is altogether excellent, being finished

throughout in black ebonised wood, covered in black leather, and having all the metal parts also of black finish. The camera is made in three sizes only—namely, $3\frac{1}{2}$ by $2\frac{1}{2}$, $4\frac{1}{4}$ by $3\frac{1}{4}$, and $5\frac{1}{2}$ by $3\frac{1}{2}$ (postcard). In the quarter-plate size the price, complete with three plate-holders and Busch "Aplanat," $f/6.5$, is £13 10s.; or with Busch "Omnar," $f/4.5$, £17 8s. In the $3\frac{1}{2}$ by $2\frac{1}{2}$ size these prices are £12 and £15, whilst in postcard the price, with $f/4.5$ "Omnar," is £21 10s. The cameras allow of extensions of 8, $10\frac{3}{4}$, and $12\frac{3}{4}$ inches, respectively, in the three sizes, and therefore, while allowing of quite a narrow angle of picture, such as that given by the single combination of the lens, are eminently suited for use with the well-known "Bis Telar" telephoto lens. The instruments are also applicable for use with the "Premo" film-packs.

CATALOGUES AND TRADE NOTICES

THE HOUGHTON PROFESSIONAL LIST.—A new list, solely for the professional photographer, has just been issued by Messrs. Houghtons Limited, 88 and 89, High Holborn, London, W.C., at which establishment, as our readers know, the requirements of professional photographers have for a year or two past been the special care of an actively conducted department. The new list contains only the items of service in professional and commercial photography: the many oddments apparently found of service to the amateur worker find no place in this well-arranged book. Cameras, tripods, and lenses occupy the first portion of the volume, after which we come to an admirable large series of reproductions of backgrounds and studio accessories. The photographer at a distance will appreciate these actual photographic reproductions of his proposed purchases. Mounts and mounting boards are subjected to a similar treatment, and Messrs. Houghtons do all that is humanly possible—short of actual inspection—in conveying an idea of the appearance and design of their wares. There are many other apparatus and materials for the professional photographer here listed, and the pages describing dry-mounting accessories, trimmers, frames, enlargers and artificial light for the studio show that Messrs. Houghtons in their professional department are thoroughly abreast of current requirements. The list, we would add, is sent free to bonâ-fide readers of the "B.J." on application.

WRATTEN LIGHT-FILTERS.—Messrs. Wratten and Wainwright have just issued a new list of the photographic light-filters manufactured by them, to the number of no less than seventy different varieties. That the mere preparation of these filters for the market within the past year or two has by no means sapped the renewed vitality of the Wratten firm is evident from the trouble which has been taken to provide the photographer with full information as to the filters. Spectro-photographs are given of the absorption, and data are appended as to the stability of each filter towards light or heat. Thus by "Quite Stable" Messrs. Wratten mean that the filter will show no change if exposed to daylight and sunlight for twelve months, whilst the other designations, "Stable," "Moderately Stable," and "Somewhat Unstable," gave an indication of the time which may be expected to elapse before any alteration can be discerned in a filter when thus constantly exposed. These data must not, of course, be taken as the life of a filter, which is kept, as it should be, protected from light and heat. The list, which runs to over thirty-six pages, most of which are taken up by the spectrum diagrams, is sent by Messrs. Wratten on receipt of 6d.

ENLARGING WITHOUT CONDENSERS.—The very convenient reflector illuminating chambers sold by Messrs. J. Lancaster and Sons, Ltd., under the name of "Ellipsoid," are the subject of a new four-page circular just published. For converting an ordinary camera into an enlarger, and for amateur enlarging and reducing work, one or other of the four models of the "Ellipsoid" supply a most inexpensive outfit. The list is sent free on application to Camera Buildings, Broad Street, Birmingham.

OPAQUE-PROJECTION LANTERNS.—The current issue of the "Prism," issued by the Bausch and Lomb Optical Co., contains an account of the new types of projection lantern just introduced by the company under the name "Balopticon." The "Prism" is sent free on application to 19, Thavies Inn, London, E.C.

SULPHIDE TONING OF P.O.P.—Messrs. Edmund and Co., Ezra Street, London, E., have just issued a leaflet of instructions for the

use of the (patented) thiomolybdate prepared by them for the toning of P.O.P. The circular gives very explicit directions for this inexpensive and reliable toning process, and is sent free on application.

MAWSON LANTERN PLATES.—An eight-page booklet, "How to Make Lantern Slides Easily and Successfully," reaches us from Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne. It gives in the fewest words the essential points in the making of lantern transparencies, together with the formulæ for the development and toning of the "Mawson" lantern plate, the good qualities of which we have had cause to appreciate during many years' regular use of them.

THE "PRIMUS" LANTERN POCKET-BOOK.—The 1909-10 issue of this useful pocket-book and diary for the use of lanternists has just been issued by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C. Under the editorship of Mr. W. F. Butcher, F.C.S., it contains a variety of useful tables, electrical data, directory of dealers, etc. It is sent free on application.

SPIDERS AND THEIR HABITS.—A set of 270 lantern slides from the negatives of Mr. R. Hancock, illustrating the characteristic forms and habits of spiders, has just been issued by Messrs. Sanders and Co., 71, Shaftesbury Avenue, London, W. A list of the subjects has just been published.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 1.

Ashton-under-Lyne Photographic Society. "Autotype Carbon." Demonstration.

SATURDAY, OCTOBER 2.

Kinning Park Co-operative Camera Club (Govan). Outing to Langbank.
South London Photographic Society. Outing to Eltham.

SUNDAY, OCTOBER 3.

Borough Polytechnic Photographic Society. Outing to Cookham.

MONDAY, OCTOBER 4.

Southampton Camera Club. Print Competitions.
South London Photographic Society. "Thunderstorms and a Camera." Howden Wilkie, F.R.P.S.

Kinning Park Co-operative Camera Club (Govan). Committee Meeting.

TUESDAY, OCTOBER 5.

Glasgow Southern Photographic Association. "Our Hobby and Critique of Prints by well-known Men." H. Marshall.
Hackney Photographic Society. Members' Lantern Slides.
Burnley Co-operative Camera Club. "Autotype Carbon." Demonstration.

WEDNESDAY, OCTOBER 6.

Worthing Camera Club. Outing to Littlehampton and Ford.
Ipswich Scientific Society. "Autotype Carbon." Demonstration.

THURSDAY, OCTOBER 7.

Southend-on-Sea Photographic Society. Indoor Meeting.
Walkley Camera and Optical Lantern Society. "Autotype Carbon." Demonstration.
Watford Camera Club. "An Hour with the Birds." W. Bickerton, F.Z.S.
Liverpool Amateur Photographic Association. "Control." T. Lee Syms, F.R.P.S.

NOTTINGHAM CAMERA SOCIETY.—Mr. T. Wright presided at the annual meeting of the Nottingham Camera Club, which was held in one of the rooms of the Mechanics' Institution last week. The annual report and statement of accounts, which showed a balance in hand of £6 12s. 5d., were unanimously adopted, and the election of officers resulted as follows:—President, Mr. T. Wright; vice-presidents, Messrs. A. Black, W. S. Ellis, W. H. Kirkland, W. Mosley, H. Roberts, Arthur Marshall, and the Revs. G. H. Heynes and G. Meek; hon. secretary, Mr. E. A. Pollard; hon. assistant secretary, Mr. S. D. Middleton; hon. treasurer, Mr. H. Roberts; hon. auditors, Mr. W. Mosley; curator of survey, Mr. J. T. Radford; delegates to the Royal Photographic Society, Messrs. A. Marshall and T. Wright; delegates to Midland Photographic Federation, Messrs. W. H. Kirkland, T. Wright, and E. A. Pollard.

A HOSPITAL FOR NEGATIVES.—The Vanguard Manufacturing Co., Maidenhead, announces a development of its activities in the way of actual work on negatives, prints, etc., which are defective. The fact that the arrangements are in the hands of Mr. W. Ethelbert Henry is ample guarantee that the staff of the "Hospital" will make good their offer to do what is possible in cases of spoilt negatives or prints. A circular just issued by the Vanguard Co. gives the conditions under which these facilities may be obtained.

Commercial & Legal Intelligence

ROTHERHAM PHOTOGRAPHER'S FAILURE.—Last week Mr. Registrar Binney made a receiving order and an order of adjudication on the debtor's own petition against John Scott, residing and carrying on business at 50, Hollowgate, Rotherham, as "E. Holt," photographer and postcard publisher. Mr. H. Fretwell, of College Square, Rotherham, is the solicitor in the matter.

DISSOLUTION OF PARTNERSHIP.—The partnership between Frank Wilkins and Samuel George Holyoake, carrying on business as photographers at 2, Sydenham Road, Sydenham, under the style of "Wilkins and Holyoake," has been dissolved by mutual consent. Mr. Holyoake will receive and pay all debts due to or owing by the late firm.

LEGAL NOTICES.—Mr. Josef Valter (described in the receiving order as John Walter), photographic art gallery proprietor, 41, Southampton Row, W.C., is to apply on October 19 for his discharge in bankruptcy.

NEW COMPANIES

ENGINEER'S SENSITISING COMPANY, LTD.—Capital, £2,500, in £1 shares. Objects: To carry on the business of manufacturers of sensitised papers, linen, and other materials used for the duplication of plans by photographic and other means, etc., and to acquire the business carried on at 1 and 2, Castle Lane, Buckingham Gate, S.W., by Norton and Gregory, Ltd. Private company. The first directors (to number not more than six) are: H. N. Hickman, G. G. Hickman, E. H. Hickman, and H. G. Carpmal. Registered office, 1 and 2, Castle Lane, Buckingham Gate, S.W.

U.S.A. STUDIOS, LTD.—Capital, £100, in £1 shares. Objects: To carry on the business of photographers, colour process and half-tone engravers, printers, etc. Private company. Table A mainly applies. Registered office, 24, John Street, Bedford Row, W.C.

News and Notes.

EASTMAN DEMONSTRATIONS AT WINNIPEG, CANADA.—The Eastman School met in Winnipeg on September 8 for a three days' demonstration. This was held under the auspices of Duffin and Co., Ltd., stock dealers, Winnipeg. The demonstrations for the first day, ably carried out by Messrs. Scott, Waide, Hazlett, and Campbell, were on lighting and posing with the Aristo lamp, tank development, Nepera, carbon sepia, and Ozobrome, followed at 8 p.m. by an organisation meeting of North-West photographers, a note of which is appended. The second day tank development was explained, demonstrations given on Seed plates, Aristo papers, Angelo platinum, fancy border tinting, and Nepera and bromide enlarging. The final day was spent in proofing negatives made at the school, obtaining sepia tones by re-development, printing-room dodges, devices, and ideas. After the strenuous work of the three days a little recreation was provided by a tally-ho ride to the Winnipeg City Park, winding up in the evening by a banquet. Messrs. Duffin and Co. and the Manitoba Photographers' Association are to be complimented on their move in getting the school to Winnipeg.

ORGANISATION (MEETING OF PHOTOGRAPHERS OF WESTERN CANADA.—This meeting was held on September 8, in the Steele Studio, and was attended by the most prominent photographers west of the Great Lakes, all of whom upheld the advantages of such an Association in a very enthusiastic manner. The officers elected were: President, W. W. Robson, Winnipeg; vice-presidents, J. B. Banks, Kenora; E. Burke, Edmonton; S. E. Prest, Morden; F. Ramsdale, Moosomin. Secretary-Treasurer: A. L. Lee, Winnipeg. Executive Committee: A. E. Gentzel, Winnipeg; R. T. McFadden, Winnipeg; G. W. Sparling, Portage la Prairie; P. W. Rowe, Yorkton, Sask.; F. Gowan, Brandon. Auditors: J. G. Jenkins, Deloraine; and W. K. Ranton, Treherne. There were about fifty present, and practically everyone joined the association. A convention will be held next year, in which there will be an art exhibit, consisting of high-class photography. This Association will undoubtedly be the means of bringing photography to a higher standard.

SEND-OFF TO A ROTARY EMPLOYEE.—Mr. W. H. Armour, who has from the beginning been on the letterpress staff at the Rotary Works, for some years as head of the department, closed his connection with it on Saturday, September 4, having secured an appointment as assistant superintendent of the Lawrence Asylum Press, Madras, India. As a mark of their esteem and a memento of his association with them, the staff subscribed for and presented him with a solid silver inkstand and a pipe in case. The lid of the inkstand was inscribed with Mr. Armour's initials, "W. H. A.," and the stand itself was inscribed, "From the employees of the R.P.C. Letterpress Department, West Drayton, Middlesex. September, 1909."

THORNTON-PICKARD COMPETITION.—The annual competition, in which prizes to the value of £100 are offered for photographs taken with the various makes of Thornton-Pickard cameras and shutters, closes on October 1, and intending competitors who have not yet obtained entry forms should apply without further delay for these and full particulars to the Thornton-Pickard Manufacturing Company, Ltd., Altrincham, Cheshire.

CLASSES IN PHOTOGRAPHY.—Evening classes for photographic instruction are being held during the winter by Mr. E. Senior at the Woolwich Polytechnic, on Wednesdays at 7, commencing September 29, and at the Battersea Polytechnic on Tuesdays and Thursdays at 7.30, commencing September 27. At the latter institute there are separate classes for elementary and advanced workers, with reduced fees to students in the trade; there is also a special class for enlarging. Full particulars as to classes, fees, etc., may be obtained on application at the respective institutions.

WINDOW DRESSING.—A London optician (writes "Advertising") has hit upon a good idea to draw attention to a special line of cameras. The camera is placed in the centre of his window, and coloured tapes are stretched from each important part of the camera to a little label on the window, the label stating precisely the merits of each particular fitting.

CINEMATOGRAPHY IN COLOURS.—A new booklet of the Smith-Urban process of animated photography in natural colours has just been issued by the National Colour Kinematograph Co., Ltd. Urbanora House, 89-91, Wardour Street, London, W. It contains an entertaining popular description of the "Kinemacolor" projections, in regard to which it is interesting to note that this latest triumph of cinematograph and colour-camera in conjunction is regular feature in the programme of three of the premier houses of variety in Europe—the Palace Theatre, in London; the Folie Bergères, in Paris; and the Winter Garden, in Berlin.

"COUNTRY AND TOWN" is a new monthly magazine for architects, builders, etc., in which there will appear, side by side with reproductions of our forefathers' skill, a series of true architectural triumphs by modern architects. It is further intended to demonstrate that the beauties of a modern home need not end with the exterior, and that it is possible to introduce carved doors, overmantels, chimney corners, staircases, and other decorations in keeping with the style of the house. "Country and Town" is issued by the Abbey Press, 13 and 14, Tothill Street, Westminster, London S.W. The first issue gives excellent promise of the manner in which the publishers propose conducting it.

VIVE CAMERA Co.—In reference to the recent query by a correspondent, several readers write to mention that the last address of the Vive Camera Co. was Regent House, Regent Street, W., but no information of the present existence of the firm is forthcoming.

R.P.S. LECTURES.—The following lectures will be delivered at the New Gallery, at 8 p.m. :—

Saturday, October 2.—"Modern Ideas about the Sun," by T. Connolly, B.Sc.

Monday, October 4.—"San Marino, the Pigmy Republic," by T. Rev. T. T. Norgate, F.R.G.S.

Thursday, October 7.—"Saints, Benedictines, Goths, and Vikings," by E. W. Harvey Piper.

Saturday, October 9.—"The Photography of Sport," by Adolph Abrahams, B.A.

WATFORD CAMERA CLUB.—The seventh annual exhibition of the Watford Camera Club will be held in Buck's Rooms, Watford, on October 27 and 28. Of the seven open classes one will be set ap

or colour photography, one for those who have never previously obtained an award in any exhibition, and one (the champion class) for pictures previously medalled. The awards will take the form of gift and bronze medals, and a number of these will be placed at the disposal of the judge, Rev. F. C. Lambert, M.A., for award. Entries close October 21, on or before which date all entry forms, accompanied by the necessary fees, should reach the hon. sec., Mr. W. J. Edmonds, 3, The Parade, Watford, from whom also the forms and further particulars may be obtained.

"PALL MALL" COMPETITION.—A photographic competition has been organised in connection with the "Pall Mall Gazette" and the "Pall Mall Magazine" in which the prizes of one guinea are offered for the best photograph submitted in each of the following classes: (a) Pictorial subjects and figure studies; (b) general interest and topical subjects, and (c) high-speed work, including sporting subjects. Photographs must be sent addressed "The Photographic Editor, the 'Pall Mall' Press, Newton Street, London, W.C.," postage paid, not later than October 25, accompanied by the back cover of a copy of the Magazine, and the winning prints, together with any others which may be deemed of special merit, will be reproduced in the December issue of the "Pall Mall Magazine."

A NEW SOCIETY has been formed under the title of the Illuminating Engineering Society. It has for its object the study of the science and art of illumination. We understand that Prof. S. P. Thompson, B.Sc., F.R.S., has kindly consented to become the first president of the society, and that influential support has been received from many distinguished authorities on matters of illumination in this country, on the Continent, and in America. In addition, a very representative Council has been formed. The society will, therefore, enter its opening session next November under excellent auspices, and as every reason to hope for a long and prosperous existence.

PHOTOGRAPHS ON APPLES.—According to the "Edinburgh Evening Dispatch," the photo-printed portraits, etc., on the skins of apples being introduced as a novelty by Messrs. Andrew S. Clark and Co., Market Street, Edinburgh. As was described in the Press some year or so ago, each of the apples when in an unripe state, and of a light green colour, has a paper shape affixed to it. As the apple gradually ripens, and the skin turns red, the paper acts as a mask does in photography, and keeps the covered portion quite green. Among the subjects seen on the apples were jockeys, stags, the King's head, and one or two other subjects. Each of the apples weighed about $\frac{3}{4}$ lb.

CITY OF LONDON AND CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—A preliminary syllabus of lectures and demonstrations for the new session, which commences on Monday, October 11, reaches us, and we are pleased to note the number of interesting evenings which have been arranged. Mr. F. J. Mortimer opens the ball with a lantern lecture, entitled "A Week in Holland with a Pocket Camera." Among other interesting items are: "A Few Hints on the Gumatinum Process," by Mr. Malcolm Arbuthnot; "Bromoil," by Mr. C. H. Hewitt; and a lantern lecture, "London through the eyes of Gossip Pepys," by Mr. A. H. Blake. Beginners will have every opportunity of improving their photography, arrangements having been made with several of the advanced workers of the society to give monthly demonstrations on technical subjects, such as development, bromide enlarging, intensification and reduction, control in printing, etc., in the spacious dark-room which the members have at their disposal. Further particulars and full details as to membership may be obtained from the Hon. Sec., Mr. H. S. Cuming, 4, North End Road, West Kensington, W., or at the headquarters of the society at Cripplegate Institute, Golden Lane, E.C.

ENSIGN FILM COMPETITION.—Mr. H. C. Leat, 2, Richmond Street, Cliftondown, Bristol, is the winner of the "Ensign" Roll Film Competition for September. Four consolation prizes were also awarded, as the entries were very numerous. Houghtons, Ltd., offer a three-guinea camera every month for the best negative on "Ensign" film. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

OLIVER GOLDSMITH SCHOOL, PECKHAM ROAD, S.E.—A course of instruction in photography at the above school on Tuesdays and Thursdays, from 7.30 to 10 p.m., commenced on September 28. The fee for the whole course is 2s. 6d. A complete syllabus may be

obtained from the secretary at the above address. Each meeting is devoted to a lecture, followed by practical work in the laboratory. Special attention is given to those students who desire to sit for the photographic examinations. A student of this school at the 1909 examination of the City Guilds obtained the silver medal in the Honours Grade. Any further information may be obtained from the lecturer, Mr. F. W. Bannister, or from the Principal at the school.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—A special meeting of the Committee of the Scarborough Photographic Society was held in the Library of the Museum on Friday the 24th ult., to meet Messrs. Godfrey Bingley (President Elect), Walter F. Potter, F. B. Cattley, and F. A. Bridge (Hon. Sec., P.C.U.K.), who had journeyed North for the purpose of discussing the proposed arrangements for the 25th. Annual Convention to be held in Scarborough in July next. The members of the Society are very enthusiastic about the meeting, and, judging by the keen interest taken in the details, and the promises of cordial assistance by several influential gentlemen residing in the district, the Convention of 1910 should be a record gathering in every way.

A CURIOUS CASE OF COLOURS FADING.

To the Editors.

Gentlemen,—I have noticed in some pictures which I am showing in my reception room—platinotype prints in which the face is very slightly tinted with water colour—that the colouring remains practically unaltered, whereas in some bromide prints (untinted plain platino-matt prints) the colouring rapidly fades away—only the colouring the print does not change at all. I have been wondering if there is any special reason for this—chemical action, for instance—to account for the fading. The colours used are Rowney's—rose madder, with perhaps the merest trace of scarlet, vermilion or raw sienna, and only a faint wash of colour is put on the face. Would some of the aniline dye liquid paints be more suitable for this work?—TINTING.

[We cannot account for the fading. Clearly it is not the fault of the water colours, as they do not change on the platinotypes. It may be possible that some trace of hypo in the silver prints has caused the change. Aniline dyes, as a rule, are not so stable as ordinary water colours when long exposed to light.—Eds. "B.J."]

A CAUTION TO ASSISTANTS.

To the Editors.

Gentlemen,—Through the medium of your paper I would like to give a few words of advice to any young assistant who might be tempted to leave (for higher wages) the ranks of the high-class photographer for those of the quick-trade, postcard, and cheap enlargement firms. In my own case I was properly apprenticed to a high-class photographer of old and good standing. I served my apprenticeship and studied at the local school of art, and was sent into photography, on good advice, to gain experience in the methods employed by other firms. I went my round, learning all I possibly could, and at last reached the rank of operator with a very good firm indeed, and in this capacity I was successful.

Then came my downfall. I accepted a position in a quick, rushing, cheap business at a salary much larger, although mostly built up of commission. I do not complain of the work, for any man who understands his trade can work under difficulties and different conditions. I had a run of prosperity, from a financial point of view, quite remarkable. I stayed there three years.

The point I wish to emphasise is the extreme difficulty in again obtaining employment with a high-class firm after having served three years with a low-class firm. I have made applications for employment repeatedly for four months, giving the latter firm as reference, which I think I am bound in honesty to do, and have received replies to about 1 per cent. of my letters. My work is just as good as it was three years ago, but I suppose my late experience and the fact of stooping to price-cutting, etc., is suffi-

cient to put the glass stopper in the bottle so tightly that nothing but a hammer will remove it.

If you think this advice is worth giving to any young assistant who is tempted to do likewise, perhaps the publication of this letter will have its good effect and prevent him wasting the best years of his life in the greatest of crimes—unemployment.—Yours, etc.,

OUT OF WORK.

Thursday, September 9.

REMOVING PRINTS FROM MOUNTS.

To the Editors.

Gentlemen,—A simple method of doing the above is to place on print a piece of blotting (fluffless side towards print) the same size, and damp it well. Leave it soaking until print readily comes away. Time from $\frac{1}{2}$ to $1\frac{1}{2}$ hours. No damage to mount. Not possible, of course, for dry-mounted prints.—Yours truly, F. NEWELL.
Manningtree, Essex.

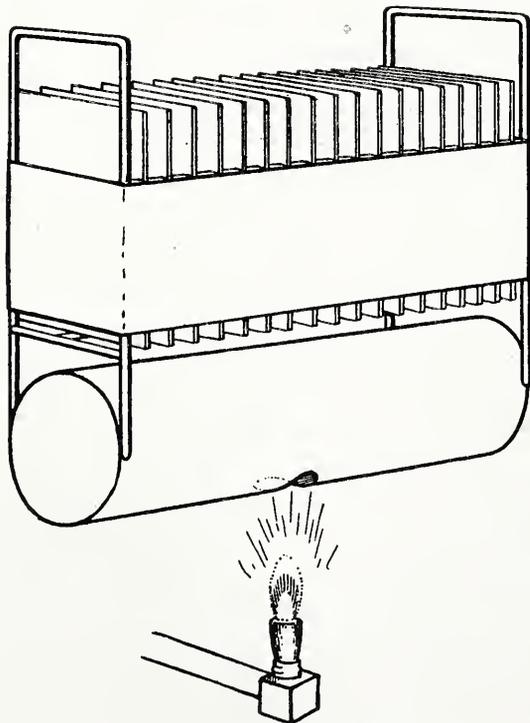

TWO HINTS ON PROOFING AND DRYING NEGATIVES QUICKLY.

To the Editors.

Gentlemen,—As the busy season is now coming with a failing supply of light and every one's aim is to get out pleasing proofs, combined with a minimum waste of time, the following may be of interest, especially as regards un-retouched proofs.

The enclosed for your inspection are proofs printed by good daylight ($\frac{1}{2}$ hour), and the same printed by enclosed arc in 20-30 seconds. Not only is considerable time saved in printing, but the better quality of the results by the arc is indisputable, and though purposely a contrasty negative was selected, it is much better than the daylight one, and, therefore, better order getter.

I find I am always enabled by electric light to get anything up to 20-30 negatives proofed next day to setting—even with a little retouching—and the distance from light modifies the contrast obtained, which is the great help.

At this damp season, a good way to ensure your negatives being dry and ready by the first thing in the morning following development, is to hang on wall a wire negative rack to hold 24 negatives about a foot above a gas bracket, and between the two suspend from the rack horizontally an empty platinum tin with cover on and a hole about the size of a penny, cut in the middle of the under side just over the burner. By leaving a very small jet of gas burning all night under the hole, it forms a hot-air chamber, and distributes heat equally the length of rack. Of course, negatives must be wiped surface-dry with a chamois leather, as any spots of water left on would show.

If centre of tin above the hole heats quicker than ends, a small flat piece of tin slipped in over the hole compensates and distributes

it better; one can soon regulate height of the burner to know greatest heat that can be safely used, and also the time wanted to dry.—Yours truly,

GORDON CHASE.

1, Prince's Avenue, Muswell Hill, London, N.

COMPARISON AND MEASUREMENT OF DENSITY AND CONTRAST.

To the Editors.

Gentlemen,—Professor Bryan's article on the "Comparison and Measurement of Density and Contrast" in "The British Journal of Photography" for September 17 leads me to write to you to point out what seems to me a somewhat serious error, and one which is very likely to increase the already considerable confusion existing on the subject of the increase of exposure produced by filters.

On page 725 Professor Bryan explains Beer's Law, and states that if a film transmits one-third of the light falling on it, then its "density factor" will be called three. This term is very unfortunate, because well accepted definitions of the constants of Beer's Law for photographic plates have already been given by Messrs. Hurter and Driffield. If a film transmits one-third of the light, they define its "transparency" as one-third, and the reciprocal of this, three, they term its "opacity." The logarithm of the "opacity" they term "density." Messrs. Hurter and Driffield's "densities" are therefore Professor Bryan's index numbers if the logarithms be taken to base two. As a matter of fact, it is customary in photographic work to take the logarithms to base ten. Anyone who is accustomed to ordinary photographic practice would therefore imagine the "density factor" to be the logarithm of the quantity which is intended, and I would suggest that in future he should call this quantity the "opacity," conforming to standard practice.

But this question of nomenclature is unimportant compared with the second paragraph on page 726, where he applies Beer's Law, which only applies to homogeneous light, to heterogeneous light with selective filters. If a given filter has a perfectly sharp absorption, and does not absorb any of the colour which it is supposed to transmit, then two such filters will transmit as much light as one, and the use of the two filters instead of one will not alter the multiplying factor of the filter. This can be seen if a sharp-cut red filter be examined. If several of these be put over one another, it will be found that the brightness is very little diminished. In order that two filters having opacities of x and y shall, when placed together, have an opacity xy , their spectral absorption throughout the region considered must be uniform.

For filters for orthochromatic work it is not desirable to have a perfectly sharp-cut filter, and, as a general rule, I should expect that if satisfactory three and five times filters were used together, they would increase the exposure seven to eight times on ordinary orthochromatic plates. On panchromatic plates they would probably increase exposure only about $5\frac{1}{2}$ times, even although they were filters deep enough to be three and five times on panchromatic plates.

I must apologise for questioning Professor Bryan's paper in this manner, but I would suggest that the way in which the paragraph is worded might lead readers to suppose that Beer's Law is universally applicable to heterogeneous light, and this note in the correspondence columns of "The British Journal of Photography" may assist in removing such misapprehensions.—I remain, yours truly

C. E. KENNETH MEES.

To the Editors.

Gentlemen,—The article by Prof. Bryan in the current issue of the "B.J." contains a paragraph on the effect of combining two "orthochromatic screens" of three and five times multiplying value respectively when used separately; and the conclusion is drawn that a combination of the two results in a "fifteen times screen." Perhaps I may be allowed to draw Prof. Bryan's attention to an oversight which has led him to make this erroneous statement.

The statement would be perfectly correct if an "orthochromatic screen" absorbed light uniformly throughout the spectrum instead of acting selectively on the blue and violet almost entirely. The description "three-times, five-times," etc., applies strictly only to combination of screen and plate considered together, the better colour-corrected the plate the lower the multiplying factor of given yellow screen on exposures made through it.

Further, it is quite impossible to say what is the multiplying factor of a combination of two such filters, except with a given plate, and as the result of experiment, and it is possible for

three-times and a five-times screen to combine to give a filter of value multiplying greater than five and less than fifteen times, according to the degree of colour correction of the plate under consideration.

Suppose, for instance, that the total light acting per second on a plate when no screen is used be 15 C.M.S. (actinic), and suppose this total 2 C.M.S. are green light which is not damped down by screens, and 13 cms. are blue-violet which is partly absorbed them. Then we get:—

	Green. C.M.S.	Blue. C.M.S.	Total.
With no screen	2	13	15
With "three-times" screen...	2	3	5
With "five-times" screen ...	2	1	3

It is obvious that the transparency, or proportion of the incident light transmitted, of the three-times screen to blue light is 3-13, that of the five-times screen is 1-13. The two combined will therefore transmit only 1-13 by 3-13, or 3-169 of the incident 13 C.M.S., or 3-13 C.M.S., and, as the green is undiminished, the total transmitted becomes 2 3-13 C.M.S., and the multiplying factor of the combined screens becomes 15 ÷ 2 3-13 = 6½ nearly.

Taking a different ratio of blue sensitiveness for the plate—say, 1:—the combined three-times and five-times screen for this plate will give a thirteen-times screen, and so on.

In conclusion, it may be useful to call attention to the fact that at Prof. Bryan calls the "density factor" of an image is the "opacity" (O) of Hurter and Driffield, and the "index number" proportional to H. and D.'s "density" (D), the only difference being that in the H. and D. notation 1 is the "density" corresponding to opacity 10, 2 to 100, 3 to 1,000, etc., instead of "indexes" 2, and 3 corresponding to "density factors" 2, 4, and 8 respectively.

Seeing that the H. and D. notation possesses the merit of giving a simple relation between "O" and "D" by the equation O=D, the notation suggested by Prof. Bryan appears to me to be less convenient than that in use.—Yours faithfully,

F. F. RENWICK, A.C.G.I.

Orland House, Avenue Road, Brentwood,
September 18, 1909.

Professor Bryan, to whom was submitted the above letters, writes as follows:—

Gentlemen,—I am greatly indebted to Dr. Kenneth Mees for his valuable and important corrections. But I would like to call attention to the difficulty I have experienced in finding any references in literature dealing with such matters as opacity, density, and contrast; I have consulted handbooks by the score, only to find the same instructions repeated over and over again as to timing exposure and development, compounding various developers and intensifiers, and adding bromide. In such handbooks the terms "opacity" and "contrast" are used in a vague and ill-defined way, and the terms which Dr. Kenneth Mees describes as "well accepted" are conspicuous by their absence. On the other hand, the more scientific literature which I have seen has mainly been devoted to technical theories, discussions relating to the latent image, and other matters of theoretical interest, covering very different ground. Yet if positives are to be made in numbers by anything but a printing-out process, it seems to me that some knowledge regarding opacity, density, and contrast should be made easily accessible to the ordinary amateur. Dr. Mees has now kindly furnished me with references, but others may be in the same difficulty.

I quite agree that uniformity of nomenclature is of very great importance. But, unfortunately, the popular handbooks above referred to always speak of the density of negatives, whereas it will be found that what they mean is almost invariably the opacity of the H. and D. notation. I do not see how you can get over this difficulty. If it were suggested to replace H and D's "density" by "thickness" that would remove the ambiguity, which is also overcome by adding the word "index." "Opacity" I certainly prefer to "density factor."

As regards the choice of a base in taking logarithms, I do not consider ordinary mathematical text-books, as a rule, sufficiently emphasise the fact that logarithms to different bases only differ in their scale or unit of measurement.

If the base is ten, the unit of density is a film which transmits one-tenth of the light falling on it; if the base is two, the unit is one which transmits one-half of the light. The difference between the scales is exactly analogous to the difference between measuring lengths in feet and measuring them in metres, and densities can be changed from base 2 to base 10 by multiplying by 30103, or from base 10 to base 2 by dividing by that number, just as metres are changed to feet, or vice versa by multiplying or dividing by 3.2809.

But as regards the advantages of the base 2 in calculating ordinary photographic exposures, as suggested in my previous paper on "The Index Method," my subsequent experience has shown that this method effects a great saving of time and trouble over the ordinary exposure tables and calculators. After a very little practice, the necessary indices will be remembered, and the calculations can then be performed in the time that would otherwise be occupied in fumbling in one's pocket for the calculator.

I quite admit that the reference to colour-screens in my paper was somewhat unfortunate. Of course, I knew that Beer's Law would only apply, strictly speaking, to individual colours; so that if a screen were to transmit one-half of the light of one colour, and one-third of that of another, two such screens would transmit one-quarter of the former and one-ninth of the latter light. But a more detailed discussion appeared out of place, and it would probably have been better to omit the subject altogether.

In comparing the opacities of different negatives, it is, of course, desirable to avoid comparing negatives which differ widely in colour. With negatives of the same colour it is easy to enlarge two small negatives on to one large sheet of paper even where widely different exposures are required for them. This, of course, requires that the two enlargements shall be fully developed simultaneously.—I remain, yours truly,

G. H. BRYAN.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- Marianne E. A. Powles, 40, Sussex Gardens, Hyde Park, London, W. Photograph of a Street in Chartres with Spires of Cathedral in the Background.
- E. A. Kime, 116, St. James' Street, Newport, Isle of Wight. Photograph of Interior of Saint Mark's Church, Wootton Bridge, Isle of Wight.
- J. P. Millar, S. West Bridge Street, Falkirk, Scotland. Photograph of Falkirk Football Club Players for Season 1909-1910.
- F. Fitch, Belmont, Harlesden Road, St. Albans, Herts. Photograph of St. Albans City Football Team, First Eleven.

SCOT and others.—In our next.

SYDNEY A. CARR.—1. Certainly the same allowance should be made in exposing Autochromes as in using ordinary plates. 2. We have read your letter of the 17th. but we are unable to discover any sufficient reason for the differences.

STAINED PRINT.—Will you kindly tell me the cause of the stains on the enclosed postcard? I printed a small batch, washed them for ten minutes in running water, put them to tone in a dish which I keep for toning only, kept them moving, and towards the end of the toning the marks appeared. The enclosed is the only one of the batch that is stained. Apart from the stain, do you consider the card a passable one?—J. E. GUBBINS.

The stains are due to something coming into contact with the print while it was being washed, or maybe while in the toning-bath. A splash of hypo solution or one of developer would cause similar stains. The print, but for the stains, is fairly good.

J. B.—Apart from the many articles in our own and our contemporaries' pages, we can only refer you to No. 98 of the "Photo-Miniature" (6d.) from your dealer.

ZINC POWDER.—Kindly let me know where I can get zinc dust from for throwing down silver in old hypo bath, and how much would you advise to use per gallon?—H. SLAECK.

Powdered zinc is supplied by all wholesale chemists, such as Hopkin and Williams, Cross Street, Hatton Garden. Cuttings of zinc, which may be had from any zinc-worker, will serve the purpose, though they take longer time. The necessary quantity to use cannot be given, as it necessarily depends upon the amount of silver in the solution to be reduced.

RECOVERY OF PAYMENT.—Can you let me know what I ought to do? I took a group which I copyrighted, and was asked by the representative of a certain paper to let him see a picture as soon as possible. I submitted a copy to him and told him I wanted half a guinea if he accepted same. He thought the price I was asking was too much, but said he would see his superior about it and let me know the same day. He has not written me as promised, but I find he has reproduced my picture in his paper. I have sent an account in for the half-guinea, but have received no reply.—COPYRIGHT.

The matter is simple enough. Make formal application for the money, and if it is not paid sue for the half-guinea in the county court.

M. J. C.—You ask no definite questions, but we presume you wish to know the causes of the spots which appear on the two sulphidated prints you enclose. It is impossible to say definitely the cause of the trouble, but in the case of the white spots a probable cause is hypo dust on the print. The black marks look like ink stains, produced by the conjunction of developer splashes with the bleaching solution. In the total absence of any particulars of treatment we cannot make any other suggestions. The formulæ you give are quite ordinary, and there is nothing in them to account for the spots. The fault is evidently one of manipulation.

C.C. PAPER.—Will you kindly give me a little information on the following in this week's "B.J."? (1) What is the best formula for toning C.C. paper to procure the best possible rich, warm tone? (2) What is the best method by which the same can be glazed without fear of sticking?—H. S. B.

(1) The best results are got by first toning in a good bath and then in one of platinum. We expect the makers of the paper you are using give formulæ for these, and you cannot do better than use these latter. (2) The method is that given under P.O.P. on p. 804 of the "Almanac."

INTENSIFIER.—Would you kindly let me know, through the medium of the "Journal," what is the formula for intensifying negatives? It is composed of mercury bichloride, potassium iodide, but I forget the exact proportion.—INQUIRER.

The formula is as follows:—

Mercuric chloride	50 grs.
Water	10 ozs.

Add 10 per cent. potass. iodide solution until precipitate first formed is redissolved. About 1½ ozs. will be required, and when clear add—

Sodium sulphite	4 ozs.
Water to make	20 ozs.

COVERS FOR VIEWS.—Do you happen to know of a firm or place where I could get the cardboard covers for collotype prints such as you see on sale at seaside places? I have seen exact imitations of herrings and fishes on opening. The collotype views are enclosed. I have seen a lot of different kinds, such as soldiers' kit-bags, with views inside. I am anxious to get some done to a design of my own and put my own views in. So would be obliged if you could tell me where I could get the covers.—INQUIRER.

As you will supply your own design, we have no doubt that any mount-maker will supply the mounts. See under "Mounts" in the "Almanac" directory of goods advertised.

STUDIO.—Messrs. Winsor and Newton, Rathbone Place, Oxford Street, are agents for the pencils.

NEGATIVES BROKEN IN TRANSIT.—I have had several valuable negatives broken in transit by the railway company, several of

which I cannot replace. They were well packed in box and carriage paid at glass rate, labelled in large type "Glass." Can I claim compensation from the railway company, as this is the second batch broken to pieces this year? What do you consider a fair price each as compensation, and should I employ a solicitor to get it through for me?—FIFTEEN YEARS PROFESSIONAL

We are afraid you will have some difficulty now in obtaining any compensation, as so long a time has elapsed. The claim should have been made at once when the parcel was opened and the contents found damaged. It would have been better had the parcel been opened in the presence of the man who delivered it. We cannot give any idea as to what you should claim, inasmuch as we do not know anything of the value of the negatives—their size or the subjects. We should think that it would not be worth while to employ a solicitor.

ACETYLENE.—We think you would find the same difficulty with the four-burner acetylene lamp, but we must confess to having seen very little of acetylene for portrait purposes. You would do well, we think, to write Messrs. R. J. Moss, 98/99, Snow Hill, Birmingham.

RIGHT TO EXHIBIT.—I shall be glad if you will be good enough to give me your opinion on the following:—I opened my present business at the beginning of the year. Two months ago I took a group of two little girls, the daughters of a well-known gentleman in the district. As the children are very pretty and made a good picture I had it enlarged and highly finished for a specimen for the window, and it proved very attractive. A few days ago the father came, and in a peremptory way ordered me to take the picture out of the window at once and not show it again, saying, "How dare I make such a use of his daughters' portraits, etc." As the picture has cost me a lot I offered to sell him it at a much reduced price, and I thought that was fair, but he refused in a very indignant way, and said that if the picture was removed at once he should instruct his solicitor to take legal proceedings against me. Will you please tell me if he can do so?—B. J. W.

Yes, certainly he can, and if he does you may find yourself involved in heavy law costs. You have taken an unwarrantable liberty with the customer's portraits without first obtaining consent. As you seem to be quite a beginner in the business we can tell you that it is a very unwise thing to do anything that will give offence to customers, more particularly in a country district like yours.

LENS QUERY.—I have just bought, secondhand, a lens, bearing the name of Voigtlander. It is about 3¼ in. across and about 8½ in. thick when focussed on the sun. It gives a very sharp image on a ground glass, but I cannot get with it a sharp negative. I thought at first that the camera might be wrong, but that is all right. The lens, by the appearance of the brass work, is a very old one.—A. J.

It is clear that the lens has a chemical focus, as all the early lenses of that maker had. If you examine the sliding ring you will probably notice some small engraved marks on it. They are to show the distance the lens has to be racked out, after focussing, to obtain a sharp negative.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

THE BRITISH JOURNAL ALMANAC. One clear week still remains before the advertisement pages of the "Almanac" are finally closed. Orders, etc., should reach the publishers on or before Friday, the 15th inst.

As much common-sense advice on photographers' advertising as can reasonably be compressed into a single article is contained in that by Mr. C. H. Claudy from the "Photo-Era." (P. 781.)

The latest victims discovered by the "free enlargement" canvasser are persons letting furnished apartments. The canvasser presents himself as about to introduce a lodger, and on this basis gains an order for a frame. (P. 773.)

Steps are being taken in Germany to put a spoke in the wheel of the cheap photographer, but the difficult factor in the case is the photographic business done at ridiculous prices by large stores as a species of advertisement. (P. 774.)

Mr. Harold Hood, in an article on commercial flashlight photography, gives a number of quite necessary cautions as to the use of home-prepared flashlight powders. The article (page 776) contains also a number of useful hints.

A formula of service in providing negatives with a cheap and easily applied protective coating is given in an article by Mr. E. M. Stretthorpe. (P. 778.)

Mr. Harold Baker, in a paper in the current issue of "Photographic Scraps," lays stress on the conditions, other than those of toning process proper, in securing consistently good results in the development of sepia prints by the sulphide method. (P. 784.)

It is with the very greatest regret that we record the tragic death of our friend and contributor, Mr. Douglas Carnegie. (P. 785.)

We call attention in an editorial note to the usefulness of the thio-bamide reducer for the removal of stains caused by chromium sensitification or other process. (P. 774.)

Professor Namias, in a paper on the keeping qualities of sulphite of soda in presence of the substances most commonly used in developers, has arrived at conclusions which in some instances are in agreement with those of other experimenters, particularly in respect to sulphite mixed with caustic alkalis. The full text of the paper is given on page 779, and some editorial comments upon it on page 775.

Under "Photo-Mechanical Notes" an abstract is given of a further report of Mr. Arthur Payne respecting the "Paynetype" process of photo-engraving direct in the camera. (P. 785.)

A process of making colour screen-plates figures under "Patent Processes." (P. 786.)

EX CATHEDRA.

Still Another "Free" Enlargement Dodge.

Only a fortnight ago we commented on the shifts to which a canvasser of so-called "free" portraits was put to introduce his spurious business. The two gentlemen then referred to are now undergoing a term of six months' hard labour for making illegal use of the name of Messrs. Lever Bros. We now read in a recent issue of the "Daily News" of still another dodge of the canvasser to allay the suggestion of fraud which, unfortunately, is inspired by the mention of the phrase "enlarged portrait." "The man of enlargements is attracted by the card displayed in the window, 'Furnished Apartments.' He represents himself as being connected with a large firm of photographers, who combine the enlarging of photographs with a lodgers' agency. He looks at the rooms, is charmed with them, says he thinks the lady is not charging enough, and that he has two young men connected with a City banking firm that they will suit exactly. With regard to the enlargement, all he asks is that the firm shall be advertised in both its branches. He turns up in a few days with the enlargement, says the young men are coming, mentions the date of their arrival, and produces his samples of frames. What could she do but give the order for a frame? The price to be half a guinea. In the case known to me the lady had insisted at the outset that she must not be put to any expense in the matter of the enlargement—her finances, she explained, were very low, and, besides, she was having it done only to oblige him. Of course, the young men have never been heard of since. In this way the lady, poor and perplexed almost to desperation, was made to buy what she did not want, and chances of letting the rooms probably lost. For, on the completion of arrangements, the card was removed from the window."

The Polytechnic Classes.

The lecture inaugurating the commencement of the winter session of the Photographic School at the Regent Street Polytechnic will be delivered by Mr. Howard Farmer on Thursday evening next, October 14, at eight o'clock. The subject being "Among the Flying Men," with cinematograph and lantern illustrations. Following the custom of recent years, the teaching staff of the school will be present after the lecture, and will be glad to give intending students information or advice. We may direct the attention of assistants to the opportunities for perfecting themselves in their work and for acquiring a knowledge of other branches which are afforded by the series of classes conducted by Messrs. C. H. Hewitt, C. David Kay, Albert J. Lydden, Wolfgang Arndt, and others equally well qualified by their own professional experience to impart commercially valuable knowledge, which is often a very different thing

from the methods a worker may pick up by self-study. The school is open all day and in the evenings, and the full prospectus, obtainable from the Director of Education, the Polytechnic, Regent Street, London, W., will show the wide range of the instruction provided.

* * *

Cork Metal. A metallic mixture having been suggested under the name of "cork metal" as a suitable material for aeroplane construction, a writer in the current issue of the "Chemical News" has been prompted to make an analysis of the material, which turns out to consist chiefly of magnesium. This metal accounts for 99½ per cent., the remaining two-thirds per cent. being composed of zinc, with minute quantities of sodium and aluminium. The alloy is said to be 40 per cent. lighter than aluminium. In appearance it resembles magnalium, whilst its tensile strength cannot be much, if any, better than that of magnesium itself. Apart from the question of cost, "cork metal" would not be likely to prove of any value for the construction of metal cameras, even in the hands of a maker who was prepared to go to extremes in catering for the present craze for the *ne plus ultra* in the lightness of cameras.

* * *

Stains in Chromium Intensification. We have often had complaints of stains produced in the re-development process which completes the operation of chromium intensification, and from time to time we have drawn attention to various causes. Of late, we have been greatly troubled with stains due to the use of a different kind of developer to that which we ordinarily employ. The new developer worked excellently when quite freshly mixed, but when it had been in use for a little time it had the trick of producing brilliant yellow stains that for a long time resisted all attempts at cleansing. Finally, however, we tried the thiocarbamide clearing solution given in the "Almanac," and found that in double strength—2 per cent. thiocarbamide and 2 per cent. citric acid—it removed the stains very rapidly and thoroughly. This very useful clearer is one that deserves to be more generally used. Though the thiocarbamide is rather expensive to buy, yet it is cheap in use, as very little is required to make the bath, and this can be used over and over again. Apparently there is little, if any, effect on the intensification if the bath is no stronger than we have suggested, but a very strong bath does tend to show a reducing effect. If sulphuric acid is substituted for the citric acid a fairly powerful reducer is produced, but we have found that it is in practice a risky one to use, as it is very liable to produce a new kind of stain on its own account. No trouble of this kind has been met with in the case of the citric acid and thiocarbamide clearer, which is the solution we advise.

A German Scheme to Boycott the Cheap-jack. At various times we have called attention to the strenuous efforts photographers in Germany are making to protect their interests, and at the same time restore the profession to a better condition. The Dealers' and Manufacturers' Union, which is the main-spring of the protection organisation, has just held its twenty-first annual meeting at Dresden, passing various resolutions for the conducting of an energetic campaign against under-sellers. Within the last few years the photographic profession in Germany has run riot. All sorts and conditions of men have opened studios and are supplying the public with portraits at starvation prices. Some of them charge only 1 mark 50 pfennigs (a shilling

and sixpence) for a dozen C.D.V.s, and little more than double for a dozen cabinets. What the dealers and manufacturers propose to do in order to put an end to this is to refuse supplying these under-sellers with plates and paper. Exactly how they are going to carry on the propaganda is not altogether clear. So far they have contented themselves with a few threats without doing much. However, the Union is confident, and it will doubtless be interesting to see what progress it makes. There is more than a possibility that as soon as the manufacturers and dealers refuse to serve the low-priced man, other manufacturers will spring up to supply his wants, taking much of the trade out of its present channels without materially bettering the present situation. But this phase of the subject sinks into insignificance compared with the formidable rivalry with which the Union has to contend in the increasing number of large general stores which treat photography as a means of advertising themselves. Because of this they are turning out store photographs at a price which in all conscience "defies competition." It is these places which have done more than the cheap and nasty man to ruin the legitimate professional photographer. Their reply to the threats of the Union is that they may boycott them if they will; in which case they are prepared to manufacture their own plates and paper, for their own use and also for the large amateur trade over which they have command. Hence they are entirely independent, being practically the masters of the situation, and unless the Union can persuade them to come to some reasonable terms the likelihood is that they will continue on their own way, cheapening and helping to ruin the profession. And behind them the cheap-jack who can hold their own, can afford to laugh at an attempt to boycott them.

* * *

The Royal Society of British Artists.

The present exhibition of this Society perhaps above the average as far as oil paintings are concerned. A few of the works are of great merit, noticeable the fine and impressive "Wild Cornish Coast" (67), Alfred East. The President's other two works do not go beyond the limits of clever sketching. His portrait of Philip Laszlo is a telling, if rather matter-of-fact, piece of work, and the talented portraitist is seen to great advantage in his amazingly clever and altogether charming portrait of a little boy, called "My Son Stephen" (33). It is many a year since a child's portrait has been given with such a sensitive appreciation of childhood's characteristic such power, such reticence, and such masterly style. In a great many of the pictures show lack of originality both in motive and treatment, but perhaps this is not to be wondered at in a society that is still in the sloughing state. There is much in the way of old-time banalities that remains to be shaken off. The water-colours would be disappointing but for one or two well-known men, whose works redeem the collection. Amongst these are the rich and harmonious pastel interiors by Frank H. Swinstone, who finds good material in agricultural outbuildings.

* * *

The Beauties of the Technical Section.

A writer in the "Art and Artists" column of the "Globe" hopes that the exhibitors in the Pictorial section of the New Gallery will pardon him for saying that the most interesting display is not in the large room, which they are privileged to fill, but in the "humble balcony" where the scientific and technical exhibits are stowed away. These represent "but a fractional part of what photography is doing in unfolding the marvels of creation, but even that fraction is surpassing wonder." We doubt if all the pictorial

will forgive an art writer for such a statement, but it is in any case one that we have heard a good many times of late. After studying a fine photograph of, say, a nebula, which is beyond all question a thing of surpassing beauty, most people feel with the writer we have quoted that "the ordinary photographer fails to attract." The pictorial photographer may look upon this as heresy and treat it with scorn, but he would be far wiser to consider the matter calmly and endeavour to find out the reason for it. There is plenty of fascinating beauty in nature outside nebulae, but how is it that it appears in the nebula photograph and is missed in the pictorial efforts? May we suggest that in most cases it is because the latter remind us too much of the photographer and too little of nature? The nebula-photographs show more nearly the ideal impersonal quality that every artist strives for. They are beautiful things quite regardless of who happened to be the maker of them; indeed, if they are technically perfect, we can forget that they are photographs at all, and can imagine that we are studying nature itself.

SULPHITE OF SODA.

THE paper by Prof. Namias on the alteration of sulphite in solution, which we print on another page, is of considerable interest, as it deals with the behaviour of sulphite and soda in very varied conditions. It does not exhaust the subject by any means; but still, it contains a good deal of information of practical use. There is, however, one point that seems to require a little further consideration, and the conclusion arrived at is quite contrary to general experience. It is stated that the addition of acid sulphite affords no notable advantage in the way of preservation of the sulphite, yet such an addition is perhaps one of the most effective methods of preserving sulphite in common use. The deterioration of the sulphite in the presence of carbonate has, of course, been noted before, and it is rather important to remember that carbonate is always present in the so-called "pure" sulphite used by photographers. Strangely enough, this fact is often overlooked by experimenters, or at any rate it is not mentioned in their writings, so there is always an element of doubt as to whether it has been taken into consideration by them. Pure sulphite, free from carbonate, can, no doubt, be produced in the laboratory, but this is not the kind ordinarily used, hence experiments based upon its behaviour are apt to be misleading. It may, perhaps, be assumed that the preserving effect of an acid sulphite depends on the neutralising of the carbonate always present; but this idea requires confirmation by actual experiment. As a rule, much more is used than is necessary merely to neutralise the carbonate, and the resulting mixture keeps much better than a pure sulphite simply free from carbonate can be expected to do.

Precisely why carbonate assists the oxidation of the sulphite is a mystery. Analysis, however, shows that as the sulphite diminishes so also does the carbonate, so there is little doubt that reactions of some sort take place, either between the two, or more probably between the carbonate and some of the decomposition products of the sulphite. A sample of ordinary pure sulphite will usually contain from $1\frac{1}{2}$ to 3 per cent. of carbonate when the solution is quite fresh. When the sulphite has completely gone it will generally be found that the whole of this carbonate has changed to an equivalent quantity of bicarbonate, which suggests inter-action with an acid decomposition product. If, however, this inter-action helps to accelerate decomposition, we should expect soda hydrate to be quite effective, if not more so, than the carbonate, whereas

according to Professor Namias it is less so. From past experience, we think there is some uncertainty with regard to the action of the hydrate. We have known, and recorded in these pages, cases in which mixtures of sulphite and hydrates have deteriorated with extraordinary rapidity; on the other hand, we have also noted cases in which the solutions seemed to last remarkably well even when carbonated alkalis were present.

We fear the truth of the matter is that we know very little indeed about either the causes or the manner of deterioration of soda sulphite. No two samples of the salt behave alike, and it often happens that the better the sample seems to be at the start the worse are its keeping qualities. We have known very pure high-priced samples to become useless in a few days, while cheaper and less pure ones have retained their strength remarkably well for weeks, or even months. Professor Namias does not give full particulars of the method according to which he kept his samples, but it certainly seems that in a 5 per cent. solution his samples showed very poor keeping qualities. When we conducted our experiments we used solutions of 1.26 per cent., or just about one-quarter of 5 per cent. We adopted these weak solutions so as to ensure a reasonably rapid change, but even with this degree of dilution, while some of the samples were gone in a fortnight others still retained half their original strength. Six days is a very short period for changes of the extent recorded by Professor Namias. The analysis of sulphite is itself a rather complicated operation, and it is to be feared that some of the results obtained are often incorrect owing to imperfect analysis. It is usually assumed that sulphite and sulphate alone are to be looked for, and if this assumption were correct, then simple titration with iodine should be sufficient. There are, however, other methods beyond the iodine one of determining sulphites, and if we use two methods, checking one against the other, very curious and incongruous results are often arrived at, these results differing with different samples. If, for example, we determine the sulphite by titration with acid, as well as by titration with iodine, it will often be found that the iodine gives the higher reading with fresh solution, while as the solution becomes stale the two readings approach one another, and eventually agree. This phenomenon requires some explanation, for it suggests the presence of substances other than sulphite and sulphate. Some time ago we conducted a series of tests on sulphites over a period of about four months, with very inconclusive results. Only one point seemed evident, and that was that samples which when fresh gave the same reading with both the acid and iodine, as a rule rapidly deteriorated, one dropping from 90 per cent. to 65 per cent. in one day. On the other hand, samples which at first gave the higher iodine reading lasted better, the drop in one instance being from 78 per cent. to 54 per cent. in nine days. This sample when fresh gave a reading of 75 per cent. with the acid test and 78 per cent. with the iodine, and the suggestion is that the difference indicates the presence of some impurity which acts as a preservative. The lowness of both readings is also noteworthy, as it indicates that a high proportion of sulphite in the first instance is not a guarantee of serviceable quality. In fact, the sample that initially gave the highest proportion of sulphite, and was presumably the purest, was the worst in point of keeping quality of any of the samples tested. We may add that the sample giving the low reading mentioned is one of the best known and most serviceable brands on the market, and is very largely used by those who have experienced its good qualities. From the point of view of the practical worker, we are therefore not inclined to attach any special value to samples that show high initial percentages of sulphite.

LARGE FLASHLIGHT WORK: SOME WARNINGS AND LESSONS.

JUDGING by the frequency with which the subject of the application of flashlight work to commercial purposes is referred to in the "Journal," it should not come amiss to add some practical data based on two or three lively experiences of my own. I have, as a rule, the strongest prejudice against using and recommending so-called proprietary mixtures. The success of so many of the made-up developers, for example, seems to be based on the sublime faith placed by a certain sort of amateurs in any developer except those of which they know the composition, and that is the sort of spirit to be deprecated among professional photographers. My prejudice extends also to flashlight mixtures and torches made and sold under fancy names. The origin of my objection is perhaps based on the relatively higher cost of the "patent" flashes compared with those I make myself.

Yet—let me emphasise this important point by a new paragraph—I will say this for the improved powders, such as the "Agfa," "Bayer," or Fuerst's, that their use is vastly to be preferred until the operator becomes so conversant with flashlight procedure that he can with confidence tackle the firing of fairly large charges for comparatively big events. These improved powders differ materially from the chlorate-magnesium one, with which all my larger work, of the type described later herein, had been done, in that they are supplied to work at something less than explosion-speed, and with proportionately greater safety. Indeed, it should be borne in mind that my own experiences here recorded are more intended as a warning than as an example, and I hasten to express my conviction that carefully mixed home-made powders—even chlorate mixtures—fired in extended trains, and never in heaped mass, are next door to fool-proof. But—this is important—a milder and safer mixture than one with chlorate is one composed of three parts nitrate of potassium to two parts of magnesium, and this is strongly to be recommended from satisfactory experience. Because the energy of flash-mixtures appears cumulative—that is, that large charges seem to develop more proportionate force than small ones—the precaution to extend the train longer as the charge grows bigger is worth remembering.

Flashlight work of the lesser magnitude had always some fascination, even in the photographic tooth-cutting days. Yet it was not without some inward excitement that I accepted the invitation of the Committee of the Middlesbrough Musical Festival, 1903, to take a group of the combined orchestra and chorus during the final rehearsal in the Middlesbrough Town Hall. I had undertaken nothing approaching this in magnitude previously, and knew of no handbook on the subject; consequently I judged it best to minimise the chances of personal discredit by rehearsing operations on the night before the event. For my rehearsal I got a few friends to stand about in the main positions on the platform. Twelve ounces of the flash-mixture—simply 8 oz. of dried and pulverised potass chlorate and 4 oz. powdered magnesium, brought in separate bags, and mixed with cardboard spatulas at the hall—were placed in a specially made dish, rather like a big dripping tin. This tin was placed at the front and the extreme right of the highest gallery, which projects perhaps one-third into the main hall. The camera, 15 x 12, with Cooke lens, stopped to $f/8$, was placed in the front of the balcony (or lower gallery), slightly to left of its centre.

From subsequent observations, it had seemed inexplicable why the explosive force of this 12 oz. of mixture should seem so much milder than one-half or one-quarter the amount fired in other places. The explanation seems to be that it depends

not only on the charge, but also on the size of the building and the degree to which it may be sealed up by closed doors and windows. The state of the powder, too, is of importance. In one notable instance, to which I will refer later—in which a large group was taken by flashlight in a glass-roofed "Winter Garden"—I carefully dried the chlorate, before mixing, over a stove, and it had probably barely cooled before using. The results of that comparatively small charge are detailed further on, and will probably influence readers to pulverise gently but not to warm the chlorate of potassium.

The powder was piled in a loose cone-mound in the large dish which rested on a thick board on the broad gallery ledge. The charge was fired by the rather crude way of a taper, whose brass holder was fitted to the end of a pole about 15 feet long. Nothing untoward occurred, except that it was found rather difficult to hit the mound steadily with the taper flame, because of the "wobble" of the too-flexible pole. The powder "went off" with a sharp thud, in a way not easy to describe.

Development of the test exposure was effected by weak pyro-potass, the formula being simply:—

10 per cent. soda sulphite solution	2 oz.
10 per cent. potass. carbonate solution	2 oz.
Pyro, dry	2 grains.

No restrainer was used.

The actual plate used for the test exposure I cannot remember but it was somebody's "special rapid," and I found the image come up in a rather unsatisfactory, weak way, but in the meantime I had obtained some 15 x 12 "Monarchs" from Ilford Ltd., which had only been introduced a little before that time.

That the work was serious enough will be gathered from the fact that Middlesbrough Town Hall is roughly 130 feet long by 60 feet wide and 60 feet high, and the members of chorus and orchestra and those in front of the platform numbered about 375. To minimise the chances of fiasco, I used two of my own cameras, and borrowed a third; and that is a precaution I should very strongly urge on a professional undertaking any such work of public prominence. Any suspicion of failure in connection with such an undertaking is likely to prove a bad advertisement for the photographer; while, on the contrary, actual experience shows that the successful production of a large, reasonably well lighted group is a profit in itself, and an excellent advertisement to boot.

On the proper night, with my battery of cameras, and with arrangements as to position, etc., as before, I stopped to fire, and used exactly double the flash-powder, relying on the much higher H. and D. number of the "Monarch" plates for an increase in detail. I fired the charge personally from the gallery, an alert assistant in the balcony below removing the cap on my shouting in stentorian tones: "Now—please—look at the cameras, not at me!" (I don't know what "stentorian" means precisely, but it seems to explain the quality—a surfluously loud, clear shout.) A moment later I plunged my flaming taper into the large and distinctly formidable heap of grey powder, and—the flame was completely extinguished.

That all the members of the group had not obeyed orders, but must have noticed the light that failed, was shown by the loud titter which followed. As I feared an actinic effect might be felt from the arc lamps, which were burning high up, I called loudly: "Keep quite still, please"—and a very few seconds later successfully fired the charge. The concussion—not to say explosion—which followed was distinctly awe-inspiring and unlooked for, in view of the mild behaviour of the

quantity of the previous night; and the experience goes far to prove what an extremely dangerous element flashlight mixtures might be in the hands of an incautious or indifferent operator. The heat generated in that momentary explosion is remarkable, in that the whole length of taper was instantly consumed throughout within its brass fitting, and the tinning of the dish blasted away clear down to the iron. The finished result of this group, if not a complete success, was nevertheless very satisfactory. Out of the large company not more than two or seven persons had moved seriously between the two attempts at firing, and the arc lamps did not do nearly the work I had expected. The lighting was more natural than usual, and the exposure ample.

The lesson from the miss-fire is that one must "tickle" the powder with the lit taper rather than plunge it in overhead. An improvement in detail is to place a small charge of gunpowder—2 or 3 drachms—beneath and slightly beyond the edge of the flash-powder. But I have other and more important improvements to suggest in due order.

About three years later, I was asked to photograph a big group in the People's Winter Garden in the same town, and gained a little local notoriety by undertaking the work, or rather, by the consequences involved. The Winter Garden is long, rather low, glass-roofed building, perhaps 80 feet by 40 or 50 feet, and I admit a certain amount of reluctance in accepting this job, because of the difficulty of combining a large sufficiently actinic and yet with a minimum of convulsive force.

Yet, as my clients pressed for despatch, I had no choice but to make the best out of the conditions. I used a total of 10 oz. of the same mixture as above spread in a ridge across the bottom of a large enamelled basin. This I fired electrically, in the manner of accomplishing this should be of interest. Part of the flash-mixture was made to overlap a small train of gunpowder, and this in turn intermingled with a tuft of cotton-wool lightly soaked in spirit. I borrowed a powerful induction-coil, of the sort used for mine-firing. This, though very valuable—occupying a case about 6 in. square—gave a quite considerable spark of about $\frac{1}{2}$ in. length with a battery of four ordinary household dry-cells, costing about 1s. 3d. each. For this I simply arranged a crude terminal-board, with the wires connected down to approach each other to within about $\frac{3}{8}$ in. apart. The spiritous cotton-wool, with its "tail" merging into the small pile of gunpowder, was arranged closely about the wire-terminals.

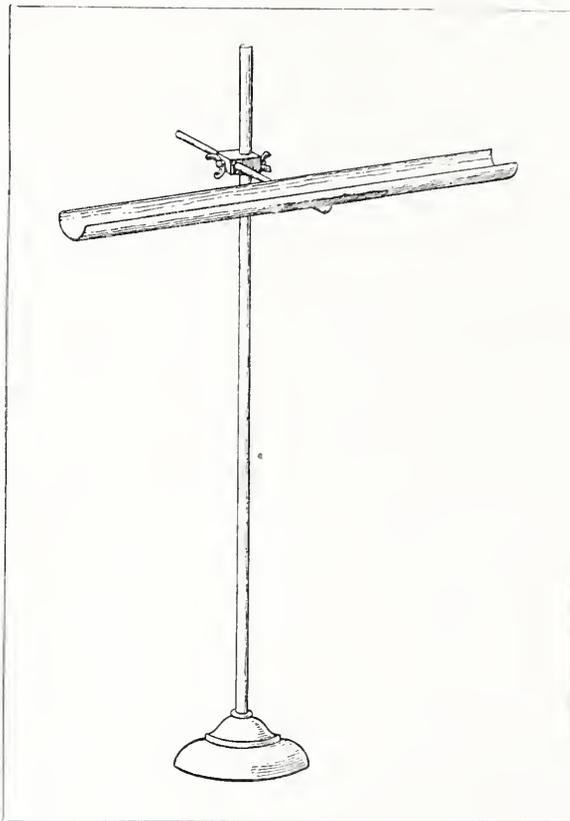

There tends to be a rather uncanny suspicion in the imaginative worker that someone is sure to switch the current on while his head is studiously bent over, arranging the cotton or powder. To minimise that, therefore, the operator must face the switch, and previously forbid anyone to approach within two or three feet of it, in the meantime setting some trustworthy person to act as watch-dog.

In the instance of the Winter Garden photograph all went well up to the firing of the flash—but, after, the effect was decidedly exhilarating. There was a report quite amazing in volume, considering the (comparatively) small charge. No one was hurt, though the crowd had pressed to within uncomfortable range of the charge. The powder basin was absurdly blown out, and the steps on which it had stood were flattened to the ground and completely smashed. An assistant quite twenty feet from the flash who was "managing" one of the cameras, knocked this over, and for a time appeared inextricably mixed up with it. He excused his clumsiness by saying that the concussion knocked him down. That might be true; though I was nearest the centre of trouble—about eight feet from the flash—I felt no inclination to sit down.

It, as showing the vagaries and great force of the explosion, could be recorded that a counter biscuit-case standing near its glass front shattered; a row of crockery, in another room,

the open door into which was about fifteen feet away, was swept clear off the shelf; at the main entrance, two large fanlight windows fifty-five feet away were blown into the street; and within three minutes of the bang I was asked by a police-inspector accompanied by a constable or two—whether I was aware that there were about 3,000 people collected outside in the street—the "Flash" having evidently been heard and seen from a wide distance! Oh, an excellent advertisement, but of the sort one would rather pay to avoid!

I believe this extraordinary contretemps was due to the fact that the powder was heaped too much together, and that there

was no air outlet open except the chimneys (which, by the way, needed no cleaning for some time afterwards). This latter event has its humorous side, but these notes are written with the very serious intention of emphasising in the strongest possible way, and bringing home to photographers, the very real danger, even to life, in the handling of mixtures of which chlorate of potass. forms a part.

All more recent flashlight exposures I have made without the least approach to explosion by firing in trains more or less elongated, the powder being fired in ordinary 5 in. section iron roof-gutters, using the electric spark-firing via cotton-wool and spirit. The gutter is fixed to a fairly robust head-rest stand, and is adjustable, so that either six feet or three feet length may be used at will, by simple screwing or unscrewing. Not only is such an arrangement safer, but the lighting is of better quality. A reflecting sheet may be used with good effect, but the fabric of it should have been soaked in 10 per cent. alum, which minimises the chances of firing.

To sum up:—

There is no such thing as a "safe" flash-powder (the "time" mixtures are excluded, their effect not being a flash proper); real safety lies in the cool, cautious, resourceful operator.

Neither is there a "smokeless" powder; it is always well to point out clearly beforehand that some perfectly harmless white smoke is to be expected, which in confined limits may show a deposit of an equally harmless white powder.

It is always best to use a minimum of powder, the quickest of reliable plates, and the maximum lens aperture the subject will allow. For dinner parties, for instance, the sensible use of the swing-back, or side-swing, may save two-thirds of your powder and a similar proportion of smoke.

Not only be perfectly cool yourself, but see that you employ no assistant whose head is not screwed on the right way. It would be foolish in me to exaggerate flashlight dangers; yet a simple mistake on your helper's part is capable of producing

for you an excellent advertisement, the fruits of which a contingency of a sort might quite prevent your enjoying.

Lastly, and most important: Keep well outside the danger zone of all fabrics, curtains particularly.

In these notes there is no intention of discouraging flashlight work, which, normally, involves but the simplest preparation, and is profitable enough to warrant the attention of capable photographers as an excellent side-line.

HAROLD HOOD, F.R.P.S.

AN AQUEOUS VARNISH FOR NEGATIVES.

VERY many photographers expend a large amount of time and patience on the production of their negatives, and after that seem to care little or nothing about their preservation for the future. They will often go long distances, perhaps to foreign countries, to expose the plates, spend a lot of time on their development, also at times go to a deal of trouble in intensifying or reducing them in order to get the best results. When all this is done they take but little heed as to the future of the negatives, notwithstanding that it may be quite impossible to obtain others of the same subject. Often when the negative is printed from it acquires a stain by contact with damp paper, and sometimes the stains produced in this way cannot be removed without a great deal of trouble. Hence the negative made after so much trouble and labour is irretrievably ruined. Only then is it generally realised that all this might have been avoided had a trifling extra trouble been expended by giving the negative a protective coating of some kind.

A Varnish for Wet Negatives.

In the above remarks I have had amateurs in mind more particularly, but what has been said applies also to many professional photographers, many of whom do not take the trouble to varnish their negatives. This neglect frequently leads to considerable pecuniary loss to them should the negative happen to get stained, and therefore it may be of service to give a method by which negatives may be given a protective coat which can be applied without difficulty, and with practically no trouble at all, while the operation is done while the negative is still wet. It should be said at once that the coating is not equal to a spirit or a celluloid varnish, but it is very much better than none at all. In a word, it is an aqueous solution of shellac. The following is a good formula:—

White lac (freshly bleached)	5 ozs.
Borax	1 oz.
Water	20 ozs.

Sometimes a small proportion of carbonate of soda is recommended, but I much prefer to omit it. The water and the borax are put into an earthen pipkin, or an enamelled iron saucepan, over a gas-burner, and brought to nearly boiling point; by this time the borax will have dissolved. The lac, broken up in small pieces, is then put in and kept stirred until it is all dissolved. Next another pint of water (hot) is added and well mixed. The solution is then allowed to stand till next day. It now requires to be filtered through paper. Before doing that it is well to strain it through fine muslin, as without that being done the solution has a tendency to clog up the filter. The above formula will be about right for most samples of shellac, but some yield rather more viscous solutions than others, so that a little less or more water may be required than that given above.

Flowing on the Varnish.

The varnish is applied as follows:—After the negative has been thoroughly fixed and washed, it is drained for a minute or

so. It is then held in a sloping position, some of the varnish poured along the upper edge, and flowed slowly over the plate in an even wave, carrying what water is on it into the sink. The plate is then slightly drained and a second lot applied in the same way. After that the plate is drained somewhat closely. Finally, a third coating is given, being this time flowed backward and forward for a minute or two so that it can well penetrate into the gelatine film. This lot of the varnish, in economy is a consideration, may be used for the first application of the next negative. The plate is then stood on one corner, on blotting-paper, and allowed to dry spontaneously. Should some of the varnish happen to get on the back of the plate it can easily be wiped off with a damp sponge or a piece of rag while it is still wet. If it is allowed to dry on it is not so easy of removal. An alternative method of using the varnish is to allow the negative, after washing, to get perfectly dry. It is then put to soak in a dish of the varnish for four or five minutes, in which time it will have well permeated the gelatine film. The negative is then drained and reared up on one corner, resting on blotting-paper, and dried spontaneously. Both methods are good; but, on the whole, I rather prefer the former, as in the latter the back of the plate coated as well as the front, and the coating on the back is not always even, so that it has to be cleaned off, when dry, before the negative is printed from.

Recipe books tell us that when the aqueous lac varnish dry it is waterproof. This is quite a fallacy, as may be proved by immersing a negative coated with it in water for a few minutes. If that is done it will be seen that the gelatine film swells up, showing that the lac has been permeated by the water; yet notwithstanding that, the lac is a fairly good protection against mere moisture. It will readily be seen that with the aqueous solution the lac to a great extent has been absorbed in the gelatine, and does not merely rest upon its surface, as it does in the case of a spirit varnish, which does not really enter it at all. The surface given by the aqueous lac varnish is an excellent one for retouching upon without any further preparation, as it takes the pencil readily.

One of the troubles that the inexperienced meet with in varnishing negatives with a spirit varnish is that it does not flow quite freely over the plate, and is apt to run off at the edges and get on the back; there is not the affinity between the spirit varnish and the gelatine film that there is with a collodion film. There is, however, no difficulty whatever in coating the aqueous varnished negative with a spirit varnish. If the plate be slightly warmed—just sufficient to prevent the varnish from chilling—it will be found to take as kindly as the gelatine negative as if it were a collodion one. After the varnish has been drained off, the negative should be held in front of the fire and made as hot as the hand can well bear. In this way, with little trouble, we have our negative well protected against moisture as well as mechanical injury.

E. M. STRETHORP

ON THE ALTERATION OF SULPHITE IN SOLUTION IN PRESENCE OF VARIOUS DEVELOPERS AND OTHER SUBSTANCES.

A Paper read before the Congress of Applied Chemistry held in London.

THE alteration which sulphite of soda undergoes in solution has been the subject of considerable research in the past. Some years ago MM. Lumière and Seyewetz undertook experiments on the change which takes place in both dilute and concentrated solutions of sulphite, and they ascertained the best manner of preserving such solutions. From these experiments it is seen that the concentrated solutions alter to a much less extent than the dilute, and, further, that the addition of a small quantity of a developing substance greatly improves the stability of the sulphite solution.

Further experiments in this direction have been in progress by the writer from, however, a somewhat different point of view than that taken by MM. Lumière, and one which it would appear of greater importance for the purposes of practical photography. These experiments have had for their object the examination of the action of the different substances which are added to developing solutions (such as bisulphite, carbonated and caustic alkalis), as well as the various developers—in each case on the conservation of the sulphite solutions.

I will first state the results of the analyses. The following additions were made to a 5 per cent. solution of crystallised sodium sulphite:—

Caustic soda	1 per cent.
Sodium carbonate	3 per cent.
Potass. metabisulphite	1 per cent.

By making these additions, four test solutions were obtained, each of which was divided into two parts. To one part no addition was made, whilst to the other 1 per cent. of hydroquinone was added. The solutions were left in similar open vessels of about 3 in. diameter, and containing about 100 ccs. The results of the chemical analyses and the keeping qualities of the sulphite solution alone, and with the various additions, are given in Table I.

The quantity of pure sulphurous acid employed in the preparation of the sodium sulphite solution corresponds almost exactly with the calculated quantity in a 5 per cent. solution of crystallised sulphite or in a 5 per cent. solution of sodium sulphite, with addition of 1 per cent. potass. metabisulphite. According to calculation, there should be (if the products used are of absolute purity) 1.27 per cent. sulphur dioxide in a 5 per cent. sodium sulphite solution, and 1.5 per cent. in a 5 per cent. solution of sodium sulphite containing 1 per cent. metabisulphite. The results given in Table I. are the mean of a number of analyses, and the figures may, therefore, be taken as representing the results with considerable accuracy. The following conclusions may be drawn from the figures:—

1. Addition of caustic alkali to sulphite solution restrains the oxidation, whilst addition of carbonated alkali appears to hasten it a little.
2. Addition of a small quantity of bisulphite (at any rate, when the sodium sulphite solution is exposed to the air) affords a notable advantage.
3. In presence of developing substances, and particularly of hydroquinone, the alteration of the sulphite takes place more quickly in a solution containing caustic alkali, whilst the oxidation takes place much more slowly (when hydroquinone is present) in all other cases.

Thus it will be seen from the foregoing that the tendency of the solution to oxidise is reduced by the conjunction in one solution of the sulphite and the developer, but that this is not the case when caustic alkali is present. And this is not

to be ascribed to the action of the alkali on the sulphite, since, as will be seen, the sulphite solution alone is of a greater permanency in presence of caustic alkali.

It has further appeared of importance to examine how the different developers compare in this preserving action upon sulphite, and experiments were therefore made with other substances than hydroquinone, employing for this purpose those which are made up with sulphite and carbonated alkali, since these are the developers in most general use.

These experiments have shown that of the different developers metol and glycin exert the most favourable action as regards reduction of oxidation. It can be said that the oxidation of the developer by the air takes place along with that of the sulphite. Sulphite and developer exerting a mutual action upon each other, it follows that in every case the absence of one causes a more rapid alteration of the other, with the exception of the case already mentioned, when caustic alkali is present.

This preserving action is independent of the reducing energy of the developing substance. It is almost the same in the case of the slow-acting glycin as in that of such a rapid developer as metol. Hydroquinone, which possesses much less energy than metol, acts much more weakly as a preservative of sulphite than metol; and in the case of the solutions containing hydroquinone the oxidising action of the air is much more noticeable as regards the developer than as regards the sulphite: the developing solution becomes dark-brown in colour, although considerable quantities of sulphite were present.

This pronounced tendency of the developer itself to be more easily oxidised than the sulphite is particularly noticeable in the case of the diamidophenol developer, as shown in Table III. In a paper which I have contributed on the influence of boric acid on the diamidophenol developer, there is pointed out the advantage which may be taken of boric acid as a preservative. Nevertheless, it is evident that even when there are still two-thirds or more of the sodium sulphite unaltered, the diamidophenol is so completely oxidised that the bath is useless.

In addition to the developing substances mentioned above, experiments have also been made with pyrogallic acid, in making which difficulties were encountered on account of the strong colour produced on oxidation of the solution, and also the action of the pyrogallic acid upon the iodine employed in determining the proportion of sulphite. The method was therefore adopted of liberating the sulphurous acid under conditions for avoidance of oxidation by means of an acid absorbing it in a solution of standard iodine, and then determining the excess of iodine by means of a standard solution of sodium thiosulphate. In the case of such determination, it appeared that the oxidation of the pyro in presence of sulphate and carbonate took place very quickly. Comparing the results with a metol developer the following was obtained:—

PERCENTAGE OF SULPHUR DIOXIDE AFTER TWO DAYS' STORAGE.
The sulphur dioxide was estimated by liberating the gas as described above.

5 per cent. solution of sodium sulphite containing 3 per cent. sodium carbonate and 5 per cent. metol	1.15 per cent.	Colourless solution.
5 per cent. solution sodium sulphite with 3 per cent. sodium carbonate and 5 per cent. pyro ...	2.26 per cent.	Black solution.

It will thus be seen that in presence of pyro and sodium carbonate, the oxidation of the sulphite took place much more

rapidly, not only in the case of a metal developer, but even in the case of a bath made up of sulphite and carbonate only.

As regards their action on sulphite, the organic developers may be classed in three divisions:—

1. Developers which retard the oxidation of the sulphite and

" 5 " boric acid	1.27	1.20	1.05	Yellow after three days.
" 5 " boric acid and 1 " potass metabi-sulphite...	1.97	1.91	1.78	Yellow after three days, but somewhat less than with boric acid only.

themselves oxidise in the air when the quantity of sulphite is very small. Among these are metol, glycin, and hydroquinone.

2. Developers which, while they retard the oxidation of sulphite, are themselves oxidised with considerably more rapidity than the sulphite in the presence of air. Diamidophenol is a developer of this kind, and therefore may be kept in single solution only for a short time.

3. Developers which hasten the oxidation of sodium sulphite in the air, whilst they themselves suffer only in presence of alkali and sulphite a less rapid oxidation than in presence of alkali alone. Pyrogallic acid is a substance of this kind.

These different qualities of the various developers in regard to sodium sulphite will throw light, it is hoped, upon the behaviour of developing solutions. It may be assumed that as a developing solution acts as a reducing agent of silver-bromide, the sulphite takes an active part in this reduction, or, on the other hand, remains indifferent, according to the kind of developer with which it is combined.

R. NAMIAS.

SOME METHODS FOR THE SURFACE PROTECTION OF METALS.

[The following paper, recently read before the Optical Society by Mr. H. S. Ryland, relates to a branch of practical manufacture of as much importance to the photographic as to the optical trade, and one which is very meagrely treated in books and periodicals.—Eds. "B.J."]

I AM venturing to give this paper, not because of my knowledge of the subject (which is small), but because of our lack of knowledge. The whole matter is one for a technical chemist, but I hope that this brief paper will draw attention to a matter that needs attention—the finish of our work. Of course, the colour of a lacquer or tone of a bronze does not improve the accuracy of a theodolite, but it does improve its selling value.

Further, the subject of surface protection is one that should interest others besides ourselves. When we see rusty girders painted over and used in the construction of skyscrapers, and when we are able to kick a hole through the girder plate of a railway bridge (this is possible in London) we realise that the whole matter is one of importance.

The protection of metal surfaces may be divided into two main types: First, protection against friction; second, against corrosion.

Under the second heading we may place ornamental protection and change of colour for purely ornamental purposes. And the second type may be further subdivided into three further types:—(1) A surface may be protected or ornamented by a coating of material, such as paint, varnish, or lacquer, or (2) by a chemical change of its surface, or (3) by the deposition of some other metal upon its surface.

Protection against corrosion, again, must be divided into two sections:—(1) Where the metal is in contact with the human

skin as in spectacle work, (2) where it is exposed to the atmosphere.

Japanning and Lacquering.

We will deal first with the protection and ornamenting of such surfaces as are used in optical instruments. For this purpose a coat of paint or lacquer is generally used. A paint or japan consists of a solvent such as oil, a medium such as asphaltum or bitumen, and a colouring pigment. It must be applied to a cold surface and subjected to a period of heating to evaporate the solvent and leave the medium and pigment as a thin and more or less even layer upon the surface. A lacquer consists of an easily evaporated solvent, such as alcohol, a medium or shellac (which may be used in conjunction with other gums such as mastic), and either a pigment or stain, such as lamp black or gamboge. Another lacquer is used in which the solvent is amyl acetate, and the medium celluloid.

The shellac lacquer is applied to a hot surface, which immediately evaporates the alcohol and leaves the medium and colouring matter as a thin layer on the surface, while the celluloid lacquer is applied to a cold surface, leaving the medium to evaporate slowly of itself.

Various metals and conditions of service will determine the choice of japan or either type of lacquer. Where the surface has to be rubbed a japan is best, since it is harder and in a thicker layer; but where a surface has only to be protected

against the atmosphere, or blacked to prevent too great a reflection of light, a lacquer is preferable. Whichever is used, it must be hard enough to withstand friction and sufficiently elastic to follow the expansion and contraction of the surface with varying temperatures. Also, the effect of heat on the pieces to be treated must be considered. A piece which has been soft soldered together must not be subjected to too great a heat.

Blackening Metallic Surfaces.

It is often necessary to render a surface black, and a lacquer is unsuitable. A chemical change of surface is then required, termed bronze. The method adopted must depend entirely upon the piece to be blacked and the metal of which it is made. We will take the brasses first. Where heat may be applied, a bronze, consisting of nitric acid, copper, and silver, may be used, but where heat may not be used an ammonia bronze, or a bronze giving a deposit of iron, should be used. If the piece be of steel it may either be coppered first, and then treated with a cold brass bronze, or a sulphur, or phosphoric acid bronze may be used.

In cases where the metal is in contact with the skin, as a spectacle bridge, a deposit, or coating, of an incorrodible metal must be used. Sometimes where an instrument is to be used in extremes of temperature it is absolutely necessary to cover each part which comes into contact with the skin with vulcanite, india-rubber, or leather. The metal absorbs heat more readily than vulcanite, and in very cold climates the loss of heat by the skin may be so rapid as to act almost precisely as if the skin were brought into contact with a very hot surface.

Metal-Surfacing.

For protection against friction, we may either face the wearing surface with a harder metal or, in the case of steel, harden the surface; while iron may be case-hardened. At the same time, for instrument work, the provision of sufficient bearing surface and the exclusion of grit will not only save expensive hardening, but also expensive adjustments to take up wear.

Among other methods of protection against both friction and corrosion, by means of a metallic coat, may be mentioned electroplating, which is an industry by itself; and galvanising, both by the hot process and the zinc dust process.

To turn to bronzes, for the brasses I have found the following useful for different purposes.

(1) The silver nitrate bronze. I have found this work best when used as follows. Make a saturated solution of silver nitrate, and add an equal amount of nitric acid, as one solution. The second is nitric acid, which has dissolved as much copper

as possible. The piece to be bronzed is dipped successively in each, and steadily heated until black.

(2) The ammonia bronze. This is an excellent bronze, and is made and used as follows: Take 8 ozs. ammonia .866, add 1 oz. copper carbonate, and 4 ozs. water. Work is to be cleaned and immersed until black, and then wiped dry with cotton waste, and lacquered or not as desired. The only precaution to be taken is to see that no soft solder is on the surface.

(3) For darkening a surface antimony chloride may be used with good effect. This can be applied with a soft brush.

(4) Platinum chloride applied as No. 3.

(5) The ordinary iron bronze. 1lb. hydrochloric acid, $\frac{1}{4}$ lb. white arsenic, and $\frac{1}{4}$ lb. iron perchloride. The worker should be protected against the fumes of this, and the work must be brushed dry with sawdust and bran or blacklead.

(6) The mercury sublimate bronze used as No. 5. This bronze has the peculiar effect of rotting drawn or rolled brass, but for cast work it works well.

Numerous colouring effects may be obtained by the use of hypo. reduced with sulphuric acid; mercury nitrate, iron nitrate, and other materials, but the above selection in skilful hands will give every effect desired for optical work.

For iron or steel we may use the new phosphoric acid bronze, which not only gives a good black, but affords an excellent protection against rust. A steel spectacle frame protected by this method is exceedingly good. Also the various nitric acid and sulphur blacks are good.

For such work as the leaves of iris diaphragms the work may be dipped in a copper sulphate solution and bronze No. 2, 3, or 4 used afterwards.

For aluminium I have found No. 5 useful, but it must be washed in plenty of running water. Also dipping in copper sulphate and finishing with No. 2 or 4 gives a good effect. There is room for a good deal of work on aluminium protection and soldering.

As regards an actual coating, I shall not spend time in discussing the various japans and blacks; but one method is exceedingly useful. That is to give the work a coat of medium, such as colourless lacquer, allow it to cool, blacken it evenly by the smoke of an acetylene gas (or candle) flame, and warm till bright. All lacquers and blacks of the lacquer type are improved by the addition of a little boracic acid and a few drops of ammonia.

I think that this matter of surface protection and colouring might well be made a special study by one who has the time and knowledge, since it is not only of interest to us but to everybody who has to deal with metals at all.

H. S. RYLAND.

METHODS OF ADVERTISING.

[In the following article by that well-known writer in the American photographic Press, Mr. C. H. Claudy, attention is directed to methods of value to the professional photographer to which we have at one time or another drawn attention in these pages. The booklet, the calendar, systems of follow-up letters, etc., etc., are all expedients which are of value, according to individual surroundings, and no apology is needed for again directing notice to a department of the photographer's business which is too apt to be neglected.—Eds. "B.J."]

If it were possible for you personally to address an audience of ten thousand people, all of whom you wanted to impress with the fact that you were a good photographer, that your pictures were unusual, and that they should patronise you rather than someone else, and if, in that address, you had but one minute to speak, what would you say? A newspaper advertisement must occupy considerable space to require one minute of reading.

You pay a newspaper for the privilege to tell its readers why

they should buy of you. To be careless in the manner in which you tell your story is to throw away both money and opportunity. It is for this reason that the man who writes his own advertisements is like the layman who handles his own case—he has a fool for a client!

You would laugh at the idea that an amateur photographer of average ability could make his own portrait as well as you, with all your experience and equipment. But what difference is there when you attempt to write your own advertisements.

instead of going to the man with the equipment and the experience and get him to do it—he who can do it well?

Whatever form of advertising you adopt, don't stop spending money with securing the opportunity—spend a little more to use the chance up to the limit of its possibilities.

Advertising schemes are without number; but certain ones are more or less standard. Some of these I am going to discuss in detail.

The Booklet.

It is probably the most effective shot in your locker if it is properly made, well loaded, carefully aimed and deftly fired. So many people believe that any advertisement is all advertisement, that it is difficult to get credence for the statement that the printed matter is only a part of any campaign for business. Yet if you had a million copies of the finest booklet in the world, descriptive of your work, and sent them all for distribution to Hong-Kong, you wouldn't expect much in the way of immediate results!

A booklet should have a purpose. A booklet should have meat in it, a reason for existence, a story to tell. If you have won a prize, a medal or diploma, a little brochure modestly telling about it, the causes which led to the prize being won, and something about the prize-winning picture, is a case in point. If you have a new camera, a new lens, a new method, a new style, a booklet which will attractively portray it to your customers should prove an investment yielding good returns. But a booklet which says merely that your name is Smith, that you make pictures, that your prices are thus-and-so, and your address such-and-such, is money wasted. Never use the booklet, which is expensive, when a less expensive form of advertisement will do the work. But *never* issue a *cheap* booklet, unless you do cheap work. To put good advertising on poor paper with poor presswork is to reduce its value fifty per cent., and to advertise refined photographic work of high quality in any but the highest-class manner is to throw coin away.

The Calendar

is sometimes an effective advertisement and sometimes a delusion and a snare. In my humble opinion it is more often the latter than the former, when it comes to the photographic business. Few men would pay any attention to the name and address on the calendar in their offices if their wives wanted a photograph—they are much more likely to credit the last picture they have seen with your name.

But I recall one brilliant exception, in which a photographer designed an ingenious calendar and found that it paid. Just before Christmas he advertised that with every order of a dozen prints of a certain popular style he would give a Christmas present. He worded his advertisement so that it seemed rather that he was anxious to enter into the Christmas spirit and give his customers a little gift than as if he were offering a premium. When he came to deliver his gifts the customer received a package neatly done up in tissue paper, tied with red ribbon, stamped with a holly seal—exactly as if it were a genuine Christmas gift from some thoughtful friend. Inside the package was a neat, plain card, on the bottom of which was a small and dainty calendar and on the upper half a *platinum print corresponding to the order supplied*. Above was engraved a tiny card bearing the greeting: "Merry Christmas from me to you!" The inference was irresistible. Besides creating good feeling between the photographer and the customer, the gift was of a nature to be given away again immediately, since no one cares for a calendar adorned with a picture of himself. And the advertising value came in this way: the clever photographer had permitted himself to place a neatly embossed card of his own, not too conspicuous, at the lower left corner—"Smith, Portraits. 101 Elm." Besides, he had signed the platinum print, as usual, and his name was printed on the back of the card!

Oh, canny Smith! Something for nothing has ever been a lure. When that something is a good advertisement, and morally certain to be passed on; when it costs little and, in addition to making friends with the person to whom it is first given, is likely to make a customer of the second, as well as of the various people who are told of the idea, it is certainly one to pay. *That* was advertising with brains.

The Street-Car Card

can be made of service anywhere, but not unless it is carefully designed, well executed, and frequently changed. There is one objection to it for photographers' use: large advertisers can afford to have lithographed and three-colour half-tone cards in cars, printing them in huge quantities. *You* cannot. A plain, printed card suffers by comparison, and you can't afford to have your business or your name seem less refined or less successful even than some one's premium ham, another's floating soap, or a third's patent medicine. Better cut out the car cards, unless you feel you can afford a dainty set. Personally, I don't see why you can't afford five hundred cards in sets of fifty, each decorated with a D. O. P. portrait. Ten 4 x 6 portraits, in lots of fifty each from ten negatives, all of pretty girls, daintily dressed women and babies, and finished, half in black and half in sepia, ought not to be more than two days' work for a small force, and a set of fifty cards in fifty cars, changed weekly, for ten weeks, during the Christmas rush, will bring big results. But be very sure you have permission to use the pictures, or you may run against trouble.

Blotters

are fairly well exploded as advertising mediums. When an advertising campaign has so thoroughly covered the territory that all that is necessary is to keep a name before the public, so that the advertising which has been done will not be forgotten, blotters may well serve their turn. The same is true of rulers with names and businesses printed on them, paper-cutters, and other advertising novelties. But as business-getters such articles are generally a failure, particularly when they are aimed at people whose pocket-books must open to some wideness to deal with you.

Follow-up Letters

are vitally important to most advertising campaigns. A really good follow-up letter is a jewel without price. It is used to go after names secured in some way or other, to produce business which is shy in coming. Different communities demand different methods. Large cities are less fruitful ground for follow-up letters than small ones, and certain localities will stand a larger number sent after names than others. But your advertising man must lay out your system for you—every business is a law unto itself in such matters. Alas, however, many a good advertising man is a failure when it comes to writing follow-up letters, and doesn't know it. Beware, as you would the devil, of a follow-up letter which reproaches, which complains, which finds fault, which reproves, or which makes any accusation. For instance, "We cannot understand why you have not taken advantage of our liberal offer—surely you cannot afford not to have us take your picture," is going to make the average man say to himself, "Well, I don't care a hang whether you understand it or not!" and throw the letter away!

To say to a prospective customer, *via* form-letter, "We cannot afford to draw your attention again to our offerings at this season," is just throwing space away. To write a man who you believe, may sometime have his portrait taken by you "You are neglecting an opportunity to get a rare bargain—don't delay any longer, but let us make an appointment," is so trite and commonplace as to be altogether wide of the mark. One vital mistake you and a thousand others like you make when it comes to sending out four or five consecutive form letters at intervals of a week or ten days, is to think that each must contain some reference to the last; that the letters must

tell a definite, continued story. Thus, Number 1 tells your name and business and what you want; Number 2 mentions that Number 1 has been sent, and, "Why don't you take advantage of the chance?" Number 3 says that Numbers 1 and 2 have been sent you, and you cannot understand why the recipient hasn't come in and spent money; Number 4 ends up with the statement, "We have sent you Numbers 1, 2, and 3 letters, and have had no reply, and now beg for the last time to inform you that Smith's is it when it comes to making pictures!"

This is all wrong. Numbers 1, 2, 3, and 4 should be entirely different letters in form, in tone, in contents, and in method. Each should be a shot in itself. If Number 1, telling him (the recipient) of new panel platinums at \$7.00 per dozen, doesn't bring forth a reply, let Number 2 speak of 16 x 20 or 1 x 2 vignettes. If the customer-to-be doesn't want either, tempt him with a miniature or an exclusive head. In Number 4 show him where money is to be saved on some style at this time of the year.

Make each letter cheerful. Make each one courteous, each one optimistic. Let nothing go into your letter you wouldn't let your receptionist say to a customer. Imagine your young lady saying to a man who had spent half an hour looking over samples and then decided he would call again, "Well, I can't understand why you don't buy. Surely these are cheap enough!" Do you suppose that man would ever come back? Not a bit of it. But if the young lady smiles him out, asks him if she can't show him something else, asks him to come to her for waiting-on when he returns, and makes him feel at home, when he *does* decide he can afford a sitting, he is coming where he was well treated. Exactly the same principle holds good with form-letters. You can create either a favourable or an unfavourable impression—you can interest a man in your methods or your business or your styles, or all three, or you can antagonise him with your tactless words. Remember always that you are, in a letter, going to say perhaps two hundred words to a man; pick these two hundred with care, and make them breathe not only success and good prices and the picture he must have, but courtesy and good will.

Canvassing.

There are photographers who do it. I disappoint one young woman regularly every month. She wanders into my office with samples and a large red hat, and sits down and endeavours to ingratiate herself with a smile, and tries to look as if she would cry. I decline to order. I always do decline, and she never does. I would never think of going to the gallery she represents for photographs. It seems to me that, needing such methods to get work, the work itself cannot be first-class. To send out agents to solicit by the ticket or coupon method is a precarious business. It is somewhat like purloining a man's watch in a street-car in order to get two years' free board—State's prison. To promise a house and lot or an automobile or a ninety-seven-piece dinner set with every dozen pictures all that is necessary to keep every thinking man and woman in your city away from your doors. But I forget I am talking of respectable photographers!

Miscellaneous Schemes.

There are several ways to get publicity, some of which come more under the head of business-getting than simple publicity. Thus, the man who opens a new studio and neglects the opportunity for a reception—well-advertised, with engraved invitations to the best people in his town, and something in the way of a souvenir—is letting a chance slip by. But it takes brains and tact and some social skill. Ill done, it is better left undone. Well done, and it will bring notices in the papers and business will follow. Invitations to certain people to have their pictures taken free

"to complete our gallery of public men" or "to finish our set of prominent society people" sometimes result in orders from the negatives so made. But it always seems a catch-penny scheme—unless, indeed, you are truthful, and really do need the pictures to fill out a set from which newspapers and magazines are constantly ordering.

You fight shy of the dentist with the free-sample filling; the drug-store with the free-sample medicine; the doctor with the "thirty days' free treatment." What guarantee have you that your invitations will not be received in the same spirit? Different localities and circumstances need different methods of treatment from an advertising standpoint; but human nature is pretty much the same in New York and Kamchatka. It is the general consensus of opinion that any advertising scheme which has "free" attached to it, as applying to anything else than booklets or advertising matter, is likely to do more harm than good among the class of people photographers try to reach.

Free Pictures to the Press

is a scheme with many advantages. To see "Photo. by Smith-Jones" every day in a newspaper is first-class advertising for you. But it means that you have to go, at any and all hours, anywhere, for any kind of a picture; if your town is large and your papers alive, it means that you have to keep one man busy doing nothing but that. Yet even the salary of one man and the cost of plates and paper he uses do not make an exorbitant sum when you consider the advertising you get in this way. Much more critical attention is paid to pictures illustrating a news-story than to any other single thing in a newspaper. The advertising comes in having your name associated with such pictures. I can recall one firm, now very prominent in photographic circles, which made its reputation and its business largely through this means of advertising.

But whatever scheme or schemes you try, there are certain points to be remembered in connection with all. No advertising of a high-class studio is good advertising unless it is dignified. None is worth considering which may antagonise a possible customer. It's poor advertising which is iconoclastic. It isn't enough to tell people what a picture ought not to be, and what the other fellow fails to do; you must let your public know what a picture should be, and that you can supply it. Thus, in this advertisement,

DON'T BUY CHEAP PHOTOGRAPHS.
CHEAP PHOTOGRAPHS ARE NEVER GOOD PHOTOGRAPHS.
Try Ours.
SMITH'S

the impression is given that you are an expensive man, and that to be good a photograph must be costly. Compare with this, which expresses the same idea, constructively:

YOU CAN'T BUY SOMETHING FOR NOTHING.
But

YOU CAN BUY THE BEST PICTURES FOR A REASONABLE PRICE
At
SMITH'S.

Of course, these are mere skeletons—"sketches," the ad. man calls them, containing the germ to be worked out. In this case it is the most obvious of all germs, the price-germ, and was chosen here as being the easiest on which to hang a deadly parallel comparison.

Finally, never forget that advertising is just a talk between you and the man who reads it; never say in advertising what you can't afford to say face to face; and, inasmuch as your space (time) is limited, consider most carefully what you will say and—equally important—how it shall be said.

For so, and so only, shall you find advertising paying you the dividends it pays the man who is master of the subject, or who has the good sense to choose for his advertising man him whose experience is large and whose success in advertising is measurable in results.

C. H. CLAUDY.

TONING BROMIDE PRINTS WITH SULPHIDE.

[The following article, giving the author's experience in the sulphide toning of bromide prints, appears in the current issue of "Photographic Scraps." It will be seen that Mr. Harold Baker finds it necessary to pay more attention to the choice of developer than to refinements in the toning process itself.—Eps. "B.J."]

IN actual work, the difficulties of the sulphide method of toning bromide prints do not appear to be great, especially when the process is carried out almost daily. Success or failure seems to depend far less on the toning itself than on the preparation of the print.

I use a bleacher composed of equal parts of potassium ferricyanide and ammonium bromide dissolved in a convenient quantity of water (the strength of the solution seems of no consequence). Variation of the proportions of the two salts, within moderate limits, does not seem to make any difference in the ultimate result. I do not think any change in colour is obtained by increasing or decreasing the proportion of bromide, and I cannot detect any alteration in the result by using potassium bromide instead of the ammonium salt. All differences in colour, freedom or otherwise from stains and so on, depend entirely, I believe, on the exposure and development of the print.

Developers for Gaslight Papers to be Sulphide-Toned.

Gaslight papers usually produce browns of a yellower colour than bromide papers, and they are also, I think, less susceptible to change of colour due to exposure and development. They may be developed with hydroquinone and metol, in conjunction with sodium carbonate, well restrained with bromide, and will give a good colour, on the yellow side; but the same paper developed with metol and potassium carbonate and little bromide will give a very similar colour. If bromide paper were used, however, there would be a great difference between the two prints. The one developed with well restrained metol-hydroquinone would be far warmer in colour than the one developed with metol-potash; but the exposure in the second case would have to be much shorter than in the first. The colour of the toned bromide print, in my opinion, depends entirely on exposure and development.

The Need of Clean Working.

One of the greatest troubles in sulphide toning is the frequent occurrence of blisters. This has been greatly increased in Birmingham, and probably also in Manchester and Liverpool, by the substitution of soft water from lakes for the old hard water from wells. At one time in this district, blisters were so frequent as to cause most serious losses to photographers. But the use of Ilford "Carbon surface" bromide paper has changed all that, and blisters even in toning are of the rarest occurrence, and can always be traced to a bruise in the paper, caused by rough handling. When soft water has to be used, especially if the prints are to be toned, an acid fixing bath containing alum is essential. When printing and developing prints intended for toning, greater care as to cleanliness must be exercised than is necessary for black prints. The right hand should be used for moving the print in the developing dish, and, as soon as development is complete, the print should be picked up with the right hand, and both back and front be drawn over the edge of the dish, to remove as much developing solution as possible. The print should then be dropped face down into the fixing solution, pressed under with the left hand, and quickly moved about to allow the fixing solution to act upon the surface as rapidly as possible. If this is not done dark marks will appear when the print is toned. The fixing bath should be reasonably fresh and not be used long enough to weaken it. It is almost impossible to avoid uneven toning when a worn-out fixing bath has been used.

The right hand should never touch a print after it has entered the fixing bath, and the left hand should never touch a print before it enters the fixing bath.

An interesting and convincing experiment is to handle a print in the developer with fingers on which there is only a trace of hypo, and afterwards tone it. Towels for wiping the hands while developing must not be used too long, or hypo will be conveyed to the right hand and cause untonable marks, generally streaming from the corner by which the print is picked up.

Insufficient fixing will also cause dark stains in toned prints; this is another reason for not running the fixing bath too low

The Effect of the Negative.

As the colour of the toned print depends on exposure and development, it is necessary to keep to negatives of fairly even density. It is impossible to get prints of the same colour from an excessively thin negative, and from an excessively dense one.

In order to obtain a good print from the thin negative, a restrained developer would have to be used, while for the dense one as little restrainer as possible would be necessary. Of course, in the case of the thin negative, a short exposure as to time must also be given, and in the case of the dense one a long exposure; exposure does not mean length of time, but actinic effect on the silver salts in the paper.

Help with the Developer.

If I wish to secure a rich, warm sepia colour from an average negative, I use a developer containing more hydroquinone than metol, and plenty of potassium bromide; I use sodium carbonate as the alkali, and use rather less sodium carbonate solution and more metol-hydroquinone than if I were printing for black prints. For a cool sepia I use equal parts of metol-hydroquinone and potassium carbonate solutions, and my exposure would be half as long as that for warm sepia. Exposure and development for cool sepia is also very suitable for black prints, not intended to be toned.

Ilford bromide paper affords such exceptional latitude that it may happen, when a trial is being made, that a print may take quite a long time to develop to the full depth and yet give a beautiful result. Another trial should be made with a longer exposure, so that development will be complete in half the time required for the first. When fixed and dried it will be difficult to distinguish between the two prints, but when they are toned they will be quite different in colour. If carefully examined while both are wet, a slight difference may be detected; the short exposure and long development will give a cold, almost blue-black print, while the other will have a slight suggestion of brown, or even green. Metol, without hydroquinone, will give the blue-black colour and will tone to a cold brown.

I have heard of prints that refuse to tone at all, but have never met with an instance; I have, however, sometimes had trouble through using the bleacher too weak, when all kinds of stains have resulted. If the bleacher is dissolved in hot water, to save time it must not be used until it is quite cold, or the delicate tones of the prints will be bleached away.

Precautions in the Toning Process Itself.

Prints should never take longer than five minutes to bleach. A sulphide solution should not be used too strong, as it softens the gelatine of the prints; but it should not, on the other hand, be too weak, or the bromide may not be completely changed into sulphide. When the image has darkened over its whole surface it should be left in the solution for quite a minute, in order to ensure complete conversion of the bromide into sulphide. The print should then be removed to a solution of alum to prevent all risk of blisters; if the prints have been dried before toning the alum bath is not necessary with Ilford paper, but it is not much trouble to use and reduces the danger of blisters to a minimum. If the prints are toned as soon as they are washed from hypo the alum bath is necessary if the water used is soft; without it, blisters are sure to appear.

It is better to keep the prints face down in the alum solution, as they are liable to have a white precipitate thrown down on their surface which does not show until they are dry; a certain amount of this precipitate almost always shows, but it is much less when prints have been laid face down. This white deposit can be cleaned off with a tuft of cotton wool moistened with methylated spirit, but if this fails, sometimes does, a little of the "encaustic paste," well known to old photographers, will remove it entirely and at the same time improve the appearance of the print. It will also, I think, prevent the iridescent appearance of the shadows which shows itself when the prints are exposed to an impure atmosphere.

It is advisable to keep the prints face down in the acid fixing bath also, because after the bath has been in use for a short time a white precipitate forms, which is likely to be deposited on the face of the prints if they are fixed face upwards.

P.O.P. Effect on "Gaslight,"

It may not be generally known that a "Gaslight" print will tone to a colour very much resembling a cold toned P.O.P. print, if it be left in the acid fixing bath for 12 or 14 hours. The photographic postcards, produced in such large numbers, are said to be toned in this way.

Photographers must not expect to secure the same colour in all their prints by sulphide toning, unless the negatives are fairly uniform in density, so that conditions of exposure and development may be substantially the same.

It is important to remember that warmer colours are produced by longer exposures and restrained or weakened developers; and colder colours by shorter exposures and developers which act quickly, such as metol, "Certinal," or "Rodinal."

HAROLD BAKER.

THE LATE MR. DOUGLAS CARNEGIE.

To many of our readers the sad news contained in the evening papers of Friday in last week, repeated in the morning papers of the following day, will have come with a sensation of grief which will not quickly pass away. For the past few years Mr. Carnegie had been engaged in lecturing upon scientific subjects under the University Extension Scheme, principally in the North of England, where his courses of instruction were received with almost phenomenal enthusiasm. Yet he himself was subject to moods of depression, during which he took the most pessimistic view of his work. His death in a Darlington hotel on Friday, October 1, came as the tragic ending to this strange illusion. The funeral took place at Chesterfield on Tuesday last.

The son of a doctor; Carnegie was born in China, but received his early education at Staveley Grammar School and at Epsom College. From the latter place he gained an exhibition scholarship of London University and proceeded to Caius College, Cambridge, where, after a distinguished career in science, securing a double-first in Parts 1 and 2 Natural Science Tripos, he became assistant lecturer and demonstrator in the chemical laboratory of Caius College, a post which he held from 1884 to 1889. In 1890 the care of his health led him to accept the chair of chemistry in Colorado University, U.S.A., but in 1893 he returned to England to become science master of Leys School, Cambridge. For some time also he acted as research chemist to the Cambridge Colour Works, Loughton.

In the domain of pure chemistry, Carnegie will be remembered by a number of contributions, both literary and experimental. He wrote the article on the periodic law in the last edition of Watt's "Dictionary of Chemistry," and he was the author, with Professor Atkinson Muir, of a textbook published in 1887 under the title of "Practical Chemistry, a Course of Laboratory Work." He was the first to suggest the analytical method in which zinc is used for the reduction of ferric iron in the quantitative estimation of that metal with bichromate solution, and many pieces of apparatus employed by chemists and demonstrators are due to him. In his lecture work he showed the greatest ingenuity, himself constructing most of the apparatus he used, and very largely employing photographs of the stages of an experiment which he could not perform before an audience. On the last call he paid to the office of this journal he brought with him a number of Autochrome transparencies of skeins of wool, showing the extraordinary matches of colour made by combinations with various types of colour-blindness. These were for use in his lectures on Light and Sight, now broken off.

In photography, our readers will no doubt be aware of his work in conjunction with his friend and neighbour, Welborne Piper, on the action of bichromate on the silver negative image, published in the "Amateur Photographer" in 1905, experiments which led to the present chromium intensifier. His later papers on the theory of multiple photography, on the H. and D. photometer, and, quite recently, on the sulphide toning process, have been published in our pages and do not need to be further referred to. Carnegie was one of the few scientific chemists who was both acquainted with and

interested in practical methods of photography, and there is no doubt that with life and leisure he would have done valuable service in the investigation of many of photography's unsolved problems. As it is, we mourn the departure of a brilliant scholar, a type of man that is meant by "English gentleman," and a sincere friend.

Photo-Mechanical Notes.

Photo-Engravings Direct on the Metal in the Camera.

A further patent has been granted to Arthur Payne in connection with the process of preparing photo-etched plates by direct exposure in the camera already the subject of patent No. 28,415, 1908. ("B.J.," March 12, 1909, p. 198.) According to the later patent (No. 18,775, of 1908) there is provided the following alternative method of converting a negative into a positive image by means of an electrolytically deposited resist.

A positive image from a negative original or a negative image from a positive original is first prepared according to the methods described under the headings "Special Manipulations No. 1 Method" and "General Manipulations" of the prior specification.

If, having obtained the negative image, a positive resist is required or vice versa, the prepared plate is immersed in a bath such as is used in the electro-deposition of metals and a coating of a suitable metal is deposited, either by means of, or without, an electric current, upon the face of the metal plate to be etched (the particular metal deposited would be one that is not affected by the etching solution used, and so protects the metal plate where it is deposited), the substratum resist preventing the metal being deposited except where the metal is exposed. When a suitable thickness of "metal resists" has been deposited upon the plate, it is removed from the bath and washed, the substratum resist being then removed from the plate, leaving the "metal resist" on the plate. The plate is then etched in the usual manner.

For example: A negative image is prepared upon a zinc plate from a line drawing in such a manner that if this plate were placed in the etching bath an intaglio plate would be obtained, but in the preparation of a positive image the plate receives a coating of copper by immersing it in a copper cyanide bath with the prepared surface facing a copper plate and passing a weak electric current through the solution in the usual manner. The substratum resist is then removed and the plate etched in an etching bath of nitric acid of about 5 per cent. to 10 per cent. strength as usual. Other suitable metals than copper may obviously also be used.

The copper is deposited from a hot or cold solution of copper cyanide or such as is usually used for this purpose, the following solution being a suitable formulæ:—

Water	80 oz. (fl.)
Soda bisulphite	1 cz.
Potassium cyanide 50 per cent.	3/4 oz.
Copper acetate	1 1/4 oz.
Ammonia .880	3/8 oz. (fl.)

Dissolve the bisulphite and cyanide separately in small quantities of the water. Place the copper acetate in a mortar and moisten with a little of the water, rub it into a thin paste and add the cyanide solution. Add the bisulphite solution to the bulk of water, then add the acetate solution, and lastly add the ammonia. Any of the usual electro-plating solutions of copper cyanide may be used in lieu of above.

Silver may be deposited upon copper or brass from a solution of silver cyanide used in the usual manner, and the plate etched in a perchloride of iron bath.

By first etching the metal plate and then electrically depositing a metal upon the plate before removing the resist, metallic plates may easily be prepared with pictures and designs in inlaid metal.

This process may also be used for the production of engraved metallic plates for ornamentation, such as illuminated or memorial brasses, or for ornamental metallic fittings of any description, or for name plates, engraved dials, etc., either in intaglio or relief made in the manner already described, and if required the hollows may be filled in with coloured wax or other suitable material.

FORTHCOMING EXHIBITIONS.

1909.

- September 10 to October 23.—The Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.
- September 23 to October 30.—Royal Photographic Society. Sec., J. McIntosh, 35, Russell Square, London, W.C.
- October 6 to 13.—Portsmouth Camera Club. Sec., James C. Thompson, 23, Elm Grove, Southsea.
- October 21 to 23.—Rotherham Photographic Society. Entries close October 11. Secs., H. C. Hemingway, Tooker Road, Rotherham, and F. Sargeant, 17, Aldred Street, Rotherham.
- October 27 to 28.—Watford Camera Club. Entries close October 21. Sec., W. J. Edmonds, 3, The Parade, Watford.
- November 10 to 13.—Hackney Photographic Society. Entries close October 12. Sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E.
- November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138 Glasgow Road, Wishaw, N.B.

1910.

- April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for between September 20 and 25:—

- PHOTO-PENDANTS.—No. 21,397. Improvements in photo-pendants, lockets, and charms. William John Renfrew Pellow and George Adams, 128, Colmore Row, Birmingham.
- ANIMATED PICTURES.—No. 21,491. Improvements in or relating to apparatus for producing animated pictures by the movement of a vehicle. Waclaw Czerniewski, 111, Hatton Garden, London.
- CINEMATOGRAPH.—No. 21,568. Process for manufacturing bands for cinematograph films. Henry Danzer, 1, Queen Victoria Street, London.
- RETOUCHING.—No. 21,586. New or improved instrument for retouching photographic negatives, matt prints, and the like. Athole Victor Davis, 236, Ifley Road, Oxford.
- REFLEX CAMERAS.—No. 21,588. Improvements in or relating to reflex cameras. Arthur Lewis Adams, Birkbeck Bank Chambers, Southampton Buildings, London.
- CINEMATOGRAPH-PHONOGRAPH.—No. 21,675. Apparatus for maintaining the synchronous running of cinematographs and phonographs. Jules Greenbaum, 231, Strand, London.
- TOY-CINEMATOGRAPHS.—No. 21,800. Improved stage with projecting surface for toy-cinematographs or the like. Oskar Messter, 100, Wellington Street, Glasgow.
- TOY-CINEMATOGRAPHS.—No. 21,801. Improvements in toy-cinematographs. Oskar Messter, 100, Wellington Street, Glasgow.
- CAMERAS.—No. 21,818. Improvements in or relating to photographic cameras and to means for introducing plates into and removing them from the same. Walter Ernest Chapman, 139, Queen Victoria Street, London.
- CINEMATOGRAPHS.—No. 21,891. Improvements in cinematograph films. Oskar Messter, 100, Wellington Street, Glasgow.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

- COLOUR SCREEN PLATES.—No. 18,744, 1908. (May 26, 1908.) The invention relates to improvements in the process for the manufac-

ture of mosaic colour-screens according to Patent No. 11,698 of 1908 ("B.J.," March 19, 1909, p. 221). In this addition, the distribution of the greasy material on the original layer of gelatine may be obtained by any known method of printing as, for instance, lithographic copper-plate, or by spraying, etc., in place of photographic methods as in the prior specification.

The drawings represent on an enlarged scale a fragment of screen at the various stages of its preparation.

The transparent support *a* (glass, film, etc.), intended to form the support for the screen, having been coated with a thin layer *b* of gelatine or of other suitable substance, is submitted to the following operations:—

1. A suitably chosen fraction of its surface (for instance, two-

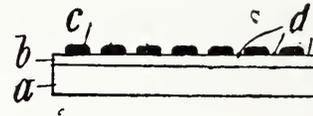

Fig. 1.

Fig. 3.

thirds) is covered with greasy material *c* of any desired fluidity, any well known printing process, or spraying being used for the purpose. The part played by the greasy material *c* is simply to constitute a temporary resist, in the form of lines, points, grains, etc., either regular or irregular, or having any geometric or irregular shape. Its colour is, therefore, immaterial, it is preferably black, so as to enable the work to be more easily observed.

Figs. 1 and 2 show the application of the greasy material in the form of vertical equidistant lines *c c* indicated by vertical hatching.

2. Dye by imbibition all the part *d* of the surface which has been left uncovered by the greasy resist. This is done (e.g., with orange dye) by immersing the plate in a dye bath or by applying a dyed plate (Fig. 3).

3. The whole surface is varnished with a varnish *e* (Fig. 4) ful-

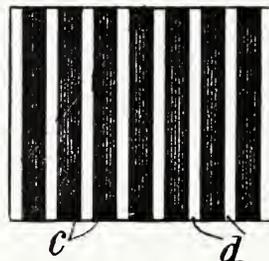

Fig. 2.

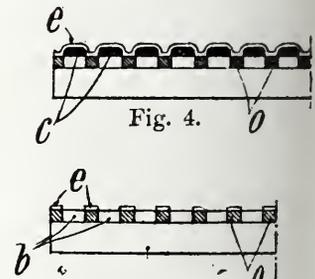

Fig. 4.

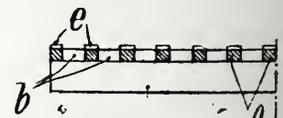

Fig. 5.

filling the two conditions: (*a*) Its solvent must not dissolve the greasy material used; (*b*) its resin or gum resin must be insoluble in a solvent of the greasy material used, and incapable of becoming incorporated into the material.

For instance, if the greasy material used contains linseed oil and the varnish is composed of gum-lac previously extracted with means of ether and dissolved in alcohol (which is a solvent of the varnish), the alcohol must not dissolve the greasy material, and on evaporating must leave on the whole surface a thin layer of gum-lac. Such a varnish adheres strongly to the uncoated gelatine exactly at the points where the colour was able to adhere, and forms an impermeable insulating layer; but wherever it comes in contact with the greasy material *c* which has remained soft it covers it without becoming incorporated with it.

If, after the drying of the spirit varnish, the support thus treated is subjected to the action of a solvent of the greasy material, such as, for instance, benzine or essence of turpentine, the preliminary greasy impression will dissolve very easily by rubbing slightly, which will remove from the support, with the greasy material, those parts of the spirit varnish which, having come in contact with this greasy material, have not been able to adhere to it, and consequently to the support, allowing only the adherent parts to remain on the latter.

The gelatine *b* is thus exposed at every point at which it is protected by the greasy impression. After the operation, two-thirds *b* of the free surface of the screen will be free and a third *o* coloured orange, the colour being covered with an impermeable varnish *e* (Figs. 5 and 6).

4. Half of the total surface is covered with greasy material, either in the form of horizontal lines *f* as shown in Fig. 7, or in any other form, whereupon the surface remaining free is dyed, for instance violet *w*, the surface in the present case consisting of

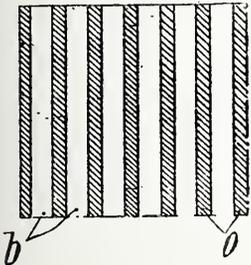

Fig. 6.

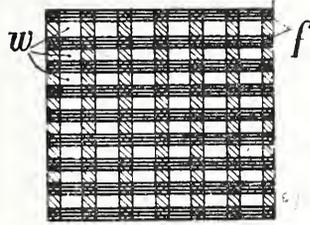

Fig. 7.

rectangles *w w*, limited on the one hand by the greasy material just deposited, and on the other hand by the varnish covering the orange colour already applied.

5. The surface is again varnished, then the greasy material is dissolved and removed as described in Paragraph 3. There remains then (Fig. 8) one-third *o* of the surface coloured orange (continuous hatching), another third coloured violet (long dotted hatching) and the third portion *b* uncovered.

The coloured surfaces being covered with a varnish, there will only remain one-third of colourless surface where the gelatine is exposed, the third being dyed by simple imbibition with the third colour *v* (green, short dotted hatching, Fig. 9).

The whole surface is then cleaned by means of a solvent for varnish, e.g., alcohol, so that the screen will be constituted merely by the layer of the original gelatine dyed on the whole of its surface without superposition or deficiency, the primary colours alternating with a perfect regularity. The homogeneous coloured layer

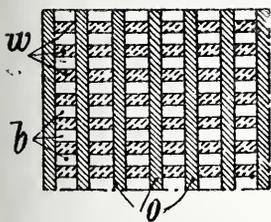

Fig. 8.

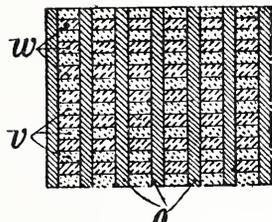

Fig. 9.

thus obtained is then preserved by means of a colourless and neutral impermeable layer. The screen is then ready for receiving the sensitive emulsion. Louis Dufay, Villa Jean Simonne, Rue Andre, Chantilly, France.

PRINTING MACHINE. No. 27,047, 1908 (December 12, 1908).—The invention relates to automatic apparatus for taking prints from photographic negatives, etc., and consists of an improved construction in which the necessarily close superposition of the printing paper over the negative is automatically secured at or about the same time that the actinic light is automatically admitted to the case containing the negative; also the duration of exposure can be automatically regulated and determined.

The apparatus comprises a cam arrangement for controlling and varying the length of exposure, for which, and the other features of the apparatus, the full specification and five diagrams require to be consulted. Louis Brochery, 15, Rue David d'Angers, Dunkirk, France.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

APPARATUS.—No. 21,217. Apparatus for taking pictures either automatically or by hand. Debric.

Analecta.

Extracts from our weekly and monthly contemporaries.

Mounting Slides.

No lantern slide should be bound up (writes Mr. T. Orton Murray, in "Photography and Focus" for October 5) until it has been examined in the lantern to make sure that it is right. The examination should also be used to show whether the slide needs spotting. Some spots which are noticeable when the slide is held in the hand may not be very conspicuous on the sheet, and it is as well not to do any more spotting than is absolutely necessary. A dark spot in a deep shadow may go unnoticed, just as will light ones in a light portion; and when the subject is very much broken up spots are often quite unobtrusive, and are best left alone. The best instrument for filling up clear spots will be found to be a mapping pen, as its point is more easily directed to the exact place to which the colour is to be applied than is the tip of a brush. A little water-colour should be mixed up until it is as good a match with the tone of the slide as can be managed, always remembering that the matching must be done by looking through and not on to both slide and pigment. The merest trace of colour will be found to be sufficient, and the aim must be to apply sufficient with a single touch of the pen point to obliterate the spot. Any attempt to move the pen about will in all probability damage the film.

New Books.

"An Atlas of Absorption Spectra." By C. E. Kenneth Mees, D.Sc. (London: Longmans, Green and Co.; and Croydon: Wratten and Wainwright, Ltd.) Price 6s.

In this volume, which represents the measurements of over 150 dyes made in the research laboratory of Messrs. Wratten and Wainwright, Dr. Mees has provided experimenters with a most valuable work of reference. The best book giving data as to spectral absorption has hitherto been that of Uhler and Wood, which does not contain many of the dyes of importance in modern orthochromatic, and in any case pays no regard, as a rule, to absorption in the ultra-violet. The records supplied by Dr. Mees consist in each case of a photograph of the absorption spectrum taken by the wedge method, a brief account of which is really the only reading matter proper in the atlas. In the index of dyes particulars are given of the strength of solution in which the dye was examined, of the commercial source of the dye, and a note as to its chemical character, acid or basic. Finally a rough numerical idea is appended as to its stability towards light. Thus it will be seen that the data available will be of the greatest use to the student or to anyone who has to employ dyes in mixture for absorption of light. The half-tone reproductions of the spectrum photographs are excellently printed.

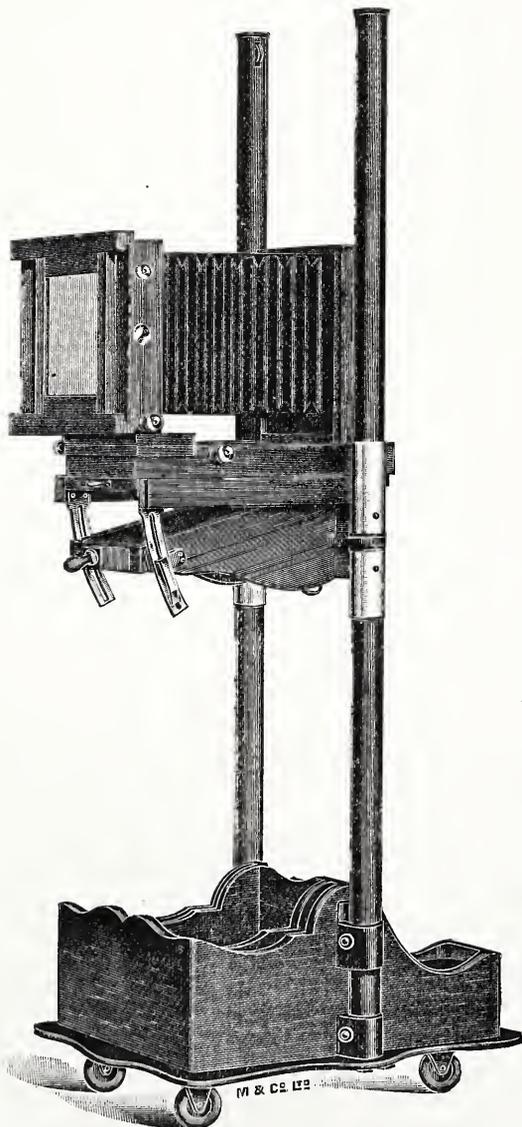

ENLARGEMENTS FROM SMALL NEGATIVES.—The current issue (No. 100) of the "Photo-Miniature" deals with this seasonable topic. The author, Mr. Walter Zimmermann, writes in an eminently practical way on the use of simple apparatus—he explains how to make one or two convenient fitments—and on the most advisable methods of making enlarged prints and negatives. An appendix by Fedora E. D. Brown gives details of making enlargements on Velox and other gaslight papers. As always, what our up-to-date contemporary has to say is concise and to the point. It is published in England by Dawbarn and Ward, 6, Farringdon Avenue, London, E.C.; in the United States by Tennant and Ward, 122, East 25th Street, New York.

THE GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION has enlarged and improved its club premises at 169, Eglinton Street, so that three enlarging rooms and two developing rooms are now at the disposal of members.

New Apparatus, &c.

The "Hana" Studio Stand. Sold by Marion and Co., Limited, 22 and 23, Soho Square, London, W.

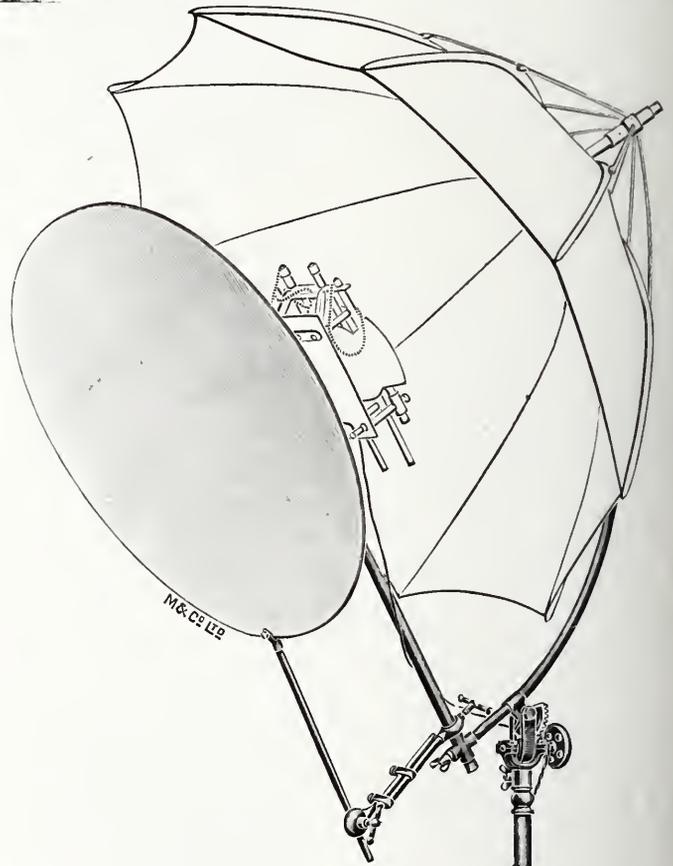

Professional photographers, who have craved a studio stand which should permit of the very widest range of up and down movement, and at the same time allow of the rapid manipulation of the camera with the minimum physical exertion, should be satisfied with the new stand placed on the market by Messrs. Marion, from the designs of Mr. Hana, the well-known photographer of Bedford Street, Strand. The stand consists of a pair of upright parallel hollow tubes, rigidly bolted to a base stoutly constructed in polished wood. Between the tubes a platform travels up and down vertically, its course being controlled by the two tubular pieces moving on the upright pillars. The platform is attached to these two pieces in such a way that the photographer standing at the back of the camera can tilt it at any desired angle. The whole combined weight of platform and camera mounted upon it is counterbalanced by weights moving in the tubular support, a thin wire cable, tested to a weight of 200lbs., connecting

the platform with the counterweight. As a result of this, the force required to raise or lower the camera is infinitesimal, whilst the length of the pair of supports allows of the camera being placed as high as 7ft. and as low as 2ft. above the ground. After placing at any point the camera is instantly clamped by a species of band-brake, which is operated by a single pull of its lever. Similarly, the angle at which the platform is tilted is fixed by turning down the handle seen on the right of the drawing. The support of the camera in each case is of the most rigid description. It should be added that the counterbalancing weight can be removed at the base of the tubes and removed or added to as may be necessary, or, if

more convenient, the exact balancing can be struck simply by placing a small weight, or even a box of plates, on the camera platform. The stand is made to take studio cameras up to 12in. by 12in., and costs complete, £8.

ARTIFICIAL LIGHT EQUIPMENT.—In a new catalogue which Messrs. Marion and Co., 22-23, Soho Square, London, W., have just issued, exclusively of the electrical lamps of all types supplied by their special department under the direction of Mr. Boardman, full particulars are given of all the types of arc lamp (open and enclosed), mercury-vapour light, and the necessary accessories in each case. The list contains also some very good reproductions of photographs

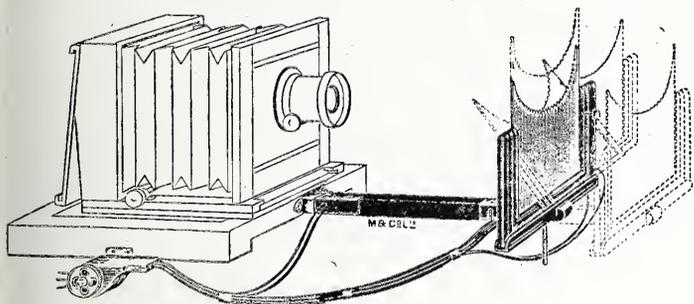

in leading studios from negatives taken with commercial lamps. We may mention that, as shown in the drawing, the diffusing screen for the studio arc lamp is now attached to the rod supporting the arcs so that it is much more readily manipulated. The diffuser (32in. in diameter) is fitted easily. It is adjustable in every direction, and greatly assists the operator in lighting. One advantage in this form of diffuser is that it takes up no floor-space. It can be fitted to all existing outfits without alteration of any kind. Strongly made in bronzed metal and well finished. The price is 21s.

The "Good" Studio Vignetter. Made by Marion and Co., Limited, 22 and 23, Soho Square, London, W.

This ingenious piece of apparatus provides a new and very facile means of working the vignetting mask which is used at the time of photographing the sitter. In place of rigid metal adjustments which are liable to stick, and in any case do not give a great range of movement, the vignetter is operated by a modification of the Bowden flexible wire connection. As shown in the drawing, the vignetting mask is mounted in a frame which travels upon a bar of square section attached to the front of the camera baseboard. The travel of the vignetter—as also its adjustment up or down, sideways, and in a swing direction—is done by means of pressure only on any one of four levers all placed together in a single mount. This may be attached to one side of the camera, as illustrated, or may be placed practically in any convenient position, the mechanism operating the vignetter irrespective of the length or force of the connections. The operator can thus modify the action of the vignetter whilst watching the effect upon the screen, in which connection it may be mentioned that the vignetter is pivoted along an axis opposite to the lens &

hat, when tilted, the displacement does not alter the level of the serrated edge. This useful apparatus is sent out with the arm in

two pieces and complete with screws for putting together. The whole attachment is fitted to the camera in a few minutes. The price of the "Good" Vignetter is £2 5s.

New Materials, &c.

"CHALLENGE" ART MOUNTS.—A series of art mounting papers has just been placed on the market by the "Challenge" Works, Macclesfield, England, in a series of 1s. packets, the 8 by 6 size containing forty-eight pieces, the 10 by 8 thirty-six and the 12 by 10 twenty-four. The papers, which are of a very agreeable matt somewhat mottled surface, are mostly cool greens, greys, and browns, with one or two papers of somewhat stronger colour. The series should be appreciated by the now numerous professional photographers who adopt individual mounting of their prints.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, OCTOBER 11.

City of London and Cripple Gate Photographic Society. "A Week in Holland with a Pocket Camera." E. J. Mortimer.
 Marylebone Camera Club. "Ramble in the Ardennes." H. G. Bailey.
 South London Photographic Society. "Home Portraiture." F. W. Memory.

TUESDAY, OCTOBER 12.

Ginning Park Co-operative Camera Club (Govan). Opening of Winter Session.
 Hackney Photographic Society. "Saints, Benedictines, Goths, and Vandals." E. W. Harvey Piper.
 Leeds Photographic Society. Social Evening.
 Glasgow Southern Photographic Association. Demonstration: "Autotype Carbon Process." "Multiple Gum Printing." R. Ure.
 Southall-Norwood Camera Club. "Autotype Carbon." Demonstration.

WEDNESDAY, OCTOBER 13.

Roydon Camera Club. "The Carbon Process." A. C. Braham.
 Edinburgh Photographic Society. Lantern Section, Member's Slides. "British Architecture—Saxon and Norman." R. Berry.
 Preston (Lune Street) Brotherhood Camera Club. "Autotype Carbon." Demonstration.
 Balham Camera Club. "Lantern Slide Making." J. S. Child.

THURSDAY, OCTOBER 14.

Leek Photographic Society. "Beautiful Manxland." R. Hill.
 C.C. School, Bolt Court, E.C. "The Arts of Engraving." William Strang, A.R.A.
 Watford Camera Club. Lantern Slide Trials.
 Liverpool Amateur Photographic Association. "To the Algerian Sahara." J. Carlton Stitt, J.P.
 Landsworth Photographic Society. Demonstration: "Bromide Toning." A. E. Cope.
 London and Provincial Photographic Association. "Autotype Carbon." Demonstration.
 South Norwood Photographic Society. "Autotype Carbon." Demonstration.

Commercial & Legal Intelligence.

LEGAL NOTICES.—John Scott, carrying on business as E. Holt, photographer and postcard publisher, 50, Hollowgate, Rotherham, has been adjudicated bankrupt. The receiving order was made on the debtor's petition.

CATALOGUES AND TRADE NOTICES.

FOREIGN ROSS LISTS.—Our readers in countries speaking the Spanish and Italian languages should make a note of the fact that catalogues of their optical and camera goods have now been issued by Messrs. Ross, Ltd., in these tongues, and may be obtained free on application to 3, North Side, Clapham Common, London, S.W.

MESSRS. BOWES' PRICE-LIST.—Messrs. E. W. Bowes and Co., of 122, Becklow Road, Shepherd's Bush, London, W., one of the enlarging firms who base their business first on the good quality of their work, and whose printing and enlarging, as we know from years' experience of it, is consistently of high standard, have just issued their catalogue for the winter season. They give the prices for all description of work for professional photographers, inclusive of carbon prints on ivory and artistic mounting in styles for exhibition purposes by the dry process. The list is one which we can advise every portrait photographer to have at hand.

Dews and Notes.

WHY THEY ARE PHOTOGRAPHED.—"Got a boat?" she brusquely demanded of a Detroit photographer as she walked in the other day.

"Yess'm."

"And a fish pole?"

"Yess'm."

"And a painted ocean for a background?"

"Yess'm."

"Look like Cape May?"

"It does."

"Can you get a good-looking young man to sit on the boat with me?"

"I can."

"Then I want six photos."

"Yess'm. Do you go to the seashore this summer?"

"Naw! Dad's busted in business and we've got to take a cheap board on a farm. I want the photos just the same, you know. Want 'em to send to a girl friend who is sick and can't get anywhere this summer. She'll think I'm down there all right."

"Sort of an illusion, eh?"

"Sort o' revenge, rather. We were down there last season and she stole my summer young man back. Hurry up with the feller, and tell him he can sit with one arm around me and his moustache touching my ear?"—"Detroit Free Press."

ATTRACTIVE WINDOW DISPLAY OF CAMERAS.—Since quoting the note from "Advertising," on page 768 last week, we have learnt that the window in question was that of the City Sale and Exchange in Fleet Street, the staff of which establishment deserve credit for the employment of this method of calling attention to the "points" of a camera.

CORRECTION.—An error was made in reviewing Messrs. Butcher's "Lanternist's Pocket Book" last week. This publication is not sent gratis, as stated, but is supplied at a price of sixpence.

R.P.S. LECTURES.—The following lectures will be delivered at the New Gallery, at 8 p.m. :—

Saturday, October 9.—"The Photography of Sport," by Adolphe Abrahams, B.A.

Monday, October 11.—"Holy Days and Fête Days in Spain," by R. Falconer Jameson.

Thursday, October 14.—"Pictures from Portugal," by George E. Thompson.

Saturday, October 16.—"London Through the Eyes of Gossip Pepsy," by A. H. Blake, M.A.

HACKNEY PHOTOGRAPHIC SOCIETY.—The last day for the receipt of entries in the Society's annual exhibition is October 25.

THE GLASGOW PHOTOGRAPHIC ART CIRCLE is holding an exhibition (closes to-morrow, October 9) of the pictorial work of G. L. A. Blair. The pictures, to the number of forty, are arranged in the rooms of the Glasgow Southern Photographic Association, 169, Egtinton Street, Glasgow.

THE AFFILIATION.—The Affiliation of Photographic Societies held their annual gathering at the Royal Photographic Society's Exhibi-

tion, New Gallery, on Friday evening, September 24. Fifty-one societies were represented by nearly four hundred members, again evidencing the popularity of the "Red Book" night. The Chairman of the Executive Committee, Mr. P. Bale Rider, after extending a hearty welcome, went on to outline the spirit of mutual assistance underlying the work of the Affiliation. He pointed out that while the London societies, from their geographical position, were brought into closer touch with the Affiliation than was the case with the provincial societies; it was also true that the societies up and down the country had received no little benefit from their attachment to the Affiliation, and he hoped that the forthcoming "Monthly Circular" would increase still more the benefits resulting from inter-communication one society with another. It was gratifying to find the work of the Affiliation appreciated in Australia and New Zealand, and it gave him pleasure to report that colonial societies were again on the active list, lectures and slides being despatched to them at regular intervals. The Chairman showed that the tendency to break up into little societies was something to be carefully guarded against, for it often led to a dissipation of energy. Societies should bear in mind the value of conservation of energy, and to this end it was extremely desirable to cultivate inter-club meetings. These local gatherings, he said, might again be combined into larger areas or federations, and thus the whole of the federations might form the groundwork of affiliation with the Royal Photographic Society. The scheme was a big one, and one that would take time to carry out, but he thought it should be the ultimate goal of the Affiliation. The Chairman stated that the information received in connection with the Consular Scheme was being tabulated, and would shortly be ready for use. He then presented the plaques and certificates awarded in the recent slide competition. The 1909 competition slides were then shown upon the screen, Mr. W. R. Bland personally reading the critical notes he had written upon them. Mr. Bland struck a distinctly new note. His frank criticisms may, as he put it, tread upon some people's corns, but must eventually effect more good than the "butter and jam" variety of criticism, unfortunately so common. A vote of thanks to Mr. Bland for the great trouble he had taken was proposed by Mr. C. F. Inston, seconded by Mr. F. J. Mortimer, and passed with acclamation. The vote of thanks to the Royal Photographic Society for their courtesy in again placing the New Gallery at the disposal of the Affiliation, was moved by Mr. A. H. Blake, and seconded by the Rev. F. C. Lambert. It was carried unanimously.

The prints and slides entered in the competition in connection with the affiliation outing to Epping were shown at a meeting held at the rooms of the Royal Photographic Society on Friday, October 1. Awards were made by popular vote, and went to (1) E. Alwyn Biscoe; (2) A. G. Buckham; (3) J. C. Nunn. The award for the best lantern slide went to H. Creighton Beckett. Mr. F. J. Mortimer kindly undertook to write critical notes on the prints, and these were read by Mr. P. Bale Rider. Mr. Rider remarked that it would be a pity to disband such an interesting set of prints, and eventually it was agreed, with the permission of the authors, to circulate the whole collection, together with Mr. Mortimer's criticisms, among the affiliated societies. In proposing a vote of thanks to Mr. Mortimer for the trouble he had taken, the Rev. F. C. Lambert said he knew the difficulty of securing pictures while with a crowd of workers, and he thought the results achieved on the occasion of the affiliation outing to Epping were a gratifying success. Mr. Mortimer's criticisms were full of helpful hints, and should prove of great assistance to the affiliated societies. Dr. Evershed seconded the vote of thanks, which was carried with acclamation. Dr. Walshe Owen moved a vote of thanks to the Royal Photographic Society for the use of the room in which to hold the meeting. Mr. A. H. Miles seconded, and the vote was passed unanimously.

PHOTOGRAPHY AS AN AID TO THE CONFECTIONER.—At a recent meeting of the Liverpool Bakery Students' Society, Mr. T. Curtis (the secretary) gave a lecture on "Photography as an Aid to the Artistic Confectioner." In the course of his remarks he said that during the last few years he had photographed many cakes, chiefly of an ornamental character. He had also photographed ornamental sugar, nougat, and gum-paste work, as well as chocolate plaquet and eggs. This had led him to think "Would not a collection of such photographs materially aid the confectioner in his artistic

work?" There were many decorative pieces of work executed by the confectioner, which usually passed from him to the shop or packing department. He never had the opportunity of seeing it again. If such work was photographed the makers would have a life-long record which would enable them to note the advancement in their artistic abilities as time went on. The bad and good points of their work could be easily noted, and they would in consequence be better able to remedy the failures and improve upon good work. To shops which had not sufficient accommodation for a show-room the photographic album was a valuable substitute. In many shops, when a customer ordered any special work of the kind, there were no means of showing the designs beforehand, and the customer had thus to leave the matter entirely in the confectioner's hands, a condition of things which rendered the former very liable to disappointment.

Correspondence.

- *• *We do not undertake responsibility for the opinions expressed by our correspondents.*
- *• *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

ENGINEER'S SENSITISING COMPANY, LIMITED.

To the Editors.

Gentlemen,—Our attention has been called to a paragraph on page 768 of your issue of 1st inst. in which it is stated that the above company is formed to acquire our business. Will you be good enough in your next issue to state that the Engineer's Sensitising Company, Limited, only acquires that part of our business which deals with the manufacture of sensitised papers and linen.—Yours faithfully,

For Norton and Gregory, Ltd.,

G. CARTMAEL, Director.

Castle Lane, Buckingham Gate, London, S.W.

A CURIOUS CASE OF COLOURS FADING.

To the Editors.

Gentlemen,—Referring to the letter on the above subject in your issue of October 1, I would suggest that the "fading" of the colours on bromide prints is probably due to the hygroscopic nature of the gelatine surface. In damp weather the gelatine takes up a certain amount of moisture from the air, so rendering the water-colours more or less soluble; in this state they would tend sooner or later to be absorbed into the film. If this theory be correct, hardening the print with formalin (or our old friend—and enemy—alum) would cure the trouble. It would be worth while trying the following experiment:—Cut a bromide print into two halves, treat one half only with formalin, mount the two halves side by side, colour in the usual way, and note the result.—Yours, etc.,

Pontypridd,

ALBERT O. FORREST.

October 4, 1909.

A CAUTION TO ASSISTANTS.

To the Editors.

Gentlemen,—I fully agree with the letter in your issue of Oct. 1 signed "Out-of-Work." A man who has been trained to high-class work and had experience with the best class firms should never go to the cheap class work unless he wishes to stay there. I would advise parents not to foster any desire on the part of their children to enter the ranks of professional photography. And to assistant who are not yet too old or who may have any influence to help them I would say, get out of it as quickly as you can. I have worked for some of the best class firms and obtained good salaries, also plenty of harsh and unjust treatment. My experience teaches me that the number of gentlemen employers in the profession are few and far between. Specimens are kept, even when stamps and addressed labels, etc., are enclosed. Only last week I wired to a man who had had my specimens six days to return them at once. They arrived two days after, and I lost a chance of a berth through his unbusinesslike action (to put it very mildly). During the last three weeks I have been requested by eleven firms to send particulars and photograph of self. Up to the present not one has been returned, and my stamps have been retained also. I hope they have framed my photograph. A great many of the well-known men seem

think it an honour for one to work for them. A bare living salary is a purely secondary consideration. One well-known West End man offered me an engagement, and said to me: "Look what my reference will be worth to you." I was to appear in a frock-coat suit, and to receive the remuneration of 21s. per week, paid when he thought or was forced to. For there are plenty of men who don't pay regularly, especially to lady assistants. At present I am like the writer of last week's letter, out of work, but I am young at it yet, only three weeks (not by Elinor Glyn). My last sovereign went to a pal who had just got a berth, but had not the wherewithal to get there, and when I get one that pal will help me. Photographs are still a luxury, and unless one has money and can afford to be always at the risk of being out of work, then don't try and get a living at this luxury. Leave photography severely alone. It's good advice by one who, if the chance comes to earn a living in some other way, will never want to handle a camera again.

A SERIOUS OUT-OF-WORK.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. Usherwood, 25, Fisher Street, Workington, Cumberland. Three Photographs taken of the Boiler Explosion at Distington Iron Work, near Workington, September 19, 1909.

Harker, 63, Market Street, Longton, Staffordshire. Photograph of the Very Rev. Dean Stringfellow.

J. Ferras, Lawhead View, Markinch, Fife, N.B. Three Photographs for Reproduction as Pictorial Postcards: Balgownie Woods, Markinch; Balgownie House, Markinch; On the Leven, Markinch.

HOW NOT TO ASK A QUERY.—Can you enlighten me on the cause of yellow stains on prints both on the film and back?—G. S. S.

If you were to mention the kind of paper you are using, or to send examples of the defective prints, we might be able to help. Apparently you credit us with supernatural powers of divination.

"OIL" PORTRAITS.—I see in this week's "Journal" a mention of Mr. F. C. Tilney as prepared to make portraits in the oil-pigment process from photographers' originals. I hope you will do yourself, and possibly other professional photographers, the favour of informing where Mr. Tilney can be addressed.—MINOTAUR.

It is usually against our rules to give the addresses of private individuals, but as that of Mr. Tilney occurs in the current catalogue of the R.P.S. Exhibition, there is no reason why we should not give it—it is "Walden," Red Lion Street, Cheam, Surrey.

SALE OF MATERIALS.—Could you inform me, through the "Journal," whether I can legally sell plates, papers, and bottles of fixing and fixing and developer, to local amateurs, as I could dispose of a fair amount? Also what I cannot sell, without a licence, that is sold photographically, which, of course, would include all poisons, I suppose?—SOLUTION.

You are at liberty to sell any materials except solutions, powders, etc., containing a scheduled poison. For these you must be a registered pharmacist, but if you steer clear of mercury intensifiers and any preparation likely to contain potass. cyanide you will be quite safe.

SNOW ON THE STUDIO.—I am thinking of putting a light upstairs in another building to which I expect to move. The roof is a flat. The building is on a corner, and I should put the light on the street, giving me a north light. Now, we have a good deal of snow in the winter, and though I may clear the bulk of it off after a storm, still a little will remain, and, gradually melting

from the heat inside, will form icicles. If I made the window by removing coping running round side of flat roof, and put the window in, having the glass of upper window coming as close as frame will allow to side-light, and partly overhanging the pavement beneath, I am afraid icicles forming at the edge of the glass might be dangerous for passers-by. 1. Would it be all right as regards light were I to put the top light inside of the coping? This would, of course, leave a rather large space between the top and side light, but the coping would prevent the snow falling into the street. A single slant might perhaps be all right, as it would be too sloping for the snow to stay on it. The operating-room will be about 15ft. or 16ft. wide. 2. Would this be all right for a single slant light, as I understand this kind of light needs a wider room than the top and side light? By answering these questions you will much oblige.—CANADA.

The sketch does not make the thing at all clear. 1. So far as we can judge from it, we should say that what you suggest doing will be about the best. 2. A single slant would also do for a studio of the width stated, and would appear to offer some advantage in your case.

GOLD CHLORIDE.—We have been making gold chloride from worn-out necklets, and have employed the method mentioned in the issue of September 10. On the first occasion we were successful, but on dissolving an 18-carat gold ring were surprised to find that the gold would not precipitate when the sulphate of iron was added. We have made no mistake in the manipulation, and any information you could give us would be a favour.—A. A.

We cannot account for the gold not precipitating, except by assuming that the ring was not gold at all, particularly as you get on all right with other old gold. You might try diluting the solution more before adding the sulphate of iron.

RESIDUES.—Can ammonium sulphide be used instead of potass. sulphide in precipitating silver from used hypo baths, and does it make any difference to the value of the precipitate? I have plenty of the former in hand, and should like to use it up in this way if possible.—A. E. J.

Yes, it may be used, but care must be taken not to use more than is necessary to precipitate the silver, or some of the sulphide may be re-dissolved and thereby lost. There is no difference in the value of the precipitate, but you are more likely to lose silver when using the ammonia sulphide.

STUDIO QUERY.—I am building a studio, 35 x 20. (1) What height ought the walls to be? (2) What height to ridge? (3) How many feet of glass would you advise? (4) It is facing the west. Do you consider this a drawback?—SCOT.

(1) By walls we presume you mean the side lights, in which case 7ft. 6in. or 8ft. (2) About 15ft. (3) About 6ft. at either end may be opaque. 12ft. or 13ft. of glass will be sufficient. (4) No. Not if you have a good arrangement of blinds or curtains. A west light requires a little more skill in lighting the sitters than does a north one.

CORRUGATED WRAPPERS.—Could you, through the JOURNAL, give me names of manufacturers who supply corrugated paper and boards, also postal tubes for packing enlargements? I hear there is a firm supplying packing boards same as those used in some tea chests—three layers of wood put at cross grains. Being very light, should think them the best medium for big enlargements. Address would be appreciated.—O. B.

Try Corruganza Manufacturing Co., Summers Town, S.W., Eburite Paper Co., Dane Street, High Holborn, W.C., but we cannot say whether either supply the particular material you require.

BEAUMONT.—Practically all your queries are answered by referring you to the "Kinematograph Journal," published (1d. weekly) by E. T. Heron and Co., Tottenham Street, London, W.

SPOTS ON NEGATIVE.—The enclosed is a portion of a valued negative by an amateur, pyro-soda, — plate. Can you tell me the cause of the numberless minute spots, yellow by transmitted light, silvery blue by reflected, and give remedy, if any? The negative was made two or three years ago and packed away in box. This is the only one of same batch of plates treated in the same way at the same time on which the spots have appeared.—SPOTTY.

It is impossible to tell you the exact cause of the spots, but

seeing that each shows a series of concentric rings it is evident that it has spread outwards from a central nucleus, which may have been either a speck of chemical dust or a fungus spore. In any case, we fear that no remedy is possible save that of re-touching.

A BUSINESS MATTER.—I should feel glad if you will give me a little advice on the following matter:—A customer brought me an old glass photograph to be copied, so I took it to Mr. ——'s studio to have a half-plate negative made. It was all right when I left it with them. When I go this morning they bring down the original with all the faces rubbed off, and said it was like that when I brought it, and that they could not copy it, and got quite cheeky about it. I told them that they had rubbed it off, and they said it could not be rubbed off at all, but I rubbed a corner and proved it would come off. I asked him what he would do in the matter, and he told me to get off his premises, so I told him I should see further into it; and he said, "Do what you like," so he took the photos out of my hand and told me to sue him, he would keep the original for evidence. What would you advise me to do? I have had dozens of negatives made here before and they have been all right. It is the only photo my customer has, the person himself being dead, which, of course, makes it valuable, beside me losing my order.—T. CHICK.

Evidently the picture has been ruined by being carelessly handled by somebody. Your only remedy is to sue Mr. —— in the County Court for its value and the damages you have sustained by the loss of the order. These old pictures should not be entrusted to people who do not understand them. In such hands they frequently come to grief. We do not answer queries by post.

VALUE OF GOODWILL.—Will you kindly inform us, through your journal, what is the usual means of determining the goodwill value of a photographic business?—E. ROFF.

The value of the goodwill of a photographic business is generally based upon the net annual profits, whatever they may be. About from two to three years, according to the length of lease and the opposition there may be in the neighbourhood. These are important factors in the valuation of a business.

DAGUERRETYPE.—Would you kindly give me, through the medium of the BRITISH JOURNAL OF PHOTOGRAPHY, some idea of the working of the process known as "Daguerreotype"; also, could you let me know of a book dealing with same?—T. W.

In the Daguerreotype process a silver, or silvered copper, plate is exposed to iodine vapour in admixture with bromine, and a film of sensitive iodide and bromide formed on the surface. The plate is exposed in the camera in this state, and the latent image developed by exposing the plate in a box to the vapour of mercury. There is no modern handbook to the process since it ceased to be used commercially about the year 1860. Any text book of photography of about that period will give you full working instructions. If you cannot pick up one locally you had better try E. George and Sons, 151, Whitechapel Road, E.

COPYRIGHT.—A orders and pays for some photographs of his child to B, a local photographer. B sells the negative after without permission, to C, a postcard publishing firm, who reproduce it on coloured postcards. Postcards are on sale, photo is not yet registered. What can A do to claim his rights?—A. G. W.

He can at once register his copyright in the photograph, when he can stop any further use of the negative, i.e., prevent reproductions of the photograph being made in any form. It is probable also that he might be justified in taking action against the photographer for breach of contract. The latter had no right to sell the negative.

AMYL ACETATE.—I have occasion to make constant use of celluloid varnish, and I find that the smell of the amyl acetate becomes very nauseating. I have been told that there is a method by which this smell may be, if not altogether removed, considerably reduced without injury to the qualities of the amyl acetate. Can you enlighten me upon the matter? If so I shall be grateful.—VARNISHER.

If you purchase a highly purified form of amyl acetate you will find very much less odour, but the solvent will still have, of course, its characteristic smell of essence of Jargonelle pear.

SCOTS WHA HAE.—The address of Messrs. Holmes Bros. is 41, Oxford Street, Manchester.

FADED PRINT.—Would you please give me formula and directions for restoring faded albumen print?—C. J.

There is no really successful way of restoring a faded albumen print. If you put the print in a weak solution of bichloride of mercury that will remove the yellowness, but it will not restore any detail that has faded away. Still, it will improve the picture somewhat.

PUZZLED.—We should say the card is printed on bromide or gas-light paper at the same time as the lettering, the two being made up together on the one negative. This is done by the method given at the foot of page 791 in the "Almanac."

GRATEFUL.—1. A north-east light is a very good one to work with, and we see no objection to it. 2. The length of the main building will do, but we would suggest that the extension be 8ft. instead of 6ft., for the convenience in working. The extension may be at either end, but preferably the more easterly. 3. We are surprised that the lens you have, if it is by the maker named, does not fulfil your requirements both for cabinet and 1/1 portraits. All the lenses in the list you send are good, but you must not expect any cabinet lens to cover a whole plate. The last name on it might possibly do so, but any lens of 10 $\frac{3}{4}$ in. focus, although it may cover the size, will not yield pleasing perspective if used for whole-plate portraits.

BOOKER AND SULLIVAN, of 67 and 69, Chancery Lane, W.C. engineering and commercial photographers, have opened a branch for portraiture. For this purpose they have taken premises at 58, Pall Mall, S.W., exactly opposite Marlborough House, where sittings will be under the direct supervision of one of the partners.

THE LINKED RING AT HOME.—That most delightful of photographic functions, the conversazione held by the members of the Linked Ring during the season of the Photographic Salon, took place on Tuesday evening last in the Gallery of the Society of Painters in Water Colours. Mr. Craigie, in welcoming the guests explained that during the period of the 1908 Salon the presence in the gallery of the Autochrome stands did not leave space for the holding of the usual conversazione, but the Linked Ring welcomed its guests still more heartily after a year's enforced absence. As a company of *entrepreneurs* the Linked Ring proved again worthy of its traditions. The singing, piano-playing, and "other performances," included contributions from Mr. Walter Emanuel, Geoffrey L'Epine, Walter Churcher, whose "Commercial Value of Art" never seems to lose its freshness, Mr. Fred Rome, Charles Pond, and a vocal trio consisting of Messrs. Reginald Craigie, H. R. Elkin, and W. A. Vincent, not to mention the admirable sleight-of-hand of Dr. Byrd-Page. A late hour arrived when, on behalf of the visitors, Mr. J. C. S. Mumby proposed a hearty vote of thanks to the members of the Linked Ring for their hospitality. Mr. Craigie and Mr. Alex. Keightley, in responding, expressed the pleasure which the members feel in having their guests with them. A further vote of thanks to those who had contributed to the evening's entertainment, followed by the singing of "Auld Lang Syne," brought still another Smoker to its close.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

Mr. Bernard Shaw is announced to "improvise on the subject of photography" at the Photographic Salon, 5A, Pall Mall East, on Monday evening next, at 8 p.m.

The things—such as money and reputation—to be gained or lost by resorting to the coupon system of obtaining business are dealt with in an article by Mr. L. Haweis, the first portion of which appears on page 797.

Some of the points of contention between masters and apprentices are the subject of an editorial article on page 796, in which is pointed out the advantage of training in a technical school as a supplement to practice in a business establishment.

In a recent lengthy address before the Museums' Association Sir Martin Conway laid stress upon the extent to which the collection of photographs is neglected. Collections of photographs fully covering a given branch of knowledge would be of inestimable value to students, but little interest in work of this kind can be discovered among either private collectors or public institutions. (P. 799.)

It is hoped that the new Camera Club will be opened in the West-end of London early in the New Year. (P. 793.)

In an article on page 795 directions are given for the most readily applied methods of restoring engravings. Work such as this, which is sometimes pressed upon the photographer, should not be undertaken until after some experience with worthless originals.

A patented method of securing grain in photo-engraved plates, the protection of the eyes from arc-light, the conditions necessary for successful collotype work, are some of the topics treated under "Photo-Mechanical Notes," on page 804.

An unsuspected cause of pinholes on films exposed in a camera of the folding focal-plane type is the subject of an editorial note on page 794.

Those taking up the use of roll-film should bear in mind that most operations, such as development, bleaching, etc., need to be somewhat longer than when employing glass plates. (P. 794.)

In using Canada balsam for cementing lenses, prisms, or other glass apparatus, dry heat for a short period will produce a firm joint, where long standing, at the ordinary temperature would be insufficient. (P. 794.)

EX CATHEDRA.

Work-Room Benches.

Much better work would be done in many establishments if a little more attention were given to the work benches. Too often any dirty corner is considered good enough for making bromide prints or mounting them, or for toning P.O.P. The soft wood of a table top or a bench becomes impregnated with various solutions, and efflorescence is quite common as the wood dries. This may be prevented in various ways. A bench top of hard wood, such as mahogany, teak or oak, into which boiled oil is frequently rubbed, is, of course, excellent, but at the same time somewhat expensive to provide and requiring constant oiling if to be kept in good order. When the bench is made of good clean deal boards and is quite level an excellent covering material is to be found in a hard linoleum. The soft varieties of this substance, somewhat akin to cork carpet, are not of any use, but a stout, hard, well-seasoned linoleum costing three or four shillings a yard should be chosen. It is easy to obtain this sort of thing in pieces quite large enough at the annual sale in a good furnishing warehouse, and such remnants are usually well seasoned. The inlaid Greenwich linoleum is usually very hard, though a plain brown or green looks better. It should be tacked down all round the edges with gimp pins, and can be wiped over with a cloth and left perfectly clean in a moment.

* * *

A Camera Club for London.

Very little having been heard of late as to the steps which are being taken to refound a camera club in the West End of London, attention may be drawn to the announcement made by Mr. Craigie last week at the Salon smoker that premises for the club are being secured in that still unspoiled corner of Old London, John Street, Adelphi, near to the house of the Society of Arts. Those who have the arrangements in hand hope that the club will be opened early in the New Year. We have no precise details before us as to the facilities which will be at the disposal of members, but we have no doubt that intending members will receive all the facts available on application to Mr. Reginald Craigie, at 5A, Pall Mall East.

* * *

Spots on Prints.

From time to time we have sent us batches of prints which are more or less covered with spots, and we are asked to say whether the fault is with the paper or the mounts. As a matter of fact, it most usually is with the manipulation, but it is not a very simple matter to say decisively when the carelessness has occurred. Some of these spots are white, bleached spots, while others are reddish-brown, brown, or nearly black. In cases where the bleached spots occur they will be found as a rule on silver prints only, that is on prints in which the image is formed by the use of silver salts, such

as-P.O.P., platinum toned C.C., and, of course, bromide and gaslight prints. Such spots are often traceable to dust from coke stoves, the ashes of the stove being raked out in the morning before the prints, mounted possibly the night before, have become quite dry. During the autumn the nights are often misty and the atmosphere laden with moisture, and drying is slow. Slow drying alone is sufficient to produce spots on C.C. prints, and after mounting such prints should be dried as quickly as possible—say within a couple of hours. The brown or reddish-brown spots may occur on any kind of print, and are undoubtedly due to minute particles of a developing salt, particularly amidol, settling on the damp prints. Chemicals should never be weighed out in the room in which prints are manipulated.

* * *

Stock Solutions.

The use of stock solutions as a method of saving labour and ensuring rapid work is not so largely adopted as it might be in the majority of businesses. Take, for instance, such substances as alum, hypo, and potassium oxalate, used extensively in the carbon, silver and platinum printing processes, and consider the usual method of preparing the solutions. A handful of the salt is taken and placed in a dish, into which a pint or so of water is poured. The dish is rocked until solution is complete, or nearly complete. Time is wasted, the strength of the solution is inexact, and, in the case of hypo, the temperature of the solution is too low for satisfactory fixation. Large stoneware jars may be obtained for at most a few pence, and in many cases are already to hand, having arrived with carbonate or sulphite of sodium in them. One of these jars holding a gallon or a couple of gallons may be filled up with the solution, saturated, or almost 10 per cent. strength in the case of alum, 25 per cent. strength for hypo, and 25 per cent. for potassium oxalate. The jar should be closed with a sound bung covered with parchmented paper. These stock solutions may be prepared at odd moments, as opportunity offers, and are always ready for use. Labels will, of course, be attached, and they may be sized with gelatine and varnished with oil varnish so that they will not drop off if the jars are stood in a damp corner.

* * *

Pseudo Daguerreotypes.

Among the numerous questions which are addressed to us we sometimes receive one that we find it impossible to answer, and that barely admits even the suggestion of a possibility. A week or two ago we had such a query that we had to give up, after consulting several experts. An Englishman travelling in Germany handed some exposures on ordinary fast dry plates to a German photographer, for the purpose of development, and, much to his surprise, he received back what were to all appearances a set of Daguerreotype positives on glass. Seen by reflected light, the effect was as nearly as possible that of a Daguerreotype, the high-lights being represented by pure white silver and the shadows by a highly polished black reflecting surface. By transmitted light only a mess of green and red stains was visible, and the plates were quite useless for printing purposes. The question was, what had the German photographer done with them? The negatives baffled us completely at the time, but since then we have been experimenting with a method of combined development and fixation, and several times noticed an effect somewhat similar to that produced by the German, but only on the margins of the plates. In these experiments this effect disappeared on applying a supplementary fixing-bath, so it at once occurred to us that it might be as well to try the effect of plain hypo on the pseudo Daguerreotypes. We had one put into an ordinary fixing-bath, and very soon afterwards a quite ordinary but very much under-

exposed negative was taken out of it. The bright silver and the red stain, and all the rest of the mysterious effects, had disappeared completely, and the inference was that the German photographer had also been experimenting with a combined developer and fixer upon the exposed plates supplied by his customer. The fact that such a thing has presumably been done will doubtless serve as a warning to other travellers. One striking feature of the results was the enormous amount of detail shown by the pseudo Daguerreotypes in places where the cleaned negative shows practically no detail at all.

* * *

Films v. Plates.

Though the modern film is of such fine quality that just as good results can be obtained with it as with plates, yet there is still much prejudice against it in some quarters. Many try it once or twice, and because the results are unsatisfactory they reject films altogether. It is, of course, undeniable that a glass negative is a more convenient thing to handle still, films have so many advantages that it is a pity they should be condemned without due reason. We believe that the sole cause of the trouble many find in dealing with them is the fact that, for some not very obvious reason, they yield more slowly to chemical treatment than do plates. They take longer to develop, and very much longer to bleach and re-develop, hence many spoil them by under-development, and afterwards fail in the endeavour to intensify them. We have had scores of films sent to us that, according to the owners, would neither bleach nor intensify, and yet they invariably yielded in our hands. We have known films to take ten minutes to bleach when a plate yielded in a minute, but we have never known one that would not yield to the same treatment as a plate if given sufficient time. In reduction this slowness of action is also very marked, and in that operation it is a very considerable advantage, as it is not so easy to spoil the result by over-reduction. Why films should yield to various solutions more slowly than plates is not apparent, but if the fact be recognised half the troubles so often met with will disappear.

* * *

Pinholes and Film Packs.

It is not infrequently alleged that exposures made with film packs show a quite superfluous crop of pinholes. We met with the same trouble ourselves when we first made use of the film pack, but in our case the cause was very speedily apparent. All the trouble was due to the fact that we used a folding camera, and sometimes closed the camera before inserting the shutter of the pack adapter. As nothing could touch the film and the camera was perfectly light tight, it did not at first seem to be of any great moment whether we replaced the shutter after each exposure or not, but then the mere act of opening or closing the camera creates a great air disturbance inside it, and stirs up every particle of dust inside. On adopting the precaution of replacing the shutter after each exposure, the trouble ceased, and this fact leads us to suggest that a hinged shutter that cannot be drawn completely out would be somewhat of an advantage with film packs. It is less trouble to replace than the loose shutter, while the fact that it is a little in the way of the hands when changing films will induce the habit of replacing it every time.

* * *

Cementing with Balsam.

A little time ago we had the task of fitting up a piece of apparatus which required the inclusion of a train of right angled prisms cemented together. After a good many failures, we succeeded in accomplishing the task perfectly, but we found quite a number of methods of spoiling the result before success was attained. Our previous exper-

ence of balsaming was confined to the preparation of microscopical objects, and when we attempted the cementing of several heavy prisms we found the conditions very different. A good many people seem to have the idea that if two pieces of glass are placed together with balsam between and left under pressure they will in course of time become firmly cemented. Possibly they may do so if the time is long enough; but generally we are not prepared to wait for months before attempting to handle the combination, and in our case we found a month under pressure quite useless. It is absolutely necessary to set the balsam with the aid of heat, and the trouble is that the surfaces are apt to slip when the heat is applied if the pressure is not exactly uniform, while beautiful fern patterns appear as the result of the slipping. Further than this, there is danger of over-heating the balsam and turning it yellow, while in some cases the glasses may crack. Our method was to apply plain balsam softened by heat to the warmed and well-cleaned glass surfaces. We then clamped the whole together and placed it in a cold-air oven, the temperature of which was then slowly raised to 200 deg. F., at which temperature it was kept for an hour. The gas was then turned out and the oven allowed to slowly cool down. When cold, the prisms were found to be quite rigidly cemented together, and the whole combination would stand any amount of rough handling. The same method can be applied to lenses, which are somewhat easier to deal with, as they can be more readily clamped together by simply winding with string. Prisms require to be enclosed in a frame made to shape, and arranged to bring pressure to bear in several directions, so as to avoid all tendency to slip. Failure is generally due in the case of prisms to uneven pressure, and it is advisable to equalise it on the different surfaces with soft pads of thick paper. When finished, all superfluous balsam that has exuded from the edges is cleaned off with a pad of cotton wool dipped in purified (not methylated) spirit, awkward corners being cleaned out with a brush used instead of the wool.

* * *

On the Titles of Photographs. A writer in the "Globe" draws attention to the absurd titles that many photographers attach to their efforts, quoting as examples a picture of a yacht on the port tack which was labelled "On the starboard tack," and a sea-beach scene called "On the sands at Brighton"! These are somewhat outrageous examples of blundering, but many photographers are trapped in much more subtle ways. For instance, many, labouring under some strange delusion, persist in naming an obvious figure study as "Spring" or "Summer," or perhaps "Ceres" or "Apollo," according to the sex, but quite regardless of the application. Somehow it is often forgotten that the title of a picture when once adopted becomes part of the picture, which must live up to it to satisfy the observer. If there is any trace of a ridiculous incongruity that picture is spoilt completely. Another blunder that is frequently seen nowadays is the labelling of photographs as "decorative." We meet with "decorative portrait" or "Decorative landscape" only too often, but never by any chance is the decorative quality very apparent. How the principles of decorative art can be observed in photography is somewhat of a mystery, and it has not yet been solved by the efforts we have seen. The use of the expression "decorative" only serves to draw attention to the decorative deficiencies of the result, and surely it is safest to leave the discovery of defects to the critic, and not necessary to point them out in the title.

* * *

Blackening Brass. The paper on "The Surface Protection of Metals," by Mr. H. S. Ryland, which was reprinted in our last issue, gave some useful formulæ for blackening metals, but it omitted one for brass that is

very commonly used for photographic apparatus, and can be carried out with perfect ease by the amateur workman. It is the one we invariably employ, but it must be admitted that it only gives a black finish, not a dead black surface. Still, it minimises reflections, and also renders the outside camera fittings very inconspicuous. The first operation is to clean the brass very thoroughly with a smooth file or with fine emery or glass paper. Scraping with a knife is also effectual, and if carefully done gives a nice finish. When clean, the metal must not be touched by the fingers, but be held with a piece of wire or pliers. It is then made hot over a Bunsen burner or any smokeless flame, and when too hot to touch is immersed suddenly in a saturated solution of copper nitrate that has been made distinctly acid by the addition of nitric acid. This, of course, rapidly cools it, and when cold it is taken out of the solution, and the superfluous liquid allowed to drain off. It is then heated again over the flame, when it rapidly turns to a bright green colour. The heating is continued until this green changes to a very dead black, which appears in the form of a powder dusted over the surface. As a rule, it is desirable at this stage to repeat the process, and when for the second time the black stage is reached we can proceed to finish it off. This finishing consists simply of a vigorous brushing with an old toothbrush which has first been lightly rubbed on a cake of blacklead. We soon arrive at a black, smooth finish, with only a very slight trace of polish. The article may be left like this, or we can, of course, apply a lacquer if desired, but for outside fittings we prefer to give no more polish than results from a brisk rubbing with a slightly oily rag. This finish will last a long time, and stand a great deal of wear, while it always looks well.

CLEANING OR RESTORING ENGRAVINGS:

PROFESSIONAL photographers are frequently called upon to copy old engravings. In many instances these old prints are in a very dirty and discoloured condition; often they are spotted with mildew through, perhaps, hanging for a lengthened period against a damp wall. Of course, when in this state it is difficult, or impossible, to obtain satisfactory reproductions, and we have had inquiries from time to time as to the means by which the stains can be removed or the print restored. The advice usually given has been that the work of restoration should be handed over to one who is an expert in restoring paintings and engravings. This advice we again repeat, particularly when the engraving is a valuable one, as it may be utterly spoilt in the hands of a novice. Nevertheless, we will here give a few of the methods employed in restoring engravings. In the first place, it may be explained that many of the plate papers on which engravings are printed are very much like blotting-paper when they are saturated with water, and are almost as tender to handle. It may also be mentioned that when the impression is on an India paper, the print will probably come away from the plate paper during the operations, because it is not really cemented to it; and when it is off it is equally as tender to deal with as the plate paper.

Before, however, saying anything with reference to the methods of bleaching prints we may mention that in some instances a great deal may be done in the way of cleaning without wetting the print at all. We are speaking of mere surface dirt. In this case the print is carefully dusted with a brush, and is then rubbed over lightly with a piece of the crumb of stale bread, or a piece of clean india-rubber. Care must be taken to remove all dust before using the bread or rubber, otherwise the dust will be rubbed into the paper, and perhaps make matters worse.

than they were before. In using either the rubber or the bread, it should be applied lightly, so as not to raise the fibre of the paper more than can be helped.

As all methods of chemically cleaning prints depend upon the bleaching action of chlorine, it follows that the process has a tendency to soften the paper, hence great care must be taken in handling the print while it is in a wet condition. The following is one method of restoring engravings:—The print is put into a shallow dish and water poured over it until it is thoroughly saturated. The water is then poured off and a much-diluted solution of chloride of lime poured on. The formula for this is:—

Chlorinated lime (bleaching powder)...	1 part.
Distilled water	10 parts.

After trituration shake well in a bottle during three hours, then strain. Of this liquor, one part is added to thirty-nine of water. Usually the stains, unless very bad, will disappear in this preparation in a very short time. If they do not, the undiluted liquor is poured on. If the stains are very obstinate and do not yield, a few drops of very dilute nitro-hydrochloric acid are added. There are no stains that will not succumb to this treatment. As soon as the print is clean, it must be carefully washed with successive changes of water to get rid of the chlorine, for it goes without saying that if any remained it would eventually rot the paper. The print is now placed in a very weak solution of isinglass and dried between blotting-paper. This will strengthen the paper. When dry, the print is ironed with an ordinary laundry-iron with a piece of smooth paper between the iron and the print. This will restore the gloss of the paper.

Another method, which we may quote from "Cooley's Cyclopædia of Practical Recipes," is as follows:—Place the engraving on a smooth board, and cover it with finely powdered and very clean salt. Next squeeze lemon juice upon the salt so as to dissolve a considerable proportion of it. Now elevate one end of the board, so that it may form an angle of 45 or 50 degrees. Next pour on the engraving boiling water from a kettle until all the salt and lemon juice are washed off. The engraving will then be perfectly clean and free from stains. Care must be taken to dry it on the board or on some smooth, flat surface very gradually.

Still another method that has worked well in our hands is, perhaps, a little simpler than either of the above. It has the further advantage that it has somewhat less tendency to rot the paper, and for this reason it may be the better appeal to some. It is as follows:—The print, after being thoroughly dusted to remove any surface dirt, is put into a photographic dish. Water is then poured in so as to completely saturate the paper. After a few minutes' soaking, the water is closely drained off. Next a dilute solution of hypochlorite of soda is poured into the dish, which is then well rocked. The formula for the solution is:—

Chlorinated lime (bleaching powder) ...	4 oz.
Water	60 oz.
Carbonate of soda	8 oz.
Water	20 oz.

The lime should be mixed with the water and well shaken up in a bottle, and after resting a few hours for the sediment to settle down, the clear portion is decanted off. The solution of carbonate of soda is then added, and will precipitate the carbonate of lime formed, leaving the hypochlorite of soda in solution. This latter is then filtered for use. One part of this solution is diluted with three or four parts of water. At this strength the stains, unless very bad, will disappear within a short time. If they

do not, more of the stock solution must be added, and in very bad cases it may be used without dilution. If they do not then go, a little of a solution of oxalic acid may be added, but that is seldom required. The print must then be well washed. As just said, no trace of the chlorine must be left in the paper. If the paper is too tender to bear much washing, a very dilute solution of hyposulphite of soda may be used as an anti-chlor., the print being afterwards rinsed in one or two changes of water. The print is then dried between sheets of clean blotting-paper under pressure to keep it flat.

If the impression itself is on India paper, it will probably have become detached, in which case it must be remounted on the plate paper. This may be done with flour or starch paste, and the prints, when dry, should be rolled or hot-pressed to restore the gloss of the paper. Frequently print restorers mount the restored print on cardboard, and then roll them. After an engraving has been bleached it will be very white, and have lost the slight yellow tint that it had acquired by age—the mellowness so much admired by connoisseurs. When this is the case, it can to an extent be restored by immersing the picture in a weak infusion of coffee, though we hardly imagine that the treatment will be approved by an expert in old prints.

In the case of an engraving damaged by grease stains the latter are not removed by the methods of bleaching above described. They should be got rid of beforehand so that the bleaching agent has free and even action. This is not always an easy matter. Benzole is, perhaps, the best thing to use. The stain is moistened with the benzole, which, after a minute or two's soaking, is blotted off with clean white blotting-paper. This treatment repeated several times, or until all the grease is entirely removed, which may be judged of by looking through the paper before a strong light.

In the foregoing we have described the methods more generally employed in cleaning or restoring discoloured or stained engravings; but we would, in conclusion, add a word of caution to those who attempt to carry them out for the first time, which is that before doing so they should experiment with some prints of no value until some proficiency has been acquired in the work; otherwise they may, possibly, irretrievably ruin a valuable engraving. Old prints, suitable for the experiments, are often to be met with at second-hand bookstalls for a mere trifle.

PHOTOGRAPHERS AND APPRENTICESHIP.

FROM time to time we receive letters from irate parents with reference to the alleged indifferent training their sons are receiving at the hands of the professional photographer with whom they have been apprenticed. We also receive letters from irate employers regarding the alleged unreasonable attitude of parents of apprentices. The question is one which is frequently burning, and, like everything else, it is a question which has two sides. Nine out of ten of the difficulties arise out of the failure—which is, unfortunately, a very common one—to settle something of the matter from the other person's standpoint. Thus, on the one hand, the youth's parents expect him to be somewhat indulged because he is an apprentice, and not a paid hand; they expect him to have a day off now and then if he wants a holiday, and at the same time they expect him to make rapid progress in learning his business, and to have special facilities for acquiring the higher branches without going through too much of the drudgery of routine. Boys are not drilled and disciplined at school as they were fifty years ago, and if a boy is an

only son he is often in a parlous state for making his way in the world. It would do many modern boys and their parents good to read the indentures of apprenticeship of sixty or eighty years ago.

On the other hand, the master is usually ready to jump at the chance of getting some cheap labour, and the lump sum down in the shape of a premium is too often an inducement to accept a lad whom his perception tells him is quite unsuitable. In some cases it is to be feared the small premium appears so desirable that it and the apprentice are accepted without any definite thought being given to the fact that a certain amount of work must be done in training the youth, and that the sum fixed is a quite inadequate recompense.

There are two difficulties standing in the way of securing adequate sums as premiums with apprentices. The first is that most people believe that there is nothing to learn in photography. Some young schoolgirl that they know has bought a film camera and has taken some quite beautiful portraits with it, and they hastily assume that what can be done once can be done every time. The professional photographer, in fact, has a grievance against the dealers, manufacturers, and amateur journals, who all set out to prove to the beginner and his or her friends that "it is quite simple." We know it is simple up to a certain point, but the professional who would earn his living by the work must get far beyond that point.

The second difficulty is that the prospects which photography has to offer are not sufficiently good to tempt into the ranks many of the better educated lads, the sons of parents who can afford to pay for adequate training. It would indeed appear that the day of apprenticeship with an adequate premium has gone by, never to return. The fact must be faced, and if apprentices are wanted, boys will have to be taken who will work, and work hard, accepting moderate wages by way of return for their training. By working hard we do not mean working for long hours, and that, unfortunately, is too often the employer's idea of hard work. From 9 to 6 or from 8 to 5 is a day quite long enough for a boy of sixteen or seventeen, with, of course, one half holiday a week. The dinner hour should be from 12 to 1 or from 1 to 2, and the half holiday should commence with the dinner hour and be a full half holiday.

Obviously, when the basis of apprenticeship is such, the

youth cannot expect much definite instruction, though we think he should be taught something more than the printing of P.O.P. or bromide postcards. But at this juncture the technical schools come to the aid of both employer and apprentice. In London and in many of the large towns evening classes are held for workers in the photographic trades, and we have reason to know are highly appreciated by those who have availed themselves of their aid. Such classes are advertised from time to time in our columns, and at this season of the year the various winter sessions are just commencing. It rests with the apprentice to avail himself of the opportunities provided for him; but we take this occasion to urge upon the employer the necessity for his co-operation. Many lads are kept working for much longer hours than those we have mentioned above. While we know that in rushes of business it is sometimes necessary for a little overtime to be worked, we would urge that employers might acquaint themselves with the evenings on which their apprentices—and assistants also—are attending classes, and see that as far as possible they leave business in time to get a comfortable meal and to their class in time and without undue hurry. A little consideration will generally be appreciated, and will have the effect of making the class more helpful to the worker and indirectly of improving the quality and quantity of output.

Some employers, we fear, hold the somewhat narrow view that improvement means sooner or later a demand for increased pay, and so discourage effort. But if a youth is worth his salt he is bound to improve. The point too often lost sight of is that the master's work improves as the employee's ability increases.

A further step in technical instruction is now being taken, for we notice in the current prospectus of the Polytechnic School of Photography, Regent Street, W., that arrangements can be made for apprentices and other assistants to attend the day classes for half a day a week, and it is very justly pointed out by Mr. Howard Farmer that the improvement in their work resulting from systematic instruction will be very marked. Undoubtedly technical instruction supplements in a very satisfactory way ordinary workshop practice, and hand-in-hand the two should be productive of the best type of assistant. We may hope that assistants anxious to take advantage of this instruction will have the help of their employers, who, as we have said, have equally to gain.

THE COUPON SYSTEM AS APPLIED TO PROFESSIONAL PHOTOGRAPHY.

THE coupon or agent system as applied to professional photography is so universally practised nowadays—here* as elsewhere—that the man who owns a skylight is hardly to be found who has not at least a nodding acquaintance of the principles which go to make up this signally modern method of creating trade. Yet how few of us, of even those of us who practise the method systematically, realise the power, for good and ill, they control! Their knowledge is frequently bounded by the condition of their bank-book; the "proof of the pudding," they will tell you, "is in the eating," but although the proverb conveniently ends with the allusion to mastication, the true analogy carries as far as the digestion and general health of the body photographic. No food is proper that necessitates either a violent gnashing of teeth or its assimilation, or results in an unpleasant after-taste. Non hic piscis omnium," this being so, some inquiry into the conditions which the system encourages, or is liable to induce, may bring home to many of us the danger of a practice so easily, so frequently, and so unworthily abused.

The ticket system of business is certainly one into which almost

any amount of double-dealing can be introduced; but it is also true that, conducted properly and responsibly, it has proved itself a boon alike to photographer and customer. But the method, taken as a whole, is one of wheels within wheels, and is complicated with every conceivable variation of the relations existing between photographer, agent, and client. Nor is this quite all, since the stress is not only along the direct line of business, but also laterally through every channel of reception-room substitution and bluff, of misrepresentation and invention on the part of the agent, and on the part of the client of a desire that calls for more than is reasonably legitimate, or of the spirit that prompts the possibility of getting something for nothing. The fraud may be introduced at any point, but the fraud that starts from the studio is rarer than that promulgated by the agent. We know this. But what many of us do not know, and may never know, is "what the agent told the customer."

At the outset it must be clearly understood that the agent system is suitable only for the gallery that wants business. This sounds like a truism; but although the natural assumption is that every studio wants business, or more business, not every

* British Columbia.

studio will accept business at the price entailed by the agent system. So much fraud has been perpetrated in its name that in many quarters the fact that a certain studio was putting out coupons would be quite sufficient to deter a visit to that studio, with or without a coupon. And this is apt to be the case precisely among that class of customer, the great well-to-do middle-class, it is most desirable to attract. The very best people, on the other hand—and who, by the way, are by no means the very best payers—are quite unapproachable by the ordinary house-to-house canvasser; consequently, the gallery they would be likely to patronise may be ruled out of the expediency of such a system by the impossibility of practising it. The servant who opens the door, however, is a real possibility, and probably a far better payer than the mistress who summons him or her by pressing an electric button. Also, the class of business canvassed is generally a cheap one, or one that appears cheap. There are oral as well as optical illusions (of which more anon) practised by the ticket man which not a studio, high or low, in the five continents, is not at times compelled to resort to in the way of business. The receptionist must dance to the tune of the customer, whose demands, if unconscionable and extortionate, must be met with weapons in kind, wielded, of course, with the most polished and diplomatic skill. As long as legitimate bounds are not overstepped no exception can be taken to this. The good receptionist knows these bounds, and will not overstep them. What these bounds are will be more or less succinctly defined by the proprietor of the studio himself, and these bounds will not be overstepped by the employees except at the price of dismissal. But that which binds the hired receptionist and operator does not bind the canvasser for business. His employment is of a different nature. He has neither salary nor supervision, in the ordinary way, nor prestige for curb. His remuneration is made up by his collections; he is out to sell tickets, and, if he chooses, at anyone's cost but his own. And because his responsibility is largely nil, an unscrupulous agent carries with him to every house the good name of your firm, which is less to him than the quarter (*anglice*, shilling) it is his prime object to entice from the pocket of the prospective customer, to whom you, as proprietor of the studio mentioned, will finally have to answer for every phrase which may or may not have been used to your cost or to your advantage.

It may be urged that the agent should not be allowed to collect his salary, that he should be paid a weekly or monthly wage, or be on commission. But hardly any competent agent will accept a commission payable on completion of orders. Also, by the usual system the photographer is not necessarily out of pocket in the event of laziness or sickness. It has also been shown in practice that people who come lightly by coupons rarely, if ever, use them. Gratis coupons offering special terms by paid agents are a failure. The whole virtue of the system is to induce the prospective customer to part with a piece of money he or she will not willingly forgo the value of. If her payment means anything, it means that she wants photographs. Other things equal, that is all the reputable photographer wants; the agent is welcome to the quarter. So it remains for you to employ only agents who will not misrepresent you. This is even more important than that the wording of the coupon the agent carries should be clear and generous. Most purchasers of coupons have neither the time to read, nor the capacity on the spur of the moment to grasp the meaning of the ticket they accept from the agent. No wording unaccompanied by talk will sell a ticket; on the contrary, a clever agent will sell any sort of ticket. Talk sells, money talks. Therefore the agent must be well selected, for he holds you in the hollow of his hand.

Speaking in this way, and arriving in the course of conversation at the above conclusions, I ventured to put the question to a brother:

"Is the agent system really worth the risk?" The reply came quick:

"No, but there must be no risk."

"How do you insure that?" I asked. My American friend smiled all over his shrewd face, and merely remarked that he supposed he had been lucky.

But there is one bond which may bind the agent and photographer, a slender one, but where it exists it is effectual. The agent, after all, has to make a living; he can do his best by working in with photographers in general, and the only recommendations of any value he can carry are letters proclaiming that his services have been faithful and are consequently in demand. It is needless to say that, failing your own inquiries, your own business acumen must inform you on the question of forgery. There is nothing more than this to be said on the choice of a suitable agent. It is "up to" you.

Agents fall conveniently into two classes, those who are out to sell tickets for their own benefit only, and those who will sell as much for the benefit of the studio as for themselves. It is clear that, as their remuneration is dependent on their sale of tickets, to sell with discrimination implies loss of hard cash, to no possible end except their own pecuniary impoverishment and the good opinion of the proprietor of the gallery for whom they are working. It follows also that this latter class is a *rara avis*, and only exists at all owing to its habit of working for the same studios frequently and often at regular intervals. No agent of this class is ever out of work except by choice.

As a matter of fact, not one agent in a thousand sells tickets "on the straight." As talk is his business, trickery enters largely into it. It is so easy to twist a phrase sufficiently to sell a ticket, and leave the studio-man to settle the matter later—by twisting another phrase. Are they not both after the dollars, and has not the photographer more to gain than the agent? Should he not have his share of the talk? The very best agent I ever employed declared that he would not sell a ticket which rendered talk in the studio unnecessary. His reasons were obscure and selfish. He was out to sell tickets, it was not his business to carry reception-room talk afield, and so forth. He also confessed that, after a bad day, he would sell tickets "any old way," to get his fare back or pay an hotel bill. In other words, he would mortgage your good name at the first obstacle in his way rather than suffer any personal inconvenience, deserved or otherwise.

To the making of offers there is no end, but, in spite of this coupons, and the terms they propound, like agents, fall conveniently into two classes, namely, those that cheapen the work of the studio, and those that do not. The following is an instance of a ticket that cheapens:—

TICKET A

GREAT ADVERTISING OFFER
BY THE
REMBRANDT STUDIOS
(ADDRESS).

IN order to introduce to our numerous Patrons the Latest and Most Charming Parisian Style of Portraiture in Photography, we are now offering these Exquisitely Designed Vignettes at a price now within the reach of all. A glance at our specimens will convince that this is

THE GREATEST OFFER EVER ATTEMPTED

consistent with first-class work by any artist, no matter where located,

REGULAR \$6.00 LORD STRATHCONA CABINETS FOR ONLY \$1.75.

By paying my representative 50c., for which this contract is a receipt, and the balance of

ONLY \$1.25 AT STUDIO

we will make the holder hereof

SIX

of our High-grade EMPRESS PHOTOS, same as sample shown by advertiser. Accept our offer, and we will surely do your pictures in future.

No contract sold at Studio. Groups and copies extra.	PRIVILEGE OF EXTENSION ON APPLICATION TO STUDIO ONLY	Good for Ninety Days from Date,1909.
--	--	--

And here is the script of another ticket which does not cheapen:—

TICKET B.

THE
GRANVILLE GALLERY OF PHOTOGRAPHY.
(Address.)

NO CONTRACT SOLD AT STUDIO.	PRICE 50 CENTS. Only 100 of these Certificates Issued.	GROUPS AND COPIES EXTRA.
--------------------------------	--	-----------------------------

Good for Thirty Days from date of Sale 1909
Extension of time on application at Studio.

That we may become thoroughly acquainted, and place a sample of our very best work in your home, we are making this
SPECIAL SPRING OFFER.
Do not miss this exceptional opportunity.
It can never be repeated.
TWO OF OUR BEAUTIFUL LEIGHTON ALLIGATOR AND SPIDER-WEB TISSUED FOLDERS

FREE.	Ordinary Price \$15.00 per doz.	FREE.
-------	---------------------------------	-------

We make this exceptionally handsome and limited offer for the simple reason previously stated, and trust that no one will allow this privilege to pass by as **ONLY ONE CALL WILL BE MADE.**

N.B.—If customer desires full dozen we will make the balance of ten pictures for half price, viz:—\$7.50

PAY OUR REPRESENTATIVE 50 CENTS ONLY.
ONLY ONE TICKET ACCEPTED FROM EACH PERSON.

This Certificate also entitles the holder to a similar reduction on all other high-grade work as shown at Studio.
(Appointments only.)

Now, practically every person solicited by the agent knows perfectly well that neither is the agent out for his health, nor is the photographer a public-minded philanthropist. The assumption is that an increase of business such as these, or any similar sort of ticket, will induce, is going to pay the photographer to do a special line of his work at apparently starvation prices. So what is the trick behind the ticket?

That is the attitude of the generality of customers. In the way of business every coupon put out—such is their unenviable reputation nowadays—is suspect. But it is also a fact that every coupon put out that is a “seller” must be clearly and generously worded. If the terms were strictly adhered to on both sides—that is, if all classes were more than human—no cause for complaint could possibly arise. But it is so easy to juggle the straightest-looking ticket that, provided the customer does not find it out, it is prevalently supposed to be business to ignore the verities.

The mildest instance I can think of in this connection is to mount postcards in substitution for cabinets. There is hardly a client who would believe he had not been cheated “up to the eyes” if the print ever became detached from the mount and so betrayed its character. The customer would be wrong and right at the same time. He would be wrong, as it would be easy to prove that the value of the picture was not in the stock but in the work, where, in fact, it should be. He would be right, because the photographer is not justified in providing his customer with an article which certain circumstances, however unforeseen, would have the effect, however erroneously, of cheapening. At best it would be a fine point to argue, and “there’s the rub.” No business man argues. Argument causes friction, and no known amount of iodide will compensate for friction in the reception room.

This is the obverse of the medal. The reverse is easily illustrated by means of a brief analysis of the two fictitious tickets referred to above.

L. HAWES.

(To be continued.)

SOME PRACTICAL NOTES ABOUT OLD LENSES.

I HAVE noticed of late that many replies have been given in the “Answers to Correspondents column” as to the value of some one or other old form of photographic lens. Frequently the old lenses, with regard to which the questions were put, may really be very good and useful instruments from a practical point of view, although, as has been often remarked, they have little or no market value at the present time. Many people nowadays seem to be under the impression that unless a lens is of the very latest construction—say an anastigmat—it is of little or no use. But if we look back to the time anterior to their introduction we shall see that pictures were taken with the lenses then in use that are every whit as good—whether landscapes, portraits, or anything else—as any taken at the present time.

Old Landscape Lenses.

As one who is quite familiar with all the older forms of lenses a few practical notes on the subject may be of interest to those who may have some of the earlier ones in their possession, or may, possibly, become purchasers of them, for they are often to be met with for a very small figure. For example, a friend of mine, a year or two ago, bought an old “A Ross” landscape lens of about 3½in. diameter and 18in. focus, for something under half a sovereign. The mount was very shabby, it is true, but the lens itself was all right. It was probably made in the early fifties. Now there is no lens now made that is so good for pure landscape work as this very early form—it is far superior to the half of a R.R. lens, which is often used for this class of work, inasmuch as it will work with a larger aper-

ture than the latter. The only thing against it is that it is somewhat cumbersome. As issued by the maker the largest aperture is about *f*/15, but if that be opened out to *f*/11—or even a little larger—it will still give fairly good definition, and it then becomes a useful tool for outdoor groups.

An old form of lens that is now and then seen in pawnbrokers’ windows is the orthoscopic, orthographic, or caloscopic. These are practically the same though under different names. This form of lens was introduced by Voigtländer more than fifty years ago, and a useful lens it is to-day for some purposes. It has a fairly flat field and even illumination. Its aperture is about *f*/10 or *f*/12, and with that it gives a sharp image over a tolerably large field. There is one property of the orthoscopic lens which it may be well to mention here: it gives a larger image with less extension of the camera than other lenses inasmuch as the back combination is a dispersive one; in fact, this instrument is a weak telephotographic lens.

The Dallmeyer triplet lens is another instrument that is often to be met with at a low price, and an exceedingly good one it is, particularly for copying purposes. It is also a useful one for such things as outdoor groups and the like. It gives very fine definition over a moderately large field with the full opening, which is about *f*/10, so that it is not a very slow lens, though a little slower than the R.R.

Early Portrait Lenses.

In the above notes I have dealt with the principal forms of lenses that are sometimes to be bought for a small sum. Although they are now looked upon as obsolete ones they are

still very useful things in the hands of the practical photographer. I now come to the portrait lens, to which I have noticed so many queries have applied. It does not follow that because a portrait lens may have been made forty or more years ago that it is not really a useful lens for portraits at the present time, though it may not be equal to those of more modern construction. Many of these old lenses have a chemical focus; indeed, all the earliest ones of Voigtländer were of this type, and most of the early portrait lenses of the Continental makers were more or less exact copies of Voigtländer's. They also do not work to focus. As an instance, I call to mind that some time after the C.D.V. picture became the fashionable portrait, I bought, secondhand, a bi-lens camera of the half-plate size, fitted with a pair of quarter-plate lenses of French make. I tried the apparatus before purchasing by taking some portraits with it, and found the lenses excellent ones. I worked with the apparatus for many months before I found—and then only by accident—that the lenses did not work to focus. Then I discovered that the glass of the focussing screen had been set out of register with the dark slide to the exact distance between the chemical and visual foci of the lenses. This case is merely quoted to show that lenses that do not work to focus may be excellent ones if the necessary allowance be made for that, and when the conditions of work remain the same.

Most of the old portrait lenses that did not work to focus had a scale engraved on the sliding tube of the mount, which showed the distance it had to be racked out after the image had been sharply focussed on the screen. When a lens is seen with such a scale on the mount it may at once be taken for granted that it does not work to focus.

If one comes across one of the old portrait lenses bearing such names as Lerebours et Secretan, Jamin, Maugey, Hermagis, and the like, it may fairly be assumed that they are tolerably good instruments for the time they were made, as these opticians were the leading ones in Paris at that period. Many of the early French lenses bear the names of English dealers,

but they are French all the same. As a rule they are not free from spherical aberration, hence with the full aperture they do not give microscopical definition, and for that reason they are frequently said to possess great "depth of focus," which makes them very useful tools for portraiture. There is, however, one thing against them that it may be as well to refer to; they usually have a much rounder field than have modern portrait lenses, therefore they will not give the head, feet, and centre of a standing figure so sharp as the latter does. This disadvantage, it is true, may, however, to a great extent be remedied by stopping down. Flatness of field, it may be mentioned, was not the desideratum when these early lenses were made that it is now, for until the C.D.V. picture was introduced full-length portraits were seldom taken.

Sometimes if these ancient lenses have a diameter of three and a quarter inches they are advertised as cabinet lenses, but from what has just been said they really are not, and, therefore, should not be classed as such, as they will not take a full-length portrait sharp in all parts without considerable stopping down.

In conclusion, I may say that it does not follow that a theoretically perfect lens is necessarily the best photographic tool. That is evidenced by the patent portrait lens of Dallmeyer. This lens, when in its normal state, is as perfect, theoretically, as it is possible to make a portrait lens of large aperture. But when a certain degree of diffusion of focus—i.e., spherical aberration, is introduced (for doing which there is now a most convenient device) it becomes a more generally useful tool, though theoretically it is a less perfect optical instrument. Although I have said above that many of the early lenses that are often to be met with for a "mere song" may be exceedingly useful ones in practice, I would counsel everyone not to buy one without previously trying the lens for the purposes for which it is to be employed, for there is not the same general uniformity in them that there is in lenses of the present-day construction.

WM. MICHELL.

ON GENERAL AND LOCAL PHOTOGRAPHS IN MUSEUMS.

(A Paper by Sir Martin Conway, M.A., read at the Maidstone Conference of the Museums Association.)

WHY not collect photographs? The question might provoke a retort, why collect anything? But as a matter of experience we know that there are many people who must collect—people who are born collectors, and who for the most part begin by gathering postage stamps. Indeed, a few years ago the postage stamp collector might have been called a type of a class; nowadays, however, people collect all sorts of things, as magazines published in their interest amply demonstrate. They collect buttons, tobacco pipes, the shoes and gloves of celebrities, and so on up to snuff boxes, ancient manuscripts, and, finally, pictures. And in so doing they follow some natural instinct, as deep perhaps as that which leads a dog to bury bones, or a jackdaw to assemble all kinds of miscellaneous objects for no apparent purpose. The instinct of collection being then admitted as part of the natural equipment of many persons, it is evident that it may be either usefully or uselessly employed. But to collect any given kind of object is not a thing that can be undertaken without some sort of apparatus and the co-operation of other people. The reason why so many collect postage stamps is because the apparatus for collecting is so elaborate and so efficient. It is not that the objects themselves are of any special interest that attracts the collector, but it is rather because his hobby, once adopted, forms a link between him and numerous other persons already interested in the matter, and because he finds ready to his hand suitable collecting books and an entire literature devoted to the subject, journals that appear periodically relating to it, catalogues provided by dealers with prices current, auction sales at repeated intervals, and yet more perhaps because his collection, of whatever size or character it may have assumed, always possesses some market value, so that the money

spent upon it is not absolutely thrown away at any time the hobby ceases to attract him.

The Difficulties of the Collector.

But if instead of collecting postage stamps a man were to select, let me say, playing cards, he would find no such assistance prepared for him. He would have to do all the work of collection himself. New cards he could, of course, easily buy, but supposing, for instance, that he wished to represent all the kinds of cards supplied to passengers by the various shipping companies of the world, with the names and devices of the companies on their backs, there is no shop to which he could go to purchase them, there is no list that would enable him at once to discover what companies issued such cards, and what did not; there are no blank books ready printed for him to gum the cards into; there is no periodical publication that would announce to him the appearance of new issues; and, in fact, the whole work of the collection would have to be done by the man in question for himself. Obviously under such conditions the collection would advance slowly, and there would be no means of telling how far it was complete or whether the particular objects it contained were common or rare, whilst the hobby would be a purely personal one, probably shared in by no one else, the cost of making the collection would be relatively large, and the value of the collection when made would be almost nothing. Hence, if the assembling of any kind of object is to be made the purpose of a collector's energies, what he will first desire is, not to stand alone as a collector of that kind of object—he will want to be one of several, one of a sufficiently large clientèle to be worth catering for by some trade organisation

competition must necessarily arise under those conditions, and prices consequently advance, but, nevertheless, each individual collector will profit by the fact that his collection will thus have a value which, if no competition existed, it would not have.

The Interest and Value of Collections.

It will perhaps be admitted that there is a greater intrinsic interest in some kinds of collectable things than in other kinds. The intrinsic interest, for instance, of autographs is certainly greater than that of postage stamps. The intrinsic interest of pictures is greater than that of autographs. Tobacco pipes can scarcely be claimed as very interesting objects in themselves, however much an assembling of them together may result in a certain interest attaching to the collection. I claim that the intrinsic interest of a collection of photographs may obviously be very great. Of course, a collection is not the same thing as a mere multiplication of objects of a certain sort. Five thousand different postage stamps loose in a bag is not a collection of postage stamps; it is only when they are sorted, identified, geographically distributed, chronologically arranged, that they become a collection or are worthy of attention. It is the same thing with photographs. To sweep together five or ten thousand photographs of all sorts and kinds, place them in any order into a set of books with their subjects unidentified, their dates unknown, would not be to collect photographs. The output of photographs at the present day is enormous, and for the most part the prints made in any one year have become scattered and for the most part destroyed in the course of the following decade. The result is that records of priceless value are being lost almost as rapidly as they are made. It is certain, for instance, that photographs were taken of the great herds of bison that not so long ago ranged over the American prairies, but so far as I can discover not one of these photographs is preserved in any of the institutions where one might expect to find it. The herds have disappeared, and nothing but the literary record of them seems to have remained. Again, the great buildings of Paris were no doubt photographed before 1871, in which year many of them were destroyed and others terribly mutilated; yet you may search Paris all over and, as far as I have been able to discover, you will not find any photographs offered for sale representing the façade of Notre Dame and the splendid sculptures upon it in their unutilized condition. The ancient cathedrals of France have suffered a terrible injury of recent years at the hands of so-called restorers. Probably all of them were photographed before their respective restorations, yet it is the photographs of the restored buildings that are offered for sale, and it is almost impossible to obtain copies of negatives made before the restorations. A single individual can do but little in the way of hunting up negatives of past date. I myself spent a couple of days in Perigueux trying to acquire photographs of the church of St. Front before its recent practical rebuilding, but what I could accomplish was the discovery that negatives do, in fact, exist, or recently existed, but that where they were was doubtful, and that the ordinary travelling public was only supplied with photographs of the new building and asked for no other. Now if photographs were systematically collected by any considerable number of people, it would be the business of someone to hunt up such negatives of former days, or at least to find old prints and produce them as well as possible, and he would make a living by so doing. Dealers' catalogues would indicate where such prints might be purchased, and a collector of architectural photographs would find the path smoothed for him. No one, of course, could collect photographs of all sorts and kinds. He would have to select one class of subject and confine himself more or less exclusively to that. Of late years natural history subjects have been photographed with extraordinary success; birds on their nests, tigers in the forests, and wild life generally in its undisturbed surroundings. What could be more interesting than a properly classified collection of such representations of the animal world? What could be more stimulating to a youngster than to begin his collecting career with the images of live animals of all countries and climates, and how much more valuable information he would derive in making such a collection would be than that which is yielded by a collection of postage stamps. Of course, where a boy now obtains thousands of postage stamps, his collection of animal photographs would scarcely number hundreds, and these things are not costly to buy if they are bought as opportunity arises; they can be cut out of magazines sometimes by dozens, and out of the illustrated papers; they are found in the catalogues

of zoological gardens, and they are often purchasable for small sums at the ordinary photographers' shops. As scattered sheets they have little value; but once arranged in an orderly fashion, different kinds of animals properly grouped together, divided from one another, a collection of that sort would immediately derive great interest.

Collections of Various Subjects.

What is true of animals is true also of scenery. How many thousands of photographs of modern scenery, for instance, exist? For the most part people buy them as a kind of illustration of their own lives—places they have been in, views they have beheld, mountains they have climbed. But it would be easy and at least interesting to collect types of mountain scenery representative of the material, for instance, of which the mountains are built—granite mountains, sandstone mountains, and the like. Or the mountains of different parts of the world, manifesting the different effects of the climate upon them; of the vegetation they support, and the special phenomena they show. There certainly exists one collector of volcanic views, but I believe he has actually to take all the photographs himself, though probably almost every view he takes had already been taken by someone else if he could know where to go for it. A man might make photographs of desert scenery the subject of a collection if he happened to feel that way inclined, or of the Arctic and Antarctic regions; or views in the city or cities in which he is particularly interested. He might collect photographs connected with any given sport, and if he brought them orderly together and identified each by an explanatory statement, his collection as it increased in numbers would be found interesting by numbers of people not primarily interested in the sport in question.

The nation officially collects the national portraits; possibly there may be some people who make a hobby of the collection of the portraits of the prominent people of their day. For such, indeed, the apparatus does exist provided that they avail themselves of current issues, but if anyone were to begin now and attempt to make a complete collection of the prominent people of the Victorian era he would find the quest an exceedingly difficult one. I suppose photographs of Lord Beaconsfield are still purchasable, but I imagine that it would be a matter of, at all events, some slight difficulty to buy photographs of Lord Palmerston. Yet the day must come when such representations of persons of historic interest will have a definite money value, to put the thing on its lowest plane. And so it will be with the views of buildings that have ceased to exist, of streets that have been rebuilt, and of the vanished past generally. To collect these things is indeed to tend to make them valuable. And, more than that, the collector performs a definitely useful function by saving from destruction objects that would otherwise have perished. How many postage stamps of thirty years ago would be preserved to-day if there had been no postage stamp collectors? The collector is essentially the preserver. If what he collects is of small intrinsic interest, it is unfortunate, but if what he collects has an intrinsic interest, and one that grows as the years pass by, he performs a function of real value in any intelligent society. It is not the case that no one collects photographs at the present time. Multitudes of people buy them, of course, but that is not collecting. Yet some people actually collect; and institutions—especially in the United States—are beginning to pay attention to this important subject. The French Government, rather late in the day perhaps, has made the photographic record of the ancient buildings of France a public undertaking; and there are photographic collections illustrative of French architecture in most of the centres of France where they are likely to have educational value. Far more elaborate are the architectural collections in many of the American Universities, whilst in Germany the matter is even more thoroughly and scientifically taken in hand. The ordinary English private collector—if collector he can be called—confines himself to such photographs as illustrate his own life. If he took care of them and pasted them, as they came into his possession one after another, into a series of books, so that the places he visited and the friends he enjoyed were recorded in the order in which they passed across the field of view of his life, the ultimate assemblage would be extraordinarily interesting; but the fact that he generally buys his photographs, or has them given to him mounted upon cards, and that as a rule he sticks them up on his walls or tables as though they were artistic objects and could perform the functions of pictures, leads to their early destruction or removal to some chaotic receptacle where they get

mixed and jumbled together, and where dirt collects upon them, so that presently they are consigned to the fire as valueless. This, in fact, is an instance of the difference between a collection and an assemblage. Everyone assembles photographs—few people collect them. It is the rarest thing, indeed I do not ever remember to have seen, a collection of photographs chronologically illustrative of a man's life. And how interesting such a collection would be. The first thing it would contain would be a series of photographs of himself from his earliest years down to the present time, each dated and each in its proper place amongst such contemporary photographs of his friends, the places he lived in, the places he visited, as would naturally come into the possession of every one of us. But the last thing an individual keeps is a photograph of himself. No one else can possibly be likely to own a series from childhood to age of photographs of any given individual. The result is that it is the rarest possible thing to find a tolerably complete series of the photographs of anybody in different stages of his life, and such a series would be extremely interesting, entirely apart from any interest we might have in the particular person represented.

A Photographic Record of Art.

The commonest kind of collection of photographs and the least interesting is a series illustrative of a particular journey through the parts of the world ordinarily visited by tourists. The only link that connects them is the person who made the journey, and that is of the feeblest. Views of cities and of scenery acquire an interest only when assembled according to some principle concerned with the things they represent.

Not all subjects lend themselves with equal facility to photography. Some can be reproduced almost perfectly, others lose almost all their charm when seen through the medium of a camera. Wide views of natural scenery are generally of little attraction to persons who have not beheld the prospects themselves. On the other hand a black and white drawing may be reproduced by photography with almost faultless exactitude, so that the photograph possesses almost every quality possessed by the original. Architecture can be better photographed than painted, bas-relief better than sculpture in the round, and so on. In a general way, however, it may be broadly asserted that articles of human manufacture lend themselves more readily to reproduction by photographic processes than do natural objects. If a man has the inclination thereto, he is doubtless best rewarded by collecting photographs of works of art. The field of activity open to him there is of almost boundless dimensions, as those who have attempted to work in it have quickly discovered. It would require a great national institution and the co-operation of a considerable number of specialists and many assistants to bring together and organise a representative collection of all the art of all the world, from the time of prehistoric man down to the present day. I have sometimes amused myself by endeavouring to draw up a scheme for such a museum, and roughly to estimate what the cost of it would be. Perhaps the history of Italian painting in the 14th, 15th, and 16th centuries might be represented with fair completeness by the photographs of some 20,000 pictures. Add to these the drawings of artists of the same period, contemporary sculpture, the buildings erected in Italy at the same time seen from without and from within, the mosaic decorations, the engravings, the goldsmiths' work, the medals and plaquettes, the manuscript miniatures—and it will easily be seen that half a million photographs might be devoted to this one country for these three centuries alone. At least an equal number would be required for the rest of Europe. Oriental art at the same period was prolific and important; so that we may say that the age of the Renaissance alone would require a million photographs properly to record it. If each of these photographs were mounted upon a thin card, 100 of them in a suitable box would measure some 27ins. in thickness; this would mean 10,000 boxes, and they would occupy over 2,000ft. of shelf room. Or if the boxes were built upon five rows of shelves, they would occupy over 400ft. of wall space. The cost of such a collection, if all the photographs were purchasable at the usual rate averaging about one shilling apiece, would be £50,000, and it would cost another £20,000 to mount them. And the shelves to contain them would cost not less than £500. But to arrange any such quantity of photographs would require the assistance of a number of experts. Each photograph would have to be identified and inscribed and placed, which would involve no inconsiderable amount of research

and, at all events, exhaustive reference to current art history literature. Perhaps an expert might arrange an average of fifty photographs a day, which would be 20,000 days' work for the whole collection. A suitable man could not be hired under £300 a year, and certainly could not be expected to work so much as 300 days. So that to put his remuneration at £1 a day is to under-state the cost. We have therefore to add £50,000 to the cost of arrangement. Thus it will be seen that a fairly complete representation of a single period of artistic production would be a very costly affair.

The Need of Assemblage and Classification.

If a single period of three centuries would thus involve so considerable an expense and such large accommodation for a fairly complete collection of representative photographs, it will easily be seen how great an institution would be necessary to accommodate a photographic index to the art of the world. Such an index would naturally include not merely the works of fine art but representatives at all events of whatever product of human handicraft had come down from remote ages. It certainly would not refuse the likenesses of Viking ships or Egyptian utensils, still less the implements of prehistoric man. The collection when complete, with its cross arrangement of geographical distribution in one direction and chronological sequence in the other, would thoroughly represent all formative human activity in every period and in all regions of the earth. No one will deny the utility and importance of such a collection, and it is easy to see how powerful an instrument it would be for the furtherance of research of every historical kind. Some day, let us hope, the sporadic energies of various institutions may be concentrated somewhere to the production of such a collection as this. In the meantime, however, all we can reasonably hope for is that those institutions which do make the collection and preservation of photographs one of their functions, will pay more attention to arrangement and classification than at present they do. Only too frequently photographs of important objects are published as stray illustrations in books, or attain a momentary accessibility in the pages of some magazine which disappears from the market almost as quickly as it appeared. The photographs thus distributed are of little use; it is necessary to bring together those which belong together. To make a list of references to perhaps forty books in which are to be found scattered reproductions of the works of a single individual is of little use. The only thing to be done is ruthlessly to extract plates from the books to which they belong, and to group them all together with references written on each to the work and to the page from which they were taken. Moreover, for an organic collection of this kind, it is essential that, by cutting and folding, all prints be reduced to one maximum size. The work of a single school, still more those of a single individual, must be rigidly grouped together in a single box or series of boxes standing side by side on a row of shelves. In the case of a painter, for instance, let us say Raphael, his pictures and his drawings will need to be chronologically arranged, entirely regardless of size; and the only accessible photograph of a given work is larger than the standard box, it must be cut and folded to go into it in its right place. Otherwise chaos must necessarily follow.

By pursuing this system consistently, there will necessarily come into existence a library of books from which plates have been abstracted which must remain organically attached to the collection of photographs. And this library, as the collection increases will grow to considerable dimensions.

And here let me take occasion to protest against the bad habit which is far too common with publishers of illustrated magazine. This is the careless and unnecessary frequency with which processes of photographs of different objects are printed back to back on the same leaf, so that if you cut one of them out the other is necessarily carried off with it to the same ultimate receptacle. If illustrations were always printed, as for instance in "The Burlington Magazine," on separate leaves and only on one side, they would be far more valuable to the purchaser as being more easily capable of proper classification. Moreover, the text of the articles would remain complete for future reference after the illustrations had been grouped in the index box. Magazine editors in general, indeed, fail to realise the condition to which the multiplication of printed issues has brought students in the present day. There is hardly a subject on which you may not find some article of interest in one of the hundred periodical publications. Few people, as a matter of fact

nowadays bind and keep the whole series of any periodical. And it is folly to suppose that a person interested, let us say, in some natural history subject, will keep on his shelves volumes of periodicals of general interest which may chance to contain one or two articles bearing on his special subject. Most of us now have acquired the habit of tearing magazines to pieces and taking out such pages as may be of permanent interest to us, whilst throwing away the rest. The ideal magazine, therefore, would now consist of a number of separable pamphlets, and though, of course, no magazine could in practice be so printed that by cutting a string the various articles would fall asunder from one another, there is no reason whatever why it should not be the rule with every magazine that all articles should commence on a right-hand page *au recto*, and that if necessary a blank page should be left at the end of any one article so that the next might be similarly commenced on a right-hand page. The blanks thus left would in fact be a saving of expense both in copy and type-setting to the magazine publisher, whilst the utility of the magazine to the buyer would thereby be greatly increased. At present it not unfrequently happens in the ordinary contrariety of things that a man wants to preserve two consecutive articles on different subjects in both of which he is interested; and if he is a methodical person he would have to keep one of them in one place with others on the same subject, and the other in another place. But he will almost invariably find that the end of the first article and the beginning of the second occupy different sides of the same leaf, and that one or the other must of necessity be mutilated when they are divided. This, however, is a digression which does not primarily concern the collector of photographs. For him the great consideration is that two illustrations should not be printed back to back.

The Trials of the Private Collector.

It will probably be a long time before any great public institution of the kind I have been outlining is actually formed. Needless to say, Governments will not be moved to spend money for such an object, whilst the private wealthy donor does not care to give money for an institution of a novel sort. Museums full of objects of great intrinsic value appeal to the pocket of wealthy men; they will give money to universities, laboratories, and even to libraries, but I doubt whether any millionaire would be attracted to spending his millions upon the purchase of such an apparently valueless object as photographs. Few museums of sculpture are so interesting as would be a great collection of casts of all the important sculptures in all the world. Yet, with the exception of the cast collection in the Trocadero in Paris, which is devoted almost entirely to mediæval and Renaissance French sculpture, there does not exist anywhere in the world a really great collection of casts. One might have thought that to form and house such a collection would appeal to the generosity of some man of great wealth, but it has never done so. Small illustrative historical collections of casts have been made by different educational institutions, but there is no really great collection anywhere in the world. To house it would require a building

at least as large as the Crystal Palace. One wonders sometimes what better use for the Crystal Palace itself could be found than to contain the finest collection of casts that could be brought together. But if casts do not in fact appeal to the millionaire, how much less likely is it that he will be appealed to by photographs. Not till the small private collectors increase in numbers and make their purchasing power felt will the necessary organisation be created to make photograph collecting relatively easy and safe. When it is certain that at least 200 copies of a photograph will be sold, it is possible to print it at once cheaply and in a permanent form; but when only here and there a purchaser may be hoped for at intervals of a series of years to buy copies of some particular photograph, it does not pay the photographer to print it by any except the ordinary relatively perishable processes. Nowadays you can buy readily enough reproductions of the principal pictures and other important objects in the galleries and museums of Europe. But the moment you desire to obtain representations of minor objects or of important objects in private collections, your difficulties as a collector begin. I have recently been endeavouring to make a complete collection of reproductions of the works of Albert Dürer. The first steps are easy enough. One can buy the four great volumes of Dr. Lippman's reproductions of his drawings; the five or six portfolios of photographs of his paintings published by some Nuremberg firm; Amand Durand's reproductions of all his engravings, and other easily accessible reproductions of his four books of woodcuts. But these together by no means complete the list of his known works. There are a few other paintings, one for instance at Odessa, which I believe has never been photographed at all, and one or two more scattered about the world. More important are the drawings not covered by Dr. Lippman's publication and the stray woodcut sheets not included in the four books. Some of these drawings and woodcuts can be obtained by buying the Dürer Society's publications, but the purchaser of them will find himself immediately loaded up with duplicates of many prints, woodcuts, drawings and pictures of which he already possesses reproductions. If he subscribes to the many series of reproductions of drawings in the different galleries such as the British Museum, Berlin Museum, Munich, etc., which have been and are being issued at frequent intervals, he will again obtain a further set of duplicates. And the more persistent his efforts to complete the works of some one individual artist, the more numerous will become the duplicates and triplicates that pour in upon him.

Now if the collector of photographs were as well catered for as is the collector of postage stamps, he would have opportunities provided for him for the exchange of such duplicates, which no doubt would be gladly acquired by some collector at work elsewhere. At present he has no means of obtaining anything for them, while they grow to represent a very considerable fraction of the whole expense of his collection. In my own case, for example, the duplicates that have poured in upon me begin to be counted probably by thousands, and not one of them has been intentionally purchased.

MARTIN CONWAY.

(To be continued.)

NEW APPARATUS FOR MEASUREMENTS OF GELATINE.

(A Paper in "Photographische Korrespondenz.")

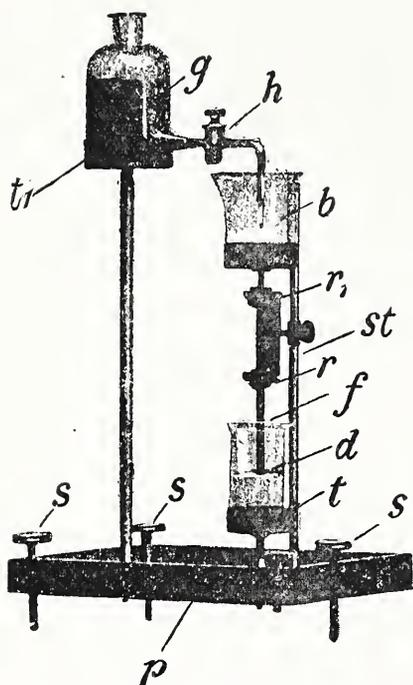

KNOWLEDGE of the physical, as well as of the chemical, properties of gelatine is of importance to the emulsion maker. Among these properties are particularly to be mentioned the degree of absorption of water by the gelatine, as also the melting and solidifying points of the jelly and its degree of solidity or strength. The measurement of the absorptive powers of the gelatine towards water is very simply done by weighing out 10 gms. of gelatine, allowing it to stand twelve hours in water at 60 deg. F., pouring off the water, and, after removal of the water which mechanically adheres, weighing the swollen gelatine. The removal of the adhering water is best done by a centrifugal. The swollen gelatine is then made up into a 10 per cent. solution, this being done by placing it in a tared beaker and adding water until the total weight is 100 gms. It is then heated up on a water bath until a solution is obtained. Of this half is employed

for the measurement of the melting and solidifying points, and the other half for ascertaining the solidity.

The determination of the melting point is best done by the method used by J. J. Pohl for fats. A small particle of the jelly is caused to adhere to the side of the bulb of a thermometer graduated into $\frac{1}{2}$ -degrees, which is hung vertically in a glass tube. The latter is heated in an air bath until the jelly melts and collects as drops on the lowest point of the thermometer bulb. For ascertaining the solidifying point the thermometer is placed horizontally and turned on its axis until the drops of solution no longer keep on the lowest point of the bulb, but begin to be carried round. The solidifying point may also be taken by melting about 50 gms. of the jelly in a small beaker on the water bath, placing the beaker in cold water, and stirring round with a thermometer until solidification commences.

For ascertaining the viscosity, the process recommended by Lipowitz is used. This consists in ascertaining the load which it is necessary to apply in order to force a stamp into the solidified gelatine. For this purpose the writer has employed a simple form of

apparatus in which a stamp of shape  is attached to a rod communicating above with a funnel. The stamp is allowed to rest on the surface of a jelly contained in a small beaker, and small shot

allowed to enter the funnel until rupture of the jelly takes place. This apparatus gives, with one and the same gelatine, very notably different results, a fact which led me to seek the cause of error. As I noticed that the friction of the rod used in Lipowitz's apparatus caused a variation in the results I made this rod of square section, and substituted for the bag connection two pairs of rollers with their axes at right angles and resting on two opposite surfaces of the conducting rod. In this way the friction was reduced to practically nothing as long as the rod remained normal to the surface of the jelly, and whilst the load was uniformly distributed in the funnel. It is not easy, however, in adding a shot to secure this latter condition, and I therefore substituted for the shot ordinary mercury, which was delivered into the funnel by the bottle and tap shown in the drawing. The whole apparatus, which is made by the firm of W. Rohrbeck, 59, Kärtner Strasse, Vienna, consists of a solid iron plate, provided with raised edges and placed horizontally by means of the set groove, *s*. On this plate is a small movable table, *t*, which serves to hold the beaker containing the jelly to be measured. The stamping rod, *d*, is made in a solid piece with the conducting rod, *f*. This latter is provided with a frictionless extension by means of the two pairs of rollers, *r* and *r*, which are fixed to the upright rod, *s* *t*. The mercury is contained in the reservoir, *g*, and is allowed to enter the funnel by the tap, *h*, in a stream of any desired fineness. For use the apparatus is levelled and the jelly first liquefied on the water bath and then poured into the beaker to a depth of about 4 to 5 cm., requiring about 50 gms., and here it is left for 12 to 24 hours at ordinary temperature. It is then brought to a temperature of 60 deg. F. in a water bath placed on the table, *t*, and the stamping rod brought over the central point of its surface. By opening the tap, *h*, a very thin stream of mercury is allowed to enter the funnel, *b*, the flow of mercury being cut off the moment the end of the rod effects disruption of the jelly. The weight of the rod, etc., is ascertained once and for all, and it is therefore only necessary for each experiment to ascertain the weight of the mercury in order to have the total weight acting on the jelly. To save measuring the mercury the latter may be run into a tube graduated into ccs., and the film multiplied by the specific gravity—namely, 13.56: correctly

used the apparatus gives results in exact concordance. The numbers obtained in this way for different descriptions of gelatine exhibit a considerable range. Good examples of hard emulsion gelatine have a solidity number of from 800 to 1,500 gms. The degree of absorption of water in the gelatines which I have examined amounted to, at least, five times the weight of the gelatine employed.

E. VALENTA.

Photo-Mechanical Notes.

Dragon's Blood.

We have received from the Star Engravers' Supply Company, of New York, a sample of dragon's blood and circulars relating thereto, in which it is claimed that the dragon's blood is 99.9 per cent. pure. This ranks it with the very finest of fine chemicals, and, whatever the demands of the etcher are, we should not have imagined them to be so exacting as that. There is also a claim that with such a blood the etching will be straight down, whereas with impure powders the etching is terraced or "shouldered." Well, all the writer can say is, that he has etched hundreds of plates with all sorts of powders, none of them of 99.9 per cent. purity, and yet he has succeeded in getting straight-down edges to his lines with all of them, the fact being that the bad shoulder is entirely a question of the way the work is done, and could quite easily be obtained with the pure blood. In England, too, great pains have been taken to purify the blood, but for some reason or other the etchers have not been so successful with it as with the commoner sorts; not but what it is desirable to have a standard article and not have powders which are constantly varying as, the circular rightly states, they do now. The point whether it is most advantageous to have the utmost purity or whether some dilution is not actually better, is not yet settled. In the meantime, the efforts of the Star Engravers' Supply Company to supply a definite article regularly deserve recognition, even if all their claims about it are a little doubtful.

Standard Rubber.

The same company also market a pure and easily soluble rubber for use by photo-engravers to make stripping solution and rubber substratum. Again, a material has been chosen that badly wanted standardising, as every engraver knows to his cost, and if the Star Company have succeeded in this we can only hope they have English agents for their rubber.

Lenses for Colour Work.

Our American correspondent also asks us about this, and in reply we can only state, as we have frequently done before, that most good lenses are quite suitable for three-colour work. If he wants to know the lens that is most favoured by the houses in Europe doing the greatest amount of colour reproduction, it is the Zeiss Apochromatic Tessar. He must not forget that, however good the lens is, its performance will be spoiled unless the filter used in connection with it is also first-class.

Gum Grain for Photo-Engraved Plates.

ACCORDING to a recent patent specification, No. 17,480, 1908, drawn up by R. and R. D. Bain, of 126, Queen's Gate, South Kensington London, S.W., a grain is produced on a photo-engraved plate by means of a vegetable gum containing the substance bassorin, and rendered sensitive to light by means of a bichromate salt.

This film, or coating, which is sensitive to light, is composed of bichromate of ammonia, bicarbonate of ammonia, chrome alum, fish glue, gum arabic, and any vegetable gum containing bassorin such as is contained in gums pertaining to genus *astragalus*, or any other gum containing amyloidal substances or starch or similar compounds, such as cerasin, arabin, tragacanthin or pectin, having an indifferent chemical nature and capable of swelling in water, being more or less soluble in the same. For example, a solution made of gum arabic oxydised with (about 1 per cent.) chrome alum, 20 per cent.; fish glue, 20 per cent.; vegetable gum, containing bassorin

per cent.; bichromate of ammonia, neutralised with (2½ per cent.) carbonate of ammonia, 40 per cent., gives very practical results.

The temperature and concentration of the ingredients of the film coating being primary factors in the achievement of the results desired, care should be taken during the preparation of the solution that the temperature is not less than 105 deg. F. or more than 140 deg. F.

The coating, in liquid form, is placed upon a metal surface, or any other suitable material capable of being etched.

As soon as the plate or other object to be etched has been properly dried, it is (without further treatment, except lining and backing by known means) ready to be used for printing.

The original is photographed without the use of a half-tone screen, any screen, and the negative or positive, as the case may be, is printed direct upon the prepared plate. It is not necessary, after the copy is taken upon the plate, to prepare such plate or other object for the etching bath by any further treatment, except backing and lining with shellac varnish or the like by known means.

Electric Light and Eyesight.

In a recent number of "Process Work" a question was asked as to how to avoid the agonising pain caused by looking at the arc lights, and several correspondents have given their advice. Most are of opinion it is caused by the ultra-violet light, but only one recommends the use of glasses which absorb this light. M. Calmels, of Paris, has just put on the market yellow glasses for this purpose, which absorb all the ultra-violet. It is certain that blue glasses, which are often advised, are not of much use, but it is doubtful if the damage is not caused by the intense brilliancy of the light, as well as by the ultra-violet. Thus the correct glasses would seem to be smoked yellow, the colour to absorb the ultra-violet and the yellow to reduce the intensity of the light. This view is borne out by the experience of Dr. Cook on his journey to the North Pole, as the following quotation from his narrative in the "New York Herald" shows:—"Though the heat of the sun was barely felt, its rays began to pierce the eye with painful effects. The bright light reflected from the spotless surface of storm-driven snows could not be endured even by the Eskimos without some protection. Amber-coloured goggles, which we had made at Annotok from the glass of the photographic supplies, now proved a priceless discovery. They effectually removed one of the greatest torments of Arctic travel. Darkened or smoky glasses, blue glasses, and ordinary automobile goggles had all been tried with indifferent results."

Collotype.

There is probably more work, and that of a higher quality, done by this beautiful process than ever. We have recently seen some collotypes, which were so rich and well printed, and of such an extremely fine grain, as to be almost indistinguishable from carbon prints. There are also the fine coloured collotypes which are becoming more frequent in the print sellers' windows, and colour collotype is now being used for book illustration, as in the "Florence" series published by Messrs. Chatto and Windus. It is a pity that most of the best of this work is done abroad, though we have seen some fine coloured collotype done here for the British Museum which could not be better.

It is true that collotype is an uncertain process, because gelatine enters into it, but then gelatine is probably an equal source of annoyance to dry-plate makers, yet English dry-plates are the best in the world. The reason probably is that dry-plate makers have standardised their conditions, while collotype printers are apt to let things take their chance and simply bewail the climate. Many of the conditions could be standardised. For example, electric light might always be used for the exposure, as it is in nearly all other branches of reproduction work, including the "photography by the mile." Houses doing this find it pays them better to do ordinary copying with electric light rather than daylight. This plan would probably need some alteration of the formula for the coating mixture, the amount of bichromate used for daylight being excessive for printing by the enclosed arc; but a few experiments would easily determine the correct proportion to get exactly the right effect of contrast with the light, and thenceforth there should be no difficulty in exposure. The plates themselves ought to be baked at a standard temperature, and how many collotype ovens are fitted with an automatic heat

regulator. Not one that we know; yet surely this should be the simplest attachment to a gas supply. Though the printing machines appear to be as good as can be wished, and there is no complaint of the skill of the printers, it is in printing the edition that the greatest waste occurs, a defect for which our climate is held responsible, and earns the deepest anathemas. But why does not the collotype printer make his own atmosphere for the printing-room? When he has determined the exact amount of moisture necessary to enable the plates to be printed with ease, would it not be possible to instruct a ventilating engineer to arrange some method of forcing air of exactly this degree of warmth and moisture into the printing-room, and no other, drawing it off as frequently as may be necessary and supplying fresh? If these details were attended to, and the process standardised in other ways, there should be no more difficulty with collotype than with any other process, and an English firm should be able to do collotype prints for less money and in less time than the foreign competitor.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

REPRODUCING DRAWINGS.—No. 22,417. Improvements in the process of reproducing drawings by line, zincography, or photo-etching, photo-lithography, or similar processes. John Wellesley Ross, 173, Fleet Street, London.

Exhibitions.

PHOTOGRAPHS BY MR. G. L. A. BLAIR.

THE Glasgow Photographic Art Circle exists for the express purpose of promoting photography as an art; that is the end and object of its being. There are those, a rapidly decreasing number, who would have us believe that the profession and art of photography are wide as the poles asunder, but this Art Circle is a standing contradiction of such a doctrine. Perhaps its principal propaganda whereby it makes known to the public the presence of art in photography is in its one-man shows. These naturally are the product of its more prominent workers. It is notable that both one-man shows promoted by the circle should be the work of professionals. Last year's was the work of Mr. J. M. Whitehead, of Alva. This year Mr. Geo. L. A. Blair supplies the exhibits. In this connection it occurs to us that the Edinburgh society have also shown activity in the way of one-man shows. Last year they had Mr. Wm. Crooke and Mr. J. Craig-Annan, and this year they are to have the work of Mr. F. P. Moffat—professionals all.

But to our subject. The exhibition under review is housed in the rooms of the Glasgow Southern Photographic Association, 169, Eglinton Street, Glasgow. It is tastefully displayed in panels around the walls, while a welcome touch of colour is given by the flower-laden table in the centre of the room.

The exhibition consists of forty pictures, many of them well known, such as "Lead, Kindly Light," the most discussed picture at the Scottish Salon at Paisley; "February"; "While London Sleeps," a very popular night picture of the Embankment; an effective portrait of "J. M. Whitehead," and a fine series of Dutch pictures.

The new picture that is the subject of discussion is "The Sun Worshipper." Here "G. L. A." wanders into the ideal, as he did in "Lead, Kindly Light." The picture represents an early Briton paying his devotions to the rising sun. The conception is frankly idealistic, and, as many photographers hold the realm of the ideal is forbidden ground for the man behind the camera, much argument has been spent on this subject, and it is safe to prophesy that it will form a never-ending theme of debate: in fact, the echoes of the discussions on "Lead, Kindly Light" (exhibited three years ago) have not yet died away.

"Twilight" represents a "gaslight" view of a city's square. "The Rowan Tree" is also new, but rather disappointing. "Winter" carries out its title well. While no doubt the exhibition would have been strengthened by the exclusion of some of the pictures, still it

is telling proof of the art tendencies of one of our younger professionals.

At the opening there was quite a gathering of the prominent photographers in the West, who criticised the exhibits with all heartiness and praised and blamed with delightful impartiality. Another point that falls to be noted was that on the opening night ten pictures were sold—ten out of a total of forty. Twenty-five per cent. of an exhibition sold on the opening day should surely constitute a record.

FORTHCOMING EXHIBITIONS.

- September 10 to October 23.—The Photographic Salon. Sec. Reginald Craigie, 5A, Pall Mall East, London, S.W.
 September 23 to October 30.—Royal Photographic Society. Sec. J. McIntosh, 35, Russell Square, London, W.C.
 October 21 to 23.—Rotherham Photographic Society. Secs., H. C. Hemingway, Tooker Road, Rotherham, and F. Sargeant, 17, Aldred Street, Rotherham.
 October 27 to 28.—Watford Camera Club. Entries close October 21. Sec., W. J. Edmonds, 3, The Parade, Watford.
 November 10 to 13.—Hackney Photographic Society. Sec., Walter Selfe, 24, Pembury Road, Clapton, London, N.E.
 November 10 to 13.—Cambridge and District Photographic Club. Entries close October 28. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.
 November 23 to 26.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
 November 29 to December 2.—Lancaster Photographic Society. Entries close November 20. Sec., Thomas Holt, 4, Parliament Street, Lancaster.
 December 31, 1909, to January 8, 1910.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 139, Glasgow Road, Wishaw, N.B.
 1910.
 April 5 to 9.—Sheffield Photographic Society. Secs., J. A. George and J. R. Wigfull, 14, Parade Chambers, Sheffield.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following patents have been applied for from September 27 to October 2:—

- CINEMATOGRAPHS.—No. 22,244. New or improved cinematograph or like apparatus and process in the production of pictures. John William Bracewell, 54, Colne Road, Burnley.
 CAMERAS.—No. 22,263. Improvements in and connected with photographic cameras and photographic apparatus. Warren Bodon Smith, 66, College Street, Chelsea, London.
 PLATE-HOLDER.—No. 22,274. Photographic plate or film-holder. Frank Whitney, Birkbeck Bank Chambers, Southampton Buildings, London.
 PRINTING FRAMES.—No. 22,310. Improvements in photographic printing frames. Benjamin Napoleon, 4, South Street, Finsbury, London.
 PRINTING FRAMES.—No. 22,311. Improvements in automatic printing frames. George S. Edwards, 323, High Holborn, London.
 PHOTO-TELEGRAPHY.—No. 22,457. Photo-printing telegraph. Donald Murray, 3, Lombard Court, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

- ADJUSTABLE TRIPOD HEAD.—No. 18,995, 1908 (September 10, 1908).
 —The head or plate of the tripod stand is provided with a screwed pin which engages with the internal thread 7, of an attachment, or

socket piece, 5. The socket, 6, of this piece takes a ball, 9, the outer side of this ball being attached to the camera by the screw, 10. The parts are held together and adjusted by means of a union, 14, provided with a shoulder and closing over the ball, 9.

Of the drawings Fig. 1 is a view, partly in elevation and partly in section, of the device showing union screwed home on ball.

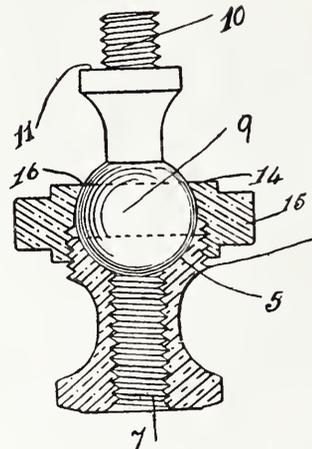

Fig. 1.

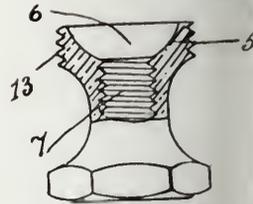

Fig. 2.

Fig. 2 is a view of the socket portion partly in section.

Fig. 3 is a view of the ball portion, showing screwed stalk fitting into base of camera, and

Fig. 4 is a plan and section of screwed union for taking on the socket portion.

The camera is adjusted upon its stand, supported by legs by means of the adjustment device, consisting of a socket portion provided with an open mouth 6, and tapped screwed hole 7, to take on to a screwed stud or pin 8 on the camera stand. Taking into the mouth of this socket portion and working thereon is the ball end 9 of a screwed stalk 10, provided with shoulder 11, by screwing into the base 12 of the camera.

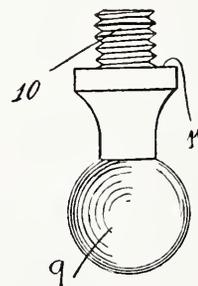

Fig. 3.

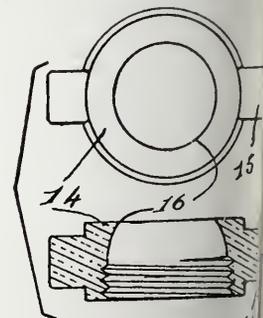

Fig. 4.

Taking on to the outside screwed portion 13 of the socket, so as to partly enclose the ball, is an internally threaded union 14, provided with finger pieces 15, and retaining rim or shoulder 16, preventing displacement of ball. The screwing or unscrewing of this union on its socket permits the ball to move more or less freely within its socket and the camera on which it is mounted to be adjusted in any direction to the required extent. William P. Willcox, 99, Bradford Street, Birmingham.

VACUUM HEAT CUT-OFF FOR CINEMATOGRAPHS.—No. 147, (January 4, 1909). According to the invention a cell or case, exhausted to a vacuum, is interposed between the source of light and the object or objects to be illuminated.

For convenience the exhausted chamber may be constructed of glass and placed behind the condensers, if any are used, but the apparatus may be made of various other substances, wholly in part, and placed in any other position. Percy Sheard, Duxley Villa, Droitwich, Worcestershire.

New Trade Names.

FEROL.—No. 313,810. Chemical substances used in manufacturing photography, or philosophical research and anti-corrosives.

Alexander, Fergusson and Co., Ltd., the Glasgow Lead and Colour Works, Ruchill Street, Maryhill, Glasgow, Scotland, merchants and manufacturers. June 9, 1909.

VARPAINTO.—No. 316,211. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives Aspinall's Enamel, Ltd., 1, Goodwood Road, New Cross, London, S.E., manufacturers. September 9, 1909.

Dew Apparatus, &c.

The "Cirkut" Panoramic Cameras. Made by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

Under this name the Kodak Co. have introduced a quite new type

agents, and others desiring to present a complete and attractive photograph of a scene which cannot otherwise be shown in a single photograph. While hitherto the photographers who have been called upon to do this class of work have had to resort to tedious methods involving the use of a number of glass negatives and processes of combination printing to secure a single photograph, the use of the "Cirkut" camera makes the production of a photograph—even of one including the whole horizon of 360 deg.—as easy a matter as the taking of a single negative with a stand camera.

For in the "Cirkut" a special tripod is provided, round the circumference of which a metal rack is fitted and guides the rotary course of the camera. The camera itself, or the "Cirkut" attachment, which is also sold for use with the Kodak "Century" camera, is provided with clockwork motive power, the pinion gearing with the rack on the tripod head. Two brakes are provided so that the speed of rotation can be modified. The camera, therefore, as soon as

Copyright by the Notman Photo Company, Boston U.S.A.

This and the following illustration are reproductions of the print from one single film negative made with the Cirkut camera. The effect of the panoramic photograph may be seen by placing the reproductions end to end.

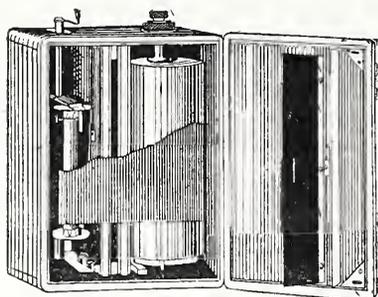

Copyright by the Notman Photo Company, Boston, U.S.A.

of panoramic camera, designed, it need hardly be said, for roll film, at serving for the widest range of panoramic photography. The "Cirkut" has not been designed for, nor is it offered to, the amateur photographer, who would take panoramic pictures as a form of entertainment. The apparatus is intended for the most exacting descriptions of expert and commercial photography, and it is not too much to say that from this point of view it is an instrument which occupies a place by itself among photographic equipments. It supplies the means of producing photographs for which there has been in the past a very considerable demand among certain classes of customers, such as railway companies, municipal authorities, estate

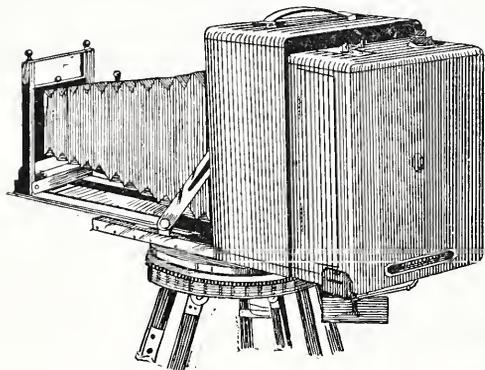

affixed to the tripod head, is pointed to the subject, and the rotation of the instrument started by pressure on a release. The mechanism of the instrument shows the length of film which is being used for the exposure, and further perforates the film on the completion of exposure, so that the operator when removing it from the apparatus knows exactly which portion to develop.

The exposure which each narrow section of film receives as it moves in relation to the lens is about 1-10th sec., a fact which may suggest to some that in the case of street scenes and other subjects where there are rapidly moving objects this speed will be quite inadequate to secure freedom from blur. It should therefore be

pointed out that from the circumstances of the case the "Cirkut" camera has to be placed at a considerable distance from the subject being photographed, and on that account the effect of moving objects is of less importance. When we say that the large panoramic photographs taken with the "Cirkut" of such scenes of incessant traffic as Piccadilly Circus and the Place de l'Opéra are practically free

from any blurring due to the movements of vehicles, it will be understood that the scope of the "Cirkut" camera is not restricted on this account. The two illustrations represent first the roll-holder of the camera, whilst the second shows the "Cirkut" attachment to one of the Kodak Company's "Century" cameras. In addition to the apparatus for making the negatives the company also supply

long box printing-frames taking film up to 10ft. in length for taking off the prints.

For all those engaged in photography for advertising and commercial illustration the apparatus is certainly one which may be expected to pay for itself within a short time, since the results obtained with it are not to be compared with those secured either by a wide-angle lens or by the tedious processes of double printing.

The Watkins Focal-Plane Meter. Made by the Watkins Meter Co., Hereford.

This meter approaches the exposure of the plate from a different standpoint from that which has hitherto been the case with exposure meters. It places first in importance the rendering of a moving object sharply (i.e., without fuzziness due to movement during exposure) in the negative. In other words, it aims to guide the photographer first in this respect and places the full exposure of the plate in a minor category. It will thus be seen that the meter appeals particularly to those who on many occasions have to get a photograph the sharpness of which is of more consideration than the correctness of the tone-values, a condition which, as we know from daily inspection, prevails in a very large proportion of press photography. Thus the reverse side of the meter states the maximum exposures which can be given for various classes of moving object when using a 5-inch lens at a distance of fifty feet from the object, which latter is supposed to be moving diagonally across the lens axis. When the object is crossing the lens axis at right angles or when a 10-inch lens is being used the speed of the shutter must be doubled (half the exposure). The light is tested in the ordinary way, and the actinometer number on the metal rim turned to the plate speed number on the central paper dial. On now looking at the diaphragm scale there will be seen opposite the stop number the exposure which may be considered the minimum for each.

With the focal-plane meter the exposure indicated is half that given by the Bee meter, the assumption being that working conditions will usually not allow of the full exposure which is necessary for the plate. We think that hand-camera workers will welcome this ready means of showing them without any calculations the limits within which they may safely work, or, at times, that certain exposures are quite inadequate for a satisfactory negative. It should be pointed out the name "Focal-Plane" given to the meter is selected for the reason that the speeds of a focal-plane shutter are usually more accurately expressed than those of diaphragm shutters; at the same time the meter may be used with diaphragm and other shutters, some allowance being made for the somewhat lesser efficiency of these varieties of shutter. The price of the meter is 2s. 6d.

Steel Castors for Furniture. Made by the Invisible Castor Company, 40, Trinity Square, London, E.C.

Under the name of "Domes of Silence" the Invisible Castor Supply Company are placing on the market, through retail ironmongers, a series of hard steel domes of the form shown in the drawings. These are affixed to the base of furniture simply by

hammering them in gently with a hammer, or in the case of a heavy article of furniture by the weight alone. The castors provide a very rigid series of supports for a table, studio stand, or other accessory, and at the same time greatly assist the moving of such

articles over a wooden or carpeted floor. On this account we believe that photographers will be interested in having their attention called to the very moderate prices at which they are sold—viz. 6d. per set of four, or 24s. for 48 sets. The second illustration shows the way in which the castor is affixed.

CATALOGUES AND TRADE NOTICES.

SHEW CAMERAS.—Messrs. J. F. Shew and Co., 88, Newman Street, London, W., have just issued a new 120-page list of their special manufactures in the shape of the excellent "Xit" and other cameras, as well as of selected lenses, shutters, finders, and other apparatus. The list, which is very fully illustrated, is sent free.

EDWARDS' PLATES AND LETO PAPERS.—A new "Leto" price-list for the season 1909-1910 supplies a convenient reference to the standard varieties of self-toning, gaslight, and other papers, as well as to the plates and other specialties formerly made by Messrs. B. J. Edwards and Co. The list (thirty pages) is obtainable free from the Leto Company, Roman Wall House, Crutched Friars, London, E.C.

JUPITER STUDIO LAMPS.—Messrs. John J. Griffin and Sons have just prepared a catalogue of these specially designed studio electric lamps. They offer to send it free to any professional photographer. As the catalogue records the experience of a number of high-class studios with the lamps, and reproduces some of the very excellent results obtained, it should be worth any photographer's while to obtain and study it.

New Materials, &c.

CROWN CHRISTMAS MOUNTS.—The Crown Manufactory, Rotherham, send us a selection of their folder and other mounts bearing mottoes for the Christmas season, among which we find a number of very pleasing styles, both in colour and design. The "Classique" mounts (paste-on) for prints $2\frac{3}{8} \times 3\frac{3}{8}$ is of "natural surface" cream board, with gold lettering. The price is 1s. 6d. per dozen. Other mounts, mostly folding, which we would select for mention are Nos. 73, 325, 173, and 61. The Crown Manufactory also issue calendar mounts for stock sizes of prints at prices from 1s. per dozen.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, OCTOBER 16.

Kinning Park Co-operative Camera Club (Govan). Outing to Nitshill.

MONDAY, OCTOBER 18.

South London Photographic Society. "Critique on the 1903 Affiliation Competition Prints." Walter J. Morgan, R.B.A. Monthly Competition—(Lantern Slides).

Stafford Photographic Society. "Around Cardigan Bay." Herbert A. E. Hey.

TUESDAY, OCTOBER 19.

Glasgow Southern Photographic Association. "Pictorial Quality." Peter Mitchell.

Hackney Photographic Society. "Outdoor Portraiture without Retouching." S. Woodhouse.

Leeds Photographic Society. "The Autochrome Plate." Thos. K. Grant.

Manchester Amateur Photographic Society. "Intensification and Reduction." H. Wade.

WEDNESDAY, OCTOBER 20.

Sale Photographic Society. Discussion.

Borough Polytechnic Photographic Society. Summer Outings' Print Competition.

Balham Camera Club. Members' Night.

Croydon Camera Club. "Photography as an Aid to Astronomical Research." Chas. W. Raffety, F.R.A.S.

THURSDAY, OCTOBER 21.

Watford Camera Club. Criticism of July Portfolio.

Rodley, Farsley, Calverley, and Bramley Photographic Society. "Flowers." Mr. Atkinson.

L.C.C. School, Bolt Court, E.C. Holbein's "Dance of Death" Woodcuts. Emery Walker.

Leek Photographic Society. Whist Drive.

Handsworth Photographic Society. Annual Exhibition.

Liverpool Amateur Photographic Association. "Modern Photographic Chemicals." F. C. Hart.

Optical Society. "The Theory of Vision and Colour Perception." Dr. F. W. Edridge Green.

CROYDON CAMERA CLUB.—The President, Mr. J. M. Sellors, opened the session with a demonstration of his method of working "Bromoil," published lately in a contemporary. Recognising, apparently, that a section of his audience were hardly bromoil enthusiasts, and that the subject had been previously dealt with, he kindly intimated that no offence would be taken if such members went to sleep, or disported themselves as their fancy dictated. The suggestion was gratefully and immediately taken advantage of, and the demonstration proceeded amidst a hum of conversation entirely foreign to the topic of the evening. A member in the centre of one group gave a thrilling account of a motor-car chase of a hare, started on a main road and paced for over three miles at thirty-eight miles an hour. A sharp bend in the road resulted in the pursued being thrown into the ditch owing to its inability to turn, whilst the car proceeded on its way. The incident was not recorded photographically. Another group discussed quack nostrums, with particular reference to a recent book, "Secret Remedies." A doctor present warned his hearers that two plus two did not necessarily make four, in a medicinal sense. Assuming one drug to have a potency of a in a certain direction, and to be partaken of at night, another drug of similar tendencies of value b to be taken in the morning, then the combined effect would approximately be represented by the formula $(a + b)^2$.

During the consideration of these and other momentous questions, Mr. Sellors, amidst a select number of artistic workers, had completed several bromoil prints of good technical quality, full of that vivid atmospheric charm peculiar to the process, if to nothing else. Mr. F. J. Terry, on behalf of all, thanked the President for one of

the best lectures he had never listened to; the club was to be congratulated upon the remarkable success of its opening night.

ROTHERHAM PHOTOGRAPHIC SOCIETY.—The annual meeting of the Rotherham Photographic Society was held in the Society's room, Frederick Street, on Tuesday, October 5. Mr. W. Firth presided in the absence of Mr. C. H. Moss, J.P., who had been called away to London. There was a good attendance. The Hon. Secretary (Mr. H. C. Memmingway) presented the annual report, which recorded a year's progress without any special phenomenal achievement. The membership was about 100. In the previous twelve months the programme had been more varied and more largely contributed to by members themselves, and this feature, as far as possible, was to be continued. The Mayor's appeal for the Hospital Fund was taken up by the members, and resulted in a contribution of £17 8s. 5d., of which £11 7s. were the proceeds of the lecture generously given by the late Mr. A. Muir Wilson. The annual exhibition was a success. Various improvements had been effected in regard to the room, and others were now in contemplation. The report asked for greater interest on the part of members in regard to lantern-slide production and record work, by which was meant photographs of old buildings, streets, and customs. It concluded with an allusion to the fact that the Society was now entering on its twenty-first year, and it would be a question a little later on of how the "majority" would be celebrated.

Mr. F. Oldham (the Treasurer) read the financial statement. The annual exhibition last year yielded a profit of £16 0s. 1d., which had been added to the general fund. The balance remaining in hand was £40 0s. 5½d. The report was approved, on the proposition of Mr. Froggatt, seconded by Mr. H. A. Hill.

The election of officers resulted as follows:—President, C. H. Moss, J.P.; Vice-presidents, J. Leadbeater, W. Firth, and J. W. Stamp; Council, J. Allport, J. M. FitzClark, H. A. Hill, and F. W. Thomlinson; Hon. Treasurer, F. Oldham, 2, College Street; Hon. Auditor, R. Chislett; Hon. Secretary, H. C. Memmingway, Tooker Road, Rotherham; Assistant Hon. Secretary, F. Sargeant. Mr. Hemmingway and Mr. J. M. FitzClark were appointed to represent the Society on the Royal Photographic Society Affiliation Committee. Amongst the votes of thanks were the recognition of the services of Mr. C. H. Moss and Mr. H. C. Hemmingway.

HEREFORDSHIRE PHOTOGRAPHIC SOCIETY.—At the annual meeting of this society, on Monday evening, Mr. Walter Pilley was unanimously re-elected president. Mr. W. Williams resigned the secretaryship, and Mr. F. C. Pritchard, who formerly held the position, was elected, with Mr. A. J. Manning as assistant. Mr. Walter Marchant again undertook the post of treasurer. The accounts showed a small balance in hand, and the members number about 100. Mr. Alfred Watkins urged the members to go in more for lantern-slide making during the coming winter. On Tuesday evening Mr. Steadman, representing Messrs. Houghtons, gave an interesting demonstration with the new "Ensyna" paper.

Commercial & Legal Intelligence.

NEW COMPANIES.

H. E. BELLAMY, LTD.—Capital, £2,000, in £1 shares (500 Preference). Objects: To take over the business of photographic, lantern, microscopic, and general scientific apparatus, instrument and implement manufacturers, carried on by H. E. Bellamy and Co. at Stanley Works, Factory Lane, Harpurhey, Manchester. Private company. The first directors (to number not less than two nor more than ten) are: H. E. Bellamy, A. H. Bellamy, T. Clough, and T. H. Halsall. Registered office, Stanley Mills, Factory Lane, Harpurhey, Manchester.

"LONDON." By Alvin Langdon Coburn. Messrs. Duckworth and Co. have published a large volume of plate reproductions of Mr. Coburn's photographs, an introduction to which is written by Mr. Hilaire Belloc.

News and Notes.

THE WARWICK TRADING CO., LTD., have been afforded facilities that will enable them to take a series of pictures of the first aviation meeting in England, which takes place at Blackpool on the 18th of this month. The length of the series will probably be about 400 feet, and the price will be, as usual, 4d. per foot nett.

THE HALIFAX PHOTOGRAPHIC COMPANY advise us that they have received an order, with remittance, for P.O.P. cards from Mr. J. E. Huntrods, who, however, has omitted to state the name of the town in which he lives. If this note should meet Mr. Huntrod's eye perhaps he will rectify the omission and send the Halifax Company his full address, when the goods will be despatched to him by return post.

LANCASTER PHOTOGRAPHIC SOCIETY.—The eighth annual exhibition of this society will be held in the Friends' Hall, Fenton Street, from November 29 to December 2 (inclusive). There will be three open classes for framed prints, lantern slides, and framed colour work (prints or transparencies) respectively, in each of which silver plaques will be placed at the disposal of the judge, Dr. C. Thurston Holland, for award. Entries close November 20, on or before which date entry forms duly filled up and accompanied by the necessary fees should be sent to the secretary, Mr. Thomas Holt, 4, Parliament Street, Lancaster, from whom the entry forms can now be obtained.

CAMBRIDGE AND DISTRICT PHOTOGRAPHIC CLUB.—This club will hold its fifth annual exhibition in the Guildhall and School of Art from November 10 to 13, inclusive, when the work of judging will be performed by Mr. F. J. Mortimer. In the open classes, one of which is set apart for Autochromes or other colour transparencies, specially designed bronze plaques will be placed at the judge's disposal for award. There is also one class open to members of those societies comprising the Midland Photographic Federation. Entry forms are now ready and may be obtained from the secretary, Mr. T. J. Sowdon, Sunny Side, Guest Road, Cambridge, to whom the forms, duly filled up and accompanied by the necessary entry fees, should be returned not later than October 28.

R.P.S. LECTURES.—The following lectures will be delivered at the New Gallery, at 8 p.m. :—

Saturday, October 16.—“London Through the Eyes of Gossip Pepys,” by A. H. Blake, M.A.

Monday, October 18.—“Wild Birds and their Ways” (Second Series), by W. Bickerton, F.Z.S.

Thursday, October 21.—“The Home Life of some familiar Wild Birds,” by W. Farren.

Saturday, October 23.—“The Romance of Plant Life,” by F. Martin-Duncan.

THE TERRITORIAL STUDIO, Umtata, Tembuland, S.A.—Mr. E. W. Eland advises us that he has recently taken over the above studio, which was occupied by Mr. W. G. E. Robinson up to the time of the latter's death last year.

PAGEANT PHOTOGRAPHS.—An exhibition has been opened at Messrs. W. H. Smith's Milsom Street depot of pageant photographic enlargements by the official photographers to the pageant, Messrs. Lewis Bros., of Seymour Street. The photographic successes of the official “picture takers” of the Bath Pageant have been obvious enough in the Pageant souvenir, and in the postcard reproductions, and need no comment, and the enlargements which they have now prepared of the beautiful pictures they took are worthy of the subjects portrayed. Chief among a series of 70 or 80 is a magnificent picture of the final scene, with Mr. Lascelles on the Temple steps and 3,000 performers acclaiming his triumph. This has a measurement of about 60 by 40, and is a wonderful picture, everyone's features being clearly distinguishable.

INDECENT POSTCARDS.—At Marlborough Street, before Mr. Mead, William Schmidt, newsagent and tobacconist, of High Street, St. Giles's, was summoned for exhibiting improper postcards in his shop window and to show cause why 125 of them found at the premises should not be destroyed. Mr. H. Muskett prosecuted for the Commissioner of Police. Mr. Mead sentenced Schmidt to six weeks'

imprisonment with hard labour, and ordered the cards objected to to be destroyed.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—The members of the Borough Polytechnic Photographic Society and friends spent a very enjoyable afternoon on Sunday, September 26, when, under the able leadership of Mr. A. H. Blake, M.A., they visited some parts of London of historical interest. The ramble commenced at the Horse Guards, and from thence to Charing Cross, down the Strand, where several places of interest were pointed out, to the York Steps, the Dark Arches, Adelphi, to Garrick's house. Fleet Street, where the old trade signs were noted, Alsatia, Johnson's house, Lincoln's Inn, Staple Inn, Giltspur Street, Smithfield, Clota-fair, and Bartholomew Close were among the places visited, and at six o'clock the party made their way to London Bridge Railway Approach, where tea was partaken of.

MR. SHAW TO LECTURE AT THE SALON.—Mr. G. Bernard Shaw will “Improvise on the Subject of Photography” in the Pall Mall Gallery on Monday next, the 18th inst., at 8 p.m.

BIRDS AND BEASTS, LTD.—According to the “Daily Mirror,” Mr. Cherry Kearton, whose wonderful photographs of bird life have won him a world-wide reputation, has been converted into a limited liability company. The company is called the Cherry Kearton Company, Ltd., and its nominal capital is £4,500, divided into 2,000 preference shares of £1 each and 2,500 ordinary shares of £1 each. The general public, however, will not have an opportunity of becoming shareholders in the company, as all the money has been subscribed by Mr. Kearton and his friends. The object of the company is mainly to buy all photographs of bird and animal life taken by Mr. Kearton, and to show them all over the country at living picture entertainments. Mr. Kearton is now in East Africa, taking a series of moving pictures depicting the life of wild animals of the forest and jungle, and from accounts already received from him in London the photographs will be not only of great value to students of natural history, but also of deep interest to the general public.

KOH-I-NOOR HOUSE.—Owing to the ever-increasing demand for their celebrated productions, the well-known house of Messrs. L. and C. Hardtmuth have decided to erect a building, worthy of its magnitude of their business, in Kingsway. This fine erection will be commenced shortly from the designs of Mr. J. S. Gibson, of 5, Old Bond Street, the builder being Mr. Jas. Carmichael, of Wandsworth. It is superfluous to add that Messrs. L. and C. Hardtmuth are the world-renowned manufacturers of pencils, including the celebrated Koh-i-Noor pencils, besides being the sole European representatives for Waterman's Ideal fountain pens. The building will bear the appropriate title of “Koh-i-Noor House.”

A SET OF LANTERN SLIDES, together with notes dealing with some of the most beautiful parts of North and Mid Wales, may be had on loan by anyone desirous of giving lantern lectures on Wales, on application to the General Manager, Cambrian Railways, Oswestry. To prevent disappointment, early application should be made for a set to be booked, stating whether coloured or uncoloured slides are preferred.

THE CINEMATOGRAPH BILL.—The text of the Cinematograph Bill, as amended in Committee, has now been issued. The following is the text of the principal provisions of the Bill :—

1. An exhibition of pictures or other optical effects by means of a cinematograph or other similar apparatus, for the purposes of which inflammable films are used, shall not be given unless the regulations made by the Secretary of State for securing safety are complied with, or, save as otherwise expressly provided by this Act, elsewhere than in premises licensed for the purpose in accordance with the provisions of this Act.

2. (1) A County Council may grant licences to such persons as they think fit to use the premises specified in the licence for the purposes aforesaid on such terms and conditions and under such restrictions as, subject to regulations of the Secretary of State, the Council may by the respective licences determine. (2) A licence shall be in force for one year or for such shorter period as the Council on the grant of the licence may determine, unless the licence has been previously revoked as hereinafter provided. (3) A County Council may transfer any licence granted by them to such other person as they think fit. (4) An applicant for a licence or transfer of a licence shall give not

than seven days' notice in writing to the County Council and to the chief officer of police of the police area in which the premises are situated of his intention to apply for a licence or transfer: Provided that it shall not be necessary to give any notice where the application is for the renewal of an existing licence held by the applicant for the same premises. (5) There shall be paid in respect of the grant, renewal, or transfer of a licence such fees as the County Council may determine, not exceeding in the case of a grant or renewal for one year £1, and in the case of a grant or renewal for any less period 5s. for every month for which it is granted or renewed, so, however, that the aggregate of the fees payable in any year shall not exceed £1, or in the case of a transfer 5s.

3. If the owner of the cinematograph or other apparatus use the apparatus, or allows it to be used, or if the occupier of any premises owned those premises to be used, in contravention of the provisions of this Act or the regulation made thereunder, or of which any licence relating to the premises has been granted under this Act, he shall be liable on summary conviction to a fine not exceeding £20, and in the case of a continuing offence to a further penalty of £5 for each day during which the offence continues, and the licence (if any) shall be liable to be revoked by the County Council.

4. A constable or any officer appointed for the purpose by a County Council may at all reasonable times enter any premises, whether licensed or not, in which he has reason to believe that such an exhibition as aforesaid is being or is about to be given, with a view to ascertaining whether the provisions of this Act have been complied with. The Act (if passed) will come into operation on January 1, 1910.

Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE VALUE OF GOODWILL.

To the Editors.

Gentlemen,—As this week is the second time that a reply has been given to the above query lately, I feel that it would be only fair to call attention to a slight error in the answer, which not only would be calculated to mislead an intending purchaser, but also gives the advertiser "shark" a better opportunity of getting a much larger price for his "business" than he otherwise would do if dealing with a person who understood what he was about. The mistake lies in the statement that the goodwill is based upon the *net annual profits*, which is fair enough in fact, but as the net profits must necessarily be the profits after all deductions for outgoings are made, those deductions should include the *salary of a manager*, or, what amounts to the same thing, the cost of living of the proprietor in the event of his looking after the business himself. This will often not only bring the returns shown well below the apparent amount given, but in most cases show that the affair is being run at an absolute loss when perhaps £200 or £300 is claimed to be correct. Accountants and valuers are well enough acquainted with this item, but perhaps if it is made more public it may be the means of saving some few experienced people from sinking the whole of their available capital in the hope of the "magnificent" undertakings so frequently advertised as "magnificent bargains," and which seem to be selling to the gullible amateur at the present time like "hot cakes."—I remain, yours
 Sincerely,
 BUSINESS MAN.
 October 8, 1909.

AMYL ACETATE.

To the Editors.

Gentlemen,—"Varnisher" will find that the disagreeable smell of amylic acetate is completely neutralised by the addition of a small proportion of common oil of lavender. When the amount is exactly adjusted the mixture smells of neither the one nor the other. No harm is done to the varnish.
 E. J. MILLS, F.R.S.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. P. Quinn, 52B, Grand Parade, Harringay, London. Photograph entitled: "North Pole Burlesque."
- T. H. Bamford, 45, Montagu Street, Kettering. Photograph of a Freak Potato (resembling an Animal) grown at Kettering.

F. SMITH and others.—In our next.

SULPHITE OF SODA.—(1) With reference to your interesting article on the above, I should be much indebted to you if you would inform me, through your "Correspondence Column," whether it matters what particular acid one uses as a preservative. I employ sulphuric acid in my fixing bath, and should prefer to adhere to one throughout. (2) Is the bottle with an oil seal and a glass tube a good means of preserving a stock solution? One cannot shake it as one does the ordinary bottle, so one may draw off all the sulphite at the beginning and be left with very weak stuff. (3) "Das Photographieren," which I bought on the strength of a review in the "B.J.," recommends camphor as the best of all methods. You simply drop in a piece, which floats on the top, and acts as a sort of charm. Does English experience corroborate this mystery?—
 J. ROW FOGO.

(1) Acid sulphite was stated in the article, by which we meant acid sulphite (or bisulphite) of soda, or potassium metabisulphite. One dram of the metabisulphite to every ounce of sulphite of soda is an excellent preservative. (2) Certainly it is a good way of keeping any stock solution from contact with air, but we have not actually tried it with sulphite. Oxidation by contact with air is, however, not the only cause of deterioration with sulphite, as we have known some samples to deteriorate badly in solution when well sealed up. (3) We know nothing of this method of preservation, but if effectual it is a very simple one.

GRATEFUL.—We should choose No. 4 (better if of 12in. focus), No. 6, or No. 5.

H. R. ROBERTS.—We do not know of such a thing on the market. We advise you to write Messrs. Marion, who are specialising in this class of apparatus, and could no doubt supply you.

PERCY LONDON.—From R. J. Moss and Co., 98-99, Snow Hill, Birmingham.

OMNICOLORE PLATES.—Will you kindly let me know the formula of the reversing solution recommended for Jougla's "Omnicolore" plates, as mentioned in the "B.J. Colour Photography Supplement" for October 1, page 74?—E. F. GUITON.

The formula is:—

Potass or soda bichromate	8 gms.
Sulphuric acid	12 ccs.
Water to make	1000 ccs.

QUICK PRINTING.—Can you tell me the method employed in turning out bromide postcards quickly while you wait? Is it the developer? If so, would you kindly state formula? Is there a process of dry developing that would suit?—M. S.

The usual method is to print from the wet negative, with a thin piece of celluloid laid on the film. The bromide print itself is developed by a quick-acting solution, such as metol-hydroquinone, fixed in strong hypo, and rinsed and dried in spirit. We know of no "dry" developer which could be used.

FOCAL-PLANE IN REFLEX.—I should be glad to know if a reflex camera with shutter release is as efficient as a focal-plane shutter; or to be sure I make myself understood, would you get a negative as well exposed with a shutter release with, say, 1-50 of a sec. as with a focal-plane shutter 1-50, other things (stop, etc.) being equal.—REFLEX.

Provided that the shutter blind is at the same distance from the plate in the two cases, there is no difference. The mirror is out of the way before exposure commences.

F. R. P. AUSTIN.—Address the Tress Company, 4, Rathbone Place, London, W.

DISSOLVING DYE.—I wish to combine fast scarlet dye with collodion by adding the dye to the liquid collodion. This is to make screens. I have dissolved the dye in alcohol and added to the collodion, but cannot get the combination sufficiently intense or deep enough. Can you suggest a way?—E. Y. E. N.

If you cannot get enough of what you call fast scarlet dye, you will have to use another kind, and, without knowing what you want it for, we cannot well suggest a dye. If you want a tri-colour red filter, you might find "Rapid Filter Red," spirit soluble, satisfactory. This you can get from Fuerst Bros.

DYES FOR COLOUR PHOTOGRAPHY.—I have been reading an article by H. Q. on "Reproduction of Screen-plate Transparencies in Paper" in your number of October 1, and am much interested in same. Can you tell me where the dyes therein mentioned can be procured?—G. W. WELLS.

We advise you to try Messrs. Fuerst Bros., 17, Philpot Lane, London, E.C.

ACID FIXING BATH.—Some time ago Messrs. Lumière published a formula for an acid fixing and hardening bath, which contained, in addition to hypo, bisulphite lye and chrome alum. I have mislaid the formula, and cannot find it in any of my books of reference (it is not in last year's "Almanac"). Will you please give it to me, with directions as to mixing?—CATHAY.

The formula for the bath appears in the "Almanac" for 1907, p. 759. It is:—

Hypo	3 ounces.
Soda bisulphite lye	100-150 minims.
Chrome alum	50 grains.
Water	20 ounces.

2. So far as our experience goes, it is quite safe when used as directed.

JAMES HOMER.—It is possible the paper is at fault, but developer made up with water highly charged with air would give the same the spots, and is very probably the cause of the evil recurring irregularly. You cannot have a better toning process than the sulphide or thiomolybdate. You will find formulæ for the former in the "Almanac," page 809. The latter you may obtain from H. Edmund and Co., Ezra Street, Columbia Road, E.

CARBON PRINTS.—1. Could you kindly inform me as to the cause of white marks like dabs with the finger, and also little fine white lines on double transfer carbons, appearing when developed on flexible support? I have tried a new bath, and taken great care not to touch anything with the fingers, also new supports, and using less waxing solution. 2. I should also like to know the method of obtaining the best possible vignettes for small carbon prints in double transfer. I should be very pleased to have some advice on these subjects, as I have had a lot of trouble with them.—CARBON.

1. We cannot account for the marks, unless they are really caused by finger-marks on the tissue. The white lines may possibly be due to the tissue having been dusted with an unclean brush. If you had sent us two or three prints as samples of the trouble we should have been in a better position to assist you. 2. Small vignettted carbon prints, by the double-transfer method, are not easy to obtain. The vignetting mask for the work should not be so abrupt as is permissible with silver prints. It helps matters somewhat if, after the print is taken from the frame, it

is exposed to the light for a very brief time, but not sufficient long to produce a tint that is not removable in the developer. You will find the single transfer method simpler and better vignettes.

MATT VARNISH.—Would you oblige by giving me a good formula for matt varnishing negatives for working up on glass side of the negative?—S. JENKINS.

Sandarac	90 grs.
Mastic	20 grs.
Echer (.720)	2 ozs.

Dissolve the two resins in the ether and then add benzole 1 ½ oz. The more benzole the coarser the matt.

T. OSMAN.—If the negative sent is a fair sample of your general work it is by no means a thing to be surprised at that you cannot get on well with the platinotype process. From such a thin and veiled negative it is quite impossible to get good and brilliant platinum prints. For that process tolerably vigorous ones must be employed in order to obtain good results.

X. Y. Z.—The pictures sent are very good photographs. If you publish them you would be sailing very close to Lord Campbell Act. You may call them artists' studies, but they are too coarse and vulgar for that. They are bordering on the indecent, and I doubt if any respectable stationer or print seller would show them in his window. If you wish to publish artists' studies they must be very different things from those you enclose. Calling such pictures "Artists' Studies" will not relieve you from possible trouble.

"KRISTAL" LANTERN-SLIDE COMPETITION.—The Leto Photo Materials Company, Limited, announce a competition, open to all amateur photographers, for sets of four slides taken on Edwards' "Kristal" plates. Thirty cash prizes are offered, the first three being £5 3s., £2 2s., and £1 1s. respectively, with two of 10s. 6d. each and fifteen consolation prizes of 5s. each. The winning slides will become the property of the Leto Company, who reserve the right of reproducing them; unsuccessful slides will be returned if accompanied by a stamped addressed wrapper (not loose stamps) for that purpose. The competition closes on December 31, 1909, on or before which date all slides, accompanied by the necessary coupon and packed in the original box in which they were purchased, must reach the office of the Leto Company, Round Wall House, 1, Crutched Friars, London, E.C., marked "Kristal Competition."

THE ANTARCTIC EXHIBITION.—The very interesting exhibition of the equipment and collections of Lieutenant Shackleton and his fellow-explorers of the *Nimrod*, which has been held in Savoy for the past few weeks, will be remembered by photographers for the really excellent photographs shown of the scenes and incidents of the dash "farthest south." The photographic outfit was provided by Messrs. Newman and Guardia, and the majority of the photographic results were obtained with the "N. and G." cameras, two of the "Special B" patterns of which are shown in working order after the long journey to within 100 miles of the South Pole.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

A most entertaining evening was spent at the Photographic Salon on Monday last, when Mr. G. Bernard Shaw "extemporised" on photography, or rather on art in photography. (P. 814.)

The publishers of "Photograms of the Year" are to be congratulated on issuing this annual review of pictorial photography whilst the exhibitions are in full swing. (P. 826.)

In addition to the Royal and Salon two photographic exhibitions are now open in London: That of members' photographs at the Lyceum Club and pictures by American workers at the "Amateur Photographer." (P. 824.)

The conclusion of Mr. L. Haweis's article on the coupon system in professional photography affords further instances of the possibility of lowering prices as a whole by resorting to the coupon method. (P. 816.)

A very strong case for the red-sensitive plate in portrait photography is put by Mr. R. J. Wallace, who very clearly points out that the sitter is a coloured object, and that, therefore, the most satisfactory method of obtaining a good negative is by means of a colour-sensitive plate and adjusted filter. Mr. Wallace states the difficulties in the way, but describes colour-correct photography as the "coming factor in portrait work." (P. 818.)

A writer in "Photo-Notes" describes some recent experiences indicating the advantage of keeping ordinary gaslight paper in a perfectly dry state. (P. 833.)

Professor R. Namias has experimented with boric acid in the diamidophenol developer, a combination which he recommends on account of its greater sensitiveness to restraint by bromide, as also of its lesser degree of sensitiveness to temperature. (P. 820.) An editorial note on the paper appears on page 814.

In the conclusion of his paper on the collection of photographs, Sir Martin Conway lamented the fact of the non-existence of a trade in second-hand photographs. (P. 821.)

The description of the new form of mount of the Dallmeyer portrait lens is given under "Patent News" on page 825.

Process cameras and multi-colour machine-printed photographs are among the topics dealt with under "Photo-Mechanical Notes." (P. 824.)

EX CATHEDRA.

Halation in Night Photography.

A necessary feature of the "night photograph" is the presence of the street and other lamps, by the light of which the photograph is taken, and the fact that these lights face the camera renders halation a very important matter to guard against. Backed plates are, of course, essential, but backing will not, as a rule, eliminate all blur around the lights. This fact, however, does not necessarily prove that the backing is ineffective, for in many cases the effect remaining is not halation, properly so called, at all. That is to say it is not an effect due to reflections or any other phenomena in the plate, but a true record of an actually existing fact. The air at night is seldom free from mist, and hence around each light there is a certain amount of visible light scatters that should be recorded in a true photograph. This is one of the phenomena of nature that often escapes the observation of the untrained eye, though artists are quite familiar with it, and while the effect may appear unnatural to the photographer, its truth will become apparent even to him if he examines in a stereoscope a stereoscopic slide of the scene. The idea that the lights should be sharply defined dots in the photograph is altogether a mistaken one, and when the lights do take this form it is simply an indication that the exposure was too short to record the blur properly. Such effects of under-exposure are often seen in photographs of illuminations, such as those at the White City. A very short exposure will show nothing but lines of sharply defined dots, without halos and with hardly any trace of the buildings upon which the lights are fixed. A correct exposure will show the lines of the buildings and also the light scatter around each lamp, and if this scatter is very pronounced the dots will merge into lines of light. Such an effect is probably quite true to facts, and halation may play no part in it, though many photographers will actually try for the under-exposed and untrue effect. The worst defect in night photography is not halation, but reversal, the effect of which is that the light itself sometimes shows as a black spot in the centre of a luminous globe. Backing diminishes the chances of this to a certain extent, but when the light is very bright, as in the case of an arc lamp, it is best to avoid a direct view of the light altogether. True halation can be distinguished by the appearance of a bright ring of light surrounding the lamp and at a little distance from it. This ring will have a sharp inner margin by which we may distinguish it from an actual halo ring due to mist.

* * *

Halation in Interiors.

In interior photography very erroneous ideas often prevail with regard to halation, just as they do in the case of night photographs. There seems to be a prevalent idea that the tracery and bars

of a window should in all cases be shown perfectly defined and in sharp contrast, however brightly the window may be illuminated, and if this effect is not obtained after taking the precaution of properly backing the plate, then the backing is presumed to be a failure. It does not, however, follow that this idea is correct, for if the sun is shining on the window it is impossible that the bars should appear sharp to an observer, and if they are made to so appear in a photograph the effect is unnatural. The effect that the photographer has perhaps laboriously retouched out was in all probability quite a natural and true one, though want of observation prevented him from seeing it at the time of taking the photograph.

* * *

A Fermentation Method of Developing Carbon Prints.

According to a recent German patent (No. 213,772, of July 19, 1908), taken out by Dr. L. Jacobsohn, of Charlottenburg, it has been found that the exposed and unexposed parts of a bichromated gelatine film exhibit differences in respect to the action of digestive ferments, such as bodies of the pepsin class. The exposed portions are not digested or rendered soluble by the pepsin, whilst the unexposed portions are fully acted upon. The fact is made the basis of a method of development. For example, if a pigment film be sensitised with a 3 per cent. bichromate solution exposed with its non-sensitive side behind a negative, placed in 1 per cent. pepsin solution, containing also $1\frac{1}{2}$ per cent. of hydrochloric acid, the print will become fully developed in three hours at a temperature of 80 deg. Fahr. Owing, it is said, to the longer time of development, finer details are obtained in the half tones, whilst it is further claimed for this method of development that it affords good results in cases of considerable over-exposure of the print.

* * *

Portraits of Men.

If we have to thank the "individual" portrait photographers for one thing more than others, it is their demonstrations of the success which can be made of full-length and three-quarter length portraits of men, despite the opinion very commonly expressed that the severity of the lines of masculine clothing forces the photographer to portray only the head and shoulders of his male sitters. And this has been done in many of the portraits which have been shown of late without recourse to attiring the sitter in a cloak of the Inverness type, which some have advocated in reaction from the almost geometrical cut of modern clothes. Flowing lines are readily obtained by this artifice, but in nine cases out of ten the sitter will appear to his friends strangely clad, and the photograph suffers as a likeness. The ordinary overcoat of thin, clinging cloth, such as that used for rainproof overwear, may, however, be requisitioned with equal success, and in several studios of late we have noticed the skilful use made of these garments in producing portraits of men which, apart from lighting and likeness, had very pleasing qualities of composition.

* * *

Boric Acid and Amidol.

The paper by Professor Namias on the action of boric acid with diamidophenol suggests that in over-exposure the addition of the acid may be useful, as it apparently gives the bromide greater restraining power. We cannot, however, agree with all the remarks made upon the action of acid sulphite with amidol, or even with those concerning the action of amidol alone. For instance, it is stated that amidol tends to give weak images, and that this tendency is increased by the

addition of acid sulphite. Any developer can be made to give a weak image under certain conditions, but amidol will give as strong an image as can be desired if the formula is adapted to that purpose. Indeed, one of the things that renders amidol such a favourite developer for bromide paper is the strong, rich black that it so readily gives. The remarks with regard to the effects of acid sulphite almost amount to a condemnation of the popular acid amidol developer, yet so far as our experience goes this formula is in no way behind the plain amidol and sulphite one in respect of giving good blacks. It is a matter of common knowledge that the blacks are spoilt with any of the usual amidol formulæ if over-much bromide is used, hence it is difficult to take full advantage of the action of bromide in cases of over-exposure. If this difficulty disappears with Professor Namias's boric acid formula it is a distinct gain, but this can readily be admitted without throwing doubt on the well-tried formulæ in common use, and so generally successful with correct exposures.

MR. G. B. SHAW ON THE LINKS.

A MOST entertaining evening was spent last Monday at the Photographic Salon, when Mr. Shaw improvised upon the subject of "Photography." At least, it was entertaining to those who had nothing to suffer from the speaker's caustic fun directed against modern pictorial tricks. There was certainly a grim irony in the fact that the apostles of high photographic art should be told in their own house and by their own guest to go back to the plain ways of photography, to abjure imitating certain effects that were the natural outcome of the development of painting. Many a member of the Linked Ring was seen to writh and look apprehensively around. But they took heart of grace whenever the lecturer, in his usual conciliatory manner, denied, in particular cases mentioned by name the sweeping generalisations of blame. He professed at the outset to be too old and too tired to go into the matter of art and photography; yet he managed to talk of little else for two and a half hours. Naturally, he remained at his old standpoint of the vast superiority of photography over art, excepting in one particular, namely that art was a much quicker business. He compared dry-point etching made by Mr. Strang in two sittings with a photographure by Mr. Coburn made in many days, and a platinum print by Mr. Evans which took five days to print. In fact, the evening was not untruthfully described by one speaker as an apotheosis of Evans and Coburn with a passing vote of mild censure upon the "British Journal of Photography," which, Mr. Shaw said, always lost its temper whenever anyone said that photography was art. He, however, admitted reading our literature with great regularity, which, of course, immediately and entirely won us over, especially as we perceived that our whole attitude for years past towards pictorial efforts was precisely that which he himself was taking in his animadversions upon certain wrong tendencies of photographers. He maintained that many faults were common to both photography and painting and for the most part they were stated to be untruthfulness in the former, due to wilful neglect of simple photographic qualities, and in the latter to the inability of the modern painter to paint. And here followed one of the highly amusing "tomfool" digressions about oil painting being a lost craft because the Royal Academicians do not put paint on as a carriage-painter does. It is as useful to take Mr. Shaw jocularly as it is to take him seriously. He thinks that Van Eyck, who is his pet painter, painted

with the same material and in the same manner as a carriage-body painter. Well, he must continue to think that, that's all. He gets his cash and his kudos for thus bringing his ignorance, and his public love him for it. It would spoil the fun to tell him that carriage painting is much more akin to lacquering, and consists of endless rubbings down"; it would be futile to suggest, further, that the Academician has materials and means different from either Van Eyck Wendover of Long Acre. It was for the sake of stating his ideal of the smooth and shiny art, and of glorifying the enamelled silver print, that he let these pleasantries run away with him. The worst of it is that he insists during discussion that he is serious, and thus everybody finds themselves upside down in a *cul de sac*, in the dark, and with no language but a cry. A good many of Mr. Shaw's arguments cut both ways. For example, the "Juliet" instance, which, together with that of the "Aunt Maria" and other plums for public taste, has been seized upon by the daily papers whose reporters did not wait for the discussion, where Mr. Shaw shone at his brightest. The "Juliet," in the case of the painter, was a model dressed up and painted with certain realisations and eliminations, and made to be exactly what the public liked and wanted. This is absolutely truth—the sole method possible, practised from Pheidias to Rossetti; but Mr. Shaw let it all tilt off his tongue as though it were a matter for scoffing, and the gaping part of his audience, who came to laugh and didn't intend to go away without it, took their cue, and laughed! When the speaker explained that the photographer took the same model and dressed her up and photographed her and called her "Juliet," but that the public wouldn't have her at any price, but said she was Miss Wilkins, *that's* where the laugh should have come in, as indeed it did to a fair extent. If Mr. Shaw had said no more than this he would have stated the case of art and photography with admirable sententiousness, and discussion would have been for. To tickle an audience with assertions that Academicians should be apprenticed to carriage-painters is simply to become a public entertainer, and nothing beside, and Mr. Shaw should have been at the Salon speaker for the utterance of such gems, between Churcher and THE Odell.

There was one dictum of the lecturer's that nobody seemed to regard seriously, although, in talking with him afterwards, we found that he honestly meant what he said. It was that painters should be paid for their work according to time, and not according to merit. It was a gross injustice, he implied, that a man like Sargent should get such fabulous sums as he does for his portraits. Say that Mr. Strang did his dry-point in two hours, and Evans and Coburn their prints in a week; allow the eight-hours day, and what shall we say an hour? A shilling? (All men are equal except the carriage-painter, who is a excrescence of worthiness.) Strang gets a florin for a dry-point etching much admired by Mr. Shaw, and the photographers get £2 8s. for their prints. Sargent would get less still for his charcoal portrait done in a few minutes, and which would be a thing worth a hundred thousand photographic prints. Mr. Shaw overlooks the fact here that the training of the artist is a life-long affair that is never paid for at all, but without which the rapid masterpiece would be impossible. He did not overlook it when he was pointing out the advantages of photography over art in the matter of their relative ease of mastery.

Perhaps the funniest thing Mr. Shaw uttered was that Dlmeyer would sell you for £30 a lens which was a marvel of accuracy, but useless without the contrivance kindly supplied with it, by which one could make it do the work of a spectacle lens at eighteenpence. He scattered gratuitous advertisements with a lavish hand.

We ourselves came in for one, for which we are duly grateful. The Cristoid film was also singled out for approval; but as to papers, Mr. Shaw thought that photographers ought to make their own. He even extended this recommendation to films, being pushed for an answer by one of the after-speakers.

The discussion which followed included some of the matters we have already alluded to. It was participated in by the following gentlemen:—Mr. Warburg, Mr. Evans, who disowned the five-days negative; Mr. Coburn, who spoke of his photogravures; Mr. Arbuthnot, Mr. Radford, Mr. Tilney, who called the lecturer a viper in the bosoms of the Links; Mr. Emanuel, who deplored fogs, mists and dusks in photographs, which the lecturer said was impressionism derived from under-exposure; Mr. Holbrook Jackson, who maintained that art was art and photography was photography; and others. Mr. Craigie was chairman. The meeting closed at a late hour.

SOME SEASONABLE HINTS.

NOTICES have for some time past been posted up at post offices in most places enjoining the public to post early all parcels which are required to be delivered during Christmas and the New Year in distant parts. This should remind photographers that the Christmas season—which sometimes is a profitable one to many—is getting near. A question that occurs to us just now is, whether professionals—particularly middle-class ones—as a rule profit from this transient class of business as they might do if they put more enterprise and energy into it. Manufacturers have long been putting Christmas and New Year cards of their newest designs on the market, and artistic and excellent most of them are. In past years we have learnt from manufacturers that photographers have delayed ordering until many of the designs their travellers have submitted had been sold out, and it may well be understood that it is the best and most taking ones that sell out first. People then sometimes complain that they are unable to obtain what they require. We may therefore remind them that there is none too much time for decision as to what shall be issued for Christmas use.

Portraits on postcards are now very commonplace things and, after all, carry but little profit to the photographer. What is really to be cultivated is something of a more *recherché* character—say a portrait of the sender mounted on one or other of the superior Christmas or New Year's greeting cards with the sender's autograph appended. If a specimen of such a card were sent to customers with a small portrait of themselves from the latest negative, or possibly one of a group of their children upon it, together with a politely worded circular or note, saying that such cards can be supplied at such or such price, we have little doubt that in most instances business would result. We happen to know that in several instances this system has proved a good stroke of business. Should it not secure a direct order the outlay involved is but little, and is generally more than recouped by the advertisement—the photographer keeping his name before his customers. The prints so used, we might suggest, should not be the usual black bromide, but prints toned to a sepia or some of the more novel colours obtainable by toning bromides. In fact, novelty is what should be aimed at in this particular class of business, as it will then the better appeal to those who are most likely to give orders.

Enlarged portraits are sometimes given as Christmas presents, but they, if large and highly finished, are somewhat costly. However, if a feature were made of small enlargements—say of the 10in. by 8in. size—lightly finished, and neatly framed in an inexpensive frame, they would lead to business in many places and prove a re-

munerative line, but to make the thing a success the pictures must be brought prominently before the customers, that is, specimens submitted at their homes, and it is none too soon to do this. Instead of showing the pictures in frames, they may be bound up in the *passee partout* style, which will be less costly than framing, and the prices might be quoted at per half dozen. The old proverb, "Procrastination is the thief of time," is one which we fear is not always realised by every photographer with regard to the business of a season. Hence our recommendation now is to take time by the forelock and lose no opportunity in preparing for the coming Christmas season.

While writing upon "seasonable" topics, we may make one or two suggestions of a directly practical nature. One is that the roof of the studio should receive some attention. The rain, of which we have unfortunately had too much of late, has no doubt made itself manifest through the roofs of many studios, and no time should be lost in making them water-tight. Bad as the weather has been, it is but natural to anticipate that worse, so far as leaky roofs of studios are concerned, will follow as winter advances. Snow, while melting, seems to be able to find its way through roofs, though rain may not. But whichever gets through, it is liable to damage the backgrounds, the furniture or anything else in the studio. Nothing

looks much worse, or is more depressing to sitters, than to see stained blinds and curtains, with possibly dishes or basins placed about the floor to catch the dropping water.

Another point that should receive consideration just now is the temperature of the studio. Up to the present the temperature has not been such that fires have been needed, but we cannot expect that to last much longer; therefore it will be well to see to the heating arrangements, whatever they may be, as they have been out of use for so long. In the case of stoves burning solid fuel it is almost certain that the flues are more or less choked up with soot. When these have been cleared it is possible, in the case of iron pipes, that they have become more or less rusted at the joints, and allow smoke to escape into the studio. This is a thing that should be seen to at once, as the escaping smoke, though it may be but trifling, produces a certain degree of fog in the studio, and, further, its condensation on the cold glass produces a yellow-brownish film on it, which greatly reduces the actinic quality of the light. This thin film on the glass may not really be noticeable to the eye, but it is there nevertheless, and has its effect, though the cause of the prolonged exposures is sometimes not suspected. Moreover, smoke, however slight in the studio, is often irritating to the nasal and other organs of sitters, as they come into it from the outer atmosphere.

THE COUPON SYSTEM AS APPLIED TO PROFESSIONAL PHOTOGRAPHY.

II.

Now, these coupons*—which are a fair sample of what is put out—both proclaim an astonishing reduction. Clearly this may be engineered by over-pricing the goods in the first instance. The class of studio to patronise Ticket A will, as likely as not, willingly accept \$3.50 per dozen for cabinets no whit inferior—here over-priced at \$6. As \$1.25 is quoted for half-a-dozen, \$2.50 would buy twelve. To this figure must be added the fifty cents paid by the customer to the agent. So that the customer pays \$3 for what would ordinarily cost him but \$3.50—a hook which, unadorned with all the lurid paraphernalia pertaining to artificial bait, would catch no one. But as the fifty cents goes to the agent, the photographer has undercut his price \$1—that is, nearly 30 per cent.—on the score of increased business; and unless his business temporarily increases something like 50 per cent., he may be put down a loser on the transaction (bar the advertisement, if it was any), since he has not only to make up the 30 per cent., but also some considerable profit to offset the extra work entailed. On the other hand, as the ticket is out for only half-a-dozen (to disguise the dozen price), the receptionist will not always succeed in talking the customer into a full dozen. It is true that not every customer would take a whole dozen in the ordinary way, but the best way to induce this habit is not to quote for less, except when compelled to. The suggestion of half-a-dozen only helps to sell the ticket, and, in the event of not selling more than six pictures the photographer loses considerably more than 30 per cent., having the plate to make for half the money. So much for the ticket which cheapens: the instance is not by any means an extreme one.

In Ticket B the apparent reduction is even more astonishing, for here we read that \$15 per dozen is the usual price for these fine folders, two of which are priced at only fifty cents. \$1.50 for fifty cents! Here, again, the ordinary price was \$7.50, and "glad to get it." "Only a hundred of these certificates issued"—a considerable understatement. "Good for thirty days from date of sale"—anything to hurry them along! "The simple

reason previously stated," namely, "that we may become thoroughly acquainted" for the genial occupation of decorating "your home," etc. And this is business?—or is it?—or is it not?

This ticket is built on the well-known lines of the "two-for-a-half" proportion, and it must not be supposed that, in those localities where this style of ticket "has all others skinned" its terms are not fully patronised by many customers quite alive to the terms of it. The photographer offers two pictures for fifty cents, and two for a half these will have, and, positively refusing to be talked into ordering more, they take their two pictures and smile themselves into the street. And the popularity of this ticket—on the Pacific slope, at any rate—has been such that, no sooner is one gallery through than another will start a ticket on the same principle. Then the "live ones" get another two pictures for fifty cents, and so on.

And this is legitimate, for the best picture sells, orders for extra copies being the rule. Nevertheless, it may be imagined that the members of this class of customer are not popular among the galleries, and they have their name—they are called "two-fers." But because the best picture sells, extra copies can only be had at a greatly increased price, which in this case is 75 cents each. This figure may be too much for some "two-fers" to give, and they may be lost in consequence if the terms are strictly adhered to. But, at any rate, the advertisement remains, and the work of the gallery is not cheapened.

One method adopted against the "two-fers" has been that of insisting upon having an appointment. But the "two-fer" who applied for an appointment was postponed indefinitely until either he was tired of using the elevator, or he decided to take more than the two, in which case no further delay occurred. But this very unwise method cures itself as the gallery which practises putting its clients out of patience so discovers, the news spreads apace, and the chances of another ticket on the same studio in the near future are "queered"; the coupon will not sell.

The value of an appointment with all coupon work can hardly be under-estimated, and the request for such should

* See "B. J.," October 15.

be printed clearly on the ticket, as, if there is a crush of work, as at times there will be, it is very necessary to be able to keep the ticket-clients well in hand. For this also prevents the system materially obstructing the usual work of the studio. It is most annoying to have to turn away a dozen cabinets at \$7.50 to make room for three half-dozen at a total remuneration of \$3.75. It is good to appear busy, but the price of appearances may be too high, as they would be in this case.

Also, the time to put out coupons, as well as the number of them, should be most carefully considered. With a busy time coming to canvass people for photographs who need no canvassing is simply to mortgage your clientèle hand over fist. With probable depression of trade ahead tickets will go as flat as they are printed. Either they will not sell, to the disgust of the agent who, if he is spiteful, may very likely declare abroad that "you can't sell tickets on that gallery now"; or else, having sold, they will not be presented, to the disgust of clients, who vow they will never buy another.

For a time-limit seems almost necessary, if for no other purpose than to make it quite clear that the offer is a temporary one. In this case, when next canvassing the same people, instructions should be given the agent to exchange the old coupons for new and make it up to him on the terms of some arrangement satisfactory to both parties; or, what is more usual, to let the new coupon go at half price to possessors of those out of date, to which the agent will generally agree. And here I may mention the practice of buying up the coupons on other galleries, as well as record, once and for all, the case of the photographer who advertised that he was prepared to honour the coupons of all other galleries!

It is useful sometimes to "keep tab" of the agent when possible. This can be done by insisting upon him taking the names and addresses of all those to whom he has sold tickets, in order that customers may be circularised, should they fail to present their tickets within a reasonable time, and, also, if necessary, to back up every day's canvass with a notice through the post assuring customers of the genuineness of the offer. Here is the circular adopted by one man for this very purpose:—

DEAR MADAM OR SIR,

.....1909.

We beg to confirm the terms of the contract purchased by you from my Special Representative, and to inform you that we have no share in the 50c. you have paid him therefor, and which covers cost of distribution only.

As far as we are concerned the two pictures contracted for are given freely, this entailing upon you no obligation whatever except that, should you desire to avail yourself of the very exceptional terms it introduces to your notice, the said contract or certificate must absolutely be presented at this gallery one month from date it bears, either for use or for extension of time, otherwise it will become null and void in the terms of its provision.

We have adopted this method solely for advertisement purposes; and, in the orders for extra copies we expect to book, coupled with clients' good opinion of our high-grade work, you will be pleased to read not only our sole chance of profit, but also your own guarantee.

Any complaints of misrepresentation or incivility should be at once reported to us here.

Finally, we hereby certify that only One Hundred of these contracts have been issued for distribution, and that none are sold at the gallery.—Thanking you in anticipation of an appointment,
Yours faithfully,

Miss Julia Juggins.

P.S.—All clients requiring more than the two pictures will be given precedence as a matter of course.

As the news gets about, a typewritten circular of this kind gives the agent a standing in the town which will go far to help him sell your tickets. Besides serving in some measure to discountenance agents using the name of your gallery without permission—a common practice—it helps in a way to check the bona fide canvass, and the class of customer approached. It is clear that the "two-for-a-half" proposition should be in reliable hands, as to have a large number of tickets all placed in one small area of the town is a heavy mortgage on the connection which may be assumed to come into existence in response to your advertisement.

Be sure, also, to make the agent return all undelivered coupons and specimens whenever you shall deem it advisable to withdraw your offer. Otherwise, in the case of any friction arising between you, the agent may choose to sell the tickets over your head in any unscrupulous way which it will occur to him may injure you most. Likewise, the specimens are anybody's to use, to whomsoever the agent may care to give or lend them for that purpose. In which case some stray customer may one day call you to account for letting copies of his picture get into strange hands; and yet you could not restrain the vindictive agent from either of these practices without an infinity of trouble, and probably considerable loss of prestige.

Many proprietors of studios calculate to switch the customer on to something quite different or more remunerative than that advertised. This is only business, and a clever receptionist will frequently reap a harvest for her employer. But unless her talent for talk is exceptional, the procedure will be found to waste a good deal of valuable time that were better spent—not at the time of sitting, but later—on the examination of proofs, which you should try to arrange to take place at the studio. After all, the straight ticket is the only ticket in the long run, as it is far less liable to create friction than one requiring considerable explanation.

Some men will profess a partiality for a style which will *not* appeal to their customers. They depend, they will tell you, solely on the excellence of the photographs themselves to sell the tickets, the agent to explain that clients can have their choice of styles at the studio. This method is believed to play into the hands of the smart receptionist. Customers arrive ready primed to decide on a style they have yet to see and approve. The suggestion once made, there is frequently less difficulty in inducing the client to part with more hard cash than it is likely he or she would otherwise do. That is the root-idea, and no doubt some agents can make it pay—when it is really inconvenient to carry styles mounted. Generally, however, the coupon will bear some such phrase as "This certificate also entitles the holder to a similar reduction on all other high-grade work"—which occurs on Ticket B aforesaid.

Have I now said enough to prove that the man who puts out coupons ought to have plenty to think about some time or other? If not, I will add that there is much else which will thrust itself upon the notice of studio proprietors, due to peculiarly local conditions—the class and temper of their clientèle, the class of work they cater for, and the temper in which that work is executed. There is no gauging all these things here, and I have already exceeded my space.

L. HAWES.

L.C.C. LANTERN SLIDES.—At the meeting of the Education Committee of the London County Council on October 13 it was reported that the lantern slides in the Council's collection had now been catalogued for the first time in a single complete volume. The committee have been in communication with the Colonial Governments with a view to securing modern slides illustrative of Colonial scenery, and industries, and they have been able to include some 320 new slides made from specially selected photographs and negatives which have been placed at the Council's disposal by the Govern-

ments of the Cape of Good Hope, Canada, Natal, New Zealand, and Western Australia. As similar facilities have been promised by the Governments of most of the other Colonies, it was anticipated that a large number of additional slides will be available at an early date. Sets of slides illustrating places of interest on the Cape Government Railway, and Grand Trunk Railway system (Canada), and the North-Eastern Railway have also been presented to the Council. Some 948 slides have been placed in the collection, which have been made from negatives, photographs, and slides lent by teachers.

THE USE OF RED-SENSITIVE PLATES IN PORTRAITURE.

[The following article on a subject to which we have on several occasions drawn attention appears in the current issue of "Photographic Progress," from the pen of Mr. R. J. Wallace, whose appointment to the directorship of the Research Laboratory of the Cramer Dry Plate Company we recently noted. Mr. Wallace's writings have in the past dealt almost exclusively with sensitometric questions, but it may be hoped that in taking a seat upon the scientific direction of the Cramer factory he will apply his expert knowledge and facility of exposition to such every-day problems of the photographer as this—of securing better rendering of tone and colour in studio portraits.—Eds. "B.J."]

It is the general custom in portraiture to make use of a plate which is selected solely on account of its general speed to "white light." Consequently, as the "isochromatic" or "panchromatic" emulsions are somewhat slower than "ordinary" plates, the latter are almost universally used.

There are two factors, however, which enter into consideration regarding practical utility, viz.: first, the nature of the subject (or object) photographed, and second, the nature of the white light under which the exposures are made.

The Sitter is a Coloured Object—

In portraiture we are dealing with the copying of a coloured object—not only that, but a coloured object which presents the maximum of its hues in the longer wave-lengths—viz., the red end of the spectrum. That this is obvious is apparent upon but a moment's consideration, for the dominant hues of flesh tones are yellow, pink and red. If we were dealing principally with hues situate in the region of shorter wave-length, then the dominant colour reflected to our eye from the flesh would be a bluish violet.

The face, however, does not present one even gradation of tints in yellows and pinks, but is marred by many imperfections, such as freckles, etc. These freckles are brownish in hue, but brown is simply red and green mixed (or degraded) with black; in other words, red and yellow of low luminosity.

—and the Ordinary Plate is Colour-blind.

Turning now to the "ordinary" photographic plate, it is very thoroughly known that it is extremely "colour blind." This is easiest proven by the exposure of such a plate to the spectrum.

If we divide the solar spectrum (which is the analysis of white light) into the three primary colours, we have red, green, and blue-violet; these three colours cannot be produced by admixture, and are therefore primary. Yellow is a mixture of green plus red, while pure blue is a mixture of green plus blue-violet. Besides these three primaries there is another spectral region which is utterly invisible to the eye, termed the ultra-violet, but while invisible, is yet strongly active upon the photographic plate. Tabulating these regions in a semi-graphical manner, we may show the relative sensitiveness of photographic plates thus:—

Spectral Primaries.	Red.	Green.	Blue-violet.	Ultra-violet.
Sensitiveness of the various plates	Plate.	Plate.	Plate.	Plate.
