This, to my mind, implies something more and something less than bad business methods; it means that the business opportunities offered by New Westminster, the third largest town in British Columbia—to take only one case—are disappointing. Not but what New Westminster is somewhat exceptionally situated, since, being only twelve miles from Vancouver by electric-car line, it is to some extent overshadowed by its prodigy younger sister (Vancouver), with a population of ninety thousand by the last census.

Further, the distances in this wonderful country being comparatively enormous, representatives of firms stock themselves with quantities of goods which it is often impracticable for them to hawk from gallery to gallery. Some will carry round a gripful of samples; but these and others who do not carry a single sample will have two or three gripfuls at their hotel, which they will ask you to visit and inspect. This means that outsiders will be invited by letter, either from the representative on arrival or from the firm, warning him of their traveller's visit, or he will be neglected and left to discover the "man with the goods" by accident.

But that is not to say that an English firm introducing its own goods would proceed about their business in the same way; nor, I will confess, is it to say that any traveller of an English firm would do any differently from his Canadian brethren of the road. That, however, is not so much the point as that representatives do not cover the ground as, from the professional standpoint, they should, and that they do not implies either lack of time, expense, or inclination.

Eliminating the item of expense, which may be debited to advertisement account, and of time, which is another measure of the same thing, I suggest that personal inclination is frequently discounted by business results, and if these are poor in a certain district, the tendency will be for that district to suffer in consequence. But this should not be. The whole spirit of modern advertising is to "keep it up," to continue hammering on the same nail till that nail is home, not to give up because the tack happens upon a knot, and to leave it to get trodden over by the next more energetic solicitor for business who has a point to make, and will see that it gets, if not at once, at any rate finally, to its destination.

Then, again, rival goods are frequently in the same hands. I had a circular from a man the other day advertising the fact that he was agent for Ilford, Barnet, Wellington, Paget, and Rotary stock. Is this the best way for these respective firms to be served? And is there no other? Moreover, although this circular reached me in B.C., its terms were only truthfully applicable to other parts of Canada. Two of the agencies were not his to hold in B.C. at all, and another agency was pending; consequently the circular in question was calculated to make a quite erroneous, and perhaps damaging, impression upon one who might be supposed to know no better. And here I may interpolate that I cannot too strongly recommend English houses who have goods to push in B.C. to put this province in a separate agency of its own. I hardly think many Eastern firms would demur, and "sole agent for British Columbia" is a capital business phrase for the live Vancouver man.

But it is not live business for two different manufacturers to list their half-plates at the same price, and their 10 by 8 plates at different prices. For that is the case here at present. Two different plates in what is here called "cabinet" size ($6\frac{1}{2}$ by $4\frac{3}{4}$) at 65 cents, in 10 by 8 size are listed at \$2.00 and \$2.40 respectively. If prices are not calculated *pro rata*, comparison is invited which were better avoided.

And it must be recorded that, chance for chance, the "Trust" is not differently situated from any other firm not actually native to the country, with the distinction to which I have already alluded, namely, that they know the ground. Hence it comes about that "Seed" plates are now being manufactured in Toronto, thus saving to themselves the duty originally charged

up to the consumer. The "Climax" plate is, I believe, a purely Canadian manufacture, but, rightly or wrongly, it has not the patronage commanded by the "Seed." If, then, the two plates are not in the same class, neither are the prices, the "Climax" being supplied to Eastern photographers at 45 cents per dozen cabinet—that is, nearly half the price of the "Seed." But I do not gather that the price of the "Seed" plate is in any way threatened either by the present competition of the "Climax" or by the fact of the "Seed" being now manufactured in Canada duty-free. I should be inclined to believe, failing any information to the contrary, that the "Trust" is merely preparing for the future: that future when English firms will wake up to the value and profit of manufacturing in Canada, and will instead of finding a fair field and no favour, they will find themselves confronted with a full field and favour, in the form of bounties, discounts, rebates, and the rest, all waiting for them very much against them.

The Coming Canadian Market.

Neither do I forget that, vast as is this Canada, it cannot boast a population of more than six millions—at present I speak of the future, and counsel an early start. And this applies to every class of manufacture: plates, papers, and mounts. At present what B.C. wants in the way of mounts and mounting-papers it purchases from Montreal and Toronto in the East, and from San Francisco in the South, which involves the freight charges over a trifle of a few thousand miles, and considerable delay, which is not so trifling. The influence of Seattle and Portland are (I speak under correction) comparatively negligible. On the other hand, we have in B.C. enough timber to supply the world with paper for years on years. The ready American and Canadian syndicates are busy with the forests. English investors interested in newspaper-farming and kindred trades are not far behind; but I do not hear of any mount manufacturers directly or indirectly preparing for the future.

Tariff Relations with Canada.

And, lastly, in the third place, whether English firms although having the goods and knowing how best to supply them, are able or unable to compete with Uncle Sam and his methods, must depend largely upon themselves.

What Canada is doing with regard to Imperial preference for Old Country manufacturers, and what she will do, may or may not be two different things. But, in order to prepare for the future, it is reasonable not to neglect the present; and I would remark that the tariff along the international boundary and that facing the East are by no means the same. There is a preference with the Old Country which should be made the most of; and, although better terms would doubtless be acceptable, Canada would far rather see firms manufacturing on their own soil.

Ocean and rail freights are charges which must be met, and added to the cost of goods; but it may not be generally known that the through rates from the Old Country to B.C. are actually less than those between Montreal and Vancouver, these having recently been quoted here showing all the difference between \$3.10 per 100lbs. for the rail freight, and \$1.80 for the through rate—London to Vancouver. Besides this, as the Cape Horn Route has practical possibilities at 30s. per ton, it should not be impossible for English goods to be laid down in Vancouver at prices which it would pay respectable agents to handle.

So that the practicability of a market for English goods depends largely with what discounts English firms are prepared to allow, and Canadian dealers are willing to accept. One dealer accepts 35 per cent. on plates through from London via Cape Horn. He pays duty and shipping charges, and makes a profit of 7 cents per dozen on half-plates. Another dealer gets 33 per cent. on plates from Montreal via C.P.R. and makes 11 cents per dozen, and should be satisfied. A Missouri firm has offered a dealer 40 per cent. and 10 per cent. and 10 per cent. at sixty days

irty days with an extra 3 per cent., and it does not pay him handle their plates. An Ohio rate quoted for papers is 20 r cent. below list price, which, after duty and freight have en paid, permits of a profitable surplus. I shall not attempt reconcile these apparently contradictory conclusions. I quote em to show that considerable discounts are called for from glish firms if they are to compete with the really capital ock offering in the States, and that 40 per cent. on English pers has been cited to me as too little for the dealer who looks e a paying profit and an incentive to push. One word more, and I have done. I have heard it said here at the best way to popularise photographic materials (I do not y in Canada, for it may or may not apply universally, but in C.) is not to stock the druggists' windows with these articles, d simultaneously to push them among professional photo-

graphers. It seems absurd that such a prejudice should exist, if it really does exist. But commercial prejudices, to whatever mistaken ideas they may be due, must be respected. It is easy to cater for the amateur after the professional has been satisfied: I am led to believe that the reverse is not so easy.

It would be interesting to know whether the "Trust" has any knowledge or experience of this prejudice. If they have, they have known how to overcome it; if they have not, it may or may not be of negligible importance. It is possible that professional photographers have become inured to the ways of the "Trust," but that they are apt to resent or to regard with some degree of misgiving similar methods of any other less well-known firm.

Prejudices are frequently unaccountable, but they are none the less palpable for all that.

L. HAWES.

PRESS PHOTOGRAPHY IN CANADA.

most every newspaper in Canada makes use of photographic illustrations at some time in its career. If they have not yet published a special illustrated edition, it is one of the things that is to be achieved in the future. The daily or weekly in the cities that makes a feature of photographs of happenings and of persons who are brought into prominence are the envy and inspiration to the papers of the country, and causes a more frequent appearance of the special illustrated or souvenir number. These usually make some work for local photographers, though occasionally a specialist is employed. This work, however, is only occasional and necessarily limited, and can hardly be classed with what is now understood by press photography. Only in the larger cities is the press photographer fully developed, and the men who make this special work their business can be counted on the fingers of one hand. There is, however, a numerous class who occasionally make a hit and sell their work to newspapers, and a still larger class of amateurs who send in prints and consider the publication of such with their name sufficient reward for their skill and ability.

The dailies and illustrated weeklies of Toronto and Montreal are the largest users of current photographs. Among the dailies making use of illustrations in their regular issues may be mentioned the "Star," "News," "Globe," "Mail-Empire," and "World," in Toronto. The "Star Herald," "La Presse," and "Gazette" in Montreal. The "Globe" and "World" in Toronto issue a special illustrated edition on Saturday. The latter is called the "Sunday World," but is printed and sold on Saturday night. (No papers are allowed to be published or sold in Canada on Sunday.)

The "Standard" of Montreal is one of the most profusely illustrated weeklies in Canada. The "Courier," published in Toronto, is well illustrated and often uses a photographic design cover.

There are dailies and weeklies in the smaller cities which use illustrations from photographs, but to a more or less limited extent. Buffalo, Detroit, New York, and Chicago illustrated papers have considerable circulation in Canada, and are frequently supplied by Canadian press photographers with photographs of local events.

Among the men who are successful press photographers, perhaps the best known are Messrs. Pringle and Booth, of Toronto. Both of these men have wonderful enterprise, courage, and great capacity for hard work. Their prints are sold all over the continent (of America) and are not unknown in England. One example of their successful work was shown in connection with the Tercentenary celebration at Quebec last summer. Out of 162 illustrations used in Toronto papers during the first week of the celebration 150 were made by this firm. The following week the Montreal "Standard" used forty illustrations of the affair, twenty-four of these were by this firm, yet the "Standard" had its own man down there all the time.

The pictures of the Bishop of London, made during his visit to Canada, which have been used in London, are examples of what this firm has done here with some of our prominent politicians and others brought to the public eye. Their pictures of Sir Wilfrid Laurier and Mr. Borden added interest to the recent political campaign. One newspaper man said that there was only one complaint that he could make about the photographs, and that was that they cost so much.

Messrs. Pringle and Booth believe in getting full value for their work.

A. A. Gleason, of Toronto, is another enterprising and successful specialist in this line. He has obtained some remarkable records of horse racing, close and spectacular finishes, jumps at the hurdles, and of some terrible tumbles and falls. Some of his foot-race finishes are unequalled. Messrs. Smith and Rice, of Montreal, have done creditable work, but with each of these it is only a side line. W. Sharpe, of Montreal, an amateur, has been most successful in records of diving feats. One man whose photographs of Canadian life and industry command high prices, and while not exactly press photographs, are largely used as illustrations of more artistic merit, is R. R. Sallows, of Goderich.

Some of the exploits of the Canadian pressmen may be worth telling. One man was sent by his editor to get a picture of the delegates of a large convention "swarming" into the church. He arrived before nine o'clock, the time announced for gathering, but found only a few straggling in. There had been some misunderstanding as to the time, an important train was late, but he was sent to get a "swarm" of delegates, and it must be half-toned and ready for the press by one o'clock. He went into the church, and, in spite of objections, induced a goodly number of representative delegates to pose outside for a group. Making a bluff at making an exposure, he thanked them, and hurried around to the main entrance and got them as they were "swarming" into the church.

As an example of enterprise and perseverance, the photographing of a prominent politician is good. Life and action were wanted. No outdoor meetings had been addressed by this man so far in the campaign, and he was to speak to five thousand at the great hall that night. He could not be induced to leave his hotel. Next morning the organ of the party had two modest views of their leader seated at his desk. Imagine the editor's rage to see their leader in his most effective moments pictured to the extent of a full page in a rival paper. It was the wonder of the town and particularly of the newspaper men. "How did you get him?" "They are old pictures?" "We got them," replied the photographers, "but we're not telling how. We got them all right, and they are not twenty-four hours old." This is how:—The persistent person arrived at the hotel but could not see his man. He was engaged. The P.P. left his companion as guard, and the latter was soon rewarded by seeing a rival come out with camera and broad smile. The P.P. did not waste time, but got after the party organiser, an influential member of Parliament, and another prominent politician, and convinced them that it was desirable to arrange for him to get what he wanted. So back to the hotel he went with his reinforcements, and soon persuaded the prominent politician to go up on the roof of the hotel, and against the sky he rehearsed his speech, with all the gestures, for the great meeting, to the accompaniment of the clicking of the shutters of reflex cameras. The rest was easy.

The best men have reflex cameras of the latest and best type, special lenses for different kinds of work. These are often used for portraits. A clamp on the back of a chair is sufficient, and the great railway magnate, the political leader, or man of the hour is photographed amid his usual surroundings.

DAVID J. HOWELL.

THE WORK OF THE PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.

[An address given by Mr. Hector Maclean, F.R.P.S., at the Seventh Annual Meeting, March 20, 1909, at the Borough Polytechnic Institute, Southwark.]

IN moving the adoption of the report, I think you will all agree with me that it contains many gratifying features, to which, however, I need not particularly allude. Enough that it indicates that we have already done a good deal, although at the same time we realise that there is very much more which remains to be done. Considering for a moment merely the particular corner of Surrey in which we are this afternoon assembled, there is a vast amount of subjects and objects which clamour to be recorded. Not that our members have entirely overlooked the claims of this ancient and historic district, for, to begin with, some very painstaking and valuable records have been made of your great cathedral church. I also recall the unique photographs which some of our members made of curious monastic remains, which a few years ago were laid bare not far from this room, and which indicated that some of the Surrey men in those early days were, judging by the gigantic skeletons, which were preserved in stone sepulchres, decidedly "fine and large." I will not now further refer to Southwark, for probably most of those in this room know a good deal more of the neighbourhood than I can tell them, but I would like to take the opportunity of alluding to those grand old galleried inns of which you, until comparatively lately, still possessed one particularly fine example, if not more; because some of you may have in your possession photographs of various parts of these inns, which would be great acquisitions to our collection. I therefore ask such of you that my words may reach, and who have such photographic records, to at least lend them to us to be copied.

Here let me remind you that the activities of this society are directed into two somewhat distinct channels, viz.: the making of records and their collection.

Until last year the latter phase of our work has not been so productive as might have been expected. But the securing of a large number of West Surrey photographs taken by Miss Jeckyl has drawn attention to the utility, and the necessity of rescuing from oblivion and destruction some of the numberless photographs relating to the county that are at present in the hands of various individuals, many of whom do not realise that certain of their prints may be of extreme importance to this Society, although possibly of no pecuniary—or other—value to their owners.

To my mind it is of far more importance to preserve the photographic records of the Victorian Age than to exhaust our efforts in making current records. Only those who have been actively engaged on county record work can fully realise what a deplorable destruction of grand old structures—the offspring of ages—took place during that period of architectural debasement—the 19th century. There was apparently a more or less organised gang of architectural wreckers who went about persuading gullible squares and parsons that the out-of-date, and dilapidated, church or chapel ought to be put in good order and beautified. Once in possession these architectural pot-boilers showed no mercy, but ruthlessly destroyed the olden order that they might be paid fat fees for designing their own vile improvements. It is possible that in several instances those who ordered the "restoration" of a church, chapel, or other important building had photographs made of the unrestored edifice for their own personal satisfaction; these would either be framed, or, what is more likely, relegated to an album or a portfolio. These then are some of the sources which should be tapped for records of the long since destroyed.

It should be remembered that such photographic records may—may, do—go back as far as the year 1841, when the so-called "Talbotype" was used. I have seen photo records done by this process by Mr. D. O. Hill which were taken at or about the above date. At the same time, although Surrey records on Talbotype (or Calotype) may be discoverable, the process was not very largely used. But in 1851, with the advent of the collodion process, there was an immediate expansion in the art of photography. Now it is between the years 1851 and 1876 that those records which are likely to be most treasured by our Society were made, because this period,

more especially the earlier part of it, coincides with the years when church wrecking was at its very height.

May I take this opportunity of appealing most earnestly to men of intelligence who are interested in the county, to rummage amongst their portfolios and albums, and those of their friends, for old photographs of persons, places, and things. The buildings need not be ecclesiastical, for there are plenty of other edifices which are every whit as important. For instance, I have in mind the "Fox and Hounds" Inn at Burford Bridge, where Keats wrote part of *Endymion*, and where Nelson said a last farewell to Lady Hamilton.

Has anyone got a photograph of this place before it was modernised and if so will he send it to us? While on this subject of wants, I may add that the Society would be grateful for a print of the Dorking Football Saturnalia, which has for some years been suppressed.

Amongst a host of objects which vanished with the nineteenth century, special attention should be given to prints of old bridge wind and water mills, and columbaries. A special class of subjects which also deserves particular attention is that of "Locomotion." The main forms of vehicles in use in Surrey during the past century should, if possible, be found in our collection. Although many such records would not be *exclusively* connected with the county it had some forms of locomotion which were peculiar to itself.

To give only one instance. There was the iron railway which ran from Gatton to Wandsworth. Again, let me emphasise that we do not ask for the gift of rare or precious records. Lend them to us, and one of our skilled amateurs will in very quick time copy your print without in the slightest degree harming them. None the less, if the actual and original print can be spared for our collection, we would naturally prefer to file it than to reply on a copy, which is often very inferior to an original.

I have sometimes been asked whether, bearing in mind the enormous output of illustration matter by the illustrated journals, and in the form of picture postcards, there is any real need for making such a collection as ours. Cannot everything be found by future generations in our current picture papers and postcards? My answer is that at least nine-tenths of our photographs depict subjects which cannot be seen elsewhere.

Sir Benjamin Stone, M.P., told us only last year what he estimated as the effective life of the average picture paper and illustration magazine, and stated that the mixture of wood-pulp and barytes which goes by the name of paper will hardly last out a generation. But even if these publications would resist decay for a century or two, they entirely fail to cover the ground which we are working over. Perhaps I may make this point clearer to you by citing a hypothetical case.

Supposing we wanted to illustrate the subject of man so that for instance, an inhabitant of Mars might learn everything about him. We should obtain a typical model and photograph him from different points of view, we should picture his skeleton, and his subcutaneous physiological structure, including his chief organs. We might furthermore depict him engaged in various characteristic operations, such as eating, drinking, writing, singing, walking, talking, running, riding, and so on. We might also include examples of the various races of mankind such as the Caucasian, Negro, Mongolian, Red Indian, and so forth. So that in the compass of perhaps two or three hundred photographs much of the salient information respecting man would be present. How much of all this would you get out of a collection of postcards? The chances are that you would not get 20 per cent. of this information from all the postcards in the world. The President of the Royal Photographic Society not long ago described the contents of an anthropological collection of postcards which had come under his notice, and which contained no less than 1,623 different pictures. And yet all the information that these cards embodied was little more than the "smile of Phyllis Dare"; every one of them depicting the laughing teeth of this fascinating lady! *Mutatis mutandis* it is somewhat the same all along the line.

the illustrations in the Press are chosen for their sensationalism, that every other consideration has to go by the board. In the way only spicy views of conspicuous or notorious persons, events, or things, find their way on to postcards. So that practically nine-tenths of the objects which should be pictured in our collection would be absolutely unrepresented in picture papers and cards.

I have commended the work of the Society to all Surrey men, and I trust that they will give it their hearty support, some may, not unnaturally enquire "What good shall we get out of it?"

Although there are, fortunately, but a few altruists in the field—some of whom, I know, belong to this Society—the average man always wants to hear whether he is going to receive any reward for his labour. To this I reply that you may be sure that in helping you will be in several ways helping yourselves.

To give one instance. Suppose that you spend a day in photographing some objects which are awaiting record; apart from the social recreation which this involves, at the end of the day your personal and direct knowledge of the things you have been engaged to photograph will be so much greater than it originally was that you will be a palpable gainer. Instead of having a vague, second-hand notion of the objects which have come under your microscope, you will have acquired a vivid mental conception of them which will be *all your own*.

Our days, when from very early morn to late at night a succession of newspapers ply us with news and fiction, the habit of obtaining information at first-hand has almost been completely suppressed. We really know nothing from our own actual knowledge, but are content "to take the world on trust," as described for us by the pithy journalist. So that two or three days of record photography will provide what I consider to be a distinctly precious and much needed addition to each one's personality.

Even those whose help is confined to hunting out half-forgotten photographs for the survey, are storing their minds with facts which enrich the sum of their knowledge.

I daresay there are some people who, priding themselves on their common sense, will refuse to allow that the indirect benefits which have been alluded to are worthy of consideration. Perhaps some people will respond to the claims made upon them by gratitude. Past generations have accumulated and carefully preserved for our advantage an almost endless number of ancient and valuable records. Shall we, then, with the wonderfully efficient power which photography places at our disposal, repay the past by neglecting the future? Is it not almost a sacred duty for the present generation to strain every nerve in order to perpetuate, as far as may be possible, the life and aspect of the world we live in?

There is, of course, no need for me to emphasise that these preserved records will prove of splendid value to our descendants, but that, I suppose, you all realise. What is perhaps not fully recognised is that the practical utility of our present collection has already been discovered by hundreds—if not thousands—of the present generation.

Writers, archaeologists, antiquarians, historians, lecturers, scientists, students and others are continually travelling to Croydon, where the collection is housed, in the Free Public Library, in order to fortify their work by the aid of our photographs; which, it should be said, now cover such a wide range of subjects connected with the county that very few branches of research which are capable of pictorial expression are unrepresented. In the course of a very few years a small band of amateurs have done as much as is indicated by our report, why, it may be asked, do I trouble to press the claims of the Society for support? Because, valuable and encouraging as is the work already accomplished, what we have so far done is as but a drop in the ocean.

As we have three thousand, we should have at least ten thousand prints. And if only one per cent. of the people of the county took about one per cent. as much practical interest in the Society's work as is done by the handful of enthusiasts who are engaged on this priceless labour of love, our rate of progress would be increased tenfold.

Therefore, I confidently appeal to my hearers, and to that wider circle which may read these remarks, to lend us their aid. If you do not take photographic records, you may send us such suitable objects as may be in your possession; failing which you may make it your care and duty to rummage all likely collections of prints and to beg or buy those which bear on our work. Finally, if you are too busy, or otherwise unable to contribute prints, it behoves

you to compound for your remissness by giving the Society financial support. If you can do no more you can become a member, for the 5s. annual subscription will be very welcome. But there are some few fortunate people whom I have in mind, and who are closely connected with Surrey, who might well be expected to give this Society liberal pecuniary assistance. I trust that the only reason that they have not already done so is ignorance on their part of the pressing need we have for more funds, and of the enormous value of the work which we have initiated.

HECTOR MACLEAN, F.R.P.S.

PRINTS ON PARCHMENTISED PAPERS.

A CORRESPONDENT of our Philadelphian contemporary, the "Bulletin of Photography," has worked out a modified procedure of a process of printing on parchmentised paper recently recommended in that publication. The following are the revised instructions for preparing what will be seen to be a variation of the plain salted-paper process:—

* * *

Although I was informed that the proportions of acid and water must be adhered to, I found that I could work better with more dilute acid bath. My plan is this:

Sulphuric acid (strong)	4 ounces.
Water	4 ounces.

Immerse the paper—a good stock paper being necessary—in this solution, raise quickly up, place on a glass, and see that all bubbles are dispelled. Immerse again, and again quickly place on the glass, with the contrary side up, and remove any air cells. Plunge successively into three changes of water, as directed in your formula; finally into water in which a little ammonia is placed. After a few minutes take out of the ammonia bath and press between clean blotters; then hang up to dry. Observe always to keep the ammonia bath alkaline by adding a few drops of ammonia when it tests red with litmus.

The paper is quite different from the parchment paper made by the plan you published. It is not at all difficult to manage, and the puckering up of the fibre is not so decided.

The paper does not contract much, and is slightly more absorbent.

To prepare a sensitive surface on this paper, which gives beautiful rich-looking proofs of pleasing brown colour, make the following solution:—

A.

Potassium iodide	1 grain.
Cadmium bromide	½ grain.
Barium chloride	10 grains.
Sugar	10 grains.
Water, impregnated with camphor	1 ounce.

Camphor in aqueous solution may be had of the apothecary.

Take a flat, smoothed, dry sheet of the prepared paper and apply with a brush or wad of cotton in the usual way this salting solution. Let it lie flat for a minute or two, then hang up to dry. When dry it is ready for the sensitiser:—

B.

Nitrate of silver	100 grains.
Citric acid	4 grains.
Nitrate of uranium	60 grains.
Distilled water	2 ounces.
Alcohol	½ ounce.

Dry quickly, but not too near the heat. Expose until the image is faintly visible, about as in the platinum print.

The developer consists of—

Pyro	4 grains.
Citric acid	8 grains.
Acetic acid (glacial)	1 drachm.
Water	8 ounces.

The development is rather slow, being retarded by the quantity of the acid, but this is advantageous. The dish is kept in motion during the development.

Develop the image until it shows considerable intensity, as it weakens somewhat in the fixing-bath.

FIXING-BATH.

Hypo	½ ounce.
Water	8 ounces.
Alum	2 drachms.

Fixing is accomplished in 15 or 20 minutes. The print is now placed in—

Alum	50 grains.
Water	8 ounces.

Let it remain in this bath for half an hour or more, until it assumes a rich brown colour. Wash as usual with other prints. I believe this parchment paper might be used in gum bichromate printing to good advantage. I intend trying it shortly.

LLEWELLYN GRIFFITH.

Exhibitions.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.

We never go to an exhibition where so much is crowded into so small a space and short a time as at the Cripplegate Institute. From the moment that the Lord Mayor (and suite) alights outside its doors in Golden Lane on the Monday afternoon to declare the exhibition open, to the hour of closing on the Thursday night, there is a round of musical selections, lantern projections, demonstrations of oil, ozobrome, bromoil, carbon, and platinotype, as well as of attractions at near a dozen stalls of leading manufacturers—leaving out of consideration for the moment from this *embarras de richesse* the pictorial portion of the exhibition—all of which could never by any possibility have been inspected by the Lord Mayor (and suite), but during the later hours of each day is inspected with every mark of interest by innumerable “somethings in the City,” to say nothing of visions of feminine grace, at whose feet the Cripplegate Institute, among other gifts of instruction, lays the inestimable boon of modern photography.

We crushed our way round the walls, and managed to see some of the exhibits. The members' classes, though not large, contain work most creditable to those responsible for it. “When the Day's Work is Done” (No. 62), by P. Schillang, is just a little cold and thundery in tone, not quite of the warmth to carry out the title. It receives a bronze plaque. In No. 73, J. G. Denyer has certainly produced a “Symphony in Grey,” the greyness somewhat overdone, we fear.

In the open classes we are glad to see an award go to Mrs. E. Peake's “Seeing the World.” Miss A. B. Warburg takes the other award for her photograph of “Church Parade, Dalecarlia.” No. 136 should surely have been “The Hear Maiden,” since the young lady would seem to be taking a telephone message. Why, in Class F (straight prints from straight negatives), an award should have been given to No. 219, a semi-silhouette of a figure standing nowhere in particular, is a mystery to us. And we are not with the judges in their award to No. 226. In “The Cathedral Steps” (No. 250), Mr. A. I. Hensler cleverly uses a figure to suggest the immense stature of St. Paul's. We do not know what Mr. D. Elgar wishes to suggest in No. 254, “An Englishman's Home,” a very factual photograph of a tiled house in a suburban road. No. 286, “Staple Inn by Night,” is the best night photograph on the walls.

The class for results in oil, bromoil, ozobrome, and gum did not bring forth much pictorial fruit, and the one coloured oil might have been dispensed with.

The trade attractions, as we have said, were great, and the number of stalls would have taxed the floor space but for the constant stream of fixtures, etc., which carried off bands of interested ones to “Classroom 4,” or the “refreshment room,” which latter, however, when we visited it, was the scene of an incisive demonstration of the platinotype process. The moral of all which is that our readers in the City inform themselves as to the Cripplegate Society and its annual exhibition.

PAISLEY PHILOSOPHICAL INSTITUTION (PHOTOGRAPHIC SECTION).

The twenty-third annual exhibition of the Paisley Philosophical Institution (Photographic Section) was held in their rooms, Oakshaw Street, from March 19 to 26, when over a hundred pictures were on exhibition. All the classes were for members—with the exception of one which was open to Associates of the Scottish Federation—and had thirty-two entries. The following is the full list of awards made by the judge, Mr. Dan Dunlop:—Federation Class.—

Bronze plaques: W. C. S. Ferguson, Glasgow; Robt. Ure, Glasgow. Commended: Thos. Carlyle, Paisley; Bert L. Forrest, Shotts; John Stewart, Paisley. Portrait, Figure, etc., Class.—Bronze plaque: Andrew Hamilton. Commended: Robt. E. Glasgow. Landscape and Seascape.—Bronze plaque: John Stewart; this picture, “Eight Bells (Midnight),” also gained the challenge gold medal. Commended: Thos. Carlyle. Novice Class.—Bronze plaque: J. Rankin Dunlop. Commended: J. B. Martin; Charles McConville. Outings.—Bronze plaque: Eric Mackay. Commended: J. B. Martin. Lantern Slides.—Silver plaque: Thos. Carlyle. Bronze plaque: John Stewart. Lantern Slides (novice).—Bronze plaque: J. B. Martin.

There was also a loan collection of photographs by leading workers.

THE BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

The fourteenth annual exhibition of the Borough Polytechnic Photographic Society was opened on Thursday last, the official duty falling this year to Mr. F. C. Tilney, who also acted as judge. The chair was taken by J. Pascall, Esq., who is one of the Governors of the Borough Polytechnic, and much amusement was caused by the adroitness of the honorary treasurer in seizing the opportunity of a vote of thanks to the chairman, to elicit future favours for the society from him in the name of his co-Governors. The exhibition reaches a remarkably high standard, and is numerically strong in relation to the membership roll. Many of the works, particularly those of the secretaries, Mr. A. G. Buckham, show considerable artistic feeling. This gentleman's misty landscapes are highly pleasing in their delicacy and truth of effect. One of them gains an award as the best print of the year. Good work is shown also by Messrs. Bedding, Bull (whose architectural views display choiceness of selection and lighting), Burdett, J. N. Spare, and E. H. Roberts, the President. The exhibition includes a collection of excellent lantern slides.

In the opening speech Mr. Tilney referred to the growing affinity between art and photography, and recommended the members to avail themselves of methods of control in printing, warning them at the same time that such methods were edged tools, and exhorted them to the cultivation of artistic taste by means of observation of Nature and works of art.

The awards were formally presented on Saturday evening by Mr. Coote, Esq., J.P.

Patent News.

Process patents—applications and specifications—are treated in “Photo Mechanical Notes.”

The following applications for patents have been received between March 15 and 20:—

CAMERAS.—No. 6,194. Improvements in photographic cameras. William Morris Jones, “Beauregard,” Babbacombe Down, Torquay.

CINEMATOGRAPHS.—No. 6,210. Improvements in cinematographic cameras. Simeon Hughes, 37, Moorfields, Liverpool.

STEREOSCOPIC REPRODUCTION.—No. 6,309. Improved method of reproducing animated and other pictures stereoscopically. William Friese-Greene, 3, Broad Street Buildings, Liverpool Street, London.

ENLARGING.—No. 6,413. Improvements in apparatus for enlarging and copying photographs, objects, and the like. Ralph Winward Robinson and Leonard Leslie Robinson, 4, South Street, Finsbury, London.

PLATES.—No. 6,455. Daylight-loading apparatus for photographic dry-plates. Albert Hawkins Clark, Fern Villa, Goodwick, Pembrokeshire.

CINEMATOGRAPHS.—No. 6,595. Improvements relating to cinematographs. Arthur Herbert Benson, 17, St. Ann's Square, Manchester.

PHOTOGRAPHIC CHEMICALS.—No. 6,652. Improvements relating to the preparation of packeting of chemical substances used in photography. Thomas Oliver Kent and Oppenheimer, Son, and Co., Limited, 322, High Holborn, London.

ILLUMINATION.—No. 6,747. Illuminating apparatus or appliances for the distribution of artificial light for photographic and other purposes. Curt Karstedt, 37, Essex Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

Price in brackets is that of application in this country; or 10s. in the case of patents granted under the International Convention.

SCREEN-PLATES FOR COLOUR PHOTOGRAPHY.—No. 20,971, (January 25, 1908). This invention relates to the making of colour plates by means of dyed particles artificially produced in an emulsified state. For example, a solution of shellac spirit is divided into three portions, one of which is dyed red, the second blue, and the third green, with appropriate dyes. The three portions are then separately emulsified in turpentine, which emulsion, when only small quantities are concerned, can be made by pouring the shellac solution into the turpentine and shaking the whole by hand. For larger quantities known emulsifying machines can be used. The turpentine is, after the emulsifying, mixed with minute globules or particles of the shellac solution, which will sink to the bottom, the larger globules settling first. Leaving the emulsion at rest for some time and then drawing it to a certain height, it will be possible to draw off an emulsion of shellac grains or particles of about same size.

When three emulsions with differently coloured shellac grains of suitable size have been obtained it is necessary to spread these grains on a transparent plate—for instance, glass or celluloid. This can be done by applying a thin layer of lac to the plate and then pouring the lac emulsions over the plate, either separately or after previous mixing. The lac globules or particles gradually sink down to the lac layer, which, if necessary, may be sticky and become fixed to the same, and by placing the plate a little obliquely or by turning it by hand the dyed lac particles will cover the surface of the whole plate without, however, being superposed. By cautious heating or by pressure, or by a combination of both, the lac particles can be brought to amalgamate more closely with the under layer, at the same time becoming flattened so as to still better cover the plate.

Instead of shellac, other kinds of lac, resins, gum resins, or the like can be used for the coloured grains, and, of course, the turpentine can likewise be substituted by other liquids, as, for instance, toluol, petroleum, benzine, etc. It is sometimes advisable to add to the emulsifying liquid—in this case the turpentine—a substance having a specific emulsifying power. As regards aqueous solutions, it is known that casein has such power. A similar effect is obtained where turpentine and several other organic liquids are concerned by adding gum dammar or some other resin, soluble in the liquid in question.

Likewise, in place of lac grains or the like, for the same purpose in quite similar manner, gelatine emulsions can be used (the gelatine must then be melted at the moment of emulsifying) or other emulsions, albumen emulsions, etc. Emulsions of gum arabic, for instance, be produced by shaking a solution of 50 parts of gum arabic in 100 parts of water, which may be dyed with appropriate dyes, with a dammar lac consisting of 60 parts of gum arabic and 100 parts of turpentine. The gum dammar, which serves for emulsifying, can afterwards be removed by means of turpentine, for instance. Aqueous solutions of albumen and gelatine emulsions of these substances can be made in a corresponding manner.

Emulsions of lac and the like have the advantage that the film is not attacked by aqueous solutions (developer, fixing solution), thus not needing protection by a cover of lac solution, celluloid, or the like.

In many cases no special preliminary layer on the plate is needed to cause the emulsion particles to adhere to the same. On the other hand, a special effect can be obtained by the dyed particles in liquid or gelatinous state being able to yield dye to an underlayer by diffusion, the under-layer itself then constituting a screen if the screen particles are removed. Jens Herman Stensen, Sterrehus, Holte, Denmark.

DAYLIGHT DEVELOPMENT OF PLATES.—No. 25,370., 1908 (November 25, 1908). The invention consists in the use of a fogging method of developing plates for the proper time. The inventor has found that a fogged sensitised plate, when immersed

in any developer, will, in any condition of light, turn to a certain depth or shade of colour in a certain period of time. This period of time is not materially affected by the strength or quality of the light surrounding the plate at the time, but is dependent in the main upon the strength or quality of the developer. On this is based a method of estimating the correct time of development of a plate. For this purpose there is used a small surface of sensitised film on a suitable support in conjunction with a surface of any suitable substance coloured to a certain fixed standard depth or shade.

The sensitised surface is fogged by exposure to daylight before the device is issued from the factory. In this case the surface would be developed by the user in the same developer as the exposed plate is being treated to the depth of shade judged to be the correct one.

For general convenience, however, the whole surface of the device may be fogged in like manner and part only developed in the factory until the standard shade is reached and there fixed in the usual way, leaving the other part of the fogged surface to be developed by the user with the previously developed part as the standard. In place of fixing the part developed in the factory in the usual way it may be coated with varnish or grease or other suitable material, which would be equivalent to fixing for the purpose. The extent to which the plate is fogged is immaterial.

In using the device it is inserted into the same developer as that in which the exposed plate is being developed. The plate need not be disturbed until development is complete, and this is judged by the depth of shade of the fogged surface being developed at the same time. The latter may be from time to time removed from the developer for examination of the progress of development. This examination may take place in bright sunlight. When the fogged and previously undeveloped surface of the device has darkened to suit the judgment of the user or to correspond with the fixed or permanent standard shade thereof the plate may be removed from the developer as efficiently developed.

The standard shade, when indicated on the device, may be somewhat lighter than that required for correct development, so that when the latter is complete there will be a slight contrast visible on the device. Arthur Augustus Brooks, Cranleigh, Park Avenue, Ashton-on-Mersey, Cheshire.

DAYLIGHT DEVELOPMENT OF PLATES.—No. 25,074, 1908 (November 21, 1908). The invention relates to improved apparatus for developing plates, the improved apparatus being chiefly intended for developing plates contained in box-like sheaths divided in the plane of the plates, and particularly plates packed according to the system described in Patent No. 11,816, 1908.

The apparatus comprises a deep flat receptacle with a cap at one end and a hole in one of the broad sides for opening the sheath and separating the plates when inserted therein, means being provided for holding the plates apart while being developed. For facilitating the development of the plates there is a tank large enough to immerse the receptacle when upright or the plates therein, and preferably of a suitable size for receiving several receptacles at a time and keeping them apart. Arthur Augustus Brooks, "Cranleigh," Park Avenue, Ashton-on-Mersey, Cheshire.

CINEMATOGRAPH-PHONOGRAPH.—No. 27,435, 1908 (August 13, 1908). The claim is for the method of securing synchronous action of a cinematograph and a talking machine by including in the subject-matter of the photographic record an object moving at a rate proportional to the rate of movement of the cinematograph, projecting on to the screen, at the time of reproduction, an image of object moved by the actuating mechanism of the talking machine, and controlling the action of the apparatus so that the images of the objects, projected on to the screen, preserve a uniform positional relation to each other. Deutsche Bioscop G.m.b.H., 236, Friedrichstrasse, Berlin.

CINEMATOGRAPH MECHANISM.—No. 23,275, 1908 (October 31, 1908). The invention relates more particularly to the means used for imparting movement to the shutter by the act of adjusting the film feed mechanism and consists in using a shutter-spindle, the two parts of which are coupled with each other so that axial displacement of one part, produced by adjustment of the film, produces rotation of the other part. This construction has the advantage of occupying less space than, for example, the known arrangement of a planet-wheel carried by an adjustable pivoted

arm, and meshing with co-axial bevel-wheels which are connected with the driving mechanism and shutter spindle respectively. Alfred Duskes and Duskes Kinematographen und Film-fabriken, G.m.b.H., 46, Friedrichstrasse, Berlin.

New Trade Dames.

H. (DEVICE).—No. 310,248. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Arthur Holden and Sons, Limited, 218-9, Bradford Street, Birmingham, manufacturers of varnish paints and colours. February 8, 1909.

WE PUT THE WORLD BEFORE YOU (DEVICE).—No. 309,155. Cinematograph apparatus included in Class 8 and films for use therewith bearing taken photographs. The Charles Urban Trading Company, Limited, Urbanora House, Wardour Street, London, manufacturers and dealers in animated picture specialties. December 24, 1908.

CRITERION.—No. 309,752. Photographic printing papers. The Birmingham Photographic Company, Limited, Criterion Works, Albert Road, Stechford, near Birmingham, manufacturers. January 22, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Bromoil Without the Acid Bath

Mr. C. H. Hewitt, in the "A.P. and P.N." for March 30, 1909, describes a modification in the Welborne Piper formulæ for Bromoil, which he has found successful with at least one bromide paper, Barnet "Smooth Ordinary." He dispenses with the acid bath.

In looking round for some other softening agent to use instead of sulphuric acid, ammonium sulphocyanide occurred to me, its softening effect on P.O.P. being well known to all users of the sulphocyanide toning bath. . . . If a print is bleached, rinsed in a dozen changes of water, and then placed in a 5 per cent. solution of sulphocyanide of ammonium, and rocked for five minutes two effects will be observed. First, the yellow image will be lightened just as it would if the print were placed in hypo; and second, a very satisfactory relief will be obtained. After again washing in a dozen changes the print is ready for pigmenting in the usual way.

The solution of ammonium sulphocyanide thus takes the place of both the sulphuric acid bath and the subsequent fixing bath, for the 5 per cent. strength would appear amply sufficient to dissolve out of the print all the silver bromide. Tests made with a precipitate of silver bromide in a test-tube confirm this.

With these suitable papers then the simplified routine becomes as follows:—

1. Bleach the bromide print in the ordinary way.
2. Wash in, say, a dozen changes.
3. Swell and fix in the ammonium sulphocyanide 1 ounce to water up to 20 ounces.
4. Wash in, say, a dozen changes.

The print is then ready for pigmenting in the usual way.

CATALOGUES AND TRADE NOTICES.

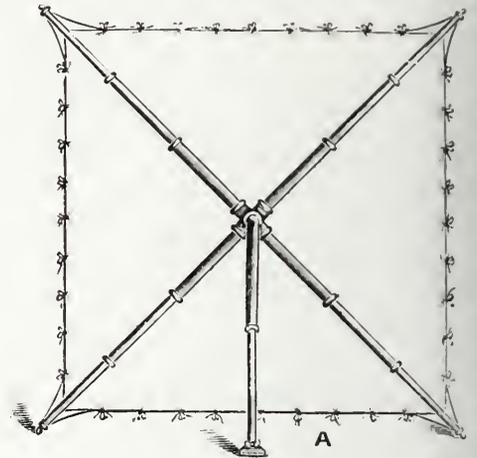

MESSRS. WILFRED EMERY, LTD., of 39, Cricklewood Broadway, London, N.W., have issued a price list of the various kinds of photographic work undertaken by the firm. The list also includes particulars of the "Apek" apparatus and materials which they manufacture and supply. Copies may be obtained post free on application.

"ENSIGN" ROLL FILM COMPETITION.—Mr. George Dutilh, Crédit Lyonnais, Alexandria, Egypt, is the winner for March of the three-guinea camera which Messrs. Houghtons offer every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

New Apparatus, &c.

The "Merito" Telescopic Tilting Screen Stand. Made by V. L. Parkinson, Ltd., 5, Commutation Row, Liverpool.

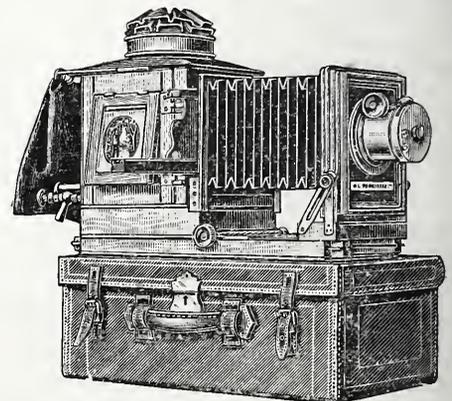

This very portable lantern screen stand consists of a telescopic seamless steel tubes, which, with the aid of a centre-way piece and a bracing cord, form a screen for a 12ft. sheet once strong and rigid, and possessing the advantage that the

can be tilted. The stand requires but one screw to affix it to the platform, where it stands firmly without projections, such as a lecturer might stumble against in the dark. The whole outfit packs into a waterproof canvas case 3ft. 6in. x 4in. x 4in., making room for a 12ft. sheet as well, a triumph of compactness upon which the makers are to be congratulated, and in verifying which all the above claims we have ourselves been most satisfied. The price with case, but without sheet, is £3 15s.; but a cheaper pattern is made, with tubes of iron in place of the seamless steel, at £2 15s. 2ft. square, best quality calico screen, with one seam, £1 2s. 6d.

The "Parkinson" Folding Optical Lantern. Made by V. L. Parkinson, Ltd., 5, Commutation Row, Liverpool.

A fully-equipped optical lantern, which packs within a suitcase case measuring 18½ x 10½ x 6½in., and even then leaves room for a 12ft. lantern screen, is what Messrs. Parkinson have accomplished in this apparatus. They have achieved this result without any sacrifice of the efficiency of the instrument by an ingenious construction, by which the side and front walls of the lantern body are hinged so as to fold on themselves, the objective front, with the objective still in position, also folding on to the baseboard extension, and the whole apparatus when thus closed for carrying representing a block with scarcely any interspaces unoccupied. The work

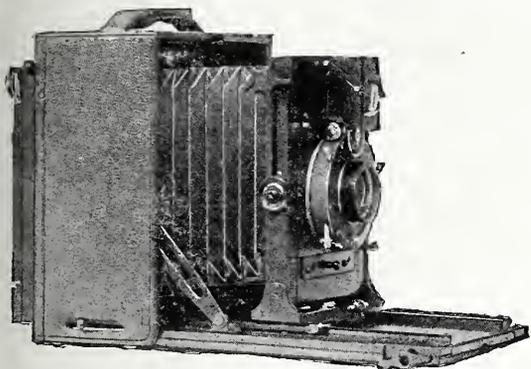

ever, of erecting the apparatus for use is a matter only of few seconds. The lantern body is 8in. in width, and can accommodate a full-size lime-jet. It is fitted with a Russian iron lining, one also of asbestos, and has one specially excellent feature—the 3¼ x 3¼ ground-glass panel in the door, by which the slide can be comfortably examined before being placed in the lantern. The stage is open at the top, and accommodates the very convenient "Parkinson" carrier, in which the slides are inserted and removed from the one side of the lantern. Focussing is by rack and

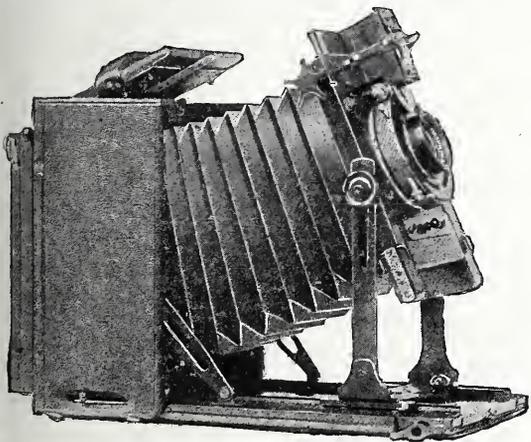

sion of the baseboard, and also by the rack and pinion on the
ive, which is provided with slit for tinting-glasses and the
r-flasher. Complete with a real leather case, with lock and
the price of the outfit is £7, or with a superior case of solid
r hide £8.

Adams "Vaido" Universal Camera. Made by Adams and Co.,

ed in this instrument of the self-contained hand-stand type.
show the result obtainable, but unfortunately they do not

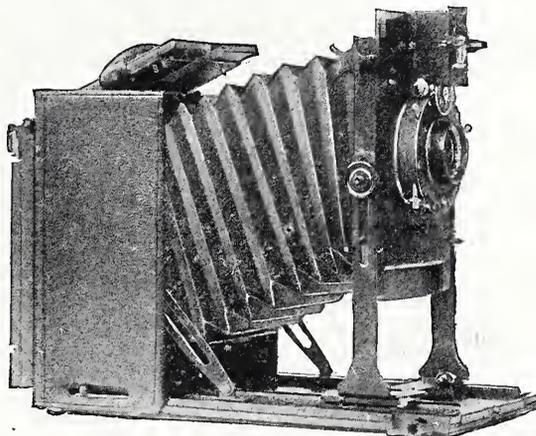

cannot show the many nice devices and ingeniously contrived
of mechanism which permit of convenient and rapid manipula-
Remove the occasion of fumbling with a screw or a catch
ou provide a camera capable of better work is a sound
le, and one which makers who know not only cameras but
rs of them will confirm. And that principle is evidently one
ich the makers of the Adams cameras keep prominently
them. It is because the new "Vaido," one of the first of

instruments we have just examined in detail, has numerous
of superiority which the discriminating worker will appre-
Take, for example, the rise of front. Mr. Adams provides,
many makers, the most convenient rack and pinion adjust-
f it. But he goes further, and gives the head of the pinion
form seen most plainly in the third photograph, so that
he front is close in at the wide-angle position, the worker
e one finger only and do easily with a poking movement
e could not readily do in the case of screw-head requiring
gers to move it. A refinement perhaps, but nevertheless
ich the worker will be grateful for. The same purpose to
fittings which make for smoothness of manipulation might
anced in other items—but why should we demonstrate to
world how the photographer is so pampered by makers
ssrs. Adams that he has but to pull out a lever somewhere
ow the rest to happen? At any rate, he is relieved of the
thinking much as to the adjustment of his instrument.
e drawings show, the "Vaido" is fitted for use in the
y aid of its focussing scale and the most valuable Adams
which indicates the change in the picture when the front
l. The "Vaido" has a large rise, and useful as that move-
in hand-camera work, its value is practically negated
he finder shows what is happening.
olly valuable, too, is the rotating back, which dispenses

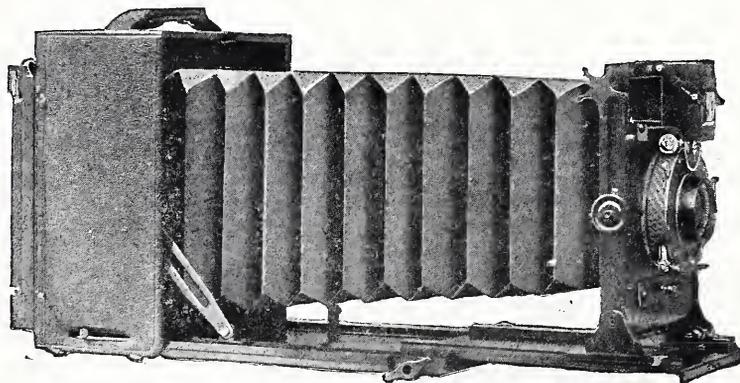

with the loose reversing frame, and permits the change from upright
to landscape with the plate all ready for exposure. The central-
swing movement of the lens panel is still another feature that earns
our commendations, not only for its simple method of being put
in and out of action, but for the fact that though the whole camera

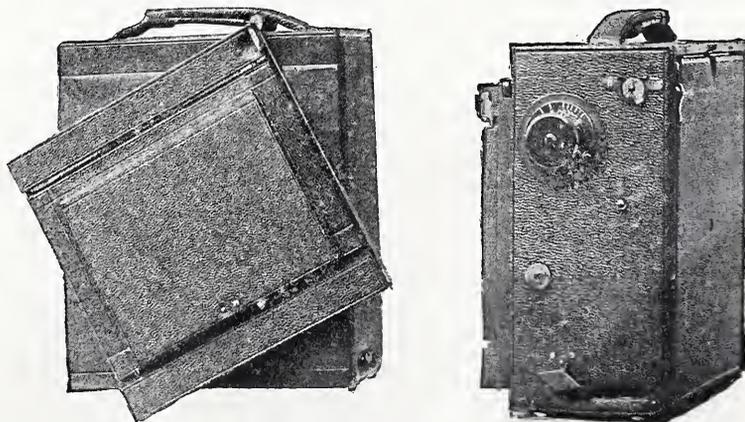

is highly compact, the lens panel accommodates the large $f/4.5$
anastigmats of suitable focus.

The camera provides a full long extension, and is fitted with a
second scale for the half-lens or a second lens of long focus, while,
of course, the hooded focussing screen allows of actual focussing
being done in the many circumstances when such course is necessary.

We have left to the last the new focal-plane shutter, the
"Minex," fitted to the camera. This is a quite new pattern, em-

bodying features which give one good cause to think that the last
word in focal-plane shutters has here been said. First, the
shutter is self-capping. Secondly, the shutter is set by a half
turn of the key. Thirdly, the speed is changed by turning the
same key with the shutter set or run down, and the speed dial
is marked with the actual speeds. Fourthly, with the shutter set
at a certain speed, the repeated release and rewinding of it brings
it always to that speed; it has not to be adjusted for speed at

each rewinding. Added to this, it gives the usual wide range of
instantaneous exposures— $\frac{1}{8}$ to 1-1,000—automatic time exposures
up to 3 seconds, and time and bulb adjustments.

This triumph of shutter design is supplied only with the "Vaido"
camera, and with a new studio reflex camera which Messrs. Adams
are shortly issuing.

We have said enough to show that in the "Vaido" the makers have provided an instrument without a single loose part, light, compact, and simple, yet capable of responding to the most extreme claims of the photographer.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 2.

Sutton Photographic Club. Ten Minutes Lectures by Members.
Guernsey Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

SATURDAY, APRIL 3.

Kinning Park Co-operative Camera Club (Govan). Outing to Inchinnan.

MONDAY, APRIL 5.

North-West London Photographic Society. "How to Develop a Plate." Beginners' Night. Walter Kilbey.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 30, the president, Mr. J. C. S. Mummery, in the chair.

Mr. E. Fenske gave a demonstration of his "Aurora" colour screen-plate, beginning by coating a plate with powdered colour and showing the result in the lantern. He next developed and reversed a plate which he had exposed that morning and showed the result, together with a number of other examples, by projection in the lantern, at the same time giving full working particulars. A short discussion, concluding with a hearty vote of thanks to the lecturer, brought the proceedings to a close.

CROYDON CAMERA CLUB.—An interesting lecture was given by Mr. John Bawcomb last week, illustrated by nearly 150 slides, and entitled "An Evening with the Microscope." The majority of the slides were not secured by ordinary transmitted light, but by what is known as "dark ground illumination," obtained by means of a stop in the sub-stage condenser, a method of lighting giving very beautiful effects and frequently neglected by workers in photo-micrography. Generally speaking, the system is only applicable to low or moderate powers, though Messrs. Zeiss provide a somewhat expensive apparatus for use with high-power objectives. Irrespective of other advantages it readily permits of the subjects being tinted with various dyes to match the originals as far as possible, and some fine slides fully illustrated the effectiveness of the addition of colour.

Beginning low down in the scale of life with the minute Amoeba, which without any properly organised being is capable of performing its vital functions, the lecturer passed on to deep-sea surroundings, foraminifera, strange crustacea, marine worms, and many other wonderful and frequently beautiful denizens of the microscopic world. The extraordinary structure of the sponge well illustrated Socialism in its most simple form. A poor, degraded mass of animal life at one

dead level, each individual patiently waiting for the food to find his way through the minute channels of the sarcodae. Other examples showed a common stomach for a community, a state of social infection mankind can never hope to attain. The Entozoa, such as trichina spiralis, were pictured embedded in the human muscle, and their marvellous, if extremely unpleasant, metamorphosis explained. It appears that trichinae are inherent to the economic rat, with its dead; pigs in turn eat rats, and so transmit the disease to man.

In the discussion following the lecture, Dr. Mees inquired for some of the very high magnifications shown were obtained. A member said that, having partaken of pork for dinner, he was interested in the slides of trichinosis; he understood that it was destroyed the nematoid worm. He derived comfort from the fact also from the fact that he had never seen a pig chasing a rat. A fair field and no favour he would lay heavy odds on the rat. The rat. Mr. Bawcomb said he had never suggested pigs were suitable quadrupeds for rat-catching. A dead rat, however, would be a succulent morsel. Trichinae would resist considerable heat, and all forms of pork should be thoroughly cooked. In reply to Dr. Mees, the lecturer said he never used a higher power objective than was absolutely necessary, preferring the employment of low, or moderately high, powers, with a long camera extension. With a 1 1/2 inch apochromat and a high power compensating ocular, with a long extension, magnifications up to 5,000 could be obtained without difficulty.

PETERBOROUGH CAMERA CLUB (Canada), since its organisation four months ago, has had a remarkably good programme, and the work has been fortunate enough to have attended the meetings of all regularly have been much benefited. It consisted of papers at the "Dark-room," "Photography as an Aid to Surveyors and Surveying," "Art of Negative Making," etc. The officers of the society are: Dr. J. A. Morgan, president; his Worship Mayor Rush, hon. president; R. S. Rose, first vice-president; Mrs. A. M. McCarthy, sec. vice-president; N. A. Howard-Moore, 191, King Street, Peterborough, secretary-treasurer. Committee: A. W. Patterson, A. Rogers, J. A. Brightman, R. Pecord, J. A. Dealisle, A. McCarthy, and Jos. English.

HACKNEY PHOTOGRAPHIC SOCIETY.—At the meeting on Tuesday, the 16th inst., a very interesting and useful lecture on the gum bichromate process was given by Mr. C. Wille. The lecturer considered this to be the best of all photographic processes, and showed that by systematic working it was possible to get almost any result desired, and by modifying the treatment equally good results could be got from negatives varying greatly as to their scales of gradation. This, however, applied to "multiple" gum, for single gum would not allow the use of a wide scale of gradation, and the negatives must consequently be soft. Mr. Wille explained in detail the whole process, from the preparation of the materials to the final print, and the examples of finished work quite confirmed his claims as to the value of the process worked by him.

Commercial & Legal Intelligence.

ROTARY PHOTOGRAPHIC COMPANY, LTD.—Particulars of £10,000 debentures, created May 25, 1908, and secured by trust deed dated May 25, 1908, filed pursuant to Section 10 (3) of the Companies Act, 1907, the amount of the present issue being £10,000. Property charged: The company's undertaking and property, present and future, including uncalled capital, and lands and buildings at Newbury, but excluding leaseholds for less than thirty years. Trustees: R. Back, 46, King William Street, E.C., and E. Haenel, 1, New Union Street, E.C.

LEGAL NOTICES.—At the Bradford County Court recently a receiving order in bankruptcy was made against Arthur Sagar, residing at 27, Hall Road, Shipley, and carrying on business as a photographer at The Studio, Church Street, Keighley.

COMPENSATION.—At the meeting of the L.C.C. on Tuesday it was reported that the claim of Miss F. Collings, photographer, in respect of disturbances to part of 53, East Hill, required for the Wandsworth Road to East Hill improvement, had been settled by the payment of £75.

Correspondence.

respondents should never write on both sides of the paper. notice is taken of communications unless the names and addresses of the writers are given.

THE BANE OF CHEAPNESS.

To the Editors.

Gentlemen,—I have read the letter signed "Disgusted" with great interest. There is a lot of truth in the remarks, but at the same time I think your correspondent is a little hard on the class he terms "traders." I suppose I am what he would term a trader, although entirely the fault of circumstances. After serving an apprenticeship of three years and working as assistant for a further two, I set up on my own account in my native town. About the time I married, and as my wife is an expert photographer we had a good chance. I took an empty studio and fitted it with the latest and best apparatus, aiming at a high-class trade. My window with sepia carbons, sent out nice little booklets, and generally did what a new man must do if he expects to become successful. Weeks passed, my stock of money began to grow less and my wife came and looked at my work, and would remark, "Ain't it nice?" then, like the weeks, they passed—to a cheap man further down the street. I knew my work was good, but I couldn't persuade him to buy it. For twelve months I stuck at my profession and my dwindling capital, what time my cheap rival kept a staff of men in order to cope with his weekly rush. People used to ask me, "Why don't you charge the same price as ———?" In the end I came down to his price, and incidentally descended from the rank of a "professional" man to that of a mere "trader." My business immediately began to grow better, and when I had had about six months of fairly good trade a new rival opened his doors at half my low prices, and as a bait he is offering stamp photographs at 2d. per dozen! Here is a list of his prices: Twelve post-cards, 6d.; four cabinets, 1s. 6d.; framed 12 x 10 enlargements, 5s. Could "Disgusted" do? I know what I intend doing at the earliest possible moment, and that is getting out of photography anything more profitable.

"Disgusted" says about men with no training, and his suggestion I thoroughly agree with. Why cannot photographers band themselves together and get a law passed compelling anyone who contemplates setting up as a photographer to pass an examination showing himself to be competent? At present the trained photographer is at the mercy of any broken-down tramp who can either beg, borrow, or steal a camera, and then set up as an "artist." If photography is a profession, why not make it impossible for anyone but a competent person to enter it? A man must needs be something more than an ordinary man to become a doctor or barrister. The same requirements ought to apply to photography. Until that happy time I am afraid I must sign myself
A TRADER.

To the Editors.

Gentlemen,—May I be allowed to express my views in reply to your correspondent who for obvious reasons signs himself "Disgusted"? Only about six years ago I opened my business in a very attractive style, and with an artistic display of pictures, etc. I was, in every way what your correspondent would term a "successful" professional. As such I carried it on for about two years, with a result that all I could get out of it was a mere pittance. Naturally, with that I was not satisfied, and began to think that something should be done to improve my position. I soon started to consult with what he calls a "second class" or a "mere trade" photographer. I have still the cheek to call it a "profession" by inviting the local clergy, local doctors, and other local people of note to patronise my gallery. I found this paid me very well, so went further and now I have such clients on my books as I am certain to have even as much as have known of my existence; in fact, I have had my schemes so far that, far from their being likely in any way to lower my dignity, it is just the contrary, and my banking account is at present quite all right. Should your Mr. "Disgusted" care to have my name and address, kindly give it him, for if I have any desire to communicate with me I should prefer to do so through you. For the above, and obvious other reasons, I sign myself,
SATISFIED PROFESSIONAL.

QUOTATIONS AND MISQUOTATIONS.

To the Editors.

Gentlemen,—Mr. Bland's strictures on the subject of quotations, misquotations, and non-quotations, should be a very wholesome warning to the editors of photographic journals, and, in fact, to editors and photographers generally. In the case of the misquotation (how can it be a non-quotation?) under notice, it is to be hoped that the majority of your readers are sufficiently subtle-minded to appreciate the far greater incisiveness and wit of the correct version. Indeed, but for the editor's footnote, readers of this and other photographic journals might have been inclined to give the "misquoters" credit for a deeper and fuller knowledge of the inner meaning of the original text than we ordinary people possess, and to regard what, at first sight, seem to be serious lapses from accuracy merely as revised translations. If the axiom that "a quotation must be made *correctly* or not at all" is to hold, how would Mr. Bland deal with a well-recognised mistranslation? For instance, if the editor of a photographic journal, in scanning the "copy" of an exhibition critic, should read, among the usual illuminating remarks, that a certain artist was at last promising to "blossom as the rose," would he feel it his duty to amend the quotation (as per axiom) to "blossom as the polyanthus-narcissus"; or, if the text were not sufficiently Solomonesque, to put it, as I once heard a learned preacher quote it, to a country congregation, "as the crocus of Sharon"?

Take, again, what would generally be accepted as a quotation, even in literary circles, "One swallow does not make a summer," should not a well-equipped purist go strictly back to Aristotle's *Ethics*, where it appears in "literary" form, probably for the first time (and quoted correctly, by the way, by the Rev. F. C. Lambert, in the current number of the "A.P."), and rule out, by axiom, of course, all more recent versions, including that, for example, by the misguided Cervantes?

Lastly, one may misquote with a purpose. Look at the picture (and the title) on p. 291 of this week's "A.P." and you will find that the author of the canal-like scene was too good an artist to call the water "ocean," so he adopted the unimpeachable compromise of "sea." One hopes that, in this case at any rate, the shade of Coleridge (and possibly Mr. W. R. Bland) will be sufficiently charitable.—Yours obediently,
F. H. CLIFFE.

Haileybury College, Hertford.

March 22, 1909.

To the Editors.

Gentlemen,—I cannot tell whether Mr. Cliffe is holding a brief for me or whether he is merely heaping blame with one hand and mercy with the other, as when the discriminative interloper says: "Don't hit him; tell his mother!" I only know that I am overwhelmed with a growing consciousness of the enormity of my crime, and that my punishment is greater than I can bear, in writing which I intentionally omit inverted commas. Peccavi! Peccavi!! That I should have been weak enough to use a phrase, as I have heard and read it so often, without hunting it up in a quotation dictionary—a thing I do not possess! Of course, pedantry is the essential thing. It is the letter, not the spirit, that counts. Behold, all is vanity and vexation of spirit. As it happeneth to the fool, so it happeneth even to me. The fool walketh in darkness. The words of the wise are as goads. This also is vanity and vexation of spirit. Let us hear the conclusion of the whole matter. Much study is a weariness of the flesh. There is nothing better for a man than that he should eat and drink. For which you'll overhaul your Ecclesiastes.—Yours,
THE MISQUOTER.

FAILURES IN SULPHIDE TONING.

To the Editors.

Gentlemen,—I noticed a letter on the above subject in your issue of March 19, which, to my mind, shows very clearly the futility of photographers who are not chemists attempting to conduct chemical experiments and form theories from their results. To begin with, the writer doubts the fact that hypo is formed as the result of the decomposition of sodium sulphide, and says he has been assured by several authorities that such is not the case. I cannot understand anyone posing as an authority on chemistry making such a statement, as it is proved beyond a doubt that one of the products of the oxidation of sodium sulphide is sodium thiosulphate (hypo). Then, I am afraid that his experiments are quite valueless for one very simple

reason; all along he uses a 1 per cent. solution of presumably pure sodium sulphide, and even when the solution contained quite a large quantity of hypo it also contained still the same 1 per cent. of pure sulphide.

Now a 1 per cent. solution of sodium sulphide will act on a bleached photographic image in a very few seconds, long before anything but a very strong solution of hypo would have any solvent action. But in the case of a solution of sulphide that has become partly oxidised things are very different, as instead of 1 per cent. the proportion of pure sulphide is perhaps only one-tenth of this, and before it has time to convert much of the silver bromide present to silver sulphide the remainder of the bromide has been acted on and dissolved by the hypo, giving a weak yellow image. Of course, if you add hypo to the bleaching bath you form a modification of the well-known and popular Farmer reducer, and after a print has had its image removed in this it is not surprising that it does not darken in the sulphide bath, but I think that anyone who gets their bleacher contaminated with hypo deserves to spoil their prints for their carelessness.

In conclusion, I should like to suggest a simple experiment to Mr. Brown that I think will prove to him the way in which sodium sulphide deteriorates. Let him take some pure sodium sulphide that will give good tones in practice, fill a bottle with this, and cork it tightly, then spread a layer of the same sulphide on a dish in the open air and leave for a week. Then compare the action of the sulphide from the bottle with that kept in the open air. After this I do not think he will again doubt that sodium sulphide does deteriorate, and is the cause of prints refusing to darken.

EXPERIMENTER.

To the Editors.

Gentlemen,—Our experience, now spread over a good many years, confirms that of your correspondent, Mr. J. Brown. Among other experiments, we have kept a 10 per cent. sodium sulphide solution in a large jar merely loosely covered, for over six months, and at the end of that time it has acted perfectly. We have now a 10 per cent. solution, bottled in January, 1904, which tones prints quite satisfactorily. We find that prints insufficiently washed will sometimes bleach satisfactorily to all appearances, but only tone in sulphide to a disagreeable yellow, and we are inclined to believe that many troubles arise through insufficient fixing or washing, as well as to contamination of bleaching solution with hypo.—Yours faithfully,

Avenue Road, Southgate.

WELLS AND CO.

March 23, 1909.

[The letter by Mr. J. Brown, referred to above by Messrs. Wells and Co., is commented upon in "Ex Cathedra" this week. Quite pure sodium sulphide will sometimes keep a very long time. If prepared in the way advised by Mr. D. J. Carnegie it will keep well even in a weak solution, but the commercial white variety, as a rule, must be kept in a strong solution of at least 10 per cent. We believe the trouble mostly arises when weak solutions of working strength are kept. We cannot admit that hypo is at all likely to exist in the bleaching solution as an impurity. It might be carried in with an unwashed print, but then the effect could hardly be a loss of density in the heavy shadows alone. We should like to see and experiment upon some of the yellow prints described by Messrs. Wells, if they have any available.—Eds. "B.J."]

LONDON PHOTOGRAPHERS' FIRES IN 1908.—The annual report of the London Fire Brigade for the year 1908, which has just been issued, states that during the twelve months there were only six fires in photographers' establishments, none of the outbreaks being serious. The causes of the outbreaks were as follows:—One from curtains coming into contact with gaslight, one curtains coming into contact with spirit stove, one defective electric circuit, one hot ashes, one over-heat of gas stove, and one stove improperly set. There was also an outbreak in a studio, the cause of which was unknown. No serious damage was caused. There was one fire in an artist's premises, caused from a spark from fire. Another fire occurred in an artists' colour-man's premises, caused through a light being thrown down, no serious damage being done. The total number of fires during the twelve months was 3,238, and by far the largest number (894) occurred in private houses. Licensed victuallers head the list of trades with 67 outbreaks, an increase of ten on the previous year.

Answers to Correspondents.

PHOTOGRAPH REGISTERED:—

J. W. Rogers, 46, Stanley Road, Wellingborough. *Combination Photograph entitled: "Percy Agutter's Studies in Songs and Rag Pictures."*

D. I.—The use of silver nitrate is quite impracticable for gelatin plates, as plates so treated would stain and fog to an enormous extent, and, of course, would not keep at all. We should advise your best course would be to colour-sensitise the plates, say with 1 in 50,000 pinacyanol, as suggested by Mr. Payne in the "Journal," March 8, 1907.

It is no use using either ammonia or silver with pinacyanol. Silver and ammonia work with many dyes, but not with the isocyanines and their relatives. We doubt if you are right in using so fast a plate as the "350." The essential thing for sensitising with the isocyanines is to have an emulsion which has not been made with ammonia, and there is no doubt that your plate is made with ammonia. As a general rule, a medium speed plate is much better than an extra rapid plate for sensitising.

AUTOCHROME, SYRIA, and others.—In our next.

COLOURED VARNISH.—I wish to try the effect of varnishing the backs of negatives with varnish coloured with yellow or blue aniline dye. I find that the negative varnish decomposes on adding the dye dissolved in water, and the same result occurs by adding water, hot or cold. Can you inform me how the varnish is prepared for this purpose?—DYN.

All the trouble is due to using dyes dissolved in water. Dissolve them in alcohol and you will have no trouble. Water will always precipitate a spirit varnish.

VARNISH FOR MIRROR.—I should be obliged if you could tell me of a transparent varnish for silver mirrors, such as is used in the trade for the mirrors of reflex cameras. Could you give a formula, with directions? I have heard of a varnish made by dissolving celluloid in ether, but do not know the proportions or method of preparing.—REFLEX.

Dissolve transparent celluloid in a mixture of equal parts of amylacetate and alcohol. Make the solution about the consistency of ordinary negative varnish or a little thinner.

INTERNATIONAL COPYRIGHT.—I have in my possession a fine enlargement of Villars, Switzerland, and should like to reproduce it. Supposing it has been copyrighted, how does it apply to this country? It is not marked copyright, but may be all the same.—A. MCG.

As Switzerland is a party to the International Copyright Convention, if the photograph is copyright in that country it is also copyright here.

J. GIBSON.—The B instrument is of rather simpler construction, but A will give you a finer line of colour, otherwise there is very little to choose between the two.

STEREOSCOPIC SLIDES.—Can you tell me where I can obtain stereoscopic views of the White City, also the great earthquake?—T. L. HOWE.

Messrs. Valentine and Son, Dundee, will supply you with the former, and probably the latter also. Better communicate with them.

COPYRIGHT.—A photographer asked a gentleman, whom we will call A.C., to give him a sitting, to which he consented. The photographer gave A.C. two mounted photographs from the negatives. Now A.C. has given me an order for a thousand postcards from one of the photographs which was given to him. What I want to know is, can I accept this order without infringing the copyright; also, whom does the copyright belong to?—E. A. B.

Your statement points fairly clearly to the fact that the copyright is the property of the photographer who invited the gentleman to the sitting. He (and no one else) has the sole right in what shall be done with the photographs. Therefore, you will be liable for infringement if you make the postcard copies, and A.C., who has given you the order, will be equally liable.

IMPROVING NEGATIVE.—We have a 12 x 10 large group negative, taken very late in the day in ordinary room with skylight only.

quence, negative very much under-exposed, also slightly in prolonging development. As this is a most important we wish to know if by any possible means we can make a negative of same. I am afraid ordinary intensification would them too white in the faces, with the shadows very black. Is there any method with which we could bring out the detail and shadows in greater proportion than the high-lights?—C. H. F. I could have told better by seeing a print, but if it is simply a case of bad under-exposure we are afraid there is not much to be done, and we should think your best course is to either intensify the uranium (single solution) intensifier, or to take off the print you can, say on gaslight paper, and make a new copy-plate in the camera.

PHOTOGRAPH.—I am twenty-six years old and in a situation as a photographer, wages 30s. per week. I have also a good private position. I do not find sufficient scope, however, and see no prospect of further improvement. I am ambitious and suffer from a very great longing to travel and improve my position. What do you advise me to do? Does cinematograph work offer scope, or are there any positions to be had which would give a variety of experience and opportunity for travel?—FOTO-STO.

PROGRESS OF THE CINEMATOGRAPH BUSINESS NOW IS IN THE WAY OF increasing and photographing dramatic stories. The older firms of course, make a great feature of taking films of outdoor sports and current events. We should advise you to apply to the following for the most convenient list of them in the present issue of the journal, "The Kinematograph Weekly," published by Heron and Co., 9-11, Tottenham Street, London, W.

ADON LENS.—I use a Euryplan lens, $f/4.5$, $5\frac{1}{2}$ in. focus, on a quarter-inch Adon lens. I wish to lengthen this focus for portraiture by means of an Adon lens. What loss of intensity will there be with the lens working at $8\frac{1}{2}$ in. focus and $10\frac{1}{2}$ in.?

ADON LENS.—The back lens of the Adon is only three-quarters of an inch in diameter it will reduce the aperture of your lens to about $f/7$. The intensity should still be the intensity when the focal length is about 8 inches, but the question is a somewhat complex one. If you refer to the "B.J." for May 23, 1902, you will find an article by Dallmeyer, in which this matter of intensity is dealt with.

ADON LENS.—I have a Darlot's universal lens, set No. 2, portrait size, covering up to 10×8 , landscapes, 45 deg. covering $6\text{in.}, 7\text{in.}, 10\text{in.},$ and $14\text{in.},$ doublets 90 deg., covering $3\frac{1}{2}\text{in.}, 4\text{in.},$ in all about 23in. combinations all in perfect condition, in a size-lined leather-covered case. Could you give me any estimate of their value? I think the set was listed at eleven pounds.—G. C. CUNNING.

ADON LENS.—I do not appraise the value of second-hand apparatus. We can tell you, however, that although the set you have may be valuable, it has but little present market value, having been superseded by more modern sets that are much more rapid in action. You are under a misapprehension in saying that the portrait lens in the No. 2 set will cover 10×8 , as it will only cover about 8×6 at that size, also with regard to the cost, which, if we remember the set, was £9 only.

ADON LENS.—We wish to know if there is a book published on photographing pictures and antique furniture. Your reply will be highly appreciated.—MARK E. MITCHELL AND CO. There is no book specially devoted to these subjects. Articles on the subject, however, are to be found in back volumes of the journal. If you consult the advertisements in the "Almanac" for the present year you will find the addresses of several firms that deal in cinematograph apparatus, accessories, films, and all other requirements for cinematography.

ADON LENS.—There is no doubt that your trouble is due to the use of the sulphite.

ADON LENS.—The address of the "Thames" Colour Plate Company is 254A, High Holborn, London, W.C.

ADON LENS.—Could you oblige by stating (1) whether an agreement made with an apprentice to photography just out of time for a further term of service, bearing a sixpenny stamp signed by the employee and employer, in addition to a witness, would be legal in a court of law? Further (2) if it would be necessary to have the said employee's father's signature or not, employee

being just of age? (3) Where could particulars of the British Photographic Association be secured?—KNOWL.

(1) Yes, if the employee be of full age at the time he signs the agreement, not without. (2) No, not if the employee is over twenty-one. (3) We know of no such association. Possibly you mean the Professional Photographers' Association. If so, the hon. secretary, Mr. A. Mackie, 89, Albany Street, N.W., will send you full particulars.

SKETCHY PORTRAITS.—Would you kindly inform me how the crayon portraits or pencil sketched photographs are done that you see in most of the high-class firms of to-day? Are they hand-done?—SKETCH.

Yes. The portrait is printed with a white, or nearly white, background, and the figure and accessories sketched in by hand.

STRIPPING FILMS.—Will you kindly tell me how to prepare plates so that I can strip off the film when dry? I have tried to obtain stripping film plates, but the makers have ceased to issue them.—NEW READER.

Make a thin solution of indiarubber in benzole and coat the plates with it and allow them to dry. Then coat with the sensitive emulsion and dry as usual. When the negative is dry the film is cut round the edges and stripped off. Most persons now prefer to use ordinary plates and strip the films by the hydrofluoric acid method.

METOL-HYDROQUINONE DEVELOPER.—The following is the formula I usually make up, diluting it to one-sixth strength for actual use:—

Metol	10 gms.
Hydroquinone	5 gms.
Sulphite	100 gms.
Carbonate	100 gms.
Water, to	1000 ccs.

My difficulty is that it does not keep very well, and I should be grateful if you could suggest how this should be overcome. Would the addition of potassium metabisulphite attain this end, and if so, how should it be added and what would be the effect on speed of development?—Q. S.

Our experience of this developer is that it keeps excellently. We do not, however, keep it in quite such a strong solution; we use twice as much water. Perhaps your sulphite is at fault. Try a better quality, also be careful to let sulphite solution cool down before adding the metol. Dissolve sulphite first in warm water, add hydroquinone, and when cool add metol already dissolved in cold water; add carbonate last. Metabisulphite would be of no use in a single solution developer.

WASHING.—Would you kindly give your advice on the following points? (1) Does a plate require more washing to eliminate hypo, after being hardened with alum, than one not hardened? (2) What is sufficient washing in either case? (3) If a plate is washed free from hypo and then hardened in formalin or alum, what amount of washing is necessary to free film from the alum or formalin? (4) Is a trace of alum or formalin injurious to a plate?—STAIN.

(1) The film being somewhat harder, it is advisable to wash a little more. (2 and 3) That will depend upon the way the washing is done. No harm accrues from a prolonged washing, so it is well to be liberal with the water. (4) If much alum is allowed to remain in the film it will crystallise out and impair the transparency of the image.

REPAIRING LEASE.—We should be grateful if you would, through the medium of your valuable journal, kindly inform us in what position we stand, also what procedure to take in the following:—Our premises are rented on a lease. The flooring of studio is gradually giving way, owing to rot caused by dampness. Although the floor at one end of studio (brick building) is three feet or more below ground level, there seems to be no protection, by means of concrete or other material, for keeping damp out. There is a clause in lease as follows:—"And also will at all times during the said term keep the inside of the said premises (including all fixtures and additions thereto) in good and substantial condition, and the same in good repair and substantial condition deliver up to lessor, at the expiration or sooner determination of the said term." As the dampness is caused through faulty construction (upon which the borough surveyor has given his opinion, and says plans ought not to have been passed), I do not see that we are liable. We have complained to agent of property some months ago, and cannot get any definite

reply as to whether landlord will repair it. As it is a danger to operator and sitters we would like to know whether we can make landlord repair same and also provide efficient protection.—F. BEESTON.

We expect that you will have to do the necessary repairs. The clause you quote makes it clear that you are to keep the premises in good and substantial repair, and we don't see that the alleged faulty construction of the place will relieve you from it. If the landlord does what is necessary it seems to us it will be as a matter of grace, and that only. If an accident happens, either to the operator or a sitter, you will be held responsible, as you know the faulty state of the floor.

LONDON COUNTY COUNCIL.—Could you kindly inform me, through your valuable columns, where to apply for a situation on L.C.C. photographic staff, and what degrees are necessary?—READER.

You had better write to the L.C.C., Spring Gardens, S.W., for the information you require.

COPYRIGHT.—Having sent an assistant out to take some photographs (my material and time, etc.), he has secured rather an exceptional one. He now claims the copyright of same. Is he entitled to it, or does it belong to me?—H. L.

The assistant, being paid by you to do the work, has no copyright in the picture. That belongs to you, and when you register it mention his name as the photographer who took the negative.

PYRO.—So far as our information goes, the photographic labour market in Canada is as well stocked as it is in England. Unless you are capable of doing the very highest class of work we should advise you (a lady) not to emigrate to that country without due consideration.

WOODEN TRAYS.—In the "Journal" I notice you advise use of wooden dishes. I have often tried to get these made to special sizes, but so far have not been successful. Would you be good enough to send me address and prices, so that I can get some made?—S. W. B.

Any local carpenter will make the trays if you explain to him what your requirements are. Those we have were made by a local man, and they answer their purpose well.

PRICE OF PHOTOGRAPH.—(1) I should be very glad if you will be good enough to advise me on the following:—I have a taking photograph of a milkmaid, which I want to sell for advertising purposes to some milk or milk chocolate firm. Can you tell me how to set about it? Also what price I ought to get? It is a half-plate negative, three-quarter length figure. Ought I to deal with an agent, and can you recommend me one? (2) I also want advice about a camera for taking portraits in their own homes and for general work. What should you advise? I thought 1/2-plate size, and I suppose I ought to have a portrait lens and an R.R.—ELEANOR DUNDAS.

(1) The best way is to write to such firms as you think the picture would be useful to. You cannot expect them to pay much for such a commonplace subject, if they will buy at all. (2) The portrait lens will be the quicker of the two, though an R.R. will be the more useful for work other than portraiture.

ALBUMEN PAPER PRINTING.—Would you be kind enough to inform me, through the medium of your inquiry column, (1) if there is any guide book on the market on the working of albumenised paper? (2) What class of negative is most suitable for this process? (3) Is it possible for me to obtain almost equal results with readily sensitised albumenised paper as if I sensitised for use myself? (4) What baths and processes are recommended in sensitising my own? (5) Could you oblige with any formulæ for, or hints on, the toning process to obtain plucky results of a good rich tone? My past experience is that the tone is too red and the whites not clean-looking, and, although I have tried many baths, I cannot get a bluer tone without washed-out-looking prints.—PROCESS.

(1) "Albumen and Plain Paper Printing" is about the latest. It may be had from Dawbarn and Ward, 6, Farringdon Avenue, E.C., price 6d. (2) Good vigorous ones, such as are best suited for carbon and platinotype. (3) Yes. (4) A solution of nitrate of silver, 50 to 60 grains to the ounce of water, with about a couple of drops of nitric acid to the pint. (5) The above-named book gives formulæ. We expect your trouble is due to the use of unsuitable negatives. Unless they are of a vigorous character it will be impossible to get rich purple tones, no matter what toning bath be employed.

CARBON PRINTING.—Kindly let me know the latest and most practical book on carbon printing. I have the "A.B.C. of the Art of Carbon Printing"—CARBON.

"Carbon Photography Made Easy," by Thos. Illingworth, 1s., is a later book. It is published by Thos. Illingworth, Willesden Junction, N.W.

E. WOOLCOTT.—The pictures are very pretty. On the whole, it will be better, in the long run, to sell the copyright than to spend £50 on photogravure plates and printing and publishing them yourself. A fair price for the copyright of the pair would be from five to ten guineas.

RUSTED BURNISHER.—I have a burnisher which has been in my studio, not used in the winter, and now the bars are rusty. I clean it? If so, how? If not, would it be better to send it to the makers? Can you give me the address of one, as if I sell to a wholesale house there is a double expense?—WEEDEE.

(1) If the rust is not deeply in you may possibly be able to do the work yourself with very fine emery-cloth and afterwards rubbing the bar longitudinally on an oilstone. Failing this, the burnisher should be sent direct to its maker. (2) It is quite against our rule to express any opinion on the comparative merits of different makers' goods. Both the firms you mention have good reputation, and you will get full value for your money from either.

TWO AMERICAN EXHIBITIONS.—Two interesting exhibitions have recently been held in the Photo-Secession Galleries, 291, Fifth Avenue, New York. The first, which was open from February 26 to March 15, consisted of a number of etchings, dry-points, and book-plates by Mr. Allen Lewis, the front cover of the catalogue being artistically illustrated with a design by the artist. The second, open from March 17 to 27, comprised twenty-six drawings by Miss Amelia Coleman Smith, of London and New York.

NATURAL HISTORY PHOTOGRAPHS.—We have recently had an opportunity of inspecting some excellent examples of natural history photography, the work of the well-known photographer, Mr. R. B. Lodge. These include some of the rarer species of birds, such as the eagles and vultures of the Carpathians and Southern Spain, herons and ravens of Albania, together with a number of others, which being photographed in their natural surroundings, should prove of interest to lovers of natural history. These photographs (the work of the "Birdland" camera) are sold by Messrs. Sanders and Co., 71, Shaftesbury Avenue, London, W., from whom prices and full particulars may be obtained.

NEWMAN AND GUARDIA, LTD., have transferred the whole undertaking of their firm to Nos. 17 and 18, Rathbone Place, Oxford Street, W. The new premises comprise on the first floor a well-appointed show-room, wherein it is hoped to establish a gallery of photographic prints, in conjunction with an elegant and comfortable lounge for the convenience of patrons, a waiting-room for trade customers, general and private offices, and a suite of drawing-rooms. On the upper floors are located the factories, stores, testing and experimenting room, packing-rooms, and the works manager's office. A hydraulic passenger lift from the street level serves all floors.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

are sorry to record the death on Sunday last of Mr. Hector Maclean. (P. 289.)

Another link with the past history of photography is also severed by the death of Mr. R. H. Bow. (P. 290.)

C. M. Kurtz, of Buffalo, U.S.A., who was to have taken a prominent part in the forthcoming international exhibition of pictorial photography in America, died on March 21. (P. 294.)

Bromoil Process.—The first part of a paper by Mr. Harold Baker on Bromoil printing contains many useful hints by this well-known worker in the process. Mr. Baker has found best a semi-glossy paper such as the Ilford "Carbon" bromide. He gives detailed instructions for bleaching and pigmenting the prints. (P. 279.)

Give in this issue the paper recently read before the R.P.S. by Mr. E. A. Salt, in which is described the apparatus for testing the efficiency of shutters devised and made by the author. The apparatus is described in a simpler form the principle of the rotating plate shutter described by Sir William Abney. As Mr. Salt's paper, however, describes in a very simple way many of the somewhat obscure points in connection with shutters, the whole of it is deserving of careful reading. A number of the measurements made both of speed and efficiency are particularly interesting, as showing, among other things, the remarkable efficiency of some diaphragm shutters even at the highest speed. (P. 282.)

Under "Photo-Mechanical Notes" some practical advice is given concerning the many causes of imperfect register in three-colour work. (P. 290.)

An apparatus for daylight development and a method of cinematograph projection in a lighted room figure under "Patent News." (P. 290.)

An unorthodox but efficient method of removing silver stains from negatives is described in an editorial note on page 277.

Give on page 278 a simple rule for calculating the magnification produced by the "Adon" lens.

E. W. Foxlee, in a short article on page 281, calls attention to a new and useful test for the photographic purity of a mounting-board.

Photographers in Cardiff have to thank their Public Librarian for having issued a classified list of the photographic text-books in the reference and lending departments of the Libraries of that town. (P. 277.)

EX CATHEDRA.

Photographic Books in Public Libraries.

We congratulate the Libraries Committee of the City of Cardiff on having issued a classified list of the photographic text-books included in the reference and lending departments of their library. This list, which costs one penny only, is one of seven classified lists which have been issued, whilst four others are in preparation. By thus putting compactly before the student the material which is at his disposal, a library is greatly adding to the help it provides. In the case of the photographic list the work of classification and cataloguing has been done by someone who is either intimately acquainted with photographic processes, or has taken pains to become so. Much good might be done by drawing the attention of other library committees to the useful work done by Cardiff.

"Proofs to be Returned."

A recent instance of the trouble which is still occasioned to many photographers by the non-return of proofs sent out to sitters makes us think that such causes of annoyance will not be completely set on one side until some standard of etiquette among photographers themselves is established. The particular grievance to which our attention is now drawn concerns the sending out of a number of proofs, from none of which an order was given, but instead the sitter took the prints to a rival (and cheaper) photographer in order to get a considerable number of prints of a cheaper class. There are, we know, some photographers who, if ordered to do such work, would consider it *infra dig.*, and would advise the customer to go to the studio where the negatives were taken, but instances of such *esprit de corps* are, we fear, all too rare, and therefore the photographer who wishes to safeguard himself against such happenings must make it clear to the sitter that the proofs, if not returned, are to be paid for, or must so deface the proofs themselves that no use can be made of them.

* * *

Silver Stains.

The following treatment for removing silver stains from negatives has been found quite efficient, both in cases where a drop of rain or other moisture has caused a print to adhere to the plate, and where the spots have formed while the negative has been stored away. Plunge the negative with adhering print, if any, into a strong hypo fixing bath, one containing a hardener for preference. After a time a print which has stuck can be quite easily removed, without fear of damaging the negative, as the gelatine will become saturated and so lose its adhesiveness. The negative should then be thoroughly washed and dried in the usual

way. When absolutely dry lay the plate film up on a perfectly even surface, but not a slippery one. A few flat sheets of paper laid over a large plate-glass cutting shape answer the purpose admirably. Saturate a large tuft of cotton-wool, in which there must be no trace of grit, with methylated spirit, and hold the negative firmly to the level pad by pressing on its edge with the fingers of the left hand. Then with the right hand rub the wet wadding on the film with a very firm pressure, working swiftly and evenly in small circles all over the plate until every stain has disappeared, which should be very soon. On no account rub in straight lines, or the negative may be reduced in streaks. The motion required is the same as most retouchers use to apply medium, but the pressure should be quite hard, and the whole of the negative must be gone over, so that if there is any reduction in density it will be quite even and so negligible. If the bed on which the negative is laid is even, no amount of pressure will crack the plate. Finally, with a fresh tuft of wool and more spirit, wipe off any scum that may have been formed by the previous "polishing" process.

* * *

Toned Bromide Prints.

The hypo-alum bath which, despite the modern improvements in sulphide toning methods, continues to be used for much commercial work, is a solution with which the beginner usually experiences a crop of difficulties, the chief of which is the tendency of the freshly made bath to exert a semi-bleaching action upon the prints placed in it. While the hypo-alum mixture speedily improves as regards this defect with use, its ripening may be accelerated by such a simple expedient as stirring up with it a handful of clippings of ordinary untuned or fixed P.O.P. This may be either gelatine or collodion, the only essential being that the bath shall quickly take up the silver salts from the paper. Probably the very finest results with the hypo-alum bath are obtained on prints which have been developed with iron (ferrous oxalate), but with a suitable paper—all papers do not tone with equal readiness in hypo-alum—the rich warm purple, described in the trade as the "hypo-alum" tone, is readily obtained.

* * *

A Useful Accessory.

A little piece of apparatus for the technical photographer, who is often called upon when away from the studio to photograph small objects, such as vases, glass-ware, etc., is a pair of boards, about 2 ft. square, hinged together with a leather strap screwed to each outside edge to serve as a pair of handles. The inside surfaces of the boards are covered with good black velvet, affixed with glue. The boards, when opened out, provide both a base and a background for the object being photographed, and although a black background is not very suitable for many objects, a penny sheet of cartridge paper, purchased at the stationer's, will complete the photographer's outfit, and may be thrown away when the work has been done.

The Magnification of the Adon.

In a paper on the Adon lens read by Mr. T. R. Dallmeyer before the R.P.S. some years ago, and republished in the "B.J." for May 23, 1902, the author stated that he found it convenient to make the positive lens of the Adon of the same focal length as the ordinary lens with which it was to be used, and the negative lens of half the focal length of the positive. He did not give a reason, but recently, while going into the optics of the Adon, we noted that when these conditions are fulfilled the use of the Adon is very greatly simplified. Under the conditions described by Mr. Dallmeyer, the magnification is always equal to the focal length of the Adon positive, divided by

the separation of the Adon components. Thus, if the positive is of $5\frac{1}{2}$ inches focal length and the separation is 2 inches (which will be the case when the camera lens is working at its own focal length of $5\frac{1}{2}$ inches), the magnification is 2. With a separation of 3 inches (which involves racking in the camera), the magnification is $1\frac{5}{6}$, with one of $2\frac{1}{2}$ inches it is $2\frac{1}{5}$, and the camera is extended. The smallest separation possible seems to be about 2 inches, at which the magnification is $2\frac{3}{4}$, therefore the greatest focal length that we can get is about 15 inches. With a longer focus camera lens a greater magnification can be obtained, but then the rule will not apply. The separation of the Adon components can, of course, be marked on the mount in such a way as to either show the magnification or the focal length. The Adon actually in use does not conform with Mr. Dallmeyer's conditions as described in his paper in regard to aperture, and we are not sure whether it does so or not in respect to the relative focal lengths. If it does, then there is no difficulty in making use of the very simple rule of magnification that we have described.

IRIS AND FOCAL-PLANE SHUTTERS.

MR. E. A. SALT's paper on shutters, given at the R.P.S. on February 23 and reprinted with some few additions in this number, covered many points of interest, amongst which the very high efficiency of some of the modern iris shutters was not the least interesting. The efficiency of these shutters is not very great at their highest speeds when used at full aperture, but at the lower speeds they give very remarkable results. It need not, however, be assumed that they excel the focal-plane shutter in this respect. Even though both shutters may give exposures with efficiencies a very little under 100 per cent., yet the focal-plane generally comes out slightly best.

The modern iris shutter of the best type owes its high efficiency to the fact that it always requires the same time to open and close, whether set to a high speed or a low one. At its very highest speed there is no measurable period of full opening, while the movement is practically continuous, and may be considered uniform, therefore we shall not be far out if we consider the efficiency to be one-third when the lens aperture is the same size as the shutter aperture. This means that a total duration of exposure of, say, $\frac{1}{200}$ second, is equivalent to keeping the aperture full open for a period of $\frac{1}{600}$ second, so that the real exposure is deficient by $\frac{1}{300}$ second. If, then, we run the shutter at a lower speed, the same deficiency will exist, so that a nominal $\frac{1}{10}$ second will really equal $\frac{1}{10} - \frac{1}{300}$ or $\frac{29}{300}$ seconds. This is, of course, a very highly efficient exposure, but it is worth while to compare it with a similar $\frac{1}{10}$ second exposure given by a focal-plane shutter.

Assume that the blind of our focal-plane shutter works at the rate of 40 inches per second. A 4-in. slit will pass a single point in $\frac{1}{40}$ second, so that if the blind works in the focal-plane, a 4-in. slit will give a fly efficient $\frac{1}{10}$ second exposure. Usually, however, it works half an inch from the focal-plane, and if we have a 5-in. lens working at $f/5$, the blind intersects the lens pencils in a plane in which they have a diameter of $\frac{1}{10}$ inch. To give a duration of exposure of $\frac{1}{10}$ second in this plane the shutter-slit must be reduced by $\frac{1}{10}$ inch, so that a slit 3.9 inches wide is required. Such a slit passing across a pencil $\frac{1}{10}$ inch in diameter has an efficiency of $\frac{3.9}{4}$. The true value of the $\frac{1}{10}$ second exposure is therefore $\frac{3.9}{40}$, which is greater than $\frac{29}{300}$ by $\frac{1}{1200}$ part of a second.

If we use a bigger lens shutter having a full opening equivalent to $f/4$, then the efficiency with a lens aperture

$f/5$ is increased to $\frac{1}{3}$, or the deficiency is $\frac{5}{9}$ instead of $\frac{7}{9}$. In these circumstances the relative efficient exposures on the focal-plane and the iris shutters will be as $\frac{39}{400}$ to $\frac{7}{2}$, or the former will still be the more efficient by the $\frac{1}{5}$ part of a second. If we increase the shutter aperture to $f/2.5$, while still using a stop of $f/5$, the iris shutter has the advantage over the focal-plane by $\frac{1}{1200}$ second. These figures show how very nearly equivalent shutters are, but also indicate that the focal-plane shutter has a very small advantage over the other in conditions that will generally prevail in practice. It must also be noted that the focal-plane slit will usually be more than four inches wide, and that its efficiency is then higher than the amount given. Suppose, now, we compare the shutters when both work at $\frac{1}{200}$ second. As already explained, the iris shutter under these circumstances gives an efficient exposure of $\frac{1}{200}$ second. The focal-plane shutter naturally will give the least efficient exposure if we alter the slit only and keep the tension the same. Assume, as before, the blind travels at the rate of 40 inches per second, then a distance of $\frac{1}{5}$ inch in the focal-plane will represent a duration of exposure of $\frac{1}{200}$ second, so that in this position the slit must be $\frac{1}{5}$ inch wide. If, however, the blind is half an inch from the plate and intersects the light pencils in a line where they measure $\frac{1}{10}$ inch in diameter, a $\frac{1}{5}$ slit will give a duration of exposure of $\frac{3}{400}$ seconds. The slit must be reduced to $\frac{1}{10}$ inch to give $\frac{1}{200}$ second, or be made the same width as the diameter of the light pencil. In this case the efficiency is $\frac{1}{2}$ and the efficient exposure is $\frac{1}{100}$, which is 50 per cent. greater than the efficient exposure with the iris shutter. To counteract this

difference we must use a bigger iris shutter, with an aperture equivalent to $f/3.75$. We are, however, assuming that the focal-plane shutter is being used at a disadvantage. If we simply double the slit and increase the tension so as to still give $\frac{1}{200}$ second, the efficiency goes up to $\frac{2}{3}$ and the efficient exposure to $\frac{1}{300}$, which can only be equalled by the iris shutter when it opens out to an aperture equivalent to $f/2.5$. It is apparent from these calculations that the focal-plane shutter still has advantages over the other form in spite of the great improvements that have been effected in shutters that work on the iris principle. It is, however, also evident that the efficacy of the latter type is greatly increased by using as large a shutter as can be fitted to the lens. It must of course be remembered that the efficiency of $\frac{1}{3}$ which we have taken for the iris shutter when working at full aperture and top speed assumes that it resembles an actual iris in always having a circular opening. Many have non-circular or star-shaped openings, and on this account their efficiency is over one-third. Assuming it to be one-half instead of one-third, and the shutter aperture to be equal to the lens aperture, then at an exposure of $\frac{1}{10}$ second the focal-plane and the iris will have equal efficient exposures in the first of the cases that we considered, and the iris will have a little advantage in the other two cases. When set to the highest speed of $\frac{1}{200}$ the iris will only be equal to the focal-plane shutter when the latter is working under the worst conditions, that is, with narrow slit and low tension. It is, however, a matter of doubt whether an efficiency of one-half can be realised in lens shutters under the conditions assumed unless their size is increased.

BROMOIL PRINTING.

[Brief working instructions for the Bromoil process were given in last year's "Colonial Issue" by the inventor, Mr. C. Welborne Piper. Mr. Baker, one of the most skilled Bromoil workers, now gives very full instructions in the working of this fascinating process, wherein a bromide print or enlargement is bleached and then "re-developed," with any desired modifications, by applying greasy ink with a brush.—Eds. "B.J."]

The rapidity with which oil printing has grown in popularity is remarkable. I do not remember any new process coming so quickly to the front, and this fact speaks volumes in its favour. On my own part, I consider it is the finest and most adaptable printing medium that has ever been invented. Of the two methods I prefer Bromoil, for several reasons. In the first place, no daylight is necessary, and this makes it suitable for a busy man who has but little time in daylight to devote to photography. In the second place, Bromoil seems to me more certain, and less liable to failures than oil printing; and I think it gives more control in producing the effect desired. And, in the third place, enlargements can be made without a large negative. The great advantages of oil printing are obvious—limited choice of colour, enormous control over effect, and permanency as great as paper and printers' ink can furnish. It was the account of the exhibition at the office of the "British Journal of Photography" which first induced me to try the process. I must confess that, for some weeks, my efforts resulted in a ghastly failure, and I was almost giving it up in despair. Success came at last, and I think I may claim to have succeeded as any one who has tried it.

A Suitable Bromide Paper.

The method is peculiar, for, after a good bromide print has been obtained, it has to be destroyed before the really interesting part begins. One important element in successful working is the bromide paper used, for I have utterly failed to obtain good results with any kind of "matt" paper. I attribute this

to the addition of arrowroot to the emulsion to secure the dead surface. Such paper, in my hands, will not take enough ink on the shadows, and will take too much on the light parts. I believe the best results are obtained on paper which is made with nothing in the emulsion but pure gelatine, and, of course, the silver salts. The paper on which I have secured all my best results is Ilford "Carbon" Bromide, either "white," or, for brown ink, "ivory"; in the latter the cream colour is, apparently, in the emulsion, and not in the paper. This is an advantage, as it is easy to see by the back of the print when the yellow colour of the bleaching solution is washed away. This paper has a very pleasant surface, smooth but not shiny, and finished oil prints give a suggestion of being on parchment. This is especially so with the "ivory" colour. I do not like many Bromoils I have seen on matt paper; they have a coarse, speckled appearance, which is very objectionable to me.

No doubt rough papers, such as Kodak "Royal," can be used with success, when they have a good coating of gelatine; but I have not tried them since my early efforts, and I am very well content with the smooth paper. Rough papers might, perhaps, be better for large work: so far, I have not tried anything larger than 15 by 12.

The Kind of Bromide Print.

The quality of the bromide print is of great importance. Some recommend that it should be brilliant and dark. I do not find this the case. *The print should be the best the negative will give*—full of detail in the high-lights, and not too dark in the deepest

shadows. It is especially necessary that there should be full detail in the high-lights, as it is just in these parts that loss may occur, and if the shadows are very dark, the deepest tones and those not quite so deep will ink to the same depth.

The development of the print is of some importance. Quick-acting developers, like metol, are not satisfactory. Many workers recommend amidol as a slow-acting developer. I have not tried this, as I have been well satisfied with that recommended by the makers of the paper—viz., metol-hydroquinone, with soda, not potash; but I prefer to use it more dilute, or weakened by previous use for ordinary bromide prints, so that a full exposure may be given.

It seems necessary to give a full exposure, so that the silver image shall be deep down in the body of the gelatine film. I imagine this result is produced by a full exposure and a slow developer, and that a short exposure and a rapid developer gives an image much more on the surface of the gelatine, so that a great deal of the thickness of the gelatine, in the latter case, escapes the tanning action of the bleaching bath.

The "Bromoling" Solution.

I find that where the water is soft (as in some of our large towns, where it comes from mountain reservoirs) it is necessary to fix in an acid hypo bath containing alum, and I prefer to bleach the prints as soon as the hypo is washed out of them, and I have found that this washing need not be very long. I have bleached and inked successfully prints that have been washed for only ten minutes. The bleaching solution is made by adding 80 grains of potash alum and 20 grains of citric acid dissolved in 15 ounces of water to a 5-ounce bottle of Ozobrome solution, or the formula given by Mr. Welborne Piger, the inventor of the process, in the "British Journal of Photography," March 27, 1908, may be used, namely:—

Ozobrome stock solution	4 parts.
10 per cent. potash alum solution	4 parts.
10 per cent. citric acid solution	1 part.
Water to make solution	20 parts.

The bleacher should be kept in a yellow bottle, and sufficient taken to bleach as many prints as are ready. In a few minutes the prints should appear as if bleached for toning with sulphide: a good washing is necessary to remove the iron salt in the Ozobrome solution, or blue stains will afterwards appear. The used solution should be put away in another yellow bottle, and may be used again if it remains bright yellow; if a black tinge appears in the solution it should be thrown away, as prints bleached in it will not ink well. If the contrast of the print needs to be made stronger, the quantity of citric acid may be increased. When the yellow solution has been thoroughly washed away the prints must be removed to a 5 per cent. solution of sulphuric acid for two or three minutes; in this bath the yellow-brown image becomes paler, and they should remain in it (with constant moving, to ensure even action) until a slight relief is seen on the print. The best way to look for this is to blow a piece surface-dry, where a high-light comes against a dark shadow, and the high-light should stand up slightly above the shadow. It is then washed to remove the acid, and it may be dried, or, better still, fixed again, to remove the silver bromide still remaining. For the second fixing plain hypo should be used, but a small quantity of sulphite of soda may be added, to prevent precipitation of sulphur by the acid which may be left in the prints. The fixing should be followed by a short washing, and the print may be inked at once; but I prefer to dry it and re-soak before applying the ink. If it is dried at this stage, the surface moisture must be blotted off; for, if beads of water remain on the print, they prolong the drying in patches, which may afterwards refuse to take the ink. The blotting-paper must be clean, and quite free from particles of iron, such as float about a room heated by a stove. Every speck of iron will produce a blue stain which cannot be removed.

The Acid Bath.

The preparation of the dilute sulphuric acid requires care, or serious accidents may occur. If the concentrated acid is measured in a graduated glass, and cold water poured into it, sufficient heat is generated to break the bottom of the measure, which may fall off and splash the acid in all directions. It destroys clothing and burns the skin badly. It is best to take 19 ounces of water in a measure, add 1 ounce of acid, and pour out into a porcelain dish. Enamelled iron dishes should never be used either for bleaching or acid baths, as some of the iron is sure to be exposed where the enamel is chipped, and blue stains will appear in the prints.

How the Print Should Look Before Inking.

When the dried print is to be inked, it should be soaked in water until a decided relief is to be seen on the surface. In cold weather it may take some time to produce the relief, and it may be hastened by giving a minute or two in the acid bath, or by a short immersion in tepid, not hot, water. The need for the acid or tepid water must be decided by the condition of the print. Some of my prints that inked beautifully and made successful pictures never had any acid bath at all, neither after bleaching nor after drying. I never ink a print now until it has been dried after bleaching, as I find they always work much better. Those inked at once without drying will often take the ink very well for the first half of the necessary time, but they soon become too soft, and the ink is deposited in a coarse granular manner, and the detail in the lighter parts is lost, sometimes completely, and they require great care to finish them.

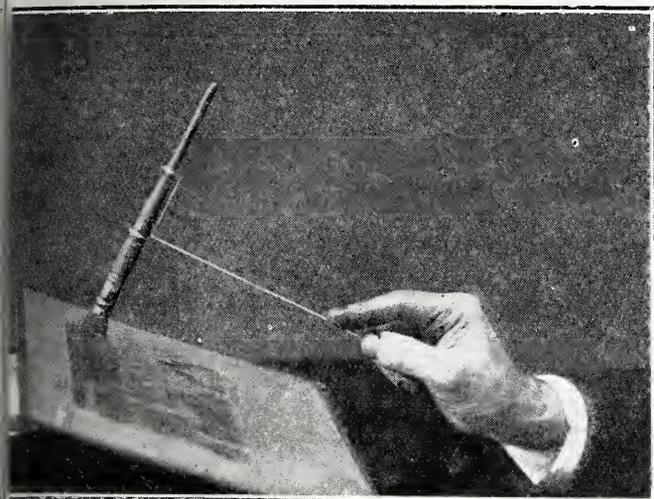

Those that have been dried will take the ink just as well at the end as they do at the beginning of the process, and the lighter tones and the details are not lost. I prefer to bleach the print before it has been dried, because the process goes on in a very uniform manner: in bleaching after drying some parts are very obstinate, and require a long time to bleach, and although eventually they do bleach, those parts will not take the ink well. Some recommend using the bleaching solution at a temperature of 80 deg.; but the results have proved very uncertain in my hands, sometimes quite good, and at other times utter failures. It is better to keep to the usual method of bleaching, etc.; the results are likely to be more uniform.

Brushes and How to Use Them.

As to brushes, the bevelled ones of fitch hair, known as china painters' "dabbers," are very suitable; but those specially made for oil printing are far the best. I prefer those sold by Jas. A. Sinclair, of 54, Haymarket, London, S.W. One cannot have too many brushes: it is a great convenience to be able to pick up a clean, dry brush at any moment when inking a print. But it is just as well to buy only two or three at first, and purchase others as experience may suggest. One or two brushes of square will be useful for "hopping," but hopping should be avoided as far as possible; it is necessary sometimes, although the best results are usually obtained without it.

The brush, when applying the ink, should be held upright, with the index-finger resting on the top of the handle, the other three fingers on one side, and the thumb on the other, and the elbow resting on the table. By this method the bristles at the "toe" of the brush press on the paper first, and bend and spread out a little before the "heel" of the brush comes down. This gives a beautifully fine, grainless deposit of ink, but I doubt every worker finds his own particular way; and, of course, to him, that is the best. When the brush is first applied the ink "takes" everywhere, lights and darks alike, but a few gentle dabs on the same spot will bring up the details and tones in a manner most fascinating; and very soon one finds that different methods of dabbing produce different effects: quick, smart touches produce contrast and detail; very gentle, smudging dabs give softness, and reduce the sharpness of the details.

can be made to obliterate it. But patience and persistence are necessary, and a print which at the first few touches seemed to be, by repeated application of the brush will grow into a fine one. If too much ink has been put on, a clean, dry brush often put matters right. A dark part may be lightened by "hopping," allowing the brush to fall from the height of an inch or more, and catching it as it rebounds, or by fixing in a wire a continuous series of taps, gentle or vigorous, may be used. For this a square-cut brush is best. The result is a considerable lightening of the light tones and a strengthening of the darks, with occasionally a coarseness of grain that is un-

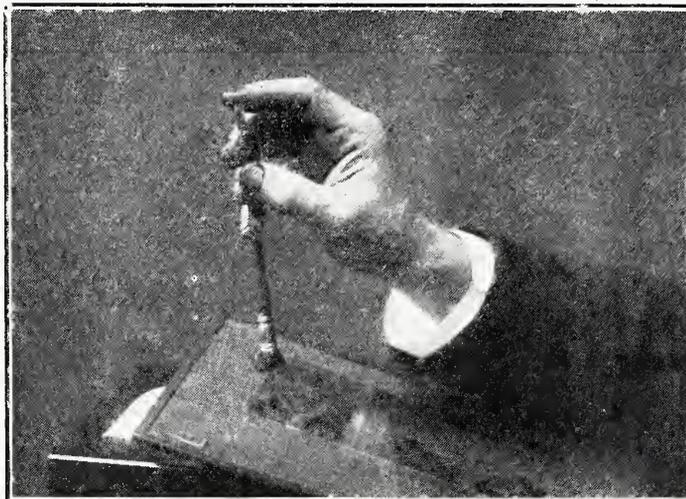

"Hopping."

pleasant, and possibly a harshness of the "values." But both defects may be remedied by very gently dabbing with a clean, dry brush of the sloped "hart's-foot" shape. Sometimes when the distance has been lightened by hopping it may show too much detail; this may be softened by the gentlest dabbing, and the detail reduced as far as may be necessary. But all this the enthusiastic oil-printer will speedily discover for himself, and the beginner may find the hint will help him over his first mistakes.

Whenever the brush has been recharged with ink it is best to apply it to a dark part of the subject, and to wait until the

amount of the pigment in the brush has been reduced before proceeding to the lighter parts, and those places which are intended to be very delicate may be inked with a clean brush, relying on picking up enough ink from the surrounding darker parts. It will soon be found that enormous control may be exercised over the "effect" of light and shade desired by under or over inking. One danger must be guarded against, and that is loss of aerial perspective by piling up dark on distant shadows. It is so easy to obtain lustrous, juicy shadows that one is liable to be carried away by their beauty, and tempted to scatter fine deep shadows everywhere. But this belongs more to the artistic

Inking.

side of the process, and each one must work out his own salvation, getting whenever he can the advice of artist friends.

After some practice it should be possible to pigment a Bromoil of whole-plate size in half an hour, unless it contains an elaborate sky, which itself may take longer than the landscape part of the picture. When skies are attempted trouble begins with fluff floating in the air, and hairs from the brushes, especially when they are new. It would be very nice to have a small room like an operating room in a hospital, where dust, etc., is regarded as a deadly enemy.

HAROLD BAKER.

(To be continued.)

A USEFUL WORKING TEST FOR THE PHOTOGRAPHIC PURITY OF MOUNTS.

It is by no means an unusual thing when a photograph shows signs of fading, or within a short time becomes yellow in the corners, for the mounts to be suspected as the cause. In many instances correspondents have written us that they are almost certain that the fading was due to the mounts, since they knew that the prints were thoroughly washed, evidently overlooking the fact, which has been constantly pointed out in the "B.J." thirty years past, that washing is but of secondary importance. The prints have been perfectly fixed in the first instance. There is no question that in days gone by a considerable amount of fading was brought about by the use of unsuitable mounts. It was not altogether surprising, seeing that at that time the mount-makers were scarcely to blame. They did not know the requirements of photography, and they merely supplied a board that was of good quality as a cardboard. The paper, however, of which a board is composed may be of the best quality for the ordinary purposes to which card- or drawing-boards are applied, and yet may have a deleterious action on silver photographs. Now, however, mount-makers

know the requirements of photographers, and, as a rule, supply only such boards as are suitable. Still, complaints are occasionally heard of fading said to be caused by the mounts.

One of the alleged proofs of such fading is that unmounted prints of the same batch have remained unchanged, while those mounted have shown signs of fading within a comparatively brief period. That, however, though exciting suspicion, is not conclusive evidence, since the actual cause may be, and frequently is, the mountant. For instance, I have observed the use of starch paste that would certainly have more or less injurious action on silver prints. This mountant soon becomes unsafe, even while it retains its adhesive properties. It should be made on the day of use.

Many are under the impression that the testing of mounts in order to ascertain if they are free from such matter as would act deleteriously on photographs requires considerable chemical knowledge. So it does if one wants to know what the injurious matter consists of; but what a photographer wants to know in practice is whether there is, or is not, anything present that will

act on his pictures. There is a very simple and practical way of deciding this point. The following is the procedure:—

The mount to be tested is taken, and half of it covered with a thin piece of glass or celluloid. It is then laid on a glass plate, and on that, face downward, is placed an albumen or collodio-chloride print—preferably made from a thin negative and lightly printed. On that is put five or six thicknesses of pure blotting-paper that has been well moistened with water. On this, again, is put a sheet of celluloid or a glass plate. It is well for convenience in examining from time to time to secure one end of mount, celluloid, print, and blotting-paper together with a couple of paper-fasteners. The whole is then put into a printing-frame, pressed tight, and kept in a warm place for a time. It will be seen that the glass plate, back and front, is for the purpose of preventing the evaporation of the moisture. Any silver pictures kept under these trying conditions will eventually succumb. If, however, that portion of the print which has been kept in contact with the mount shows signs of deterioration or spottiness before that which was insulated from it by the glass or celluloid, it is obvious that that change is due to the mount. In very bad cases we have known three or four days to produce a marked change. In others a month or more of this treatment has shown no difference between that portion which has been in contact with the mount and that which was protected from it. The prints had changed equally all over alike. The reason why albumen or collodion prints are used is that gelatine ones, if kept damp so long, would be liable to

stick to the mounts, and so prevent examination from time to time.

P.O.P. prints are not so liable to suffer injury from mounted on impure mounts as are albumen ones, for this reason: with both of them the raw paper has a baryta coating, which, to an extent, insulates the image film from the paper, and consequently the mount is the less likely to affect the picture.

It may sometimes happen when coloured mounts, more particularly those of chocolate colour, are tested in this way, after a time, the print becomes stained by the colouring-matter on the board. That, however, does not show that they are entirely unsuitable for their purpose—supposing the image itself remains intact. That is best judged of by examining the picture by transmitted light. On some of these mounts the colours are liable to tint the whites of pictures mounted upon them. This can generally be avoided if they be mounted dry with a thick mountant (one that contains but a minimum of water), and then put up to dry as quickly as possible. This course is advisable in all cases of mounting, especially if the mount is not above suspicion, for it is obvious that the longer a print is kept in a moist condition on an impure mount the more likely it is to suffer injury therefrom.

With the dry mounting system impurities in the mounts, for a little moment, inasmuch as the print is not in actual contact with it. The intermediate sheet of adhesive material serves as an insulating medium between the print and the mount.

E. W. FOXE.

SOME POINTS IN PHOTOGRAPHIC SHUTTERS POPULARLY EXPLAINED, AND A SIMPLE "SHUTTER-TESTER."

[A lecture given by Mr. E. A. Salt before the Royal Photographic Society on the 23rd February. In the following report a few points have been slightly amplified.]

THE subject of photographic shutters can be dealt with in several different aspects: "Mechanically," involving methods of construction and design. "Theoretically," which is almost synonymous with a mathematical treatment. "Historically," an interesting point of view which does not seem to have received the attention it deserves; and finally, for want of a better term, "Practically," considering the applicability of shutters to varied photographic work, and their respective merits and limitations.

With your permission I propose to-night, in plain language and without formulæ, to touch upon a few points which seem to me interesting, though selected, perhaps, in a rather haphazard sort of way. Also, I propose to bring to your notice a simple shutter-tester possessing some novel features, to explain its construction, and finally to show some characteristic diagrams of well-known shutters on the market. The difficulty in preparing a paper of this description has been not so much what to include, but what to exclude. Little which is new can be said on a subject which has received fair consideration in the past, though information is rather scattered, and occasionally contradictory.

Manufacturers of lenses have given us objectives of such precision and excellence as to almost approach the ideal. The shutter lags behind a little for the reason that it is almost impossible to comply with every condition. These are many and varied, and frequently conflicting in nature. Still a considerable advance in certain directions has been achieved in recent years, and the modern instruments can fairly be described as efficient, some are highly so. In many cases they exhibit a marvel of mechanical ingenuity packed into a very small space.

Classification.

Photographic shutters may be divided into three broad classes:—

1. Those that work in front of, or immediately behind, the lens.
2. Those that work between the components of the objective.
3. Those that work contiguous to the focal plane, immediately in front of the plate.

In the first class the familiar Thornton-Pickard roller-blind

shutter—of which I think Kershaw's was the pioneer—undoubtedly the most popular. Other types are "studio," "foreground," and the almost obsolete "drop-shutter."

Shutters of the second class, working close to the diaphragm, may be subdivided into those forming part of the lens mount, such as the Goetz "Sector," Staley's "Compound," the "Union," and many others; and those built into the camera, and more or less inseparable from it, as is instanced by the type adopted by Messrs. Newman and Guardia.

The third class, working immediately in front of the plate, of course, represented by the well-known focal-plane shutter, which much inventive talent has been exercised. The foregoing classification is, however, arbitrary, and relates more to the type of shutter rather than its performance. All shutters, in fact, of type, might be separated into two divisions, namely those which are efficient so far as light-action on the plate is concerned, and those that are of low efficiency. Again, it would be possible to draw further distinctions in the nature of classification. Firstly, in the case where the light-action on the plate does not vary in proportion to the duration of exposure, and secondly, where it is approximately proportional for one particular stop.

Conditions Involved.

As already indicated, the conditions which a shutter designer has to meet are so many and formidable that it is almost out of the question to embody them all in any one instrument. It is a wonder is that so many have been closely realised. It is not worth while just glancing at a list of these, which certainly appears sufficiently long, and might possibly be extended:

1. Freedom from vibration.
2. Non-liability to get out of order.
3. To have a fair range of speeds.
4. Marked speeds to approximate actual speeds, and to vary from time to time; or ratio of speeds to remain constant.
5. The amount of light transmitted to be as great as possible.
6. To work equally well in horizontal and vertical positions.

- To be light and portable.
- To possess simplicity of adjustment.
- To be reasonable in price.
- So far as possible, to illuminate the plate evenly.
- To be fairly noiseless in operation.
- Not to open on being set.

First comes "Freedom from vibration," a shutter which gives no vibration being useless. A shock after the exposure is not much moment unless so severe as to injure the lens. It has been suggested that a glass of water be stood on the camera, and the surface observed to see whether it shows signs of tremor on use of the shutter. Such a test trial has shown is too unreliable, and might condemn a useful and serviceable tool.

The second requirement, that the shutter shall not be likely to get out of order, is of self-evident importance.

The third, providing for a fair range of speeds, say from half second or longer to 1-40th or 1-60th, is not asking too much of a lens-shutter.

The fourth condition, that the marked speeds shall approximate the actual speeds, is reasonable, also that they shall not vary widely from time to time; or, alternatively, that the ratio of actual to marked speeds be fairly constant. Very few shutters comply with either of these conditions, the slower speeds in the region of 1-20th second being generally faster than indicated, and the higher speeds slower. In many cases there appears to be hardly any relationship between the "actual" and "marked" speeds. It is curious to note, but a fact, that many workers express a complete indifference on this point, frequently justifying their attitude by urging there are many uncertain factors present when taking a photograph that more or less will make no difference. In this connection I have been gravely informed by a plate-maker that he did not care a farthing whether his shutter "banged off" at 1-20th or 1-40th second, though he subsequently admitted that if one second exposure for a portrait in a studio he would be indifferent to prolonging it four times, which seems hardly reasonable.

Thanks to the latitude of modern dry-plates, presentable results can be obtained from widely varying exposures, but the average hand-camerist accepts, with the resignation of the inevitable, a much larger percentage of failures than he would tolerate in giving time exposures. The panchromatic plate and its associated filter are coming more and more into use, and have a tendency to stay. They certainly demand more care in exposure than the older monochromatised plates, even of extreme speed.

Artificially indeed is the case of the would-be careful beginner, who scrupulously uses a meter, and for future reference and convenience tabulates, with other factors, "Ananias" and ever increasing shutter speeds as records of fact. Provided that the actual shutter speeds—even if they do not agree with those marked—are fairly constant, accurate work, based on past experience, can no doubt be done. It is easy to be captious on the question of shutter speeds. In my opinion, if the "actual" and "marked" agree within 25 per cent. there is not much to be said about.

The fifth requirement relates to the ratio between the time required in opening and closing and the amount of light admitted during that period. It is of importance and will be dealt with later.

The remaining conditions do not require much comment; No. 11 is of distinct benefit to the up-to-date press photographer, as tending to prevent breaches of the peace, or even on occasion destruction of, or injury to, the camera. The last requirement is, of course, essential for magazine and roll-film cameras, and is advanced in all cases.

It would be possible to try and estimate how far the various shutters on the market meet the conditions laid down. No definite conclusions could be drawn, and it would be more or less waste of time to attempt it. To the shutter-designer the necessity of complying with commercial requirements as to weight, bulk, price, and so forth, or even with the fads or fancies of users, must be the most exasperating restrictions and limitations.

Methods of Controlling "Speeds."

We can now turn our attention to the various methods adopted for controlling "speeds," the most ineffective and erratic results

being due to variation in spring-tension alone. Shutters fitted to the cheapest hand-cameras are examples. The highly efficient and reliable roller-blind shutters might be held to fall under this category, but here the spring has a long uncoil, and the blind must act somewhat in the nature of a brake.

Another and favourite method depends upon pneumatic regulation. This may be accomplished by packing a piston air-tight in a cylinder, the piston being connected to the actuating parts of the shutter, and allowing the air to escape through an orifice adjustable in area, in turn permitting a variable rate of movement. Messrs. Thornton-Pickard in their familiar "time-exposure valve" employ an ingeniously devised air-leak, and have applied a neat modification to their latest diaphragmatic shutter, the "Sunbeam." Speaking generally, this method has been largely superseded, but it may be remarked in passing that enlarging a hole by means of a slide allows leakage out of proportion to area. By opening a series of minute holes of equal area, a more proportional effect is obtained. The difference observable is doubtless due to air friction.

The system of pneumatic regulation chiefly adopted at present, illustrated in the "Unicum" and other shutters, is to fit a plunger loosely within a cylinder, with a consequent air leak between the two, the cylinder is linked up to the actuating parts of the shutter, and alterations of speed are made, not by varying the air leak, but by altering the length of travel of the cylinder. The slowest speed utilises the full travel, the higher speeds proportionally less. In theory this is admirable; in practice the plunger and cylinder are usually made far too small. In a valuable paper read by Mr. Wm. Taylor on "Shutter Design" some years ago,* it was pointed out that at the highest speeds the range of movement of the cylinder is sometimes so small as to be inoperative. Before air can leak it must obviously be compressed, and a very short travel probably merely compresses the air, without allowing the controlling leakage to come into play. Consequently, the "1-50th" and "1-100th" second marked on the shutter may be one and the same, and at the same time neither of the marked speeds. A deposit of damp or dust may very seriously alter the rate of air-leak, as when plunger and cylinder are of small dimensions they must necessarily be fairly close fitting. If made larger, a looser fit is allowable, with a greatly lessened tendency to alter through outside influence. Shutters fitted to, and forming part of, the camera front generally allow of this being done. To obtain retarding action approximately proportional to the travel, the residual air-space should be constant, but this is more a matter for the designer than the user. The plunger, of course, should never be oiled. Irrespective of any deficiencies in the pneumatic control, in some shutters the leaves are pivoted so close to the thrust that a deposit of damp on the sectors must exercise a powerful leverage against the somewhat weak spring. Under these conditions "speeds" will vary with climatic changes.

Mechanical friction brakes acting by pressure are occasionally adopted in lieu of pneumatic action. Such brakes require making with great care, and it has been stated they vary largely from time to time without apparent cause.

Another method of regulation which ought to be mentioned has application to a disc or segment of a circle, having an aperture passing across the diaphragm without alteration of spring tension. The method consists of reducing the aperture to increase "speed," and is the principle adopted by Messrs. Beck. Ltd., in their "Frena" and "Cilverex" shutters, presently to be referred to.

Efficiency.

The next point in shutters which can usefully be examined, and at somewhat greater length, is that of "efficiency." This question is certainly a most complicated one if all factors are to be considered. On the other hand, if we are content with approximations, but approximations amply sufficient from a practical aspect, then the subject can be simplified. The "speed" of shutters has been several times alluded to, a common if not precise term for expressing "the total duration of time occupied between the first opening and final closing of the shutter or lens-aperture"; an expression merely indicating an interval of time, not necessarily having any definite relationship to the amount of light allowed to pass during such period. This is usually and conveniently designated "dura-

* "Phot. Journal," 1905, p. 34. Abstracted in "B.J. Almanac," 1906, p. 739.

tion of exposure." The duration of exposure contrasted with the amount of light allowed to pass may be considered in one or two simple examples. In the first place, suppose we give a "cap exposure" of five minutes, then the time occupied in taking the cap off and replacing it is obviously so small in proportion to the whole exposure that it may be neglected. The duration of exposure has been five minutes, the plate has seen the full aperture of the lens practically all the time, and has therefore received an effective exposure of five minutes also. The "effective exposure" and the "duration of exposure" in this case therefore coincide. Different would be the case of an "on and off" cap exposure of, say, half a second. Here the plate would only see the full aperture of the lens for a fraction of the total time. If we assume that during the total duration of exposure, half the light which would otherwise have reached the plate has been obstructed by the lens cap, then although the duration of exposure has been half a second, the effective exposure is quarter of a second only.

Exactly the same course of reasoning applies to all photographic shutters, excluding the focal-plane, which in a sense may be taken to uncover the plate, not the lens. Some light must be obstructed by the sectors of a diaphragm shutter, or blind of a Thornton-Pickard, whilst in the act of opening and closing. In a hypothetical and ideal shutter, taking no time to open and no time to close, then the duration of exposure and the effective exposure are identical, and it is convenient to gauge all shutters in comparison with this ideal. Let us suppose an "iris" shutter opening and closing in circular form at constant or uniform rate and having no period of full opening—that is to say, no sooner is it fully open than the leaves begin to close. Such a shutter on paper is one-third

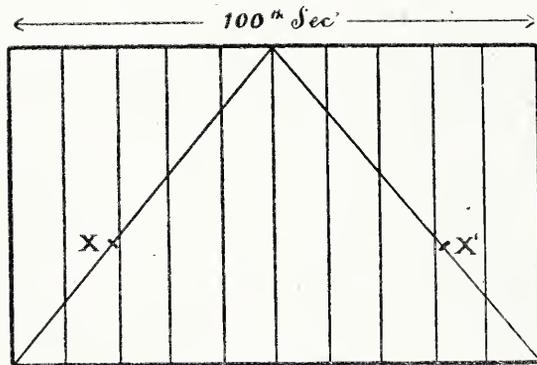

Fig. 1.

of the ideal, or in usual phraseology has an efficiency of $33\frac{1}{3}$ per cent. If the duration of exposure is one second, then the effective exposure is obviously $\frac{1}{3}$ sec.

To determine the efficiency of shutters with complete accuracy we should have to ascertain the time the shutter takes to open and close, the way in which this is effected, any acceleration or retardation, and the period of full opening. Next we should have to calculate what part of the initial opening and final closing will have no appreciable light-action on the plate. To solve this pretty little problem the type of shutter would have to be considered, and the capability of the plate for registering minimum light-action, which I understand is a relationship between the H. and D. number and the power of giving density. The result obtained might be true for the centre of the plate. For other portions, corrections would have to be applied for the loss of light due to the obliquity of the iris, together with any cutting off by the lens mounts. A change of stop would necessitate still further calculations. The final result if correct would be a splendid example of misdirected energy, utterly out of proportion to any good that might accrue.

Qualifying Factors.

Fig. 1 is a conventional diagram of an exposure given by a shutter having no period of full opening, and moving at a constant rate. If we assume the total duration of exposure to be 1-100th sec., and the shutter to be an iris one, then the theoretical efficiency as just stated will be $33\frac{1}{3}$ per cent., and the effective exposure 1-300th sec. only. This looks very bad, but is not quite so bad as it seems, one of the factors, and the most uncertain one, in the calculations just mentioned, coming into play. To illustrate this, let us divide the total

duration of exposure into ten equal parts, as shown by the vertical lines. Each division, therefore, will represent 1-1,000th sec. Now let us give an f value to the full opening—say $f/6$ —and with a pair of dividers find out where the iris first reaches the diameter represented, say by $f/16$, and again closes down to that aperture, point X X' in the diagram, nearly four divisions. Taking three divisions only, representing about 1-330th of a second duration, is there any operating at such a small average effective aperture that the exposure may be inappreciably affected, especially if it has to record a rapidly moving object. The net result of this is that although on paper the duration of exposure is 1-100th sec., in actual practice it may work out at nearly 1-150th sec. It follows that as the d

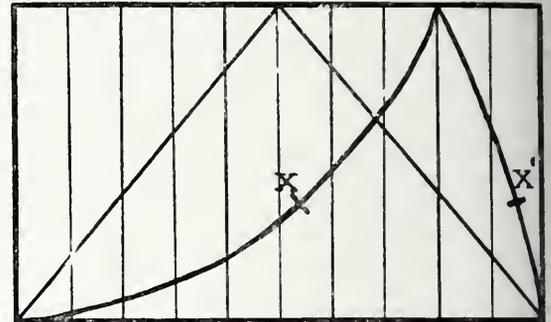

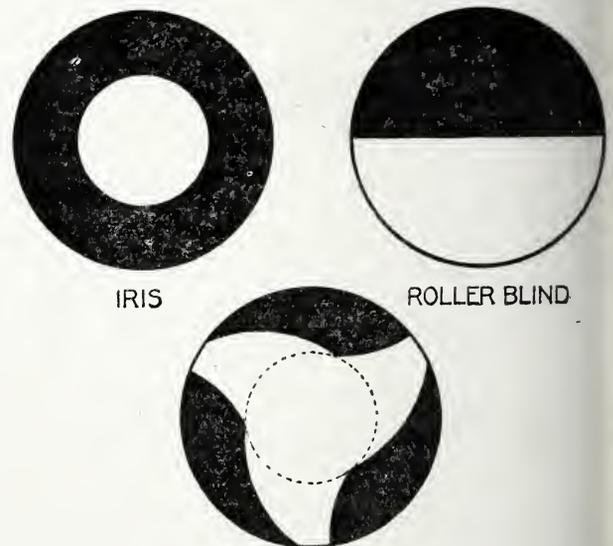

Fig. 2.

tion of exposure in effect decreases, the efficiency of the shutter so increases, and that very noticeably. I have not worked out the value representing the average area of opening to $1\frac{1}{2}$ division on each side of the diagram, but it would be a small one. The point is by no means new, but it frequently escapes notice. It is a disturbing factor which can hardly be allowed for, it applies more strongly to diaphragmatic shutters, and probably most powerfully of all to the iris shutter instanced. It diminishes the theoretical value of "lap" in the shutter, and in the case of the "iris" tends to upset calculated depth based on a stop representing average aperture. In the case of shutters which open and close from the side, it may happen that owing to the length of the lens-barrel, the centre of the

STALEY'S COMPOUND

Fig. 3.

plate may receive no light until an appreciable amount of underexposure has taken place. The same problem presents itself in a slightly different way. We assumed "constant rate" in the case of the iris, whereas probably in all shutters acceleration occurs. Acceleration on paper infers diminished efficiency. Fig. 2 is a rough representation of acceleration as the square, every fifth division will illustrate an extension of the principle under consideration. Here, compared to "constant rate," the efficiency has been apparently very seriously reduced; but if we take similar points X X' , representing diameters of $f/16$, the efficiency of the acceleration curve may agree fairly closely with that of constant rate. The

Comparison is not exact, for in the case of "acceleration" a longer time is occupied in reaching the aperture stated. Various values representing "efficiency" have been given to different types of shutters, on the assumption that there is no period of full opening, or occasionally on certain other assumptions that may not occur in practice. From what has been said they can only be approximations at best, but they are useful in estimating the efficiency of the different portions at the beginning and the end of the exposure. Generally speaking, provided the rate of opening and closing is uniform and there is a fair range of full opening, it does not matter much in what manner that opening and closing is effected. It is, however, material with diaphragmatic shutters when the lens is not at full aperture, the period of full opening being small or nil. Fig. 3 shows three diagrams of popular shutters are shown, each having a diameter equal to half its diameter. The roller-blind, as can be seen, rapidly covers a considerable area. The iris at this stage shows up badly. The first half of the diameter is very inefficient; from this point on it greatly improves. The method of opening adopted in the "concorde" gives undoubtedly greater efficiency than does the "iris," under conditions remaining the same. The "Unicum" would occupy an intermediate position, its initial opening being elliptical. No comparison, based purely on the mode of opening and closing, can be made between the roller-blind and diaphragmatic shutters; any conclusions drawn from the diagrams must not be pushed too far.

Methods of Testing Shutters.

According to the methods adopted for testing shutters, these have many and varied, and can be sharply distinguished into two classes:—

Those that measure the duration of exposure only, either by visual inspection or photographic impression; and

Those that not only record duration, but by calculation, simple or otherwise, enable the effective exposure and efficiency of the shutter to be deduced. They are the more useful.

Class (1), the revolution of a bicycle wheel with silvered beads attached to reflect a point of light; or the oscillation of a pendulum with a similar bead against a scale; the rotation at variable rates of a slotted or slitted disc, allowing flashes of light to pass; a wavy line on a dry-plate made by movement of a camera with lens fixed on a naked arc of known alternating period, are examples. Carnegie has ingeniously recorded the travel of a falling ball by photographic means, different distances representing different durations of exposure. A defect in most of these systems is that when records are made photographically, the beginning and end of the exposure are usually vignette away so imperceptibly that it is difficult to say where one begins or ends. Neither is the method of visual inspection free from error. A suggestion has been made to give a long-known method by hand with a very small stop, and to compare the results obtained with those secured by shutter exposures with a large stop. Coming from memory, it was, I think, claimed that the shutter durations—viz., durations of exposure—could by this means be arrived at accurately enough the method would only show effective exposures, though even here disturbing factors creep in. No indication of the efficiency or duration of exposure would be possible, unless the former were known in advance the latter might be approximately calculated.

A Pneumatic "Speed" Recorder.

Another method of timing "durations" was evolved by Mr. J. Smith, of the Platinotype Co., quite recently. It applies to diaphragm shutters only opening from and closing to the centre. It is certainly very simple. In fig. 4 "T" is a tube adjustable up and down, out of which a gentle current of air is flowing. B is a board having the circular opening shown. M is a mica disc, attached to one end of the board by means of a flattened watch-spring, which has just sufficient force to allow the disc normally to close the opening. On the underpart of the disc, M, is fastened a camel-hair brush, charged with aniline dye solution. S is a stop to limit the action of the disc. R is a drum rotating at known speed, around which is wound some white paper. The shutter to be tested is placed over the aperture in the board, the pipe brought down centrally. Air is turned on, either by a stopcock into the tube, or in any other convenient way, and the

shutter released. The mica disc is instantly depressed, and the brush leaves a recording streak on the rotating paper indicating the duration of exposure. Time has not permitted a complete test of this appliance. For a given varying shutter-speed repeated, it will indicate, practically speaking, the same length of trail each time, and there is little doubt that such trail will be a close approximation of the duration of exposure.

The contrivances in class No. 2 vary in detail, but in nearly all cases cause a shadow-image, or image focussed by a lens, to be recorded itself on a film or dry-plate, one of the earliest and probably as

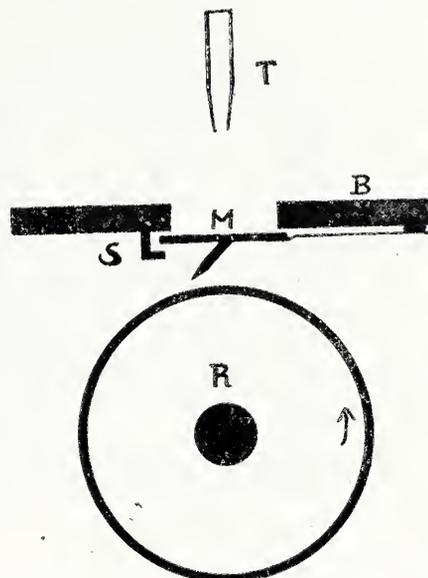

Fig. 4.

efficient as any being Sir Wm. Abney's. It is, however, complicated so far as number of parts are concerned and not within the scope of the ordinary amateur.

A Simplified Shutter-Tester.

The shutter-tester now to be described was an attempt on my part to reduce the device to the simplest proportions, and can only claim to be a modification of what has gone before. It is fairly easily constructed, comparatively inexpensive to make, is portable, and will record duration of exposures within reasonable limits with exactitude, and the efficiency with quite sufficient accuracy for practical purposes. Fig. 5 is a diagrammatic representation of the appliance. On the right is a light-tight box

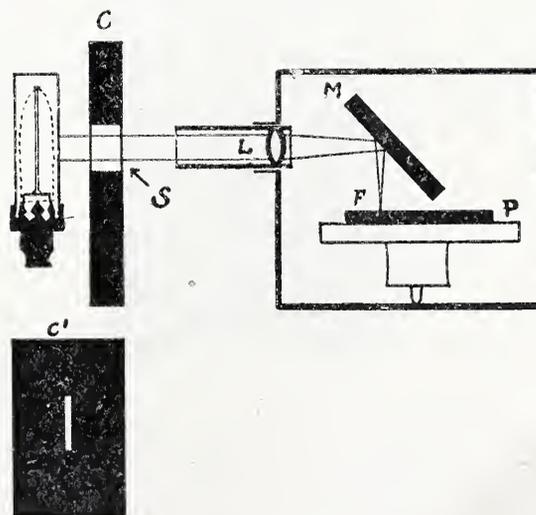

Fig. 5.

or camera, fitted with a lens in sliding tube for focussing. On the left is seen in side and front elevation, a board CC, behind which is an incandescent burner illuminating a slit S. This illuminated slit is focussed on a dry plate P, by the lens, by means of a mirror M, set at an angle of 45 deg. The dry-plate is supported by a carrier capable of rotation at definite speed.

On the release of the shutter a point of light is first recorded:

on the rotating plate at F, broadening into a circular band representing full aperture, and tailing off again into a point on the completion of the exposure. By applying the developed plate to a home-made protractor on glass, secured by copying a drawing in the camera, the number of degrees covered can be read off, and deducting the width of the slit image the duration of exposure is ascertained. The efficiency of the shutter can be closely arrived at by noting the number of degrees occupied in opening and closing, and in the period of full aperture. The *tailing-off* portions of different types of shutters are given a value. The "iris," for instance, $33\frac{1}{2}$ per cent., the roller-blind, and diaphragm shutters

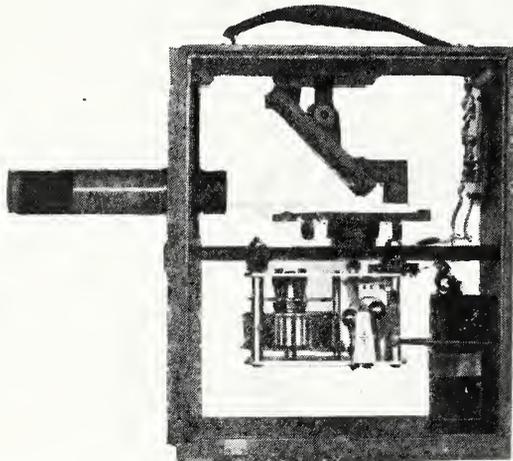

Fig. 6.

such as the "Cilverex," 50 per cent., and so on. A simple sum will then give the efficiency direct. The lens and slit both rise and centre to allow several diagrams to be made on one plate.

Fig. 7 shows a side view of the camera with both sides removed.* The carrier holding the mirror slides in and out, in grooved pieces affixed to the top, parallel with the front. The lower part can be swung into a horizontal position to permit removal of the plate-carrier underneath. The latter movement is a refinement which can well be dispensed with. One occasionally may forget to restore the carrier to its normal position, prior to making a test. The mirror is surface-silvered. If any difficulty is experienced in either doing this or getting it done, Mr. Calver, the

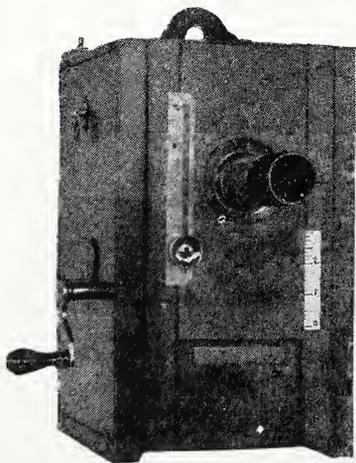

Fig. 7.

well-known maker of reflecting telescopes, will silver a slip of thick plate-glass at a nominal cost. The block of wood protruding to the right is bored vertically to take a pencil, which, when inserted and pressed down, describes a circle on the dry-plate, and allows of its being subsequently centred on the protractor. A special spring motor sold by Messrs. George Adams and Co., of High Holborn, for driving gramophones is used to rotate the plate. It is extremely well made, and at two revolutions per second repeated tests have failed to record more than one per cent. variation in speed. There is plenty of power in the main spindle, which at one

* In the illustration the lens is shown too low.

winding will revolve about 400 times at a maximum speed of three revolutions per second. At one revolution per second does not run with so much accuracy. In practice two revolutions per second are adhered to. Speeds of half a second and slower can be recorded if necessary, by slightly lowering the rising front when an exposure is made. A rackwork attachment would facilitate this. The lower part of the plate carrier is conically tapered to take the main spindle, which slightly tapers at its upper end. At the right of the motor is seen a dry-cell, the current from a contact point on the main spindle, actuating a small magnet and armature shown above it, giving an audible click at each revolution. A switch is placed on the top of the camera to prevent possible contact being made when not in use. The interior of the camera is divided into two, to prevent leakage of light from the winder aperture.

The motor is stopped by a push and pull knob at the back. Both sides are removable and are rebated to prevent light entering.

Fig. 7 shows the rising front and scale, the winder being on the left, the regulating knob just behind it. The other side is quite free and can be removed in an instant.

Fig. 8 is a diagram of the plate-holder. The shutter mechanism illustrated was originally designed to take plates $4\frac{3}{4}$ inches square. The more handy quarter-plates have been substituted with no apparent disadvantage. P is the plate. It is held simply and securely in position by a slotted sliding piece B, which causes the plate to bear against the stops S S'. The stop S' shows the

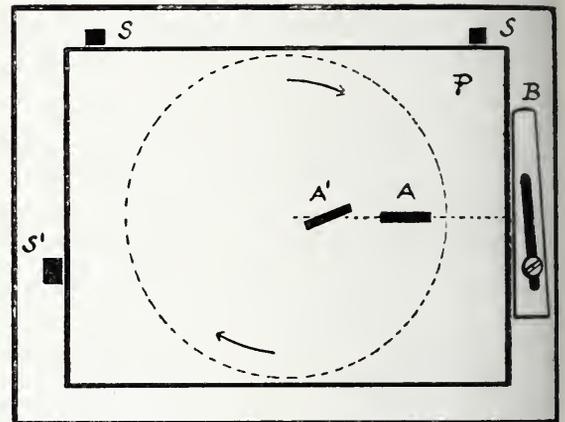

Fig. 8.

opposite the thrust of the sliding piece, viz., the screw in the slot. In use the image of the slit is focussed on a piece of white paper gummed on to an old quarter-plate negative, which can conveniently be ruled into fractions of an inch, so that the length of the slit image can be noted, and the amount of rise necessary for each successive exposure arrived at. The slit image is recorded at the end of the plate, or in the middle, when stationary, so that its width may be deducted from each reading. Its value, of

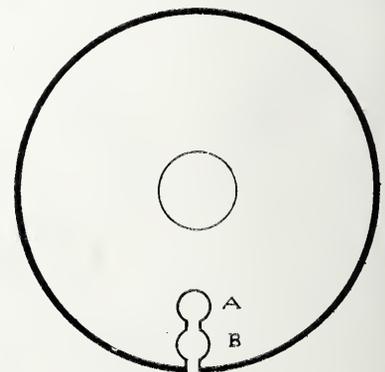

Fig. 9.

course, varies, very materially close to the centre. It is of importance that the slit image shall coincide with a radial line from the centre of rotation as shown at A. If non-coincident as illustrated nearer the centre A', actual durations of exposure will be lengthened, except in the case of diaphragm shutters opening and closing to the centre; but even here the record will be dis-

ted in shape. A slight error due to inaccuracy of construction can be remedied by an inclination of the slit from the vertical. The apparatus is also designed to take a drum, around which sensitive film on celluloid is fixed. At very high speeds 1-100th sec. and over (rare in lens shutters) the readings on the plate are all, and errors in readings may occur. An easy way devised for attaching the film is to bore two slightly tapering connected holes, shown in Fig. 9 in plan. The film is wound round the drum, and its two ends brought together in A, a tapering wedge is then inserted which grips the film, a second wedge at B tightens it. Fig. 10 shows the slit-carrier on the left, slits of various lengths being held in the square recess. The circular black lines drawn

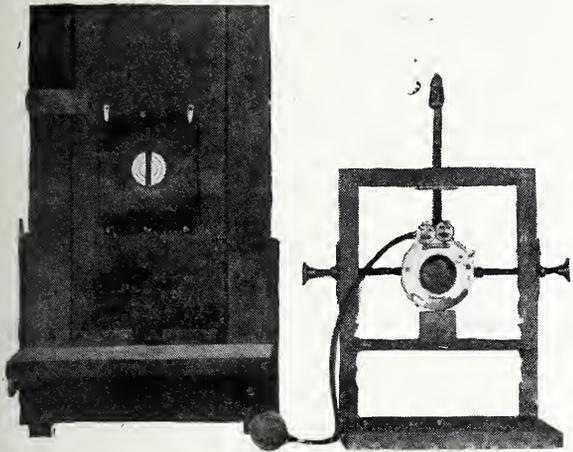

Fig. 10.

and the slit enable the shutter to be centred with ease. On the right is the shutter-carrier, which is self-explanatory. The ends of the screws are filed flat and faced with leather to prevent injury to the shutter. The shutter-carrier is clamped to the shelf of the slit-carrier.

Fig. 11 is a side view showing the back of the slit-carrier, with a gas jet behind, and with pointer on scale to indicate amount of rise, the clamping screw being underneath. The whole apparatus is mounted on a baseboard, on which the camera slides, and strips being attached underneath. Several slit images, six

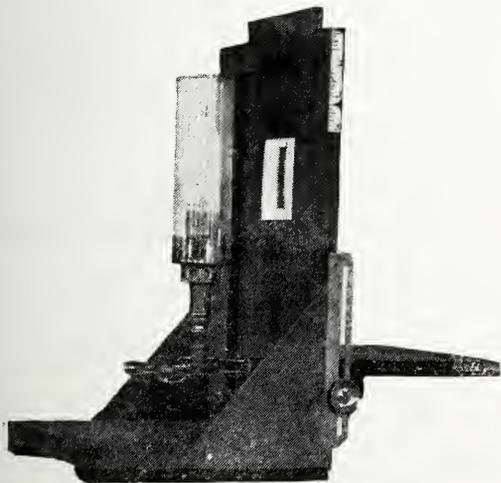

Fig. 11.

more, can be taken on one quarter-plate according to the scale provided. If large scale diagrams are required, focus should be adjusted for a few varying lengths of slit images which should be referred to, the amount of rise ascertained, and tabulated for future reference. This is not quite so simple as it appears, for the rise of the slit-carrier causes the image to traverse the plate in the opposite direction to that imposed by the rising front of the camera, and the ratio will alter with alterations of distance. On the other hand, if the object is merely to record speeds, or durations of exposure, then the slit-carrier and camera can be set at such a distance apart that the rising front of the latter will be practically equivalent to the movement of the slit-image on

the plate. An alternative method of construction would be to dispense with the rise altogether, and cause the plate-carrier and motor to slide bodily back in grooves indicating the amount of such movement by a scale. This would cause the slit-image to fall on different portions of the plate; a rise, however, is necessary if a film on a drum is employed.

The protractor used is shown in fig. 12. In order to avoid crowding it is divided into twenty-five divisions, each being sub-divided into five—125 in all. These can again be mentally sub-divided into quarters, should an inexact number of divisions be occupied. In practice each division is read as representing four degrees. Then with the motor rotating twice a second, each degree will represent 1-1,000th sec. The highest speeds are taken towards the circumference to obtain wider readings, the slower ones towards the centre, where errors in draughtmanship in the protractor are more likely to occur, and are of the least consequence. The readings could be made to automatically record the speeds by the simple expedient of mounting the protractor over, and in contact with, the dry-plate.

Some Typical Diagrams.

We can now consider some typical diagrams of representative shutters on the market. In all, the beginning of the curve repre-

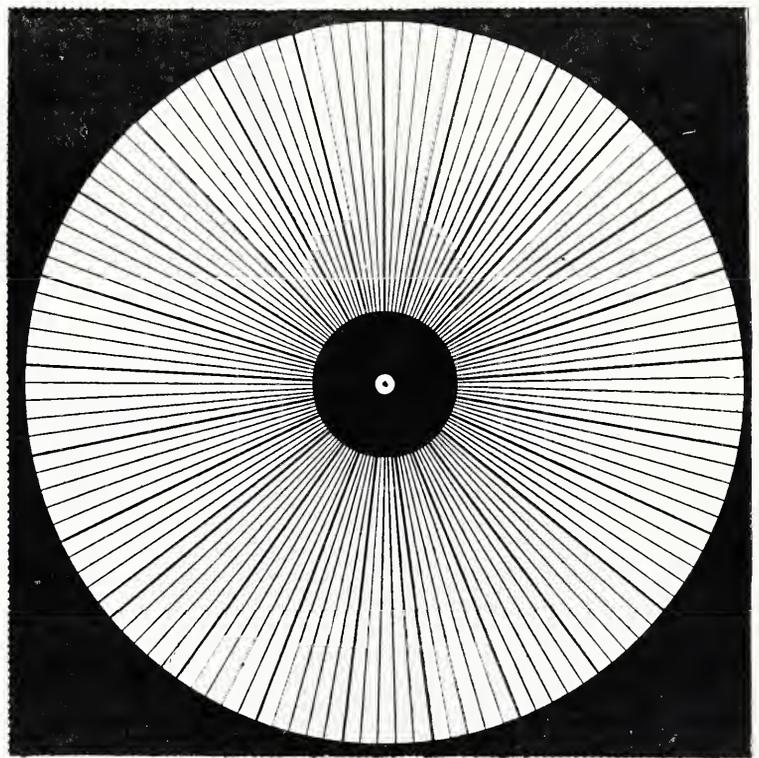

Fig. 12.

senting the opening of the shutter points in the direction of rotation, indicated by the arrow head. Slow speeds are taken nearest the centre, and vice versa.

Fig. 13 shows a diagram of an old form of iris shutter at full aperture, opening and closing at approximate constant rate, and having little or no period of full opening. The theoretical efficiency is 33 1/3 per cent. A large part of the tailing-off portions would probably have little or no action on the photographic plate, and the efficiency is therefore greater than it might appear. The departure from the circular form is due to the lowering of the camera front for a test of one second, which it lamentably failed to record. Subsequent tests revealed the fact that occasionally it omitted to entirely close. When set to "time" it opened to one aperture, when set to "instantaneous" to another. It would never give the same diagram twice, or record the same speed. By an irony of fate its owner is a particularly careful worker in the field, and if he had not habitually used the instrument with its vulcanite leaves in front of an enlarging lantern in the dark-room, the foregoing eccentricities probably would never have developed.

Fig. 14 is a diagram of a similar, but later, model, the leaves having greater velocity. Approximate actual exposures 1-30th and 1-5th.

It will be noticed that at the slower speed the leaves open considerably faster than they close, due, no doubt, to the pneumatic regulation not becoming effective until the air begins to be compressed. At the top speed there is no period of full opening, and the efficiency is low.

Fig. 15 represents the same shutter, each record being 1-5th sec. The outside one full aperture, 1½ in. diameter. The second diagram shows the effect of substituting a slit of three-quarters of an inch representing a medium stop. Much greater efficiency is obtained, as can readily be seen. In this type of shutter the leaves themselves form the stop, and open only to the point indicated by the iris scale. Stopping down did not materially alter the efficiency, the same characteristic diagram being obtained. In the majority of sector shutters, such as the "Unicum," the "Volute," etc., the leaves open to constant diameter, and, as is well known, with smaller stop a very great gain in efficiency results. The diagram illustrates this, and not the particular shutter tested; the slit being reduced, not the iris.

A record of Messrs. Beck and Company's "Cilverex" shutter is illustrated in Fig. 16. Here variations in speed are obtained solely

gives a diagram closely resembling the outside one in fig. 16, and therefore not quite so efficient as some other models. To counterbalance this, the ratio of "duration" to the effective exposure is roughly the same at all speeds, a no mean advantage; it is simple design and construction, and consequently there is little chance of derangement even under adverse conditions. Accurate adjustment of speeds is not only possible, but attained. The cameras are in use all over the world, and have acquired a reputation for reliability second to none.

Fig. 17 is a record of a 1½ in. Thornton-Pickard roller-blind shutter. Actual speeds 1-20th and 1-50th approximately. A lens of one inch was used, representing *f*/6 in a 6-inch lens, or *f*/8 in a normal focus for half-plate. The length of the aperture in the blind was 2.9-16ths inch. This being so, high efficiency was expected, and, as the diagram shows, is realised. The 1-20th sec. shows slight retardation of the blind towards the end of exposure. With this shutter and others of equivalent type, the stop is reduced the efficiency is increased. The "effective exposure," however (as Mr. Welborne Piper has shown), remains the same throughout. Thus, suppose with full aperture the du-

by varying the length of the aperture in a blade passing across the diaphragm, the spring tension remaining constant. Owing to the system adopted it is claimed that the speeds are proportional to each other. Thus 1-40th sec. will be always half of 1-20th, and so on—a valuable feature in itself. Unfortunately the efficiency diminishes as the area is reduced, and the ratio of the "effective exposure" to "duration" alters with each exposure. In the diagram marked exposures of 1-10th, 1-20th, and 1-40th sec. are recorded. The gradual drop in efficiency is indicated, though there is not much to complain of anywhere. Acceleration is observable in the slower speeds. The 1-80th sec. consists of an opening little more than half the area of the lens, and is therefore very far from being efficient. The shutter, from a mechanical point of view, is well thought out, and beautifully made. Notwithstanding inevitable limitations, the principle involved is undoubtedly good. The excellent results obtained with the "Frena" cameras are sufficient evidence of this. The type adopted in one of the most expensive cameras on the market, in its essentials also consists of a blade passing across the diaphragm, but of constant aperture, with extremities of reversed curvature to that of the lens to gain a little in efficiency. Variations in speed are pneumatically regulated. This shutter, at moderate and fast speeds,

tion of exposure was 1-35th sec. and the effective exposure 1-50th sec. Then on stopping down, the duration of exposure might be diminished to, say, 1-45th sec., but the effective exposure would remain as before, 1-50th sec. For reliability and efficiency this shutter is most certainly hard to beat. The name attached to it is sufficient guarantee of its being well made.

Fig. 18 is a diagram of Messrs. A. E. Staley's "Compound" shutter. The outside diagram marked 1-100th sec. is as a matter of fact slightly faster, viz., 1-120th sec. It is not usual for the actual duration of exposure to be less than those marked. I must confess the diagram astonished me. It speaks for itself. The tapering ends of the 1-25th sec. (nearest the centre) are almost radial, and even the higher speeds show little signs of falling off. For all practical purposes the effective exposures may almost be regarded as equivalent to the duration of exposure. The leaves must open and close with great velocity. As this shutter opens in irregular form, the diagram, strictly speaking, is approximate only; the slit, however, occupied a fair average position, and no appreciable error is introduced. The shutter is a very fine example of workmanship and is exceedingly neat in design. The present model gives a better diagram than the same type preceding it.

the inner of these two figures (fig. 19) is not a representation of a tadpole, but a diagram of 1-5th of a sec. given by Messrs. Busch and Co.'s foreground shutter, a very useful instrument for securing natural clouds and landscape on one plate. As the lifts and descends. The portions of the diagrams away from the centre represent exposure to the foreground, which naturally receives more attention than the sky.

At the 1-5th sec. the shutter opens quickly and closes slowly. At higher speeds the travel is more regular. The shutter is well made and highly finished.

The author concludes the diagrams of lens shutters. Their main object would of course usually be to check the veracity of speeds marked on the dial, but they are instructive in other respects. They show that some types closely approach the focal-plane shutter at high speeds recorded, though at high speeds the latter must hold its own. Its position is, however, threatened, for from a pamphlet I have perused, a new shutter will shortly be on the English market, with speeds up to 1-2000th sec. On special occasions 1-1000th sec. is said to be reached.* Some very unkind things have been said about focal-plane shutters in general, supported by reasons which are particularly novel. For instance, it is pointed out that "a small slit irritates the light"; probably if the slit were further reduced, it would be positively exasperated, which could hardly be otherwise than detrimental. From a testimonial published it would appear that the shutter is about 15 times more

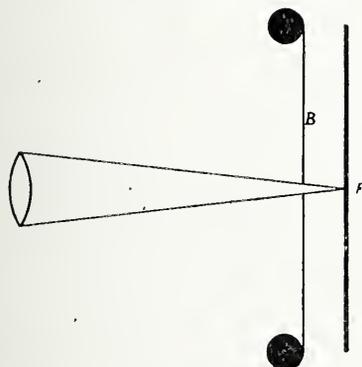

Fig. 20.

efficient than a sector shutter; at a moderate computation this would make it about 5 times better than perfection.* It need hardly be said this shutter hails from America, and no doubt is a good one, irrespective of exaggerated claims made on its behalf.

Focal-Plane Shutters.

Focal-plane shutters are within the capacity of the shutter-tester. The downward passage of the narrowest slit takes place at right angles to a vertical slit placed in front, which may be divided into two or more equal gaps, to see what acceleration or retardation occurs. One incandescent burner set back, with ground glass interposed, has been found to give sufficient illumination for 5 x 4 plates. The camera is placed about six to eight feet from the shutter being tested.

A good deal of discussion has taken place as to the direction in which the slit should travel with regard to the plate. Messrs. Thornton-Pickard, who have a wide experience in focal-plane work, inform me, in their opinion, the best method is for the slide to travel independently, and the blind to travel down vertically across the plate. Exception to this might be taken on the ground that in certain subjects it would be more advantageous to reverse the direction and allow the slit to travel horizontally in the same direction as the moving object (viz., travelling in the opposite direction to the image on the plate) so as to counteract distortion in a slight degree. This is theoretically correct, but the duration of the exposure from first to last is so very rapid that any advantage which might be thus obtained is practically inappreciable, and perhaps not worthy of consideration. On the other hand, in actual work this almost imaginary advantage is more than counterbalanced by the fact that owing to the length of the blind no focal-plane shutter made will work as easily and smoothly in a horizontal direction as when working vertically, and, of course, when working horizontally, there is some tendency on the

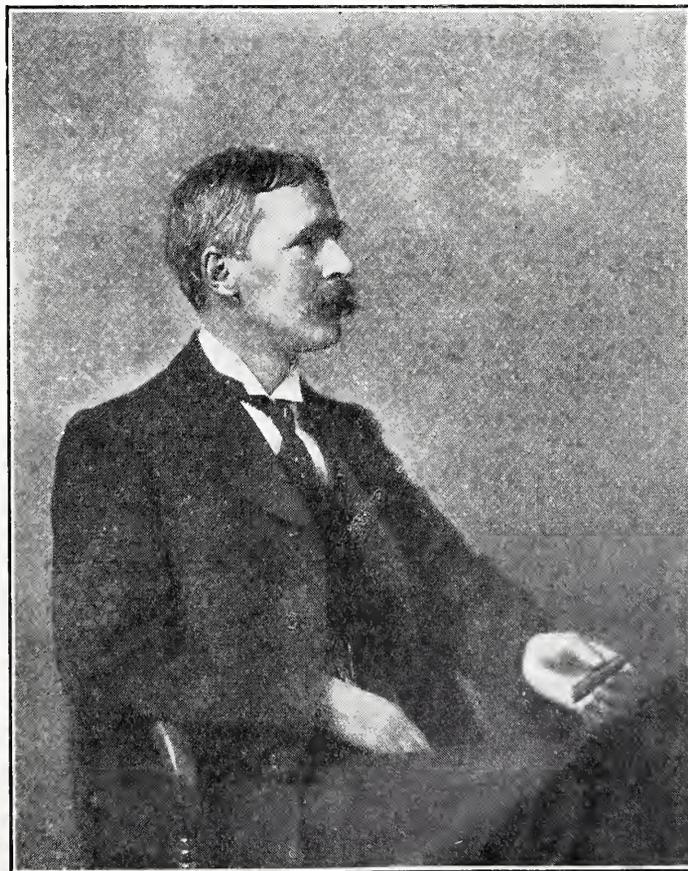

part of the blind to "drag" or catch on the sides of the shutter box, whereas, when travelling in a vertical direction, it is assisted in its course by gravitation, and greater uniformity of speed is thereby secured.

Another point which hardly seems to have received sufficient attention is the employment of very narrow slits, one-eighth of an inch, or even less. In the diagram a condition of affairs is shown which may actually occur in practice. B is a representation of the blind, and F the focal-plane. The lens is assumed to be working at f/4.5, a not uncommon aperture in these days; the width of the slit is that of an actual shutter—viz., 5-32in. The distance between the sensitised plate and the slit is 9-16th inch, the standard distance in the Thornton-Pickard cameras, the interposition of the reversing back necessitating a wider separation. Now it is evident that the lens is not acting with full aperture on all parts of the plate immediately behind the slit; points on the plate opposite the top and bottom of the slit only seeing a little more than half the diameter of the lens. One series of points only, representing an infinitely narrow band across the plate, receives the full cone of rays. Contrast this with the case where the diameter of the lens is the same as the width of the slit. It is then obvious that all portions of the plate behind the slit see the full aperture of the lens. In the former case, it appears to me, there must both be some loss of efficiency, and to all intents and purposes, a decrease in the duration of exposure. The subject in all its bearings is undoubtedly complex, and appears to be one which the mathematician might usefully direct his attention to. There are also other cogent reasons against the employment of very narrow slits, one-eighth inch or less, which time will not permit me to enter into.

E. A. SALT.

DEATH OF MR. HECTOR MACLEAN.

By the sudden death from heart failure on Sunday last of Hector Maclean there is removed from the photographic world a personality not readily replaced. Mr. Maclean was essentially a commentator on men and things. Gifted with a power of facile expression and

THE LATE HECTOR MACLEAN, F.R.P.S.

in a sense of ironic humour, he enlivened many a photographic passage at arms which, but for him, would have been dull. Without a very deep knowledge of the principles of photography he was, nevertheless, a very capable expositor of new processes and methods, and was the

* In the daily press and elsewhere these statements were quoted as originating with the writer, who is unable to vouch for their accuracy.

author of several text-books and the writer of many articles in the photographic press. His personal interest in the photographic societies with which he was connected, formerly the Croydon Camera Club, and latterly the Sutton Photographic Club, was very actively displayed. He took a very large share in the survey and record work in the county of Surrey, and, as our columns of last week duly testified, did a great deal by public addresses to encourage this important application of the camera. In the "Morning Post," to which he contributed weekly for some years past a column of photographic notes, he brought the current progress in photography very simply before his lay readers, and in other ways assisted to popularise the use of the camera. His death, at the age of 56, will come as a shock to the many who were intimately associated with him in photographic affairs. By the courtesy of Messrs. Houghtons Ltd. we are enabled to reproduce a portrait of Mr. Maclean, which was taken with the "Ideal" flash-lamp some year or two ago.

DEATH OF MR. R. H. BOW.

In the death of Mr. R. H. Bow, at Edinburgh, on February 17 last, another of the links connecting us with the earliest days of photography is severed. Mr. Bow had attained the great age of 82, and therefore had largely outlived the reputation of his optical and scientific investigations carried out about the middle of the last century. Indeed, many of Mr. Bow's papers and researches did not at the time receive the attention they deserved, and it was left to Dr. von Röhr in our pages some two years ago to remind the present photographic generation of the pioneer work in photographic optics. It was R. H. Bow who, with Thomas Sutton, pointed out the true orthoscopy of a symmetrical lens for one scale of reduction only. Bow also investigated the unevenness of illumination by photographic lenses due to the thinning of the glasses at the margins, and he sought to overcome this defect by tinging the substance of the crown glass. He investigated the conditions of anastigmatism in 1863, and first published a plan of registering the results of anastigmatic calculations.

Mr. Bow also anticipated much of the later work in his views of perspective, and constructed apparatus for the correct observation of views made with a short focus lens. His papers on these subjects, as well as his masterly treatment of stereoscopic photography, appeared in "The British Journal of Photography" and in "The British Journal Almanac." Mr. Bow was a member of the Edinburgh Photographic Society from the year of its foundation (1861) until the time of his death, and in the old days was one of its most active supporters.

Photo-Mechanical Notes.

Imperfect Register in Three-Colour Work.

With the spread of three-colour work one hears increasing complaints of want of register. Generally the first thing to be blamed is the lens, and yet, although the writer has tested a large number of lenses for their performance in this respect, he has only once found one at fault, and this was abroad, with a very expensive type of lens and one that is not often met with in England. A very simple test for the suitability of a lens for three-colour work (in effect exactly the same one as that devised by Sir Isaac Newton to test achromatism) consists in covering three strips of colour-filter gelatine, red, green, and blue, placed close together, with a hair or very fine wire. This is now photographed either as a transparency or laid on a sheet of white paper, with the hair behind the filter strips. Then if the lens is a suitable one there will be no displacement of the line, and it will be equally wide; if not, it will either be displaced across one of the strips or altered in size.

The next source of trouble is the filters, and they are certainly more often in fault than the lens. A simple way to test them is to photograph something having fine lines, such as a scale or any subject having register marks, through the three filters, and after the negatives are made make three contact transparencies from them, taking care there is good contact when exposing. Now each of the transparencies can be placed in contact with the negative from which it was not made: thus the red transparency will be placed in contact with the blue and green negatives. If there is the slightest failure in register it will be instantly detected,

and if there is none, then the filters are not to blame. Supposing error lies in the filters, it is often awkward to get them replaced soon as one would like; in this case one should use a liquid filter cell and use the same cell for all three negatives.

Another cause of want of register which may be unsuspected in the case where two screens are used, one the 45 deg. ruling and the other the 15 deg. by 75 deg., and they are not both the same thickness. The consequence is that the images will not be the same size at the focal plane, owing to the differing amount of refraction. This is often noticed when using a metzograph screen for one of the colours, as these screens are nearly always much thinner than the cross-line screens.

If the copy has been put up damp, sometimes it may change in size during the exposure from the heat of the lamps—the remedy for this is obvious. It is possible also that if the camera, stand, and board are made of wood, and the temperature of the studio is not kept equable, that these may alter in size and so occasion want of register. Another cause may reside in using more than one slide and the slides not registering with each other. It is also impossible that the operator, when placing the plate in the slide, not in all three exposures push the plate quite home to the face of the slide, or he may not push the dark slide quite home; it takes a very slight alteration in size to show a want of register.

Provided the same metal is used and good contact is made between the printing on metal, it is difficult to see how any cause can be found in the etching on the metal; but when we come to the printing-plate, of course, the sources of want of register in the sense that the three colours do not truly lie one on top of the other, are too numerous to detail; but there is only one cause of want of register of the kind under discussion—viz., the differing size of the component parts, and that is due to the stretching of the paper, owing to varying conditions of moisture and temperature of the printing-room while the job is being printed. This can be prevented by always keeping the paper at an even temperature day and night, and carefully covering up the paper, top and sides as well, after the printing of the first and second colours.

A. J.

ANSWERS TO CORRESPONDENTS.

PROCESS WORK.—(1) I should be pleased if you would kindly give me any information on half-tone process work. Is there a book published? If so, where can I get one? (2) I am after a process to squeegee on a copper or brass plate, leave the film on the plate and the paper to come off. Will you please advise me what to get?—A. G.

(1) The best book on the half-tone process is either "Jenkins' Photo-Engraving," revised by N. Amstutz (8s. 6d.), or the "Half-tone Process," by Verfassers (5s.) Both can be obtained from Penrose and Co. (2) There are numerous films which are called on paper, and which can be squeegeed on to glass and the paper pulled away afterwards. If an exposure is made, just ordinary carbon tissue would probably be the simplest. This can be obtained without pigment under the designation of photographic paper. If you would say exactly what work is required to be done in this matter we might be able to give you more definite advice.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents have been received between March 22 and March 27:—

DARK SLIDE.—No. 6,921. Improvements in and connected with a light loading and unloading camera dark slide. Alfred Mead, Field Lane, High Heath, Pelsall, Walsall.

PIGMENT PRINTS.—No. 7,000. Improvements in the production of pigment prints and the like. Wilhelm Triepel, 55, Chancery Lane, London.

CINEMATOGRAPHS.—No. 7,184. Improvements in safety devices to prevent the spread of fire when a cinematograph film is ignited. Leo Kamm, 27, Powell Street, Goswell Road, London.

CHARGING GAS CYLINDERS.—No. 7,185. Process of and means for charging cylinders or steel bottles with oxygen and other gases.

uch as carbonic acid gas. Leo Kamm, 27, Powell Street, Goswell Road, London.

TOGRAPHIC SURVEYING.—No. 7,201. Improvements relating to apparatus for photographic surveying. Arthur Cyril Webb Aldis, 8, Southampton Buildings, London.

NETTING APPARATUS.—No. 7,222. Apparatus for enabling photographs to be vignetted in the camera by artificial light. Alexander Hood, 72, Ranelagh Road, Ealing, London.

Y-MOUNTING.—No. 7,250. Improvements in metal folders for use in connection with the dry-mounting of photographic prints or the like. George Wilson Morgan, 121, West George Street, Glasgow.

VELOPMENT.—No. 7,361. Improvements in machines for developing, fixing, and washing photographic roll films. George Beattie Toole, 41, Reform Street, Dundee.

EMATOGRAPH-PHONOGRAPH.—No. 7,426. Means for synchronising the conjoint action of cinematographs and talking machines. Jules Greenbaum, 31, Bedford Street, Strand, London.

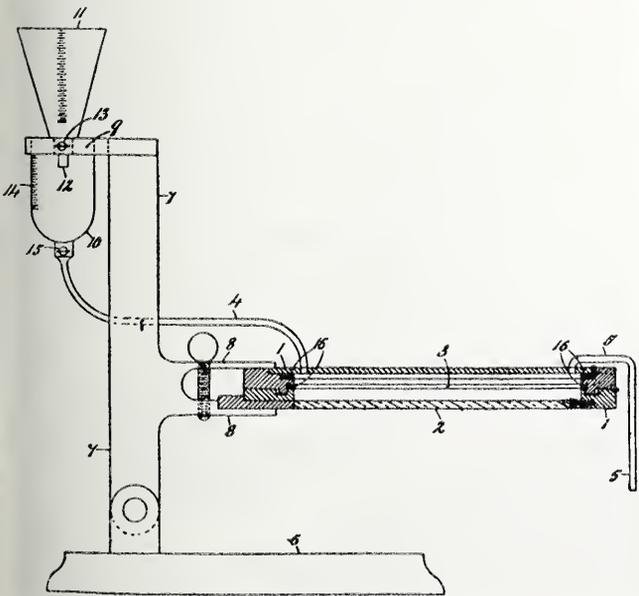

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or broad, in the case of patents granted under the International Convention.

DARK SLIDE AND DEVELOPING DISH FOR COLOUR PHOTOGRAPHY.—No. 2,746. 1908 (August 7, 1908). A dark slide 1 is so constructed that when a plate—e.g., an Autochrome—is inserted there is provided at the back a water-tight space, 3, that is to say, on the side remote from the lens of the camera. Two tubes, 4, 5, communicate with this space 3, and are attached at opposite corners of the plate, one, 4, being provided with a branch connection.

The exposure having been made in the ordinary way, the dark slide is removed and attached to a special form of stand 6, having a pivoted arm 7 projecting upwards. To this pivoted arm 7 is attached, at a short distance above the pivotal point, a strong

lip 8 for holding the dark slide 1, and at the upper end of arm 7 is provided a suspension bracket 9 for the measuring funnel 10.

The liquids used for developing are poured into a funnel 11, temporarily connected to one of the tubes 4 leading to the hollow space 3 behind the plate 2, which now becomes the developing dish, the bottom whereof is constituted by the film side of the plate.

A measuring apparatus 10 is provided for ensuring the using of a definite quantity of the developer, according to the process employed. This apparatus consists of two vessels, 10, 11, suitably arranged one above the other, communication between the two consisting of a tube fitted, 12, with an adjustable cock or valve, 13, such as a glass tap.

The stand 6 for holding the dark slide 1 and measuring and timing

apparatus is so constructed that while the liquid is flowing through the hollow space and out of the variable outlet the dark slide 1 is in a horizontal position, so that the branch tube 5 is out of action. As soon as the measuring vessel is empty the dark slide 1 will, by gravity, be caused to take up an oblique position, and the liquid contained at the back of the slide be caused to flow away through the tube 5. Roger Barwick Hutton, Heselton Cottage, Pitsea, Essex.

DAYLIGHT DEVELOPMENT.—No. 14,757. 1908 (July 11, 1908). A light-tight tank is constructed sufficiently large to receive the plate or plates. When the tank is constructed to receive several plates it is divided by partitions into a number of separate compartments. Each compartment is provided with a draw-off tap. Each plate is mounted in a carrier or slide, which has an attachment by which it may be raised from its developing compartment.

The developing tank is covered at the top and sides with a cover made of light-tight material, with red panels at the sides, or it may be made entirely of red transparent celluloid or glass. This cover slides on to the outside of the tank and fits this latter light-tight. The cover has a number of funnels in its top, which are so constructed as to admit liquid (but not light) to the various compartments. This cover is so made and caused to slide into position on the tank so that it cannot be entirely withdrawn from the tank when pulled upwards.

The inspection chamber may slide laterally into position on the top of the tank, and may then be slid down over the outside of the tank, or it may be fixed on the tank, with capability of sliding up and down, and may have a top carrying the funnels. The tank may have a recessed piece pivoted to its bottom and approximately of the same shape as the recessed portion of the bottom, which may be rotated to project from the bottom and act in conjunction with the extreme ends of the bottom to retain the tank in a vertical position.

The plate or plates to be developed are each mounted in a slide or carrier and inserted into the tank. The inspection cover is placed in position. These operations are performed in the dark or in a dark room. The tank is then taken into the daylight and developer is poured through a funnel into the compartment or compartments containing the plate or plates.

After a short time the inspection cover is lifted, carrying with it one of the slides with a plate therein, which is examined by looking through the red panel or the sides of the inspection chamber. If necessary some of the liquid may be run off and more or other developer may be added. When the plate is sufficiently developed the developer is run off and water is allowed to run through the tank. Edmund Hodgson Smart, 8A, Clareville Grove, South Kensington, London.

CINEMATOGRAPH SHOWS IN LIGHTED HALLS.—No. 4,829. 1908 (March 25, 1907). This invention relates to improved means for displaying animated pictures, and its object is to increase the illusion of life obtained by means of cinematograph projections, and at the same time to permit of operating in a lighted hall or in daylight.

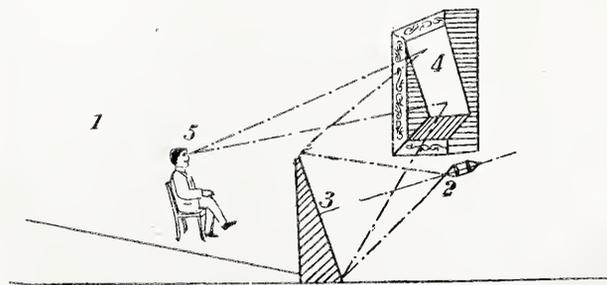

Fig. 1.

These results are obtained by painting dead black the background and sides of the stage on which the pictures are shown, and by dispensing with the ordinary visible white screen on which cinematograph pictures are usually projected. This screen is replaced by a combination of a screen out of view of the spectators, upon which the pictures are projected, and a simple glass-plate reflector mounted upon the stage, inclined more or less to the vertical and by which the pictures are reflected into the view of the audience. Owing to the ground and sides of the stage being painted dead black representations are obtained which are visible in artificial

light or in daylight. The screen may be either an opaque white surface or a translucent screen.

Fig. 1 shows the arrangement by reflection: 1 is the lighted space allotted to the spectators, 2 is the cinematograph or projection lantern, 3 is the opaque white screen, 4 is the non-silvered glass at the back of the stage, and 5 is a spectator.

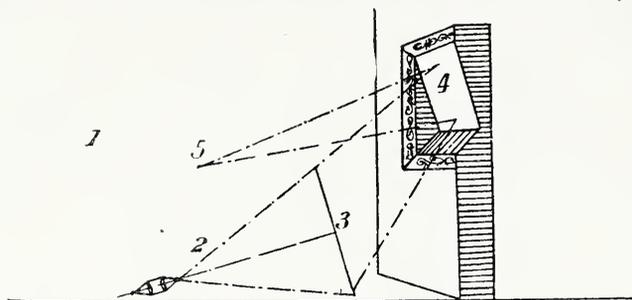

Fig. 2.

Fig. 2 represents the arrangement with a translucent screen: 1 is the lighted space allotted to the spectators, 2 is the cinematograph or projection lantern, 3 is the translucent screen, 4 is the non-silvered glass, and 5 is a spectator. Frederic De Mare, 122, Boulevard Leopold II., Brussels.

CINEMATOGRAPH MECHANISM.—No. 8,758. 1908 (April 22, 1908). The claim is for (in cinematograph projectors) the provision of means for (a) maintaining a film in engagement with a lower sprocket drum; (b) maintaining the film out of engagement with the drum; and (c) maintaining the film in engagement with the drum at a point further around the circumference of the drum, and in the direction of rotation. Vincent Edward Horsman, "Cratfield," Grove Road, Wallasey, Cheshire.

New Trade Dames.

(DEVICE).—No. 309,753. Photographic plates (sensitised) and films (sensitised). The Birmingham Photographic Company, Ltd., Criterion Works, Albert Road, Stechford, near Birmingham, manufacturers. January 22, 1909.

STAMPHOGRAPH.—No. 310,702. Photographic prints included in Class 39. Harry Reginald Ellis Coker, trading as the "Stamphograph" Portrait Company, 1, Hanover Street, Peckham, London, S.E., surveyor. February 20, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Photographing Jumping Greyhounds.

Mr. Philip Oyler, writing on the above subject in "The Amateur Photographer and Photographic News" for April 6, says: "I found early in my experiments that it was useless to hold the camera still in the act of releasing the shutter; a tail, or head, or nothing appeared on the plate. I had to follow the greyhound all the way, swinging the camera as one swings a gun in following a crossing bird. In this case, too, as with a gun, it was a failure if one stopped in the swing when releasing the shutter. I cannot say to within one or two how many plates it cost me, but it was something over eighty, and I do not advise anyone to experiment unless they have unbounded patience, patience being needed not only for the photographing, but also for the training of the greyhounds to jump exactly where one wants them. The photographs are taken at from $3\frac{1}{2}$ to $4\frac{1}{2}$ yards from the lens, with the greyhounds passing at right angles to it; the highest speed possible is always necessary."

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—An exhibition of photographic record work in connection with the paper on this subject will be on view during the Canterbury meeting. The exhibits will, as a rule, be restricted to (1) record work done during convention meetings, or (2) records of ancient buildings, etc., which have since disappeared or have been materially altered. Members of the convention who can contribute prints (mounted) of these kinds are invited to communicate with Mr. C. H. Bothamley, M.Sc., F.I.C., Weston-super-Mare.

New Books.

TWO NEW NATURE SERIALS.—Messrs. Cassell and Co., Ltd. of La Belle Sauvage, London, E.C., have recently made two additions to their popular works issued in serial form, dealing respectively with "Familiar Wild Flowers" and "Trees and their Life History." Both will be issued in fortnightly parts, the former at 6d. and the latter at 1s., and, judging from Part I., which is before us, should prove of considerable interest and value to the botanical student, both as regards the letterpress and illustrations.

"LEAVES FROM AN AMATEUR'S NOTE-BOOK."—No. 96 of our choice and always practical contemporary, the "Photo-Miniature," presents under this title much practical advice on the whole range of photographic topics by Mrs. Katharine S. Stanberry. This lady writes interestingly on her photographic outfit, on lenses, lighting, and development, on enlarging and retouching, on mounting, framing, and framers, and on platinum printing. The writer is not afraid to confess her failures with processes prescribed as "sure things," and this, no less than her bright recital of methods found reliable, makes this number of the "Miniature" a particularly interesting and useful one. Our little contemporary is sold in New York by Tennant and Ward, 122, East 25th Street, and in this country by Dawbarn and Ward, 6, Farringdon Avenue, London, E.C.

New Apparatus, &c.

Equipment for the Morgan Process of Dry Mounting, Plate Marking, and Die Stamping at One Operation. Sold by O. Sichel and Co., 52, Bunhill Row, London, England.

We have within the past few days witnessed a demonstration by the inventor, Mr. W. Morgan, of Aberdeen, of a new system by which the photographic print is secured to its mount, the paper impressed with a plate-mark, and also with the die impression of the photographer's name or address or other wording—all at one single operation. This is done, firstly, by the use of a new dry-mounting material or medium, which is applied to the backs of the prints as they come away from the last washing water, or may be applied to the raw paper used for any of the usual printing processes before

it is coated. Papers thus ready for dry-mounting are shortly placed on the market, but at the moment the only ready-made material for the process is a transfer paper for use in the carbon process, the tissue being transferred direct on to this, and the special coating on the back employed in fixing the carbon print to the mount. The plate-marking is done by laying in register upon the mount a suitable template, or cut-out sheet of metal, which is hinged to a second plate of similar size on which the mount with the print in position is laid, and the former pushed up against the stop upon the plate. The template being then laid over and the whole given hot pressure in a special form of press, the two operations of plate-marking and mounting are done together, whilst for the die-marking a suitable die is made to form part of the template. We were able to see the

in the way of embossing or plate-marking obtainable by this method, which, besides saving time, allows the photographer a very great latitude in the selection of his mounting materials, permits him to indulge his own tastes up to a large degree, and further reduces the manipulation to a degree of simplicity, such that it may be carried out by assistants of very little skill. The press, it should be understood, may be used equally well for these three purposes—namely—that is to say, it may be used by the photographer to damp his mounts, or to plate-mark or emboss his mounting materials.

The following are the directions for mounting photographs on any commercial mount, from which a good idea of the process may be obtained:—

Use this plain folder has to be used, that is, one that is not fitted for plate-marking, etc. Heat press to correct temperature, say to 200 deg. slowly, so as to get an even heat all over bottom. Light gas heater half an hour before commencing to mount

on sufficient gas to have temperature nearly correct in that this allows the iron plate to absorb heat equally throughout. Thoroughly heat the folder by putting into heated press for a few seconds along with a piece of the hard cartridge paper that goes with the folder, this is in order to make certain that there is no damp in the paper; remove from the press, turn the paper, and heat to heated press again for a few seconds, and mounting is then to be proceeded with.

Mount, open folder and remove paper. Lay the mount face up on the right hand leaf of open folder. Lay trimmed print upon the left hand leaf in its proper position. Put the sheets of dried paper on top of the right hand leaf with the right hand, keeping the print in position with the right hand thumb and fingers. With the fingers of the right hand press the dried paper down against the print, at the same time withdrawing the fingers of the left hand. Close the folder, turn it upside down and place into heated press under a good firm pressure for

eight seconds, then remove and repeat the operation with other prints *ad lib.*

To mount, plate-mark, and emboss all at one operation, heat press slowly to required temperature, 160 deg. to 200 deg. or thereby. Place patent folder in press for a few seconds to heat and thoroughly dry. Place trimmed print *face down* on ruled lines of plate-marking die, holding in position with the tips of thumb and fingers of the left hand. Lift the mount with right hand, and lay it face down against the gauge at the top of folder; gradually lower until it presses against the print, at the same time gradually withdrawing the fingers of the left hand, close the folder, and put into press *without reversing* for six or eight seconds with good firm pressure. Should print not adhere to the press is too cold, or the pressure has not been sufficient.

Should prints have a tendency to gloss, the press is too hot. An expert mounter can use the fingers of the left hand to hold print in position without any inconvenience from heat of plate, but a glove made of flannelette or cotton may be used for the left hand; experience has shown that it is an advantage at all times to wear cotton gloves to prevent moisture from the fingers touching the prints. It is of very great importance that the temperature of the press be carefully noted during mounting, as if mounting proceeds rapidly a deal of heat is extracted from the press, and the quicker the mounting proceeds the higher the gas must be raised to maintain an equal temperature. From 160 deg. to 200 deg. is correct, but the class of thermometers used for this purpose do not all read alike, and experience will soon show the correct heat for the particular press in use. It must also be noted that prints must be quite dry before attempting to mount. Patent folders can be made to give any desired depth of plate-mark, and they are so constructed that the mounts will not crack. All parts are in perfect alignment, scientifically made and tested.

The presence of atmospheric damp in the mount is an advantage, causing the fibres of the paper of which the mount is composed to open slightly and at once combine with the adhesive preparation.

In very dry weather or for hard and very dry mounts it may be an advantage to slightly damp the surface with a sponge previous to mounting, laying one on top of the other back to face. In a few minutes the mounts will have absorbed the moisture, and mounting can then be proceeded with. Photogravure printers always dampen the paper used, in order to make the engraving ink "bite" quickly and "lift" cleanly; whereas bone-dry paper would only lift partly, and the ink would, when quite dry, be readily chipped or rubbed off. Note.—The prints to be mounted must be bone-dry.

It must be noted that the temperature of the mounting press has to be slightly higher than that used for commercial tissue. For large prints, 12 and 10 or over, it is recommended that these get a liberal coating of adhesive mountant. On no account attempt mounting unless prints are absolutely dry.

The photograph shows the template opened with the mount in position, and the second illustration shows one or two of the effects obtainable by this very ingenious and time-saving method. A booklet describing the process and the materials supplied for working it has just been prepared, and may be obtained from Messrs. Sichel.

New Materials, &c.

"Dreadnought" Matt C.C. Paper. Sold by F. E. Jones and Co., 22, Gray's Inn Road, London, E.C.

In the variety of collodion paper which Messrs Jones have commenced to market under this name, we find a printing medium of a very fine quality, toning to fine warm blacks in the gold and platinum baths. The paper is sold in two substances (thick and thin) in sheets 24x20, and Messrs. Jones will be happy to send samples on receipt of trade card.

"Criterion" Slow Bromide Papers and Postcards. Made by the Birmingham Photographic Co., Stechford, near Birmingham.

In this new product the Criterion factory has provided its customers with a paper of speed intermediate between the well-known gaslight and bromide papers of the Criterion make. In speed the paper is about four or five times that of the gaslight emulsion, and like the latter, tones to an excellent sepia by the usual sulphide

process. The paper can be handled without a dark-room if treated with care, as exposure to direct light, and by its clear-working character and freedom from stress marks bears out the good reputation of the Criterion manufactures.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 9.

Croydon Camera Club. Excursion.
United Stereoscopic Society. Excursion to Southampton and District.

MONDAY, APRIL 12.

Cripplegate Photographic Society. "Trimming, Mounting and Finishing Prints."
J. B. Bensley.

TUESDAY, APRIL 13.

Royal Photographic Society. No Meeting.
Southampton Camera Club. Affiliated Societies' Prize Slides.
Kinning Park Co-operative Camera Club (Govan). Club Meeting.
Hackney Photographic Society. Exhibition of Prints on Paget Bromide and Gravura Papers.
South London Photographic Society. Committee Meeting.

WEDNESDAY, APRIL 14.

South Suburban Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Cowes Camera Club. R.P.S. Affiliation Competition Slides.
Croydon Camera Club. "A Cruise in the Western Mediterranean," with Views of Tangier, Algiers, Gibraltar, &c. C. H. Dymond.

THURSDAY, APRIL 15.

Oldham Photographic Society. French Lantern Slides. A. E. Staley & Co.
Maidstone and Institute Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Handsworth Photographic Society. Papers and Discussion on the Various Printing Processes, Bromide.
Midlothian Photographic Association. Members' Night. Hand Cameras, with Examples.
Southeast-on-Sea Photographic Society. "Autochrome Photography and its Applications." H. O. Klein.
Liverpool Amateur Photographic Association. "Stereoscopic Photography." Demonstrated by W. H. Tomkinson.
Rodley, Farsley, Calverley, and Bramley Photographic Society. Members' Night.
Blenheim Club. "Monte Rosa and Cloudland. Part II." Hy. Speyer.
Folkestone and District Camera Club. Demonstration on the Carbon Process.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting on April 1 Mr. Will. G. Barker lectured upon and demonstrated the "Synchronising of the Gramophone and Cinematograph by Photographic Means." He shortly explained the methods in use by which the two machines were synchronised, and said that when electrical methods were in use they necessitated a large amount of heavy apparatus, running up to as much as 16 cwt., and if by any chance anything went wrong it could not be put right without stopping the show for a short time at least. The means of doing the thing by the aid of photography was, he said, so very simple that it was with the greatest trouble that he was able to protect himself by patenting it. The extra cost for the needed fittings was, in comparison with other methods, a very small matter. What he did was to have an extra fitting to the gramophone or talking machine, which was connected with a disc dial marked in the four quarters with an illuminated spot. When the talking machine was started running a brilliantly illuminated hand or needle went round the dial clock fashion, and in making the recording negative film of the singer or dancer this clock face was put in such a position that it just came into one corner of the negative. The needle was, of course, running with the music, and the movement was registered upon the film. All then that was needed when showing the positive film upon the sheet was to so arrange the talking machine that the disc was near to the sheet corner, where the registering disc was on the film, and the operator was only needed to keep the two hands running together to get perfect synchronism. Should the operator get a little out he could very easily put matters right by the mere slowing or quickening of the speed of his handle.

CROYDON CAMERA CLUB.—The president, Mr. J. M. Sellors, gave a demonstration last week on "Enlarged Paper Negatives," a report of which is unavoidably held over.

WARNING.—A 4-plate Pamos camera, No. 3,213, with Series II. homocentric lens, No. 64,606, and one No. 1 Koilos shutter, were stolen from the exhibit of Messrs. Ross at the recent photographic exhibition at Cripplegate Institute, E.C.

Commercial & Legal Intelligence.

LEGAL NOTICES.—In the case of Joseph Sharples (trading as the Romanus Publishing Company), photographer and publisher, 54, Church Lane, Marple, Cheshire, and formerly of Hollinside, Lockport Road, Marple, a receiving order was made on March 27 of the debtor's petition, and he was adjudicated bankrupt the same day.

ALLEGED ADVERTISING FRAUD.—At the Marlborough Street Magistrate's Court, on April 2, William Thomas Regan, 22, a deaf mute, described as a photographer, living in Gray's Inn Road, was charged with obtaining by false pretences a camera and photographic apparatus belonging to Mr. N. L. Craig, a photographer, of Mar St. Stirling, N.B. The Rev. F. Gilbey interpreted the evidence. The prosecutor deposed that he advertised for sale the camera and photographic apparatus produced, which were worth about £20, in "The British Journal of Photography." On March 5 last he received a reply from the prisoner, and in consequence forwarded the articles to him in London. He never received any money in payment and subsequently learnt that the accused had sold the camera for £10.

Detective-Sergeant Durrant, D Division, said that the prisoner voluntarily surrendered himself at Tottenham Court Road Police Station, and made a confession, which was taken down in writing. He said he had sold the camera two days after he had received for £6, that he had an unfortunate mania for betting, and that he had lost £4 of the money backing horses. He added that he had done the same kind of thing before.

In reply to the magistrate, Sergeant Durrant said the accused had been previously convicted three times, having once been sentenced to nine months' hard labour for burglary.

Mr. Mead committed the prisoner for trial.

[We must draw the attention of those using our columns to the instance this case affords of the folly of sending goods to unknown persons unless payment for them is safeguarded by our "Deposit" system.—Eds. "B.J."]

News and Notes.

ART PHOTOGRAPHY, LTD.—This new title has been taken by the Stereoscopic Postcard Company, Ltd., Essex House, Leyton, in order to better indicate the growing business of the firm in the way of portraits, etc., in oils, and other forms.

A SPECIAL EXPORT ISSUE of our contemporary, "The British Colonial Printer," is a large and well-printed sheet, which shows a large variety of printing house equipment and tools which is produced by British manufacturers and vendors. And we see one of two articles and advertisements also of interest to the photographer. For example, there is an interesting note on the gelatinising and embossing department of Messrs. McCaw, Stevenson, and Orr, Ltd., who make a special line of this work for postcards, showcards, etc. Another note describes the Aerograph Company's stencilling table, which is much in the full issue of interest to those engaged in, or connected with, commercial printing.

PHOTOGRAPHS OF CONVICT LIFE.—In the House of Commons on March 31, Mr. Crooks asked the Home Secretary whether his attention had been called to the sale of copyright photographs of the work-shops and convicts of Portland Prison, and what steps he proposed to take to stop those who, against orders, allowed such photographs to be taken. Mr. Gladstone, in reply, said that the sale of these photographs was, in his opinion, most reprehensible, and involved a gross breach of faith, which, he hoped, had now been put to stop. He also said that steps would be taken to render, not only the sale, but the taking of such photographs impossible in future.

DR. CHARLES M. KURTZ, director of the Albright Galleries, Buffalo, N.Y., died on Sunday afternoon, March 21, at the Buffalo General Hospital, as the result of an operation. Dr. Kurtz was a most successful art director, who did valuable work for the Paris International Expositions of Louisville, Chicago, Saint Louis, and Paris (1900). Shortly before his death he was busily planning for a great international invitation exhibition of pictorial photography, and had gone so far as to consult certain British and European colleagues.

exhibition promised to be more widely representative than any has been held, but it is doubtful whether the plans were sufficiently mature to enable the directors to carry out the work without Kurtz' guiding hand.

R. E. A. SALT exhibited his shutter-testing appliance at the Institution's *conversazione* on Friday last, together with a series of diagrams recorded by it. A representative collection of camera shutters by Messrs. Busch, Beck, Goerz, Staley, and Thorn-Pickard added to the interest of the exhibit, which attracted much attention. A photograph shown, taken by Mr. H. Andrews, Albeck and Co., with the new "Multi-Speed" shutter, illustrated the capacity of this instrument for high-speed work. It depicted a motor-car travelling between 35 and 40 miles an hour, at right angles to the camera. The shutter dial was set to 1-500th sec., and little of movement was apparent.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—The members of the North Middlesex Photographic Society and their friends assembled on Saturday last at the Holborn Restaurant to partake of their annual dinner. The society this year celebrates its twenty-first birthday, and to this fact possibly something is due to account for the eminently successful evening that was spent. The chair was occupied by Mr. W. Fincham, the president of the society, who replied to the toast proposed by Mr. Tilney, with his accustomed dry humour, to the effect "N.M.P.S." Mr. H. Stuart proposed "The Health of the Society at the Recent Exhibition," and Mr. A. H. Blake, M.A., responded on their behalf. In this reply the menu, which included a photographic reproduction of the society's winning picture of the year, came in for some praise, and Mr. Blake also made some very flattering and encouraging remarks about some of the members themselves.

The certificates, which are awarded by the society to the successful members, were distributed by Mr. J. C. S. Mummery, the president of the Royal Photographic Society.

A testimonial, in the shape of a lens, was presented to Mr. S. C. Ly upon his retirement from the office of secretary after five years' service.

The musical programme was under the direction of Mr. G. E. Adams, and the following ladies and gentlemen contributed to the entertainment during the evening:—Madame Ada Williams, Miss Florence Wainwright (at the piano), Mr. Chas. Winter, Mr. Harry Ward (who sang an original lyric upon the N.M.P.S., in which our good-natured personalities were indulged in), Mr. Fred. Rome, E. A. Morgan, and the entire company in a chorus of "Auld Synne."

During the evening it was mentioned that the society was endeavouring to arrange a pictorial photographic exhibition, to be held at the Clington Central Library some time during the summer months of this year.

Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

SOUTH AFRICA AND PHOTOGRAPHIC ASSISTANTS.

To the Editors.

Gentlemen,—Allow me to protest against the exaggerations in your letter of F. Collett, Cape Town, contained in your issue of January 26. I cannot trace any "F. Collett" in connection with our society, and any reciprocal esteem would justify acceptance as an honorary member, but his experience of Cape Town, whence he writes, would be that of a recluse. Trade throughout South Africa has suffered through the lasting effects of the 1899-1902 advertisement, and it was a money-making place for many, with the result of substantial surplusage of artisan labour that has not yet diminished to the level of the country's actual needs. The "depression" exists in comparison with the war boom; in a sequence of normal times South Africa has progressed remarkably, discounting never before. The imports of photographic material were never so high as during the past twelve months—with the reservation of the material. The next ten years, spoken of by Mr. Collett as

prospectless, should show in the same proportion a trebling of present figures. These statistics of import, of which 80 per cent. are from England, are apart from a very large business in photographic papers of South African manufacture established within the past two years, and usurping a large portion of the field. As to £20 a month here being only equal to £8 in England, the comparison is absurd. There is no material difference, excepting rent, due to the fact that the white population cannot herd together as in an English town, herding being a privilege of the coloured people. Otherwise, household cost is practically the same, with many advantages in cheap and abundant fruit. As to the climate being trying, the Cape Peninsula has for centuries been a health resort from Europe and India. The statement regarding photographers closing their business in every direction is contradicted by an inspection of my trade lists, which monthly receive additions in new businesses. In the matter of agreements the equity of Roman-Dutch law leads to non-recognition of agreements made outside the colony, all arrangements made elsewhere having to be formulated into definite agreements made in the colony when the immigrant employee is able to realise his new conditions.

Finally, as to never coming in touch with any new processes, not forgetting colour photography, only by reading the articles in the "B.J." I may point out that Autochrome work was demonstrated in Cape Town in November, 1907, for the first time and repeatedly since in the colony, that carbograph was demonstrated in Cape Town before it had been shown to any English provincial society, a matter of date noted later, that demonstrations of Azol led to a rush for that product from August last, that new Velox, S.C.P., and lantern slides, and other novelties have been demonstrated as produced, and that two demonstrations of Ensyna have already been given.

I regret that a series of so completely erroneous statements should have been given publicity in your columns, and as I am as greatly interested in the welfare of photographic assistants as in that of the trade or employers, I trust this refutation may amend knowledge of South African conditions.—Yours sincerely,

MUDIE THOMSON.

Editor "South African Photographic Journal."

Camera House, Adderley Street, Cape Town.

SINGLE LENSES FOR PORTRAITURE.

To the Editors.

Gentlemen,—In reference to the matter of the use of a single lens for portraiture, I would like to mention to readers who happen to be dissatisfied with their present lens for portraiture that I have been using for some time the back double convex glass of an old Darlot lens (combination 10 x 8 landscape and portrait) with perfect results for cabinet head or full-length work. But I find upon experiment that this lens gave me no satisfactory result until I built on to the front of lens case (whatever the technical term for the brass casing holding the glasses may be) a cardboard tube and inserted my stop right in the front of same, making it about 7 inches from the lens itself. Have any of your readers tried this? If not, it is worth while. I claim to be getting as good a result as when I used a lens of good standard present make at £25. Enclosed is a sample of result.—Faithfully yours,

ADRIAN HARDING.

38A, High Street, Godalming.

[It is well known that when using the back lens of a doublet alone the stops are generally too close to the lens to give good results, and our correspondent's idea of lengthening the lens mount is not exactly new. It is, however, a very useful thing to remember. The example submitted shows very sharp definition, quite as sharp as is desirable in a portrait. The chief objection to using the single lens is, of course, loss of rapidity, and Mr. Harding does not state what exposure he found to be necessary.—Eds. "B.J.]

DEATH OF AN ABERDEEN PHOTOGRAPHER.—Mr. John S. Greenacre, a well-known photographer in the Rosemount district of Aberdeen, passed away at his residence there on March 25, aged forty years. Having gained a knowledge of photography in Yarmouth and with Messrs. Wilson, Aberdeen, Mr. Greenacre acquired the Rosemount studio about ten years ago. He was also secretary to the local branch of the P.P.A. during its existence. Mr. Greenacre is survived by a widow and three children. Among the large number who attended his funeral were his brother professionals, Messrs. Jas. Ewing, E. M. Middleton, D. Milne, H. J. Rennie, Jas. Sharp, and Hardie.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- A. F. G. L. Gower, 31, Gloucester Place, London, W. *Photograph of the Dean of Salisbury, Dr. Page Roberts.*
- H. E. Appleton Roseville, Forest Moor, Knaresborough, Yorks. *Two Photographs of Knaresborough Dropping Well in Winter.*
- A. E. Roxburgh, The Studio, High Street, Cowdenbeath, Fife. *Combination Photograph of the Cowdenbeath Public Brass Band and Instructor.*
- J. D. LAWSON.—Apparently the paper you are using requires an alum bath after fixing, or you could use 10 per cent. solution of formalin instead. Very likely a change in the weather from cold to mild is the cause of the prints sticking. The quicker prints are dried the better they strip.
- J. B. STUBBS.—It is contrary to our custom to give the addresses of contributors and others. If you care to send stamped addressed envelopes with the names only written on we will forward, or you could obtain all the addresses by purchasing a list of the members of the Royal Photographic Society.
- WHITE INK.—Would you be good enough to give me a method for making white ink? Using oxide of zinc is common, I believe, and would gum arabic be best to add to the zinc to ensure its drying with a little gloss if possible and not easily rubbing off, at the same time not to interfere with its flowing freely from a pen to paper.—C. WILLIAMS.

The materials you name are those generally used. A solution of gum arabic (1 oz.) in water (4 oz.) and enough zinc white added to make a smooth sufficiently fluid ink.

COPYRIGHT.—In connection with the "Daily Mirror" Fair of Fashions to be held at the Horticultural Hall on June 26, there is a photographic competition, competitors to select their subjects from history, literature, or representations of famous pictures by great artists. Can you inform me if it would be an infringement of copyright to reproduce, by the aid of living models, a picture in which there is a copyrighted reproduction from original painting in existence?—GILDER.

In the series of lawsuits which resulted from the "Living Pictures" at the Empire, it was held that the actual living picture is not an infringement, but that a photograph or sketch of the living picture is an infringement.

COPYRIGHT.—1. I have several prints which I wish to copyright. Can you tell me whether it is necessary to register the copyright of each one separately, or whether one may fasten them together, in a kind of leaflet, say, and register that? In this case would the rights over each be registered? 2. What are "Charbonel" prints? Are they printer's ink prints, or a real photographic process? 3. Can you recommend me one or two reliable agencies who place amateurs' photographs in current periodicals on commission, similarly to the way in which the London Literary Agency do literary work?—H. H. B.

1. Each picture must be registered separately in order to secure the copyright. 2. We do not know the name. 3. Illustrations Bureau, 12, Whitefriars Street, E.C.

RETURN OF DEPOSIT.—"H. H. H." agreed, about two and a half years ago, to purchase a camera outfit from a well-known firm, and paid 20s. on account. After this agreement, which was only by letter, "H. H. H." was not wishful to complete the purchase. The firm refuse to refund the 20s. or its value, and say that unless the purchase money (which I believe was about £4 4s.) is paid in a month from date that the 20s. will be forfeited. Will you kindly let me

know, through your column in "B.J.P.," if I can do anything in the matter or if I shall be obliged to forfeit the 20s.?—H. H.

As the firm have held the outfit for you for two and a half years we are not surprised that they refuse to return the deposit money. We doubt if you can recover it after so long a time, if you take proceedings against the firm.

APPRENTICE.—There was a leading article on the subject of apprentices and assistants in our issue of last week. We cannot call to mind any decided case on the point you mention. However, as you have already consulted your solicitor on the matter (and he has seen the indentures) he is better able to advise you than we are, and we have not seen them.

PERPLEXED WORKER.—The proposed alteration will certainly give you more side light, particularly if you have the wall of the adjoining premises whitewashed, so that it reflects light into the studio. You would then be able to work both ends of the studio. For so short a studio, for standing figures cabinet size, you require a lens of about 10½ inches focus.

TOE THE LINE.—(1) It would have been better if the assistant had given you notice on Saturday, but as you were away then he gave it early on Monday, and that, under the circumstances, might be considered a week's notice. (2) If he gives you a week's salary he can leave, as he wishes to do.

PHOTOPHIL.—Apply to Messrs. Fuerst Bros., 17, Philpot Lane, London, E.C., or to Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne.

SULPHIDE TONING.—Kindly inform me whether a bromide enlargement, intensified by the chromium intensifier, can be toned satisfactorily in the sulphide bath.—IX DOUBT.

Certainly. It should tone very well indeed.

AUTOCHROME SCREEN.—(1) Kindly state what allowances are to be made in using the Autochrome screen inside the tube of a portrait lens next the diaphragm. (2) Also in using it in hood of lens in the front. Of course, I understand in using it behind the lens no allowance need be made, but I should like to use it at the diaphragm, as a smaller screen would do.—AUTOCHROME.

(1) Quite impossible to answer this definitely; a good deal depends on the front lens. The only practical method is to put the screen in position and focus on the reversed ground glass. (2) If in fact of lens no special adjustment is required for distant objects, or near ones it is necessary to test focus on screen. It is not practical to rely on calculated adjustments.

THE 1909 WHITE CITY EXHIBITION.—In connection with the photographic section of the Imperial International Exhibition, 1909, at the White City, Shepherd's Bush, a competition of the photographic clubs of the United Kingdom will be held. A special award will be made for the best collection of framed pictures, not exceeding fifty, sent by a photographic club. There is no entrance fee or charge for space. Amateur photographers are also invited to send for particulars respecting individual exhibits. The photographic section will occupy a portion of the Fine Arts Palace, the side walks of which are set apart for draped alcoves, in which will be shown the work of professional photographers. The centre of the sections will be devoted to the display of the most recent inventions and improvements in apparatus, materials, and accessories. Inquiries should be addressed to the organiser, Mr. J. F. Peasgood.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

A recent paper before the Croydon Camera Club, Mr. J. M. S. had much practical advice to give on the making of enlarged negatives, a practice which he recommended not as equalling results with plates, but for the greater facility of "control" when giving at a pictorial result. (P. 300.)

A method of modifying the developer to deal with errors of exposure on fogged paper is recommended by Mr. T. H. Greenall in the article "Photo. Notes." (P. 307.)

An American worker, who gives the preference to the electrical method of igniting flash powder, has described the apparatus employed for the purpose. (P. 308.)

The concluding portion of the paper on the Bromoil process by Harold Baker appears on page 302.

"Photo-Mechanical Notes" deal with the marking of lenses for test work and with American claims for machine-printed photographs. (P. 309.)

"Sulphide Toning," "The Efficiency of the Focal-Plane Shutter," "Charges for Unreturned Proofs," appear under "Correspondence." (P. 314.)

Points out the present opportunities for revising or completing of view negatives. (P. 298.)

Would draw attention to the caution on page 298 as to dealings with enlarging firms.

Pirie Macdonald has given a vivid and truthful impression of the wireless Herr Dührkoop. (P. 306.)

L. Lumière have recorded the results of their experiments in the use of the diamidophenol developer for the tentative method recently recommended by them in conjunction with pyro for the development of bromide plates. They conclude that the rapidity of appearance of the image is a drawback to the use of diamidophenol, but that by the use or addition of potassium bromide improvement in errors of exposure may be made. (P. 305.)

EX CATHEDRA.

Long or Short Exposure in Portraiture.

The claims put forward with all the materials offered to the portrait photographer, make it evident that in the eyes of the manufacturers, minimum of exposure is the desideratum in portrait photography, and so, of course, it is in the case of women or children, yet the portraitist should not ignore the fact that when the character of the sitter permits of it a very much longer exposure will give a better result as regards the all-important "likeness." The expression which is caught in an instant as being "happy," is very frequently unusual, and, as a rule, the portrait which gives lasting satisfaction is one which is without any very marked or distinct expression, and for this reason an exposure of five or ten seconds, which forces the sitter to assume an attitude of composure, is frequently more satisfying to himself and his friends than the more rapid result obtained by the popular conjunction of a rapid shutter exposure, and a remark thought by the operator to be felicitous.

Parabolic Mirrors.

Professor R. W. Wood, in the "Astrophysical Journal," describes an ingenious way of producing a parabolic mirror that may lead to further developments. He placed some mercury in a suitable vessel and then rotated it, with the result that the centrifugal force caused the mercury to assume a paraboloid surface of excellent optical qualities. He hopes to succeed in making a cast of this paraboloid surface in some material, such as fusible metal, in which case the production of cast parabolic mirrors for use in telescopes will be a relatively simple operation. The production of permanent accurate moulds would, of course, greatly facilitate the manufacture of such mirrors for any purpose, and they are so often required, and have so many uses, that it is to be hoped Professor Wood's experiments will be successful.

* * *

Some Methods of Control.

A short time ago we pointed out how the well-known system of producing warm tone lantern slides by long exposure and restrained development could be utilised to save a badly over-exposed plate. Mr. Hubert Mills, in the "Photographic Monthly," points out another application of the method in using up fogged gaslight paper. He found that paper which was quite useless for ordinary purposes yielded excellent results when given four times normal exposure and developed with a highly restrained developer. We may assume that in this case the extra bromide kept the fog in check while the extra exposure counteracted the effect of the bromide so far as the image was concerned. A little time ago we found yet another

use for the process. In this case we had to deal with a badly over-developed negative that would give no detail whatever in the high-lights when printed for ordinary times. We, however, tried increasing the exposure to about 100 times that required with an ordinary negative, and developing with a well-restrained developer containing ammonium carbonate. The result was unfortunately over-developed and too dense, but the high-light detail was brought fully out, and no trace of fog was visible. Evidently the method could be successfully applied in such a case just as well as with Mr. Mill's stale paper.

* * *

The Moon by Earth-Shine.

The effect of earth shine upon the moon is a familiar one to many people, though probably few of them know the cause of the effect. When the moon is in its first quarter the dark portion of it is often faintly visible. The bright quarter is, of course, illuminated by direct sunlight, but the remainder is only seen by virtue of the faint light reflected from the earth. This faintly illuminated portion has been successfully photographed by M. Quénisset at the Kuvisy Observatory, and it appears likely that the results will present many points of interest to astronomers. The light received from the earth naturally falls at a different angle from that at which light is received from the sun, therefore it is reasonable to expect a slightly different effect of light and shade on the irregularities of the moon's surface.

* * *

Special Local Views.

As we have before pointed out, now is the time to secure many of those views which cannot so satisfactorily be taken at other seasons of the year. During the winter, when the trees are absolutely bare, there is often a chilling effect produced which is undesirable. In the height of summer the density of the foliage destroys many of those "peeps" which give interest, frequently *selling* interest, to a view. But during the next few weeks the happy mean is available, the trees are just bursting into bud in many of the more favoured spots, and even in the somewhat bleaker north another month will bring about this state of things. Photographers, therefore, who do anything in the local view way should look around and secure those views which require these special conditions. It sometimes happens that a church or other building of interest may be photographed peeping through a partial screen of trees, so that some of the possibly hideously ugly modern surroundings are obscured. In many cases negatives of stock views are already in existence, but perhaps some trifling change has taken place or a slightly different position is now obtainable, and, if so, the view may well be taken over again. A new negative often means increased sale for a view. In cases where the view is an important one it is quite worth while to expose a plate on it each week during the spring, afterwards selecting the particular exposure which gives the most pleasing effect—that is, of course, in this case, that negative in which the screening effect of the budding foliage is just what is wanted.

* * *

Special View Series.

The country photographer—and, indeed, for the matter of that, his town brother also—who does nothing in the way of producing special series of local views is often neglecting his opportunities. There are few, if any, districts which do not provide material for such series. Of course, a little personal initiative is necessary, and it may be an advantage to get into touch with some local society, such as an antiquarian or archæological society. The subjects for such series of views are almost unlimited. For examples

we may suggest the following: Parish churches built prior to the nineteenth century, a series which might branch in various directions forming sub-series of fonts, carved woodwork such as screens, poppy-heads, misereres, etc. Then there are Norman doorways either in use or disused, porches, lych-gates, spires or towers, devil's doors, and so on. Such series might include all the specimens in the county, or a division of the county, and should be as complete as possible. Or in another direction we might suggest a series of views of the principal places of interest in a fishing neighbourhood or a hunting country—views of these instances which would find ready acceptance, if well produced, with one of the sporting publications. Photographs of all the available sections of rock strata, quarries, railway cuttings, and so on, giving a fairly complete idea of the geology of a district, might form a series, each print carefully marked with the exact spot and the direction of the cutting. Work such as we have suggested might not bring in the guineas the moment the prints were mounted, but it would provide pleasant occupation for occasional half-days, would cost little beyond the cost of a bicycle and a few plates, would bring the worker in touch with educated, well-informed people, and would undoubtedly bring a cash return in the long run from the sale of prints for reproduction, and the supply of lantern slides for lecture purposes.

Enlargers—A Caution.

It is occasionally our painful duty to interfere in circumstances where an enlarger, by taking advantage of the publicity obtainable in our advertisement pages, has entered into contracts which, either from negligence or fraudulent intentions, has failed to carry out. Such instances, we are glad to say, are of comparatively rare occurrence, and are invariably found to be the fault of the enlarger. But when repeated complaints prove to us that the enlarging firm is either very unbusiness-like in its methods, or is carrying on a bogus business, we naturally take steps to refuse further use of our advertisement pages. As these people will then resort to the general press and to other means of getting in touch with photographers, we would utter a strong general caution to those dealing with an enlarging firm, of the bona fides of which they are not convinced, on no account to send negatives or originals until they have obtained a satisfactory reference from a reputable photographer, preferably in the country or at a distance from the address of the enlarging firm. Many such firms exist by moving the scene of their operations every few months or so—a method which has the advantage in the eyes of enabling them to evade payment for rent, paper, and other necessities of their business. One instance of such a method of trading—if trading it can be called—which has come before us within the last few days leads us to caution photographers in the strongest terms at our command.

* * *

Flashlight Powders.

We are frequently asked for formulæ for the preparation of a flash powder which will not give any smoke, and our invariable reply is that while we know of many formulæ for flash powders we know of none which will give a non-smokeless flash, nor do we know of any commercial powder which is quite free from smoke or fume. More important, however, is it to note that the preparation of a flash powder, apart from its requiring considerable care in order to secure a quick-burning powder, is a matter of no little danger, due chiefly to the fact that both the materials of the powder must be in the finest division, and if by mischance a portion of one is contained in the other while the latter is being powdered, the most likely result is a sharp

xplosion. Flash powders being required usually at not very frequent intervals, the photographer cannot be better advised than to purchase the ready-made powder in small quantities. In so doing he gets a more efficient product than he could possibly make for himself, and he avoids the really considerable risks of manufacture.

* * *

Local-Plane versus Diaphragm Shutters. Perhaps no piece of photographic mechanism has been so improved within the last few years as the focal-plane shutter. This has been particularly evident to the user from the reduction of the movements necessary to adjust the shutter to various speeds, the greater rapidity of setting, and the locking of the slit aperture during use so that the exposure remains constant for a given setting. Notwithstanding these many respects in which progress has been made, it may be doubted whether the focal-plane shutter is destined to survive in general use for a period as long as that which has passed since its evolution to its present state of perfection. The improvement in diaphragm shutters has been almost as marked, and though the majority of diaphragm shutters cannot give the great range of high speeds afforded by the focal-plane, the compactness and lightness of this type of shutter will surely induce inventors to obtain also the required higher speeds. The "Multi-speed" shutter, which was reviewed in our issue of March 26, is, in fact, such an instrument, capable of giving, as we have since had an opportunity of discovering for ourselves, an extraordinarily rapid exposure. The "Multi-speed," it will be remembered, differs from the ordinary type of diaphragm shutter in having its plates pivoted, the actuation of each plate by the spring of the shutter causing the plate to undergo a half revolution. This method, which obviates any checked return action, obviously allows of very high speeds being produced, and while we know of no other shutter which is designed on these lines, it cannot be supposed that other manufacturers will not follow suit in designing a between-lens shutter capable of giving the very shortest exposures. And the user will certainly welcome a shutter which is of less bulk than the focal-plane and dispenses with the dust-raising blind.

* * *

The Daylight Development of Plates. One of those fallacies which never cease to put money into the coffers of the Patent Office is the idea that there must be a demand for an apparatus sufficiently portable to be carried with the camera and allowing of the plates being developed in full daylight. The records of the Patent Office show that from the very earliest days of photography no piece of apparatus has been so frequently the subject of claim for Royal Letters Patent as this. Fox Talbot took out a patent for an apparatus of this kind, and, if our memory serves us correctly, he was by no means the first. Inventors of these ingenious pieces of apparatus overlook the fact that it is frequently impossible to obtain the necessary supply of water for carrying out the photographic operations, and, even supposing this obstacle overcome, the safe transportation home of such a delicate thing as a wet gelatine negative is by no means an easy or certain matter. At the best these pieces of apparatus are makeshifts, since the examination of the progress of development cannot usually be satisfactorily done, whilst the variations in temperature at which they must necessarily be used deprive them of the virtues of regularity which the tank method of development at home possesses. We have read many descriptions of apparatus of this kind, but we have yet to hear of an apparatus which has come into general use.

ALBUMEN PRINTS ANCIENT AND MODERN.

THE fashion in the colour of photographs has, from time to time, undergone many changes. At one period nothing but a rich purple-black was considered a good tone. At another it was only rich reddish-browns that met with favour. Then we had deeper browns and sepias, and now we have a great variety of tints, which are obtained by the various modern development processes with subsequent toning. However, what we wish to refer to now is the tones that are to be obtained with print-out papers. Our older readers will well remember the excellent warm black colours which used to be obtained on what was once known as plain salted paper, and how permanent many of them have proved; also the deep purple-black once obtained on albumen paper at the time when this latter and the one just mentioned were the only papers in vogue. When one turns up an old family album one usually finds some of these old prints, and although they may be forty or more years old, many of them are almost as good as when they were first made, yet they were produced under conditions which, according to present ideas, would not be considered conducive to permanency. For instance, they were toned in a combined toning and fixing bath, though it must be admitted that it was under conditions that do not obtain in the modern combined bath. The bath of those days contained only hyposulphite of soda, gold, and water—nothing more.

Several times of late we have been asked for formulæ for toning baths that would yield deep purple-blacks such as were got by the old photographers. These tones, we may at once say, are not readily obtained unless we go back to the old methods, for it is next to impossible to obtain them on glossy gelatine P.O.P. with the type of negative now in vogue, and this brings us to the point that the tone of the prints depends as much, or more, on the character of the negative from which it is made than upon the composition of the toning bath. That seems to be a fact which is not fully recognised by many.

Let us for the moment hark back to the early days of the art—to the time when the negatives were by the wet collodion process. They were made very strong as compared with gelatine negatives, the deepest shadows being represented by quite bare glass, while the highest lights were very dense. Hence there was a very long range of tones from the highest lights to the deepest shadows, whereas with the present type of negative there is no such great scale. As regards the paper then used, it was either the plain salted or, mostly, the albumenised. But the albumen paper of that time was very different from that of the present; it was what would now be classed almost as a matt paper, since the albumen was considerably diluted with water before it was applied to the paper. It also contained a larger proportion of chloride than does the modern albumen paper. Furthermore, it was sensitised on a much stronger silver solution than is now employed. Hence it will readily be seen that when this paper was printed from negatives, such as those just referred to, that the image was of quite a different nature from that obtaining when the present gelatine P.O.P.s are printed from gelatine negatives of a more or less delicate and feeble type. In the former case the light penetrated deeply into the paper, sometimes even showed on the back, the shadows became deeply bronzed, and as a consequence a large amount of silver was reduced in the image. Under these conditions a good amount of gold was deposited in the toning, and that gave the deep purple-blacks then so much admired.

It has just been said that the paper used in the olden times was only lightly albumenised, but with the highly albumenised paper of the present day deep blacks are not

easily got. The more glossy the paper the less black will be the tones obtainable. It is generally found that the ready sensitised albumen paper will not, as a rule, yield such deep purple tones as that which is sensitised at home. If two pieces, the one of home sensitising (on a plain solution of nitrate sensitised, such as used to be employed) and the other ready sensitised, be printed from the same negatives, they will each be found to take a different colour in the printing. The latter will be much redder than the former, by reason of the citric acid introduced as a preservative, and if either be printed from a feeble negative it will be impossible to obtain a rich purple-black, whatever toning bath be employed. If with this class of negative we are content with warm tones, excellent results may be obtained, but if the toning be carried beyond that stage, the prints will become more or less mealy and of an unpleasant grey colour, as well as lacking in brilliancy.

One of the most used toning baths for albumen paper is the "acetate bath." It is as under:—

Water	8 ounces.
Chloride of gold	1 grain.
Acetate of soda	30 grains.

The bath should be made at least twenty-four hours before it is required for use, otherwise it is prone to yield mealy prints. If it is required for use in less time than that, it should be made with nearly boiling water and allowed to get cold. This bath is very suitable for rich, deep, warm brown, but with very vigorous negatives the toning may be carried to the purple stage without mealiness. The phosphate bath yields, with vigorous negatives, a more or less cold black, and so does the lime (chloride) bath.

The following is a formula for a modified lime bath that has been given to us by an old portrait photographer who used it exclusively in his business for many years, and his

prints were noted for their deep purple-black tones. The formula stands thus:—

Chloride of gold (a tube)	15 grains.
Distilled water	15 ounces.
Lime water	q.s.
Chloride of calcium (pure)	2 drams.

The solution is prepared as follows: The gold is dissolved in two or three ounces of water. A piece of blue litmus paper is then put in, which will be reduced by the acid of the gold. Lime water is then added, a little at a time, until the blue colour of the paper is just restored. The chloride of calcium is then added and the bulk made up with water to fifteen ounces. This is a stock solution which will keep well if stored in the dark. For use, one ounce, which contains one grain of gold, is added to eight ounces of water. This bath may be used over and over again, more stock solution being added as the gold becomes exhausted. With this bath, unlike the chloride of lime bath, very little over-printing is necessary.

In the foregoing what has been said is more particularly with reference to albumenised paper, but it applies equally well to other printing-out papers—collodion, chloride, and gelatine. Unless the negative is of a vigorous character—not necessarily dense—it is next to impossible to obtain brilliant prints of a rich purple or black tone whatever toning bath be employed. It should not be assumed that if vigorous negatives are used the tones must necessarily be purple or black, for if the prints are removed from the bath at an early stage they may be obtained of a warm brown; indeed, of any tone from red-brown to purple-black with almost any bath. The object of this article is to impress on those who write for formulae for toning baths for different colours that more really depends upon the negative than the formula by which the toning solution is compounded.

ENLARGED PAPER NEGATIVES.

(Abstract of paper by Mr. J. M. Sellors, and discussion at the Croydon Camera Club, on the 7th inst.)

THE President, Mr. J. M. Sellors, opened his remarks by pointing out the advantages possessed by enlarged paper negatives over direct enlargements on bromide papers. The former permitted a selection of printing processes, the introduction of figures and clouds, and the like, and a wide amount of control generally, by manipulation of the original transparency and enlarged negative; in addition, they were cheaper and could be worked with ease and comfort. On the other hand, paper negatives took longer to print, showed more or less grain, and were probably incapable of giving such a perfect scale of gradation as a good dry-plate.

Procedure.

The procedure was very simple, and should present no difficulty to those accustomed to direct enlarging on bromide paper. A suitable transparency having been made, it was placed in the lantern, and a trial slip of bromide paper pinned on to the enlarging easel. It was advisable to have the slip of reasonable size, as, when viewed by transmitted light, the eye was apt to be misled in judging gradation and contrast by the unobstructed light at the edges of the slip. For a 15 x 12 negative, for instance, a sheet should be cut in three pieces. The paper should be adjusted so as to include a portion of the two extreme ends of the scale. The whole strip should be given one exposure (not exposed in sections), and then developed; the density judged by transmitted light and the time of development noted. If, after

fixing, the trial slip appeared correct both as to time and exposure and period of development, it only remained to expose and develop the full sheet of paper for the same time with a developer of identical composition. If incorrect exposure or development were indicated, anyone accustomed to enlarging would find no difficulty in making the necessary corrections; but, in doubt, further tests should be made until a satisfactory result was attained. The paper required much fuller exposure than for positive work, and the image in consequence flashed up quickly. The best way was to utilise a dish an inch or so longer than the paper, and pour the developer into the unoccupied end of the tilted dish, and to send it, by depressing the dish, in an even wave over the paper. Should the developer be poured or carelessly, the part which received the first impact frequently showed greater density than the surrounding portions, which might obstinately refuse to "catch up." A somewhat weaker developer, and plenty of it, met requirements better than solutions of normal strength. Almost all developers were suitable. I had years ago employed pyro-ammonia with satisfactory results for developing Morgan and Kidd's old negative paper. Pyrosoda with sufficient sulphite was quite stainless, but he now used either amidol (3 grains to the ounce) or rodinal (15 minims to the ounce). He had recently been surprised to read in a paper in "Camera Craft" that Mr. D'Arvy Power found it necessary to superimpose an ozobrome image on paper negatives to obtain

ficient contrast. In his, the lecturer's, opinion, unless care is exercised, one was apt to get a negative too strong even for a carbon.

The Selection of Papers.

In selecting a paper there were four things to consider: the character of the emulsion, the thickness of the paper, its grain, and the surface of the paper. Among other papers which he had experience of were Kodak *old rapid A*, the present Kodak "Slow permanent," Paget "Platino-matt," Illingworth "Smooth," Wellington "Thin Enammo," and, a recent introduction, Special Smooth." The first-mentioned was excellent for small work, but was apt to tear in large sizes; it was very thin and free from grain. The emulsion, however, would hardly bear the ordeal of waxing, and was best treated with an alternative compound. The paper was not listed, but might still be obtained in order. The Paget paper had a tough emulsion, which would stand anything, but there was a faint diagonal grain, which could be distinguished on close examination of the print. Enammo papers were hardly adapted for the purpose, as the process rendered working-up difficult, and pumice produced scratches which printed. The "Platino-matt" were good. For general work the Wellington Special Smooth was particularly to be recommended; its surface was perfection for working on, the paper was tough and homogeneous, and took wax readily.

The Transparency

Transparencies should be made to suit the speed of the negative paper, and the proposed degree of magnification. A quick paper, or a low magnification, did not require so soft a transparency as a slow paper, or a high magnification. It was difficult to give a satisfactory description of an average transparency suitable for enlarged negative work; it should possess no clear spaces, and the deepest shadows should show an opacity sufficiently low to enable good printed matter placed in contact with the film to be read through the glass. A very slow plate was always the best; for a hard negative a quick plate was to be preferred, but of as fine a grain as possible. Considerable modifications could be made in the transparency by retouching on the front, or by rubbing down with Baskett's reducer. The glass side should also be treated with retouching medium, and worked upon with pencil or stump. Personally, he always placed a piece of etched patent plate behind the negative in the enlarging apparatus, and further broad effects could be introduced by working on the etched surface with pencil and stump, or certain parts might be lightened by the local application of an oily rag. Very delicate effects, such as clouds, could be put in with different shades of soft grey pastel, applied with a camel-hair brush. The glass could be washed and used over and over again, but the etched surface required treating with care, as it was easily damaged.

Translucency of the Negative

An important point which many demonstrators shirked was that of rendering the paper negative translucent. Some met this difficulty by printing from the paper in its natural state. The reason for treating the paper with wax or other medium was to render printing quicker and to minimise grain. He considered the first the more important of the two, as in some cases the medium used, instead of decreasing grain, actually increased it. A certain amount of the right kind of grain in a large negative was not only negligible, but might sometimes be a positive advantage. He had experimented with hard white beeswax, paraffin, Japanese, and vegetable waxes, also spermaceti and ceresine, with little difference in results; the last two, however, were unsuitable, owing to their brittleness. There were three methods of applying the wax: (1) by rubbing a hot iron over the paper with a lump of wax in contact with it; (2) by placing the negative film side down on a hot plate, and rubbing a lump

of wax over it; and (3) by employing a shallow tin tray containing a thin layer of melted wax, kept fluid by placing the tray in a dish of boiling water, the negative being floated on to the wax, film up. In every case superfluous wax had to be removed by placing the negative between blotting-paper, and ironing with a hot iron. This was not so simple as it appeared, for if the paper were not bone-dry the emulsion might run in places; and the right temperature, which should not exceed that of boiling water, should be maintained, an excess of heat frequently giving a badly mottled texture, completely ruining the negative. The first method in the lecturer's hands had been found unsuitable, the paper absorbing the wax unevenly, and resulting in streaks and lines. The second method was better, but with some papers lines were apt to form. The third method had been found satisfactory; if any wax inadvertently came into contact with the emulsion side, the subsequent ironing would remove it. An alternative and good way of treating the paper was to rub in a mixture of equal parts of salad oil and terebene, applied thickly with a brush or rag. The negative was then put on one side in a warm place free from dust, until the paper had soaked up as much of the mixture as it would hold. Several hours were required for this, and a second application might be desirable; should the paper in course of time dry in patches, it could be re-oiled. The only drawback to this system was that the negative was slightly greasy. Another satisfactory method consisted of saturating the paper with paraffin or petroleum lamp oil, surplus being removed with a rag: the oil evaporated in a few months, necessitating a repetition of the process.

Finishing Touches.

To finish the negative, its surface should be lightly rubbed over with fine pumice powder on a pad of cotton-wool, surplus powder being dusted off; any small black specks should next be removed, and shadows deepened, if necessary, with a sharp knife, which naturally worked more evenly on a smooth surface than on a grained one. Broad rubbing down with pumice-powder might next be resorted to, followed by retouching with lead pencils, which are not required so hard or finely pointed as for ordinary negative work. Modelling with stump or cotton-wool and blacklead completed matters; any excess of lead could be removed with pumice and cotton-wool. A final observation by the lecturer, "that it was quite a pleasure to work up paper negatives," made some of the already severely tried photographic purists present look positively ill.

For a solid half-hour prints in carbon, platinotype, bromide, and gum-bichromate, together with enlarged negatives, and direct prints on P.O.P. from the original small negatives, then proceeded from the presidential table with a profusion and liberality that was most satisfying. These started in sets, but got slightly mixed in transit, which was unfortunate, for a presumed set showing a carbon print of sheep, with a companion negative of a rustic style, and a P.O.P. representation of an open landscape, might well have misled a beginner as to the potentialities of "control." Speaking generally, the enlarged prints were of first-rate pictorial quality, and, apart from a certain amount of grain, and limited range of gradation, of good technique.

Discussion

Mr. W. H. Smith pointed out that enlarged negatives, if made on paper, should be on paper expressly prepared for negative work. It was almost impossible to combine the qualities respectively required in negative and positive processes in any one paper. For positive prints the paper must necessarily be opaque, and that involved the addition of certain loading materials. No manufacturer could produce a thick paper reasonably transparent and free from grain. To test for clots of fibre—which would take up more wax than adjacent parts, and give the mottled appearance complained of—a little alcohol should be poured on, and the structure of the paper noted by transmitted light. He

doubted whether in any case waxing decreased grain, though it certainly added to speed in printing, with Mr. Sellors' negatives about 50 per cent. Most waxes were semi-opaque; yellow beeswax was one of the most translucent, though its colour might slightly prolong printing. In this connection a little treatise "On the Treatment of Paper for Special Purposes" gave a recipe for making lantern-slide pictures on paper, which were stated to be equal to those on glass. With this object thin paper (bank post, for example) is placed in a bath of creosote oil, or brushed over with that liquid, and left in contact therewith until any fibrous structure can no longer be detected. The superfluous oil is removed with blotting paper, and the paper transferred to a solution of colophony, or similar substance in alcohol. When dry, the paper is coated with a thin film of gelatine (this merely to take printers' ink), and finally coated with thin spirit varnish.

Mr. Smith then passed round a platinotype print eighteen years old, made from a calotype paper negative taken fifty-five years ago, the exposure on a brightly lit open scene being thirty minutes. Little signs of grain were visible, and in point of general technical quality it left nothing to be desired.

Dr. Mees said that if a substance were used for making the paper transparent, it should have approximately the same refractive index as cellulose; probably creosote oil was satisfactory for this reason. Mr. Smith had shown that the paper support was generally unsuitable for the purpose in view; in his opinion, the other factor, viz., the skim-milk emulsion, was equally ill-adapted. Bromide papers were designed to give gradation when looked at, not when looked through. To use them as negatives meant an entire collapse of gradation and absence of tone values. The striking difference in quality shown in the print from the

calotype negative, resulted from the fact that silver was a constituent of the developer, and built the image up.

Mr. A. E. Salt thought that the autotype and platinotype prints passed round hardly seemed at their happiest. Evidently a more responsive printing medium was required. He suggested that cocoon matting sensitised with a bromide emulsion would supply this want!

Mr. S. H. Written said that many of the pictures passed round were excellent; paper negatives, no doubt, had disadvantages, and, on the other hand, advantages, not the least being cheapness of production.

Mr. Terry said that a convenient way of limiting the temperature of a flat-iron for waxing purposes was to heat it in boiling water; this tip might be useful to those who worked the venerable process. He tendered his best thanks to the President for having so ably demonstrated the immense superiority of dry-plates.

Mr. Sellors, in replying to the appreciative criticisms which had been made, said that he held no special brief for paper negatives, and quite admitted there was a loss of gradation and delicacy, and increase of grain; still, the resulting prints were suitable for such low-grade work as exhibition pictures, which might incidentally be medalled. Personally, they satisfied his artistic aspirations, and, he defiantly added, he should continue using them. He desired to gratefully acknowledge the kind assistance of the Autotype Company and Platinotype Company for making prints at very short notice, and under unfavourable climatic conditions; he was also indebted to Messrs. Wellington and Widdowson for a very complete exposition of the subject.

BROMOIL PRINTING.

II.

A Hint—Filter the Ink.

At one time I was very much troubled with hairs in my ink, but just then I was in the habit of mixing some inks to obtain the colour I wanted, and when I had pigmented several prints I put what was left of the ink into a tin, and some time after used this mixture of a dozen different batches. I certainly secured beautiful colours, and the consistency of the ink was perfect, but when skies or delicate passages were in question the hairs and dust were appalling. A friend who tried my method improved on it by thinning the colour with petrol and filtering through fine muslin; the petrol rapidly evaporated, leaving the pigment in splendid condition for work; and he told me that he never could secure such good colours, especially browns, by careful mixing. Now I adopt another plan. I mix up colours until I get one I like, and then carefully put it away in a small tin box with a close-fitting lid (such as boot-polish tins), and take out a small quantity for use, and throw away any that may be left. I take fresh ink for each print, and clean my brushes with petrol before starting a fresh one. The petrol in the brushes should be allowed time to evaporate before they are used again, but rapid drying is dangerous, for a friend of mine, anxious to dry his brushes in a hurry, placed them in the fender in front of a good fire; the vapour of the petrol caught fire, and his brushes were cremated. They should be wiped dry on a clean fluffless cloth. Whenever a brush is picked up it should be rubbed on the back of the hand to remove any dust or hairs adhering to it, before applying it to a print. But, in spite of all precautions, hairs and dust will find their way on to the print. If they are small ones they may be left alone until the print is dry; they will then come off with a little rubbing, or, if obstinate, they must be picked off with a surgeon's small scalpel. Large hairs on the lighter parts are better removed

while the print is being inked, and this can be done with a softening-brush, preferably dry, but it is often necessary to moisten the brush; this will leave a white mark, which, however, disappears with a few touches of the inking brush.

While we are considering the question of brushes, I may say that a great variety of shapes and sizes is useful, but it is not necessary that they should all be of the expensive fitch kind. Many of the smaller brushes sold by dealers in artists' materials will be useful, especially some of the cheaper kind, said to be made of cow-hair. These, as sold, are rather too long in the hair, and need cutting down to about a quarter of an inch long with a sharp knife. This will produce a slight raggedness at the end of the bristles; but it is of little consequence, as the brushes will be needed only for picking out lights and clouds, etc. If a smooth brush is wanted, it may be obtained by dipping the cut-down brush in hot glue and allowing it to become quite hard by keeping it in a warm place until next day, and then grinding the end smooth on a dry grindstone, or a door-step, which is usually of a fine grit stone. These little extras are best obtained after some practice has been shown what kind are needed. When the work is finished for the day all the brushes used must be cleaned with petrol and wiped dry on clean rag; the bevelled ones should then be slipped into the paper cone in which they are sent out by the dealers. This preserves the shape, which is apt to suffer from frequent use.

Inks and Mixtures of Inks.

One of the most important tools of the Bromoil worker is the ink. I have never succeeded with the special inks sold for the purpose, but with the best ordinary printing ink made for letterpress or litho' work. The kind made for litho' work dries

too stiff. For black prints I have found nothing so good as good quality half-tone ink, and, mixed in various proportions with burnt umber, a series of the most beautiful blacks and tints can be made. These inks are usually sold in tins, and cost from 2s. to 3s. a pound, but a pound tin would last a very long time, and the ink skins over, and some waste is caused; I have persuaded Messrs. Frank Horsell and Co., of Leeds, to put up their ink in smaller tins at 1s. each, and, as the "gentleman" in "Punch" said of soap, "since then I have used no other." I may perhaps add that I do not get a percentage on the sales, I only recommend them from my usual philanthropic motives. Of the black ink, I prefer one called "Congo Black": it is cold enough for suitable rendering of snow or frost, and, when mixed with burnt umber, gives a very fine sepia. A piece of opal glass or a white tile is useful for mixing colours upon, as the result of the mixture can be seen. When a mixture is made the colours must be thoroughly blended together by spreading out with the palette-knife, scraping up to a heap, and spreading out again repeatedly. It is very annoying to find when a print is finished that one part is quite a different colour from another. Some discretion is necessary in choice of colour. I have seen big oil prints in which a great deal of trouble had been taken to reproduce the too dreadful colour of a P.O.P. print fixed without toning. For my own part, I prefer a sepia colour with a suggestion of green; this is easily obtained by mixing a cold blue-black with burnt umber, or raw umber, and sometimes a small addition of blue will produce a beautiful greenish-brown, which gives on the "ivory" paper a pleasant suggestion of old parchment or ivory, a resemblance aided by the surface. Some patience is needed before the newly pigmented print is ready to handle, as the ink dries slowly, owing to the fact that it cannot sink into the paper, but lies on the gelatine surface, and there is no drying by absorption into the paper. In fact, there is no "drying" in the ordinary sense of the word, by evaporation, but rather a "setting" by absorption of oxygen from the air, and I have found a cupboard arranged for drying carbon-tissue very convenient for Bromoils, they are exposed to a good current of air, but protected from dust: a lighted spirit-lamp placed in the cupboard hastens the drying, as it supplies heat and increases the air current.

Finishing Off the Bromoil.

Some inks dry very quickly, especially reds and browns; black is rather slow and some mixtures are very slow. At the end of a week the ink should be so dry that the print may be handled with care, but even when quite dry the image is very easily damaged by scratching or rubbing, and some further protection is necessary. Siccative or specially prepared shellac varnish can be used, but I have found celluloid varnish a very great deal better; the surface is pleasanter, it is more easily applied, and the prints can be mounted by the dry method, which would quite spoil those coated with shellac. As much of the necessary spotting, or working up, as is possible should be done before varnishing, all picking off of hairs, dust, etc., and also the brightening of high-lights (if necessary), with a fine ink-eraser, or indiarubber, should be carried out at this stage. The ink may be still not quite dry when this work is done; it may even be slightly "tacky," so that the hand should not touch the surface when working up. The celluloid varnish should not be too dilute, or the ink may be washed off. The consistency of that sold for varnishing negatives is just right. It must on no account be put on with a brush, or the ink will be removed; it should be applied as in varnishing a negative. If a pool is poured into the middle of the print, and the bottle set down, both hands may be used to bend the print so that the varnish flows over the whole surface. I find this method better than pinning the print on a piece of card-board. The surplus is drained off at one corner, and the

print pinned up to dry in a warm place, keeping, of course, the corner at which the surplus was poured off at the bottom. In an hour or less the surface is quite dry, and will bear any amount of handling, and it can be mounted either wet or dry. The celluloid does not make the surface so shiny as shellac, and any varnish that may find its way on to the back of the print will not show when dry.

When the print is mounted the more delicate spotting can be done, but as much as possible should be done before varnishing. For spotting I always use water-colours, mixed with oxgall to make them take on the greasy surface. Some prefer to put some of the pigment used in inking the print on the edges and to mix up with medium or turpentine for spotting. This ensures an exact match in colour, but I find it difficult to use myself. Some workers advise inking the shadows first with a very stiff ink, and then the half-tones with some slightly thinner. I have not found any advantage in this; it seems to produce coarseness and granularity. I have obtained the best results by inking with one consistency of ink from start to finish. It may be found that a print will not take the ink in the lighter parts, and only coarsely in the shadows; the ink must then be thinned, and either Roberson's medium or Horsell's special thinning medium may be used, but only a very minute quantity should be added. Copal varnish as used by artists will answer the same purpose.

To the busy professional photographer Bromoil should come as a "boon and blessing." I suppose, like myself, they become a little bit tired of going on producing the "usual thing," and they would like sometimes to make a "pictorial photograph," but they have not the time to do the necessary dodging, etc., to secure the effect desired. With Bromoil they need only give the favourite negative to an assistant to make the enlargement or print, have it bleached, and put away until they have a little spare time. It can be prepared for inking in a quarter of an hour, and then they can put into the inking all control they desire. The print before bleaching need only be just a "good straight print." I have found nothing more fascinating myself than inking prints of my architectural negatives, nearly all taken as an antiquarian hobby, and of which in many cases I had no print, because I had not the time to do any prints I cared to keep. For architecture and landscape the process is ideal. Portraiture is much more difficult, especially in those of ladies and children, for the one shortcoming of the process, in my hands, has been the difficulty of rendering large masses of very delicate tone. Heads of old men are much easier, as the tender half-tones are broken up with wrinkles and lines.

The "Mortimer" tray is excellent for keeping the paper moist while it is being pigmented; the device for covering the blotting-paper with fine muslin is very effective in keeping scraps of blotting-paper off the print. A thickness of at least half an inch of blotting-paper is necessary, and it should be "sopping" wet. If the pigmenting of a print is interrupted, it may be left on the pad and covered with the metal cover, and put in a cool place, and the work continued next day. Mr. Mortimer advises the addition of a few drops of formalin to the water with which the pad is moistened, to prevent mouldiness. A small quantity only must be used, or the gelatine of the print will be hardened by the formalin. Probably carbolic acid, or some other antiseptic soluble in water, would prevent the growth of mould in the blotting-paper without the risk of an excess of formalin.

I am afraid that, as in all branches of knowledge, there is no royal road to oil printing, and the experience necessary to success must be bought by taking pains; but to those of artistic taste, who are dissatisfied with ordinary photographs, and yet have no time to devote to the difficult task of dodging negatives, oil printing will appeal strongly. And it so often happens that the necessary modification of a light patch here and a dark place there is so slight and subtle that it is well-nigh impos-

sible to do it in printing, or on the negative; yet those slight modifications may make all the difference between a mere photograph and a picture. If a "straight" print is desired, it can be produced in Bromoil with all the detail of the negative, but without the knife-edge sharpness that most printing methods will give.

It is well to make two prints of each subject that is to be attempted in Bromoil, and bleach one, and work up the other

with chalk or water-colour to the effect desired, and then carry out the modifications while inking. I say it is well to do this but I must admit that I never do it myself; I prefer to let the print grow under the brush, and the desired effect seems to appear without effort. At least, it does so sometimes, but sometimes it doesn't. I shall not be satisfied until I can produce satisfactory portraits; but at present they are very difficult.

HAROLD BAKER.

PHOTOGRAPHY AND OUR ANCIENT CHURCHES.

ECCLESIOLOGY, as a department of antiquarian research, has been defined as the study which concerns itself with those of our old buildings which have been erected for distinctively religious or ecclesiastical purposes, with the view to determining from their architectural and art features their special archaeological character.

Since, however, in carrying out his object, the attention of the practical ecclesiologist is, as a rule, not confined to the study of the buildings alone, but is also bestowed on the examination of their contents and immediate surroundings, it will be seen that the ordinary definition requires to be considerably enlarged if we would express in precise terms the nature of his investigations. It is, however, a matter of but little moment whether we accept the definition in its restricted or in its extended form. In either case, the point, or rather the two points, that are of real importance are those which it is my present object to bring prominently under the notice of readers of the "Journal," namely, the facts, firstly, that ecclesiology offers a most fascinating and instructive field for the employment of the camera; and, secondly, that as this field, though still an extensive one, is gradually but surely being reduced through the force of circumstances over which we have no control, there is, therefore, urgent necessity for steps being taken to preserve an authoritative record by photographic means of the appearance of these sacred memorials of the past, seeing that it is impossible in all cases to avert their destruction. It will, I think, be more convenient if at this stage I deal briefly and summarily with the latter of these two points first, before proceeding to a consideration of the former, that being one on which, for technical reasons, and because of its probably greater interest for photographers as a class, it will, in order adequately to describe the subject in its details, be necessary for me to dwell at some length.

A Compromise between Utilitarians and Archæologists.

It seems hardly needful for me here to do more than allude to the magnitude of the losses which ecclesiology, both in England and Scotland, has sustained of late years through the selfish prejudices and uncompromising attitude of utilitarians on the one hand and the sentimental wrong-headedness of the supporters of the so-called restoration movement on the other, since evidence of the harm which has been done is, unhappily, only too abundant. The protests of local antiquarian associations, the Society for the Protection of Ancient Monuments, leading archæologists at home and abroad, and of many private individuals, to all of whom much credit is due, have, it is true, been effectual in preserving from destruction or disfigurement not a few of our ancient sacred buildings. In many cases, however, mere protests and entreaties, as it is not surprising to learn, have unfortunately failed to avert the impending evil. As Mr. Thomas Hardy, in an article on "Church Restoration" which appeared in one of our leading periodicals recently, very justly points out, the exigencies of the situation are, and from the very nature of things always will be,

such as to necessitate compromise on the questions at issue between the archæologist and his utilitarian opponents. Mr. Hardy's remarks do not of course apply, save in one or two cases, to our abbeys and monastic churches, most of which remain in the ruinous condition in which they were left at the Reformation, nor yet to the numerous churches and chapels of ancient date, likewise ruinous, that are to be met with in our rural districts, but only to such of our old religious edifices as are nowadays actually used for purposes of public worship. These latter, however, it must not be forgotten, constitute the bulk of the sacred edifices of Great Britain, including, as they do, our cathedrals, our parish and our collegiate churches, the chapels pertaining to the universities and to the various ancient charitable institutions, together with a few of the larger churches which in former days belonged to the monastic orders. Without attempting to recapitulate Mr. Hardy's arguments, I may be permitted to express my agreement with his general conclusion, namely, that under the peculiar circumstances in which we are placed, some form of compromise to meet the views of both parties must be regarded as inevitable. What, however, Mr. Hardy omits to mention is, that in cases of this kind we usually find that the so-called compromise, when such has been arrived at, is in reality, whatever it may be in name, a victory for the aggressive party. It is certainly difficult to account for the circumstance, no less unfortunate than remarkable, that the well-founded protests of the archæologist should be thus disregarded and that the comforting verbal assurances so frequently bestowed upon him at the outset of the proceedings by those in authority should, like those made to the Thane of Cawdor on the blasted heath, be "broken to his hope" in the subsequent course of events.

The points here at issue, it will, however, probably be seen, only indirectly concern the photographer. This may be admitted; but at the same time it is undeniable that to all who are interested—as not a few nowadays are—in the preservation of such historical memorials from demolition or ill-treatment at the hands of ignorance and incompetence, they are of a very real degree of importance, and may therefore justifiably be cited as arguments which are calculated to appeal with force to the artistic instincts of the educated photographer. When all is said, the position of the latter is an extremely simple one on the part which he is called upon to play being obviously of a practical nature. Calling to his aid the many resources of modern photography, he will approach the subject of ecclesiology primarily with the definite technical object of producing those means a series of trustworthy pictorial representations of the buildings and monuments which serve to furnish the student with materials for the study of that branch of archæological research.

After what has already been said in regard to the iconoclastic tendencies of the present generation, it will readily be granted that work of this description is very urgently required. Such a photographic survey, not only of our ancient churches, but also of the other existing monuments of antiquity in the country, has indeed become a matter of national necessity.

of the circumstances that in this way only, in most cases, it can be found practicable to preserve for the benefit of posterity a permanent record of the appearance of many precious and unique objects which are in hourly danger of being swept away or destroyed beyond recognition to meet the requirements, real or ideal, of their present-day custodians.

Profitable Subjects for Photographic Record

I shall now proceed to give the promised sketch of the architectural and monumental materials of ecclesiology to which attention was made in the introductory paragraphs of this article. In doing so I shall, however, keep in view the fact that various classes of objects which are included under the wide category just referred to are not all equally well adapted as subjects for the purposes of photographic reproduction. Calling to my aid, therefore, the aid of the principle of selection, I shall attempt rather to direct the photographer's attention to what he will find profitable subjects for the exercise of his art than to invite him to bestow it upon objects which, however interesting in themselves, are nevertheless incapable of being satisfactorily depicted by the means at his disposal.

It would certainly seem advisable, and prove advantageous in the direction of facilitating his subsequent progress, that the beginner should at the outset make himself acquainted with the general principles of ecclesiology as these are laid down by the various architectural authorities.

Among useful works of reference on the subject may be mentioned Rickman's "Architectural Styles," the admirable series of text-books on English church architecture published by Messrs. Parker and Co., of Oxford, and Murray's well-known text-books to the counties of England. For the ecclesiology of Scotland, works of a cheap and popular character are far more numerous. Enquirers, however, may consult with advantage Mr. T. S. Muir's "Ancient Parochial and Collegiate Churches of Scotland," the same author's "Characteristics of Old Scotch Architecture," and "The Ecclesiastical Architecture of Scotland," of Messrs. MacGibbon and Ross, whilst among books of a more expensive kind the late Mr. R. W. Billings' "Baronial and Ecclesiastical Antiquities of Scotland" will be found a repository of valuable information.

Periods of English Architecture.

Architecture in England, so far, at least, as it concerns the ecclesiologist, may be divided into six chronological periods. The first is the Saxon period, which extends, roughly speaking, from about the middle of the seventh century of our era to the year 1065. The limits of the second, or Norman period, known also as the Romanesque, may be fixed as lying between the year 1065 and the last decade of the twelfth century. The third period is that known on account of the prevalent architectural style as the First Pointed or Early English. It includes the century immediately succeeding the Norman period, or approximately the years between 1190 and 1290. During the next or fourth period, which lasted from 1290 to about 1390, the Decorated or Middle Pointed style of architecture came into existence. This in its turn was succeeded by the Perpendicular or Later Pointed style, which prevailed in this country from the end of the fourteenth century to the era of the Reformation. The closing of this fifth period may be regarded as the last chapter in the history of Gothic architecture as a living art in England, for though efforts have been made from time to time by those of subsequent generations to emulate the achievements of the mediæval builders, the glories and distinctive artistic qualities of the earlier styles have never been successfully revived. The sixth and last period assigned to the architecture of this country, i.e., that extending from the middle of the sixteenth century to our own times, may therefore without impropriety be termed the Decadent era. It is, however, sometimes known as the Renaissance period, on account of the extensive use of debased classical forms of the church architecture of England and Scotland during the seventeenth and eighteenth centuries.

Space does not, unfortunately, here permit me to give a description of the architectural features that are distinctive of the different styles pertaining to the several periods of British ecclesiological history. This information, however, my readers may easily obtain for themselves from the works above referred to, as well as from numerous others of a similar kind.

MATTHEW WILSON.

(To be continued.)

THE DIAMIDOPHENOL DEVELOPER IN THE CORRECTION OF OVER- AND UNDER-EXPOSURE.

I have recently pointed out a method of using the pyro developer in which the composition of the working solution was modified during the progress of development according to the degree of exposure in such a manner as to correct, within certain limits, errors in the exposure. This method having given good results with the pyro developer, we have sought to apply it to other developing bodies, and first of all to diamidophenol. In order to fix upon a formula we have examined a number of plans of improving, in the developer, the results of over- and under-exposure. In consulting many sources of information on this subject we have come across a very great disparity of opinion. Some experimenters declare that the addition of sulphite to the developer, whilst accelerating development, favours the production of detail in the shadows, and tends to give grey negatives, such as those obtained by addition of alkali to developers which require to be used with alkalies. It is for this reason that we recommend the addition of excess of sulphite when dealing with under-exposed negatives. Other writers, however, dispute this effect of the sulphite, and maintain that the best means of obtaining negatives of the necessary softness consists simply in the dilution of the normal developer. Writers on the subject are equally at variance as regards

the method to be adopted in improving contrasts and dealing with over-exposure, but they are in agreement as to the very slight effect of bromide when used with diamidophenol, and they express the view that this retarder cannot be used in order to correct over-exposure. Since acid diamidophenol has come into use as a developer, it has been generally thought that sodium bisulphite forms a much more effective restrainer than bromide. In order to throw some light on these different points, and to ascertain the best average conditions for reducing or increasing the contrasts in the negative, the following experiments were made:—

Plates were exposed under identical conditions in the Chapman Jones sensitometer for a time not so long as to give rise to solarization. These plates were developed with a normal diamidophenol developer of the following composition:—

Diamidophenol hydrochloride	5 gms.
Sodium sulphite, anhydrous	30 gms.
Water	1,000 ccs.

Also with a series of developers prepared as described below, so as to give a greater or less variation of the above normal formula:—

- (1) By addition of sodium sulphite up to a saturated solution.

(2) By dilution with increasing quantities of water.

(3) By dilution with sodium sulphite solution of greater or less strength.

(4) By addition of potassium bromide.

(5) By addition of sodium bisulphite.

(6) By addition of both bromide and bisulphite.

After all these additions development was taken up to the point when a given number of the sensitometer appeared of certain equal density: the other densities and the contrasts obtained between the different numbers were then made a useful basis of comparison. The following were the results obtained:—

Correction of Under-Exposure.

The experiments showed that in the case of under-exposure the tendency of hardness in the negatives, when developed in the normal solution, was best corrected by the following methods:—

(a) Dilution of the developer with three to four times its volume of water.

(b) Addition of a strong solution of sodium sulphite.

(c) Dilution of the developer with three times its volume of 5 per cent. sodium sulphite.¹

Of the three methods the last appears to give negatives of the least degree of contrast, but with a tendency to fog. In those negatives obtained by simply diluting the bath, or by the addition of sulphite, no fog was apparent. In cases where it is desired to obtain greatly lessened contrast with, at the same time, the maximum of detail in the shadows, it is desirable to add one volume of developer to three volumes of 5 per cent. sodium sulphite solution, which comes to the same thing as using a developer of the following formula:—

Diamidophenol	1.25 gm.
Sodium sulphite, anhydrous	45 gms.
Water	1,000 ccs.

Despite the smaller proportion of diamidophenol in this developer, the time of development is not appreciably increased owing to the larger proportion of sulphite.

Correction of Over-Exposure.

According to our experiments, the contrast of plates which have received excessive exposure may be improved, but only within comparatively small limits, by adding to the developer one or other of the three following restrainers.

A.—Potassium bromide.

¹ The rise of temperature of the developer, which in the case of certain developing substances gives a distinct reduction in contrast, has no appreciable action in the case of diamidophenol. The only effect produced by warmer developer is a reduction in the time of development, whilst at the same time a certain amount of fog is produced.

AN IMPRESSION OF DUHRKOOP.—Mr. Pirie Macdonald, in "Abel's Photographic Weekly," records his impression of a visit to Hamburg to Herr Dührkoop's unique place of business in the Jungfernstieg, overlooking the beautiful Alster See. Of Dührkoop he writes:—

Short, wiry, compact, fair sandy hair and beard, blue eyes that everlastingly twinkle, for he has a keen appreciation of the humorous and takes more joy in living than any man I know—an alert and tireless worker, a quick thinker with endless perseverance, versatile, sentimental, strongly appreciative of the good in other men, a most generous friend, and I would venture my last "sou" that he could be a mighty unpleasant man to have on one's list of enemies!

His professional activity is simply enormous—the amount of work that he gets through is almost beyond belief—for beside his strictly business affairs he is always up to his eyes in photographers' societies, conferences, exhibitions, and all manner of affairs that take labour and energy; he is constantly preparing exhibits of his work to be sent to all parts of the world—and through the collections he has gathered the world has come to know the German work of to-day.

His is the energy which has brought about the sending of the American professional exhibit to Dresden, and the interested activity

B.—Sodium bisulphite.

C.—Diamidophenol hydrochloride.

By addition of potassium bromide to the extent of 5 gr per litre of normal developer we obtained the most marked increase of contrast. Beyond this point contrasts do not further increase, but the time of development becomes a good deal longer.

The action of the sodium bisulphite, in contradiction of the views which have been expressed hitherto, is distinctly less effective than that of potassium bromide. The bisulphite increases the time of development, but it improves the contrast only to a very small extent. Diamidophenol gives approximately the same result.

It was necessary to make the experiments above described in order to discover if it was possible to lay down a ready method of development with diamidophenol, using two solutions the relative proportions of which could be modified during the progress of development in accordance with the degree of over-exposure. With this object our work was done on plates which had been exposed for very different times—that is to say normally, 2, 4, and 8 times normal, on the one hand, and $\frac{1}{2}$ and $\frac{1}{4}$ normal on the other. We have found that the times of appearance of the image for varying degrees of exposure are very similar, even when working with very much diluted solutions. It is, therefore, not very practical to obtain in this way an indication of the degree of over-exposure, nor to employ a control method for correcting, with certainty, such errors.

In short, while the experiments showed the impossibility of applying to diamidophenol the method of development which we have worked out in the case of pyrogallie acid, yet the results allowed of the following points being established in reference to the improvement of errors in exposure.

(1) In the case of development with diamidophenol the contrasts may be reduced, and under-exposed negatives thus improved, either by diluting the developer with three times its volume of water, or by increasing the quantity of sodium sulphite in the developer, or by diluting the developer with a solution of sulphite in place of the ordinary water. This last means is the most effective, a useful formula being to mix the developer with three times its volume of 5 per cent. sodium sulphite.

(2) The best means of increasing the contrasts and thus improving the result of over-exposure consists, not, as has been usually done hitherto, in adding bisulphite, but by adding to the developer with .5 gm. per 100ccs. of potassium bromide. Nevertheless, the corrections which are thus made are notably less in extent than those which can be secured by using the pyrogallie acid formula previously given.

A. AND L. LUMIERE.
A. SEYEWETZ.

with which he has handled the matter is most surprising when one considers the extent of his business, which in the Hamburg studio alone requires twenty-one people on the permanent staff.

Nor is the work turned out in a routine, commonplace way. All through the establishment you feel Dührkoop! Dührkoop! in everything. He is the arch enemy of the stereotyped. The pose, the order of print, the mount, will often be of half-dozen varieties in a dozen order. Then, too, he finds the studio irksome at times, and goes to make portraits of his people in their homes, in their gardens, their business places, anywhere to break away from the rule and to get them when they are close to themselves—and then to describe them in mere catalogue of facts, for, with Coleridge he believes that a picture is "a middle quality between a thought and a thing."

Of course, before now you have scented the mystery, the woman in the case, and of course the tale would not be complete unless it gives the answer.

The answer is that there is a daughter—a great, strong Rubene blonde—womanly to the utmost degree, but with executive capacity unusual even in a man—sympathetic, enthusiastic, and an accomplished photographer, who will some day make the name even more famous than it now is!

A REFLEX CAMERA FOR PHOTO-MICRO-GRAPHIC WORK.

II.

OR instantaneous exposures of objects which are sensitive to light an accessory piece of apparatus is employed in conjunction with the whole installation described in these pages for March 12 last. Fig. 2 is a diagram of this accessory. The arrangement consists of a plate which is movable in the directions S and A. At 1 and 2 this latter shows square openings, and at 3 it is complete. The arrangement is brought into the path of the illuminating rays at a point where the intersection of the bundle of rays is at a minimum. This means in practice that the accessory must be placed as near as possible in

in the position D E¹ electrical means are put in operation to work the release of the shutter-plate, and the spring then draws the shutter-plate in the direction A. At 2 the shutter-plate has an opening, which gives the exposure, whilst at 3 it again obstructs the light. It follows that the dampening of the light at 1 must be so adjusted that the light-sensitive body is in no way affected. For such exposures the shutter must be taken out at V. The speed of working the shutter may be adjusted by means of a brake, also by winding a spring. Herr Volk mentions, in "Mitteilungen über die biologische Elbe-Untersuchung Ver-

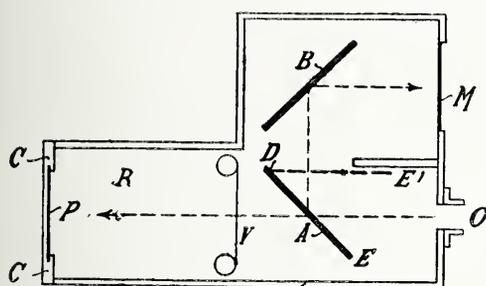

Fig. 1.

front of the microscope condenser. The plate moves in grooves in the direction of A there is a spring. When making an exposure the plate is drawn in the direction of the arrow S against the spring. It thus snaps into a catch as soon as the opening transmits exactly the illuminating beam of rays. Light-filters of any desired kind may be inserted in 1, and whilst in this position the light reaching the object may be reduced or dampened, as desired. Focussing is done with things adjusted as described by means of a weak lens. The ground glass M (Fig. 1) can be replaced by a clear piece of glass. After exact focussing, the lever H is depressed, and as soon as the mirror is

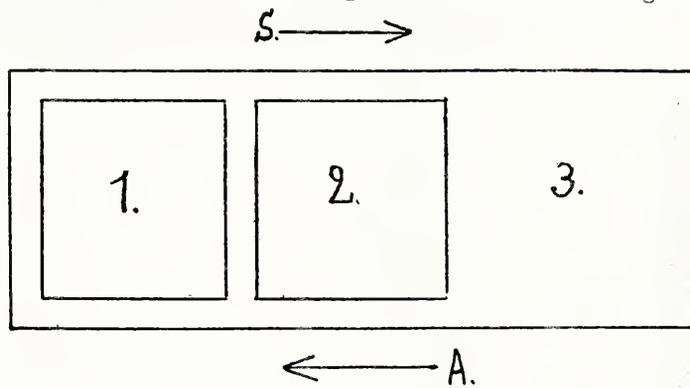

Fig. 2.

handlungen des naturwissenschaftlichen Vereins in Hamburg, 1907, Folge XV.." an arrangement serving a similar purpose. My notice was drawn to his description after I had worked out the arrangement here described in the Carl Zeiss factory, and after I had used it some time with good results. In the prospectus of "Heating Microscopes," issued by Carl Zeiss, there is a description of an arrangement for the instantaneous photo-micrography of heated objects. This arrangement is constructed specially for the purposes mentioned in the prospectus.

DR. W. SCHEFFER.

CONTROL IN THE DEVELOPMENT OF BROMIDE PAPER.

[In the current "Photo-Notes" of the Rotary Photographic Company, Mr. T. H. Greenall further extends the method of tentative development worked out by him for gaslight paper to bromide paper, and gives the following directions and formulæ.—Eps. "B.J."]

Now in working bromide paper, I did not think it possible to deal with such varied exposures as in the case of gaslight paper, but made exposures of the same negative on Rotograph bromide paper, varying as five seconds is to thirty seconds. This is a very considerable difference, and in ordinary development one or other of the prints would be lost. Assuming that five seconds is the shortest possible exposure for the negative, and using a fresh unrestrained developer of maximum vigour, then thirty seconds will give a very foggy and overdeveloped print. On the other hand, if we use a highly restrained developer, the five seconds' exposure will give a hard and chalky result. With the solutions given below, however, which I have found the best for the purpose, the two exposures of five seconds and thirty seconds respectively give prints which are equally bright and of almost equally good gradation, and this without knowing which exposure is which beforehand. It is true that the longer exposure gives a print of a very slightly brown-black, but not objectionably so, and all intermediate exposures will, of course, be quite satisfactory if properly treated during development.

The solutions used are as follows:—

No. 1.	
Pyrocatechin	12 grs.
Sulphite of soda	24 grs.
Potass metabisulphite	6 grs.
Potass bromide	4 grs.
Potass carbonate	60 grs.
Water	4 ozs.

This solution may be used repeatedly.

No. 2.	
Eikonogen	16 grs.
Soda sulphite	64 grs.
Water	4 ozs.

This solution contains no alkali. It will keep, in a full bottle, and may be used repeatedly if the prints are rinsed back and front before immersion. In practice the prints are placed in No. 1 solution, the dish covered and rocked occasionally, and the prints kept properly covered with solution. At the end of six to nine minutes, according

to temperature, they are examined, and those which show little or no image are taken out, rinsed back and front, and transferred to the No. 2 solution, in which they will develop quite satisfactorily unless, of course, the exposure has been hopelessly short. They are then put to fix, and the prints remaining in the No. 1 solution are again examined. Some of these will appear nearly finished, excepting that detail is lacking in the high-lights. These are taken out, rinsed, and given a shorter time in the No. 2 solution, which will bring out the detail in the high-lights if it is at all printable, whilst others of the prints, and these are the maximum exposures, will require none of the No. 2 solution, which, indeed, would veil them, but will yield good prints in the No. 1 solution alone, in a total of twelve to twenty minutes, according to temperature and other conditions, and provided the exposure has not been greater than six times the minimum.

Needless to say, the worker who adopts this method must have abundance of yellow light in his dark-room. I use two sheets of

yellow tissue paper behind which is an incandescent gas jet. This would fog some of the very rapid bromide papers unless used with caution. Then he must know beforehand what his negative can be expected to give—i.e., he must fix on the high-lights which are printable, and for which he intends to develop. In dealing with various negatives he will give a flat one a short or medium exposure and long development in the No. 1 solution, whilst he will give a contrast negative a full exposure, followed by short development in No. 2 solution, and relatively more in the No. 2. Also he must bear in mind that other bromide papers may require some modification of the No. 1 solution, or in the time of development, and that the very rapid ones will be likely to show least latitude, and most liable to fog. The carbonate of potash recommended is of "B.P." quality which is good and cheap. It does not keep well in powder, but makes a permanent 50 per cent. solution. An acid fixing bath must be used. Finally, the prints may be sulphide toned if desired.

T. H. GREENALL.

AN ELECTRIC DEVICE FOR FIRING A FLASHLIGHT.

[The ability to fire a flashlight with certainty in an instant and from a distance being an essential in commercial flashlight work for stage groups, etc., a description of such an electrical device which is given by Mr. F. E. Keller in the "Photo Era" is worthy of notice. The author gives the palm to the electrical method of ignition for certainty of action.—Eds., "B. J."]

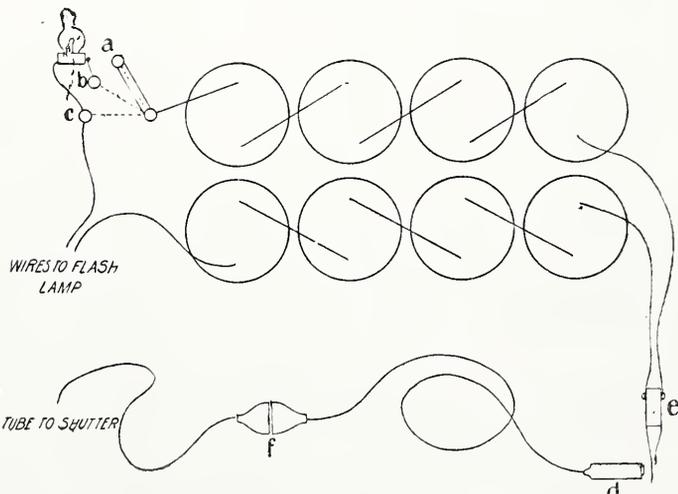

AFTER years of experimenting I have come to the conclusion that the most up-to-date and practical way to fire a charge of flashlight powder is to use electricity. There is no burning alcohol lamp, no inflammable substance to be carried about. Should some one by accident get entangled with the conducting-wire and upset the lamp, all that happens is that a little powder is spilled, which is easily swept up, and surely less injurious to a good carpet than burning alcohol.

My knowledge of electricity is not expert, but I will endeavour to the best of my ability to describe the device I constructed. The battery consists of eight dry cells (Columbia, 1 3/4 x 4 1/2 in.) connected in series. At the one terminal a three-point switch is interposed so as to enable the operator to cut off the battery entirely when the switch is at *a*; at *b* a small incandescent lamp is brought into the

shutter is thrown open, and closed again, of course, the moment the bulb is released.

If a camera with a square bellows is used the lens-board opening will be found plenty large enough to permit the fastening of the shutter on the lens-board, and the contact-fork can be placed on the plunger of the shutter and the contact made with the opening movement of the instrument.

The electric flash-lamp is very simple in construction. Fig. 1 shows

General Plan of Battery.

circuit, which cuts down the current low enough so that the fuse will carry the current safely. This is advantageous, as the operator can test the entire system with the flash-lamp charged with powder ready for firing. When the switch is moved to *c* the incandescent lamp is cut out and the fuse will receive the full current the moment the circuit is closed, which burns the fuse, and, at the same instant, ignites the powder. On the opposite end of the battery-system is a contact arrangement operated with a plunger *d*. At *e* the two terminal points are connected with a fork made of flat German-silver springs fastened to a non-conducting base. The bulb *f* is connected by rubber tubing with the plunger *d*, the other tubing being connected with the shutter (I am using Packard or similar shutters). When pressing the bulb, the plunger will force the two points of the fork together, closing the electric circuit; at the same instant the

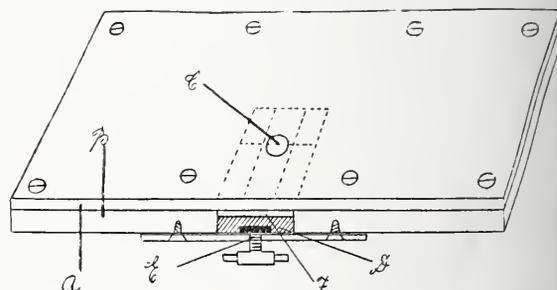

Fig. 1.

the top, and the front sectional view. The top of the lamp *A* consists of 1/8 in. of slate screwed on a wooden base *B*. At *C* the fuse is provided with an opening about 3-16 of an inch in diameter, across which the fuse-wire is placed, making it the firing-point of the lamp. *D* represents a loose wooden clamping-block operated by a clamping screw *E*. At *F* the opening for inserting the fuse is shown. The approximate position of the fuse under the slate top is indicated by dotted lines.

Fig. 2 shows the base of lamp *A* with slate top removed.

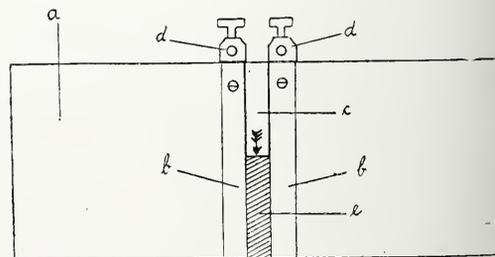

Fig. 2.

German silver contact-springs *bb* are countersunk in grooves their width, and connected with the binding-posts *dd*. The springs are bent so that the clamping block *e* is forced downward, enabling the operator to insert the fuse as far as the shoulder *c*, which acts as a stop.

The fuses are made of thin sheet mica. Fig. 3 is to show the perforation, and method of stretching, the fuse-wire over it.

shows the German-silver contact-shoulders. These thin metal extend on both sides as far as the edge of the perforation. It is readily understood that when the fuse is inserted at the opening C, Fig. 1, the perforation of the fuse will be brought into register with the opening C.

The German-silver shoulders of the fuse rest on top of the con-springs, *bb* in Fig. 2, and when tightening the clamp-screw both and springs are forced against the slate top by the clamping-D.

The advantage of the perforated fuse is that it may be inserted side up, as the powder will reach the fuse as long as the latter is inserted proper end first, so that the perforation will register with the ring-aperture. Another advantage of this lamp is that the con-

Fig. 3.

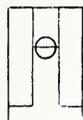

Fig. 4.

springs are not soiled by the explosion of the powder, since they are protected by the mica fuse.

Another very effective method of working a flashlight ignited by electricity is to use a reflex camera. The curtain is opened to its full width, and the spring-tension wound to fairly high speed. The mirror is wound up in the same manner as if a time exposure was made by lifting the mirror and sending down the curtain by additional pressure of the release. A contact-device is so arranged that the flash will explode just when the mirror has cleared the lens, the curtain covering the plate the next instant. This device is of great value in photographing children, as the operator does not have to focus until he sees the desired pose, and then quickly press the release, making the exposure. The curtain covers the plate so quickly that a double image is impossible.

When photographing against the light, this device is invaluable, as it enables one to obtain the most charming effects by combining day-light and flashlight at the same instant. Patents for the use of electrically controlled flashlight devices in conjunction with reflecting mirrors are pending.

F. E. KELLER.

Photo-Mechanical Notes.

The Marking of Lenses for Process Work.

The marking of the F numbers on lenses intended for copying is of much service, as if the work is to be done according to calculation, especially in screen negative making, what is required to be done is the particular diameter of the stop opening and the possibility of making this the actual diameter required for the camera lens then in use. Therefore, instead of, or in addition to, the F numbers, there might be engraved on the mount a series of marks corresponding to millimetres or 1-32nd of inches of stop opening where the indicator pointed to, so that the operator, if accustomed to working with an aperture of, say, one-ninetieth of the normal extension, could, as soon as he knew the latter, instantly set his stop to give him the required aperture. A convenient automatic indicator of the camera extension is in use at the L.C.C. School of Photo-Engraving, and is provided by a spring tape fixed at the side of the camera. This indicates automatically, even though the camera is focussed either from back or front. If such a spring tape were applied with the lens it might be marked for that lens with the indication of the more common enlargements and reductions, and this is another suggestion that might be worth consideration by the makers of lenses for process workers.

A. J. N.

French Method of Preparing Zinc Blocks.

Ch. Gravier, at a recent meeting of the French Photographic Society, gave a description of what he called a simple process employed by the printer, M. Paul Roustan, in order to obtain in a short time a photographic block from a photograph of which a screen-negative had been made. This process was described as being generally used in M.

Roustan's establishment, and the blocks obtained by it printed in his journal, "L'Independant Roannais." A sheet of gelatine paper of the ordinary double transfer kind, such as used in the carbon process, is sensitised in a 3 per cent. solution of potass bichromate, dried in the dark, and exposed for a few minutes under the screen-negative. The print is fixed, by means of pins, to a board, and inked up with a roller and ink of about the thickness of honey. It is allowed to stand for about a minute, then put into cold water for about a quarter of an hour. On removal from the water the ink is taken off with a tuft of cotton wool, and the image is then visible in black on a white ground. The print is then allowed to dry completely. It then only remains to soften it between two sheets of wet unsized paper, and to transfer it to zinc in a press, afterwards etching with acid, in order to obtain the zinco. The advantage of the process is that it dispenses with reversed negatives and with the preparation of the whirled albumenised or enamelline-coated zinc.

This process is a reversion to the very earliest method of making photo-mechanical blocks, namely, "Gillotage." So far from it being more simple than the method generally in use, it is actually being discarded by photo-lithographers themselves, who prefer to print direct on to metal rather than put up with the tediousness and uncertainties of transfer paper. It is true that a reversed negative is not needed, but with a prism or mirror fitted to the camera, a reversed negative is as easy to make as a direct negative; the coating and whirling of a zinc plate is surely no more trouble than the sensitising by bathing of the transfer paper, and does not take anything like the same time. Apart from the ludicrousness of describing this process as simple when compared to the ordinary method, the results as far as quality is concerned must be far inferior, for it is impossible by transfer methods to get the same sharpness as by printing direct.

An American "Mezzochrome" Process.

According to the "British and Colonial Printer and Stationer" of April 1 the Americans were actually the first to publish photogravure in colours printed from rollers by the same method as the well-known Rembrandt prints, as it is stated they were shown prior to May, 1908. Whether this is so or not, there can be no dispute that the Rembrandt Intaglio Photogravure Company were the first to produce black-and-white photogravures machine-printed from rollers, and the coloured photogravures which they produce under the name of "mezzochromes" are simply an extension of the same process. Their long experience of the process is likely to serve them in good stead, and we do not in the least fear the American competition, though to judge by this article there is going to be a strenuous attempt to secure English business. The American process has been worked out by Mr. C. W. Saalburg, a cartoonist of the "New York World," whom photo-engravers will remember as being over here a few years ago selling, as a secret process, inverted photogravure, which many firms bought but none now work. We believe he discovered a former employee of the Rembrandt Company, and engaged him to go back to America with him and help him to invent his "Van Dyck" photogravures. The only example we have seen of the process, so far, is a portrait in the December "Inland Printer." As this, however, could not be put forward as in any way comparing with the results shown here by the Burlington Fine Arts Company, we shall await the further specimens that are promised with interest.

UNITED STEREOGRAPHIC SOCIETY.—The results of the competitions for the session 1908-9 are as follows:—

Annual.—Silver plaque.—Best Collection, S. W. Shore. Bronze plaques—Class A (landscape), "Heaped Hills by the Sea," S. W. Shore; Class B (architecture), "Lucerne Cathedral," A. T. Mole; Class C (portraiture), "I'm a-looking at you," A. Lester; Class D (miscellaneous), "Young Cuckoo," J. E. Ellam. Honours certificate—Class B (still life), "White Currants," S. W. Shore. Certificates—Class A (marine), "To Their Daily Task," A. T. Mole; Class B (still life), "Roses," P. Snow; Class C (architecture), "Nave, Brussels Cathedral," F. Low; Class D (portraiture), "Raising Steam," A. Lester; Class E (miscellaneous), "Denizens of the Lake," A. T. Mole.

Outings Competition.—Value, half a guinea (offered by F. Low), A. T. Mole.

Monthly Competitions.—Prize, Wynne's exposure meter, F. Low.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents have been received between March 29 and April 3:—

- CINEMATOGRAPH.**—No. 7,463. Cinematograph producing and reproducing machine for home use, containing the idea of a living-picture newspaper. Lawson Billinton and Thomas Sapt, 11, Fairlawn Mansions, New Cross Gate, London.
- PRINTING.**—No. 7,480. Improvements in photographic printing apparatus. Philip Middleton Justice, 55, Chancery Lane, London, for John A. Dick, United States.
- PRINTS.**—No. 7,518. Treating photographic prints. Edward Albert Cunningham, 19, Holborn Viaduct, London.
- ANIMATED PICTURES.**—No. 7,702. Improvements in means connected with the exhibition of animated pictures. Jules Paul Martin, 321, High Holborn, London.
- PROJECTION APPARATUS.**—No. 7,910. Improvements in and relating to photographic and projection apparatus. Archer Lloyd Lawrence, 53, Chancery Lane, London.
- POWDER PROCESS.**—No. 7,932. Photographic powder process. Josef Rieder, 323, High Holborn, London.
- TRIPOD DEVICE.**—No. 8,054. Improved device for fixing optical instruments to tripods and other stands. Optische Anstalt C. P. Goerz A.-G., 31, Bedford Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

OPAQUE SENSITIVE FILM.—No. 5,641. 1908 (March 13, 1908). The invention relates to photographic sensitive surfaces of the kind in which the sensitive gelatino-bromide emulsion is applied to an opaque base or support, and has for its object the employment of the negatives obtained on the flexible sensitive surfaces, after exposure in the camera and development in the ordinary manner, in any of the known hydrotype methods of contact printing—printing or obtaining positives without the action of light—as, for example, the method described in Patent No. 13,874, 1907. The flexible opaque material, which is rolled on spools in the manner usually adopted with "roll-films," may be black paper, dark mackintosh, or waterproof cloth, or opaque pigmented celluloid. It is furnished with a sensitive coating as above described, is rolled on a spool, and exposed in an ordinary camera. After exposure the film is removed from the camera and developed. The negative being upon an opaque base or support, is not capable of yielding positives or prints by the usual methods in which light passes through the negative, but is especially suitable for obtaining prints or positives by any of the contact printing methods in which light is not a factor. When an opaque band of light-tight material is coated with emulsion or sensitised as here described, a daylight film spool is obtained by merely rolling the material on a plain reel or spool without any further addition, such as black paper.

The use of the opaque base ensures safer handling of the film in relation to light, as it is absolutely anti-halative and offers complete protection against light acting from behind. Edmund Seal Donisthorpe, 5, Southampton Street, Strand, London.

CINEMATOGRAPH SHUTTERS.—No. 16,420. 1908 (August 4, 1908). The object of the invention is to provide effective means (controlled by the passage of the film through the machine) for automatically closing the shutter in the event of a breakage of the film in machines of the type which have a safety shutter operated by centrifugal mechanism, whereby the shutter is opened when the machine has attained a certain speed, and is closed when the machine is stopped or driven at a lower speed.

The shaft carrying the centrifugal mechanism controlling the

shutter with the main shaft of the machine is connected through a clutch which is controlled by the passage of the film through the machine, in such a manner that immediately the film is broken the clutch is thrown out of action and consequently the shutter is closed owing to the stopping of the shaft carrying the centrifugal mechanism. Albert Arthur Lippold, 172, Lambeth Road, London.

CINEMATOGRAPH-PHONOGRAPH.—No. 8,496. 1908 (April 16, 1908). The invention relates to the connection of a talking machine with a cinematograph, to provide means for synchronously operating the two. The novel features consist in the provision of a disc with contact rings and a contact pointer running in front of the disc, which, with the contact rings, are actuated by the cinematograph and the pointer by the talking machine. The different electric contacts move all in the same direction, and are operated by the machines to be controlled, whereby the contacts when the cinematograph and talking machines are running synchronously are out of circuit, while they, on the other hand, when the machines are not synchronised, close the circuit and thereby put in operation signals which are arranged in the circuit. Alfred Duskes, 17, Friedrichstrasse, Berlin.

New Trade Names.

ROY OAK BRAND (DEVICE).—No. 305,835. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Ragsosine and Co., Ltd., Albion Wharf, Bow, London, E., oil, paint, colour, and varnish manufacturers and merchants. August 28, 1908.

(DEVICE).—No. 310,987. Cinematograph films bearing taken photographs. The Charles Urban Trading Company, Ltd., Urbana House, 89-91, Wardour Street, London, manufacturers and dealers in animated picture specialties. March 3, 1909.

ACMETINT.—No. 310,375. Metal process blocks. The Acme Engraving Company, Ltd., Callow Land Studios, Acme Road, Hatfield, Herts, photo-engravers. February 10, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Titling Negatives.

A writer in the "Bulletin of Photography" for March 31 gives the following method for writing titles on gelatine plates:—"Practically all that one has to do is to write on the film. Use a needle-pointed steel, or a point of any metal, or even bone. There is no chemical action whatever upon the plate. The result is due wholly to pressure. The writing appears fine black on development. A number of scientific experiments have recently been made of the effect of stress on plates. Of course this plan cannot be used on a finished negative, as the action is a developable one, but it may be used for numbering exposures or for writing titles, etc., which is often desirable. The facility and rapidity by which the work may be done are sufficient inducements for naming before development, and not deferring the operation."

FORTHCOMING EXHIBITIONS.

- April 10 to 17.—Midlothian Photographic Association. Sec. B. Sherratt, 8, Castle Terrace, Edinburgh.
- April 27 to May 1.—Maidstone and Institute Camera Club. Sec. J. Harris, 23, Knight-riding Street, Maidstone.
- April 29 to May 17.—Photo Club de Paris. Secretary General, Photo Club, 44, Rue des Mathurins, Paris.
- May 20 to 27.—Malvern Camera Club. Entries close May 10. Sec. J. B. Nickolls, The Exchange, Malvern.
- July 7 and 8.—Canterbury Camera Club. Entries close June 23. Sec., B. J. Fisk-Moore, St. George's Gate, Canterbury.

New Books.

Photography of Coloured Objects. By C. E. Kenneth Mees, D.Sc. Croydon: Wratten and Wainwright, Ltd. 1s. nett.

The theory of the use of the colour-sensitive plate and filters is the subject of this text-book, but the theory is so frequently and copiously instanced by reference to practical work that even those whose cry is all for "practice" will not be disappointed. The person who will be disappointed should such readers skip the parts of the book dealing with general principles will be the author, whose evident aim throughout is to lead the photographer to reason out for himself why such and such a subject requires such and such a conjunction of plate and filter. But we are glad to hope that our author is not destined to feel these pangs of unspiced labour. Certainly, in this instance, he does not deserve them for he has provided in the three opening chapters of the book a most lucid and readable account of the nature of colour, the manner of absorption of light by colour filters and the means to be used to bring the colour-sensitive plate by means of light-filters into correspondence with a required condition. We have no doubt that our author considers these three chapters the section of the book most to be studied, and so it is for an understanding of the use of plates and filters. If the reader presses on to the later chapters it will be because they deal with specific applications of commercial and artistic importance. While these serve the purpose of illustrating the principles of colour-sensitiveness and light absorption they are none the worse for giving a good deal of very useful information. This remark applies particularly to the section "Colour Contrast for Special Purposes," in which the advantages of a properly selective filter in the photography of furniture are most effectively shown.

In Chapter V. on "Portraiture," the author makes a very good case for the use of panchromatic plates and a suitable filter in portraiture. As he admits, the retoucher is a factor to be reckoned with in this case, perhaps to a greater degree than our author concedes, since he would seem to disregard the extensive use made of the knife by retouchers in the passage (page 35): "Even if the retoucher were able satisfactorily to lighten those parts of the print which the ordinary plate has failed to render with sufficient density he would still be unable to darken those parts where the excess of sensitiveness to blue and violet has produced too heavy a deposit in the negative." Apart from the question of the prolonged exposure necessitated by a screened panchromatic plate, the photographer has to balance the lessened cost of retouching against the increased cost of the plates, and thus the merits of the ordinary plate, highly retouched, versus the panchromatic plate, with a minimum of retouching, fall to be decided on other than purely technical grounds. Dr. Mees deals very clearly indeed with the retoucher's system; the pair of portrait examples by Barraud is very striking, and this chapter in particular should be studied most carefully by the portrait photographer. Dr. Mees, it will be understood, aims to dispense with retouchers only as regards tonal values, texture of skin and hair, etc.; even he cannot make a plate which will omit part of a nose or err in kindness as to a lady's waist.

The later portions of the book deal with the photography of coloured objects from the process-worker's standpoint (this chapter by Mr. A. J. Newton) with colour-sensitive plates in landscape work, and with three-colour photography. In all the 70 pages there is not a redundant paragraph, and the volume, in everyday language, is a clear treatise of the important branch of photography which is its subject.

CAMERA WORK, Nos. XXV. and XXVI., New York.—We usually find more entertainment in the letterpress of this magazine than in the pictures, fine though the latter always are, considered as photographic plates. But the articles are, as a rule, more ingenious, more the outpourings of fevered spirits, who take themselves seriously. Some are distinctly clever, some are ostensibly humorous, and others, the most delicious of all, are unconsciously so. Here, for example, is a gem culled from an article upon last year's London Exhibition, by J. T. Keiley:—

Had the jury been heartlessly faithful to the high standard set them, the exhibition would have gained materially in strength;

but there were evidently moments in which the Committee of Selection permitted kindness to influence discretion."

We hope all the outraged "links" will not forget that.

An excellent article, by C. H. Caffin, upon the work of the painter Matisse enlivens No. 25, in which number the usual trumpet-blowing for the "Little Galleries" falls to Paul B. Haviland, and Fredk. H. Evans gives a modest blow for his own concerns in "Personality in Photography."

As to the plates, for those by Annie W. Brigman, much belauded by somebody else on another page, we do not confess to much enthusiasm. Her "Blasted Pines" and "Dying Cedars," which are much mixed up with writhing nudités, appear too far-fetched in idea, and when one thinks of the preliminary machinery necessary for these daring "exposures," one has a feeling that the pictures are vamped up, and lack that easy spontaneity of which a true work of art should bear the impress. Miss Brigman cannot keep us from seeing behind the scenes. She gives us a nude ankle-deep in water, upon the surface of which she floats what appears to be an air-ball. The title is "The Bubble," and we know, by its conformation, that this single shining thing in water, otherwise black in its stillness, is nothing of the kind. The phenomenon is apparently in a cavern, because of certain stalactites above the figure, and the low-lighting from one side. But there is also a willow growing in the cave, which is not the way of willows. Hence the jar to artistic proprieties. There is about all her five plates a certain quality of tone, very agreeable in itself, but entirely foreign to the conditions demanded by the facts depicted. It is a specious sort of artistic effect, Miss Brigman's one and only, by which she does the trick every time. Frauk Eugene's hard and eerie profile of Mr. Stieglitz, with his eye like a black boot-button, we have never liked; but his "Lady of Charlotte"—a title that sounds like a wilful miswriting of the Lady of Shalott—has a beauty of form and modelling.

Those who are interested in the American development of the King's English will be pleased to note the following inventions:—Climatic, expertry, crafter (for craftsman).

In No. 26 there is not so much to read, but two articles should not be missed. They are one upon "Caricature," by B. de Casseres, and one upon "Modern Chiaroscuro Deficiencies," by "A. Chameleon." These are both learned and excellently expressed. Among the pictures, another lady, Miss Alice Boughton, supplies the chief attractions. Like Miss Brigman, she revels in nudes, O Shades of the Pilgrim Fathers! But the one of her six that is not a nude is quite the nicest, called "A Danish Girl." This is a fine piece of lighting and effect. The others are unconvincing allegories in the Brigman manner, but without her feeling for composition and pattern. The group of wormy-looking girls all undressed is positively ugly, and hasn't even the saving grace of an attempted allegory, being simply called "Nude." Despite all of which Mr. Stieglitz, in his sumptuous quarterly (which he produces, edits, and publishes from 1,111, Madison Avenue, New York), challenges the attention of those interested in pictorial photography. One may scoff at, but one cannot afford to ignore, "Camera Work," every page of which has the impress of an enthusiastic tireless personality.

"FIRST STEPS IN PHOTOGRAPHY."—A fourth edition of this very excellent manual, by Mr. J. C. H. Wallgrove, has just been issued by Messrs. Percy Lund, Humphries, and Co. It has been improved by freshly drawn illustrations of apparatus, the lettering of the parts of which make for ready comprehension by the beginner. The book supplies a very reliable guide to negative-making, printing, enlarging, and the preparation of lantern slides, and at the price of 6d. should command a ready sale. Dealers certainly have no cause to complain of the cover, which, in the fourth edition, is a most attractive one.

"T.Q.," No. 5.—It would seem that if you want to develop the Mark Tapley temperament, the best thing is to edit a quarterly photographic periodical. Presumably Captain Owen Wheeler is able to say of his "Telephoto Quarterly," "the work is light and, I may add, it's most remunerative." At any rate, the first part of a new volume of our quarterly contemporary is discovered to be on good terms with itself and the world in general, and so it deserves to be for its very personal and readable contents and its prompt announcements of what is new in telephoto methods. The current issue contains an article by Mr. Harvey Collingridge on "Telephotography Applied to Civil Engineering," and a number of editorial contributions of the eminently helpful description we expect from

Captain Wheeler. We are glad to watch the continued progress of "T.Q.," the yearly post free subscription to which is only 2s., from Captain Wheeler, "Strathmore," Princes Road, Weybridge; or in the U.S.A. from Tennant and Ward, 122, East 25th Street, New York, at a price obtainable on application to them.

New Materials. &c.

LINGRAIN CHAMOIS BROMOIL PAPER.—Messrs. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., have added to the rough and smooth grades of the paper made by them for the bromoil process a new grade, the "Lingrain Chamois." It has a linen-like surface and cream tint, and therefore is very suitable for pigmenting in sepia, whilst giving prints of pleasing surface texture.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 6, Mr. George E. Brown in the chair. A paper by Dr. C. E. K. Mees and Mr. S. H. Wratten on "Some Interesting Absorption Spectra" was read by Dr. Mees. The authors had measured the absorption spectra of a large number of dyes such as would be most suitable for the making of light-filters for orthochromatic photography and three-colour work. Many of the dyes of which measurements were given were of comparatively recent manufacture and data relating to them had not previously been published. The authors described the photographic methods which they had used for recording the absorptions, the most rapid and convenient method being by means of a wedge-shaped cell containing the dye solution illuminated by a small powerful source of light, such as a Nernst lamp. The photographs of the absorption spectra were projected on the screen, and the whole series of measurements, to be published in the full text of the paper, will evidently provide a most useful source of reference to those engaged in the making of light-filters.

Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 6d. in the £ will be paid on the 19th inst., by the Official Receiver, 23, King Edward Street, Macclesfield, on behalf of Alfred Fletcher, photographer, The Studio, Town End, Chapel-en-le-Frith, Derbyshire, and residing at Town End in the same district.

Notice of intended dividend has been given in the case of Walter George Lewis, photographer, 1, Seymour Street, Bath. Papers must be sent to the Official Receiver, Mr. F. L. Clark, 26, Baldwin Street, Bristol, by the 23rd inst.

A first meeting of creditors in the case of Joseph Sharples (trading as the Romanus Publishing Company), photographer, etc., 4, Church Lane, Marple, and formerly of Hollinside, Stockport, Manchester, has been called for the 22nd inst. at the Official Receiver's office, Castle Chambers, 6, Vernon Street, Stockport. The public examination will be held at the Court House, Stockport, on the 30th inst.

An adjudication order, dated April 2, has been made in the case of Florence Pattie Brown, widow (trading as Mrs. F. V. Brown), Liphook, Hants, photographic chemist, etc. The first meeting of creditors will be held at the Official Receiver's office, Portsmouth, on April 19. The receiving order was made on the debtor's petition.

NEW COMPANIES.

W. T. COLE AND SON, LTD.—Capital, £1,000, in £20 shares. Objects: To take over the business of a chemist and druggist, optician, and dealer in photographic materials, carried on by W. B. Cole, at 7, St. Mary Street, Weymouth, and at Melcombe Regis, Dorset, as W. T. Cole and Son. Private company. Registered office, 17, St. Mary Street, Weymouth.

AMERICAN BOUDOIR STUDIOS.—116-117, Chancery Lane, W.C. £1,000 (£1). To take over the business of art photographers carried on by H. O. Dean and C. Clark, at 119, Upper Tooting Road, S.W., as the American Boudoir Studios. Private. 119, Upper Tooting Road, S.W. (101,937.)

News and Notes.

GRANT FOR X-RAYS VICTIMS.—In the House of Commons, last week, Mr. Hobhouse (Secretary to the Treasury), on behalf of the Prime Minister, informed Mr. Bowerman that a grant had been made from the Royal Bounty Fund to Mr. H. W. Cox, who recently sustained serious and permanent injuries in connection with X-rays research work.

DISSOLUTION OF PARTNERSHIP.—The partnership between Arthur Francis Clark and Arthur Victor Mann, carrying on business as commercial photographers, at 1, Adelaide Street, Strand, W.C., under the style or firm of Clark and Mann, has been dissolved by mutual consent as and from the 31st day of March, 1909. All debts due to and owing by the late firm will be received and paid by Arthur Francis Clark.

ROYAL INSTITUTION.—A general meeting of the members of the Royal Institution was held on Monday afternoon (the 5th inst.) at the Duke of Northumberland, K.G., President, in the chair. Mr. L. J. Baker, Mrs. S. G. Brown, and Miss Carvill were elected members. The special thanks of the members were returned to Dr. Hugo Müller for a donation of £100 to the Fund for the Promotion of Experimental Research at Low Temperatures.

WEST SURREY PHOTOGRAPHIC SOCIETY'S EXHIBITION.—At the twenty-first annual exhibition of the West Surrey Photographic Society, held at the Railway Hotel, Battersea Rise, London, from March 31 to April 3 inclusive, the following awards were made by Mr. A. H. Blake, M.A.:—Silver plaque for best picture in exhibition, "In the New Forest," W. H. Goy. Bronze plaques: "Thaw," C. A. Clear; "The Moon Rose o'er the City," A. Lockett; "Wier's Garb," G. E. W. Herbert; "Our Rockbound Shore," R. H. Bassett; "On a Tidal River," V. Nichols. Honourable mention: W. E. Dickford, G. E. W. Herbert, V. Serin, C. A. Clear, B. Gilbert, V. Nichols.

Collins, R. H. Baskett. Lantern slides.—Bronze plaque, Nichols. Honourable mention: V. Nichols, C. A. Clear, and Lovegrove.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—It is proposed to hold a series of exhibitions during the summer months in the rooms of the above society, at 9, Eberle Street, Liverpool. The "A Series of Impressions Rendered by Photography," by John Arbuthnot, will be on view from April 19 to May 10, daily 10 to 7 (Saturdays, 10 to 4). Admission will be free.

THE PHOTO-SECESSION GALLERIES, 291, Fifth Avenue, New York, section of sketches in oil by Alfred Maurer, and also of water-colours by John Marin, both of Paris and New York, have recently been on view, and would appear to have attracted a considerable amount of attention by their original and distinctive schemes of colour. The next exhibition, which is announced to open on April 19, is devoted to a series of photographs of Rodin's "Balzac," by Edward J. Steichen, also of Paris and New York.

BEAUTY AND FASHION PHOTOGRAPHS.—In connection with the "Series of Fashions" to be held at the Horticultural Hall from April 23 to July 3, there will be a competition in which prizes to the value of £150 are offered for photographs illustrating periods of fashions of dress, portraying celebrated women of history, or presenting pictures by great artists. A committee of society members and several artists will select the photographs to be placed before the judges, who are John H. Bacon, A.R.A., W. Hatherell, and R. Child Bayley. Entries are to be delivered to 12, Friars Street, E.C., on or before May 15.

THE THORNTON-PICKARD COMPETITION.—The Thornton-Pickard Company have just issued particulars of the prizes to the total value of £100 which they offer to users of their cameras and shutters. Their competition remains open during the present season, the competing photographs requiring to be sent in on or before October 1 next. The classes into which the competition is divided are:—
Photographs taken with T.-P. cameras, fitted with any T.-P. shutter other than focal-plane.
Photographs taken with any T.-P. focal-plane shutter.
Photographs taken with any T.-P. shutter other than the focal-

Architectural subjects taken with any T.-P. camera.
For beginners (using a T.-P. camera) who have not taken a photograph in any competition.
For stereoscopic photographs taken with a T.-P. camera, or other camera fitted with stereoscopic shutter.
Enlargements from negatives taken with T.-P. cameras or other cameras, or from other negatives enlarged in T.-P. enlargers.
Full prospectus and new rules of the competition are obtainable from the Thornton-Pickard Company, Altrincham, and our dealer in particular should see that they have a supply for their cameras.

AWARDS FOR SCIENTIFIC AND APPLIED PHOTOGRAPHY.—In the hope of creating increased interest in photography in general, and in the annual exhibition of the Birmingham Photographic Society in particular, Dr. Hall-Edwards has formulated a scheme for offering awards for scientific and applied branches of the art. With this end in view he had already secured promises of four subscriptions of one guinea each, and he hoped to get sufficient promises to enable him to offer the Birmingham Photographic Society a complete scheme, which, in the event of the society's acceptance, would cost them nothing. Seven Birmingham firms have already promised to contribute to the fund for providing medals and certificates. The following is a suggested list of classes in which it is proposed to offer awards:—
Scientific.—(1) Prints or lantern slides illustrating the life history of a bird, animal, fish, or insect; (2) photographs or lantern slides illustrating the life history of a plant; (3) prints illustrating the natural history of a back garden; (4) telephotographs; (5) photographs; (6) radiographs (X-rays, radium, and other radio-active substances); (7) geological photographs; (8) prints illustrating the principles of various processes; (9) various scientific applications of photography.

Applied Photography.—(1) Set of photographs illustrating camp and military manœuvres, etc., to be used for recruiting purposes; (2) photographs illustrating the various processes a manufactured

article passes through in its making; (3) best set of photographs of a factory, workshop, bakehouse, dairy, brewery, electric light station, fire station, tramway depot, gasworks, sewage farm, etc., etc.; (4) best photograph suitable for advertising purposes; (5) prints suitable for illustrating a trade catalogue or price list; (6) best set of lantern slides illustrating life in our streets.

THE TYRO IN JOURNALISM.—A most curious departure is observable in the current number of the "B.P.S. Journal," the little organ of the Birmingham Photographic Society, which has hitherto run an orthodox, if undistinguished, career. It has now a London letter—not, of course, a remarkable or improper feature of a provincial periodical, but in this instance attracting comment from the fact that the London correspondent takes the somewhat unusual course of informing his (Birmingham) readers what they of the B.P.S. are doing. We read:—

"Rumours are rife as to important changes in B.P.S. management and procedure during the present year. Some new blood has been elected on the council, and the pace is to be 'hot' for a time.

"Your fellow townsman, Walter I. Morgan, R.B.A., has made quite a hit with his lecture on 'Composition and illustrated criticisms of the recent affiliation print competitions.' His sketches, along with the selected prints, now form the House Exhibition at the B.P.S., and are much appreciated.

"It is much to be regretted that your society is not represented by a single print. Who is to blame for this? Now that the B.P.S. medal has been abolished, the beautiful plaque awarded by the affiliation judges is considered by many pictorialists to be the 'blue ribbon' of photographic competitions, and I cannot help thinking your members have a ground of complaint if they were not properly advised of the competition."

All this no doubt would be interesting enough to Birmingham if it were a fact, whereas the truth, of course, is that Mr. Morgan's sketches are being shown at the Royal Photographic Society, Russell Square, London, and the Birmingham Society, far from abolishing medals, scattered them in profusion at its last exhibition. Inconceivable, of course, that both correspondent and editor have passed "B.P.S." for "R.P.S." Yet perhaps here we may get some explanation for the pseudonym of "Haggard" which the gifted correspondent assumes. Most distressing how printers positively will not make those corrections!

CINEMATOGRAPH REGULATIONS.—The Theatres and Music Halls Committee of the London County Council have drawn up revised regulations for the use of cinematograph lanterns, etc., in premises licensed by the Council. In this they have been partly guided by the views of the Cinematograph Manufacturers' Association of Great Britain and of the National Association of Cinematograph Operators. The proposed new regulations have also been submitted to the Theatres Alliance and Entertainments Protection Association, and no alterations have been suggested by these associations. The revised rules provide that where cinematograph displays do not form a regular feature of the entertainment notice of any intended exhibition must be given to the Clerk of the Council three days before the exhibition takes place. Opportunity is also to be given for the Council's Inspector to examine the apparatus at least four hours before the public exhibition takes place in order to allow time for any alterations to be carried out. In no circumstances is a cinematograph chamber to be placed so as to interfere with the free use of an exit-way, and any temporary alteration in the regular line of a gangway must be amply compensated for by the rearrangement or removal of seats. This is an entirely new rule. The old rules as to the cinematograph room and the lantern have been deleted and entirely new regulations drawn up. These provide that where cinematograph displays form a regular feature of the entertainment the apparatus is to be placed in a permanent enclosure of sufficient dimensions to allow the operator to work freely. This enclosure is to be constructed of solid incombustible materials not less than three inches thick, and be provided with a proper ventilating trunk carried from the highest point of the interior of the enclosure to the outside air. The entrance to the enclosure is to be fitted with a self-closing, fire-resisting, smoke-proof door, placed at the rear of or on the operating side of the apparatus, and opening outwards. Where the cinematograph displays are only occasional the enclosure is not insisted upon, but the lantern must be contained in a smoke-proof box constructed of sheet iron. It is also

laid down that all lanterns shall be placed on firm supports of fire-resisting construction, and provided with a metal shutter which can be readily inserted between the source of light and the film gate. This film gate is to be of massive construction and with ample heat radiating surface, and the passage for the film is to be sufficiently narrow to prevent flame travelling upwards or downwards from the light opening. As before, where possible, electric arc light is to be used as the illuminant, but the new rules provide that circuits where there is a pressure exceeding 250 volts between the poles, or from either pole to earth, shall not be allowed. Where the apparatus is used in a portable box a permanently installed circuit shall be carried to a convenient point. If limelight is to be used in the lantern special attention is to be given to the tubing, which must be of sufficient strength to resist pressure from without. All cinematograph projectors are to be fitted with two metal film boxes of substantial construction and not more than 12 inches in diameter. Such boxes must be made to close in a manner which will prevent the ingress of fire, and must be fitted with a film slot capable of preventing the passage of flame to the interior film box. All films, when not in the machine and still in the operating enclosure, are to be contained in such closed metal boxes. Finally, the following general regulations are laid down: (a) Smoking within the enclosure forbidden at all times; (b) no storage of any description within the enclosure; (c) adequate small fire appliances, including a bucket of sand available outside the enclosure in charge of a special attendant; (d) general lighting of the hall and exits not to be controlled solely from within the operating enclosure; (e) a suitable barrier to be placed round the temporary box to prevent the audience coming into contact with same.

SULPHIDE TONING.

To the Editors.

Gentlemen,—Mr. Brown's difficulty, as described in his letter in the "B.J." of March 19 last, is really very easy of explanation. He found that when he added eight grains of "hypo" to a ferricyanide-bromide bleacher he got an image apparently the same as when no "hypo" was used, but which would not tone. The image given by bleaching with the ferricyanide-bromide bleacher consists of a lake of silver and silver bromide, and the visibility of this is due to the silver. The "hypo" dissolved away the silver bromide and left the metallic silver. Hence, although the image looked the same as a plainly bleached image, it was in reality very different, and, of course, would not tone.

As pointed out in the "B.J.," there is not the slightest doubt whatever as to stale sodium sulphide solutions containing "hypo" or a mixture of "hypo" and the sodium salts of some of the thionic and other sulphur acids. It is also absolutely certain that the majority of bad tones obtained from good silver images are due to stale sulphide. I have assured myself by experiments that even the most careless photographer could hardly leave enough hypo in a print through insufficient washing to affect the toning process. There is, of course, not the slightest need to use stale sulphide solutions. If pure crystalline sodium sulphide is bought in the first instance and kept in a properly corked bottle in the form of a 25 per cent. solution, it will certainly remain good for well over two years. The dilute (1 per cent. or so) solution used for toning should always be thrown away after use.

There is one other possible cause of a poor tone being produced from a good silver image. Mr. Edwards, the originator of the ferricyanide-bromide bleacher, has stated that with repeated use the solution becomes contaminated with potassium cyanide. I have never been able to confirm this, but, if it be so, the effect would

be apparent in the yellowing of the sulphide image. A grows in the ferricyanide-bromide bleacher if it be kept long time, but I have not noticed that any injurious effect results. My experience is that if one gets too yellow a tone either through using bad sodium sulphide or owing to the silver image not being the right kind, then the best chance of improvement is given by each- bleaching the sulphide image in a bichromate-bromide bleacher, and then after washing, again sulphuretting in a pure sodium sulphide solution. The bleacher should be made up as follows:—

I. Conct. sulphuric acid	160 minim.
Water	5 oz.
II. Potassium bromide	150 grains.
Potassium bichromate	90 grains.
Water	5 oz.

For use take equal parts of I. and II. The mixed bleach does not keep well, as it generates free bromine. Free bromine, besides being objectionable on account of its irritating vapour, apparently will often so affect the gelatine film as to render the print more unsatisfactory in tone than it was originally.

In my opinion, neither the ferricyanide-bromide bleacher or the bichromate-chloride one is suitable for bleaching a sulphide image, as the action of both is too slow and feeble.

If any still doubt the effect of "hypo" in the sodium sulphide solution, I would, in conclusion, suggest to them the following experiments:—

(1) Tone a bromide-bleached print with	
Sodium sulphide	0.25 part
"Hypo"	1 part
Water	100 part

The experimenter will get a similar result to that described on the "B.J." a few weeks back, *i.e.* a filmy deposit of silver sulphide on the print showing a metallic sheen. Here the concentration of the sulphide is not sufficient to prevent solution taking place, but it is sufficient to prevent any silver sulphide getting outside the film.

(2) Tone a bromide-bleached print with	
Sodium sulphide	0.1 part
"Hypo"	1 part
Water	100 part

Here a very faint image and a general stain will be produced on the paper, and a precipitate of silver sulphide in the solution. The concentration of the sodium sulphide is not sufficient to precipitate all the silver in the film, but some is dissolved out by the "hypo" and then precipitated outside.

(3) Tone a bromide-bleached print with	
Sodium sulphide	0.03 part
"Hypo"	0.2 part
Water	100 part

Here a faint image is produced, which on treating the print with a normal sulphuretting solution tones in a normal manner. The result is similar to the light images described in "Photo Notes." The image no doubt consists for the most part of unaltered silver bromide (or rather the unaltered lake). As pointed out by myself more than a year ago, and lately by the "B.J.," many have not made sufficient allowance for the fact that the oxidation of the sodium sulphide in stale solutions has not only produced "hypo" or "hypo" and other foreign substances, but has, of course, of necessity decreased the amount of sodium sulphide.—You etc.

31, St. John's Road, Putney, S.W. R. S. BLAKE

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen,—It was quite refreshing to read your remarks on the efficiency of the so-called focal-plane shutter. You very generously give the usual working distance of the blind in the plate as half an inch; I have very often found the distance as much as three-quarters; and this is sufficient under very ordinary working conditions to reduce the efficiency from 100 per cent. to something under 40. This question of shutter efficiency is most important, and I believe is not properly understood by the majority of photographers, and consequently the poor shutter-maker who aims at high efficiency has to give way and follow the lead of

whose ideal is high shine. Hence the value of your remarks from Mr. Salt's lecture; by bringing the attention of photographers to this subject they will tend to increase the demand for scientific instruments; and depend upon it, if there is a demand there will supply.

The exasperating thing is, that when we want efficiency most it is least. If I were going to photograph a house and give 1 second with a small stop I should not much care whether the efficiency of my shutter were 20 or 80 per cent.; but, if on the other hand I had to show the working mechanism of a soaring balloon, at what an unnecessary disadvantage I should be. I have to give the quickest exposure I possibly could. My shutter works at 1-1000th of a second with a slit of 1-10th of an inch, and my lens works at $f/4$, and under these conditions my plate will be nearly three times more under-exposed than was necessary just because the blind of my shutter works three-quarters of an inch from its proper place.

I can only refer to current literature and conversation on the subject to see how loose prevalent ideas are. Even Mr. Salt is a bit doubtful, and makes an appeal to mathematicians. In my example, fig. 20, the efficiency is obviously 50 per cent., and if the distance is doubled, not decreased as he seems to assume. By the way, as I pointed out once upon a time before, no matter what distance the blind may be from the plate, the duration multiplied by the efficiency is a constant quantity, and equals the effective exposure, which is the same as if the blind worked in the focal plane. The calculation for efficiency is very simple.

If we take w =width of slit; d =the distance of the blind from the focal-plane; and a =relative aperture, then

$$\text{Efficiency} = \frac{a w}{a w + d}$$

With a lens working at $f/4$, the width of slit 1-10th of an inch and the distance of blind from plate three-quarters of an inch.

$$\text{Efficiency} = \frac{4 \times \frac{1}{10}}{4 \times \frac{1}{10} + \frac{3}{4}} = \frac{40}{115} = \frac{34.78}{100}$$

This formula is not quite true, because it takes no account of the "coming down" of a beam of light as it passes through the lens; still, it is near enough to be very useful.

I have heard so many absurd claims made for shutters that work nearer the plate than to the lens, and I repeat it was quite interesting to read the remarks in the "B.J.," and I trust they will be ventilated.—Yours faithfully,

Winchester Road, Twickenham. CHARLES J. STOKES.

PROOFS TO BE RETURNED.

To the Editors.

Gentlemen,—Apropos of the paragraph on troubles over proofs to unscrupulous people, who take them to some cheap photographer to be copied, or more frequently (as I have found) copy themselves, I have on my list (enclosed herewith) single copy marked, and, as I always issue proofs finished, in the event of their being given, each proof is charged single copy price, which, as you can see, is sufficiently good to cover the cost of making negative, retouching, and printing.—Yours faithfully,

J. DOUGLAS RITCHIE.

MALVERN CAMERA CLUB.—The annual exhibition will be held in the lecture hall of the Public Library, Malvern, from May 20 to 28 inclusive. The open classes include one for colour photographs (prints or transparencies) and one for stereoscopic work. The best plaques and certificates, with the addition of a silver medal in the champion class, will be placed at the disposal of the club. Mr. Arthur Marshall, for award in both the open and ladies' classes, whilst in the latter a special award in the form of a silver plaque is offered by Mr. J. H. Clive for the best picture. Entries close May 10, on or before which date entry must be accompanied by the necessary fees, much reach the Hon. Secretary, Mr. J. B. Nickolls, The Exchange, Malvern, from whom also further particulars may be obtained. Pictures exhibited in Malvern will be conveyed to Malvern free of cost if so desired.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

F. W. Payne, 12, Shop Street, Drogheda, Ireland. Photograph of a View of Bettystown and Strand. Photograph of Lawrence Street, Drogheda, showing Old Gate and Whitworth Hall. Photograph of Bathers at Laytown.

PAPER.—Can you tell me where I can procure a paper that does not stretch or that stretches equally in both directions?—F.

It is not possible to procure such a paper. Even the best hand-made paper will stretch slightly more in one direction than another under moisture. Thus at the Ordnance Survey they find the paper used for maps stretches as 1 to 1.2. Machine-made papers stretch much more. Some tests made for the L.C.C. School of Photo-Engraving showed that some papers stretched 13 times more in one direction than another when thoroughly moistened, and the best machine-made papers stretch at least five times more in the "cross" section than in the "machine" section.

LENS QUERY.—I have a lens, No. 4,119, by Lerebours et Secretan, Paris (without flange), and would feel obliged if you can tell me use of same. If for portraits, what size? Also, if of any value? Where can I get a flange to suit?—TOM CONWAY.

It is obviously impossible to answer a question such as this. Even the form of the lens, its size, or focal length are not mentioned. We see by the heading of your letter that you are a professional photographer, and therefore should know whether the instrument is a portrait or a landscape lens. If it is the former, its use is, of course, for portraits; if the latter, for landscapes. Why not fix it temporarily on a camera and see what size it will cover? Any lens maker will make a flange to suit the mount.

TADROUS HANNA (Asseout, Egypt).—1. No, there is nothing better than the fine pencil work. 2. It is not readily employed on the negative; we should advise you to make a good enlargement, work that up with the air brush and then make a fresh negative. 3. Nothing but practice.

ANXIOUS.—(1) No registration is necessary. If the establishment comes under the Factory Act the proprietor will be required to comply with the regulations thereby enforced. (2) Any use whatever may be made of the formulæ.

REDUCER FOR CINEMATOGRAPH FILMS.—1. I have just returned from abroad, having been running a cinematograph entertainment by limelight. It has been a practice of mine to reduce dark and overprinted film by the hypo-ferricyanide process. This I found troublesome owing to the difficulties of obtaining water for after-washing. The process also has the tendency to reduce the whites more rapidly than the black, thereby spoiling all the detail of the picture. Can you advise me any other cheap, clean working reducer which would answer my purpose better? 2. Some films now on the market printed in blue, brown, red, etc., will not reduce by this process; the tinting seems to be done in printing of the film itself, no surface colouring being laid on. Can you give me any reducer to act on this kind of printing?—OLD PHOTOGRAPHER.

1. A better form of the hypo-ferricyanide reducer is the following: A. Potass ferricyanide, 1 oz.; ammonium bromide, 1 oz.; water, 10 ozs. B. Hypo, 1 oz.; water, 20 ozs. Use one part of A to eight of B. This will not eat out the detail in the light parts to the same extent as the ordinary reducer. It

is the best cheap solution we know. 2. These films are stained up with dye solutions; the only means of reducing the depth is to pass them through water, the effect of which will be enhanced by addition of, say, 1 per cent. of acetic acid.

M. EMBETE.—(1) The Goerz-Anschutz more than the reflex, on account of the greater convenience of holding at the eye level. (2) Probably 5 by 4 is the most common size. It is very common to enlarge, and in this case a smaller camera is greatly preferable. Some of the very small cameras, such as the Richard Verascope and Goerz Tenax, have come into use of late, since a large aperture lens can be used with scarcely any focussing. (3) The lamp works well. (4) "Retouching," by Arthur Whiting (Dawbarn and Ward, 1s.). (5) See "B.J.," March 26, p. 233, paragraph headed "Sulphide Toning." This will work equally well with the thiomolybdate.

T. G. SNOWDEN.—As you have electric supply, we certainly advise you to use the arc light, on account of its greater economy and lesser heat. One arc will be ample for single portraits, or, at a pinch, for a small group. There are several makes of lamps. You should write for particulars to the firms. See our advertisement pages.

T. R.—Greenberg and Son, Water Lane, Ludgate Hill, London, E.C.

ENLARGING LENS.—(1) What is the difference between a portrait lens and a lens specially constructed as an enlarging objective, both lenses being of the Petzval type? (2) Will the enlarging objective answer equally as well for portraits as the portrait lens?—OPTIC.

(1) The lens often supplied as a "special enlarging objective" is the usual Petzval portrait lens. If of sufficient covering power it is a very suitable lens for the purpose, but the smaller anastigmats of $f/6$ and $f/4.5$ aperture have largely supplanted it for enlarging. (2) Yes.

STAINED FILMS.—I find that the gelatine backing to films takes up stain from developer and fogs prints more or less. Please tell me the remedy.—ENTHU.

Anything which will remove the stain from a negative will also remove it from the gelatine backing, say acid solution of alum; but we should prefer to avoid the stain by use of a suitable developer.

H. AGI'S (Malta).—You will find the announcements of a number of such firms in our advertisement pages.

VARIOUS.—1. I want a show case in which to show my photographs. Can you tell me where I could get one, and if you can suggest any arrangement that would protect it from the sun, when hung out of doors? 2. Also I should like something for my studio that would look like a balcony, and that would be inexpensive. I have written for a catalogue from — and Co., but there seems nothing but rather expensive furniture. 3. Would it be legal when advertising to advertise oneself as retoucher for a certain length of time at a studio in same town?—A NEW READER.

1. Messrs. Marion and Co., Soho Square, stock photographers' show cases. We should advise you to get their price list. The only way of protecting it from sun when hung out of doors is to have a small sun blind over it—one that can be removed when the sun is not on it. 2. The large dealers such as Fallowfield, Houghtons Ltd., and F. E. Jones and Co., will supply such an accessory. But you must not expect to get really good things at a low price. 3. Yes, quite legal, provided you do not make your late employer's name more prominent than your own, or use it in such a way as to lead people to believe that he is connected with your business in any way.

LENS FOR STUDIO.—1. What would be the best half-plate portrait lens for a studio 19ft. long? 2. Is it possible to take whole lengths in such a studio? 3. Is the — Co. a reliable one? as it seems very moderate in the prices, and that is a consideration to us.—STUDIO.

1. The most useful lens would be a short focus cabinet one of from 9 to 9½ in. focus. Such a lens will require about 14ft. between sitter and camera for a full length cabinet portrait, and that your studio will just permit. 2. Yes. 3. Yes, we should say so.

H. D.—1. Quinine sulphate will do if you use a filter on the lens of para-nitroso-dimethyl-aniline. 2 and 3. It is a rather nice

matter of adjusting the ink and the filter. If you write the General Electric Co., of Queen Victoria Street, London, E.C. they would send you an advertisement they issue of the Osram lamp in which a grey imprint is quite invisible until viewed through the red filter.

POSTCARDS ON SALE OR RETURN.—Last summer I supplied a number of postcards of local views to two fancy shops here. They were to be on sale or return. At Christmas I asked for a settlement. They then returned a number of unsold ones, which, through exposure in the window, had faded (gone very yellow), and were useless for sale. These I, of course, refused to take back or allow for, and they then refused to pay the account unless I did. The two shops belong to brothers, and I expect they are acting together. What would you advise me to do in the circumstances?—COUNT PHOTO.

One cannot be at all surprised that the people refuse to pay the accounts unless you take back and allow for the faded pictures. You cannot expect them to be responsible for your bad work. You should not have supplied them with prints so carelessly produced that they would not stand exposure in the windows. You, of course, must allow for the faded pictures.

SEPTIMUS.—We cannot say where you can get carbon tissue of the exact tint of the piece of paper sent. We do not think such a tint is on the market; certainly we have not seen anything like it. One or other of the carbon tissue makers would possibly make you such a colour to order if a sufficient quantity were ordered to make it worth their while.

SUFFERER.—We should say, without doubt, that the state of your fingers has been brought about by the use of the metol. The appearances and irritation described are quite in accord with metol poisoning of the skin. The only real cure for it is to abandon the developer or in future work with indiarubber gloves or finger stalls. If the use of the metol be entirely discontinued the disease usually cures itself in a very short time.

APPRENTICESHIP.—My son was apprenticed to a photographer, Mr. —, of —, for four years. I paid a premium of £25 with him, and was told that at the end of the term my lad would be a proficient portrait photographer. He is now out of his time and left, and is nearly twenty-one. It appears that during the term he was engaged in mounting, spotting, retouching, printing on P.O.P., and occasionally platinum. During the last two years of the term he did all the work of this kind done in the place, but had no experience in the studio. Now Mr. — recommends him to obtain a situation as printer, where he can learn studio work. What I wish your opinion on is this. Is not studio work what he should have been taught by Mr. —, otherwise how can the lad be a proficient portrait photographer, as promised he would be?—FATHER.

Certainly, your son should have been thoroughly instructed in studio work, as that is the most important part in portrait photography. You have good cause of action for the return of the premium you paid, and also for damage for the young fellow's loss of time. Too many photographers take apprentices, more with a view of getting their work done for a nominal wage than teaching the young people their business. Still, the law will meet these cases.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

stereo camera front. We give a description and drawings of a
era front allowing of very convenient adjustment of the
ration between the lenses. By means of a flexible corrugated
section between the two lens panels the separation may be varied
1 2 to 3 1/2 inches. (P. 319.)
An American professional photographer has recorded his methods
making the view postcard a source of profit in his business, and
turning it out in a way which will make it a travelling recom-
mendation of his studio portraiture. (P. 328.)
The advantages of backed plates in portrait photography are
frequently overlooked. (P. 318.)
A description of the methods and facilities of the self-adhesive
printing papers and mounting presses devised by Mr. G. W. Morgan
appears on page 325.
A note on the regulations with which a photographer in Berlin
must comply before he is allowed to take a flashlight photograph
appears on page 318.
The method by which the photographer may prepare for himself a
printing surface from which the mount maker may impress the
photographer's exclusive design is given on page 321.
Mr. F. W. Speaight's scheme for the improvement of the Horse
Guards' Parade is not approved by the present First Commissioner
of Works. (P. 326.)
"Assistants and Apprentices" and "A Caution to Intending Pur-
chasers of Businesses" are two business topics dealt with under
"Correspondence." Other readers address us on the efficiency of
the focal-plane shutter, sulphide toning, and the history of photo-
graphy. (P. 332.)
The annual report of the Eastman Kodak Company records a year's
earnings of one and one-third million pounds. (P. 327.)
Under "Photo-Mechanical Notes" we deal with a suggested photo-
mechanical process, and a method for the facsimile reproduction of coloured
objects, which may frequently be of service. (P. 328.)
Some matters of calculation and practice in telephoto work are dis-
cussed in an article by Professor Edmund J. Mills, F.R.S. (P. 322.)
The method employed in making the Lumière non-flammable
matograph film is given under "Patent News." (P. 328.)
We utter a word of caution as to the use of the iodine reducer.
(P. 318.)
A new method of testing the speeds of instantaneous shutters, which
enables us to be able to measure speeds up to 1-2,000th of a second, has
been worked out at the National Physical Laboratory. (P. 318.)
It is hoped that a revised system of making lens tests at the
National Physical Laboratory will lead to greater use being made of
the N.P.L. certificate. (P. 319.)

EX CATHEDRA.

Photography at the Forthcoming Imperial Exhibition.

According to official information, the photographic section at the International Imperial Exhibition, to be held in the Shepherd's Bush Grounds this year, is to be housed in the fine gallery of the large Fine Arts Palace of last year. We hear that a large representation of the work of leading professional photographers is already arranged for, one gallery being broken up into alcoves, each of which is to contain a one-man or one-firm show. There are also a few trade exhibits. As regards the work of amateur photographers, the organisers of the section have chosen a method which is not likely to result in a collection of distinctive merit. Without the advice, or possibly against the advice, of an honorary committee, which includes Sir H. Trueman Wood, the editors of the "British Journal" and of the "Amateur Photographer" and several Federation secretaries, they have selected two methods of bringing together collections of examples of pictorial photography:—(1) Free admission of collective exhibits from photographic societies, each prepared by the society itself; and (2) Admission of single prints by individual amateur photographers at so much a print. Neither of these methods, we fear, can be commended as a means of securing a choice selection of the enormous numbers of photographs made by amateur photographers, and the second in particular is pretty certain to offend the best exhibitors. Owing to the postponement of the opening of the Exhibition, the last date for securing entries in the photographic section, so, we are informed by the organising manager, Mr. J. F. Peasgood, is May 8.

* * *

The "Free Sitting."

A reader of the "British Journal of Photography," who for many years past has resided in the West End of London, sends us the circular of a firm of photographers offering him free a sitting and one platinotype print if he will accept their invitation, which they extend on the ground of our reader's membership of a well-known learned society. It may therefore be of interest if we quote from a letter addressed to us by the recipient of this invitation:—

Some years ago I used to be pestered by this sort of application (if I recollect rightly, I have had as many as five in a short time), which, of course, are simply a form of touting. In this case I am quite sure that neither the Society nor myself have any desire for these photographs, which, you will understand, are offered in the hope that I or my friends may be induced to order a number of copies at a high price. Messrs. — once had a sitting from me, and their success seemed to start the whole class of touts. I brought the matter to the notice of the "B.J.," and the Editor's remarks led, I hoped, to the practice being stopped. Now either the thing is revived or it is hoped that time has weakened my memory or my intellect, and that my vanity can be worked on.

Our correspondent, in his diagnosis of the photographer's motives, should also have included the acquirement of the

sole copyrights in portraits made in such circumstances; in many cases the only reason for thus "pestering" people to come and be photographed or to let the photographer come to them. We have on previous occasions expressed our belief that such methods are undignified, and in the end most harmful to the business of portrait photography. It may not be particularly dignified for a firm of standing to tout for orders through the post, but this is a commercial age, and we all try to get all the business we can. The reprehensible feature of the "free sitting" system lies in the fact that many persons are ignorant of the result of accepting the invitation, and that the invitation says not a word of the property which the photographer is thereby acquiring in the shape of the sole right to "copy, multiply, or reproduce" his sitter's photograph when and where he chooses. The sitter who discovers this fact for himself later may legitimately describe the "free sitting" system as something worse than a "pest." It is the act of getting, in a not perfectly open way, the right to deal in a person's face which exposes a photographer working the "free sitting" system to the contempt of the public.

* * *

Styles in Christmas Cards.

The letter of "Not Self-Satisfied," which appears on another page, is prompted, it should be explained, by a protest contributed by the Editor of the "British Journal of Photography" to the current issue of the "British Printer." It is there maintained that publishers of Christmas cards have of late years shown so little disposition to depart from a stereotyped style of card that there are opportunities for printers of taste and imagination to produce some of less elaborate but more artistic character. In the great majority of the cards on the market no evidence is afforded of any recognition on the part of the makers of differences in age or sex among senders of Christmas missives, but it would seem from our correspondent's letter, which expresses the views of one very intimately associated with the trade, that the trade houses will meet criticism of their present output with the rejoinder that they supply what the public requires. Changes, however, must inevitably come, and those firms are fortunate who foresee them. Since the photographic illustration may very probably figure in the composition of future varieties of Christmas card, it may be well to watch any tendencies of the more receptive makers to move in this direction.

* * *

Testing Shutters.

The chief difficulty in the way of testing shutter speeds is that of devising some uniform movement representing time. In the method described by Mr. Salt in his paper, published in our issue of April 9, a clock is used to rotate the plate at a uniform speed, and the time is measured by the angular measure of the trail described upon the plate. To render such a contrivance serviceable for shutters of all kinds it is necessary to be able to control the speed of rotation very accurately, and also to be able to modify it to a considerable extent. Thus a speed of one revolution a second is too fast to record an exposure of over a second, and too slow to record one that only equals a few thousandths of a second. The first difficulty can be got over by giving either the lens or the plate a second movement in a straight line so as to produce a spiral instead of a circular trace, but the second difficulty is not so easily surmounted. Shutters that claim to give speeds of 1-2,000 second or less will require at least twenty revolutions a second to enable such small periods to be measured, and it is not so easy to arrange for such a speed. At the National Physical Laboratory a different method is adopted that renders it possible to accurately

measure speeds far higher than any shutter has yet reached. In this method a rotating movement is dispensed with, and a vibrating reflecting galvanometer is used instead. The period of the vibrations is under perfect control, and can be adjusted to suit the shutter under test. A light is thrown on to the mirror, and focussed in a camera, of which the shutter is attached. When the mirror vibrates the image on the plate lengthens out into a short horizontal line, and if the plate is allowed to fall down or is forced rapidly down in a vertical plane, this short line changes to a wavy one, or to a "sine curve." As the plate falls the shutter is automatically operated, and the sine curve recorded on the plate then forms an accurate record of the duration of the exposure. Such an arrangement, of course, involves special apparatus, but it is all very simple, excepting only the vibrating galvanometer and its electric control. No regular motion at a fixed speed is required, and it would not be a difficult matter to devise a similar apparatus with a tuning fork and mirror in place of the galvanometer. For speeds of a second, or over, a pendulum with a little mirror on the bob can be used, but no pendulum contrivance is of any use for high speeds. Tuning forks are somewhat expensive, but it should be possible to devise some cheap substitute that would be equally serviceable for the production of a sine curve on a falling plate.

* * *

Flashlight Work in Germany.

An instance of the thoroughness with which the police authorities in Germany seek to protect the public from all kinds of danger is evidenced by a new circular of regulations issued by the Berlin police office in regard to the photographing of groups and interiors by flashlight. We learn from "Photographische Industrie" that when such exposures are to be made twenty-four hours' notice must be given to the police department, exposures must not be made during any performance, and spectators must be present only in small numbers. As regards the flashlight to be employed, only perfectly dry finely powdered flash powder may be used, and it must be ignited by methods approved by the police, among which is the electric method; but other systems are not permitted.

* * *

A Risky Reducer.

Several times lately we have seen the use of iodine recommended for reduction purposes, the process being the immersion of the image first in an iodine solution and second in a hypo bath. A fairly strong solution (1/2 per cent.) is sometimes advocated, while very seldom is the reader warned of the danger of the operation. Any reduction method that involves a preliminary partial bleaching followed by fixing is of necessity risky; and, after all, the result is only equivalent to that produced by the familiar and safer Farm's reducer, the action of which can be watched. The trouble with all the bleaching methods is that the effect produced is not clearly apparent until after the hypo has been applied. With iodine especially, the amount of effect produced on a bromide print is very much a matter of speculation, since the blue stain imparted to the print obscures the action of the iodine.

* * *

Halation.

We are often surprised to see in professional portraiture very pronounced halation, and the number of workers who regularly employ backed plates in the studio must be comparatively small. Yet the advantages of such plates are manifold, and the cost small, whether the plates are bought backed or are backed as wanted in the dark-room. In all cases where there are

great contrasts, such as white lace against black velvet, the backed plate is practically a necessity if a passable result is desired. It should not be forgotten, however, that though less noticeable in other cases, the halation is nevertheless present. The spreading light slightly fogs the clear shadow tones, and this fog is very apparent, but the same spreading of light also degrades the delicacy in the lighter tones of the picture, destroying that sparkle in the high-lights which is so much admired by the majority of customers. The trouble of backing is after all very slight, for if a saucer is kept in the dark-room, into which a little backing is squeezed each morning from the collapsible tube and thinned with water to which a little glycerine has been added, backing of a suitable consistency will be at hand for the day's work. An old half-plate negative laid over the saucer will prevent much evaporation. The mixture may best be applied with a stiff hog-hair brush, similar to a paste brush, and should be thick enough not to run. In ordinary cases it may be used sparingly, and no trouble will be found from storing the plates for development later on in the day if they are placed in pairs, film to film, while between the two contiguous backed surfaces a small square of brown paper may be placed to prevent the backing from drying and sticking the two plates together.

* * *

Lens Tests at the National Physical Laboratory.

In the report of the National Physical Laboratory for 1908 it appears that very few photographic lenses were submitted for testing during the year, only seventeen, as against twenty-nine for the previous year. This does not suggest a very satisfactory state of things. It is assumed that the fees charged for complete tests serve as a deterrent, so for the future it is proposed to adopt a different procedure in the case of makers who wish to send lenses regularly for test. One lens of a given type must be deposited at the laboratory as a standard. This will be submitted to careful examination to make sure that it is a satisfactory standard, and further lenses of the same type will then be simply examined to see if they come up to the standard. Under this arrangement it is stated that the trouble of examination will be much diminished, and consequently the fees will be very much reduced.

* * *

Loss of Brilliance in Negatives.

It is one of the most difficult matters to decide, on looking at a defective negative, whether its flatness and foginess is due to over-exposure, dark-room fog, fog in the camera, or chemical fog or defective emulsion, and, in fact, it is often only by a system of tests and elimination that the various possibilities may be disposed of one by one, until, as Sherlock Holmes said, "what is left is the fact, however improbable it may at first sight appear." Clean margins where the plate edges have been protected by the rebates of the dark-slide always indicate, however, that any fogging is not produced in the dark-room, and that the loss of brilliance must be sought for in another direction. When it happens that it is only occasionally that plates show this lack of brilliance, it may be well to note with what lens such defective negatives have been produced. There is, of course, the possibility that the lens, by reason of dust on the glass surfaces, is scattering a certain amount of light, enough often, and especially with an air-gap lens, to produce foginess. Or the lens surfaces may have become slightly dulled through too frequent or injudicious cleaning, the brilliance of the polished surfaces being impaired. Moisture, again, on the glass—that is, condensation of moisture sufficient to produce a thin film over

the lens—will have the same effect on the plate. But if all these contingencies have been avoided, it may be well to consider whether the fogging does not arise from reflection from the insides of the camera and the use of a lens with a covering power greatly in excess of that required for the plate in use. It will be obvious that if a wide-angle anastigmat of, say, 8 in. focal length and available for a 12 by 10 plate, is used as an ordinary half-plate lens, a great deal of image-forming light which, working on a 12 by 10 plate, would give the marginal image, is in the half-plate impinging on the bellows, and is possibly being reflected therefrom on to the plate, producing the slight foginess which destroys brilliance.

* * *

Photo-Micrography by Ultra-Violet Light.

Readers may remember that in the special apparatus designed by Messrs. Carl Zeiss for photography with invisible ultra-violet light, focus is secured with the aid of a fluorescent screen.

The National Physical Laboratory have introduced a modification in their own apparatus in the form of a special compensating lens used above the objective. This compensating lens so alters the focal length of the objective as to bring the focus for visible blue light into the same plane as that in which the invisible ultra-violet focus exists when the compensating lens is removed. In other words, they have adapted the well-known expedient often used when non-achromatic lenses are employed for ordinary photography. It is interesting to see in the report that the laboratory claims to have adopted this method of focussing with success, after Messrs. Zeiss declined to make the compensator on the grounds that they regarded the plan as impracticable. The lenses and appliances were then worked out at the laboratory, for which achievement the N.P.L. certainly deserve congratulation.

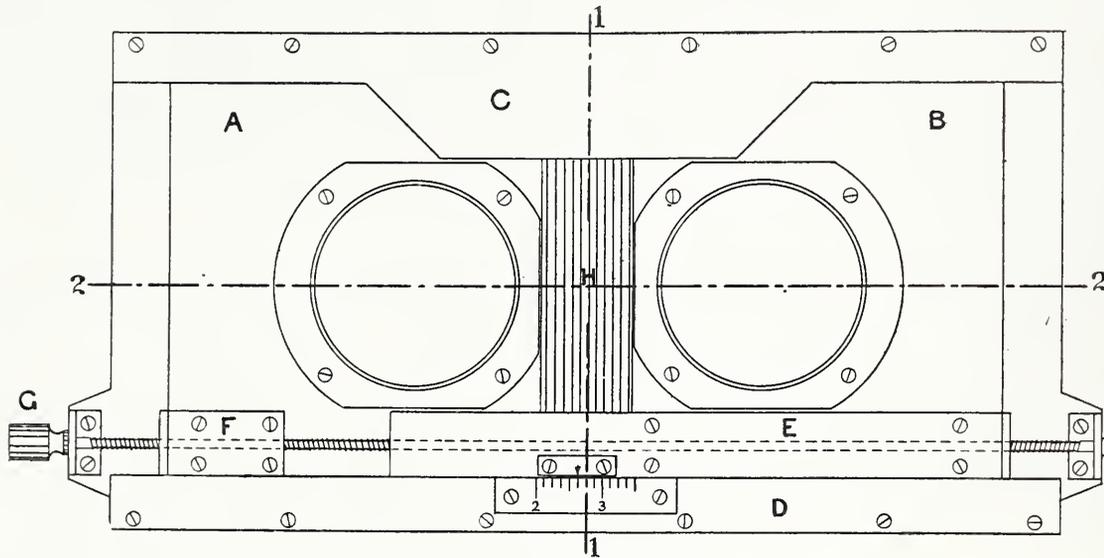

AN ADJUSTABLE STEREO FRONT.

WE have several times of late pointed out the advantages of the adjustable front in the stereoscopic camera, and have recommended that it should have a range of movement of front 2 inches separation up to, say, 3½ inches. At first this may seem rather difficult to arrange, but by practical experiment we have found that it is quite practicable in a front that with lens panels and screw is only ½ inch thick. In the front we have just made, when the separation is 2 inches there is still a space of ½ inch left between the lens mounts, and this is quite sufficient to contain a folded-up, straight bellows, that will expand sufficiently for the widest separation. The folds of the bellows, which is made of roller blind material, are ¼ inch wide, and are perforated so as to run along two guiding wires. Their edges are protected at the back by thin metal flanges, which overlap the bellows by about 1 inch, and in front by the slips that hold the sliding panels. A right and left screw actuates the two panels, and consequently the use of the adjustment is as simple as possible.

In the diagrams the adjustable front is shown in elevation and section, while sketches of the finished article are also given. In the elevation, A and B are the two lens panels, connected together as shown in section 2 by the straight bellows H. C and D are guide strips that hold the panels in place, while F and E are strips protecting the right-and-

left screw G. F is fixed to panel A, and E to panel B: they therefore travel with the panels, while E always overlaps panel A sufficiently to protect the lower edge of the bellows in the gap between the two panels. C is widened out in the centre for the same purpose. E and D are re-

proves to be most suited to the purpose. One complete turn of this screw alters the separation by 1-20th inch. The scale attached shows 1/8ths of an inch, the index moving with E and panel B while the scale is fixed. The screw fits tightly in a square slot cut half in the panels and hal-

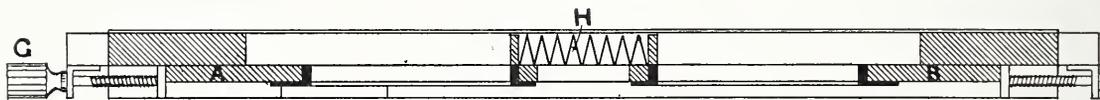

Elevation.

Section 1.

bated, as shown in section 1, so that no light can pass between them. The section shows that the upper and lower edges of the bellows, H, are perfectly protected from direct light, but not from oblique light passing behind C and E

in F and E, and this fact, coupled with the small pitch selected, renders an accidental movement almost impossible. The screw plates are fixed at the ends of F and E where shown, the end plates being bearings only. The

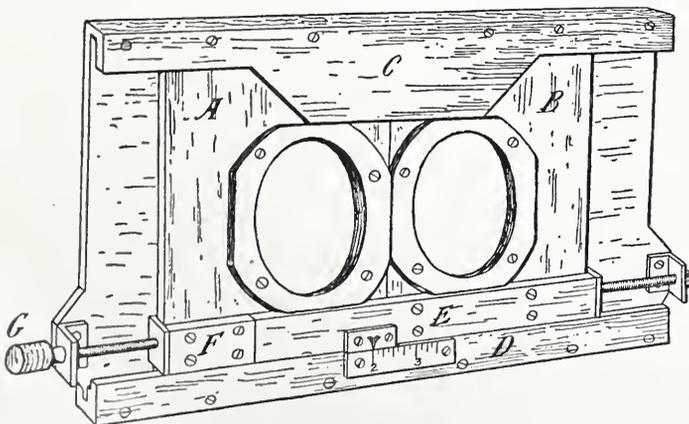

Section of stereo front along line 2-2 of above figure.

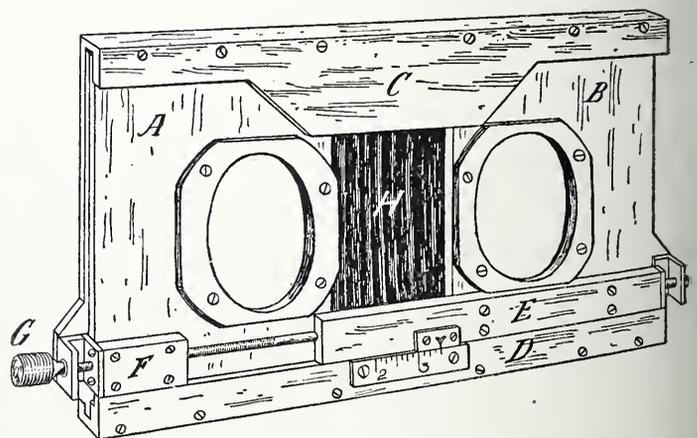

in the space left in front of the bellows when the panels are separated. Any possible leakage from this indirect light is, however, perfectly guarded against by two thin metal strips, S and S, fixed at the back of the panel. These strips also prevent any buckling of the bellows at the back, and the

head of the screw is within easy reach while focussing, and the separation can be adjusted to a nicety while watching the images on the ground glass.

The front illustrated is 3 3/4 inches wide, 7 1/8 inches long, and 1/2 inch thick. It was made to fit the front of a blind

Perspective view of the front showing the lenses at the minimum separation.

View of the front showing the lenses at the maximum separation.

absence of similar guards in front necessitates the use of the rods, R and R, which pass through perforations in the folds of the bellows, and serve as guides to keep them in place.

The adjusting screw, G, is a 1/8 Whitworth thread, which

shutter, and to give a maximum separation of 3 1/2 inches. By allowing for only 3 inches separation, and substituting metal for wood, it could be diminished in both length and thickness, but it is, as a matter of fact, by no means a bulky article as it stands.

HOME METHOD FOR PREPARING DISTINCTIVE DESIGNS IN MOUNTS.

It is not often that one sees entirely original designs on photographers' mounts—that is to say, on those confined exclusively to individual photographers. As a rule, the designs are stock ones as supplied by the mount makers. Nowadays there is not much to be said against them, for the majority are really very artistic. Yet the same design may sometimes be seen on mounts on which the highest class pictures are put, and also those of quite third or fourth-rate quality, a thing which is always liable to happen where designs are drawn from stock.

For this reason some few photographers—though the number is growing—prefer to draw, or have drawn, their own designs for mounts; but even in such cases it is sometimes found that when reproduced by the lithographic craftsman they are not altogether what was anticipated. There is, however, a way by which the photographer, after he has obtained his design, can make from it photographically an intaglio copper plate, from which impressions can be printed, and transferred direct to the stone. Of course, the mounts could be printed direct from the copper plate, but that would be costly as compared with lithography. It may as well be said that a transfer from a copper plate is, as a rule, more satisfactory than when the design is drawn on the stone. We shall now give a method by which any one of ordinary intelligence can produce copper printing plates of various sizes from a drawing, and while such methods may be thought to involve too much trouble in a photographic studio, the system of supplying exclusive mounts to the photographer may be commended to those who cater for the trade in mounts.

In the first place, the design and lettering are done in a strong black ink on a sheet of smooth white cardboard. The cardboard had best be of large size, say, a royal size board. The lines should be bold and solid, more or less bold according to the size of the design. The larger the size the bolder should be the lines; otherwise they will appear too fine, or will be lost in the negative owing to the reduced scale of the reproduction. There is another advantage in making the original drawing on a large scale, namely, that the work need not be quite so neatly done as if it were of the same size as the plate. When the design is finished it is photographed to the size, or sizes, desired; usually several different sizes are required from the one original. The negative should be made as dense as possible, so long as the lines have no deposit upon them. This latter is a *line quâ non*. The lines should be absolutely clear glass, free from fog or veiling. The best plates to use for the purpose are those of the photo-mechanical type. From each negative a transparency is made. This must be of the same character as the negative—that is, the lines must be very dense, while the ground is free from fog or veil. Having prepared a suitable transparency, we will now deal with the production of the intaglio plate.

Copper plates ready polished are stocked by all dealers and printers' requisites. Before use they should be cleaned with a little precipitated chalk, moistened with benzole, and a piece of wash leather, to remove any trace of grease that may remain from the polishing. The plate is next coated with a solution of bitumen. No very definite strength can be given, as different samples vary as regards their sensitiveness to light. But by purchasing the bitumen from those who make a specialty of materials for process work, one can rely upon getting what is suitable. As a rough guide, we may say that if a pint bottle be about a fourth filled with coarsely powdered bitumen, and benzole added so as to fill up the bottle to three-fourths its capacity, a convenient stock solution will be obtained. The best rectified benzole, that known as "No. 1," should be used. The

bottle should be well shaken occasionally for a day or two, and then allowed to subside for three or four days. The clear portion of the contents is then decanted off. This will be too thick for use, and it must be diluted, but for the reason given above no very definite proportions can be given. However, about a bulk to a bulk and half of benzole will not be far wrong. The diluted solution should be filtered before use.

It is now necessary to get a thin, even coating on the copper plate. The best way of doing this is to pour a pool on the centre of the plate, and then rotate the plate on a whirler such as those sold for quickly drying Autochrome or other plates. After whirling for a few minutes, the greater portion of the benzole will have evaporated. The plate is then stood aside for a few hours, in a part of the dark room where it will be warm, so as to allow the last traces of the benzole to evaporate. The plate is then examined, to see if the coating is perfect. If not, the bitumen should be cleaned off with benzole, and fresh applied. It is important that the coating be thin, otherwise the light will not penetrate through the transparent portions of the cliché, so as to render the bitumen insoluble right through to the copper, and it is essential that it should do so. The coating should only be just sufficiently thick to give a slight chocolate colour to the metal and no more. The plate is now ready for exposure.

It is a good plan to rub the transparency over with French chalk before putting it on the plate, to avoid risk of its sticking. Nothing definite can be said with regard to the exposure to light, for, as just remarked, different samples of bitumen differ in sensitiveness. The bitumen process is an exceptionally slow one. Three or four hours to bright sunshine will not be found too much, while two or three days in dull, diffused light may be necessary. It is, therefore, better to err on the side of too much exposure than too little. After exposure, the plate is put into a dish of rectified spirit of turpentine, and rocked for a few minutes. This should begin to dissolve the bitumen from the lines, as shown, by the turpentine becoming slightly tinted. If the action does not take place after a few minutes, a little benzole must be added. Some samples of bitumen are scarcely soluble in turpentine, so that the benzole becomes necessary to help it—sometimes (in extreme cases) to the extent of equal parts. When the lines are seen to be bare metal, the plate is rinsed two or three times in clean turpentine, and then put under the tap, and the water turned on full force to free it from the turpentine. It is then dried, and the edges and back coated with Brunswick black; when that is dry, the plate is ready for etching.

For the etching, either dilute nitric acid, or a strong solution of perchloride of iron may be used, but the latter is the more convenient and pleasant to employ. The plate is put into the etching bath and rockéd. When it is judged that the lines are bitten in deep enough—they need not be very deep—the plate is well washed under the tap, dried, and the bitumen cleaned off with benzole. If, when the bitumen is removed, the surface of the metal looks dull, it should be polished up with a small piece of very fine emery paper. That sold by dealers in engravers' and watch-makers' requisites, known as "blue back" is the kind to be employed. Our plate is now ready to be handed over to the printer, by whom the proofs and transfers are to be taken.

PHOTOGRAPHY IN JAMAICA.—Mr. Alfred B. Hitchin, manager of the photographic department of Messrs. Aston W. Gardner and Co., Kingstown, Jamaica, is now contributing a series of interesting photographic notes, weekly, to the Jamaica "Guardian." The notes will include reviews of new introductions in apparatus and materials, which will thus be brought more prominently before the notice of photographers in the island.

TELEPHOTOGRAPHY.

THE camera used for telephotography should be arranged so as to allow of high magnifications. My own camera is composite. It consists, in front, of an ordinary half-plate camera of about sixteen inches extension, to which can be adapted behind, as one would insert a dark slide, a whole-plate camera, having a pull of about thirty-six inches. Both cameras have five pieces of microscopic cover-glass cemented at the middle and the corners. For determining focal lengths the smaller camera has a vertical and horizontal millimeter scale. The composite camera is carried on a long base-board, which unfastens into three pieces.

The lenses used for telephotography must necessarily be of the finest workmanship if high magnifications are to be dealt with. Indeed, one of the best tests for lenses is their availability for these. Some expensive and much-advertised lenses are quite useless for this purpose. My own experiments have been carried out with homocentric and planar positives and Dallmeyer negatives. For small magnifications, sandwich colour screens of common "optical" glass are good enough; but for the very high ones true optical flats—such as are supplied by Wratten and Wainwright, or Staley—are indispensable.

The equivalent focal lengths of the positive and negative combinations are determined by well-known methods. In the smaller camera some true magnifications are determined by means of the scale engraved on the ground glass, and a suitable test object. These are averaged, and the result compared with the magnification obtained by dividing (the total camera extension measured from the back of the lens to the ground glass) by (the focus of the negative lens) and adding 1. It will be found that the camera extension should have added to it a certain quantity measured inwards into the negative; this quantity is readily calculated from the aforesaid comparison.

In order to focus a distant object, the positive and negative are screwed into their mount, and the two pushed together or pulled apart until, using the entire combination as a telescope, the object appears very clearly. The negative may be a longer focus than is intended to be actually used for the photograph; one obtains in this way more light to place the image on the ground glass. This having been accurately done, the negative intended to be finally employed is exchanged for the other, and a good focus obtained by means of the rack and pinion or sliding adjustment.

To obtain the final and fine focus some means of delicately altering the relative position of the lenses is absolutely necessary. I find that this can be done in a very simple way. All that one has to do is to unscrew the positive in front to the extent of about three-quarters of a turn; the fine adjustment can be very easily made by unscrewing a little further, or screwing in a little nearer.

Much has been written about exposure time. The time of exposure is in reality the time of making an enlargement, and follows the same rule. Thus, if we wish to magnify from n times to m times, the time of exposure for the latter must be multiplied by the well-known factor $\left(\frac{m+1}{n+1}\right)^2$. It is common, in ordinary enlargements, to calculate from the exposure time for equal size; in which case, $n=1$, and the actinometer time is multiplied by $\left(\frac{m+1}{1+1}\right)^2 = \frac{1}{4}(m+1)^2$. As timing for equal

size in telephotography is out of the question, we must find by trial a standard actinometer time which suits the latter equation. This time will then be always afterwards adhered to. The time is very easily found. So that, having this time in mind, we can say that the exposure time will be one-fourth of (the magnification *plus* one) squared.

It is clear that calculating from the square of the magnification only must give very great over-exposure.

The late Mr. Dallmeyer, in his treatise on telephotography, suggests the erroneous rule, but corrects it to a great extent by stating that the time so found will be sufficient to include an allowance for a 2-3 times yellow screen.

Captain Owen Wheeler, to whom telephotography is so much indebted, pointed out (*B.J.*, April 24, 1908) that the "square of the magnification" rule is "altogether wrong," and preferred to take only half the time so calculated—at any rate, for the high magnifications.

Mr. John Nixon, in an article on "Exposures in Enlarging" (*B.J.*, April 17, 1908) pointed out the true rule for enlarging. But this had been, in fact, for many years previously announced in the *B.J. Almanac*—to which source I am myself personally indebted.

Mr. Biermann ("Telephoto Quarterly," December, 1908) follows, at a magnification of twenty-three diameters, the rule announced by Captain Wheeler.

It is clear, of course, that the calculation of the exposure time must depend very much on the time taken to attain the actinometer tint. Probably Messrs. Wheeler and Biermann use a lighter tint than I do; but we should presumably arrive at the same *actual* time in field work. The rule remains. Taking it as a foundation, the experienced photographer will naturally make allowances for distance, clearness of air, and so on, which cannot be expressed in any formula. In my own work I have so far not exceeded about forty-five magnifications and forty-eight minutes' exposure; but with the lenses I have mentioned and using a good test object, I have not unfrequently obtained results undistinguishable from a near photograph of the ordinary kind.

It will be found that a tunnel of some kind cannot be done without, if sharp definition is to be obtained. Anyone who will take the trouble to look, say, at a distant house, through a cardboard tube—blackened inside and eight or nine inches long—will see at once how much clearer the object becomes. The tube acts as a sort of stop in the entering cone of rays, cutting off much of the scattered marginal light. It may have other merits. The matter is so obvious, that the tunnel has come down to us from the early days of photographic portraiture; indeed, it was not uncommon at one time to completely darken the camera end of the studio, so as to make it function as a tunnel. The tunnels I have seen made for use in telephotography are far too short to produce any adequate effect. The one that I use is a sort of square bellows camera with the front and back off, having a total extension of sixteen inches; it is five inches in the side. This is hung on to the camera front and can be collapsed and fixed at any point by means of later lazy-tongs. About six inches in front of a half-plate lens is a desirable extension. As the scattered light, which this cuts off, shortens exposure, so the use of the tunnel slightly prolongs exposure.

EDMUND J. MILLS.

HACKNEY PHOTOGRAPHIC SOCIETY.—On May 11 Mr. E. W. Harvey Piper will give a lecture, illustrated with lantern slides, on "Wells: An Idyllic Minster," at the rooms of the above society, and any

gentleman wishing to be present on that occasion may obtain an invitation by applying to the hon. sec., Mr. Walter Selfe, 70, Paragon Road, Hackney, N.E.

PHOTOGRAPHIC VIEW POSTCARDS.

[In a paragraph last week we commented on the advantage of negatives of local views for use, apart from postcard district, and contributing to the favourable advertisement of the studio. Apropos of the postcard branch of the business, "Wilson's Photographic Magazine," in which the practical methods of commercial postcard production are dealt with, specially in reference to the making of a really good high-class card which shall be a credit to the photographer and a travelling recommendation of his work. This aspect of postcard trade has, we fear, received too scant attention.—Eds.]

to the professional photographer of keeping an up-to-date set of negatives of local views for use, apart from postcard district, and contributing to the favourable advertisement of the studio. Apropos of the postcard branch of the business, "Wilson's Photographic Magazine," in which the practical methods of commercial postcard production are dealt with, specially in reference to the making of a really good high-class card which shall be a credit to the photographer and a travelling recommendation of his work. This aspect of postcard trade has, we fear, received too scant attention.—Eds.]

WHAT follows is not written for such of my fellow-craftsmen who make platinum cabinets at fifty dollars the dozen, and who, at the same time, have more work than they can well do; but for all who receive for their work the prevailing standard prices or less, and who find several weeks out of the fifty-two when they and their assistants could, part of the time, turn aside from studio routine to devote themselves to a lucrative and beneficent, though much neglected, branch of fine art and business.

We are all disgustingly familiar with low-class "spoony" (and sometimes obscene) postcards; apathetically familiar with the crude colourings of two-for-five-cents three-colour process and even lithographed view cards; and scarcely more than tolerantly familiar with half-tone monochrome view cards. And it might be added, though not to the credit of our profession, that to-day the majority of the photographic view cards throughout our land are quite poor enough in quality. Certain it is that the possibilities of photographic view cards have not begun to be realised.

For the Dull Season.

Most of us would be glad, by filling hours we could spare in dull seasons and by keeping assistants employed constantly instead of subjecting them to the unprofitable hardship of a total of several weeks "lay off" every year, or the hardship, to ourselves, of retaining and paying them when there was not half enough work to keep them occupied—we would be glad, say, instead of doing any of these things, to increase our own net annual incomes to the extent of from two hundred to a thousand or more dollars. And the thing is perfectly possible to achieve. Don't you believe it? I have proved it.

Permit me to tell you what I, an ordinary photographer, in a very pretty but not very lively town of six thousand, have done and am doing; and I think that after you have listened to any of you go and do likewise.

When I added to the usual studio work this line I found the shops well stocked—I might say overstocked—with postcards of all kinds, and, among others, a reasonably large variety of photographic view cards of average quality made by a non-resident.

I have already photographed, including additions from time to time, about a hundred and twenty different local views. And let me say right here, do not be afraid of getting too large an assortment. Each negative should be made under the most favourable conditions of light and atmosphere. Say not to yourself: These are for postcards only, and I cannot afford the time and pains. If this is your attitude you will be astonished some morning by finding in the stores, beside your cards, another and a more carefully made set by somebody else, and your venture will be, at least temporarily, at an end.

Selling Subjects.

You will find that churches sell locally, but not very much to transients. If you live in a small place, you must photograph every church, no matter how unimportant or how small its congregation, else some will needlessly be made jealous. Views down streets, panoramic and park views, views of public

buildings and railroad stations, will sell equally to transients and residents. For obvious reasons, it is usually better to photograph depots when the train or trains are in. The station agent will generally be glad to telegraph, without charge, to the next station back to ask the engineer to stop where you wish and to send forth at the right moment a volume of smoke from the locomotive stack. Except to the owners, or unless the buildings for some reason possess unusual interest, views of single business blocks are poor sellers.

Do not forget, when winter comes, to improve your opportunity to secure negatives of rare and fairy-like snow and ice effects. Delay not. Such beauties are evanescent. And if you have not time then to make up the cards, your negatives, if you have made them, will be ready for you as soon as the leisure day comes.

Preparing the Negatives.

It is well to have the exact postcard size marked on your ground glass. Of course, develop with reference to "gaslight" postcards.

Next, cut from undeveloped cards strips of from three-sixteenths to one-fourth of an inch in width. Procure a piece of transparent celluloid of exactly the size of your postcard. Hold this piece against the plate, and thus decide exactly what portion of the negative the postcard is to cover. Lay the negative flat, with the celluloid sheet exactly upon the portion to be printed. Moisten the strips and lay one each against an end and a side of the celluloid, and press firmly into contact with the negative. When you print, these will stop the card at the right place.

Next, take Higgins' India ink, and letter, with a medium pen, the title near what will be the bottom edge of the card, and in as small and unobtrusive letters as you can conveniently make. Of course, the lettering on the negative will have to be reversed. For convenience in classification it is necessary to have the number on each card. I place the number first, next the names of the town and State, after that the title of the subject. This is a logical sequence.

Glossy Cards—Fresh Developer.

It will be found necessary in every use of glossy cards to prepare the developer right in order to obviate "stress and abrasion" marks; for in most cases it is impracticable to handle the view cards in great numbers so as to exercise quite the same care about bringing surfaces into some friction with each other that would be possible in handling two or three dozen in a batch.

You may have your own ideas about a glossy surface being, for most subjects, less artistic than a matte or semi-matte surface. The public also have their ideas, and it is the public's money that you need. And if you want as much of it as possible, you had better use glossy cards.

In printing, print one card to test the time, and then go on and print your fifty to two hundred at once from a negative. Slight overtinting with Kruxo cards (which are what I use) does not produce serious results, but will even give a pleasing

olive tone. Only for snow scenes, where warmth is to be avoided, must the tone necessarily be black and white.

For developer I use metol-hydrochinone. I have found Eastman's non-abrasion M.Q. *perfect* in its use for glossy cards. With it, no bromide of potassium will be found necessary.

Of the bromide I have had to use two drops of 10 per cent. solution and one-third of a drop of a 10 per cent. solution of iodide of potassium to each ounce of developer. The use of less results in the appearance of abrasion marks, and the consequent necessity of cleaning them away with wood alcohol.

Keep the developer as cool as possible. At this season I have, before beginning, set the developing tray into a larger tray partly filled with snow, and left it there until the developer was quite cold, when I removed it. There is no harm in this. In fact, it is really a help, as development is more easily controlled, detail is better brought out, and the danger of stain and fog is reduced. You can get the developer so cold that it will waste your time by acting too slowly. But that is not necessary.

Fixing and Stop Bath in One.

It will be found an advantage to mix your hypo bath very strong, as by so doing you can reduce the danger of staining, and reduce also the time necessary for certain fixing. But don't leave the cards in a strong fixing bath unreasonably long—neither fix them insufficiently. One ounce of acetic acid No. 8 should be used with each thirty-two ounces of fixing bath. I am inclined to think this arrangement preferable to using the acetic acid in solution as a stop bath between the developer and the hypo. Instead, I use for the rinsing bath plain cold water, frequently changed and as cold as possible. This will practically stop development, and the omission of the acetic acid here permits the renewal every few minutes, without expense, of the rinsing bath.

Washing Cards in Numbers.

Washing cards is a problem. A large siphon tank admitting the water through innumerable holes in its bottom is probably the best device; but few of us possess or can possess these. On account of the thickness of the cards they actually need more washing than paper does. But because of the thickness and consequent stiffness the washing results in greater injury to the edges than paper would suffer with the same washing. It is best to wash so as to give the cards the most actual washing possible for a given amount of friction unavoidably incurred.

How to Dry Flat.

Then they must go on to squeegee boards. I use the heavy weight 14 by 20 inch ferrotype boards. These will hold eleven cards each. Roll them under blotters and spread the ferrotype boards out on racks on the floor or shelves before you go home. It is preferable that the cards should not dry rapidly, because if dried slowly they will come off in better shape.

When they come off, go over them card by card. Trim every rough edge and bad corner. If in every process you take all pains you cannot, of course, turn out in a day as many cards as you could if you slighted them. But quality tells; and if you always deliver the quality and never let a card go out that is not a credit to your gallery, the words, "Made by the — studio," with name of city and State printed across one end of the address side, will advertise your studio from Manila on the west to Melbourne on the east.

For storing your cards you will need cabinets made with pigeon-holes. Each pigeon-hole should be numbered, and should be high enough to hold a hundred cards when they lie together, and wide enough not to scrape the cards' edges when you put them in and take them out. The planed half-inch boards upon which bolts of cloth are rolled can be obtained

from dry-goods stores, will cost you little or nothing, and are just the thing to make these cabinets of. The making you can do yourself.

Best to Sell in Quantity.

Makers of sensitised cards will print on the address side what you wish, if you order in large lots. So you can offer to make for a manufacturer, merchant, or hotel landlord cards printed as he wishes if he will order in thousand lots. Real photographic cards of good quality will prove a great advertising medium for him, as they will usually be preserved and looked at often.

It will be found best for your studio not to retail. Also experience has proved it best to go round or to send round an assistant to take orders once every week from every retailer. Do not take an order at any one time from any one dealer for less than five or ten cards of any one subject.

Keeping Tabs on Orders.

In my order book I have the numbers of the cards in vertical columns, one column on the left of each page with lines ruled across the page between them. At the top of the page and between lines ruled from top to bottom are the retailer's names. Thus, all the orders for any given card will be found between two horizontal lines opposite the card's number; and the different views ordered by each retailer in a vertical column below his name—on the principle of the diagram system representing the multiplication table. This method will greatly facilitate the filling of orders, as you can lay out at once in separate piles all the cards ordered each week from each view, and then go on to the next view.

Prices.

How much should you get for your cards? Get \$3.50 a hundred if you can. If you can't get that, take \$3.00; but do not, under any circumstances, job them for less. You cannot afford to do it. If you are turning out cards of the highest grade, and in sufficient variety, you will not have to do it, not even in the face of desperate competition offering to job at \$2.00 a hundred—a price I scarcely see how any man can make, unless he turns over his work to incompetent and underpaid girls, and lets them skimp it. I have met with this two-dollar-a-hundred competition from a non-resident maker, and with the local request to meet the \$2.00 a hundred rate. When this request was repeated, I replied that I was making cards for as little as cards of such quality could be made for, and afford a decent living to the maker; that I wasn't running a sweat-shop; and that before I would reduce the price 1 per cent. I would quit the postcard field. In the face of this competition my cards grew more popular and win larger sales every day. Apparently the \$2.00 a hundred competition has not hurt me.

Brethren, right here let us strike hands not to make sweat-shop prices. Then we can look the world and our employees in the face, for we won't feel that we have to pay our assistants sweat-shop wages. And if we pay them right prices we can, and must, require right quality in their work. And I think it will then be found, in most cases, their intention and pleasure to render it.

How many cards can you job in a year? That depends largely upon the size and kind of town you work in. Small towns will probably sell more than large towns in proportion to population. From my own experience, I should say that an average town of, say, six thousand will use in twelve months about thirty thousand *photographic* view postcards. This estimate, large as it may seem, will, I believe, be found to be quite conservative.

This article is, I am conscious, a long one, but I have made it as short as was consistent with setting forth what appeared to me to be necessary to say on so important a subject.

CHARLES W. JEROME.

MORGAN SELF-ADHESIVE PRINTING-PAPERS AND SYSTEM OF MOUNTING, PLATE-MARKING, ETC., AT ONE OPERATION.

The following notes, written by Mr. G. W. Morgan, the inventor of the materials and equipment, which we reviewed a week or two in these columns, will give a more complete description of the facilities offered to the photographer and manufacturer of photographic papers.—Eds. "B.J."]

days when albumenised paper held full sway and cabinet and e-visite portraits were the universal standards in photography, estimation of how to attach print to mount did not in any way anxiety. Starch-paste, or gelatine, or dextrine, or other formous paste, did all that was required, and did it very well; sometimes the fat subject was occasionally made fatter, and n, leaner, on account of paper stretching when mounted wet. mounted pictures, which had comparatively little mount t, were passed through a heated burnisher or press, and were eady for delivery.

march of time, the desire for novelty, and the advance in al taste have swept away the old order of things, and the proal photographers of to-day are all but confused with the nt styles of portrait demanded by the public, as also the number ntng processes, and the variety in style, size, and shape of s for photographs.

increased margins of photographic mounts, as also occasionally eater thinness of the same, make mounting with water paste r kind unsatisfactory, on account of consequent twisting and d warping of the mount and picture in drying. Prints mounted watery paste have also an annoying tendency to rise at the and, moreover, wet or damped prints have to be handled with ional care to prevent the edges getting frayed.

ry photographer is familiar with the objectionable stretching y prints, and of the necessity of applying some kind of artificial to the same when dry, as, also to flatten the print generally, incidentally, the mount along with it. This is done either by shing, or pressing in a heated press, or by being passed through press. In any case pressure is an essential part of the process ving an artificial finish to a photograph so mounted; and, ally speaking, any of the above methods are effective as regards tng smoothness, and, at the same time, flattening the photo-

re are, however, serious objections to the whole process of tng and finishing of photographs as described. One is, as has ly been stated, the distortion of the picture by mounting in re or less wet condition, and another is the destruction, more s, by pressure of any embellishment that may be on the mount.

e system of mounting prints in a perfectly dry condition by ive preparations acted upon by heat has overcome most of the tions mentioned, but not all, and the writer makes this fact the gy for introducing to general notice the system recently inaugu- l by him, and founded on the more or less scientific application he laws which govern everything chemical, mechanical, or tic, connected with this department of photographic technique. e guiding principles have from the start been kept in view—viz., ency, economy, and simplicity.

Adhesive Backed Paper.

viously the simplest and most economical adhesive would be incorporated in the manufacture of the photographic paper, and, ithstanding the great difficulties of the case, this is now an mplished fact, the efficiency of the adhesive used being daily onstrated.

will be readily understood that work of this description had to one with a certain amount of privacy, and in conjunction with ers of the raw material. In this respect the writer was fortunate esiding near the works of makers of paper of the finest quality , for which purpose the pure water coming from the granite hills Aberdeenshire is eminently suitable. There is no need to dwell the various experiments—extending over a period of years— ired to produce a paper of sufficient purity for the purpose nded, and having on one side a coating of such a substance that, le being inert to salts of silver, it becomes adhesive under certain sure with heat, and produces a contact that cannot again be red. It is sufficient to state that all that has been done, and e is now on the market a British-made paper, the keeping

qualities of which are of a high order. It is free from metallic spots, or other impurities, and in the mounting of it no medium whatever is required, except that possessed by itself. For the immediate convenience of parties using special brands of paper, such as platino-type, etc., a very suitable, effective, and easily worked adhesive solution has been prepared which, while differing entirely from the coating on the paper, is quite as effective for the purpose intended. It is applied to the finished prints—either wet or dry—with a flat brush; the prints are then thoroughly dried, trimmed, and mounted, etc., as directed in the instructions that accompany each tin of solution.

The solution is made from pure ingredients, and is inert to silver salts.

Mounting, Plate-Marking, Embossing, and Die-Stamping Folders.

Another principle kept in view has been the designing and construction of mounting apparatus that, while being efficient in conjunction with such a paper as has been described, as also with commercial adhesive tissue, and Morgan's "dry-mounting" solution, would also be in the highest degree economical. That some measure of success has been attained in this direction is attested by the fact that the finished photograph can now be mounted and the mount plate-marked or embossed in any design, and the name of the artist die-stamped, *all at one operation*, and with practically one movement.

The evolution of the "folder," a special apparatus for this purpose, which, while mounting, also plate-marks, or embosses in relief more or less deeply, according to taste, and also at the same time imprints—also in relief—the name or trade-mark of the artist, took many months of study and experiment. These folders for mounting, etc., are of two kinds—viz., those intended for plate-marking as one of the operations, and those intended for embossing in cameo-relief as one of the operations.

In the first place, the plate-mark is sunk below the level of the mount to any depth desired. It may be a plate-mark of the utmost delicacy, or it may be of considerable depth, with either bevelled or rounded shoulder, and of any size or shape—oblong, square, oval, or round.

In the other case the border embellishment is *raised in relief above* the level of the mount, and may be a simple line or bead only, or it can be made as ornate as the fancy of the artist may desire. In the manufacture of folders for the productions of cameo-relief ornamentation, there is no limit to the number and variety of designs that can be introduced, and a special feature will be made of producing exclusive designs for those desiring something entirely out of the ordinary rut.

The dies are fastened upon thin plates that have by a special process been rendered unwarpable by the heat of the mounting press. The dies are also adjusted so that the mounts do not come in contact with the heated plate except where the pressure is intended, and each "folder" is fitted with a movable gauge, which can be instantly adjusted to any required size of mount, and which registers to the 1/1000th part of an inch. The whole apparatus is simple and lasting in construction, thoroughly efficient in working, not likely to get out of order, produces work of great elegance and beauty, and, what is of the greatest importance to the user, the manipulations are simple, certain, easily learnt, and do not require much physical energy.

In addition to folders for mounting, plate-marking, and die-stamping at one operation, there are other designs for mounting and plate-marking, or embossing only, at one operation, the die-stamping being done by another folder, constructed for this purpose only, and fitted with double ruled lines, permitting of instant alignment.

This is intended for the use of anyone who may not be prepared to go to the expense of having every folder used by them engraved with an expensive design for name or trade-mark, and is thoroughly efficient. The mounted print is placed within the folder, and a slight pressure given under the press, which in this case may be cold, and

the result is an imprint in relief. The only difference in the whole work is that of time, the naming being an extra operation. It is, however, to be recommended for unusual sizes; for standard sizes there is no doubt a great saving in having the mounting, embossing, and naming done at one operation.

There is also a folder constructed for embossing the covers now so usual in high-class work. These are similar in most respects to the others. The work may be done in plain relief, or in gold or colour. The manipulations are as easy as those for mounting, etc., and the work done is of great beauty. For this purpose the press must be used cold.

Presses for Mounting, Etc.

These have been specially designed to work in conjunction with special folders, and are each fitted with a powerful screw running in brass. The screw is acted upon by a heavy wheel, having a long leverage, which rises and falls by its own volition, and is exceedingly powerful and easy to work. The plate is under-heated, as otherwise the patent folders would have to be turned upside down for every print mounted. The bed plate is made very thick, to ensure an even distribution of heat, and also for resisting the great pressure necessary to give crispness to the various designs of dies required for the mounts.

Being under-heated, less gas is required, and the combustion being thorough, no bad fumes are given off.

The presses are constructed to permit of two persons working at the same time if desired, one filling while the other is pressing, and vice versa, so that the pressure wheel and screw are never idle for a moment during mounting, etc., operations. Two girls can easily mount, plate-mark, or emboss, and die-stamp, 250 prints, cabinet size or under, per hour.

The whole process as described presents certain features to the photographer that are worthy of his attention and consideration. The adoption of this process will save him at least 75 per cent. outlay in this department. There is no limit to the variety in size, shape, and designs. It will prevent a great deal of worry, inseparable from the stocking and replenishing from time to time of a large variety of more or less expensive mounts. No kind of mountant is required. Employees' time is saved. The whole work is more scientific, the plate-marking, etc., being the *result* of mounting, is therefore more correct. At a moment's notice a repeat order can be given, the same in every respect as the original order; and, lastly, the apparatus is not expensive, and can be added to from time to time.

For the whole of the operations herein mentioned there are complete and comprehensive instructions, and daily demonstrations are given at the premises of the sole agents, O. Sichel and Co., 52, Bunhill Row, London.

G. W. MORGAN.

THE PHOTOGRAPHIC RECORD AND SURVEY OF SUSSEX.

The following is the Report of the Council for the year 1908:—The last annual report was issued in April, 1908; during the interval a fair amount of progress has to be recorded, but much inconvenience has been caused by the unavoidable resignation of Mr. L. A. Gilbert of the post of hon. secretary; the best thanks of the Association are due to him for the time and attention he so freely gave to the cause; so far no successor has been appointed. Anyone willing to undertake the work should apply to the Hon. Curator, The Public Library, Brighton. It is necessary that the hon. secretary should be a resident in Brighton or Hove.

A pamphlet has recently been issued by the Association with a view of encouraging photographers to help in the work of the Association. The numerous camera clubs and photographic societies in the county surely must include some members who would be willing to devote at least a portion of their time to the distinctly and permanently useful purpose of benefiting the county and the public at large, by making records of the archaeological and antiquarian subjects which are scattered throughout the county.

The Association possesses a large collection of negatives and lantern slides; catalogues of these are drawn up for reference, and as an instance of the value of this collection, many negatives taken about forty years ago have been found most useful in compiling the article on the ecclesiastical architecture of Sussex in Vol. II. of "The Victoria County History of Sussex," while recently the Sussex Archaeological Society has availed itself of some of the lantern slides for illustrating lectures given in various parts of the county.

A further instance of the value of the records in possession of the Association is that recently a thirteenth century string course and piscina in the interesting church of Rustington were unfortunately destroyed to make way for panelling; fortunately the Association possesses both negatives and prints of the church before this occurred; still the loss of the original work itself is deplorable, particularly as its destruction was quite unnecessary; such a calamity calls for the strongest condemnation of all who value the antiquities of our county. Unfortunately this instance is only one of a dozen or so in the last five or six years. These misdoings make it all the more necessary that photographs should be secured of interesting objects before further damage is done.

A selection of photographs was shown at the Exhibition of the Hove Camera Club, at the Town Hall, Hove, in October last, and also at the Educational Museum at Haslemere.

The thanks of the Association are due to these bodies, and also to the Council of the Sussex Archaeological Society for kindly allowing circulars to be sent out with that society's announcements, thereby saving the Association considerable expense in postage.

A good number of photographs and drawings have been received during the year. Contributions have been sent by Mrs. Asden, Mr. F. S. A. Bramwell, Canon Cooper, Mr. J. H. B. Fletche J.P., Mr. F. S. Heath, Mr. P. M. Johnston, F.S.A., Mr. C. J. Lucas J.P., Mr. J. Lewis, F.S.A. (drawings of fonts), Major Astley Moberly, Mrs. Campbell Newington, Mrs. Padwick, Mr. A. Rood, Mr. W. W. Topley, of the Surrey Photographic Survey, Mr. V. G. Stevens, and the Hon. Treasurer. The thanks of the county of Sussex and of the Association and the public generally are due to the donors.

Photographs, drawings, engravings, negatives, and lantern slides should be addressed to the Hon. Curator, The Public Library, Brighton. Communications and correspondence for the hon. secretary should go to the same address.

The number of members, including the council, is at present sixty-eight; it is hoped that this number will be, in the near future considerably increased. Members are earnestly invited to act as local secretaries in their several districts and to urge the claims of the Association for support.

The hon. treasurer's account shows a total receipt of £10 2d., but the expenditure having been less than last year the balance in hand on January 1, 1909, was £7 5s.

Subscriptions of 2s. 6d. are now due; these and any donations should be sent to the hon. treasurer, J. C. Stenning, Bexley, Sfrons Road, Eastbourne.

MR. F. W. SPEAIGHT AND THE HORSE GUARDS PARADE.

SINCE the publication in the press at the commencement of March of the suggestion by Mr. F. W. Speaight for the improvement of the Horse Guards' Parade many commendatory opinions have been expressed on the scheme by both the technical and lay press, and question time in the House of Commons has been the occasion of inquiries as to the attitude of the First Commissioner of Works towards the scheme. The Right Hon. Lewis Harcourt does not regard the proposed improvement with favour, and the correspondence between him and Mr. Speaight indicates that for the present the official approval of the latter's suggestion is not likely to be forthcoming. Mr. Speaight, apparently impervious to discouragement, will doubtless think to himself that while First Commissioners come and go, he goes on for ever. He may consider the perseverance needed in connection with the Marble Arch improvement in negotiating with the two Governments, two County Councils, and three Borough Councils, as twice elected.

The following is the correspondence which has passed between his Majesty's First Commissioner of Works and Mr. Speaight with regard to the Horse Guards' Parade:—

157, New Bond Street, London, W., March 31, 1909.

STR,—I have the honour of now formally placing before you a copy of a pamphlet published on March 5, the chief object of which is to suggest a way by which shape and dignity can be given to the Horse Guards' Parade, and a vista obtained from the parade ground to the Duke of York's Column.

The further suggestion contained therein of an avenue from Marlborough Gate is, of course, not essential in any way to the scheme.

could be readily omitted, if the interference with the lake which construction would necessitate was felt to be undesirable.

nce publishing the plans I have come across a copy of Sir les Barry's design for the rebuilding of the Government build- in Whitehall, and it is interesting to find that he suggested a what similar treatment for the Parade Ground, and the con- ction of a roadway from it terminating at the Duke of York's s.

y first inclination was to submit the scheme to you before pub- ing it, but on consideration I felt that I ought not to trespass on e valuable time unless I was assured by a large and competent 7 of public opinion that the proposal was one worthy of your nderation. I therefore followed the course adopted in connec- with the Marble Arch improvement, i.e., the publication of scheme first, in order to see if those who naturally knew better myself considered it was one suitable of being submitted to the e of Works.

though I am aware that any such proposal as this will be con- red by you solely on its merits, yet I feel that I ought to men- in justification of my now placing the scheme before you, that ng the past three weeks public opinion has shown in a very arkable manner a practically unanimous approval of the general ciple of the plan.

wards of 100 articles have appeared in the chief London and ncial papers in favour of the main ideas of the suggestion, and technical press, from which an amateur might naturally expect icism, has strangely been the most enthusiastic in its praise, "Builder" stating:—"Mr. Speaight's idea for the treatment he parade ground and St. James's Park we can praise unred- edly as a very fine scheme, which would have a noble effect if erly carried out. Upon the general scheme we have no criti- to make—it is a very fine one, a great credit to its author, and should be very glad to see it carried out."

most every post brings letters of approval from members of the se of Lords, the House of Commons, and other public bodies. I hope that later on I may be allowed to submit to you a com- e list of those who have written in favour of the improvement. he kindly encouragement you were good enough to extend to- ds the Marble Arch improvement convinces me that neither you onally, nor the officials of your department, look upon these mpts of a "citizen of London" to bring about an improvement he appearance of the capital of the British Empire as an intru- , but that, on the other hand, you cordially welcome, and are anxious to encourage, the private citizen in taking a practical rest in the improvement of his city. Feeling assured that this osal will be favoured with the careful consideration of Sir omberg M'Donnell and yourself,—I have the honour to remain, your obedient servant. (Signed) F. W. SPEAIGHT.

The Right Hon. Lewis Harcourt, M.P.

14, Berkeley Square, April 2, 1909.

DEAR SIR,—I have to acknowledge the receipt of your letter of ch 31 drawing to my notice officially the scheme for the altera- of St. James's Park and the Horse Guards' Parade. You will bably have seen the answer which I gave in the House of Com- ns on March 8, in which I said that I have no intention of doing thing to destroy the historic associations or the present beauties one of the most charming of the London parks. As I believe t the alterations suggested by you would have this effect, I am ble to promise them any favourable consideration.—Yours faith- y, (Signed) L. HARCOURT.

F. W. Speaight, Esq.

157, New Bond Street, London, W., April 3, 1909.

IR,—I beg to acknowledge with thanks your letter of the 2nd ant. I am afraid, however, that I could not have made the uest contained in my letter, dated March 31, quite clear.

did not intend therein asking your consideration for that part my scheme for the improvement of the Horse Guards' Parade ich would necessitate interfering with St. James's Park.

f you will kindly refer to my letter I think you will find that the y portion of my original proposal which I ventured to press upon r attention was that part which would, if carried out, remedy e present shapeless and untidy condition of the Horse Guards' ade itself.

As I am so frequently being asked if the answer you gave in the

House of Commons on March 8 meant that you were opposed to any alteration being effected to the parade ground, I should be obliged if you would kindly inform me if that is so, or if, on the other hand, I am at liberty to state that the Office of Works hopes to remedy the present condition of the parade.—Awaiting the favour of your reply, I have the honour to remain, sir, your obedient ser- vant, (Signed) F. W. SPEAIGHT.

The Right Hon. Lewis Harcourt, M.P.

14, Berkeley Square, W., April 5, 1909.

DEAR SIR,—My objections apply with equal force to the sug- gested rearrangement of the Horse Guards' Parade and the incon- gruous collection around it of a number of miscellaneous London statues of various scales, designs, and dates.—Yours faithfully,

F. W. Speaight, Esq. (Signed) L. HARCOURT.

157, New Bond Street, London, W., April 6, 1909.

SIR,—I am the first to admit that there is much to criticise, for the reasons stated by you, in the suggestion of removing to the parade the existing London military statues, but that proposal is only incident to the scheme.

As I have before explained, the principle of my proposal is to effect an improvement in the present shapeless condition of the parade ground. To condemn the scheme on account of one or two details, surely must seem to many like condemning the plan of a house on account of the colour of one or two of its wallpapers.—I have the honour to remain, sir, your obedient servant,

(Signed) F. W. SPEAIGHT. The Right Hon. Lewis Harcourt, M.P.

H.M. Office of Works, Westminster, S.W., April 7, 1909.

DEAR SIR,—In answer to your letter of the 6th, I think it right to say that my objection to the proposed rearrangement of the Horse Guards' Parade applies to the whole scheme, and not only to the collection of the statues. In accordance with your permission I am sending the correspondence to the press.—Yours faithfully,

F. W. Speaight, Esq. (Signed) L. HARCOURT.

EASTMAN KODAK COMPANY OF NEW JERSEY.

A YEAR'S EARNINGS OF ONE AND ONE-THIRD MILLION POUNDS.

THE report of this company for 1908, and balance sheet as at December 31 last, have just been issued. The results of the year again exceed the previous records of the company. The net profits, after making provision for depreciation on buildings, plant and machinery, and after setting aside a sum of £206,185 to augment the special fund for the renewal of plant, amount to £1,334,540, as against £1,291,839 for the previous twelve months.

Dividends of 6 per cent. upon the preferred capital and 20 per cent. upon the common have been distributed—leaving £453,286 to be added to the undivided surplus fund, increasing it thereby to £1,605,485. In addition to this surplus there are now special reserves amounting to £748,984, making with the surplus profit a total of £2,354,469.

The earning power of the company shows a steady increase, as will be seen from the following statement of annual earnings:—

Year ending December 31,	1895,	£49,656
" "	1896,	£122,676
" "	1897,	£185,232
" "	1898,	£243,232
" "	1899,	£335,919
" "	1900,	£465,816
" "	1901,	£517,347
" "	1902,	£564,455
" "	1903,	£606,740
" "	1904,	£688,484
" "	1905,	£827,610
" "	1906,	£1,013,546
" "	1907,	£1,291,839
" "	1908,	£1,334,540

MONTREAL AMATEUR ATHLETIC ASSOCIATION CAMERA CLUB.—This photographic society has just held its third annual exhibition, and from the catalogue sent to us has been successful in bringing together an interesting collection of 180 prints.

Photo-Mechanical Notes.

A Photo-Litho Process.

A PATENT for the direct photographic printing on stone or metal for litho printing has been taken out by Hermann Schneider, who claims for it that it gives results of great fineness of gradation and fulness of detail. The surface of the stone is first given a fine grain by any of the ordinary methods used in litho work. It is important to obtain a fine and regular grain.

The next operation is to clean up with a weak solution of nitric acid. The stone is then rapidly dried, moderately warmed, and its surface covered with a weak solution of gelatine and kept perfectly dry at a temperature of 105 deg. F. The following solution is then applied to the gelatine substratum:—

Albumen	20 ccs.
Saccharic acid	10 ccs.
Water	200 ccs.

The stone is then dried.

The two following solutions are then prepared:—

A. Chrysaniline	2 gms.
Zinc chloride	50 gms.
Water	1,000 ccs.
B. Potass bichromate	14 gms.
Ammonium bichromate	30 gms.
Water	1,000 ccs.

A and B are mixed in equal parts and the mixture flowed over the stone, which is afterwards set up vertically in order to allow the excess of liquid to drain off. When the coating is dry, the stone is exposed under the negative for an average time of ten to fifteen minutes in a good light. The exposed surface is then gone over with a hard roller charged with ink specially prepared from the following materials:—Lampblack, Venice turpentine, and litho writing ink, mixed hot, to which has been added a paste composed of finely powdered bitumen, resin, and beef fat. The image is developed by lightly going over the surface of the stone with a sponge saturated with water. When the impression comes out sharply the stone is gummed up and dried.

It is then washed to rid it of gum, the ink removed with turpentine, and the stone again washed and treated with a weak solution of nitric acid, in order to clear away the sensitive film. It is then kept wet with salt water, and is again inked up with a lithographic roller and treated by the usual litho methods.

It will be seen that in this process the photographic design is obtained directly on the stone, the sensitising film being destroyed by the nitric acid applied after the first inking.*

The method is recommended for the reproduction on stone or metal of photographs from nature, pen drawings, and water colours, and may be employed for three- or four-colour processes.

* * * * *

There are two difficulties connected with this process. Firstly (as in all the many similar processes, where the grain of the picture depends solely upon the grain of the lithographic stone), there is the trouble of developing an image that is sufficiently well broken up to give a printable image; and, secondly, a special difficulty in connection with this process must be the nicety of practice required just sufficiently to etch the stone, after the ink has been removed, without destroying all possibility of printing. For ease of manipulation and certainty of results we do not imagine this process can approach the common methods of making a grained negative and then printing on to a polished stone.

Facsimile Reproduction of Coloured Originals.

In Dr. Mees' book on the "Photography of Coloured Objects," which we reviewed last week, there is no mention of one method used in reproduction establishments that can be of great service in rendering certain coloured drawings in "facsimile." In a coloured original, where the colours used are complementary, the photography is simple, because the appropriate colour filter and plate will give a satisfactory record of each colour by itself. But supposing black occurs, then it is impossible to photograph the colours without their being confused

* In the photographic processes on stone it is the photographic image which receives the inking. Here this image is removed and the stone itself is etched with acid, inked, and forms the printing surface.

with the black. Thus a red and a black original can be photographed to print the black only, by means of a red filter and red-sensitive plate; but a negative cannot be made to print the red only. The way out of the difficulty is to make two negatives, one as above, showing the black only, and the second on an ordinary plate, showing both red and black. A positive now made from the first negative will give the black as density, and this, placed in contact with the second negative, will then show the red only left as transparent, and from this a positive and then a negative can be made giving the black alone. Of course, the same method can be applied to the reproduction of all kinds of colours, particularly two colours lying near to each other, as, for example, yellow and red, and although it is a little roundabout it is frequently the only way to reproduce in faithful facsimile. In "Le Procédé" for December last there was an article on this subject illustrated by explanatory diagrams.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications for the following Patents have been received from April 5 to 10:—

CAMERAS.—No. 8,247. Camera attachment. John Currie, 18 Kelvingrove Street, Glasgow.

ANIMATED PICTURES.—No. 8,338. Improvement in film steadiers for moving-picture machines. John Louis Hammond and John W. Patton, 77, Chancery Lane, London.

WASHING APPARATUS.—No. 8,455. Apparatus for washing photographic plates and the like. Herbert Frederick, 53, Chancery Lane, London.

SHUTTERS.—No. 8,459. Arrangement for winding or setting roller blind shutters in reflex or reflector cameras. Alfred Herbert Prickett, 3, Gordon Road, Handsworth, Staffordshire.

REPRODUCING PHOTOGRAPHS, ETC.—No. 8,517. Method of reproducing photographs, drawings, and paintings upon precious and other metals, also upon porcelain and vulcanite, by mechanical processes for ornament and use in the form of jewellery, metal pictures, and the like. Leonard Bradbury, 66, Emmanuel Road, Balham, London.

COPYING APPARATUS.—No. 8,519. Improvements in apparatus for producing photographic copies. Georges Isidore Armand Andrieux, 18, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 8,548. Improvements in mechanism for giving rapid intermittent feed movements, more especially intended for feeding films in cinematograph cameras and machine or apparatus for printing and exhibiting cinematograph pictures. Charles Urban, 47, Lincoln's Inn Fields, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

DAYLIGHT PROJECTION.—No. 3,762, 1909 (February 15, 1909). The invention relates to the exhibition of lantern slides or cinematograph pictures on the screen by projection. For this purpose a lattice is fixed to the screen. The lattice has its meshes, which may be of rhomboidal, circular, or other desired form sufficiently close together and sufficiently raised to form cavities or recesses the walls of which are preferably of a dark colour, and projected upon the plane of the screen shadows which cover the entire surface of such screen. By this means the influence of a foreign source of light is destroyed, and the projections may be obtained in a bright light as well as in darkness. Mario Ganzini, 25 via Solferino, Milan, Italy.

NON-FLAMMABLE FILM.—No. 16,114, 1908 (June 3, 1908). The method, according to the invention, chiefly consists in forming the film, without paper backing, of two superposed layers, a pro-

one of collodion, and a final one of transparent colloid (preferably gelatine, and in constituting by this compound support for the sensitised layer, enabling all the operations of taking and preparing photographs of animated objects to be effected without difficulty. This compound support, like the collodion which it contains, is sufficiently impermeable to undergo, without deformation, the action of the photographic baths, while all the manipulations are effected as in the case of an ordinary film. After the final drying of the negative, as the case may be, when the bands need no longer be supported, the two films constituting the support are separated to completely remove the provisional membrane of collodion, leaving only the final gelatine film carrying the photographic images. Having thus been freed from all traces of collodion, the film is constituted merely by gelatine, so that it is practically inflammable, and consequently may be used without danger in cinematographic projections.

In preparing the film, a film of collodion or celluloid, or of any transparent or non-transparent material capable of forming a smooth and preferably impermeable membrane or support, is used on a polished surface. After this first film has been dried, a second film of gelatine sufficiently thick to form on evaporation a regular film having the usual thickness of an ordinary cinematographic film is applied to the surface of the first film. Finally, after drying, a layer of sensitised photographic emulsion is applied to the compound support thus constituted, the sensitive layer being applied to the gelatine surface.

When the layer of emulsion is dry, the compound film is detached. It is detached in the usual manner from the polished surface on which it has been formed, and then cut into the necessary bands of exact width, perforated or non-perforated.

The sensitive films thus prepared are, therefore, constituted by several layers, and are chiefly characterised by the fact that the layers can be removed subsequently, after exposure, etc., and also the second layer, constituted by gelatine, being of sufficient strength to form, when alone, a normal support.

This process is the simplest one for use in the manufacture of sensitive film for cinematographs. It can, however, be modified in numerous ways without departing from the spirit of the invention.

Between the various layers substances intended to increase or decrease the adhesion of the films could be introduced. The gelatine can be rendered more supple or hardened by well-known means. Its incombustibility can be increased by the addition of phosphorus in solution. In place of gelatine can be used any other suitable substance having the same or better properties from the point of view of transparency and non-inflammability. The collodion or celluloid film can be prepared separately and covered with gelatine, then with emulsion by the same continuous methods as those used for the manufacture of photographic paper.

Even in the case of the practical possibility of forming the final film in a sensitive state as a single layer made from a mixture of gelatine and a suitable material, gelatine or the like, with the emulsion, the number of layers constituting the sensitised film according to this invention would be reduced to two—the provisional one, to be subsequently removed; and the final one, to be utilised after it has been subjected, whilst connected to the provisional one, to all the necessary photographic manipulations.

The sensitive film thus constituted would have, of course, to be considered as being practically identical with that obtained by the superposition of the three layers as previously explained, in view of the fact that the film would still comprise the three essential constituent parts of the three layers: temporary support, final support, and emulsion.

The treatment is exactly the same as that for ordinary cinematographic films as regards exposure, development, fixing, washing, and final drying.

After drying, the provisional inflammable layer or film which is on the back of the band, at the side opposite to the emulsion, is removed, which can be effected in numerous ways. For instance, by dissolving the layer, by dipping the film into a liquid solvent for the inflammable film, such as ether, alcohol, acetone, benzene, etc., according to the nature of the film or that of the

layers interposed for the purpose. It is also possible to work by inflation, as explained in the inventor's French Patent No. 333266 of June 22, 1903. It is, however, preferable to proceed in the following manner:—

A few millimetres of the film to be removed are separated by means of a sharp blade inserted between the films at the end of the band. By seizing the portions thus separated with the fingers or with small pincers and drawing them apart, the film separates in a regular manner from one end to the other of the whole of its length into two portions, one the provisional film formed by the collodion or celluloid or other material used, which can be employed for preparing new films, and the other carrying the images and forming the non-inflammable final film, which can be used without danger in cinematographs. Société Anonyme des Plaques et Papiers Photographiques. Lumière et ses Fils, 287, Cours Gambetta, Lyons, France.

New Trade Names.

PARVEX.—No. 309,719. Photographic apparatus included in Class 8. The London Stereoscopic and Photographic Company, Limited, 106 and 108, Regent Street, London, W., photographers and photographic apparatus dealers. January 21, 1909.

ELECTROPHOT.—No. 310,954. Photographic enlargements, photographs. The firm trading as the Electrophot Company, 52, Gray's Inn Road, London, W.C., photographic enlargers. March 2, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Cardboard Dishes.

A writer in "Photography and Focus" for April 20 gives the following instructions for making developing dishes at a small cost:—"I have had a large developing dish in use for the past twelve months, size about 20 x 14, to make which cost me, roughly, a shilling, and is apparently good for long service.

"To make it I bought a sheet of very thick strawboard, and cut out the shape of the dish, scoring the board partly through to bend it, as is usual in making cardboard boxes, etc. The seams were papered with stout brown paper, and the corners, first joined with thin string to keep them up to shape while the glue dried, treated in the same way, after which the string was cut and drawn out, and a second layer of paper glued over the corners. I used common glue, applied hot, and plenty of it. Two coats of paint and one of cycle enamel completed the dish. I use it, as stated above, for developing, but do not know whether it would serve for fixing, although I sometimes wash prints in it, and the small quantity of hypo thus conveyed into the dish has had no deleterious effect on the enamel. A pulp dish of the same size costs about 4s. 6d., so that there is a considerable economy in making one this way."

New Books.

Allgemeine Aesthetik der photographischen Kunst auf psychologischer Grundlage. By Willi Warstat, Ph.D. Halle: W. Knapp. 3 mks.

This is a highly theoretical treatise of 100 pages. It deals very verbosely with the principles of pictorial aesthetics, and discusses the various means by which photographic results can be so managed as to give the highest aesthetic pleasure. It cannot be called exciting reading, and would appear to be too deep for the ordinary photographic amateur as he is constituted in this country.

Modern Photographische Kopierverfahren. By Dr. Erich Stenger. Halle: W. Knapp. 2 mks.

In this volume, the 63rd of Herr Knapp's "Encyklopädie der Photographie," Dr. Stenger performs the useful task of bringing into one volume a record of the technical methods of printing processes which have recently been devised or have come into prominence of late. He includes in this category ozobrome and the silver-bromide-pigment-paper, known here as "Carbograph," the

"oil," and "bromoil" processes, the catatype process and "pigment-gravure," which latter is a non-transfer carbon not yet apparently on the market. Of these methods the author gives information as to the manufacture of the materials, chiefly from patent specifications, and as to methods of working, which are technical in their nature. Thus, he has little to say on the pictorial principles to be observed in the pigmentation of oil or bromoil prints, although his description of the technical working of these processes is commendably full, and even extends to such oddments of printing processes as oil-ozobrome and gum-ozobrome, while his treatment is briefly historical in every case. He might easily add to the value of such a treatise by giving the references to sources of original publication.

The largest share of space is taken by a description of the catatype process, which we are told has now been brought into a workable state by its proprietors, the Neue Photographische Gesellschaft, of Berlin. The large number of patents taken out in supplement to that of the inventors of the process, Drs. Ostwald and Gros, has rather suggested the difficulties experienced in reducing this interesting method to practical form, but Dr. Stenger now goes so far as to say that the process now "für die Praxis brauchbare Form gebracht werden könnte." He deals briefly with the later patents and explains the aims of the makers at finding a means for reducing the activity of the catalysing agent. It appears that two varieties of the process are now upon the German market, one in which the final print is produced in a manganese compound, and one in which the catatype method is applied to the making of a pigment print. This latter would appear to be the more satisfactory of the two, but in any case the long series of operations to which the original paper negative or positive is applied rather suggests that the advantages of this process of printing without light must be very considerable indeed for the paper to compete with the modern gelatine and collodion printing media in which the after-operations are reduced to a final state of simplicity. However, Dr. Stenger's chapter on the process is the most useful review of the recent progress which has appeared, and is evidently written as the result of a practical acquaintance with the method.

"DEUTSCHER PHOTOGRAPHEN KALENDER," 1909.—No one has any reason to be at a loss for information as to houses in the German photographic trade, when he can buy Herr Schwier's "Kalender" for 2 marks from the office of the "Deutsche Photographen Zeitung," in Weimar. The twenty-second yearly issue of this most useful reference annual is a little fatter than hitherto, due, apparently, to the increase in the memberships of the German photographic societies, a full directory of the members of which occupies more than half the "Kalender." The remaining portion of the volume, printed on yellow paper, is of more frequent service. It contains, first, an alphabetical list of the firms in the German photographic trade; secondly, a classified list of apparatus and materials, in each case with the firms manufacturing or supplying; and, lastly, an alphabetical list of towns, to each of which the names of photographers or other firms established there are appended. The arrangement allows of very easy consultation.

"PHOTOGRAPHIE ALS LEHRFORSCHUNGSGEGENSTAND."—The opening address, delivered by Dr. R. Luther before the students in the photographic section of the Dresden Technical School, has been reprinted under this title, and is issued by Herr Knapp as No. 66 of his "Encyclopædie," price 1 mk.

"THE IMPERIAL HANDBOOK."—The 1909 edition of the always welcome handbook of the Imperial Dry Plate Company, Ltd., contains a varied assortment of brief notes and articles of direct practical usefulness to the photographic worker. These relate to "Interiors," "Under-Exposure," "Drying Negatives," "The Alum Bath," "The Fixing Bath," "Developing and Toning P.O.P.," "Reducers for Negatives," "Combination Printing on Bromide Paper," "Factors Governing the Character of Negatives," "Copying by Artificial Light," "Correct Exposures," and "Imperial Gaslight Paper"—truly a lengthy list, and representing a stock of information and advice very clearly and concisely expressed. The "Handbook," which is obtainable free on application to the Imperial Company, at Cricklewood, also announces the winners in the competition organised last year for photographs suitable for reproduction in the handbook. Particulars of the contest of a similar kind for next year are also given.

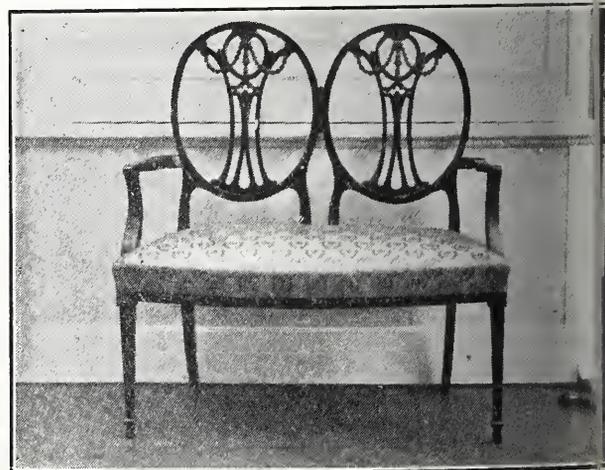

New Apparatus, &c.

Heppelwhite Chairs and Settees for the Studio Sold by Sichel and Co., 52, Bunhill Row, London, E.C.

It is satisfactory to find the houses which supply the professional photographer with his "accessories" showing their discontent with the ugly furniture which has long been found in studios.

their feelings are the echo of those of their customers: the supply is simply a response to the demand. At any rate, the chairs and settees of the graceful designs of the English makers are now obtainable at quite moderate prices. We illustrate two being shown

by Messrs. O. Sichel and Co. on their premises at Bunhill Row. The chair is sold at the price of £2 17s. 6d., the settee at £4 10s. Messrs. Sichel inform us that it is their intention to keep the showroom supplied with a variety of furniture of the English model.

FORTHCOMING EXHIBITIONS.

- April 27 to May 1.—Maidstone and Institute Camera Club. Secretary, J. Harris, 23, Knight-riding Street, Maidstone.
- April 29 to May 17.—Photo Club de Paris. Secretary, Photo Club, 44, Rue des Mathurins, Paris.
- May 20 to 27.—Malvern Camera Club. Entries close May 10. Secretary, J. B. Nickolls, The Exchange, Malvern.
- July 7 and 8.—Canterbury Camera Club. Entries close July 2. Secretary, B. J. Fisk-Moore, St. George's Gate, Canterbury.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held 20th inst., Mr. G. Lamley in the chair. Mrs. Minna delivered a lecture on "Racial Types in South Africa and the Malay and Dutch people, their homes and occupations. A number of these, of which the subjects were figure studies taken in the Malay States, presented most pleasing pictorial effects, and were much applauded by those present.

CATALOGUES AND TRADE NOTICES.

KINDS OF TRADE WORK.—In their new price list, just issued, Messrs. Dorrett and Martin, Belle Vue Road, Upper Tooting, S.W., have done themselves justice. They prominently mention the many branches of trade work which they do, and, as a rule, do very well and promptly. Apart from the stock lines of albumen, carbon, and platinotype enlargements, they make a specialty of certain very attractive mounted and finished enlargements at a moderate, but decent, price. Messrs. Dorrett and Martin are not a firm turning out the wretched stuff of the cheapest kind which passes nowadays as photography. They offer credit work at a reasonable price, and this principle rules also in their work for development, contact-printing, slide-making, retouching, and other service, such as the making of multiple and stamp negative copies of coloured subjects, etc. Tinted prints and engineers' tracings are also here priced, but perhaps the firm's most valuable department is that for the supply of miniatures, either on ivory or opal or the cheaper class of article produced with a cellulose surface. These range from 1s. 2d. to 4s. 6d., and the firm has all grades of jewellery, in which they may be inserted. The firm also does work, too, in "photo-buttons" and "stamp photos" is well known, and the whole catalogue, which is sent post free to bona fide trade or business readers of the "B.J.," suggests many ways in which the enterprising photographer may take advantage of the wide and varied work done by Messrs. Dorrett and Martin.

TELLA CAMERA COMPANY, of 68, High Holborn, London, W.C., have just issued the 1909 edition of their illustrated catalogue, which contains particulars relating to the numerous varieties of cameras, lenses, shutters, and accessories obtainable from this firm. Special attention is drawn to the "Avenue" outfit, which from the description would appear to be exceedingly good value for the low price

charged—namely, £3 2s. 6d., in half-plate size. Photographers intending to exchange old goods for new, or to add to their present outfit, would do well to write to the Tella Company for a copy of this list.

NEW PROFESSIONAL REQUISITES in considerable variety are described in the current number (No. 10) of the "Professional Photographer," issued by Kodak, Limited, from Clerkenwell Road, London, E.C.

Commercial & Legal Intelligence.

INVENTOR'S AFFAIRS.—The first meeting of creditors in the case of Birt Acres, of St. Vincent's House, St. Vincent Road, Westcliffe-on-Sea, managing director of a photographic films company, was held at 14, Bedford Row, London, on April 19. The debtor does not admit insolvency, and has not furnished a deficiency account. There are thirty-one unsecured creditors for £544 11s. 7d., and two fully secured for £4,000, but debtor estimates the value of the securities held by these two creditors at £6,300, leaving a surplus of £2,300. The other assets are 500 £1 shares in a company, 14 £1 shares in another, and one good book debt of £966. Altogether the estimated surplus is £3,235. The Official Receiver, in his observations, states that the act of bankruptcy on which the Receiving Order was made was the failure of the debtor to comply with the requirements of a bankruptcy notice served upon him. Debtor states that he commenced business on his own account as a manufacturer of photographic films at Salisbury Road, Barnet, about sixteen years ago, with certain patents and machines made by himself and about £100 cash capital. About 1897 he sold the business to a private company, which was shortly afterwards wound up voluntarily, debtor taking some of the machinery as his interest. He started business again at Athenæum Road, Whetstone, and subsequently bought land at Wickford, Essex, and erected works upon it at a cost of £500. In December, 1907, he sold the business with the Wickford premises to a company for £2,540 cash and £3,496 shares, and agreed to lease the Whetstone premises to the same company at a rent of £125 a year. This company is the one in which debtor holds the 500 £1 shares, and is also the company which with another is scheduled as debtor for the book debt of £966, but the company claim that they have a substantial call upon debtor's estate. The unsecured liabilities are in respect of debts contracted on behalf of the companies of which the debtor claims to be a creditor, a loan, and private debts. The creditors stated to be fully secured hold freehold premises at Whetstone (subject to an option to the purchasing company to purchase for £2,500), 3,000 £1 shares in the purchasing company, and a policy on the debtor's life for £1,000. Debtor was present, and was questioned by the Official Receiver and the creditors as to his relations with the company, and disputed that he owed the company money. He declared that he was prepared to pay in full all but one or two special debts, and suggested that he could successfully carry on the business under certain conditions. Doubts were expressed by the meeting as to the debtor's chance of doing this, and a resolution was passed asking the Receiver to adjudicate him bankrupt. Debtor finally consented to this course being taken.

VALENTINE AND SONS (1907), LTD.—This large Dundee photographic business made a profit in 1908 of £12,822, and after paying directors' fees, setting aside £1,500 to depreciation, and paying the preference share dividend, including the balance of £625 brought forward, there is £7,764 left, of which £2,550 is devoted to extinguish half the brokerage and formation expenses appearing in the balance sheet, and then the ordinary shares get 6 per cent. for the year. This leaves £2,213 to go forward, subject to payment of directors' and auditors' fees. The total of the balance sheet is £158,753, in which only £11,200 figures as goodwill. Sundry debtors owed the company at December 31 £39,375, and it owed sundry creditors £19,523, including £4,702 due to bankers. The depreciation fund stands at £3,000.

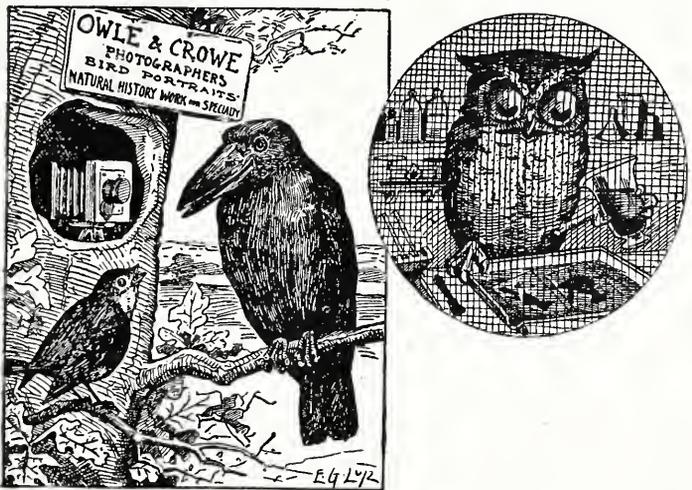

NEW COMPANIES.

W. T. COLE AND SON.—£1,000 (£10). To take over the business of a chemist and druggist, optician, and dealer in photographic materials, carried on by W. B. Cole, at 17, St. Mary Street, Weymouth, and at Melcombe Regis, Dorset, as W. T. Cole and Son. Private. 17, St. Mary Street, Weymouth.

News and Notes.

THE AEROGRAPH IN SCOTLAND.—Firms in Scotland are now having brought to their notice specimens of aerograph work. Mr. A. Aufholz, representing the Aerograph Company, 43, Holborn Viaduct, London, E.C., will be at the Old Waverley Hotel, Buchanan Street, Glasgow, from Tuesday, April 20, to May 6; and in Edinburgh, at the Carlton, from May 7, for one week. The new machine for colouring mounts, etc., will be exhibited, and all interested in this class of work should endeavour to make an appointment and see the machine in operation. Besides, there will be shown many examples of aerograph work for all branches of photographic practice. Mr. Aufholz is an expert in this department, and will be prepared to give those calling on him by appointment a practical demonstration of the work of the aerograph.

PHOTOGRAPHY IN NATURAL HISTORY.—Our contemporary, the "Camera," of Philadelphia, gives in a recent issue the drawing

Mr. Tom-Titt: "How is it, Mr. Crowe, I never see your partner, Mr. Owle?"

Mr. Crowe: "Oh, he's always in the darkroom. Greatest thing ever—he can develop plates without using a ruby lantern."

we reproduce, not stating, however, whether it is indebted for it to Mr. Martin Duncan.

THE PROFESSIONAL PHOTOGRAPHERS' SOCIETY, of New York State, on its impending meeting in New York, are to be very heartily entertained by the Metropolitan Section of the Association. A song-book composed for the occasion reaches us in advance. Under the title "Fidgety Photographers', Frolic Formulæ and Sorrow-Soothing Songster," this publication contains innumerable personal references and skits, strung together to popular airs such as "Marching to Georgia." For example, Mr. Falk on copyright (chorus of "Everybody Works but Father"):

Ben Falk he loves copy-right,
He's got it in his blood,
Congress cuts up di-does,
He falls down with a thud.
Then he ups and cus-ses
Spits on both his hands,
Kicks up some more mus-ses,
AND THEN HE LANDS.

"NATIONAL PHOTO-BULLETIN."—We have received a recent issue of the "National Photo-Bulletin," published by the Photographic Department of the National Drug and Chemical Company of Canada, Limited, Montreal. The "Bulletin" is a monthly issue, which brings new apparatus and materials before the notice of the amateur, and gives him some useful tips and articles. It is distributed gratis through the dealers—the Drug and Chemical Company are not retailers—and should prove a valuable and direct means of reaching and interesting amateur workers in the Dominion. We see that British firms occupy the leading places among the advertisements.

A CAUTION TO INTENDING PURCHASERS OF BUSINESS.

To the Editors.

Gentlemen,—May I solicit the favour of a short space in the "Journal" to warn those of my brother "procs.," especially the younger and less experienced, anticipating purchasing a photographic business? I am on the "qui vive" for a business, and amongst several replies to inquiries to advertisements I had one from a party offering me, what he termed, his "business." Now I happen to know the vendor, to my cost, also the "business," which has not been in existence more than two years. His stated "business" was one of a three years' duration!! There is no doubt that this is one of many "faked up" for sale. I am informed that the premises have been newly decorated and furnished, and replete with all new apparatus, etc., etc. I have no doubt it is all very nice and pleasing to an artistic eye, but what one would like to be assured of is the existence of a genuine turnover.

This type of business is opened and run by an expert in the photography and "slimness." The concern is "worked" and advertised for all it is worth, free sittings given, etc., so that the "book" can show a respectable turnover! The consequence is that the market becomes glutted, and people are "fed up" with photographs. Then comes the slump, and then the "business" is put up for sale, "owing to ill-health," etc., etc.!!!

My advice to those contemplating making a start on their owls is to make thorough inquiries as to how long the business under consideration has been established, and, if only a short time, to be nothing to do with it, only at a valuation of apparatus, furniture, stock-in-trade, etc.; also see that the lease is in order; see what the tenant is liable for; if any structural alterations have been made, and if so, whether the tenant has agreed to put things "as they were" on the expiration of the lease.

There are many other pitfalls for the unwary, but which the Editor cannot afford me the space to ventilate now. In conclusion, let me say that "the wisdom of the serpent" is a very necessary quality in dealing with these "D. S. Windles" and vendors of "sucked oranges."—Yours faithfully,
ONCE BITTEN

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER

To the Editors.

Gentlemen,—The observations made by you in your issue of the 9th, and Mr. C. J. Stokes's letter in your last, have been read by me and no doubt by the majority of your readers with considerable interest, affording, as they do, valuable, if somewhat discomfiting, information to users of focal-plane shutters.

I think, however, that when you assume the efficiency of a modern diaphragmatic shutter opening in iris form and of the best type to be $33\frac{1}{2}$ per cent. at top speed, you do this type an injustice. If all factors are considered, in my humble opinion 50 per cent. would be a closer and fairer approximation, irrespective of the period of full opening. In one of two iris shutters tested (subsequent to my paper) of the above description there is, however, distinct, if small, period of full opening at top speed, probably due to inertia of the leaves on reversal, coupled possibly with a certain amount of play. A test of the other shutter illustrates that at the highest speeds the period of closing is materially longer than at slow speeds; it also shows that the movement at some speeds is very far from being either continuous or uniform. An ancient "Unicum" records good efficiency at highest speed—1.40th second actual, though marked on the dial somewhat differently. The elliptical method of opening, I hear, is to be abandoned in favour of the star-shaped opening, which will result in greater efficiency, and it is to be hoped in lessened tendency to variation in speeds through outside influences.

In reference to Mr. Stokes's letter, I must cordially agree with

marks as to the absurd claims which have been made by and others in respect of focal-plane shutters, an efficiency per cent. under all conditions being frequently inferred or claimed. In the point raised—or, rather, as I now learn, by me—I had little doubt that a perceptible loss of efficiency, though my limited mathematics were unable to give it a value. Your correspondent's formula appears to furnish a and useful guide to an approximate realisation of the loss d in this and other kindred conditions.

Stokes, however, says that in the conditions shown in the the "duration" is doubled, not decreased, as assumed by possibly, indeed probably, my assumption was wrong, but I help thinking Mr. Stokes is in error also in an opposite n. With a slit in advance of the focal plane, as illustrated in gram, the image of an object reflecting light equally would on the focussing screen as a bright line, with maximum ity of no measurable width, in the centre of a band of light han the slit, and vignetting from the centre on each side, perceptibly as points opposite the edges of the slit are hed. For the purpose of estimating duration of exposure and of light cannot be considered equivalent to a slit of width in contact with the plate. A part, and probably a art, would have no perceptible action on the plate during the of the blind across it, especially if a rapidly moving object eing recorded. If we make an assumption that all the ed parts are inoperative so far as the plate is concerned, it is ent to an infinitely narrow slit in contact with the plate and quent shortening of exposure. Such a big assumption is, of not warranted, though true in part; it has a direct bearing y on the question of "speeds," but also on that of efficiency, a factor which might readily be overlooked in a purely mathe- treatment of the problem.—Yours faithfully,
E. A. SALT.

PRESENT BANALITY IN CHRISTMAS CARDS.

To the Editors.

emen,—I have read with much interest your remarks in the h Printer" on British Christmas cards, and wonder what ublishers of Great Britain will say to them. My impression cannot say anything to justify their position. The Christmas ade, I quite agree with you, seems to have come to that here originality has ceased both in design and literary mat- he real trouble, I may tell you, is this: that every Christmas ublisher believes he knows all there is to be known about the as card trade, and suggestions either for literary matter or tion are not required, particularly if any novel line be offered. ublishers' argument all along is they do not want to publish g novel, as they know what the public will buy; and so diffi- it to move the publishers to do something new or anything the way, that it is almost useless attempting to put any time e direction. It is the old, old story—British trade prejudice e self-satisfaction of the man at the helm, "who quite knows e wants, thank you," so he says.

ve just returned from a business trip in the United States, trasting this Free Trade country with America, one can only nced how hopelessly we are behind times. In 1899, when I at that country, I was quite satisfied of the go-aheadness and en-minded receptiveness, if I might say so, of the people of a; it is the want of this very receptiveness that is sending untry to the dogs.

o the literary matter that decorates most of the Christmas hat emanate from most of the so-called art publishers, this nly high-faluting and sentimental nonsense, and not at all e either for those who send or those who receive the cards. is so much that is beautiful in the English language that e taken from our poets, our standard works, etc. This, r, is simply ignored.

floral abominations that are turned out, too, I agree with you, ocking designed. The latest horror is the embossed celluloid nd I am told there is a great sale for this class of card. This o, there will always be publishers who will produce them; but e something better and to cultivate the taste of the public ething more truly artistic is quite out of the question. Their s, they are there to make money, and not to educate the although we hear something of this in the fluffy advertise-

ments and the inspired press notices which are now and again let loose on the public.

Your protest, believe me, is quite too late to affect the Christmas cards of 1909; these have been long finished with, but were they on the stocks your protest would have no weight; the publishers will go on producing the thing they consider will sell—and that they claim is the rubbish you decry—and will be quite unaffected by any criticism from any outside source.

During the last twelve months I have turned out quite a number of Christmas card designs for various publishers, but the curious thing is that when we see our work reproduced we are often unable to recognise it, so badly, indeed, has it been reproduced; and I must say some of the most original and strikingly interesting and novel lines have been turned down, while something that has been done twenty times before seems to meet the demands of the publisher. I repeat, novelty in Christmas cards is evidently not required. I have had passing through my hands some eighty original subjects of the most beautiful type—they were landscapes of the most beautiful quality, done by an artist who had exceptional genius. These subjects were absolutely the thing; they were shown to one of the largest Christmas card publishers, who made the remark that they were not buying any new material as they wanted to re-use so much old material they had got. Another said they were very beautiful, but as they were quite of a novel character they thought they would not try them, and so on. At last one publisher took twelve of them, and I have just seen the proofs, which for a wonder have been beautifully reproduced; but out of almost all the Christmas card publishers who saw these designs only one firm saw anything in them, and that is the reason why I, like many other workers, cannot waste time in catering for the Christmas card trade. Quite a number of the best and most original workers in this direction have had to give Christmas card designing up altogether, for, quite apart from the refusal of original designs, the prices obtainable are, as a rule, not worth accepting.

You are quite at liberty to publish this letter if you think well.—
Yours faithfully, NOT SELF-SATISFIED.

THE HISTORY OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—Permit a somewhat belated protest against the opinion expressed by Mr. E. West in his letter on page 225 of your issue of March 19, wherein Mr. West says that "The Photo-Miniature, No. 60" "seems too trivial for the purpose" of making up a lecture on the history of photography for a photographic society. For the particular purpose mentioned, where a few of the most vital facts connected with the subject are to be stated with brevity and interest within a short time, "The Photo-Miniature, No. 60," "Who Discovered Photography?" would seem to be most desirable as a source of information. With regard to the quality of its information, its accuracy in detail and the arrangement of the facts, I need but point out that the monograph was prepared by Mr. George E. Brown, the present editor of the "B.J.," and very carefully supplemented by Mr. Chas. W. Canfield, both of whom are known as authorities in this special field.—
Yours faithfully, TENNANT AND WARD.

122, East 25th Street, New York.

April 12, 1909.

SULPHIDE TONING.

To the Editors.

Gentlemen,—With Mr. Blake Smith's contention—expressed in his letter of last week's issue—that the failure of stale sulphide solutions is due to the production of "hypo" with concomitant reduction in the percentage of sodium sulphide, everyone who has made a study of the chemistry of this toning process will, I think, agree. At any rate, this is true for a certain degree of staleness of the sulphide solution.

But there are one or two points in the letter on which I, and probably others of your readers, would welcome some elucidation.

Mr. Blake Smith asserts the product of the ferricyanide-bromide bleaching bath to be a lake of silver and silver bromide. The term "lake," I take it, is appropriate for those bodies which with a more or less pronounced individuality nevertheless show considerable variability in percentage composition. I presume, therefore, that Mr. Blake Smith's analyses of the substance constituting the

bleached image have varied widely, and one would like to know the extent of the variation he has found to justify him in the application to this instance of the term "lake." So far as my analyses have gone they show the product of the bleaching bath to have (speaking with due regard to the unavoidable errors of a difficult quantitative estimation) a constant composition.

But if the product has a constant composition, why call it a lake? If, assuming what has not yet been disproved, the constancy of composition of the bleached product, it is to be called a lake, then consistency demands that we deny to ordinary silver sub-bromide (Ag_2Br) the dignity of a salt; we must call it a lake of silver and silver bromide! Though the term "lake" implies a negation of knowledge of the substance to which it is applied, yet it seems to minister to many as a sort of chemical "Mesopotamia," soothing and satisfying the troubled soul.

Mr. Blake Smith states that when the bleached image is placed in hypo, this reagent dissolves the silver bromide of the lake, leaving the silver of the lake as a faint residual image. Then why is not this residual image of silver silver-like in appearance? It certainly is not so. Is it, perchance, the case of a lake again—a lake of silver in gelatine, or a lake of silver in the cellulose of the paper?

Surely this faint residual image remaining after the bleached print has been treated with hypo is nothing else than what has been called the residual image of development, i.e., that portion of the original developed image which is not silver. It is, in fact, nothing else than what you get if you treat an ordinary (untoned) bromide print with persulphate or other silver solvent.

I am somewhat surprised at the prodigality in Mr. Blake Smith's recommendation that dilute (1 per cent.) solutions of sodium sulphide should be thrown away after use. I have been constantly using over and over again for a period of more than a year a 1.2 per cent. solution, and it is still acting so efficiently that I take with some demur the advice to "throw it as rubbish to the void."

I would like to take this opportunity of correcting a mistake I made in the "B.J." of November 30, 1906, in describing the mode of preparation of this practically perpetual sulphide solution. I there spoke of it as a solution of sodium sulphhydrate; from its method of preparation it cannot be other than a solution of the normal sodium sulphide. I would also add that more recent experience with other brands of paper than the Wellington (exclusively used in the investigation referred to above) have led me to prescribe and use double the quantity of water stated in the paper (i.e., 500 cc. instead of 250 cc.).—Yours faithfully,

DOUGLAS CARNEGIE.

To the Editors.

Gentlemen,—Referring to my letter on this subject in your issue of March 19, your "Ex Cathedra" article, and the further letters in March 26 issue, I may at once state that had I remembered your leader of January 29 my letter would not have been written, as this seems to fit most of the facts in a very satisfactory way. Of course, I must now admit that hypo is formed as the result of the decomposition of the sodium sulphide, as my friend found on looking up his "Watts."

What brought the matter up was this: A case came under my notice in which prints were satisfactorily bleached, one of the well-known commercial sepia toning sets being used, but would not darken. Part of the sulphide solution, which had not previously been uncorked, was measured out, diluted, and applied. When it was noted that there was no action the remainder of the solution was poured into the dish, naturally without any effect. The bleached image in one case appeared to be of the usual depth and colour, whilst in another case it had partly disappeared.

However unsatisfactory the experiments detailed in my letter may have been, I cannot lose sight of the fact that, using the same bleaching tablets and adding two grains of hypo to each ounce of bleaching solution, I absolutely duplicated my correspondent's failures. In this particular case the chemicals were above suspicion, and contamination of the bleacher with hypo seems the only explanation.

I quite saw at the time of writing that fresh sulphide plus hypo was not the same as decomposed sulphide, but it appeared to me, and it still does so, that if we are to account for this specific result by deterioration and the formation of hypo we must pre-suppose complete decomposition—all hypo and no sulphide—or very nearly

so, at any rate. Under no conditions of keeping likely to occur in practice could such total conversion take place.

The statement is frequently made that sodium sulphide decomposes, but, although I have frequently used the remainder of a large bottle when it was in a liquid state, no ill result has been observed. In the "Photo-Notes" article, which prompted this discussion, the statement is made that a weak solution "will not keep at all." To set against this, I have a 1 per cent. solution, which was made in November, 1906, with ordinary tap water, portions of which were used at the time, and the bottle was then forgotten, and bleached prints cut in two and partly toned with this and partly with a new solution, show no difference whatever. Furthermore, one of the 1 per cent. solutions in an open pyro bottle in the open air for three weeks, it still gave normal results. In other words, the deterioration bogey, in my experience, is greatly exaggerated, although I may have been fortunate in my choice of sulphides, which, incidentally, have always been of the white variety.

Of course, the easiest way of explaining failures is to assume deterioration of the sulphide, but, in my opinion, most of the yellowish tints are due to unsuitable black and white prints in the first instance. Where, however, we have the yellowing called to an extreme stage, or where it amounts to a complete refusal to develop with or without slight destruction of the bleached image, such deterioration doubtless enters into the failure, although I think that overworking the bath until the sulphide is nearly exhausted is a more frequent cause of the trouble. Apart from this, varying degrees of contamination of the bleacher with hypo will most certainly bring about precisely the same result, and the possibility of this being the correct explanation in individual cases must not be lost sight of.—Yours faithfully,

J. BRYN.

Chiswick, April 14, 1909.

ASSISTANTS AND APPRENTICES.

To the Editors.

Gentlemen,—Referring to your article on this subject in your issue of April 2, the real cause of complaint is the fact that the photographic profession is over-run with the "amateur turned professional," through finding out that "there is very little in that cannot be picked up," as you term it.

The "amateur turned professional" in his egotism thinks that because he happens to turn out a fairly good picture at perhaps a hundred or two exposures, and, probably owing to the flattery of his friends, which causes his already over-swelled head to swell still more, thinks the time has arrived for him to start a studio. His friends and relations sit for him and say, "What a clever fellow he must be!"

In about a month or two, owing no doubt to a pressure of business, you see an "ad." in the local paper, setting forth that Mr. Blank has a vacancy for an apprentice, or "articled pupil," as he puts it, in his well-appointed studio, premium required.

The poor gulled "articled pupil" commences his duties; is generally shown the way to print, tone, and develop a few poor specimens of bromide portraits; and as regards retouching, his master would not know a properly retouched negative if he saw one, leaving out proper printing in the various processes, lighting and shading in all multifarious branches that, properly done, go to make up a beautiful portrait. I can say without fear of contradiction that the overstocked labour market in the photographic profession is solely owing to the "amateur turned professional." Within the last two years seven studios have been started in this district, all but one being "amateur turned professional," and nearly every one of them has been advertising for young ladies to learn the business—of course with a premium attached. The man is not a poor mean object who would take apprentices with the idea of getting work done cheaply, and, of course, badly done at that.

There were four apprentices where I learnt photography in the South of England (before the dry-plate days), and we learnt the whole routine, starting at the bottom of the ladder: plate cleaning, albuminising plates, and paper sensitising, etc., and we all vie with each other in our work. The consequence was we have all had the highest possible situations at splendid salaries, and I believe three out of the four are now employers of artistic talent.

the other hand—having had nearly 40 years in photography, speak from experience—when a fully qualified man takes a minimum apprentice, I have found that the parents or guardians the pupil after a few weeks, want to know how is it that the pupil has not been started in the “studio,” or else has not already become a fully fledged “black and white artist,” or “miniature painter”; in fact, as a rule, parents generally want the pupil to start at the wrong end of the stick, the top of the ladder instead of the bottom.

The parents, as a rule, instead of seeing that it is to the pupil's best to “obey” the master, back the pupil up in all kinds of subordination, such as coming late to business, and wanting to do everything but the right thing; in fact, parents are conceited enough to think that they practically own the business, because of their art, or the whole, of a small paltry premium has been paid.

Have you such a case with me at present. The indentures have only been signed nine weeks, and out of that time the pupil or apprentice stayed away three weeks and four days, without leave, simply because she wants to start right into black-and-white finishing in miniature painting, and I wish her to learn the groundwork of retouching first.

I have already received several letters from the parents; the first one stated that a gentleman told her (the parent) that her daughter could easily be proficient in retouching in three months and would then command £1 per week, and that I must immediately get the pupil go on with miniature painting and the colouring of heads. Have you, or any one else, ever heard of such idiotic nonsense?

Apprentices or pupils should do whatever the master legally asks them to do, to the best of their ability, and parents should not interfere with the “genuine masters”; then one could turn out really clever photographic artists, of course, always provided that there was some artistic element in the pupil, and that the pupil wished to learn.

“You can lead a horse to the water, but you can't make him drink.” So it is with some pupils; they are stubborn and will not learn, and the consequences are, the master lets them go their own way.

The cry about not teaching apprentices studio work is all very well in its way, but some apprentices seem to lose their heads immediately a sitter enters a studio, and if it is a lady “decolleté,” they simply stare as though they were hypnotised.

In the case of an ungainly pupil I have always found it the best policy to write and inform the parents that it would be best to cancel the indentures and return the proportionate amount of premium rather than risk my professional reputation by allowing the ungainly pupil to practise on my clients. It is dangerous to ask such a catastrophe.

“You cannot make a silk purse out of a pig's ear,” any more than you can make an artist out of an apprentice who should have been a blacksmith or mason.—Yours, etc.,

ARMANDO.

DEFECTIVE TRIPODS.—A correspondent complains that little attention seems to be paid by manufacturers to the improvement of the tripod in the direction of strength, and he sends us a specimen of a tripod leg that has snapped across at precisely the same place as several other tripods that he has possessed. It is an ash tripod of the usual type, and the breakage is attributable in this case to a badly selected piece of wood cut across the grain. No doubt the failure was accelerated by a badly fitting tripod head, which is a too common adjunct to the tripod. There is, so far as we can see, little fault to find with the usual type of ash tripod in point of design; but it is an undoubted fact that the wood is often badly selected, and the head made too small. A short cross-grain is a defect that we have often noticed, while we have had personal experience of the difficulty of getting a head to fit a particular tripod. Even the heads supplied for use with particular sets of legs are often too small, while it is curious to note that, as in the tripod belonging to our correspondent, the worst and weakest piece of wood in the whole construction is placed just where the strain is greatest. These are matters of detail, but at these points it is quite easy for purchasers to note the defects for themselves, and to reject the faulty specimens.

A. LANDER and Others.—In our next.

HYPONALUM TONING OF P.O.P.—I was reading, some time ago, in a photographic paper, about a hypo-alum bath for toning P.O.P. Could you give me full particulars in your current issue of “B.J.”? M. P. H.

The only reference we can discover is the suggestion of R. Read in “Focus” for April 22, 1908, p. 381, to use an old hypo-alum bath for the toning of over-printed P.O.P. postcards. These are taken from the ordinary sulphocyanide gold bath at an early stage, and, after fixing, put in the cold hypo-alum bath, where they are said to assume a good purple tone. It is possible you may be referring to a method of toning P.O.P. with sulphide, recommended by C. Harold Smith, in the Ilford Company's “Photographic Scraps” for November, 1904, p. 180. No doubt the Ilford Company, if they have a copy, would send you one; otherwise we must refer you to the “B.J. Almanac,” 1906, p. 813.

STUDIO.—For a studio 30ft. by 15ft. and height at eaves 8ft., with a fair amount of light from N.E., what proportion of light in roof and side would be sufficient, and also at what angle would you advise roof?—STUDIO QUERY.

You do not say if you wish to work the studio from both ends or only from one end. If the former, 5ft. at each end, top, and sides, may be opaque and the rest of glass. If it is to be worked only from one end, the same length may be opaque, and about 14ft. glazed. Supposing the roof is of the ridge form, it need not be glazed to the ridge; up to a couple of feet from it will suffice. Opinions differ as to the best angle for the roof. It is, however, well to have a good slope, to carry off the rain.

STUDIO QUERY.—(1) Is it possible to obtain results equal to a north light in a room facing the sun all day by using curtains? If so, what material would you use? The room has the following dimensions:—20ft. by 15ft., height 10ft. However, the light comes from a side window only, which measures 10ft. by 7ft., about 1ft. from the floor. Would you advise me to use an arc lamp to supply the top light? If so, do you consider a small size would be efficient, in conjunction with the diffused sunlight? (2) Is the Autochrome filter suitable for orthochromatic work? If so, how many times will it increase the exposure?—STUDIO LIGHT.

(1) Yes, if the light be skilfully managed. Thin muslin or tracing linen will be good for subduing the light when the sun is shining on the window. Dark blue or green curtains will be suitable for arranging the direction of the light. At times you may find the arc light, as shown in the sketch, useful as a dominant light. (2) It is not suitable for ordinary orthochromatic work, as it lengthens exposure unnecessarily.

LENSES FOR SHORT STUDIO.—Having had to remove from my premises, have taken a small place until I can get a suitable site, and find out that I can only get 14ft. length in the studio to have the light in the right place. Would you kindly tell me what kind of a lens would be best, and what length of focus I require to take cabinet, groups, and carte de visites full length? My studio camera is a half-plate, fitted with a cabinet portrait lens, and I can only get far enough back for a C.-de-V. head.—P. B.

In so short a studio you will find it difficult to take full length portraits. You will have to have two lenses, one for cartes and one for cabinets. For the former, a lens of six inches focus requires about 12 feet between sitter and camera. For the latter, one of nine inches requires about the same distance. These are the shortest foci that will cover the respective sizes. We would suggest that

you abandoned the idea of taking full lengths and confine yourself to busts and half lengths.

VARNISH FOR OIL PAINTING.—Will you kindly advise me as to the most suitable varnish to apply to oil painting executed on china?—**A. DEBENHAM.**

If it is desirable to varnish such a picture, good mastic varnish, such as is sold by artists' colourmen, will be suitable.

COUNTRY PROFESSIONAL.—We very much doubt whether prints toned in this way would last as long as you say. It is different if the prints are completely treated, say, by bleaching and darkening with the thiomolybdate bath. The latter forms a satisfactory and inexpensive method of toning. See the circular issued by the makers, Edmunds and Co., Ezra Buildings, Columbia Road, E.

EXPOSURE ESTIMATIONS.—(1) The speed number (Wynne) of the Jougla "Omnicolore" plate? (2) What are the requisite merits and demerits of the two types of actinometer—the photometer normal and similar instruments, and those of the Wynne and Watkins' class? (3) Are there any British-made direct vision actinometers, and how do they compare with the photometer normal?—**OMNICOLORE.**

(1) In our "Colour Supplement" for February 5 you will see that Dr. Mees gives the Watkins number for the "Omnicolore" as $2\frac{1}{2}$ (about 10 Wynne), that for the Autochrome being 1. (2) The instruments that depend on visual observation are a little difficult to use at first, and practice is required to take a reading quickly; but they are much favoured for colour photography by some workers. The others are, of course, quite easy to use, but in weak light does not darken in proportion to the ratio for correct exposure of colour-sensitive plates. (3) Not that we know of.

DEVELOPMENT.—(1) In your March 26 ("Colonial Number"), page 232, is formula for "Neutral Sulphite." This appears to be 8 parts of sulphite and 1 part of potass metabisulphite. Unless I am mistaken, you have previously published and discussed *re* such neutral sulphite, but in different proportions—viz., 4 parts of sulphite and 1 of potass metabisulphite. Which is correct? (2) Is amidol and diamidophenol the same thing, as one often sees a formula in which the reducer is spoken of as amidol or diamidophenol, and Watkins calls the factor for amidol (2 grs.) 18, and the factor (no particular strength given) for diamidophenol=60. (3) What is factor for a portrait negative, using the pyro soda developer (diluted to 4 grs. of pyro in 3 oz. developer), on page 232, as above mentioned?—**SULPHITE.**

(1) Both are correct, and frequently used, but we prefer the one we last gave, as it gives a developer that acts rather more quickly. (2) Practically they are the same thing, and we use diamidophenol in precisely the same way as we previously used amidol. We are unable to explain the discrepancy in the factors. (3) This depends on the kind of negative you wish to produce. We should say it would be from 10 to 15. Consult Watkins' manual for the factors of pyro developers.

LIPPMANN STEREO PLATES.—Have you any knowledge whether the Lippmann discovery of plate for use without lens is to be placed on the market? And when, probably?—**CARL T. DUGDALE.**

Nothing commercial has so far been heard of the method, and it does not look as though it is possible to make the plates. Professor Lippmann's address is The Sorbonne, Paris.

REMOVING PAINT FROM PHOTOGRAPH.—I shall feel much obliged if you will kindly inform me if there is any known process by which oil paint can be removed from a photograph and if so, if you can give me the name and address of any firm, or anyone, who could do so for me. I have a small photograph, about 6 in. by 8 in., a landscape view, which is of great interest to me, but unfortunately the sky and the trees in parts have been painted over in oil colour, and thus the picture is spoilt. The photograph is an old one, probably taken some forty years ago.—**RICHMOND.**

We fear there is no method of removing the old paint without ruining the photograph, seeing that it has been done so many years. If the paint were new, it is possible that it could be got off by treatment with benzole. We should suggest that you copy the picture as it is, mask out the sky in the negative, and then print in a fresh one.

RAPID PHOTOGRAPHY.—Would you kindly tell me the best method of doing photo. postcards "while you wait"—that is, to turn

them out in fifteen to twenty minutes from time of asking—**RAPID.**

There is no particular method, except that it is usual to print from the wet negative by squeegeeing a piece of thin celluloid upon it. This dodge, aided by rapid development of negative and gaslight printing, is employed to turn out prints quickly.

T. G.—The process is worked under several names. A formula and brief instructions were given in our issue of February 12, p. 1, in reply to a correspondent, "Plans."

BURNISHER.—It will not give results equal to those of the burnishing.

GAINSBOROUGH.—We know of none. We imagine it will not be worth anyone's while to write one.

CATHAY.—It is contrary to our custom to make such comparisons, which, however qualified, may easily be misleading. We have reported on five of the instruments in the "Journal" and "Almanac" during the past year or two.

REVERSAL IN NEGATIVES.—I write to ask if you can explain a curious phenomenon? I exposed a roll of six films, which upon development came out as positives, and when printed the prints came out negative. As far as I know, the film was not subjected to any different treatment to usual.—**L. E. C.**

The only common cause of such reversal is exposure of a partially developed film to actinic light, the faint negative image thus impressing a stronger positive image on the unaffected sensitive emulsion. It is not possible to say whether this took place in your case.

STUDIO SHUTTER.—Would you please inform me on the following through the "Answers to Correspondents" column? I have a studio shutter, which was purchased through Marion and Co., and the name on the shutter is Cl. Guerry, Paris. The improvement is to ensure safety in exposure. Trusting you will oblige.—**GEO. O. STOTT.**

Yes, what is it you wish to know? If you will ask a question we will endeavour to answer it.

CHARGES FOR WATER.—I have for many years carried on business as a photographer, and have paid the usual water rates levied by the water company. But this quarter, without any previous notice of any kind, a demand has been sent by the Metropolitan Water Board for an extra £5 rate for the year that has passed, in addition to the usual 5 per cent., which they have already charged on my assessment. What I want to know is, Can they legally charge me for arrears, when no demand has been made and no notice previously given that this sum would be required? The charge has been levied by the Metropolitan Water Board, who has taken over the water supply in this district from the Kent Water Company.—**MAJOR.**

We regret we can express no opinion on the legality of the charges, as we have not a copy of the Metropolitan Water Board Charges Act. However, if you write to the Board we have little doubt but that it will give you an explanation of the charges that have been made and the reason for them. You can get the Act itself from Messrs. Wyman and Sons, Fetter Lane, for a few pence.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

An abstract of the paper by M. André Callier recently read at the Royal Photographic Society appears on page 341. Its practical corollary is the avoidance of excessive contrast in printing when means are taken to avoid scattering of light from film of the negative. Opal glass in contact with the film has been found the best for this purpose by M. Callier.

The chief points in regard to which caution is necessary in the purchase of a photographic business are dealt with in an editorial article on p. 339.

The improvements which may be made in the appearance of the studio and other parts of the photographer's premises at small expense are the subject of an article contributed by Mr. W. Michell. (P. 340.)

Some photographers' advertisements, which appear in our contemporary, "Advertising," as the result of a competition, are printed on p. 344.

The *passé-partout* mount may be recommended as a neat and effective means for the professional display of new specimens of prints. (P. 338.)

An American journal has published a popular description of the methods employed by one of the large firms of stereoscopic publishers, the H. C. White Company. (P. 346.)

Two factories for the manufacture of dry-plates are said to be in course of erection in Japan. (P. 337.)

At the R.P.S. on Tuesday next an exhibition of bromoil prints. Mr. F. J. Mortimer, will be opened by an address from the Liberator at the usual evening meeting. (P. 350.)

A report of a bromoil demonstration, by Mr. F. J. Mortimer at Croydon Camera Club, appears on p. 352.

Drastic changes have been made in the selecting committees for the forthcoming exhibition of the Royal Photographic Society. (P. 337.)

A viewing frame for Autochromes and a collapsible background lantern-screen stand figure under "Patent News." (P. 348.)

The efficiency of focal-plane shutters, sulphide toning, and flashlight photography are topics discussed under "Correspondence." (P. 354.)

Under "Photo-Mechanical Notes" the renovation of spent peroxide of iron, the use of pure paper for three-colour, and collotype for amateurs are dealt with. (P. 348.)

EX CATHEDRA.

The R.P.S. Exhibition.

Although a good deal was said at the recent Annual General Meeting, it will probably come as a surprise to learn that very great changes have been made by the Council of the Royal Photographic Society in the Selecting Committees dealing respectively with the pictorial and technical sections of the Exhibition. It is now announced by the Council that the committees which will deal with the forthcoming exhibition will be constituted as follows:—

PICTORIAL COMMITTEE.

A. H. Blake	Harold Holcroft	F. J. Mortimer
C. F. Inston	E. T. Holding	F. T. Hollyer
	Arthur Marshall	

TECHNICAL COMMITTEE.

F. J. Cheshire	A. J. Newton	C. Thurstan Holland
Douglas English	Major-General J. Waterhouse	W. Farren
C. E. K. Mees		

There is further created a third committee to deal with colour photography as a separate section.

COLOUR COMMITTEE.

F. Martin-Duncan	Jas. A. Sinclair	E. Marriage
------------------	------------------	-------------

It will thus be seen that the only two remaining members of the former Pictorial Committee are Messrs. Inston and Holding, who last year served on that committee for the first time, though both they and the other members, with the exception of Mr. Hollyer, have industriously acted as judges at exhibitions for some years past.

* * *

The Congress of Applied Chemistry.

From the provisional programme of the official proceedings now published, it is seen that the Congress will be received by the Lord Mayor at the Guildhall on Wednesday evening, May 26, and that the meetings will be formally opened by H.R.H. the Prince of Wales at the Albert Hall the following afternoon. In addition to the many sectional meetings lectures will be delivered by Sir Boverton Redwood, and Professors O. N. Witt, Haller, and Paterno. Receptions will be held at the Foreign Office, the Society of Chemical Industry, and at the Natural History Museum. On the last day of the Congress, June 2, a visit will be paid to Windsor Castle, by permission of the King. Those applying for membership of the Congress should address the general secretary, Mr. Wm. Macnab, 10, Cromwell Crescent, London, S.W.

* * *

Dry-Plate Factories in Japan.

According to a report in the current issue of the "Deutsche Photographen Zeitung," two dry-plate factories are now in course of erection in Japan, one in Yokohama, under the name of the "Japan Dry-plate Company," and the

other by the firm of Rokuosha, the director of which is Sugiura Roku Yernon. It is estimated that Japan consumes dry-plates to the yearly value of £25,000 to £28,000, the market hitherto having been supplied by English makers, and lately to some extent by American. It remains to be seen whether the climatic conditions of Japan will allow of the manufacture of high-grade plates. Mr. Blow, of Kyoto, writing of the photographic conditions in Japan in our issue of April 26, stated that for three months of the year the manufacture of gelatine emulsion plates would be rendered impossible.

* * *

An Optical Problem.

Several times of late we have been asked to solve a rather curious problem relating to combinations of lenses. It is one that is not usually dealt with in text books, for probably no writer has foreseen that it could be one of practical interest. Yet for some reason or other it is one that is continually cropping up. Stated generally, the problem is as follows:—A lens is fixed at a given distance from a screen, which is not at its focus. A sharp image is, however, to be produced by the interposition of a second lens of given focal length between the first lens and the screen. Where should this second lens be placed, and what is the focal length of the resulting combination? We know the focal lengths of the two lenses, but not their separation, and therefore our querists generally fail to find the focal length. A little consideration should, however, show that the separation can easily be determined from the usual formulæ. The distance from front lens to the screen is known, and this obviously is equal to the separation plus the back focus, that is, the distance from second lens to screen. In this equation the separation is the only unknown quantity, and, therefore, its value is easily determined, after which the calculation of the focal length is a simple matter. To take an instance, suppose the front lens to be a 6in. positive and the back one a 6in. negative, while the distance from front lens to screen is 14in. If a represents the separation, the application of the usual formulæ will show that the back focus is equal to $\frac{36}{a} - 6$. This added to $a = 14$

which equation can be changed into $a^2 - 20a = -36$, and from this a must equal either 18 or 2. The former being impossible, 2 is the correct answer. The focal length can then be shown to be 18 inches.

* * *

Fogging from Dark Slides.

A reminder, which at the commencement of the photographic season is particularly timely, is given by Dr. Stolze in the current "Photographische Chronik," as to the fogging nature of unsuitable leather used for the hinges of a dark-slide shutter. The writer's note was prompted by the production of bands of fog on plates exposed in a slide newly provided with leather hinges, the unsuitability of which, however, was immediately recognised by its odour. On using an older sample of leather, the odour of which had been dissipated by free exposure of the material to the air, it was found that plates exposed in the same slide showed no sign of banded fog.

* * *

Grades of Half-Tone Printing.

We have always held that, in the case of photographs the final destination of which is the page of a printed book or circular, the photographer himself should provide his customer not only with the finished print, but with the half-tone block, in which connection a word of advice as to the most suitable ruling of screen is one which is occasionally needed. If the half-tone is for the cheapest

kind of printing, such as that of a newspaper, a screen ruling of from 60 to 80 lines per inch is not too coarse. For a somewhat better paper—calendered papers and those such as that on which the "British Journal" is printed—a rather finer ruling can be adopted, from 90 to 120 lines per inch; whilst the different varieties of coated "art" paper allow of the use of the finest screens from 133 up to 150 and 175. Many of the block-makers issue an illustrated circular, showing the effect of an impression from screens of these various rulings, and the photographer who has any block orders to give out will find such a circular very useful to have at hand.

* * *

Passe-Partout Mounting.

An objection which is sometimes raised by the professional worker when he seeks a better presentation of his specimens is suggested is that the cost of framing is a very considerable item. It is without doubt a great tax on the man with a small business to keep up a good supply of new and attractive specimens, but it is unquestionably necessary if the public are to be interested and secured as customers. The dry-mounting method is now within the reach of all, and individuality may be given to the mount itself by the aid of this excellent, and at the same time rapid, method. Further, the print may be trimmed so as to suit the subject and the mount built up according to the size and shape of the print. It is, however, with regard to the preservation of the mounted print that we are more concerned at the present moment. There are in most businesses occasional throw-out negatives in the 12 by 10 or 15 by 12 sizes, either from direct large portrait work, enlarged negatives, or landscape and group work, and these form a supply of really excellent glass for passe-partout mounting or framing. The films may be readily cleaned off with a nail-brush and hot water, and if a diamond is not at hand any glazier will cut the glasses for a few pence to the exact size of the mounted print. A sheet of straw-board may also be cut to the same size, and then sandwiching the print between the board and glass the three are bound together after the manner of a lantern slide. Special binding strips are supplied for the purpose, though in our opinion it is always well to moisten these, not with a damp sponge, but with a brush and some stiff paste. There is then very little likelihood of the binding ever coming away from the glass. Small wire and cloth hanging-loops may also be had from the dealers, and, carefully done, a dozen or two prints are in a condition for making an attractive display, and will remain clean and tidy for an almost indefinite length of time.

* * *

Scatter and Contrast.

Dr. Mees' abstract of M. Callier's paper, which we publish on another page, draws attention to several points of very considerable practical moment to photographers. Perhaps the most striking point is that which deals with the matter of enlargement. It is shown clearly that with the usual condenser system of illumination an increase of contrast is inevitable, but the suggestion to use an opal glass diffuser with a powerful arc light is, unfortunately, one that many photographers will be unable to adopt. A substitute for it, very suited to amateurs' use, is the old method of using magnesium ribbon burnt in short lengths and waved about behind the negative. We are certainly of opinion that this method is capable of giving a far bigger percentage of good results from average negatives than can be produced by the lantern when fitted with a stronger illuminant than an oil lamp or incandescent gas. Years ago we used nothing but the magnesium method, and though our negatives then were far more plucky than we are accustomed to make them now, yet we obtained

satisfactory enlargements without any difficulty in order to excess of contrast. Ground glass was the screen used, and it was placed at the back of the negative not in contact with the film. The proper conditions for obviating scatter were thus not perfectly fulfilled, but probably the method of illumination adopted compensated to some extent for this defect in the arrangements. There is of course, no reason why opal glass in contact with a negative should not be used in the ordinary lantern. A condenser will then still fulfil part of its ordinary functions. That is, it will serve to concentrate the light on the negative, though it will have no effect on the intensity of the light which passes through. An interesting feature of M. Callier's paper is the fact that many photographers have attributed quite the wrong properties to opal glass screens. Such screens have frequently been recommended for use with thin negatives for the purpose of increasing contrast, though it is now proved that they prevent the increase of contrast that without them would be obtained. Photographers often make use of similar paradoxical methods, as, for example, in the use of an alum solution to protect the negative from heat, though alum in solution absorbs more heat than plain water. No doubt when greater contrast is produced with the aid of a diffuser the excitation is that the exposure has not been proportionally increased. The improvement is simply due to shorter exposure. Another method of securing greater contrast which is often advocated is the use of a weak light. In lantern-slide making we are often advised to use ordinary light for exposure when contrast is desired, and incandescent light or magnesium when softness is desired. Whether this is scientifically correct advice we are not certain, but, in any case, our own procedure is exactly the opposite. When we want strong contrast we prefer to use strong light and very brief exposure, while for soft results we prefer weaker light and long exposure. Possibly in this case a good deal depends on the plates used, and perhaps both methods are correct in certain circumstances.

ON BUYING A PHOTOGRAPHIC BUSINESS.

At present being about the time of year when many portrait businesses change hands—as a reference to our advertisement columns will show—it may be well to point out a few of the things that should be duly considered by those who are contemplating buying a portrait business, for, in many cases, such consideration would prevent much disappointment, and in the end loss of money. In our columns last week a correspondent offered a caution to those who may be intending to purchase a business, more than hinted that some businesses are really “faked” for sale, and that the stated returns are not really *à fide*. There may be, no doubt, ground for this in some instances, and it behoves would-be purchasers to thoroughly investigate and satisfy themselves as to the soundness of any concern before parting with their money. Advertisements, frequently are very alluringly phrased, but it does not follow from that that the business is what it is represented to be. Most persons when they have anything to dispose of try to describe it to the advantage with the view to its securing a purchaser—but this is but natural.

One of the first things to be done in buying a business, photographic or otherwise, is to see if the books have been kept, and then to consider the amount of the returns and what net profits they show. It is necessary that these items should be considered together, for it may be that a business which shows a return of a couple of thousand pounds a year may yield less net profit than one yielding only half, or even a third of that sum; while the

worry and anxiety in carrying on the former may be infinitely greater. A comparatively small business, with high prices, say, cabinets at a guinea to twenty-five shillings a dozen, will show a very much greater net profit than one in which the prices are only ten or twelve shillings the dozen. The material in the former case costs little more than in the latter, whilst less labour and expense is necessary to produce the smaller quantity of work. Hence it will be seen that the gross returns of a business is no actual criterion as to what profits actually accrue from it unless the prices and outgoing expenses are duly taken into consideration.

Another point that should not be neglected is to see how sittings, shown in the books, have been obtained, and whether they were really paid for. The books may show prominent local names, but they may be but invitation sittings and not really paid for, and the possibility is that the people were not, or ever will be, actual customers. It is usual in the sale of a business to quote the returns for the previous three or four years, and if the entries are genuine one may form a pretty correct idea from the annual figures as to whether the business is an increasing one or on the decline. If the latter, the cause should be sought, for it may be that opposition has sprung up in the district or, possibly, that the neighbourhood is going down. Either of these causes, of course, very greatly discounts the value of the business, more particularly if it is an old-established one.

It is always a good plan after the books have been fully investigated, for the intending purchaser to take up his residence in the neighbourhood for a few days to see for himself what the district is like. While in residence he will have the opportunity of learning much of the character of the business, and on what lines it has been run.

Another matter of importance that should be seen to is the lease of the premises, how long it has to run, whether it is renewable at its expiration, and at what rental. Also, and this is important, what are its conditions, as well as in what state of repair are the premises. One of the usual conditions in a lease is that the premises must be left in good and tenantable repair at its termination. It may happen at the expiration of a lease that it cannot be renewed, or if it can, only at an increased rental. Still the tenant has to leave the place in good repair, although he may not have been in occupation for more than a year or two, while the dilapidations may have been going on from the time the lease was first granted. The new tenant may also have to reinstate portions that may have been removed when fitting up the place for photography, and this is sometimes a very costly matter.

One often sees in businesses advertised as doing so much “under management”—thus implying that it would do more if the principal was in it. That, however, is another matter for consideration by the purchaser, for it must be kept in mind that there is nothing to prevent the late manager from starting a business on his own account, or entering the services of a rival photographer in the immediate neighbourhood. In this event he might, if he was well liked by the customers, very materially injure the old business. So might also the seller of it if he was not bound under a substantial penalty not to start in business within a certain radius, within a given time—a condition that should always be enforced when buying a business.

A feature is frequently made in the sale of a business of the number of negatives in stock. The prospective purchaser will do well to see from the books what they have produced in orders for duplicates during the previous year or so, for it should be kept in mind that old negatives are not the same valuable asset that they were in the past, for at the present time people rather prefer to have fresh sittings in up-to-date styles than order from old negatives.

In the majority of cases negatives more than a year or two old are little better than so much useless lumber.

It sometimes happens that no regular books have been kept, or if they have, only in such a perfunctory way that little can be learned from them. It does not necessarily follow that the business may not be as represented. In such a case as this the receipts for the various materials—plates, papers, chemicals, and other things—should be seen, and from them some sort of rough estimate may be formed of the amount of business done, but of course it can only be a very rough one.

A very important point in connection with the purchase of a business, particularly if the prospective buyer is, say, an amateur who is contemplating entering the profession, is that he should duly consider his own qualifications, and whether he is capable of turning out work of the same quality as the seller, also whether he has a similar busi-

ness capacity. If he has not, the trade will almost certainly pass into the hands of neighbouring competitors. A portrait business after all is a very personal one, like a medical practice. The newcomer may not have the artistic ability and tact with sitters, and, perhaps such pleasing methods of dealing with them as the vendor. In such a case the business will naturally suffer.

In the foregoing we have endeavoured to point out of the more important points that should be considered in buying a portrait business. There is one other, however, that should be alluded to. A business may have come down to quite a low ebb, but it does not follow, if an amateur is able to produce a higher class of work and with more business tact and enterprise than the seller takes hold of it, that it cannot be made a highly remunerative one. Such cases are of frequent occurrence with businesses that have been bought for quite small sums.

THE SPRING-CLEANING SEASON.

It has often been a matter of surprise to me that many photographers seem to take little heed of the appearance of their studios and apparatus, seeing that appearances go for so much in a portrait business, more particularly with new customers. The remark applies more especially to what are usually termed "middle-class" establishments, but it also applies in some instances to higher class ones I have visited. This state of things may partly be due to the fact that the deterioration being gradual, the photographer has unconsciously ignored it, or, maybe, does not realise it to its full extent. The case, however, is very different with a stranger who is entering the studio for the first time: he or she will not be favourably impressed with the look of the place, and such an impression is not conducive to confidence in the work of the artist, however excellent that may be. First impressions often tell for much in the success of a pleasing portrait—more especially with ladies.

The Look of the Studio.

A studio and the accessories in it may have looked fairly well during the dull autumn and winter light, but a bright spring and summer one gives the whole place a shabby and woebegone appearance. I happened the other day to be in a good class, exceptionally large provincial studio, which I found filled up with a lot of accessories that were shabby in the extreme, and quite out of date, as were the majority of some twenty or more backgrounds—most of them rolled up and laid at the sides. All these, like some of the accessories, would probably never be used again—they were simply so much lumber, and nothing more. They were, I was seriously informed, simply kept because they helped to fill up the place, and give it a furnished appearance. But the place would have looked far better furnished had a large portion of this shabby and dilapidated lot been got rid of, and only the more modern retained.

One is quite aware that many middle-class photographers had by no means a good year's business last year, and, for that reason, are not inclined to go to any great outlay in beautifying their places for the coming season. That, however, is a mistaken policy, unless, indeed, "£ s. d." considerations are actually imperative. Great outlay, however, is often not at all necessary in order very materially to improve the general appearance of a photographic studio and its contents, and therefore a few hints from one who has had some practical experience in this direction may be of service.

Renewing Blinds and Curtains.

In the first place nothing gives a studio a more shabby appearance than stained and dirty blinds and curtains; these are the first things to be taken in hand. If the blinds are on rollers,

spring or otherwise, it is better to replace them by new ones, and to utilise the old material for dusters and such-like purposes. Washed blinds can rarely be made to run evenly on the rollers, and, moreover, by exposure to light and damp, the fabric comes always more or less rotten. It is really cheaper in the end to buy new material, and put it on the old rollers. If the blinds are arranged to work loosely horizontally on wires, they can be washed with advantage, as they will work as well as before. With regard to the side curtains of woollen material, the dyer and cleaner will do the needful with them at a very small cost, and then they will look nearly as good as new, supposing the fabric itself has not perished.

Reviving Accessories.

Accessories are constantly being chipped, scratched, or otherwise damaged, and then look very unsightly. As a rule they are easily repaired or renovated by the photographer himself. Whenever a piece of "compo." gets knocked off, if it be a roller stuck on again with glue—every photographer has, or ought to have, a glue-pot—no real damage is done. Often, however, the piece is put aside, and becomes lost. Even then, if the surface it occupied is coloured the same tint as the ground-work, the injury will pass quite unnoticed, and also save the time of the spotter in having to touch it out in all the prints. If the accessories are "compo." work—imitation stone, or the like—the best way to renovate them is to give them a coating of the same description (distemper, or flatted oil) which they had originally. The former is made by mixing common whiting and drop or other colour to match the work, with water to the consistency of thick cream, and then adding sufficient common size oil shops (made hot) to form a thin tremulous jelly when dry. This should be applied cold and in the jellied state. The latter (oil flattening), a suitable flattening will be white lead, black, or other colour, ground in oil as sold in the oil shops, thinned with turps to the consistence of ordinary paint. About a third of its bulk of japaner's gold size is added. This should be stippled on with a hog-hair paint brush, when dry without gloss. Both the distemper and the flattening should be tried on a small piece of the work first and allowed to dry, as each becomes somewhat different in tone as it dries.

A coat of paint will greatly improve the appearance of a studio, and this the owner, or his assistant, can apply, and requires no particular skill. Supposing the paint is in a good state, soap and water will greatly brighten it up. If a portion of the studio is papered, and the paper has become dirty and stained, as it probably has, it can be re-papered by the owner, as here again but little skill is necessary in applying paper in short lengths. Carpets should be taken up and beaten. If, when relaid, they be washed with water and

hours will be greatly revived, and give quite a new appearance. At the oil shops is now sold what is called "carpet soaps," are said to restore the colours, but I have had no personal experience with any of them.

It is of more importance to the appearance of the studio, and the appearance it may have on sitters, is that of the apparatus, again at which is often quite overlooked by the photographer. It shows quite well that in its present state it suffices to produce good work, and if it looked better would be no better in respect. But this is to ignore the fact that the appearance of the apparatus may have a material influence upon the customer. If it looks "spick and span" it inspires greater confidence in the excellence of the work it will do than if it be shabby and dirty. For that reason I would suggest that the camera stands should be taken in hand. Unless the polish is in a bad state, it is not necessary to send the apparatus to the restorer: things may be made to look almost as good as new with but little trouble.

Restoring Metal and Woodwork.

In the first place, all the metal parts—racks, pinions, and screws—like that which can be taken off with a screw-driver, should

be removed: unless that be done, it is next to impossible to get the dirt off round their edges, and, if it be polished over, it will be very pronounced when the work is finished. All the parts that can be detached having been removed, the woodwork is well washed with soap and water, and wiped quite dry. The surface is then polished with a "reviver," of linseed oil, camphor, vinegar, butter of antimony, and ammonia, or the useful special preparations sold for the purpose, such as that made by the Vanguard Company under the name "Happy Thought." After the work has been washed clean, the reviver is applied after the manner of French polishing—always rubbing it on in one direction only. It should be applied evenly and lightly. A second application may be made, if necessary, after the first has become thoroughly dry and hard—say, on the next day. After that is dry, the brass fittings are replaced, and the camera will look almost new. The stands may be dealt with in a similar manner. At the oil shops polish revivers are sold, and some of them are said to clean the work as well as polish it, but it will be found more satisfactory to remove the dirt first with soap and water, and apply the reviver afterwards.

WM. MICHELL.

THE SCATTERING OF LIGHT BY DEVELOPED PLATES.

Being an abstract, by Dr. C. E. K. Mees, of a paper by André Callier, of Ghent, read before the Royal Photographic Society, and published in the current issue of the "Photographic Journal."]

It has frequently been observed that projection by means of an optical lantern to form an enlarged or reduced reproduction of a negative results in a positive which differs from the original negative in respect of the steepness of its gradation. This knowledge of this fact is usually emphasised by the technical worker with regard to two special procedures: negatives intended for the preparation of bromide enlargements are always developed for a shorter time than those from which

been printed by contact. The two positives are on the same plate, developed for the same time. Fig. 2 shows a sensitometer strip printed in the same manner, and the difference in

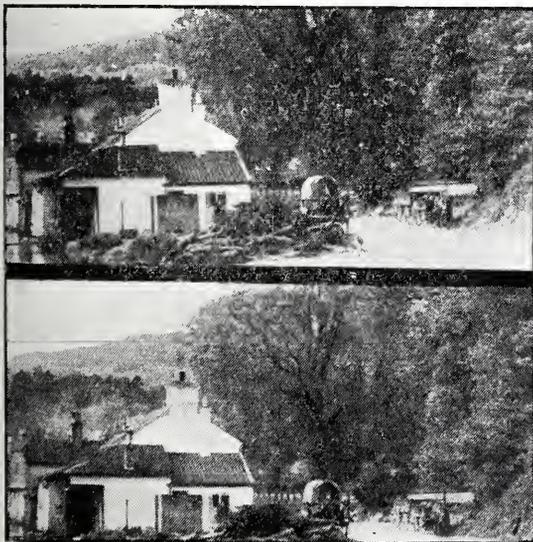

Fig. 1.

contact prints are to be made; and positives to be used for the making of enlarged negatives must be very "flat," or the negative when made will exhibit too great a degree of contrast. That is to say, a projected image has greater contrast than the negative from which it is derived, and a positive produced by projection will show greater contrast than one printed by contact.

This is well shown in Fig. 1, in which the one picture has been projected by a lantern with a condenser, the other having

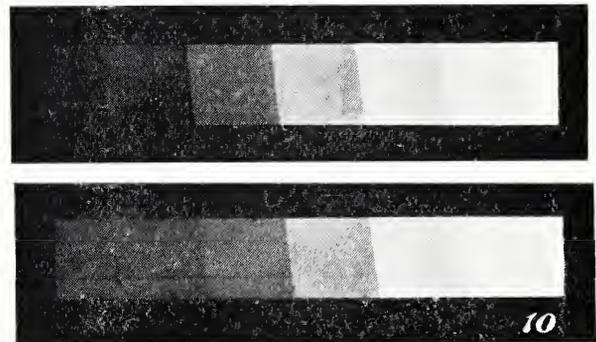

Fig. 2.

graduation between the two prints is clear. So far as I am aware, the only explanation of this which has been attempted was given by V. C. Driffield.* That explanation was, that some of the light passing through the negative when making contact prints was reflected back by the white surface of the

Fig. 3.

positive plate or paper, and, being again reflected by the surface of the negative film, was utilised by the positive film. Fig. 3 shows this. In projection, such light reflected back by

* "The Principles involved in Enlarging," "B. J.," 1894, 714.

the positive plate or paper would be lost. This explanation seems scarcely sufficient to account for the observed phenomena, and, as will be shown later, all the facts can be accounted for without resort to this double reflection at all.

It was first suggested by Sir W. Abney that photographic negatives not only absorb incident light, but also scatter it. Mr. Chapman Jones endorsed and emphasised the importance of this scattering action. S. E. Sheppard and C. E. K. Mees examined the scatter for their type of photometer (Hüfner), and concluded that it was of small importance. On the suggestion of Professor Martens, M. Callier has therefore sought to discover if scatter occurs, and to what extent it is of importance.

In order to investigate the matter, he has measured the densities of photographic "sensitometer strips" (i.e., strips of plate exposed behind a sector wheel to a standard light, and then developed), by means of a photometer adjusted in such a way that in the first place the density was illuminated by parallel light, and in the second by completely scattered and diffused light.

In the first case, any scattering of the parallel light will cause a loss of light to the photometer, and will count as if the light were absorbed, while in the second case the light (being already completely scattered) cannot undergo any further

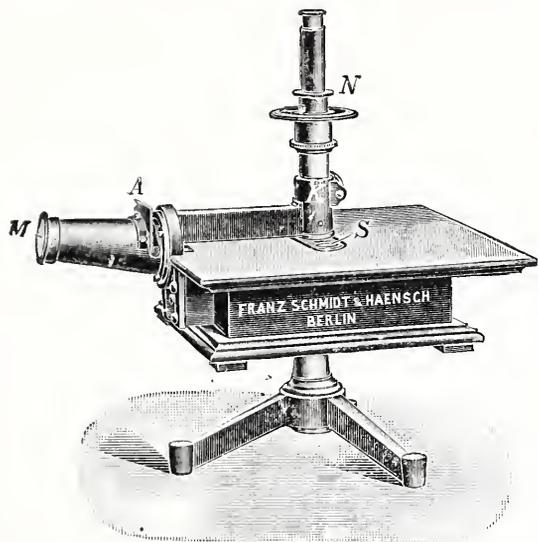

Fig. 4.

diffusion, and the measurement represents simply the absorbing power of the density.

The Method of Measurement.

The photometer used was the Martens polarisation photometer, made by Schmidt and Haensch. This is shown in Fig. 4, where M represents an opal glass, which is the source of light, S the sensitometric strip, and N the circle on which, after adjustment of the two fields to equality, the density is read. When parallel light is to be used M is the source of light, and, in consequence of its distance, the light falling on the strip is practically parallel. If, however, a piece of opal glass is placed under S with its surface in contact with the film of the density to be read, then the light falling on the density is completely diffused. The use of this second opal glass greatly reduces the available light intensity, and to overcome this difficulty M. Callier has arranged his photometer so that the glass M is very close to a large projection Nernst burner (Fig. 5.) The burner is put in an ordinary enlarging lantern without front or condenser. This lantern is fixed in position, and the photometer is fitted with levelling screws, so that its own position is fixed. Between the burner and the photometer is put a glass cell, through which a current of distilled water is circulated

by means of a small centrifugal pump, in order that the photometer may be protected from the heat of the lamp.

Results.

The results obtained show that the densities measured in parallel light (which we may call D_p) are much greater than those measured in diffused light (D_s). The ratio $\frac{D_p}{D_s}$ is nearly a constant for each kind of plate, and is called by M. Callier Q.

For the accuracy of reading, and the determination of the errors, the original paper in the "Phot. Journ." should be consulted, but I may remark that this appears to me to be one of the most accurate pieces of photometrical research which have ever been made, the measurements of Dr. Sheppard for the "photometric constant" being the only photographic example of the same degree of accuracy which I can recall.

M. Callier has also measured a strip which had been already measured on the Hüfner spectrophotometer, and shows that the Hüfner readings are intermediate between his two values, being nearer to those in parallel light. Thus, the Hüfner

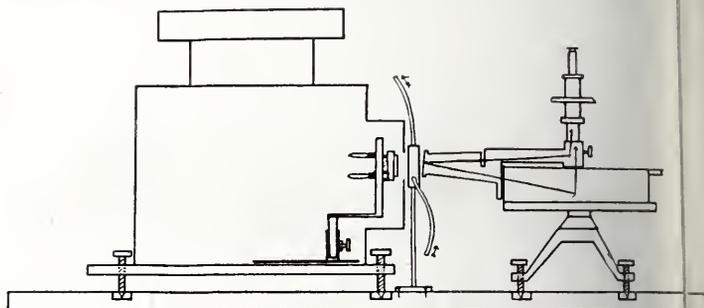

Fig. 5.

instrument shows considerable scatter, though the degree of scatter does not vary with different densities.

It may be noted that this result invalidates the measurements of Mees and Sheppard only to a very small degree, as is shown by the rigid proof put forward by them that their densities are proportional to the mass of silver per unit area.

The value $\frac{D_p}{D_s} = Q$ is not quite a constant, as is shown by the following table:—

D_s	$\frac{D_p}{D_s} = Q$
.119	1.622
.296	1.618
.628	1.567
1.072	1.542
1.544	1.511
2.011	1.483
2.404	1.466
2.693	1.473

The Effect of the Emulsion upon Q.

Measurements of Q for various kinds of plate show that the value of Q depends upon the size of the plate grain. The following results were obtained:—

Plate.	Q.
Wratten Ordinary	1.54
Wratten Verichrome	1.68
Wratten Verichrome "fog-strip"	1.52
Wratten Verichrome, intensified	1.87
Jougla extra rapid	1.67
Ilford lantern plate	1.45
Agfa Diapositive plate	1.35
Wratten lantern	1.22
Plate made of gelatine containing Chinese ink	1.00
Plate made of dye by the pinatype process	
Lippmann plate made by Dr. Lehmann ...	

It is clear that the method of density measurement adopted will have some influence upon the shape of the characteristic

and also a slight effect upon the value of the inertia. Densities measured in investigations should therefore be measured, if possible, in diffused light.

Conclusions.

These results obtained by M. Callier show that when a negative is lighted by parallel light it will have a different scale of contrast (amounting for ordinary plates to the same effect

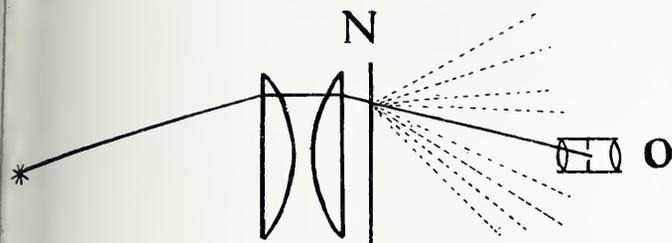

Fig. 6.

could be produced by about doubling the time of development) to that which it will have when lighted by perfectly parallel light. This difference in contrast is produced by light which is not absorbed, and which passes through, but which is scattered. Now, in projection this scattered light is lost owing to the fact that it does not enter the objective (Fig. 6). In contact printing the scattered light is, of course, not lost.

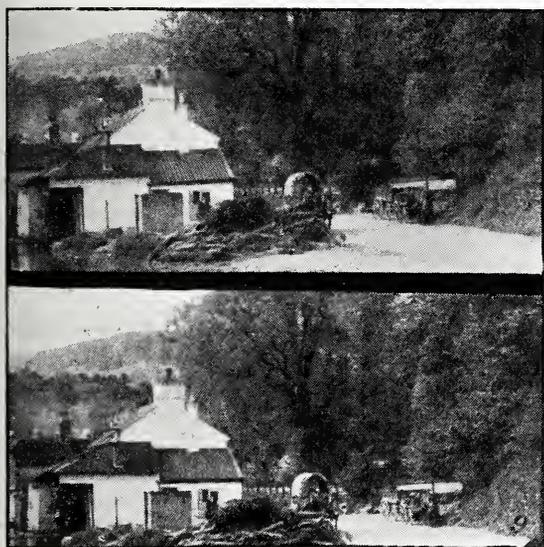

Fig. 7.

however, we light a negative for projection by perfectly parallel light, by putting it film down upon an opal glass which is lighted without a condenser, then the scale of gradation will be the same as that obtained by contact printing. Figs. 7 and 8 were prepared in this way, the one positive being projected by means of opal glass, the other being made by contact. It is well to note that the negative *must* be put film

down upon the opal, hence the reversal. It will not do to put the glass side upon the opal, as otherwise the "critical angle" seriously limits the perfection of the diffusion.

In projection by daylight, ground glass producing fairly well-diffused light is usually used, and consequently the contrast is less exaggerated than when a condenser is used. In

Fig. 8.

order to find whether the degree of parallelism in the Martens photometer is the same as that used in an enlarging lantern, the following method was used:—A sensitometric strip, with densities measured in parallel light and a series of neutral glasses of known density, but possessing no scatter, were put together into an enlarging lantern. These were lighted evenly by means of a large condenser. The source of light was the acetylene burner S (Fig. 9), and a monochromatic green screen was used to avoid error due to the colour of the neutral glasses, the densities of the glasses having been measured by the same screen. The neutral glasses R and the strip P were projected

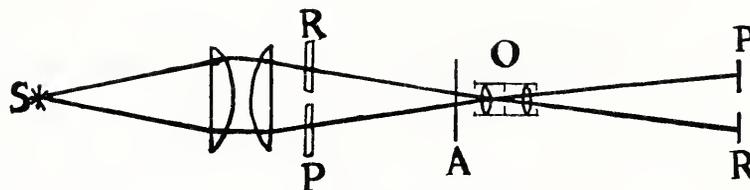

Fig. 9.

as images, R^1 and P^1 , upon a photographic plate. After development the densities of the negatives obtained were measured. Since we know the densities of the neutral glasses we can plot the characteristic curve of the new negative, and find by interpolation the densities of the strip. The values found correspond within the error of measurement with those found in the photometer for parallel light.

The results found in this work make it possible to explain why a negative appears to lose opacity when varnished. Measurements of a negative before and after varnishing show that varnishing causes a considerable loss of density when measured in parallel light. When measured in diffused light no such loss is found.

PHOTOGRAPHY AS AN AID TO TEACHING.—A course of eight lectures primarily intended for teachers engaged in secondary schools will be given at the Manchester Municipal School of Technology, on the practice of photography so far as it relates to methods which may be utilised as aids to teaching. An endeavour will be made to demonstrate in a simple manner the uses of photography as a means of illustration. The processes described will be fully demonstrated, and the different forms of apparatus used will be shown and explained at the lecture table. The lecturer is Mr. Charles W. Gamble, by whom the subject will be treated in accordance with the following syllabus:—The usual forms of apparatus used in the studio, the field,

and the dark-room—The hand camera—Forms of hand camera for particular purposes—Special plate-holding devices, as changing-boxes, magazines, and holders for films in rolls and the cut state—Daylight changing and developing contrivances—Lighting the subject to be photographed—Manipulation of the camera—Principles governing exposure and instrumental aids to determining exposure—The development, fixation, washing, and drying of negatives—Modification of negatives for varying the character of the print—Artificial light processes for the rapid production of prints—Lantern slides for lecture illustrations—Simple types of optical lanterns—Making enlargements—Mounting pictures—The Autochrome process for the production of pictures in colour. The lectures begin on May 6.

PHOTOGRAPHERS' ADVERTISEMENTS.

Our monthly contemporary, "Advertising," issued at sixpence, from 101, Fleet Street, E.C., contains in its April issue the results of a competition of special interest to our readers, inasmuch as they are forms of advertising suggested for newspaper use by readers of "Advertising." Some few years ago Mr. W. J. Casey, in a brief respite from the managerial direction of Messrs. Raines and Co., contributed to our columns a series of articles on advertisements for photographers, in which he very usefully enumerated the appeals which a photographer may make to the public, and analysed the motives which members of the public may be supposed to have in visiting the photographic studio. A shrewd appreciation of those motives is, of course, the first condition of preparing advertisements capable of drawing business; and it will be seen that the competitors in the "Advertising" competition have touched upon several though by no means all the inducements which the proprietor of a studio can hold out. We may first quote the remarks of the Editor of "Advertising" upon the advertisements submitted

A Natural Picture of Your Children

Is one in which they can be seen as you see them daily. How often we hear people say of children, when playing in their nursery, "What a pretty picture they would make." But after a journey to the Studio and a tedious attempt to make them look happy and natural, the resulting picture is either partially or completely a failure. The only way to get a real living picture of your Children is to have them

Photographed At Home

In their natural surroundings. We make a speciality of this style of *Child Photography*, studying all the details that have made it so wonderfully natural. Will you let us photograph your children in their home? You will be delighted at the result.

Our Offer.

We will call at your house and photograph your children without any obligation on your part if you are not completely satisfied with the Picture we make. Send us a Postcard to-day.

**The Natural Picture Studio,
5, Broadway, Brighton.**

By C. T. Norman, Brighton.

(Awarded first prize.)

to him, and may then comment on one or two of those considered worthy of publication in our contemporary, of which, by the way, we would mention one feature of service to those who photograph for the Press, viz., the list of periodical publications being newly issued.

"The advertisements submitted are, as a whole, good, but I find there is a recurrence of certain words and phrases through those submitted. Thus I notice 'framed sunshine,' as a specific instance, occurring two or three times. This and other repetitions suggest either a curious coincidence or that some standard reference book is being consulted. I am loth to think that the latter can be the case, but, all the same, I would urge competitors to draw upon their own imagination for ideas.

"Not so curious, to my mind, is the fact of the occurrence to so many competitors of the specialising in photographing babies. This, however, is very widely done at present by photographers, so that this class of advertisement is simply resolved into a matter of the quality of the 'copy.'

"Naturalness of pose (often a mere sophistry), artistic finish,

Unsolicited Testimonial.

Rose Villa, Benton.

Dear Sir,—“Before definitely engaging you, please send photo.”

The above is an extract of letter received by me.

The photo sent was the means of securing a good appointment.

That I chose your studio for this, to me, important work was due to having seen specimens of the excellence of your work in naturalness of expression, pose, and general finish.

I cannot too highly speak of the appointments of your studio, which tend to put one at their ease and remove at once the very prevalent idea that to face the camera is equal to the ordeal of Dentistry. That this photograph had all the elements of a *Speaking Likeness*, is proved by the acceptance of the subject. That you have secured a Voluntary Advertiser is due to your excellent work, unconscious posing, up-to-date accessories, and moderate charges.—Yours truly, A. F. JONES.

**To HAROLD NICHOLLS,

(Awarded second prize.)

picture-like effects, and prices—these are, seemingly, the main points as viewed by competitors. In some instances novel features are presented, the presence for individuality in the pictures, the necessity for care in retouching, and for careful mounting on suitable mounts. Others touch upon the sentiments and reminiscences conjured up by the photographs of those we have lost—a delicate subject, but one worthy of con-

“Enclose Photo”

80 per cent. of "Situation Vacant" advertisements contain the clause, "Enclose Photo." Has this any meaning for you? Are you wanting a better situation? Is there any likelihood of your being dismissed? If so, have you a photo of yourself? Many men have lost opportunities of securing better berths through not being able to comply with the above clause. Let me impress upon you from a business point of view, that it is essential to always have a good smart photograph of yourself handy. I am an expert in putting that touch which means so much to a photograph. Come and give me a trial now, and be ready to grasp opportunities.

A. Brown, Castle St., Sheffield.

By A. J. Henshall, Sheffield.

(Awarded second prize.)

sideration; catching the 'fleeting smile' is a neat expression, too.

"The prize-winning advertisements have been selected for three reasons—originality of idea, facility of expression, and form of display. I mention the latter, as I am giving a few selected advertisements in the same fashion as last month.

out any attempt at display. Competitors should, therefore, pay attention to this point." They are quite in agreement with the award of the first prize

**Artistic—
Yet How Natural**

Is the saying awarded our Photographic Reproductions. Babies' portraits we specialise in. Your baby would make a lovely picture. We can just catch that dear little smile on baby's face beautifully. Don't think baby would spoil a picture by crying, baby will be sure to smile at the right moment—click—and the portrait is taken by our latest improved baby photographing apparatus. Of course, it is easy to see that if we can get such good results with the little ones, it is equally certain our portraits of "grown-ups" will be as successful. Call at our studio, and see for yourself the delicately finished specimens of our Fine Art Photography. Will you?

**Coopman & Jones,
Redland Rd., Bath.**

By A. E. Tuton, Hull.

part to give much prominence to an offer to photograph children at their homes. The writer of the advertisement, if he be a photographer, knows that of all descriptions of portraiture that of children requires all the art and artifice which can be applied to it, and in ninety-nine cases out of a hundred no place is nearly so well fitted for the work as the studio. However, for once in a way, such an announcement is useful as a means of coming into touch with possible new customers who may have special reasons for wishing for at-home portraits.

The idea of making use of the phrase "send photo.," so common to advertisements of situations vacant, is one which has the advantage that it appeals with equal force to customers of either sex. It is, of course, chiefly of value in a district where the population is made up of clerks, shopmen, and others occupying minor positions. An advertisement such as this, which would draw business at Clapham Junction or Finsbury Park, would be useless at Chislehurst, or perhaps resented at Crouch End.

The last advertisement, which again seeks to play upon the desire for portraits of children, errs in familiarity, and sounds a little cheap perhaps, but for newspaper announcements in many districts it should prove a convincing argument.

One point which should not be overlooked in the consideration by a photographer of his advertisement "copy" is that no announcement, however good, will bear constant repetition. The first appearance or two will be read, but when a notice becomes familiar it loses its attractive power, and, moreover, is apt to create the impression that the photographer, from the fact of his saying the same thing week by week, is lacking in ideas.

PHOTOGRAPHY AND OUR ANCIENT CHURCHES.

II.

The Study of Minor Ecclesiastical Antiquities.
In the matter of selection of suitable subjects to illustrate his historical studies the photographer's choice will, of course, often be restricted through circumstances local or otherwise. The churches of certain districts are, as might be expected, frequently more interesting on account of their special architectural or archæological peculiarities than those of others. Paradoxical, however, though the statement may appear, it is nevertheless true that edifices of the less interesting type are, generally speaking, very suitable as subjects for photographic treatment, and this because they belong to a class of buildings of which, as a rule, satisfactory pictorial memorials are not procurable, and which, moreover, owing to its comparative insignificance, are always particularly exposed to the assaults of the modern architect and his abettors. The photographer is, therefore, strongly recommended to devote at least a portion of the time he is prepared to bestow upon practical ecclesiology to the study of the minor ecclesiastical antiquities of the district which he proposes to make the field of his researches. Among buildings of this kind the commonest are our ancient parish churches, of which examples in all the six periods of architecture are more or less abundant. Buildings dating from the Saxon period are naturally the least common of any, and these in an entire condition are now extremely rare. Examples, more or less fragmentary, are numerous in Lincolnshire, and very common in Northamptonshire and Suffolk, whilst isolated specimens occur in most of the northern counties of England, particularly in Northumberland and Yorkshire. In Scotland, the priory church of Restennet, in Forfarshire, the erection of which is attributed by the latest archæological authorities to Northumbrian builders, is the only edifice which exhibits the distinctive features of Saxon architecture.

Churches, more or less entire, dating from the Norman period, are common, particularly in England. Buildings illustrative of the four later periods of architectural history are fairly abundant in all the styles in both countries, with the single exception of those belonging to the Decorated era, examples of which, though numerous in England, are in Scotland of very infrequent occurrence.

With the object of assisting the beginner in the selection of suitable subjects for photographic reproduction, I shall now proceed to give a few hints as to the way in which he should set about his task, and as to the structural and other details to which he should specially direct his attention when engaged in the examination of ecclesiastical buildings, or their contents or adjuncts.

Record Photographs of Churches.

As a general rule—to which, however, exceptions are to be met with in certain antiquities of the monastic class—the church itself, where such exists, will naturally be the first object of the photographer's scrutiny. Of this, in its purely pictorial aspects, assuming these to have been hitherto neglected, he should in the first place endeavour to obtain a few views. If the building be one of comparatively small dimensions, as is often the case in churches of the parochial type, four photographs will usually suffice to convey a fair notion of its outward appearance. It is advisable, however, that, whenever this is possible, these views should be taken from the four angles, south-east, south-west, north-west, and north-east, or the respective equivalents of these if the building does not stand due east and west. By this means a better idea of the connection of the several parts of the structure will be obtained, and the general aspects will probably be more artistic than those of a series exhibiting only the separate sides of the building. On

the churches of larger size, particularly on those which possess transepts or similar adjuncts, the expenditure of additional plates during the preliminary stage will sometimes be necessary. Buildings, again, of the dimensions of our cathedrals and minsters make, of course, still greater demands on the resources of photography for their adequate presentment. In cases like these, where the treatment will evidently be largely determined by the nature of the subjects themselves, necessarily an unknown factor in the problem, definite rules for the photographer's guidance cannot well be laid down. The necessity for such rules will not, however, be felt, if he be willing to act on the recommendation already here given as to the class of subjects most suitable for profitable study.

The series of views exhibiting the general appearance of the exterior of the structure having been satisfactorily completed, an examination of the chief details with a view to the selection of photographic illustrations of its more characteristic features must next be carried out.

Porches and Doorways.

Church doorways, particularly those of buildings dating from the Norman and First Pointed periods, are frequently well worthy of the visitor's attention. The larger churches are usually provided with three, one being in the western gable, the other two facing respectively north and south, and situated opposite each other at the west end of the nave. A priest's doorway in the chancel wall is also occasionally to be met with. Norman doorways are often richly decorated with figure and floral sculptures. The subjects of the figure groups are usually scriptural, or taken from the mediæval "Bestiaries," a species of literary allegory extremely popular during the twelfth and thirteenth centuries. Sculptured representations of the twelve signs of the Zodiac are also of common occurrence. Over the doorways of certain churches of very early foundation may still be seen incised sundials dating from the Saxon period, and usually accompanied by short inscriptions in archaic characters. Such dials, though now exceedingly rare, seem to have been common in churches of that era. A complete series of photographs

of those that still exist would probably be of service not only to the antiquary, but also to the philologist.

Sculptured porches, both of early and late date, are fairly numerous.

Amongst the other sculptured features of the exterior to which the photographer may profitably direct his attention when engaged on his ecclesiological survey may be specially mentioned the grotesque corbels and gargoyles and carved stringcourses which frequently decorate the eaves and upper walls of the chancel and other parts of the building, the capitals, tracery, and other details of the windows, the mural arcading in the form of richly elaborated interlacing arches which is so characteristic of the architecture of the Later Norman period, and the ornamental portions of the buttresses supporting the arches of the aisles and transepts, or the walls of the tower, nave, and choir.

The window tracery of many of the churches that were erected during the prevalence of the Decorated style of architecture is remarkable for its beauty, and for the variety and intricacy of its geometrical design. The tracery of the Perpendicular period, also, though of a more formal character, is frequently of considerable artistic merit. Tracery is an uncommon feature in the windows of the Norman period, and is only sparingly employed in those of thirteenth century date. The larger grouped lancet windows of the Early English era are, however, usually striking and harmonious, and will well repay the photographer's careful study. An interesting and uncommon feature in certain churches of the fifteenth century date is what is known as a *low side window*, a small rectangular aperture in the wall of the chancel or choir, through which, during the celebration of divine service, a view of the altar might be obtained by persons who were unable to enter the building.

The interiors of many of our early churches are rich in objects of archaeological interest. Elaborately sculptured chancel arches are numerous, particularly in the buildings of the Norman era, and usually form excellent subjects for the camera. The series of ornamental pillars which mark off the aisles of choir and nave, and the carved bosses which serve to support the vaulting, are frequently no less worthy of study. MATTHEW WILSON

(To be continued.)

THE COMMERCIAL PRODUCTION OF THE STEREOSCOPIC PRINT.

[Although stereoscopic photography grew on English soil, and, as an amateur's pursuit, has seen its palmiest days in Great Britain, the commercial possibilities of the stereoscopic print have been exploited most successfully by American enterprise, which has found a large market for prints of an educational character. The current issue of "American Industries," on publishing an account of the business of the H. C. White Co., gives a graphic picture of the scale on which this firm publishes stereoscopic photographs. Photographers here will perhaps recollect that it was for the White Co. that Mr. H. G. Ponting has taken many of his photographs in the East.—E. "B.J."]

THEORETICAL conditions are such that all properly made stereographs must be produced on special stereoscopic negatives. Hence a comprehensive plan for securing such must be mapped out and executed before the production of stereographs on a large scale can be accomplished. Such a plan has been consummated by an American firm in the past decade, and in addition the production of the goods has been reduced to an exact science, and is now a large industry.

Having secured the negatives, the next step in the plan involved absolutely new methods of production. The old makers of stereoscopic photographs, of which there were hundreds, nearly all now forgotten, executed their product by hand. Inaccuracies and defects fatal in obtaining the perfect stereoscopic effect and realism necessarily followed. As perfect negatives are required, so the stereographs must be carefully and scientifically produced, else the effect of actual vision as well as true perspective is lost.

Automatic machinery now performs with unerring accuracy operations hitherto considered absolutely impossible to be accomplished except by the human hand. The cost is lessened and a vastly

superior photograph of uniform excellence is produced. An idea of the almost infinite detail and painstaking care required in its production—in the innumerable processes necessary and the mechanical accuracy of the automatic machines used, which are marvels of ingenuity—can only be gained by a careful inspection of the plant where these goods are produced.

The process of making stereographs at this plant would be a revelation even to the most up-to-date photographer. Starting with the glass plate or photographic negative the various processes leading to the finished stereograph may be described.

Machine Methods of Producing Stereoscopic Photographs.

First the print is made. The plate negative is clamped in front of a Cooper-Hewitt light and an automatic, motor-driven photographic printing machine, working in a dark room, exposes the sheets of sensitised paper one at a time. Suction pads are arranged in a circle, and, from a pack of photographic paper, they pick up separate sheets

se are carried around to the negative, placed in contact, and a ter then opens, permitting the light to pass through the negative expose the paper. The shutter then closes, the printed paper is oved from the negative, passes on and is carefully deposited in a iver. After a test has been made to secure the correct time of osure for the paper used, every succeeding print is exactly the e, a uniformity that was entirely impossible by the old hand ess.

ext the print is developed and fixed by an equally automatic hme, in which each succeeding sheet of the exposed paper is ed up, carried through the developing, rinsing, and fixing bath le held by clutches attached to an endless belt, and delivered at the opposite end. Placed in washing machines, to which hose tached, the prints are thoroughly washed. The washer works omatically, receiving a fresh supply of water every few minutes ead on a coarse net belt, and carried over steam pipes, the prints dried. Up to this point the stereograph prints are square, $3\frac{1}{4} \times 3\frac{1}{4}$ es, and the next operation is trimming, which is done by dies t must be absolutely accurate; as the right and left print when uted must exactly align.

n trimming, the tops of the prints are curved and the outer points nded. The prints are now ready for mounting. The mounts are x 7 inches in size and of a uniform dark olive colour. The titles rted in sizing on an automatic press with a speed of 10,000 our, and the title is then gilded in an automatic gilding machine ich does not throw any particles of gilt into the operating room, l passes out the cards dry and free of gilt dust. The prints, after ng mounted, are retouched where necessary and carefully ncted. The final process is the waterproof coating placed over e entire face of the stereograph, which greatly prolongs its use-ness.

The processes of making the stereoscopic instruments, while not uiring such delicate and complicated machinery, are nevertheless remely interesting. The company's business originally was that of king spectacle lenses and optical instruments. These lines have been sued since 1870. Thirty years of experience was a valuable asset embarking ten years ago in the extensive enterprise undertaken. ay be assumed from the fact that photographic processes have n reduced to a science through automatic machinery, the stereop-ic instruments of this firm are likewise made largely by chinery.

The company's photographers have not only photographed well-own scenes, but have, at great inconvenience, photographed usual scenes. Photographers went through the Russian-Japanese ar, photographed scenes of the Martinique disaster, the San ancisco earthquake, coronations, inaugurations, expositions, and merous other special events. One photographer sent out by the npany covered 140,000 miles in seven years. Another started on welve months' trip, but new demands arose, and he was sent from ace to place until he had encircled the globe, consuming forty-three onths on the trip without returning to this country.

Education by Stereography.

Through the perfecting of the world-wide organisation and the eans for presenting the scenes, the stereograph has now come to e recognised as a great educational factor. In this day of objective struction, the history, geography, and characteristics of a country come lucid to those who are enabled by this new, but old, pictorial ccess to view in the schoolroom or library actual scenes from that untry exactly as they appear to the human eye, with the exception colour, and that is suggested. Many public libraries throughout e country are now provided with "Travel Tours" as an adjunct

to the best reading of history, art, and travel. A still more signifi- cant feature is the increasing number of schools and colleges which make stereoscopic views and accessories for study.

An important feature of the business is the making of enlargements for schools and libraries. The stereoscopic negatives lend them- selves to the production of lantern slides, and the company maintains a large department for making these, including an artistic staff which has produced some most artistic colour work. The extensiv- use of the stereopticon for educational work in the public schools, colleges, and State educational departments, as well as for public lectures, has great enlarged this particular field.

Stereoscopic Prints v. Travellers' Samples.

A very successful department recently established by this company will be of particular interest to readers of the "American Industries." The company sends its photographers to large plants where stereo- scopic photographs of various processes and workrooms are made Through the instrumentality of a new invention of the company called the "stereo-pack" these scenes are reproduced conveniently in stereoscopic form at comparatively small expense. "Stereo-packs" representing tours of the plant are placed in the hands of dealers and agents. This plan not only imparts enthusiasm to representa- tives, but gives additional stimulus through showing in a realistic manner the superior facilities direct to retail customers. The "stereo- pack" is unique, pleasing, and in cost below anything heretofore put out in high grade work. The sense of actuality obtained is decidedly novel, being so strong the observer can really imagine he is making a tour of the plant. In the pack may also be included strikingly realistic reproductions of any leading product the manufacturer wishes to illustrate. The company's Commercial Department is also exploiting the value of the stereo-pack as a most satisfactory sub- stitute for the travelling salesman's heavy troublesome samples. Several large companies are planning to illustrate their line in this manner. Single photographs, no matter how large, are not to be compared with a stereoscopic reproduction and are considerably more expensive than the new "self-mounted perfect-stereographs."

To those who have been paying immense baggage excess charged on samples because no adequate means was at hand for illustrating their product, the new "stereo-pack" will be a great boon. Since the stereograph reproduces articles and scenes with all dimensions seen by the human eye when viewing the original, since the object is reproduced life size and may be coloured in exact reproduction of the original, it would seem that sooner or later the plan would be adopted by every firm who finds it necessary or desirable to show samples of their product.

The commercial possibilities of the stereoscopic photograph in the form of the "stereo-pack" seem almost unlimited. As examples of its use in illustrating the facilities of the manufacturer to domestic or foreign dealers and consumers might be cited the food product industry and cotton manufacturing. It seems impossible to conceive of so convincing a proof of the sanitary conditions existing in a given food plant, or of the marvellous facilities of the immense modern cotton mills. Then there is the railroad anxious to develop indus- tries and home building along its line and to stimulate passenger traffic. What means approaches this new plan for showing superior conveniences, facilities, and unusual beauties?

The reproduction of products has fully as wide a scope. Hundreds of products are sold by photographs which until now have been the best means of illustration obtainable. Manufacturers of furniture, machinery, stoves, vehicles, motor cars, lighting fixtures, etc., etc., have now available most satisfactory means for showing in realistic fashion and in true perspective all of their products.

THE GERMAN PHOTOGRAPHERS' UNION will hold its thirty-eighth meeting, under the patronage of His Royal Highness the Grand Duke of Saxony, in Weimar, to last from August 23 to 27. In connection with it an exhibition of photographs and photographic articles and aquisites will be arranged in the building of the Builders' School, which will be open to the general public till September 5. Besides lectures and other proceedings of a business character, the programme of the meeting comprises a day's excursion to Jena, where the new university buildings, the glass works of Schott and Co., and the far-famed optical works of Carl Zeiss will be visited. Weimar

itself is endowed with a peculiar attractiveness, concentrated in the smallest space, from a literary and artistic point of view. Goethe and Schiller, Herder and Wieland, as well as Carl August, Anna Amalia, Maria Paulowna, Carl Alexander, and Sophia, are only a few of the illustrious names connected with the history of the mental culture of Germany, from which Weimar derives its glory. The places which still bear witness of that great period and the various collections sacred to such memories will, through the courtesy of the respective administrations, be freely opened to the visitors of the meeting.

Photo-Mechanical Notes.

Facsimile Reproduction of Coloured Originals.

IN reference to the paragraph in last week's "Photo-Mechanical Notes," Dr. C. E. Kenneth Mees writes:—"In "Photo-Mechanical Notes" on page 323 of the "Journal," you mention a method of analysing coloured originals containing black, published in "Le Procédé" of December last, and you state that in my new book there is no mention of it. I think that if you refer to page 46 of "The Photography of Coloured Objects" you will find that the method is mentioned. It is referred to quite briefly, and possibly not so clearly as given by you, but I think the instructions given can be followed by a careful reader.

Collotype for Amateurs.

We have received from H. Calmels, 150, Boulevard Montparnasse, Paris, a small booklet, entitled "Le Procédé Collo," which is a detailed description of a modified collotype process, very similar to the "Sinop" process, sold here by Messrs. Penrose. All the apparatus and plates can be purchased for a small sum, the process appears to be easy to work, and the prints fair, judging by the example shown. Except that the emulsion is supplied either on the plates or in *pâte* for coating, and that the method of printing is different, the working of the process is identical with ordinary collotype. The press sold and illustrated is an ingenious modification of the ordinary letter-copying press. The process is advocated for professional photographers, but we doubt very much whether the results to be obtained by dabbling in collotype in this small manner are sufficiently good for a respectable professional to be proud of, or to make any money by.

The Renovation of Spent Perchloride of Iron.

We are frequently asked for information as to the practicability of renovating iron perchloride solution after it has been used for etching copper, but while this is no doubt practicable it does not appear to be profitable. One large firm of engravers some time ago fitted up a plant for electrically recovering the iron perchloride from the etching baths. Though this was perfectly successful it proved to be more expensive than the purchase of new perchloride. Chemical means are sometimes suggested, but these methods are almost certain to introduce irregularity into the etching, which, to be ideal, should be quite mechanical. A pure solution at a certain strength and temperature, used only for a certain area of copper and then discarded, will give definite results, that can always be repeated, and in the long run will be found both economical of time and material.

Pure Paper for Three-Colour.

We have frequently referred to the great importance to the photo-engraver of using paper other than the clay-surfaced glossy substance now general, a material which the artist, and, indeed, all book lovers, regard as an abomination. It is, therefore, with pleasure that we have seen some three-colours printed on a paper specially made by Messrs. Dickinson, guaranteed to have a minimum of "loading," and a pleasant surface with no facing clay, and to be made of pure rag fibres, and therefore as durable as it is possible to make paper. This paper when "calendered" is quite feasible for the finest screen work; indeed, we were shown some three-colours of microscopic work on it, and though this calendering makes the paper smoother, there is not the glare that there is from the "art" papers. The paper before calendering is quite suitable for all work which has not too much fine detail, and its use would enable books to be made of the same paper throughout, for both text and illustration.

Dried Albumen.

Of late years there has frequently been some doubt shown in formulae having dried albumen as an alternative to egg-white, as to how much of the former should be taken as equivalent to the latter. A correspondent now writes to the current "Process Work," quoting from the "British Journal Almanac" of 1875, to the effect that Mr. R. W. Thomas, the inventor of dried albumen, there stated that "70 grains of it dissolved in loz. of distilled water gives you a solution identical with (undiluted) egg albumen—the same chemically and better physically, neither more nor less."

FORTHCOMING EXHIBITIONS.

- April 27 to May 1.—Maidstone and Institute Camera Club. Sec. J. Harris, 23, Knightrider Street, Maidstone.
 April 29 to May 17.—Photo Club de Paris. Secretary General Photo Club, 44, Rue des Mathurins, Paris.
 May 20 to 27.—Malvern Camera Club. Entries close May 10. Sec. J. B. Nickolls, The Exchange, Malvern.
 July 7 and 8.—Canterbury Camera Club. Entries close June 23. Sec., B. J. Fisk-Moore, St. George's Gate, Canterbury.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents have been received between April 13 and April 17:—

- CINEMATOGRAPH-PHONOGRAPH.—No. 8,838. Improved means for securing synchronous movement in moving-picture and talking machines, or like records. William George Barker, 55, Chancery Lane, London.
 FILMS.—No. 8,896. Perforated photographic films. Hubert Palmer Town Hall Chambers, Great Yarmouth.
 PRINTS FROM TRACINGS.—No. 8,973. Improved apparatus for use in obtaining light prints from tracings and the like. George William Clarke, 6, Lord Street, Liverpool.
 STEREOSCOPIC CINEMATOGRAPHY.—No. 9,081. Improvements in and relating to stereoscopic cinematography. William Norman Lascelles Davidson, "Ranmore," Cross Roads, Southwick Brighton.
 FOCUSsing-SCREEN HOLDER.—No. 9,085. Focussing-screen holder for magazine cameras. Arthur Henry Arnold, 204, Woolwich Road Charlton, Kent.
 CINEMATOGRAPHS.—No. 9,106. Improvements in cinematograph or animated-picture machines. Kennedy and Moore and Harry Hunt, 11, Burlington Chambers, New Street, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

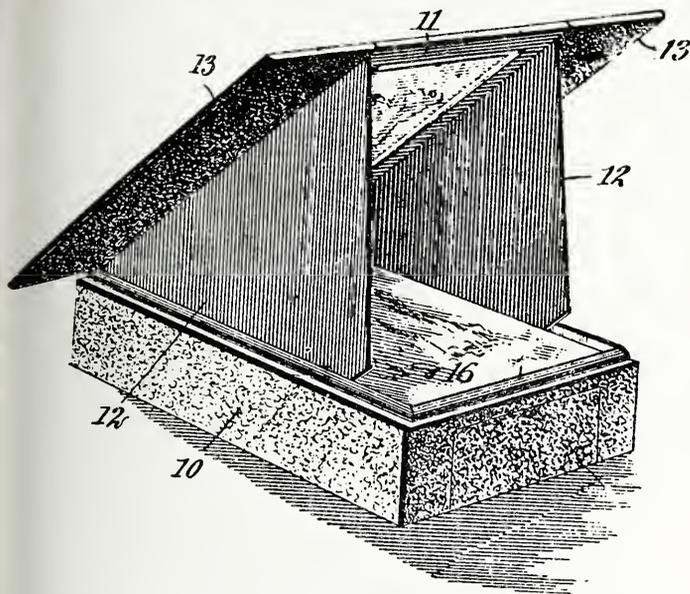

- OPAQUE PHOTOGRAPHIC PLATE.—No. 7,087. 1908 (March 31, 1908). This invention relates to photographic sensitive surfaces mounted upon an opaque medium or support, and has for its object the employment of such surfaces in contact printing according to the method forming the subject of Patent No. 13,874, 1907 ("B.J.," January 10, 1908). The base or support may, for example, be composed of ebonite, black glass, or black paper. The base or support is coated with gelatino-bromide or equivalent emulsion. The opaque support (plate) is exposed in the camera, developed in the usual manner, and a negative obtained, but owing to its opaque character it will be seen that it is incapable of giving prints or positives in the usual way by the action of light, and in order to obtain positives from such negatives a method of contact printing such as is described in Patent No. 13,874, 1907, is employed.

Owing to the facility afforded for carrying out the various operations in connection with the obtainment of negatives it will be readily apparent that expedition is ensured, and to those whose occupation is connected with the Press this will be found a considerable advantage. The use of an opaque base or support, such as herein described, also affords considerable safety in handling, it is less liable to fracture, while being absolutely anti-halation and capable of economical production. Frank Wordsworth Donisthorpe, Hohenfels, Combe Down, Bath.

- FRAME FOR VIEWING TRANSPARENCIES.—No. 11,354. 1908 (April 1, 1909). The transparency is mounted in an inverted position in its frame, and exposed directly to the light rays. The person then views the reflection in the mirror rather than looking directly at the transparency. In this manner the mirror is shaded from all

light rays except those passing through the transparency, and the latter, being directly exposed to the light, receives the full illumination.

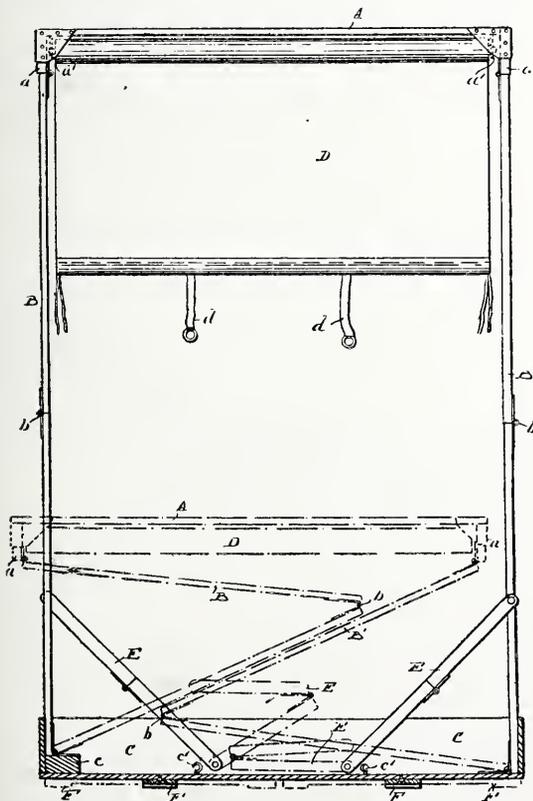

In the figure 10 is the base of the apparatus, which may be made

a receptacle for transparencies, 16 is the mirror, 11 the carrier for the transparency, 13 cover pieces for the transparency, and 12 side pieces to exclude light from the mirror. Benjamin Joseph Falk, 14, West 33rd Street, New York City, U.S.A.

COLLAPSIBLE LANTERN-SCREEN STANDS.—No. 21,245, 1908 (October 8, 1908). The invention relates to supports for lantern screens and photographic backgrounds of a portable form, enabling the screen or background to be conveniently carried about and set up in any desired position without special means for attachment.

The support consists of a light frame mounted inside a long

narrow box, to which the sides are hinged at the lower end. The sides are each in folding parts (usually two) and fold inside the box, one over the other, the top of the frame (which carries the screen or background in the form of a roller blind) covering the collapsed sides and forming the top of cover of the box. Folding struts or supports hold the frame in extended position.

Fig. 1 is an elevation of a frame constructed according to the

invention, with the box in section, and the frame consists of the top, A, and the sides, B and B¹, each of the latter parts being in two halves hinged at b to fold inwardly as shown in broken lines. The two sides are hinged at their lower ends within the long, narrow box, C, the sides, B, being hinged to a block, c, at the end of the box, while B¹ is hinged to the bottom at the other end. This arrangement allows the collapsed side, B¹, to lie under the collapsed side, B, the dotted lines showing the whole frame in the process of collapsing or extending and illustrating the manner in which the various parts fold.

The top, A, has end-pieces, a, and the sides, B and B¹, are hinged to the lower edges of these end-pieces, which, when the frame is collapsed, fit closely in the ends of the box, C. The sheet, D, forming the screen or background is wound upon a spring roller after the manner of a blind, and the roller is carried by brackets, a¹, at the underside of the top, A. When the sheet is wound up it lies entirely within the recess formed by the end-pieces, a, with the top bar. When extended it is held by the tapes, d, and hooks, c¹, on the bottom of the box, C.

The frame is held in extended position by the folding struts, E, each made in two parts, hinged at the under-side and pivoted to the sides of the box near the bottom. To give a firm support to the whole apparatus, two feet, F, are pivoted below the box, C, and are turned out at right angles to the length of the box when the device is in use, but when collapsed they are turned parallel to the length of the box, as dotted in chain lines. To enable the collapsed apparatus to be carried readily, a handle, G, is fitted to the top bar, A, and a simple catch, such as g, holds the parts in place in the box.

In collapsing the apparatus for storage or transport, the sheet, D, is first released and wound upon its roller. The side, B¹, is then bent at its hinge, and the side, B, similarly bent to bring its two halves over those of B¹, as shown in Fig. 1, the two folding struts, E, being bent at the same time, usually by the foot, to permit the folding of the sides. On dropping the folding parts they lie compactly in the box, with the sides, B and B¹, one over the other, and the struts, E, alongside, and the top, A, with the rolled-up screen, covering the whole. Frank Van Neck, 11, Cursitor Street, Chancery Lane, London.

TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.—No. 4,562, 1908 (March 20, 1909). The claim is for a process of transmitting and reproducing images at a distance in which two movable cylinders (of different diameters and placed at stations connected by an electric line, and each operated by a motor) are firstly regulated to the same peripheral speed by a preliminary adjustment of the motors, the cylinders being also regulated so that a point on one of them registers with a fixed point at the same moment that a point on the other registers with another fixed point at each revolution. This relation between the two movable cylinders is obtained by arresting by means of a hook armature held in position by a magnet in series with the line, the smaller of the cylinders during the time occupied by the larger cylinder in completing each of its continuous revolutions. The latter is provided with a tappet, which produces a single and periodic interruption of the synchronising current in the line at the end of each revolution, and consequently the release of the smaller cylinder and the resumption of its movement. An arrangement of tappets and cams allows the arrest and resumption of operation of the larger cylinder to be governed reciprocally by the cylinder of smaller diameter. Laurent Semat, rue Saptich, Cairo, Egypt.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901:—

PRINTS.—No. 7,519, 1909. Treating photographic prints. Cunningham.

New Trade Dames.

BALLOON (DEVICE).—No. 309,017. Photographic cameras. W. Butcher and Sons, Limited, Camera House, Farringdon Avenue, London, E.C., photographic apparatus manufacturers. December 19, 1908.

JONOK.—No. 310,367. Photographic printing papers and cards. M. S. Berger and Co., 106 to 110, Kentish Town Road, London, N.W., photographic material manufacturers. February 10, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

How to Vignette a Figure Direct from a Group on to a Negative.

WRITING on the above subject in "The Amateur Photographer and Photographic News" for April 27, Mr. Ernest Collins says:—"It frequently occurs that we wish to copy a single figure from a photographic group. Blocking out either on print or negative is unsatisfactory for more reasons than one; it is troublesome and generally leaves a hard line. The following process is effective and simple, and carefully carried out cannot fail to give good results:—

"Adjust the group on the copying board so that the figure which is to be copied is exactly opposite the centre of the lens, and carefully focus the image to the size required. The figure will, of course, occupy the centre of the ground glass and be surrounded by the other figures of the group. Next procure a piece of board and nail to it a smaller piece on which it may stand. I find that a piece the size of a camera front is most convenient. Exactly opposite the lens cut out a hole about the size of the lens hood, and on the side *next* the camera tack a piece of *white* cotton-wool wadding—a tack at each corner will suffice. Then pluck away the wool bit by bit until a small hole is made surrounded by a fringe of the wool hairs. This is now placed between the lens and the picture and moved to and fro until as much of the selected figure appears on the screen as is desired, and if the wool has been properly adjusted the central figure will show softly vignetted off to pure white at the margin. The wool being out of focus, no details will appear, and on the exposure being made and the resulting negative being developed to a good average density, it will yield a print softly vignetted without further trouble. This will appeal to enlargers, who generally have enough to look to whilst exposing without having to manipulate vignetting cards the while."

Hypo in the Developing Tank.

Two questions are likely to be asked (says a writer in "Photography and Focus" for April 27), as to the use of tank developing machines. One is as to putting the hypo solution into them. The amateur may wonder whether he ought to use the same tank for developing and fixing. There is no harm in so doing, if only reasonable care is exercised. These tanks are made of metal, and it is much easier to clean them than it is to clean a porcelain dish. The latter soon develops minute cracks in the enamel, cracks which are quite invisible, at least in the early stages. These cracks retain some of the solutions, and so contaminate what is afterwards put into the dish. Metal does not possess this drawback. At the same time, it is more than ever important to cleanse the tanks thoroughly after they have contained hypo.

The other question about tank development which will arise is one upon which a misconception exists. It has been stated that by using a very dilute developer plates may be put into a tank and left undisturbed for some hours, at the end of which time they will be found to have developed, automatically, to the right extent. There is no such royal road to success. Good negatives may have been made in this way by some lucky accident, just as a bird might be shot by discharging a gun at random into the air; but it would only be an accident. Whether development is quick or slow, whether it is done in a tank in daylight or in an open dish in the dark room, the duration of development has got to be determined by the photographer. Moreover, plates cannot be relied upon to develop satisfactorily in an undisturbed solution. If in a dish, the dish must be rocked occasionally, or mottling will result. If in a tank, the liquid must be agitated in some way or other from time to time. The best plan in such a case is to turn upside down at intervals either the whole tank, if it can be made water-tight, or else the container carrying the plates, so that for half the total time one set of edges is uppermost, and for the other half the other.

Photo-Sketches.

Is it not a fact (writes Mr. Nelson K. Cherrill, in "The Photographic Monthly" for May) that many greatly prefer a "sketch" to a "mere photograph," but are bound down to the latter by the feeling of incompetence to produce anything like a passable result

with brush or pencil? It is in the belief that there are many such that I come with a suggestion for a kind of compromise between the work of the camera and that of the paint-brush, which, while it suffers from the usual fault of compromises in being neither the one nor the other, is, I think, notwithstanding this, an interesting departure on its own account.

The negative, which must be of the "thin" type, is placed in an optical lantern, and its enlarged image thrown on a sheet of drawing-paper, exactly in the same manner as for producing a bromide enlargement. The paper should be of that slightly absorbent character which enables repeated washes of colour to be applied without too much danger of disturbing the underlying tint. Whatman's "water-colour sketching boards" I find to work excellently in this respect. When the image is focussed and the room nearly (but not quite) dark, all that is needed is to fill in with a brush and colour all the light parts seen on the paper, in such a manner as to make the whole present *one uniform tint all over*. When this is done the "sketch" will be complete. Of course, the *rationale* of the process is, that the negative gives a graduated image, and by bringing up the various tones with paint, so as to *appear* an even tint, more paint is insensibly added just where the tone of the work requires it. The process is quite easy, and only needs that kind of skill necessary to fill up a light patch with colour till it looks as dark as the remainder of the paper.

New Books.

"The Book of Trade Secrets." By an Expert. London: J. Haslam and Co., 15, Broad Street Place, E.C. Price 1s. net.

This is a book of recipes and instructions for renovating, repairing, and preserving old books and prints. The contents are arranged in alphabetical order, boldly side-headed. Many of the recipes are said to be invaluable trade recipes, and it is quite evident that the instructions are given by one who is a practised restorer. The directions throughout are most concise, and though one may question the wisdom of the photographer undertaking such work as the restoration of a valuable picture except after considerable experience, the volume gives just such instruction as is required.

"TRAVEL AND EXPLORATION."—The May number of "Travel and Exploration" opens with an article by Mr. L. C. Bernacchi on Lieutenant Shackleton's South Polar explorations, illustrated by a full-page portrait of Lieutenant Shackleton, three views of Antarctic scenery, and a map. Mr. Bernacchi says that the next British expedition will probably again make its way south by way of the Ross Sea, and suggests that Tibetan yaks might be employed for the journey to the South Pole. In an article entitled "Through Austria's New Provinces," Mr. Clive Holland describes a tour through Bosnia and Herzegovina. Among other articles, Mr. D. R. O'Sullivan-Beaure, formerly British Vice-Consul at Pemba, discusses the ivory trade of Zanzibar. Every article is illustrated with reproductions of photographs on plate paper, and there are reviews of books of travel and notes by specialists on exploring enterprises, tourist travel, motoring in the Antarctic regions, and aerial flight.

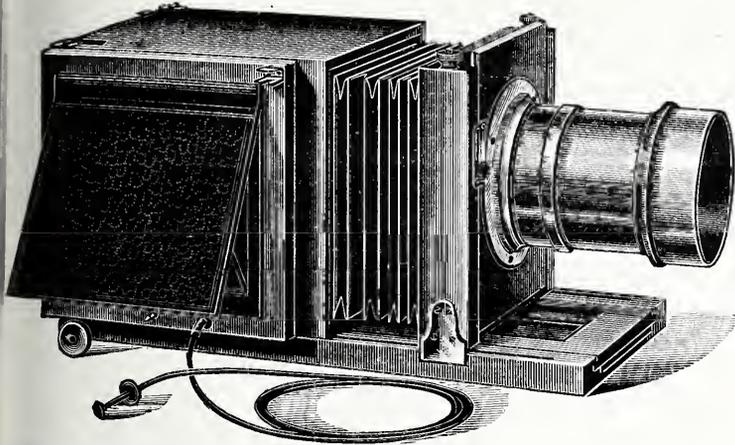

"INTERNATIONALES ARCHIV FUER PHOTOGRAMMETRIE."—The fourth number of this quarterly journal of surveying, etc., by means of the camera, contains, among others, articles on photographic survey methods in astronomy by Dr. N. Herz, and on calculation of constants by Prof. Karl Fuchs. There are notes on current progress, reviews of books, and an index to the first volume completed by the issue before us. Our contemporary is published by Herr Carl Fromme, 2, Glockengasse, Vienna II.

ROYAL PHOTOGRAPHIC SOCIETY.—A house exhibition, consisting of photographs by Mr. F. J. Mortimer (editor of "The Amateur Photographer"), will be opened at 66, Russell Square, on Tuesday next, May 4. At the evening meeting of the same day a paper will be read by Mr. Mortimer. This will be the second exhibition of his work which Mr. Mortimer has shown at the R.P.S.; the collection previously shown consisted entirely of marine studies. All the photographs to be offered for inspection on Tuesday next are by the Bromoil process.

New Apparatus, &c.

The "Sichel" Studio Reflex Camera. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

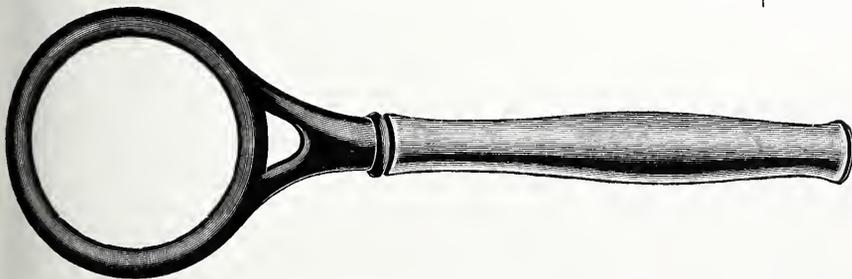

The advantages of a camera of the reflex type for studio portraiture, particularly of children, being very considerable, there is good reason to call attention to a model of camera built solely for studio work. The exposure is given by means of the mirror, which is actuated by a spring and released with the "antinous" attachment. This

allows of short exposure of the duration given with "cap off and on." The focussing screen is placed at the side of the camera, and is thus conveniently viewed when the camera is used at the usual height, but the instrument can be turned over on its side, this position allowing of a very low point of view being taken. Focussing is done by rack and pinion from the rear, whilst the total extension of 24 inches is obtained by pulling out the front. The instrument is solidly made, and complete with three double slides, but without lens, costs £10 in the half-plate size.

The "Primus" Non-Stain Print Ladle. Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

One of those handy contrivances of which, under the name of "Primus," Messrs. Butcher in their time have introduced a large number, has just been placed on the market under the above name, and, as shown in the drawing, consists of a rubber ring about two inches in diameter mounted on a handle of hard wood. This "print ladle" provides a very neat means indeed of transferring

prints from the toning or developing bath to the wash-water and thence to the fixing solution, the worker having no need to allow his fingers to come in contact with the hypo bath. The ladle serves very nicely to lift a print from its bath and after transference to press it gently beneath the surface of the hypo solution, and it should be its own recommendation to those who print on either a large or small scale. The price of the ladle issued to the trade in a cardboard box is 1s.

The "Klimax" Postcard Frame and Printers. Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

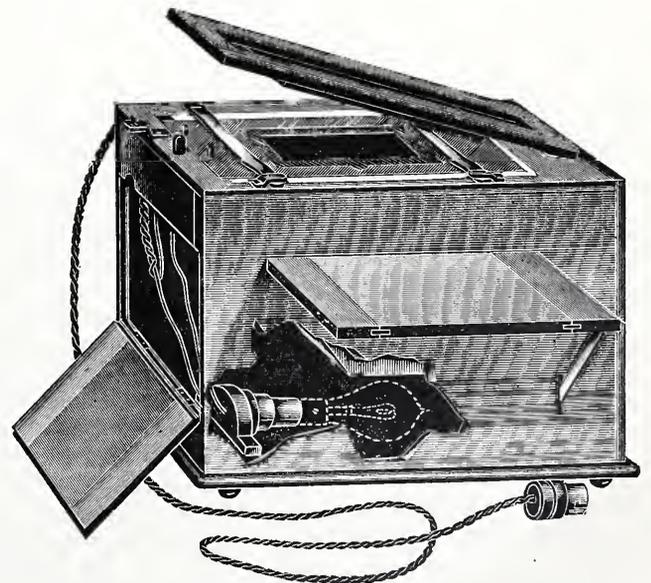

In these pieces of apparatus Messrs. Butcher provide a frame which can be used in the dark-room for taking off a number of identical prints from a negative in the ordinary way, or may be obtained as a printing machine with which exposure after exposure may be very rapidly given without the escape of any light in the dark-room.

The frame is identical in each case. In the printers it forms the top of the apparatus, two patterns of which are made, one for electric light and another for incandescent gas.

The "Klimax" frame will take a negative from 7 x 5 inches to the smallest size. As shown in the drawing, it consists of a mahogany frame, the aperture in which is filled by a piece of ground glass. On this the negative in a suitable carrier is laid, the carrier for the sensitive paper or postcard is placed over the two studs and the spring clamps brought down in order to fix both negative and print carrier. The negative is roughly placed in position when laying

it in its carrier upon the ground glass, but the final exact adjustment may be made with the springs down. Things having been thus arranged, the sensitive paper is placed in the space of the print carrier, the spring-back brought down, and an exposure made, these two operations succeeding each other very rapidly and allowing the worker to turn out a great number of prints (all identical as regards the placing of the picture) in a very short time. The price of the printing frame, complete with carriers for quarter and half-plate and with three masking gauges for the making of quarter-plate, post-

card, and half-plate prints, is 6s. 6d. Two extra sets of gauges are supplied, No. 1 to give six assorted openings quarter-plate size, and No. 2 the same number for postcard size, the price in each case being 1s.

Of the two printers we illustrate the No. 2 model fitted with electric light. It consists of a box measuring 9 x 12½ inches by 9½ inches high, the top of which, as has been said, is formed by the "Klimax" frame. The interior of the box, which is accessible by a hinged door at the front, contains an incandescent lamp, which is connected by means of a flexible cord and plug, supplied with the

printer, to any electric-light fitting. The adjustment of the negative and the printing paper is made exactly as when using the printing frame, except that as regards exposure the act of bringing down the pressure-pad upon the paper automatically switches on the light, which is switched off when the pressure is removed. When light is required for the purpose of adjusting the negative the plug seen to the left of the frame is simply pressed down. The printer, which is well made in polished mahogany, is sold for £1 5s., complete with two yards of flexible connection, plug, two negative carriers, and three printing masks, and provides a most inexpensive and effective means of postcard printing.

In the model No. 1 for incandescent gas the burner is placed outside the apparatus and a mirror is provided in order to reflect the light up through the ground-glass screen. In this case, also, the act of bringing down the pressure-board provides the illumination for the exposure, whilst also, as in the electric light model, the worker can obtain the illumination even when the pressure-board is up by actuating a stud which depresses the bye-pass of the burner. The incandescent gas model is sold at the price of £1 10s.

CATALOGUES AND TRADE NOTICES.

MESSRS. GARDNER AND CO., 36, West Nile Street, Glasgow, announce that they are closing their professional department, and have published a list of outfits, cameras, etc., to be disposed of at very considerable reductions.

PERCY J. SLATER, trade printer and enlarger, of Sawtry, Peterborough, sends us his revised list of prices for trade work of all descriptions, including carbon and platinotype enlargements, miniatures, and lantern slides. We have known of Mr. Slater for some years past, and have good reason to speak well of the quality of his work and the straightforwardness of his business methods.

BARNET SHOW-CARDS.—MESSRS. ELLIOTT AND SONS, LTD., of Park Road, Barnet, Herts, have sent us an assortment of their new season's show-cards, which, in design and arrangement, are in no way behind those of previous years, and should form an attractive addition to the dealer's window. The illustrations are printed on the various brands of papers—bromide, gaslight, self-toning, etc.—which emanate from the Barnet works, and their excellence should go far to increase the sales and popularity of this firm's specialties amongst those—if any—still unacquainted with them. An assortment of the show-cards will be sent to any dealer applying to Messrs. Elliott at the above address.

Commercial & Legal Intelligence.

A HANTS FAILURE.—The public examination was held at Portsmouth on Monday of Mrs. Florence Pattie Brown, photographic chemist, Liphook. It appeared the business was formerly carried on by debtor's husband, who died in July, 1907, when the assets were estimated at £295 and the liabilities at £602, including £335 balance of the price paid for the goodwill, etc. Since then a qualified assistant had been employed at £2 a week and board and lodging. This was too much for the amount of business done. Debtor put down her present liabilities at £535, with assets £56. The examination was concluded.

NEW COMPANIES.

FRED V. A. LLOYD, LTD. (102,477).—Registered April 8, with capital £1,500 in £1 shares, to acquire the business carried on at 15, Lord Street, Liverpool, as Fred V. A. Lloyd, and carry on the business of opticians, photographers, stereotypers, printers, etc. F. V. A. Lloyd is permanent governor director, subject to holding £600 of the shares allotted to him under purchase agreement. Remuneration £260 per annum.

FROM THE ARTICLE in last week's issue on the "Morgan System of Dry Mounting and Embossing, etc., at One Operation," a paragraph, referring to patents taken out in connection with the process, was inadvertently omitted.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 30.

Craven Naturalists Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

SATURDAY, MAY 1.

United Stereoscopic Society. "Storing and Indexing Negatives and Slides."
Borough Polytechnic Photographic Society. Outing: Down the Thames on Tug.
Kinning Park Co-operative Camera Club (Govan). Outing to Beith.

SUNDAY, MAY 2.

United Stereoscopic Society. Outing to Burnham Beeches.

MONDAY, MAY 3.

Kinning Park Co-operative Camera Club (Govan). Committee Meeting.
Folkestone and District Camera Club. "The Thames Valley." Geo. H. Sheaff
South London Photographic Society. "Further Notes on Architectural Photography." C. H. Oakden.

TUESDAY, MAY 4.

Royal Photographic Society. Address by F. J. Mortimer.
Bishop's Stortford Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Wimbledon and District Camera Club. Members' Evening.
Hackney Photographic Society. Affiliation Lantern Slides, 1908.
Manchester Amateur Photographic Society. "Foregrounds in Pictures." Illustrated with Sketches. G. H. B. Wheeler.

WEDNESDAY, MAY 5.

Edinburgh Photographic Society. "D. O. Hill and his Work." Francis Cairns.
Central Technical College Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Croydon Camera Club. "In the Solent—Coves Week." F. W. Hicks.

THURSDAY, MAY 6.

Blenheim Club. "The Camera and the Sea." F. J. Mortimer.
Southend Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Midlothian Photographic Association. "Carbon Printing." Douglas H. Watson.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 27, the President (Mr. J. C. S. Mummery), in the chair. It was announced that Mr. James A. Sinclair had been elected upon the Council, to fill the vacancy caused by the death of Mr. Hector Maclean.

A lecture was delivered on "The Bible of the Middle Ages," by Mr. Ernest Marriage, in which he described the carvings and sculpture, chiefly from French churches and cathedrals, depicting scenes from the Old and New Testaments. A hearty vote of thanks was accorded to Mr. Marriage.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, on Friday, April 23. Present Messrs. Alfred Ellis, Gordon Chase, S. H. Fry, Lang Sims, R. D. Speaight, and A. Mackie. Mr. Lang Sims (President) in the chair.

Nine applicants for membership were admitted.

The Hon. Secretary reported cases dealt with by the Association since the last committee meeting, including one case of infringement of copyright, in which compensation had been obtained, and also read letters from several members, asking advice or assistance, which were discussed and dealt with.

A letter was read from the Hon. Secretary of the Artistic Copyright Society, asking the committee to appoint a member to give evidence on photographic copyright matters before the Committee of the House of Commons appointed to consider the revision of the Berne Convention. The committee thereupon appointed Mr. Ernest Elliott. This being the first meeting of the committee after the annual general meeting, according to the rules it was necessary to elect an Hon. Treasurer and an Hon. Secretary, and Messrs. Lang Sims and Alexander Mackie having signified their willingness to serve again, were therefore re-elected.

CROYDON CAMERA CLUB.—Mr. F. J. Mortimer gave a most interesting, instructive, and highly diverting demonstration on "Bromoil" last week before a large attendance of members. With looks that belied the utterance, the lecturer first stated that he loathed lecturing and detested demonstrating. The last time he was at Croydon he talked about "water"; he was now going to chat about "oil," or rather Bromoil. Messrs. E. J. Wall and C. Welborne Pipe were, so to speak, its parents; the former originally conceived the

lea, the latter working the process out, and giving it birth about fifteen months ago. Mr. Piper's modified formula, first published in the "Photographic News," was in his (the lecturer's) opinion all the best, notwithstanding many modifications and alternative formulæ. It certainly permitted very satisfactory prints to be obtained if the instructions were closely followed; at all events it had done so in his hands, and the many pitfalls and difficulties others apparently encountered had not been personally experienced. Temperature, the quality of the initial print, the constitution of the developer and fixing bath, etc., however, opened up possibilities of going wrong.

The bromide prints must be of good quality, vigorous, correctly exposed, and developed to the full. Such a print, when looked at by transmitted light, would show plenty of silver present and a strong image. An over-exposed print, with enforced curtailment of development, naturally possessed an opposite characteristic which was not conducive to success. It followed from this that prints which took some time to bleach generally pigmented more easily than those which rapidly bleached, owing to the minimum of silver present required to be converted.

There were many varieties of bromide papers available, the "platino-matt" being generally excellent. Those with the so-called "carbon surface" and their equivalent were also good, but afforded a more shiny print. "Enammg" papers were unsuitable owing to the aggressive gloss produced. Amidol seemed to be the best developer.

Two main methods of pigmenting presented themselves. The first and the more cleanly consisted of building up the image gradually—a slow and tedious job, though the safest for the beginner. The second method which he employed might be termed "the dirty way." Here the pigment was laid on thickly, and removed where not wanted. It had the advantage of being far more expeditious, and the disadvantage of an increased tendency to accumulate hairs and dust, which necessitated their removal when the print had set.

The lecturer here proceeded to bleach, acidify, and wash some very fine studies, giving all necessary instructions as he went along. The bleached and surface-dried prints were placed on a convenient pad of his own design, and successfully pigmented. The pad, he stated, had been kept wet for months. A little formalin was added to the water used for moistening it. So far as he could see, it had no action whatever on the prints, though the contrary had been suggested.

The pigmenting of a large portrait of Dr. Mees attracted much attention, and provoked considerable comment. Without wishing to be accused of extravagant praise, in fairness it must be recorded that, judged purely as a portrait, it formed a splendid if none too kindly caricature. It depicted the doctor in profile facing a strong light, an eyeglass, apparently made of china, imparting a rigid and indignant stare in the direction of a nose heavily accentuated with (presumably) white pigment. The oil print was better than the original "bromide," and well illustrated, if it did nothing else, the effectiveness of sketchy vignetting executed by a skilled hand.

In the discussion which followed, a member mentioned that several of his prints refused to bleach, and inquired the cause. "The refusal to bleach is curious," replied the lecturer; "but never having had any failures, I am unable to assign a reason for this or other misadventure." "I used your formula," said the member, very pointedly. "Which makes it all the more extraordinary," was the genial response. No more questions on "failures" were asked.

Dr. Mees pointed out that it appeared desirable to well wash the prints after the acid bath, before immersion in the hypo solution, to avoid possible deposition of sulphur in patches, which might refuse to take the pigment. It might also be useful to formaline the prints before pigmenting to toughen the surface; this would not affect the relief. On the other hand, if a formalined print were allowed to dry, relief would not be formed on its being re-wetted.

The President, Mr. J. M. Sellors, had tried Bromoil, but had obtained no relief. Mr. Taylor complained that makers of special bromide papers for Bromoil only listed and supplied them the size of the plate, without allowing anything for the necessary margin. For the next size larger one had to pay appreciably more. Mr. Keane, on the subject of "relief," inquired whether in a portrait the sitter would be represented with a "swelled head." "It depends," said the lecturer, gazing fixedly at the questioner. In answer to another question, Mr. Mortimer said that the best way to mount an oil

print not completely dry was to cover a very stout piece of cardboard with adhesive, and drop the print on to the sticky surface. Dry-mounting should never be attempted unless the print was at least six weeks old, otherwise the picture would be transferred to the plate. Many other members joined in the discussion, which gradually assumed a contest of wit, during which the lecturer more than held his own.

In response to a very hearty vote of thanks, Mr. Mortimer said that he had much enjoyed the evening, and particularly the debate, which was quite up to the standard common report had led him to expect. Any slight misgivings he might have entertained as to the suitability of the subject for Croydon, had been quite dispelled. For one thing he was grateful—the ethics of "control" had not been raised. Discussions based thereon were profittless and interminable.

News and Notes.

ERRATUM.—In the article "Telephotography" last week, p. 322, right hand column, lines 2, 3, and 4, for "time" read "tint."

THE DEATH IS ANNOUNCED of Dr. Carl Emanuel Merck, a partner in the Darmstadt chemical factory. At the time of his death Dr. Merck was only 47 years of age.

THE LANCASHIRE AND CHESHIRE PHOTOGRAPHIC UNION.—The fourth annual excursion has been arranged to take place on June 19, when, by invitation of the photographic section of the Preston Scientific Society, that town will be the centre of the day's proceedings. The local committee and excursion leaders will meet associates and their friends at the club rooms, 119A, Fishergate, Preston, from which place all parties will start. Full particulars of the day's arrangements are now ready, and those intending to be present on the occasion should make early application for same to the secretaries of their respective societies. The hon. sec. of the Union is Mr. W. Tansley, 22, Chapel Place, Liverpool.

We regret to have to record the death of Mr. William Dobson Brigham, of 20, Esplanade, Scarborough, which took place on April 21. Mr. Brigham, who was sixty-eight years of age, commenced his business career as a wood-engraver, in the firm of Messrs. Foster and Sons, of Driffield, but the work was of too sedentary a character to suit his active temperament, to which photography appealed more strongly. His first engagement as a photographer was with the late Mr. Thos. Fall, at Bedale, with whom he stayed until shortly before the latter left Yorkshire for Baker Street. Early in 1863 Mr. Brigham opened his first studio at Pocklington, and later in the same year another in New Queen Street, Scarborough, afterwards removing to Westborough, and finally, in 1879, to the present studio on the Esplanade. Mr. Brigham's business policy was good work for good prices, and the cheap class of photography now so much in vogue in seaside towns never had any support from him. Some thirteen years ago Mr. Brigham was invalidated by a paralytic stroke, which prevented his taking any active part in the business, the management of which passed into the hands of his son, Mr. W. Foster Brigham, who will, we understand, continue to direct it.

PICTURES OF ROTHENBURG.—Among other oil and water-colour paintings, there are now being exhibited at the Fine Art Society, 148, New Bond Street, a few paintings by E. Harrison Compton of the picturesque old Bavarian town, which of late years has attracted so many artists. Mr. Compton has evidently found his subjects more among the rural surroundings of Rothenburg than in its wonderful mediæval streets. One most effective view of the fortified walls which surround the town has been obtained from a standpoint in the road which winds its way along the banks of the Tauber far below the towers of the town. Almost every one of the Rothenburg pictures exhibits beautiful effects of sunshine, which is but natural seeing that this corner of Bavaria is highly favoured in this respect. One picture of the town from the Tauber valley in particular exhibits a charming effect of evening light upon the red masonry of the walls, and any one who may be thinking of paying a visit to Rothenburg at the time of the Whitsuntide performance of the Meistertrunk will be interested in studying these works of an accomplished artist. The pictures remain on view until May 15.

Correspondence.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

REGULATION OF FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—The action of the police in Germany controlling flashlight exposures, which you report on, although rather drastic in the regulations imposed, would seem to be almost as necessary for adoption over here as the control of cinematographic exhibitions, judging from some of my early experiences in this work and from several accidents, arising usually from sheer ignorance, which have been recounted to me. In one case an operator, perched on a pair of steps near some inflammable decorations, boldly pushed a lighted taper held in his hand into a heap of flash powder! Strangely enough, in this, as in most cases, the damage was confined to the operator.

As the result of an accident, I believe, and possibly also on account of conditions imposed by the insurance company, a large hotel here, used for many important functions, prohibits flashlight work on the premises.

I think the authorities will, sooner or later, impose some restrictions on us, and we can hardly blame them. I would suggest that the P.P.A. investigate the various methods practically (excluding, of course, such as mentioned above), by inviting manufacturers and photographers to give demonstrations with various lamps and powders. As part of the tests, I would insist on inflammable articles, such as muslin and paper festoons, being hung at various distances above and around various quantities of each make of powder and each lamp. Having thus obtained tabulated data regarding the safest apparatus and methods, the P.P.A. could approach the authorities and insurance companies with a view to their approval and co-operation. The combined approval of the P.P.A., the Home Office, and the insurance companies would be an enormous advantage to manufacturers, as well as to the photographers using their productions.—Yours obediently,

D. BERLIN.

94, Gt. Clowes Street, Broughton, Manchester.

April 4, 1909.

SULPHIDE TONING.

To the Editors.

Gentlemen,—The only analyses I have made of the (bleached) image of a bromide print treated with the ferricyanide-bromide bleacher were done some considerable time ago, and were merely qualitative. The object was to see if any silver ferrocyanide was left in the image. I found none. I certainly do not consider that any analysis is necessary to prove the variability of the composition of the bleached image. The degree to which bromination proceeds depends on the strength of the solution and the time of action. It also depends on the brand of paper and the method of development—i.e., on the nature of the silver image. The above facts can be ascertained by merely watching the bleaching process. I certainly think it is probable that some sort of combination takes place between the unbleached and the bleached part of the image until complete bleaching is brought about.

The change of colour from black to brown is not easy to account for otherwise. I believe that some people assume that the brown image consists of a lake of silver sub-bromide and silver bromide, or a mixture of these two substances. It may be so. I personally don't think we can go properly as far as this without more evidence. The brown bleached image is not formed, so far as my experiments show, when a weak solution of bromine is used as the bleaching agent. Here, as bleaching proceeds, the image takes on a paler and paler shade of grey. The same thing applies to the action of a bichromate-bromide bleacher which has been mixed for some time, but with a freshly made up one we get a brownish image at first. With even a freshly made up bichromate-bromide bleacher, unless it be very dilute, bleaching soon goes to completion. My expressed opinion that the incomplete bleached image given by treating a bromide print with the ferricyanide-bromide bleacher consists of a lake of silver and

silver bromide is merely a summary of the views set out above. certainly don't pretend to know more than a very little about the real nature of this image.

If we bleach a bromide print for a fairly short time (say five minutes) in a fairly dilute ferricyanide-bromide bleaching solution and then, after washing, fix it, we get a faint but pretty well defined brown image. I think it is probable that this image is composed of metallic silver. When the print is again bleached and fixed the image entirely disappears. There is no reason whatever to imagine that it is not silver because of its colour. Silver images can be produced of almost any colour. It is not because the original bleached image is brown that I think that it is probable that some sort of combination between the bleached and unbleached parts of the image takes place, but because of the change from black to brown. I believe that the portion of the original silver image of a negative on bromide print, which is not silver, is a halide of silver. My experience is that the residual image, after treating a silver image with a "reducer," is entirely destroyed in the fixing bath. If a dry plate negative is bleached to apparent completeness in the ferricyanide-bromide bleacher, and then, after being washed, fixed, a very faint brownish residual image is left. This residual image, as in the case of a bromide print, can be destroyed by treating with a brominating solution and fixing. However, in the case of a negative a very faint kind of an image can be observed when the plate is wet. I believe this is merely due to the "ozobrome" effect of the bleacher on the gelatine. I regard the residual silver halide of the silver image and the residual silver of the bleached image as being the result of the protection afforded by solid solution, molecular combination, or lake formation—call it what you will—against the complete action of the developer and fixing bath in one case, and against the bleaching solution in the other.

When experimenting on residual images one must be on the look out for resinous stain effects, due to the oxidation of the phenol of the developer. Many a developing solution which gives no general stain at all, and which yields an apparently black silver image, gives quite a perceptible amount of stain image.

With regard to the keeping qualities of pure sodium sulphide, I am not inclined to modify what I have said. I find that if the purest crystalline sodium sulphide that I can buy is exposed in the form of a 1 per cent. solution in the toning dish to the air for six hours, a noticeable yellowing of the prints toned in it occurs. After twelve and twenty-four hours the effect is much more marked. I cannot see that for the amateur and fairly small scale worker, for whom I wrote the advice, there is no real prodigality in acting well on the safe side.—Yours faithfully,

R. E. BLAKE SMITH.

31, St. John's Road, Putney, S.W.

April 26, 1909.

THE EFFICIENCY OF FOCAL PLANE SHUTTERS.

To the Editors.

Gentlemen,—I have been much interested in the various letters which have recently appeared in the "B.J.," under the heading of the "Efficiency of the Focal Plane Shutter."

As there appears to be some doubt as to whether the shutter is as efficient when worked, say, three-quarters of an inch from the plate, as it is when worked directly in the focal plane, I resolved to make a practical test, and accordingly made a plate carrier which held the plate at a distance of one-eighth of an inch from the shutter, while the one in the usual slide was three-quarters of an inch from the shutter. After making a very careful and exhaustive test I say, without hesitation, that there is practically no difference in the result, as far as exposure is concerned. Given an abundance of light and working the shutter at, say, 1-1000 of a second, it is a very difficult matter indeed to tell which plate has been nearest the shutter. I believe there is a slight difference in cases of great under-exposure, and, to let you give an opinion on the matter, I enclose two plates, which are purposely under-exposed. The large plate was exposed $\frac{3}{4}$ in. from shutter, and the smaller one $\frac{1}{8}$ in. from same; same light, same plate, lens, shutter, and development all exactly alike.

I may mention the shutter was working at 1-1300 sec., and the light dull, so the plates needed considerable forcing.—Yours, etc.,

T. S. HARGREAVES.

[The difference between the two negatives is very slight. Of the two, the larger is slightly the better.—Eds. "B.J."]

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

E. Saville, 1, Schofield Street, Mexborough, Yorks. Photograph of Jan Hague, Champion Boxer.

Craik, 119, High Street, Deal, Kent. Seven Photographs of Wreck of S.S. "Maharatta" on Goodwin Sands.

TRUE TO SCALE PROCESS.—I should be greatly obliged if you could inform me as to where I could get a book dealing with the true to scale printing process.—B. HULLETT.

None is published. We will give a short article next week.

PHOTOGRAPH OF A CHURCH.—Amongst a set of negatives we have taken for postcard publication is the interior of a church. As the church was open, and no notice up that photography was not allowed, we did not first ask permission to take it. Since then the clergyman has said we must destroy the negative, as he had previously given permission to a photographer, with the sole right to sell the photograph of the church, and give the profits to the said church, for heating apparatus. Can he prevent us publishing this view? He says it is copyright; but we suppose he means the photographer's photograph, as the church cannot be copyright. It is a Church of England, and therefore a public church. We must add, a new screen has been recently erected, and that is why a new view is required. We should like an answer this week if possible, as our order is urgent, and we must wait for your reply.—ANXIOUS (Ipswich).

You are quite at liberty to make any use you like of the photograph. It is a case of, let us say, clerical ignorance of the law. Certainly the reverend gentleman is quite wrong in thinking he can restrain other persons from making use of photographs which they may take, and we very much doubt if he is within his rights in granting a photographer the sole right to take photographs in or of the church.

H. S. (Johannesburg).—1. The lamps are not used at all for portraiture. Although high voltages will give lamps of 700 to 1,000 candle-power, these latter are used only for projection. The cost of renewals for filaments is about 3s. to 4s. for each renewal. 2. For single figures and small groups, two tubes. If you could get renewals only from England, we should think that you would be better advised to get enclosed arc lamps, two of which would suffice for ordinary studio work, while one only is frequently used here for bust portraits.

CARBON PAPER.—Kindly inform me where I can procure a type of carbon paper called "Autopastel."—SIGMA.

The Autotype Co., 74, New Oxford Street, London, W.C.

H. P.—The method may do for quite small prints, but, as you have found out, it is erratic and of no practical use. You can buy a machine to take up to half-plate size or whole-plate at two impressions for 25s.

AUTOCHROMES.—I shall be glad if you will give me some information on the following points through the medium of the ever-welcome "B.J." I have been doing some Autochromes lately, using their method of control development, then reversing and re-developing with rodinal. I have, on the whole, been successful, except that the transparencies seem to lack brilliancy. We are told that intensification remedies that defect, but as my results

are already plenty dense enough, I cannot do that. I have carefully kept to the Lumière instructions as to length of development, so do not think that I under-develop. I want to know, then: 1. Whether I can successfully reduce and then intensify my transparencies to brighten them? 2. Formula for same. 3. Is it possible to obtain a white on these plates, such as a white background to some object, or does it only appear white by contrast with the object?—LUMIERITIS.

1. It is certainly possible to reduce and then intensify an Autochrome, but reduction should not be necessary unless you have under-exposed. You may be mistaken in supposing the results you have obtained will not bear intensification. Very slight intensification will brighten the colours without adding much to the density. 2. Use a very weak Farmer's reducer, then wash and intensify with the usual Autochrome formula. 3. It is quite possible to produce a very good white, but over-exposure must be avoided.

CARBON TROUBLE.—I am enclosing two partially developed carbon prints, that you may the better see wherein my trouble is. You will notice that, although the faces are apparently over-developed—all the delicate tints gone—the dress is still a muddy mass. The tissue was sensitised in a 2 per cent. solution of bichromate of potash for two minutes, and was quite dry in four hours afterwards. Any help you can give me will be gratefully received.—CARBONAS.

There are two causes for the trouble. One is that the tissue was not sufficiently sensitised. The other is that the tissue was very much under-exposed. The light had not penetrated the denser portions of the negatives, consequently the gelatine washed away from those parts before it could be from the others. The remedy in your case is to sensitise the tissue in, say, a 5 per cent. solution (for negatives with such contrasts as that used) for three minutes, and expose for a much longer time. You must understand that carbon tissue is much less sensitive (as compared with the silver paper in the actinometer) in a feeble light than in a strong one.

WORRIED BOOK-KEEPER.—The Tress Company issues a suitable book, we think, and Messrs. Houghtons Limited supply the convenient card-index reminder for studio appointments.

DIRECTORY.—A directory of the photographic trade, which we believe to be complete, appears in the "British Journal Almanac."

D. PALMER.—We do not know of a list which is at all complete or up-to-date.

GEO. O. STOTT.—Certainly. You can patent an accessory piece of apparatus or attachment. We imagine that any patents in the original apparatus have now expired. You had better apply to the Comptroller of Patents, Southampton Buildings, Chancery Lane, E.C., for a circular of instructions for applying for patent.

TONING P.O.P.—Would you kindly inform me of a permanent and economic method of toning large batches of P.O.P. postcards. I use the gold and sulphocyanide bath with separate fixing, but they seem to be uneven or double-toned, although I am careful to use exact proportions of solutions and keep them moving all the time.—METHODIST.

We should guess that you are using baths for too great a number of prints. Probably you would succeed better with the combined bath or with the thiomolybdate method of sulphide toning for P.O.P. (Edmund and Co.), as you appear not to be experienced in handling P.O.P.

LETTERING P.O.P. PRINTS.—Can you help me in the following?

(1) I have been asked to print by hand in large (half-inch) letters some names on P.O.P. prints. I use Chinese white, but find a difficulty in getting it applied thickly and smoothly. If too thick it will not run, and if thin it looks watery and not solid white. It falls to the bottom of the dish, and needs to be constantly stirred up. I have tried mixing a little gum in it, and find this slightly better. Is there anything else which should be used? (2) I find the pen I use—a fine Gillot—scrapes the surface of the print. Is a very stiff sable brush better to use? (3) I have sometimes to put a cloud in a print or strengthen a weak distance. What colours should one use, and how should they be mixed?—J. C. J.

(1) The Aerograph Company, 45, Holborn Viaduct, manufacture

a process "white" for use on photographic papers that should answer your purpose well. (2) Use a No. 1 red sable long-hair. A brush is a proper tool to use on a photograph. (3) The Aerograph Company's lampblack, as well as their white, cannot be improved upon for the purpose, and works well through the aerograph.

S. H. C.—1. The exposure was probably rather too long for the face, though correct for the clothes and chain. Shorter exposure or shorter development might have improved matters, but the best course with subjects presenting a long range of contrasts is to increase exposure and shorten development. Doubling the exposure and halving the time of development is a well-known device for securing clouds and sky in landscape subjects that show heavy foreground objects. 2. The permanganate solution dissolves silver, hence the disappearance of the image. To clean out developer before intensifying a very dilute solution is used, and it is only applied for a few seconds. See the original Lumière instructions. 3. It will not keep well mixed. The permanganate and acid solutions should be kept separately, and only mixed just before use. 4. Any dealer will supply a whirler, but whirling is not necessary now the frilling trouble has disappeared. 5. There should be no difficulty in seeing the sandglass if placed directly in front of the lamp. We should, however, prefer a clock. If the dish is covered and lamp is turned up to give a bright green light you can read a watch very well. 6. Celluloid varnish is the best to use, but it must be made with amyl acetate as the only solvent. If any alcohol is added the image will be destroyed.

P.O.P., ETC.—(1) Would you kindly say what causes the printer's ink sometimes coming off postcards printed from half-tone blocks? (2) What is the best way to write on P.O.P. prints? (3) Would the writing across "B.J." advertisement be written on the negative with ordinary ink?—**ECRIRE.**

(1) This "set-off" is caused by unsuitable ink or too heavy impression. (2) With a fine brush and a good opaque white. (3) The lettering was probably on the print from which the block was made.

BLUE STAIN.—We should suspect it to be due to the use of a supply of soda sulphide containing iron, or to wash water containing iron.

BACKING.—In last week's issue you advise using "backing" for plates, which backing can be kept handy in dark-room. Will you please advise the mixture you recommend, which, I presume, should become "dry" after being put on the negative back, in which case a dozen or so could be backed and stored in dark box with grooves?—**F. E. G.**

Caramel, 1 oz.; water, 5 drams; methylated spirit, 3 drams. The best brand of caramel for the purpose is the Lichtenstein, specially prepared for use as a photographic backing.

VARIOUS QUERIES.—(1) Do you consider it possible with reflected arc light to obtain results equal to good daylight pictures? (2) For an electric light studio do you consider the enclosed blue wall-paper the best shade I could use to aid exposure; at the same time I wish to use it as a background? Also, could I improve upon the green shade for canvas? (3) For a room 27ft. by 15ft., height 10ft., I believe I could just manage to obtain a full length by using a lens of 16in. focus. I suppose it would not be possible to take cabinet groups with it? However, I possess a 10in. rapid aplanat. Would you advise me to use the 16in. portrait lens up to full length cabinets and employing the 10in. aplanat for groups, or would you use a portrait lens of 13½in. focus all round? Would there be a much more pleasing effect with the 16in. portrait than with the 13½in.? Also would the 13½in. portrait cover a whole-plate?—**STUDIO LENS.**

(1) Yes, if it is used with judgment. (2) The blue paper will do quite well for the walls, but, of course, on account of the striped pattern, it would not be good as a background. We do not understand what you mean by "the green shade for canvas." (3) In a studio 27ft. long, with a 16in. focus lens, it is very close quarters for a full length cabinet picture. One of 12in. would be more convenient in use, also more suitable for groups. The most generally useful all-round lens will be the one of 13½in. focus.

GLASS FOR STUDIO.—We shall be glad if you will give us your opinion as to which is the best glass to use—plain ground or rolled—for studio purposes. The studio is situated in the garden and has a N.W. light. We are troubled a good deal with the sun, and would

like to know whether you would recommend an outside sunshade, and in what form or material. We have been using plain glass, stippled over with white paint, but find it soon becomes yellow, thus lengthening the exposure. Do you think that if we covered the plain glass with tracing paper instead of paint it would serve our purpose better?—**STUDIO GLAZING.**

Either will do, but the ground is more trouble to keep clean in towns where there is much smoke. An outside sunshade would sometimes be useful. It may be of wood or tarpaulin. The latter could be rolled up when not required and stored away during the winter months. That could not readily be done if it were woodwork. Tracing paper or tracing cloth is certainly preferable to paint on the glass, as it can easily be replaced in the event of its becoming discoloured, a thing that is unlikely with the linen.

COPYRIGHT.—As a portrait photographer thinking of going into the process block-making in a small way as a side line to help things a bit, I wish to know the following: Supposing I have a picture sent me to make a block from, and there should be a copyright in it that I was not aware of at the time, could I be held in any way responsible for making the block? I do not intend to supply prints from the blocks I should make, only to supply the block themselves.—**BLOCK MAKER.**

If you produce blocks from copyright pictures you are liable to proceedings under the Copyright Act for infringement of the copyright, even though you may be an innocent agent. The owner of a copyright picture can proceed against the maker of a block, as well as those who gave him the order for it; or against the printer of the block.

LANDSCAPE LENS.—Your valuable opinion on the following will oblige. I have a large single lens offered me for a very small sum. It is about 4in. in diameter and somewhere about 20in. focus. It bears the name "A. Ross, London." I am aware that single lenses will not give straight lines, but what I want to know is whether this lens could be used for outdoor groups—wedding parties and the like? The lens I use for that purpose is a R.R. of 15in. focus, and that does not cover the 12 x 10 plate well unless a very small stop is used, which makes it slow. Will this lens do better?—**L. E. N. S.**

The lens will do very well for the purpose, and as it is of so long a focus it will well cover a 12 x 10 plate. These lenses, as issued by the maker, have a fixed stop of about $f/15$; but you will probably find that if it were opened out to $f/11$ it would still give fair definition. It would then probably be found quicker in action than your R.R., which requires to be so much stopped down.

X. Y. Z.—If the goods were not according to order, or the same sent, you should have refused acceptance and returned them at once. As you have had them for two months, and only complained when the quarterly account was sent in, we expect you will have to pay for them in due course. That is only reasonable, as the goods were accepted without complaint.

MILLO.—Had you strictly followed the instructions you would not have met with "nothing but dismal failures." The instructions, as given, are quite right if strictly carried out, especially as regards chemical cleanliness. The two examples you send clearly show that this has not been done. The shiny marks between the plate and the film are due to dirty glass, and to that alone.

* * * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

most interesting exhibition of prints in the bromoil process by F. J. Mortimer is now being held at the house of the R.P.S. (P. 365.)

John Hall-Edwards has addressed to the Birmingham Photographic Society a vigorous plea for more adequate recognition of scientific applied photography at the Society's exhibition, and has drawn a scheme for the encouragement of workers in these directions. (P. 361.)

The Royal Photographic Society has issued its prospectus of the coming exhibition. (P. 363.)

The handbook of the Convention to be held at Canterbury from July 5 to 10, under the presidency of Mr. Snowden Ward, has been issued. (P. 357.)

The report for 1908 of the Photographic Survey of Surrey shows varied work carried out by this body. (P. 362.)

Some notes on examples of portraiture in the Royal Academy which should be of particular interest to photographers are given on page 358.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Herr Alfred Löwy gives a formula for a safe-light for the development of the Autochrome plate. Herr Löwy recounts the satisfactory way in which the Autochrome transparency has come through these tests of permanency. (P. 37.)

Count de Dalmas gives a formula for a dry preparation from which the reversing permanganate bath may be made up. It is intended for those developing on tour. (P. 40.)

Herr Gustav Müller recommends the physical intensifier of Dr. Duhauss for the re-development of Autochromes which have become weakened in the fixing bath. The Wellington intensifier would act as well, and is easier to make up. (P. 40.)

Paper prints from screen-plate colour transparencies.—A French writer has outlined a method for preparing trichromatic prints from Autochrome plates, though the method, at present, is not practicable. (P. 35.)

An interesting account by Major-General Waterhouse of early researches on the constituents of white light appears on page 34.

A recent article in the French press suggests that a screen-plate, coated with emulsion, is to appear on the market under the name "Dioptrichrome," and made according to the Dufay patent. (P. 39.)

A combination of ozobrome with the pinatype process is suggested by Dr. Engelken for the making of three-colour prints. (P. 36.)

An account by the makers of the mode of preparation of the "Omnicolor" plate has been published. (P. 38.)

EX CATHEDRA.

The Canterbury Convention.

The handbook of the meeting of the Photographic Convention of the United Kingdom, to be held at Canterbury from July 5 to 10, under the presidency of Mr. Snowden Ward, has now been issued, and is sent to members applying to the honorary general secretary, Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E. In the course of the week papers will be read by Mr. C. Welborne Piper, Mr. C. H. Bothamley, Captain Owen Wheeler, Mr. F. Martin Duncan, and by Mr. F. Bennett-Goldney, the Mayor of Canterbury. The excursions include a driving tour to Wingham, Wickhambreaux, and other villages, and visits to Rochester, Rye, Winchelsea, and Maidstone. Under the stimulating presidential direction of Mr. Snowden Ward the week at Canterbury is certain to be spent most enjoyably, whilst the opportunities for photography are probably greater and more varied than those of recent Conventions.

* * *

Two-Colour Effects on Bromide Paper.

In the current issue of the "Photo Era" Dr. D'Arcy Power discourses at some length on the methods he has found most practicable to give on a development paper the two-colour effects of gum-bichromate employed with two coatings. The two processes to which he gives preference are (1) toning the whole print to sepia with mercury and platinum-chloride, and then producing local toning (to a rich black) with amidol developer applied with a brush; (2) local bleaching as for the sulphide process, washing, and conversion of the partially bleached print into an ozobrome by the non-transfer or No. 1 method. Owing to the absence of metallic silver in unbleached portions no pigmented gelatine is thrown down at these points. The ozobrome is washed and dried, and the bleached area re-developed with a brush charged with amidol developer, again washed and brought into contact with a piece of ozobrome tissue of the desired second tint. Development is carried out as before, a second deposit of pigmented gelatine occurring solely over the re-developed area, and thus giving a print in any two of the colours in which the ozobrome tissues are obtainable.

* * *

Ozobromes from Bad Bromides.

In making bromide enlargements a few failures often occur. The correct exposures perhaps do not quite hit off at the first attempt, and a little too much exposure results in a dark flat print, in which the shadow details are quite buried. Just such a print has been submitted to us for inspection, and with it we were shown an ozobrome made from the same print, but minus its defects. The shadows in the ozobrome are full of detail, the tones generally are

much lighter, and the gradation is as good as can be wished. In other words, an extremely bad bromide print has produced an excellent ozobrome. Few would attempt to make any use of such a bad print as the one shown to us, but the success attained shows that the ozobrome method of printing is much more elastic than one would be inclined to expect. We may add that much of the shadow detail in the ozobrome is quite invisible in the bromide, only the stronger details being discernible when the print is looked through against a strong light. We understand that the process employed was the ordinary ozobrome method, but we may presume that the worker took care not to leave the print and tissue too long in contact, and that he developed the result rather fully.

* * *

The Adjustable Stereoscopic Front.

The adjustable front described in a recent article will be found in practice to have a use other than that of dealing with very near objects. If employed properly it is possible to dispense entirely with any subsequent cutting down of the prints to ensure proper trimming effects. All the adjustment usually left to be accomplished with the trimming knife can be carried out when making the negatives, so that all after-trimming can be restricted to the simple removal of the margins of the prints. To effect the adjustment in the camera, first of all make a negative, and then measure the separation between the corresponding margins of the two pictures. Note the distance, and afterwards, when making other negatives, simply adjust the front so that the corresponding images of the nearest details in the subject are separated by a slightly less distance. If the print trimming is then confined to the removal of the margins, it will be found that in the mounted print these nearest details are separated by a slightly greater distance than the print margins, which is the result that is most usually desirable. Of course, if it is desired to make any part of the subject appear to stand out in front of the mount, then the adjustment in the camera must be of just the opposite nature. That is to say, we must adjust the front so that the images of the near object are rather more widely separated than the margins of the negatives, but this is only desirable in very exceptional cases. If this method of adjusting the separation on the negatives is adopted a great deal of time will be saved in print trimming, while full size prints will always be available.

* * *

The Scottish Salon.

The reports of the Salon at Wishaw are of a very gratifying nature: the pictorial success has been already narrated, but not a few feared the financial result owing to the short time the exhibition was open, and the departure from the large cities, but Wishaw has risen to the occasion, and shows a credit balance of nearly £12, which is exceedingly complimentary to the organising powers of the committee and Mr. Telfer the secretary. The dates for the 1910 Salon at Dundee were fixed as follows: Entries to January 10; pictures to January 19; exhibition January 29 to February 19. The venue is the Victoria Art Galleries, Dundee, and the secretary Mr. Vaness C. Baird, Broughty Ferry.

* * *

Half-Tone Screen Rulings.

Apropos of our paragraph last week as to the selection of a half-tone block of the proper fineness for a particular class of work, we must refer to the book of "Screen Grains" just issued by the enterprising firm of photo-engravers, Messrs. Hood and Co., Ltd., of Middlesbrough. This booklet shows the effect of blocks of rulings from 55 to 175 on both art coated paper and the cheapest printing paper. This shows better than any written description the

advantage of the coarser block for the cheaper paper, and we cannot give better advice than that application made to Messrs. Hood for this booklet, which they are free to every bonâ fide business photographer on enclosure of one penny stamp. We now repeat what we said in our last issue as to half-tone work, namely, though there may not be much profit on each individual job, the photographer is likelier to retain his customers if he can handle their half-tone orders and get to know sufficient about half-tone work (which need be little) to advise on matters of style, paper, etc. There are countless instances of good new accounts being opened by photographers purely through their introducing good half-tone work, and for "good" in this sentence the buyer will not be wrong in reading "Hood."

* * *

Two-Solution Development.

A note made in the current "Bulletin" of the Belgian Photographic Association of the advantages of using developer and alkali in separate solutions, a method which, with some occasional modifications, is frequently finding supporters. Its present advocate, M. Lacomblé, uses as his first bath a solution of adurol and sulphite only, in which he keeps the plate for about a minute, or longer if the subjects are different in contrast, and it is desired to improve the latter. The alkali bath is a 10 per cent. solution of potassium carbonate diluted with an equal volume of water and containing a little potass bromide. The method, it may be mentioned, is a useful one for beginners, as it is difficult to get negatives which err in the direction either of being too hard or too flat. And the worker who has at times put through a big batch of fairly correct exposures may find the plan of service, since the time occupied in development is a good deal less than when adopting the straightforward method. A point in regard to which a caution may be given is, to renew the alkali solution as soon as it shows signs of slowness in bringing up density.

NOTES UPON SOME ROYAL ACADEMY PORTRAITS

In the following notes we endeavour to turn the attention of photographers to a few of the portraits which we think are of educational value, or, at least, of special interest from their own point of view.

The mantle of Sargent seems to fall somewhat heavily upon most of our portrait painters, many of whom are not only doing their best in the laudable direction of acquiring his touch, which gives the quintessence of the matter in the simplest possible manner, but are also imitating the subjects of the great American. Such a powerful influence as his could not but make itself felt in portraiture, and glad we should be of it, for it has widened considerably the limits of the art. The petrified sitter, with finger to cheek, posed and settled in a way that will least induce restiveness, is seen now in works of the older methods only. To-day we have fresher and more momentary poses, with a consequent animation and vigour. In the charming and masterly "Mrs. Astor" (24) Mr. Sargent once more shows his facile powers in this direction. The lady walks rather than stands, and looks over her shoulder at us as she goes. Direct and slick as the painting is, its subtlety is felt everywhere, even to the bases of the columns that form the background. Much the same feeling is in the "Earl of Wemyss" (179), Mr. Sargent's other masterpiece this year. This picture is a commentary upon the evergreen vigour of the nonagenarian, who stands erect, regarding us with steady and powerful gaze over the heads of all the crowd before him. Seen from the opposite side of the room he appears to be a gentleman standing in the gallery

not in a frame—so absolutely convincing is the prettiness of the treatment. In the hands, which grasp gloves, umbrella, and hat, the artist has made much of his opportunity, and these members are as eloquent of force and enthusiasm as the dauntless head. When we turn to J. J. Shannon's "Francis, Dinah, and Kathleen" (80), and to J. H. F. Condon's "At the Play" (366), another group of three figures, as well as G. P. Jacomb-Hood's "Three Sisters" (11), we are reminded regretfully of Sargent's revival of the triple portrait schemes of Reynolds, which he justified so triumphantly. In the three works now before us we find only the wish and not the achievement. Mr. Condon even signs his name like Sargent does, and Mr. Shannon goes as far in imitation as to introduce rhododendrons in the right bottom corner.

Next to the Sargents, we suppose the portrait of "The Hon. David Lloyd George, M.P." (139), with which Mr. Luke Fildes scores this year, will attract most attention. It is certainly a fine work. The Chancellor sits in a cross-legged post of petrification, but with knees apart and head turned full-face to us, he seems to be engaged on a discussion of the Budget papers, one of which he holds in his hand. He is in full robes of office, and the tinting of the gold lace upon them challenges a comparison with that on the similar robes of "The Prime Minister" (147), which Mr. S. J. Solomon has seen in a much paler key of colour. There is a lurking reminiscence of Pitt in Mr. Asquith's face by a fitting coincidence. The lighting of the figure is remarkable for a charming fleckiness, which permits the head and shoulder to catch a diffused sunbeam, and all the other parts in shade to be tempered with stray suggestions of struggling light. In the same painter's "Dr. Ludwig Mond, F.R.S." (246) this happy method in lighting is seen to even better advantage. The head is again in gentle sunlight, and the play of sun and shade goes on in tender diminution over the red and grey robes. In the matter of lighting, however, the newest thing here is the altogether photographic concentration and sharpness of Frank Bramley's "Mrs. Cobbett" (10). The effect is startlingly realistic and makes one think of an amateur snap-shot, but the ensemble is most artistic; the shadow parts melt into the background, and there is no trace of hardness.

Maurice Greiffenhagen gives us one of the most charming portraits of the year in his head and bust of "Mrs. Greiffenhagen" (60). This is a delightful harmony in grey and carnation, with all the seductions of an early Victorian silk bodice and large hat. The pose gives a pretty tilt of the head with the hands lying folded in the lap. The background is very dark. "Lady Georgina Home Drummond" (126) by J. Seymour Lucas, and "Miss Maude Valérie White" (196) by Florence K. Upton, are each represented as playing pianos, and in profile. This position gives a certain grace to the figure, and disposes the hands and arms most effectively. Both these portraits are successful, that of the well-known song writer showing the figure in smaller scale and admitting more accessories, which are an artistic help in this case.

Accessories are a stumbling-block here, as in the more humble photographic exhibitions. Not everyone knows exactly how much to insist upon them and how much to let them go. Sir E. J. Poynter's works are overloaded with them, and both in the unfortunate "Duke of Northumberland" (119) and in "E. H. Pember, Esq., K.C." (217) one feels that the President is more at ease with still-life than with portraiture. There are one or two things here that much resemble the photographic "oil-enlargements" of commerce—not in point of merit, we should add, but in the manner of attack. Oak chairs and clothing are here and there painted with such laborious realism as to suggest photography rather than art. The heads of

the sitters suffer in consequence, in spite of their qualities and character.

In the matter of character we feel that Harold Speed's portrait of "Rt. Hon. John Burns, M.P." (328) is a little unnecessarily brutal. Those of Sir H. von Herkomer and of Arthur S. Cope are, as usual, well equipped with character and personality. The title "Mearbeck Moor, Yorkshire" (431) given by Geo. W. Lambert to his characteristic group, is, of course, a misnomer. It is a finely designed portrait group of excellent pattern—due in great measure to the obvious plan of lifting all the figures against the sky. This is a trick which is fast becoming the vogue. The present instance combines a gentleman seated, a lady standing and holding the bridle of a horse, and, as lesser sitters, two dogs and a litter of game. The figures are rich and full in tone, and the work is fine, though a little less interesting than other works by Mr. Lambert which we have dealt with on former occasions. The same sky background is seen in Chas. Sims's airy life-size figure of "Mr. Harold Philips" (435) in green draperies and gauzy scarf. The skyline in this case is at the figure's foot. It comes a little higher in the landscape background to "Mr. Charles Howard" (399) by A. S. Cope—a three-quarter figure, but utterly unlike the traditional portrait with the landscape dimly suggested. This one is in full bright tones and naturalistic to boot.

We must not leave this notice without referring to a delightful work by Harold Knight, "The Letter" (692). This shows a lady standing in the atmospheric half light of a room near one or two furniture accessories. In every respect this accomplished work is satisfactory. It is Whistlerian in motive, but gets to the realisation of which Whistler fought shy. One more fine work, John M. Aiken's "Chas. Stewart, Esq." (729) demands notice. It is simplicity itself, in pose and in treatment. The figure stands with the right hand touching a table, on which is a little vase of flowers. All the right side, the arm and the flowers are in a low tone against a background of exquisite green. The result of this arrangement is a fine "pattern" in design. The head is solidly modelled, and has much character.

Amongst the miniatures we are struck by an excellent likeness of her husband, the well-known photographer, of Bond Street (986), by Mrs. Alice L. Speaight, a worker of wonderfully minute and tender touch, who also shows "Penrhyn, son of L. Godfrey Turner, Esq." (1023), a boy in a cricketer's suit. Both these works are broad, in spite of their minuteness, and the former has a well-managed interior as background. Whilst we are on the subject of photographic notables, we may mention a portrait by F. C. Tilney, whose name our readers know. This is "Miss R." (698), and is painted as a home portrait as opposed to the usual studio arrangement and lighting.

CURRENT COPYRIGHT MATTERS.

"Sharland's New Zealand Photographer," the only local organ of photographers in the Dominion, gives publicity in its last issue to certain grievances of which those practising photography in the colony may quite justifiably complain. We learn that the protection accorded to photographers by the Government is provided by three separate Acts, viz., the Fine Arts Copyright Act of 1877, the Amendment Act of 1879, and the Photographers' Copyright Act of 1896. The provisions of the first two of these Acts, so far as may be judged from the quotations in our contemporary, are those in the Copyright Act of 1862. This latter, it is always understood, applies in all the Dominions of the British Empire, and we must confess to being in

the dark as to the reason for such special enactments by the New Zealand Government. The third Act, however, embodies the result of an appeal made to the New Zealand Parliament in 1896 in order to enable photographers to obtain the benefits of copyright in certain photographs without the need of registration. The clause of the Act granting these facilities is as follows:—

"The protection of the copyright law shall, in respect of photographs other than portraits of persons or groups of persons or photographs of any subject, for the taking of which valuable consideration has been given, apply in all respects as if such photographs had been duly registered and protected under such law in favour of the person or firm taking or producing such photographs, for a period of five years from the date of the first taking the same, if the word 'Protected,' followed by the name of the person or firm taking such photographs, and the true date of such taking are made part of the original plate, and clearly appear in each reproduction thereof."

It will thus be seen that except in the case of portraits paid for in the ordinary course, marking of copies is legalised as a substitute for registration, and thus puts the photographer in a stronger position when dealing in rights for the reproduction of his photographs. Why so long a period as five years is thought advisable we cannot quite understand. We should have thought that three months would have been quite long enough a time in which a photographer could make use of a topical subject and then register or not as he deemed advisable.

As regards the cost of registration our friends in the Dominion appear to have very legitimate ground for protest. It appears that the present Registrar of Copyright interprets the Act of 1877 to order the compulsory pre-payment of fees for both registration and certificate, as he requires that this amount (of seven shillings and sixpence) be paid before registration can be effected. Many photographers who are desirous of securing the protection of copyright are unable to pay a fee which in most cases is quite prohibitive, and it would certainly seem that in New Zealand, where legislation is usually supposed to proceed on more democratic lines, the cost of registration should certainly not exceed that in England, where payment of one shilling for registration and five shillings for a certificate is all that is demanded at Stationers' Hall. The photographers in the Dominion rightly draw attention to the anomaly of the present regulations under which the fee deemed sufficient for the registration of the dramatic copyright in a play is only sixpence.

While agitation by photographers in the Antipodes is thus seen to be proving necessary to secure for them equitable treatment as regards copyright, photographers in the United States, chiefly through the tireless energy of Mr. B. J. Falk, have secured clauses in a Bill (which becomes law on the forthcoming first day of July), the effect of which will be to improve in some degree the unsatisfactory state of things which has prevailed in the past as to reproduction of photographs in newspapers, though still leaving photographers very much at a disadvantage compared with illustrators by other methods. Without de-

tailing the formalities to be observed in securing copyright which includes marking of copies with the sign (c.), we may draw attention to clause 25 of the American Act, viz that dealing with penalties for infringement:—

SEC. 25. That if any person shall infringe the copyright in any work protected under the copyright laws of the United States such person shall be liable:—

(a) To an injunction restraining such infringement;
 (b) To pay to the copyright proprietor such damages as the copyright proprietor may have suffered due to the infringement, as well as all the profits which the infringer shall have made from such infringement, and in proving profits the plaintiff shall be required to prove sales and the defendant shall be required to prove every element of cost which he claims, or in lieu of actual damages and profits such damages as to the court shall appear to be just, and in assessing such damages the court may, in its discretion, allow the amounts as hereinafter stated, *but in the case of a newspaper reproduction of a copyrighted photograph such damages shall not exceed the sum of two hundred dollars nor be less than the sum of fifty dollars* and such damages shall in no other case exceed the sum of five thousand dollars nor be less than the sum of two hundred and fifty dollars, and shall not be regarded as a penalty.

Mr. Falk, who has taken on his own shoulders the burden of pressing for a full recognition of photographers' rights in the illustrative matter of which they are such important producers, writes to the "Bulletin of Photography":—

"I am still very much depressed by reason of the cowardly, but up to now successful, trick by which photography was so unjustly discriminated against at the very last moment. The fair result of four years' patient fighting was overthrown by the unscrupulous methods, backed by the power, of the newspapers.

"It will now be our duty to get busy and acquaint photographers all over the country with the facts, so that they may earnestly urge upon their Congressmen the injustice of that portion of the new statute which denies to photographers equal protection with other producing classes. By this I mean that, whereas copyrighted works in all other classes are given uniform protection, photographs as a class are singled out and this minimum and insufficient protection afforded them. There have been and there will be many cases where photographers could not be compensated in actual damage by the maximum of \$200 allowed under the new law, by reason of piracies by the newspapers of photographs of important things or places, the taking of which often require an expenditure of large sums."

The photographers in the States have very great interests against them in the large newspaper concerns, and they may perhaps derive some consolation that the present Bill is an improvement on the unsatisfactory conditions which preceded it, though unfortunately it fails to give the full recognition which photography, as the creator practically of illustrated journalism, should have.

THE great difficulties in "genuine" outdoor portrait work (writes J. M. B. in the "Pall Mall Gazette") are the lighting of the sitter and the treatment of the background. Sunlight requires skilled and careful treatment, and should usually be avoided, unless you are making a special point of the effective rendering of sunshine in the picture. This sunshine portraiture is difficult, but one sees it occasionally very well done, and there is plenty of room for keen experimental work in this direction. The avoidance of an overwhelming excess of top-light is, generally speaking, the problem to

be solved in ordinary work, and it is well to bear in mind that the sky should never form the background to the sitter's face, which will inevitably, by force of contrast, be rendered as unnaturally dark. This brings us to the question of the background. It is possible, of course, to pose your sitter close up against an ivy-covered wall, and get everything sharp; but the result is terrible. It is no better if the sitter is moved forward, and the background represented as a mass of confused blurs. In all pictorial work incongruity is an absolutely fatal defect.

A SCHEME FOR INCREASING INTEREST IN SCIENTIFIC AND APPLIED PHOTOGRAPHY.

[Mention was made in our columns a few weeks ago of Dr. Hall-Edwards's suggestions to the Birmingham Photographic Society for creating greater interest in the more scientific and utilitarian branches of photography. A verbatim report of his suggested scheme has now reached us, and is reprinted below. Though addressed to the members of his own society, Dr. Hall-Edwards's views will surely be read by others desirous of seeing the important applications of photography take the place they deserve at leading exhibitions.—Eds. "B.J."]

DURING the last few years the interest in photography, as evinced by the results of our photographic exhibitions, has shown a tendency to decrease, due to many causes, not the least important being the general depression in trade. The total number of photographers, I am informed, has not sensibly diminished, but the amount individually spent upon the hobby has decreased. Our president, in his address delivered at the opening of our last exhibition, stated that if photography is to be practised successfully it must be taken seriously. The followers of the "black art" are now so numerous that we shall be safe in assuming that one out of every ten persons is versed in the use of a camera. That few of them take the matter seriously is shown by the fact that in a large city like Birmingham our principal photographic society only contains 150 members, and that even amongst these less than half can be numbered amongst the enthusiasts. The greater portion of so-called photographers are not photographers at all, but are merely "button pushers," who leave somebody else to do the rest. Their knowledge of the art is nil, and, not taking the matter seriously, they never reach that point of interest which ends in devotion, and engenders the keen interest and amount of application necessary to qualify them as true disciples of the art. Whilst public exhibitions of the best photography can give us have done much to improve technique and encourage the love of art, they have also played a part in producing fear in the minds of the weaklings, and, to an extent, have put a brake upon the wheels of progress. Many would-be photographers are deterred from entering the lists of competition by the fear that they will never attain the technical knowledge necessary to enable them to compete with the older and well-known workers. They therefore give up in despair a hobby which, had they taken seriously, would have been an everlasting blessing to themselves and a pleasure to their friends. With the improved methods and apparatus at our command, a successful and serious photographer is enabled to produce pictures which, if he be an artist, may be endowed with individuality, well-nigh approaching that which can be attained in the higher branches of art. An enthusiastic judge of photographs can pick out the works of our best known picture-makers with a degree of accuracy which a few years back would have been thought impossible, showing that if success is to be attained unlimited thought and application must be forthcoming. The time and patience necessary are not obtainable in but a few instances, and many have given up a hobby in which they would have attained success from the fear of their inability to reach the first rank. The existence of cranks and faddists has also played a part detrimental to the best interests of our art, but, notwithstanding these minor drawbacks, there exists such an immense field open to us that there is good work to be done by all photographers who have the energy and perseverance to apply their art in useful channels. The art of picture-making appears to have reached something approaching a dead level, and, granting that the interest in it is not declining as far as the workers themselves are concerned, there is evidence to show that the public interest is not so great as it was a few years back. When some sixteen or eighteen years back photographic competitions were first inaugurated, photographs having any artistic merit were so uncommon that few of the general public had any conception of the capabilities of the art. The offering of awards in open competition gave the necessary stimulus to increased efforts, and the result is seen in our exhibitions of to-day. Our parent society, the "Royal Photographic Society," and several others, have given up making awards, it being now thought sufficient honour to have one's pictures hung upon their walls. The reason for this is, to a great extent, due to the extreme difficulty of picking out the best pictures, which difficulty has been rendered greater by faddist judges and irresponsible critics. For years I have deeply deplored that so much photographic energy has been wasted in achieving so little, also the fact that the scientific and applied branches of our art have been neglected.

It has occurred to me that what was done for pictorial photography a few years back may perhaps be done for the more useful branches now, and with this end in view I wish to suggest a scheme for the furtherance of interest in this direction. Although I am aware that there are many who object to the offering of awards, I have learnt from experience that, with the greater majority, such a proceeding acts as a stimulus and renders them more keen and ready to work. The scientific applications of photography are by far the most important, and increased interest in these applications is certain to produce useful results. There is not a branch of science, art, or manufacture in which photography cannot in some way be employed, and its achievements in these directions have already constituted it one of the most useful servants of mankind. Now although it is impossible to make every photographer an investigator, it is possible for everyone possessed of a good camera to help us in gaining knowledge, and to help investigators in achieving their ends.

My scheme consists in the offering of medals and certificates in certain classes of scientific and applied photography, the results of which are to be exhibited at our next annual exhibition. With this end in view I have issued a list of suggested classes, which, together with an explanatory letter, has been sent to a few of our eminent scientific men, and to many firms upon whose very existence the practice of photography depends. On nearly all hands my suggestions have been received with enthusiasm, and I have received a number of letters and offers of monetary help which enable me to offer to you the scheme, the awards for which have already been promised. Amongst the various persons I have approached is our late president (the discoverer of dry-plate photography), Dr. Hill Norris, who writes: "I am in receipt of the circular letter you kindly sent me, and wish to say how sincerely I sympathise with your efforts to organise, and direct into definite channels and aims, the comparatively wasted energies of the numerous photographic societies dotted over Great Britain, and to consolidate these into a living force capable of making itself felt in connection with advancing science, sociology, trade, and commerce. In the old days the proceedings of photographic societies were very much more varied and interesting than they are to-day, for then men were engaged in calculating curves, grinding lenses, inventing new cameras, and mechanical devices for shutters, etc., etc., and ransacking chemistry for the purpose of finding new processes. We have now, however, arrived at the 'press the button' age, when everything is done for us and very little by us, and as a consequence we are becoming emasculated, and it seems that unless the societies can compass a new path they will soon become extinct, for it is now plain that they cannot be sustained by artistic interest only. As the handmaid of science, photography has more than justified the hopes of its most enthusiastic devotees. What, indeed, could be more encouraging than the recent avowal of Professor Ball that dry-plate photography has done as much for astronomy as the telescope? I repeat that I am entirely at one with you in your endeavours to make the 'black art' more subservient to progress."

Mr. Willoughby Ellis, the president of the Birmingham Natural History and Philosophical Society, writes: "I regret that I have not expressed my admiration of the scheme to promote useful photography. I feel that science in general, and natural history in particular, would benefit by a system of photographic records, and if you will permit it, I shall be glad to personally contribute one of the medals."

Mr. Ellis also promises to bring the matter before his society, who, he is confident, will support the scheme by lending material and in every other way possible. The following firms have written me supporting the scheme, and have each kindly offered to subscribe a guinea towards carrying it out, should the society be willing to accept it:—

Messrs. Southall Bros. and Barclay, Messrs. Watson and Sons, Messrs. Barker Bros., Ltd., Mr. C. S. Baynton, Mr. George Stanley

(Bingley Hall), Messrs. J. H. Whitlock and Sons, and Messrs. Wellington and Ward.

The following firms have promised half a guinea:—Messrs. James Lucking and Co. and Messrs. Aldis Bros.

The following have offered me prizes, which I have neither accepted nor refused, and which will be left in the hands of the Council of the society to deal with.

Messrs. Burroughes and Wellcome offer a guinea for the best technical photograph from a negative produced by "tabloid" photographic chemicals.

Messrs. Hurman, Ltd., offer a kodak camera.

Messrs. Dawbarn and Ward, Ltd., offer a couple of books as a prize in Class I. of applied photography.

I have sent out a number of other letters, to which I have not as yet received answers, and I shall hope, within a week or two's time, to offer you sufficient money to carry out the scheme without drawing upon the funds of the society.

With an apology for bringing forward an incomplete scheme, the following is the list of classes I have suggested to those whom I have so far approached on the subject:—

SCIENTIFIC.

1. Prints or lantern slides illustrating the life history of a bird, animal, fish, or insect.
2. Photographs or lantern slides illustrating the life history of a plant.
3. Prints illustrating the natural history of a back garden.
4. Tele-photographs.
5. Photo-micrographs.
6. Radiographs (X-rays, radium, and other radio-active substances).
7. Geological photographs.
8. Prints illustrating the capabilities of various processes.
9. Various scientific applications of photography.

APPLIED PHOTOGRAPHY.

1. Set of photographs illustrating camp life, military manœuvres, etc., to be used for recruiting purposes.
2. Photographs illustrating the various processes a manufactured article passes through in its making.
3. Best set of photographs of a factory, workshop, bakehouse, dairy, brewery, electric light station, fire station, tramway depot, gasworks, sewage farm, etc., etc.
4. Best photograph suitable for advertising purposes.
5. Prints suitable for illustrating a trade catalogue or price list.
6. Best set of lantern slides illustrating life in our streets.

It is proposed to offer a bronze plaque or medal and certificates in each class, and it is hoped that the stimulus thus given will help to divert wasted energy into useful channels, and at the same time increase the interest in our annual exhibition.

In the event of your accepting this my scheme, I beg to suggest that a special plaque or medal shall be struck, and special certificates designed. That the judging of the various classes shall be performed by experts in the particular branches of science indicated. That all pictures shall be exhibited and no selection made, and that the prizes be awarded from the point of view of scientific and educational value rather than from pictorial and technical merit, although these latter qualifications, granting that other things are equal, shall not be ignored. That, without in any way detracting from the artistic value of our next exhibition; the scientific exhibits shall be given due prominence, and that every exhibit sent in shall be hung. I would further suggest that a circular be drawn up, calling attention to the scheme, and that it be circulated amongst the scientific and photographic societies throughout the world. The many details which must necessarily be considered I leave entirely, with every confidence, in the hands of our council, and I trust that in the event of your accepting my scheme the Birmingham Photographic Society may gain more than kudos for initiating a movement which I trust will be followed by others. Hitherto (not even excepting the Royal Photographic Society) the scientific and applied branches of photography have not received that amount of respect which their importance warrants, and, in conclusion, I trust that these branches of our art may be given full play, and that the exhibits will not, as hitherto, be relegated to dark corners and to inaccessible positions.

JOHN HALL-EDWARDS.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY

REPORT OF THE COUNCIL FOR 1908.

DURING the past year 456 photographs have been received and recorded. This is a decrease of 129 on those sent in in 1907, but there has been received a splendid collection of some 350 prints (not included in the above total) given by Miss Gertrude Jekyll of domestic appliances, old industries and customs, which have been used to illustrate her delightful book, "Old West Surrey." These prints will be carefully mounted and added to the collection during the current year. The 456 prints consist of:—

Architecture	259
Art and literature	39
Anthropology and antiquities	19
Geology	1
Natural history	24
Topography and passing events	114
	456
Total brought forward from last year.....	2,925
Total of prints in Surrey	3,381

The following societies are represented among the contributors of prints and lantern slides:—The Battersea Field Club, the Betchley and Nutfield Camera Club, the Croydon Camera Club, the Croydon Natural History and Scientific Society, the Haslemere Natural History Society, the South Norwood Photographic Society, the Surrey Archæological Society, the Sutton Photographic Club, the Waddon Camera Club.

We have again to thank the following professional photographers for help in the matter of photographs received:—Messrs. Bender and Lewis, French and Co., and Mr. R. W. Robinson.

Special thanks are again due to the Platinotype Co. for making number of prints from negatives without charge, also to Messrs. Elliott and Sons, Limited, for making enlargements from negatives without charge.

The Council have for some time past pursued the policy of allowing the loan of photographs from the survey collection at exhibition in the county with a view to making the work more widely known and thus awakening interest and enlisting support.

It is feared, however, that the wear on the prints thus lent will be detrimental to their keeping qualities, and for this reason, as all that so far as possible it is desirable that the central collection should at all times be at the disposal of consultants in a complete state, it has been decided to form a duplicate set of prints, selected as typical, for the purpose of loan and exhibit; some members are kindly responding to the request of the Council, and it is hoped that others who have not already done so, will try and send us prints, so that this collection may be completed at an early date.

Upon receiving an invitation from the National Photographic Record Association to co-operate in sending to the "Record Section" of the International Photographic Exhibition at Dresden this year, request made to the members by the Council for assistance was met in a most cordial manner; and a collection of prints—typical of the work of the survey—has been duly sent.

An exhibition of over 700 prints took place at the Cuming Museum, Southwark, from July 15 to the end of September. Some 10,000 persons attended the exhibition, which was much appreciated. An excursion to Guildford took place on Saturday, May 30, when over twenty members and friends attended, including representatives of nine of the affiliated societies. The party on meeting at Guildford Station broke up into groups. Many of the principal objects of architectural and historical importance were photographed in and around the town, while several of the party went to St. Martha's, Shalford, and The Chantries. So far some 40 prints have been received from the 120 exposures made, and several members have intimated that their prints will be sent in in due course.

The third annual photographic visitation, conducted by the late Mr. Hector Maclean, F.R.P.S., took place on June 27, when the party photographed the ruins of Betchworth Castle, Leigh Place (an historical moated house), and More Place, Betchworth. During the day several other records were made at Leigh and other places. The prints resulting number about 40.

Three vacancies occur and hon. secretaries are required for the architectural, topography and passing events and photography sec-

18. Members willing to undertake these duties are requested to send their names to the hon. general or survey secretary.

SECTIONAL REPORTS.

Architecture.—The prints that have been sent into this section during the past year number 259. Ecclesiastical subjects number 100 prints. Twenty-five of these are from rubbings of brasses, which illustrate what valuable work can be done in this direction.

Seventy prints illustrate some of our finest residences in the county, viz., Smallfield Place, Leigh Place, More Place, Pendell Court, Pendell House, Chilworth Manor, Bletchingley Place, and Pirley House. Of farm houses, cottages, and public buildings 75 prints have been sent in.

Some extremely useful work has been done by a member during the year, illustrating the bridges over the Thames, some 20 prints being sent in; a like number of prints will shortly be received to complete the series.

Another member has done some good work amongst the windmills and other mills in the east of the county, 23 prints being received. The old Surrey windmills are fast disappearing, as well as the watermills that may be found dotted over the county, and their sites should be recorded.

Three good prints of Betchworth Castle have been received. Farnham Castle has yet to be done, and it is hoped that some member will undertake this at an early date.

A word may again be said here about the details of architectural work. The practice is to record the general and broader features of our domestic work, but details are often neglected. This may be to some extent due to the lack of suitable apparatus.

Art and Literature.—During the past year 39 prints have been received for this section, classified as under:—

Paintings representing Surrey scenes by Surrey artists	18
Paintings not representing Surrey scenes, but by Surrey artists	7
Carvings by Surrey artists	1
Artwork in metals	1
Portraits of Surrey men	2
Literature	2
Maps and plans	8
	—
	39

In addition to the above we were able, by the courtesy of the Ewell Parish Council, to obtain copies of several very interesting entries from the books in their possession which will be placed in the collection later on.

Antiquities and Anthropology.—Nineteen prints have been received during the year, as against 36 in 1907.

The principal subjects are views of the prehistoric camps at Waterham and Godstone, and of barrows at Reigate and Oxted.

In view of the large number of antiquarian objects in the county, it is to be hoped that the prints sent in to this section will be greatly increased in future. Many antiquarian objects can be photographed at times of the year when photographers are not occupied with outdoor subjects.

The attention of members should be directed to recording customs and occupations which are dying out.

Geology.—The work of members in furtherance of this section during the past year has been almost negligible, only one photograph

—Fuller's Earth Pits at Nutfield—having been added to the collection. As in this county special excursions for geological photography could hardly be organised, the secretary suggests that some section or noteworthy physical feature might be included in the programme when outings are undertaken. Even if the subsoil was not exposed the character of the vegetation on the various formations or soils might be recorded. This has been recently advocated from the agricultural standpoint by the Lawes Agricultural Trust in a letter which was written to the secretary last year by Mr. E. J. Russell, of the Rothamsted Experimental Station.

Natural History.—Of the 24 natural history subjects that have been sent in during the year, not much work seems to have been attempted or done.

The subjects on the whole are of a somewhat mixed order, the most interesting being a series of conifer fruit specimens from Kew Gardens, the remainder consisting of zoological records. There is no intention of suggesting that the odd print sent in from time to time is of no value: it may be of the utmost use, and may suggest to

others directions in which they may be of considerable help, especially to those in want of subjects to work at. There are numerous studies of this sort awaiting the consideration of the more energetic photographers. The present number sent in is five in excess of the previous year, but considering the wide subject and the continual chances which even the most casual worker must meet with, much more material should find its way into the section.

Topography and Passing Events.—114 prints have been received during the year, being four less than in 1907. Some interesting records of public functions have been added.

Some more prints of Mitcham Fair have been received, while one or two prints of Bletchingley One-day Fair have been sent in.

The interesting and fast declining industry of the rope walk has been recorded, as also the Toll Gate at Dulwich, still in use.

We are in want of further prints of the Shrove Tuesday football game at Dorking, and of the old practice of throwing dice for maids' money at Guildford.

Photography.—The following events of the year deserve mention:

A marked reduction in the price of platinum paper has taken place, also the introduction of a new make of platinotype paper which may not improbably add considerably to the value of the records accumulated by the society. The paper in question is known as "Black Japine Platinotype"; the particular qualities which it possesses are that, like "Brown Japine," a larger amount of detail is visible than in the case of the ordinary make of platinotype; moreover, the image being black instead of brown, it is more strongly defined than in the case of "Brown Japine."

Another printing process which has come to the front during the current year is "Ensyna," a silver phosphate paper which possesses—from the record point of view—what seem to be distinct advantages over P.O.P. or possibly over bromide papers. It gives us a print by a few seconds' or minutes' exposure to a gas burner, and may be finished and mounted within six minutes. Its latitude of exposure is enormous, so that absolutely useless prints should be few or none. It is claimed that the image (which results from "physical" development) is entirely of pure silver and is nearly as stable as that of platinotype. The paper is very easy to use, and members are advised to keep a supply by them so that during spare moments prints may be made which, failing platinotype or carbon, might be contributed to the collection.

A third process which has come to the front in 1908 is that known as the "Bromoil" process. This should be quite permanent. Its particular advantage is that in some cases by the skilful use of inking brushes it is possible to bring out portions of a negative so that details in a record which might otherwise be invisible are brought to light.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE prospectus of the forthcoming fifty-fourth exhibition of the Royal Photographic Society has just been published, and is obtainable, together with the necessary entry forms, from the Secretary of the Society, Mr. J. McIntosh, 66, Russell Square, London, W.C.

The exhibition will be held this year from September 23 to October 30 daily, from 10 a.m. to 6 p.m.

On three evenings of the week—Monday, Thursday, and Saturday—it will also be open from 7 p.m. to 10 p.m.

The three sections in which no charges are made for space are:—

- I. Pictorial Photography.
- II. Colour Photography.
- III. Scientific and Technical Photography.

In Sections III. and IV.—"Professional and Commercial Photography" and "Photographic Apparatus and Material"—charges will be made as before.

The names of members of the selecting committees in the Sections I., II., and III. were given in our last issue.

Exhibitors in Sections I., II., and III. must fill up the entry form and enclose it with the exhibits. Exhibits sent by carrier must be addressed to the society's agents, Messrs. Bradley and Co., 81, Charlotte Street, Fitzroy Square, W., and must be delivered, carriage paid, on or before Wednesday, September 1. Exhibits delivered by hand must be presented, unpacked, at 81, Charlotte Street, Fitzroy Square, W., on Thursday, September 2, between 10 a.m. and 6 p.m., after which hour and date no exhibit can be received.

All photographs, except lantern slides (and transparencies in

Section II.), must be framed. Each photograph in Section I. must be separately framed. A label bearing the name and address of the exhibitor, with the title or description of the photograph, together with a number corresponding with that upon the entry form, must be affixed to the back of every frame, and a tie-on label giving the same information must be attached to the back of every frame in such a manner as to hang over in front of the picture. The front of the frame, the picture, or the mount may bear the name of the exhibitor and the title of the picture, and these only. The fastening nails must not project, and no plates, rings, or screw-eyes may be affixed to the frames.

Foreign and colonial exhibitors may send photographs unframed. They must, however, be mounted. The society will provide frames, without charge, for accepted photographs.

Properly made wooden packing-cases will be stored by the society's agents. For purposes of identification each case should have the owner's name written or painted legibly on the woodwork. No other packing material will be preserved.

The selecting committees will make no distinction between members and non-members of the society, nor between amateurs and professionals. The committees have power to accept or refuse any work, and exhibitors will be notified of acceptance or non-acceptance as soon as possible after the selection has been completed.

Lantern slides will be suitably displayed by the society. The exhibition of lantern slides at the evening displays during the exhibition will not debar them from future acceptance.

In the pictorial section no exhibitor will be allowed to submit for selection more than six photographs, and these may be by any process.

Photographs already shown at any public exhibition within the London postal district will not be eligible for admission.

No photograph will be eligible for admission unless the exhibitor shall have subscribed to the declaration on the entry form that the work is entirely his own.

The Colour Section will comprise examples of colour photography, both transparencies—either by screen-plate processes, such as the autochrome, or by combinations of coloured positives—and of prints upon paper, including the three-colour and bleach-out processes.

Transparencies must be protected by a cover glass and bound round the edges in the same manner as lantern slides. They must not be framed, but must have the number, title, and author's name legibly inscribed on the mask or binding. These transparencies will not be shown in the lantern, except by arrangement with the author.

The Scientific and Technical section will comprise examples of work shown for its technical qualities and apparatus used in photographic investigation, e.g. :—

Nature photography, record photography, and photography as applied to industrial and educational purposes, astronomy, meteorology, spectroscopy, geology, surveying and engineering, medicine and surgery, Röntgen rays, microscopy, telephotography, military photography, and artificial light photography, recording instruments.

Transparencies, stereoscopic prints and slides, lantern slides.

New processes, general work.

This section will also include all exhibits relating to or illustrating any process of photo-mechanical reproduction—viz., photogravure, line and half-tone photo-engraving, photo-lithography, collotype, photo-zincography, Woodburytype, polychromatic printing, etc.

Exhibits may be excluded unless the points of special technical or scientific interest are distinctly stated on the entry form. Any special method of display required for an exhibit must be undertaken and provided by the exhibitor at his own expense.

Apparatus used in photography or in photographic research may, if necessary, be accepted for a shorter period than the whole duration of the exhibition.

In Section IV.—“Professional Photography”—applications for space should be made by letter not later than Saturday, July 10. The designs for all decorations, displayed signs, notice-boards, etc., must be submitted to the Organising Committee for their approval. Orders for photographs may be taken at the exhibition, but no delivery there will be allowed. Stationery cases for trade cards may be placed beneath the exhibits, but must not be obtrusive in character. No exhibitor will be permitted to transfer or sublet any part of the space allotted to him, and all exhibits will be subject to

the approval of the Organising Committee. A list or description of the exhibits to be shown in this section must be in the secretary's possession not later than Thursday, September 9, if it is desired that particulars shall appear in the catalogue.

The charge for wall space will be 5s. per foot-run. Further particulars and plans may be obtained from the Secretary.

The Central Hall will be reserved for exhibits of apparatus and material (Section V.). Floor space will be let for the erection of stalls. Applications for space should be made by letter not later than Saturday, July 10. Stallholders must provide all tables, stands, counters, show-cases, etc. The designs for all structures, decorations, displayed signs, notice-boards, etc., must be submitted to the Organising Committee for their approval. Attendance, if necessary, must be provided by the exhibitors. Catalogues, circulars, and price-lists may be distributed only from the stalls. Any special lighting required for the stalls must be arranged for by the exhibitor at his own expense, and the work must be done by the electrician usually employed by the New Gallery Company, Limited. The charge for the current consumed will be payable to the Royal Photographic Society, and each stallholder must have a meter fitted at his own expense. No exhibitor will be permitted to transfer or sublet any part of the space allotted him, and no substance of a dangerous nature will be allowed upon the premises. A list or description of the exhibits to be shown in this section must be in the secretary's possession not later than Thursday, September 9, if it be desired that particulars shall appear in the catalogue.

Photo-Mechanical Notes.

“True to Scale Process.”

This process, which has several different names, according to the firms exploiting it, is one by which a few copies (a maximum of about 25) can be obtained rapidly in permanent printers' ink and without any distortion of size. The process is so far only used for architects' and engineers' plans, and diagrams for patent specifications, &c. These are made in the first place in good black ink on tracing paper or linen, and then exposed on to a piece of ordinary ferro-prussiate paper, to make a “blue print.” The print is not developed but immediately laid down dry on to a “graph,” or jelly, thinly spread on a sheet of glass or zinc. The print is just pressed into contact all over and then directly pulled away. The jelly is now rolled over with a good letterpress ink, by means of a composition roller. The ink will take only on the lines. A piece of paper is now laid on the jelly and rolled over evenly with a light roller, and on lifting will carry the impression of the plan. It is now necessary to ink up again before another copy can be taken. If the work is done on a considerable scale it is convenient to arrange a press for the printing.

The difficulty of the process consists in getting the jelly of the right composition. All the firms working the process have their own pet formulæ, and some of them sell the composition at so much per pound. Here are two formulæ that are said to answer well. Dissolve :—

Glue	8 ozs.
Water, to make	16 ozs.
Add :—	
Gelatine (dissolved in water to make 2 ozs.) ...	1 oz.
Ferrous sulphate	$\frac{1}{2}$ oz.
Glycerine	$\frac{1}{2}$ oz.

The second is :—

Gelatine (Coignet's, 1s. lb.)	1 lb.
Water	4 $\frac{1}{2}$ pints.
Size powder	1 lb.
Iron alum (ferric ammonium sulphate)	1 $\frac{1}{2}$ oz.
Water	1 pint.

Dissolve the gelatine in the water, then add the size powder. Dissolve the alum in the water, then add to the glue solution gradually, stirring all the time. If the “graph” smells unpleasantly, a little of cloves may be added.

The composition is melted by standing in hot water and then poured on to the slab for printing as soon as it has set, as described above. After use it can be remelted and used again, but a little new composition should always be added. It will be seen that the process is quick, easy, and cheap.

where only a few copies are required, and those not of relative quality, it has much to recommend it. Where, however, quantities exist for working lithography, then the Vandyke process of the same class of work is superior, because the number of copies obtainable is practically unlimited, and each of them should be perfect. But the production of the first few prints will be more expensive and take somewhat longer than by the "True-to-Scale" process.

Technical Photography at Bolt Court School.

On Wednesday evenings during the summer term a class is held at the L.C.C. School of Photo-engraving for those operators having technical photography to undertake. The course comprises instruction in the shape of lecture demonstrations, as well as practical work of the most varied nature, for the technical photographer is called upon to photograph anything and everything. The practical work made still more "actual" by the class meeting every Saturday afternoon and going to photograph buildings (exteriors and interiors), trees, machinery, pictures in galleries, and so on. The class is successful, and the students enthusiastic. Those interested should write to 6, Bolt Court, for a syllabus.

PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—
REPEAT DESIGNS.—No. 9,774. Improvements relating to the production of repeat designs for photo-mechanical originals. Eduard Mertens, 322, High Holborn, London.
INTAGLIO PRINTING.—No. 9,775. Improvements relating to intaglio printing by means of endless metal bands. Eduard Mertens, 322, High Holborn, London.

Exhibitions.

EXHIBITIONS IN THE "BROMOIL" PROCESS BY MR. F. J. MORTIMER AT THE R.P.S.

At the announcement of an exhibition of works in a process which the exhibitor has made his own, so to speak, and to which he has devoted much propaganda as well as individual experiment, one might be excused for harbouring high expectations. The galleries of the Royal Photographic Society present an undoubted appearance of strong and individual work at the first glance, but a critical examination of the pictures does not keep pace with the level of expectation. We do not believe for a moment that this is due to any falling off in artistic feeling in Mr. Mortimer, nor to any shortcomings in the Bromoil process. We think it due largely to over-expectation in the visitor. Mr. Mortimer's name has been so indissolubly bound up with the method that we have been led to regard him as its arch-exponent. There is another fact that mitigates against the success of his group of portraits, and that is that an irrevocable accident caused many of them to be unfit for exhibition at the eleventh hour, and they had to be replaced by hasty duplicates vignettted or devoid of more than a fringe of ink by way of background. What these first and spoilt portraits were like may be seen from Nos. 26 and 28—portraits of Furley, Esq., and F. C. Tilney, Esq., which were saved from disaster. These two are undoubtedly the best of the portraits. They have length, subtlety, and refinement of handling, qualities which are sought in the stop-gaps. Particularly fine is the portrait of Mr. Percy Lewis, in pose, character, and expression. The process has no charm of photographic character, and has imported a quality of its own to boot, and this is what it should do if it is to stay with us. There is also "A Portrait Sketch" (31) in red chalk—a very interesting full-length of a lady, which deserves a better place than it received between two windows. Amongst the Dutch pictures we consider "The Mill on the Dyke" far and away the best. It has a fine sky and more convincing qualities than many pictures here. We are disposed to think that the exhibitor, in his eagerness to show the power and capacity of the process, has too often sacrificed truth of tone values for the sake of adventitious strength of tone, which, after all, is nothing intrinsically, and only of account relatively. "Painting the Boat" (5) is another example wherein the values are more faithfully kept, and it

is more admired than others on this account. The sacrifice of tone values to any end in pictorial work is not only an artistic sin, it is a folly; for people who are absolutely uninitiated appreciate their preservation, and are quickly convinced of truth, although they cannot tell why. It must not be denied that the trick—for, after all, it is nothing more—of playing with the printing ink may result in chaos which is at times most artistic. For example, "The Stream in the Wood" (46) may be described as a muddle, but it is a muddle with a message. It is a romantic puzzle—it holds one. We were drawn to it strongly, and were only too disappointed to find that its title gave the lie to all our imaginative construing of its poetry.

The landscapes we have marked as the finest are: "The Butter Market, Middleburg" (7), "The Fish Market, Middleburg" (13), "A Bruges Canal" (51), "Waterloo Bridge" (53), and "The Figure Head" (54), the last two being excellent.

BARRHEAD AND DISTRICT AMATEUR ART CLUB.

THE sixth annual exhibition of the Barrhead and District Art Club presented a goodly exhibition. Mr. A. W. Hill judged. In the open class, "Rest," by Peter Mitchell, Langside, gained the plaque, certificates going to John Baird (Glasgow), Robert Ure (Pollokshields), and J. Currie (Glasgow). In the panel class (open), three pictures from each exhibitor, the silver plaque went to "The Trespasser," "A Highland By-way," and "Into the Sunshine," by W. C. S. Ferguson (Glasgow); bronze plaque to R. Murray (Barrhead); and certificate to Robert E. Glasgow (Paisley). Robert Ure (Pollokshields) gained the plaque in the Federation class with "A Hillside Farm"; certificates to J. Harvie (Glasgow) and R. Murray (Barrhead). In the members' classes, plaques were gained by Archibald Ferguson, R. Murray, Mrs. Hutcheson, William S. Maclachlan, and Thomas Whelan; certificates by R. Murray (5) Hugh Mason, and Mrs. Hutcheson. An invitation class contained some representative pictures by J. M. Whitehead (Alva) and A. W. Hill (Shotts).

MIDLOTHIAN CAMERA CLUB.

The second annual exhibition was held in the Synod Hall, Edinburgh, when over 300 pictures were entered. In the open portraits and figure studies, Robert Ure (Pollokshields) with "St. Kildean Mother and Child," and Alexander H. Allan (Edinburgh), with "Old Ann," gained plaques. Other excellent entries in this class were fine "oil" portraits by John Moffat (Edinburgh). These showed well the suitability of this process for professional work; fine texture and an entire absence of the *outré*. E. Drummond Young and E. R. Yerbury were both well represented.

In the open landscape and seascape the plaques were awarded to Dan Dunlop (Motherwell), "The Salmon Fishers' Return," a fine open-air picture, redolent of life and technically a good carbon; and "A Highland Strath," an effective composition, with glorious cloudscape, by Edward Drummond Young (Edinburgh). J. M. Whitehead (Alva) had a splendid representation of his work in this class.

In the Federation class, "A Hillside Farm," by Robert Ure (Pollokshields), and "A Winding Path," by James M. Marcus (Kirkcaldy), gained plaques.

In the colour work, "Fruit," a three-colour carbon of fine quality, by J. Riley (Dundee), and "Roses," an autochrome by E. L. Brown (Edinburgh) were awarded plaques.

The members' classes filled up well, and much meritorious work was shown. R. B. Penman had the distinction of gaining two plaques; others were gained by Thomas Farmer, George Malcolm, and R. Glode Guyer. Mr. Robert Burns, A.R.S.A., was sole judge.

An interesting item was an exhibit, kindly lent by Miss Keith, of paper negatives of old Edinburgh, taken fifty years ago by the late Dr. Thomas Keith; while another popular item was the exhibit of colour photography by Dr. Inglis Clark, embracing autochromes, "Thames" plate, and three-colour carbon work.

The catalogue, with its sixteen half-tone reproductions of exhibits and frontispiece portrait of the president, Dr. Drinkwater, deserves a special meed of praise.

PICTURES OF ANIMAL LIFE.—The publisher of "Lebensbilder aus der Tierwelt," Herr R. Voigtlander, Leipsic, has just issued a booklet of press and personal opinions of the two illustrated volumes which we recently reviewed in these columns.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents have been received between April 19 and April 24:—

PLASTIC REPRODUCTION.—No. 9,197. Process for plastic reproduction of any solid objects. Willy Alfred Carl Selke, 65, Nürnberger Strasse, Berlin, W., 50.

CINEMATOGRAPHS.—No. 9,262. Improvements in films or strips for moving-picture machines. Rotary Photographic Company, Ltd., and Ferdinand von Madaler, 55, Chancery Lane, London.

LANTERN SLIDES.—Improvements in and relating to binding devices particularly applicable to lantern slides and the like. Harold Waring Atkinson and Ernest Cuthbert Atkinson, 1, Queen Victoria Street, London.

STEREOSCOPES.—No. 9,328. Improvements relating to periscopes, stereoscopes, and other optical instruments. Hugh Lancelot Aldis, Arthur Cyril Webb Aldis, and Improved Periscope, Ltd., 18, Southampton Buildings, London.

CINEMATOGRAPH-GRAMAPHONE.—No. 9,419. Device for indicating variations from synchronism in speed between a cinematograph and a gramophone when working in conjunction. Frederick Mayer and Arthur Edward Jones, trading as J. Bonn and Co., 97, New Oxford Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SCREEN-PLATES FOR COLOUR PHOTOGRAPHY.—No. 20,111. 1908 (October 21, 1907). The improved plate is of the kind wherein the three colours are on one plate, being carried on a colour support of gelatine or other appropriate substance, on which they are distributed in the form of lines, squares, etc., and all lie in the same plane on the support, the tints being all carried in the same vehicle. A fatty ink is used to protect one colour from superposition by another.

The plate is obtained by the colouring and successive chemical decolorations of a colour support, alternated with impressions of fatty ink: on support, the ink impressions being finally destroyed.

The process is as follows:—1. On a plate of glass or other transparent support, film, etc., a thin coat of gelatine is spread and is then tinted with one of three colours, which three colours are, say, orange, violet, and green.

2. The plate being uniformly tinted violet, for example, a series of parallel lines are printed or drawn on the tinted surface with fatty ink, the lines covering about a third of the surface of the plate.

3. The colour in the parts not covered by the fatty ink is then destroyed by means of a suitable chemical agent, which would vary according to the colouring substance used, and the parts which have been decoloured are then coloured with one of the two other colours, orange, for example. The plate now carries violet lines covered with the lines of fatty ink, comprising about a third of the surface, and uncovered orange lines occupying the rest of the surface.

4. A further series of parallel lines, crossing the first at right angles or at any other angle, are then printed or drawn on the plate with fatty ink, the spaces between the lines being approximately equal to the thickness of the lines.

5. The colour (orange) in the rectangles, squares, or parallelograms, limited by the two series of lines, is then destroyed, and these are then tinted with the third colour, green, in the example cited.

The plate now carries continuous violet lines covered by the series of lines of fatty ink, and between these lines orange parallelograms covered by the series of lines of fatty ink, these parallelograms alternating with green parallelograms which are not covered with ink.

6. The lines of fatty ink are then destroyed by washing with benzole or any other solvent of printing ink, the lines being removed without affecting the colours which they cover. The plate thus obtained is then covered with a sensitised emulsion.

It must be understood that the impressions of fatty ink need not be strictly straight lines; they may be composed of curved or broken lines, of dots or figurations of any kind, with the sole condition that the coloured surfaces which they protect are in proper relation and properly distributed with regard to the remaining colour colours. Each colour should occupy about a third of the total surface, but this proportion can be varied according to the composition and nature of the colours.

The colouring solutions used can be of any kind provided they are capable of colouring the gelatine support, by simple immersion of the support therein; for instance, as an example of colouring substances, erythrosine, chrysophenine, and diamine may be used and as decolorants bromine or chlorine water, oxygenised water, alkaline persulphates, hydro-sulphite of soda, or bisulphite of soda may be used.

The gelatine is coloured by simple impregnation, it not being necessary that the gelatine is dyed by chemical action, which, however, would not cause any inconvenience.

It can be seen that the colours on the finished plate all lie in the same plane, and that the three colours are dissolved in the same vehicle. Société Anonyme A. Lumière et ses Fils, 21, Rue St Victor, Lyons, France.

MOUNTS.—No. 11,225. 1908 (May 23, 1908). Upon a cardboard of suitable size a margin equal to the required framing is set off and cut sufficiently deep to allow for it being turned over and secured by glue nails, or any convenient method, to the general surface. The corners, being cut off at an angle of 45 degrees through the points of intersection of the marginal lines, will form the mitres, or they may be cut off in any other way that occasion may suggest. In the event of a shaped outline being required on some of the sides, these may require distinct additions to make up thickness equal to the turned-down straight sides; or these shaped edges may be left in the single thickness, and the straight sides only turned down. Thomas Smith Jacob, Hereford House, South end Green, Hampstead, N.W.

PROJECTION LANTERNS.—No. 26,789. 1908 (December 10, 1908). The invention relates to projection apparatus, adapted for both opaque and transparent objects.

Two objective lenses are used, one for opaque work and one for transparent. The former objective is arranged vertically, and is situated directly over the table on which the opaque object is placed. The rays from the illuminated opaque object pass vertically through the lens and are reflected by a mirror into a horizontal direction and thrown on to the screen. The objective for the transparent work is arranged horizontally and is directed towards the screen, and a mirror is used to reflect the beam of light emanating from the lamp into the horizontal objective. The mirror is made capable of adjustment, so that when it is desired to use the device for opaque projection work, the mirror can be removed entirely from the beam of light emanating from the source of illumination, to permit the light to be directed on to the opaque object. Emory Walter Goodrich, No. 123, Walnut Street, Somerville, Mass., U.S.A.

GLASS-PLATE CINEMATOGRAPH.—No. 7,306. 1908 (April 2, 1907). The claim is for:—

"Photographic plates for use in microcinematograph apparatus, on which the pictures are arranged in concentric-circles or spiral lines, characterised in that for every single picture there is a separate lens rigidly connected with the plate."

These plates have a number of lenses, moulded in a transparent substance such as glass or celluloid, attached to one face of the plate, whilst the other face is coated with a suitable emulsion to receive a corresponding number of photographic impressions. Frederic De Mare, 122, Boulevard Leopold II., Brussels.

New Trade Names.

FLATOLIN.—No. 310,738. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Thos. Fewster and Son, Ltd., 44, Sykes Street, Hull, Yorks, varnish, paint, and colour manufacturers. February 23, 1909.

WINGARDH AND CO. (DEVICE).—No. 310,802. Photographic printing-out paper. The firm trading as Wingardh and Co., 27, Clement's Lane, London, E.C., photographic material manufacturers. February 25, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Mounting Prints Without Mountant.

In an article describing his methods of mounting in "The Amateur Photographer and Photographic News" for May 4, Mr. D. C. Henry says: "My first idea is to make the print mount itself, so to speak. This method can only be used with gelatine papers. The print should be trimmed about an inch larger each way than the picture is required to be. In the centre of a suitable mount cut an opening the size of the picture. Damp the back of the mount with a sponge and lay it on its face on a sheet of glass. Wet the print and squeegee it on to the back of the mount, so that the required part shows through the opening. Let it dry under pressure, when the print will be found fixed to the back of the mount. The picture becomes neatly framed by the cut-out.

"If you prefer to mount your prints dry, cut an opening in the mount, as above; place the print face downwards over the opening, and fix it there with an adhesive luggage-label stuck over the back. I find this a useful method when I am in a hurry."

Photography, Art.

The interest in a photograph (writes the "Photographic Monthly") is a living interest until—until the print is dry on its mount. This interest is the photographic interest. The interest in a picture is perennial. A picture may be photographic. Its interest is not, and will not die at mounting. If your mounted print interests you day after day and it is always fresh, and if that interest is not extrinsic, such as a record, then this print came of your love—never mind pictorial intention—and you have created a picture. It is not Art.

If, however, you can, looking back, trace each step of the structure that produced the permanently pleasing print; and if you can, thereafter, use such steps with *intention* bringing up as needed, optics, brushes, photographics, Globe-polish, chemistry, anything on earth, and if you *arrive*—never mind photography—you have created a picture with intention. That is true Art. It is not Photography. Let this be clear and we are rid of much unnecessary controversy and its animus. The photographer and the picture-maker have an overlap—an overlap, not a junction.

New Books.

"Practical Guide to the Art of Tinting and Hand-painting." By an Expert. Manchester: Oriental Art and Publishing Company. 1s. nett.

This is a manual of instruction in the colouring of photographs by means of dry colours supplied by the publishers, and also by Messrs. Blinkhorn Brothers, 79, Upper Brook Street, C.-on-M., Manchester. The directions go minutely into details of colouring portrait photographs, in addition to landscapes, and are everywhere practical and to the point. A small supply of each of six colours is included with the volume, which is sent post free by Messrs. Blinkhorn for 1s. 2d.

"The Red Book, 1909-10." Issued by the Affiliation of Photographic Societies.

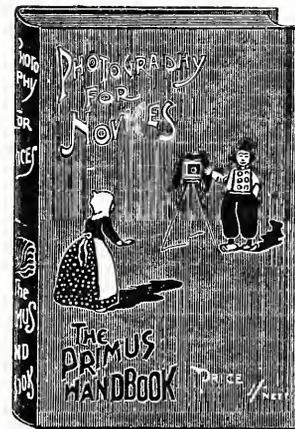

The most important announcement in the new issue of the "Red Book" is that of the addition of Kew Gardens to the list of places where the "Red Book" serves as a permit to photograph (p. 11). The fact, however, is not indicated under "Kew Gardens" on p. 52. In the list of "Consuls" now published we get the first quantitative account of the proposed scheme under which the Affiliation aims at organising an interchange system of giving and obtaining photographic information as to a particular district. The "Consuls" to whom these duties are delegated number eighty, representing as many affiliated societies. Of this number only fifteen reside in towns which may be said to be places in which a photographer would take a holiday. The most active photographic societies, we are not surprised to find, stand aloof from this scheme. Apparently the Liverpool A.P.A., the Manchester A.P.S.,

and the Southampton C.C.—to name three of the most "live" photographic societies in the country—perceive the futility of a scheme which in the first place is limited by the comparatively small number of places where there is an affiliated society, and, secondly, tends to put a premium on laziness. If the Affiliation Executive would devote its own energy and ability and enlist also the aid of its "Consuls" in limiting the so-called "Gazetteer" (which now runs to twenty pages) to information as to the quarters to which application to photograph in certain places must be made, it would be rendering a real service, and would be offering a further inducement to photographers at present not sharing in the many advantages of affiliation.

The "Red Book" contains, as before, lists of lectures available for affiliated societies, particulars of competitions, and exhibition rules approved by a number of judges. The last twelve pages are devoted to a series of tables of weights and measures, optical formulæ, plate speeds, and prescriptions for developers and other photographic solutions. Some revision appears to be necessary here. On p. 81 the number of cubic centimetres in one fluid ounce is given as 29.57, instead of 28.41, and the number of fluid ounces per litre as 33.8, instead of 35.20. "Litres into pints" should be 1.75, not 1.69, and some of the abbreviations used in the formulæ section, such as "potass carbon," "potass permang.," could do with amplification.

"Photography for Novices." By Rev. F. C. Lambert, M.A. London: W. Butcher and Sons. 1s. nett.

This new edition of Messrs. Butcher's well-known manual for beginners has been rewritten throughout by the Rev. F. C. Lambert, who in agreeable conversational style introduces the reader very simply to the practical methods of photography. He discusses the choice of a camera in regard to the expenditure of a fixed sum. The necessary outfit for the dark-room is similarly the subject of

consideration. The making of negatives and their after-improvement occupies a fair proportion of the volume, and gives the most approved methods. In the later chapters the author deals with printing processes—he includes oil and bromoil—with stereoscopic photography, lantern slides, enlarging, and, lastly, with the requirements of pictorial photography. The volume is very well printed and illustrated, and is provided with an attractive cover of green linen.

CULLEN AND KIRKCUDBRIGHT.—The attractions of these two Scottish towns—one in the north and the other in the south of the country—are described in two booklets produced and published by the St. Catherine Press, Ltd., 8, York Buildings, Adelphi, London, W.C., on behalf of the respective town councils. Both booklets are well illustrated, and impart just about enough information as to the places. Photographers in towns or districts offering attractions to the tourist or holiday-maker might find it to their advantage to bring such advertising as this before the notice of their own municipal authorities.

"MORE ORTHOCHROMATISM."—Messrs. Wratten and Wainwright have issued under this title a sequel to their booklet, "Real Orthochromatism," which latter, it will be remembered, gives a useful elementary introduction to the theory of orthochromatic plates and screens. The new booklet goes more thoroughly into the theory of

the process, and forms a useful supplementary aid to the reading of Dr. Mees's "Photography of Coloured Objects" recently published by Messrs. Wratten. The "More Orthochromatism" is sent post free on application.

"METEOROLOGICAL OBSERVATIONS."—The report for 1908 of the Stonyhurst College Observatory, compiled by the Director, the Rev. Father Sidgreaves, F.R.A.S., has been published by Messrs. Philip, South Castle Street, Liverpool. It gives the meteorological and other measurements made in the course of last year.

New Apparatus, &c.

"SANDUC" PRISM BINOCULARS.—Messrs. Staley have just introduced a series of prism binoculars of high quality at very popular prices. The A Model giving a six times magnification is a very useful field-glass for general purposes, and not too powerful for the theatre. There is ready adjustment for the distance between the user's eyes which can be set on a scale, and means are also provided for adjustment of the focus for each eye separately. The price of a glass of this power is £4 10s., its weight is 14 oz. Other sizes of Model A give magnifications of nine and twelve times, whilst still other models are supplied for marine and army work. A booklet descriptive of the instrument is just issued by Messrs. Staley, and is obtainable from them at 19, Thavies Inn, Holborn Circus, E.C.

New Materials, &c.

V.R. (Very Rough) Ilford Bromide Paper. Made by Ilford, Limited, Ilford, London, E.

This new product of the Ilford factory is a paper of surface considerably rougher than that of "Rough" papers issued by Messrs. Ilford, Ltd., for some years past. The roughness of "V.R." is that caused by a number of somewhat large shallow depressions rather than by deeper point areas. This bald statement, we know, gives a poor notion of the surface, but descriptions of the superficial figure of a paper are admittedly difficult, and if we use cold words of technical explanation it is to point out that in their new paper the makers have produced a distinctive product. The result, we would hasten to add, is a paper giving prints of a most pleasing surface, not one, of course, for small contact work, but for enlargements and prints of moderate size, particularly if of strong contrasts. We used the amidol developer and found the paper to work with great cleanness and purity, and to develop quickly. It is best to soak any paper of this class in water before developing, and doing this for the time of half a minute we found not a single instance of pinhole spots. The paper, which is of the Ilford platinum-matt bromide, and of the price of any of the maker's bromide papers, is worthy to rank with the many other Ilford manufactures used and esteemed wherever photography is practised.

The Lumière "Film Block." Sold by the Lumière N.A. Company, 89, Great Russell Street, London, W.C.

In this packet of twelve films for daylight changing, the Lumière Co. would seem to have reached the limit in compactness. The block measures 5 by 3½ by ½ inch, and is used in an adapter. Separating papers are used between the films. The latter themselves are coated each with an opaque film, which forms both an anti-halation backing and a perfect protection of the film behind. The act of changing the films is simply to pull out one by one the tabs projecting from the block. The last tab pulls down an opaque paper shutter and allows the block to be removed from the adapter.

In development the opaque backing film floats off in one piece, and the film is then treated exactly in the same way as ordinary roll film. As regards the quality of the results obtainable with the film block, it is sufficient to say that the emulsion is that of the Lumière plates, and is of high rapidity and affords excellent negatives. The price of the film block in quarter-plate size is 3s.

"SCIENCE GOSSIP."—Mr. E. Kay Robinson has commenced the re-issue, in a completely revised form, of this nature paper, which is now issued monthly at 4d., and contains nearly sixty pages of notes and articles of interest to students of outdoor life. "Science Gossip" is edited and published from 2 and 4, Tudor Street, London, E.C.

CATALOGUES AND TRADE NOTICES.

SIBYL CAMERAS.—Messrs. Newman and Guardia have issued a new list describing all the forms of "Sibyl" camera now made, including the double extension De Luxe pattern reviewed in our issue March 26 last. The list is worth perusal, as it contains all abridged particulars of the firm's other cameras.

BOOTS' PHOTOGRAPHIC LIST.—The price list of the photographic requisites supplied by Messrs. Boots, Limited, at their 350 branch is a book of 290 pages, thirty of which are literary matter dealing chiefly with modern printing processes. The catalogue gives a very complete description of requisites for amateur photography. It contains a frontispiece on Wellington "Enammo" bromide.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MAY 7.

Long Eaton Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

SATURDAY, MAY 8.

Handsworth Photographic Society. Exhibition of Photographs by Members of Societies Affiliated with the Royal Photographic Society; and Lecture thereon by Walter J. Morgan.

ROYAL PHOTOGRAPHIC SOCIETY

MEETING held Tuesday, May 4, the president (Mr. J. C. S. Mummery) in the chair.

In introduction of the collection of prints in the Bromoil process which he is showing at the house of the society, and reviewed on another page, an address was given by Mr. F. J. Mortimer. The address was of the shortest, and, as the lecturer remarked, constituted a record in this respect at the R.P.S. But Mr. Mortimer, cunning man, knew that when art is the subject at Russell Square, and particularly when the theme is the legitimacy of hand-work or control in making photographic pictures, there is no need for the lecturer to say very much. He can be quite sure that the evening will be fully, though perhaps unprofitably, employed in discussion of this time-worn theme. However, in the few remarks he made Mr. Mortimer put forward a strong plea for control by the photographer's hand. Ninety-five per cent., he said, of photographs shown at the exhibition were controlled in some way or another, and he thought that a worker should have as much credit for carrying out his artistic aims with pigment and brush on a bleached print as if he spent a week-end in getting his result in the negative. While he held that the means justified the end, he thought a caution was necessary as to mixing processes. Touches put on the print, say with an air-brush, or by other means, frequently made themselves evident by the difference in texture, and the combination of one printing process with another was liable to give rise to artistic mistakes of this kind.

Mr. E. T. Holding said that while they had heard a good deal of late as to the individualism which the oil and bromoil processes enabled the photographer to impart to his work, he was struck by the fact that in almost every case that imparted quality took the form of intense gloom. Many of the results which he had seen by this process led him to believe that they represented pictorial photography at its worst.

May 7, 1909.]

ev. F. C. Lambert, M.A., said that the aim of all using such processes was to give a reflection of their own individuality. The end and substance of all such art was selection, at whatever stage was made. The scientific adjustment of the photographer's materials to laboratory standards was not likely to improve this selection, and he would instance in this connection the making of a photograph of a field of corn in which were red poppies. Orthographically the corn field might be brighter, and the plate adjusted to photograph the spectrum correctly would so render it, whereas the artist would paint the poppies as the brighter.

Dr. C. E. K. Mees rose to say that nothing except such a statement could have induced him to intrude on the discussion of an art subject, when the facts were not as stated. A colour sensitive plate adjusted by means of a filter, so as to render parts of the spectrum correctly regarding intensity as seen by the eye, would do the same in the case of a natural scene.

Dr. P. Bale Rider thought that the lecturer's reference to the older processes suggested that these latter were inadequate for the purposes of pictorial photography, whereas the inability of the photographer to make use of them was due only, he thought, to his incompleteness of them.

Dr. C. H. Hewitt, in comparing the older printing processes with the modern, said that, after all, the problem for the photographer was to reproduce by any means not a record, but a "correct illusion" giving his own opinion of the subject.

Dr. Evershed had visited an exhibition of photographs in company with an artist, who in every instance preferred the controlled print to the uncontrolled. He thought that the speed with which prints could be made would prove bad for pictorial photography.

Dr. W. Thomas, in the course of describing what he considered the ideal process for control, let fall a hint or two as to the making of Mortimer's exhibition, from which it was gathered that the exhibitor had produced the greater portion of the prints on the walls working continuously for two days and nights with a pigmentation in each hand.

Dr. M. Arbuthnot thought that, after all, the printing process was the important thing; he would not extol any one printing method as being for universal use. He thought the process should be selected to give the effect required.

Dr. Furley Lewis expressed his appreciation of the wide range of subjects dealt with by Mr. Mortimer in bromoil.

A technical query from Mr. H. H. O'Farrell regarding a portrait of Dr. Mees brought the discussion to a close, and the brief replies to the reader of the paper concluded an evening which, like many others devoted to art topics, occupied the audience to a late hour.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—The second annual meeting of this society was held at Plough Hall, Lewisham, on Wednesday evening, Mr. P. R. Salmon, F.R.P.S., presiding, and about thirty members being present. After formal business the hon. secretary made a statement as to the position of the society. During the year they had lost thirty members by resignations and removals, and were struck off for non-payment of subscriptions, and sixteen had been elected, leaving the present membership 144. Although subscriptions amounting to £11 15s. were outstanding, and other sums amounting to £3 12s. were also coming in, the treasurer, after paying accounts due on March 31, had a cash balance of £4 19s. 7d. in hand, and, allowing for a proportion of accounts not yet paid or presented, there was an estimated surplus of about £10 10s. Together thirty-four indoor meetings and eighteen outings took place during the year. Greater attention was to be given in the coming year to the interests of beginners. The usual indoor meetings and outings had also been arranged for the summer, and a competition for two prizes of 10s. and 5s. value (offered by the president, Mr. F. J. Mortimer, editor of the *Amateur Photographer*) was also announced. While regretting that there had been so many resignations, it was pointed out that most of these were members who merely subscribed in the first instance to give the society a boost. As against the reduction in numbers, the society were to be congratulated on the greater unity of purpose animating its members, and the keener interest that was taken in the proceedings. Mr. Mortimer was unanimously re-elected president; Major E. F. Bates, M.P., Canon Barnes-Lawrence, Canon Hough, the Rev. I. Swinnerton, and Messrs. A. Haddon, P. R. Salmon, and C. Athrope Somerville were elected vice-presidents. The following

were also elected: Mr. P. B. Dannatt, A.R.I.B.A., hon. lanternist; Mr. J. Nixon, hon. secretary and treasurer; Mr. F. J. Wills, hon. secretary for portfolio; Messrs. A. E. Bache and F. N. Palmer, assistant secretaries; and a committee of twelve, consisting of Messrs. J. F. Ashby, A. E. Bache, H. J. Blane, G. J. Carr, W. C. Chaffey, P. C. Cornford, P. T. Edwards, W. V. Goulstone, E. R. Housdon, F. N. Palmer, T. H. Richardson, and F. W. Rogers.

It should further be added that the South Suburban Photographic Society has arranged to hold a series of outings during the summer months, specially designed to assist beginners. A small committee of "old photographic hands," with Mr. P. C. Cornford as secretary, has undertaken to look after the interests of the beginners in connection with the programme. These will attend the outings in question and offer practical hints and suggestions on selection of subject, pointing out on the ground glass the elementary principles of picture-making and advising generally on matters of exposure, lighting, etc. The first of these special outings will be held on the afternoon of Saturday, May 15, at St. Paul's Cray, and a general invitation is extended to any non-members desiring friendly assistance in the direction indicated. The society covers the three boroughs of Lewisham, Deptford, and Greenwich, and meets at Plough Hall, in High Street, Lewisham, near the Obelisk. The hon. secretary is Mr. John Nixon, Rydal, Ingleside Grove, Blackheath.

CROYDON CAMERA CLUB.—Mr. F. J. Terry gave a demonstration on the "oil" process last week, and an interesting and extremely animated evening was spent. The lecturer insisted on a good negative to start with, reasonably free from fog, and of fair, but not possessing extreme, contrasts. Oil-printing papers were many, those made by the Autotype Company had worked well in his hands, the latest (No. 3) being, perhaps, the easiest to deal with; it was eminently suitable for a beginner. He strongly advocated the employment of a spirit sensitiser, applied with a brush. Printing should be carried to such a point that details in the high-lights just became visible, and progress should be examined by artificial light or very subdued daylight. A close estimate of the correctness of printing, or otherwise, might be formed when the print was being soaked. At the period of highest relief stain should just be visible in the deepest shadows. In most cases it was necessary to dry the initial print and thus toughen the gelatine prior to pigmentation. The pigments sold for the purpose varied in consistency; the Rawlins pigments were adjusted to be used as they came from the tube; others—for instance, Sinclair's—required dilution with a medium. Roberson's medium was generally employed, but had a distinct tendency to dry with inconvenient rapidity. He preferred "skew-top" hogs'-hair brushes, which were much cheaper than those usually recommended. Several oil prints were pigmented by the lecturer, and, considering the rapidity with which he worked, very creditable results were obtained. At the conclusion of the demonstration the storm burst.

Mr. H. P. C. Harpur, in tones of virtuous indignation, inquired whether this hopping, skipping, and "Waltz-me-round-once-again-Willie" process, outside Bedlam, could be termed "photographic," and without waiting for an answer emphatically declared the contrary. The speaker, however, soon found he had occupied an utterly indefensible position, for past misdeeds in the shape of extensive alterations to negatives, by means of local reduction, knife, and pencil, were brought home to him. Other members with cleaner records resumed the attack, but fell out so nicely between themselves that little advantage was gained. Dr. Mees inquired where all this sort of thing was going to stop, and plaintively asked if anyone could define the permissible limits of "control." Mr. E. A. Salt said that the last question was one which no one in the room could possibly answer; it involved "good taste" and an eternal sense of the fitness of things. He gladly welcomed a process whose characteristics could not be represented by letters of the Greek alphabet, and which was not susceptible to blackboard explanations.

Mr. F. W. Hicks very much doubted whether some foremost workers gave away all their secrets. A good deal seemed to depend upon the quality of the pigment employed. The president, Mr. J. M. Sellors, observed that a variety of pigments had been tried. He agreed with the lecturer that a spirit sensitiser was the best; to apply it a "Blanchard" brush was to be recommended. Dr. Mees said that he knew one worker who certainly did not impart all the

information he might. This illustrated one difference between science and art. The oil process was admittedly only a modification of collotype, and this being so, he was at a loss to understand why collotype inks or pigments were not used. To attempt to work collotype with lithographic ink would lead to disaster. Mr. W. H. Smith agreed. Speaking without any practical knowledge of the process demonstrated, an oily ink such as that used for collotype would seem to be the right one to employ.

Mr. R. Compton, in proposing a vote of thanks—which was carried with the utmost heartiness—narrated how a budding artist displayed a first attempt in oil-printing to a sympathetic spouse, with the proud remark: "That is my own, alone I did it!" "Very likely, my dear, I don't doubt it," gently remonstrated his wife, "but it was very reckless to remove your porous plaster without the doctor's permission."

Commercial & Legal Intelligence

LEGAL NOTICES.—At the Gloucester County Court last week Henry Charles Morse, photographer, Longlevens, near Gloucester, applied through Mr. Barry-Lewis for an administration order. He owed £35 16s. 7d., and offered 10s. in the pound at 7s. 6d. a month.—Granted.

NEW COMPANIES.

PARK'S PRESS PHOTOGRAPHIC AGENCY, LIMITED (102,560).—Private company. Registered April 17th, with a capital of £200 in £1 shares, to carry on the business of general and press Photographers, etc., and to adopt an agreement for the acquisition of the assets of C. H. Park. Table "A" mainly applies. Registered by Turner and Evans, 10 and 11, Walbrook, E.C.

News and Notes.

BALHAM CAMERA CLUB.—The headquarters have been removed to 141, Balham Hill, S.W. Full particulars of fixtures for May and June can be obtained on application to the hon. sec., Mr. F. Beard, 4, Chetwode Road, Trinity Road, Upper Tooting, S.W.

MESSRS. BLINKHORN BROS., 79, Upper Brook Street, C.-on-M., Manchester, have recently rebuilt part of their premises, and have added to their enlarging business that of importers of picture mouldings, in which line they are now open to deal with the trade.

THE LATE ROMAIN TALBOT.—We are sorry to record the death of Herr Romain Talbot, of Berlin, the oldest member of the photographic trade in Germany. The deceased gentleman had been in business for fifty-four years, and had taken a leading part in the introduction and exploitation of photographic materials in Germany. At the time of his death, which took place on April 20, he was 82 years of age.

CANVASSER SENTENCED.—At the Saltash Police Court last week A. Percy, alias A. B. Pearce and A. Evans, was brought up in custody charged with obtaining 2s. from William Coombes, of St. Stephen's, on March 19.

The evidence showed that defendant and another man went to the prosecutor's house and asked that he (defendant) might take his photograph. The offer was accepted, prosecutor, his wife, and his son being taken in a group. Defendant said it was the custom to pay in advance, and that if the 2s. was paid he would get his commission. The money was paid, but the postcard and a cabinet photograph promised in a few days had not been delivered.

Defendant said the photograph was taken by a colleague, and that he did not promise the pictures in a given time. The negatives were at his residence in Plymouth. He had done £20 worth of work at Looe. Prosecutor could have the proofs, or he would refund the money.

The Bench considered there had been false pretences, and inflicted a fine of 10s. and 18s. costs, and ordered him to refund the 2s. to Coombes.

A BARGAIN SALE AT GRIFFIN'S.—Messrs. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., are selling off a quantity of shop-soiled cameras, lenses, shutters, tripods, enlargers, and sundries until May 31. These goods will be sold as low as from 50 per cent. to 60 per cent. off the list prices, and it is an opportunity for anyone

who is looking for bargains. Those calling to inspect such apparatus may make a note of the fact that Messrs. Griffin give a demonstration of the bromoil process every Tuesday and Thursday at 3 o'clock.

THE APPOINTMENT OF MR. R. J. WALLACE as head of the research department of the Cramer Dry Plate Works, intimated some weeks ago in the "B.J.," is now publicly announced. Mr. Wallace came direct from the Yerkes Observatory of the University of Chicago faculty, leaving the position which he occupied there as head of the Department of Photophysics, to undertake the direction of the factory research laboratory.

The possession of a thoroughly equipped chemico-physical research laboratory, devoted especially to this work, and probably unequalled by any other in this country, guarantees the quality of test to which new products will be subjected, while the published work and practical commercial experience in trichromatism and photo-chemistry assure intelligent consideration of the needs of this large and constantly increasing class of workers.

Consultation upon special technical matters connected with the photography of light and colour will receive prompt and careful consideration, and suggestions offered when necessary.

MR. W. L. F. WASTELL, of Malmesbury Road, South Woodford, has distinguished himself by winning the "Ensign" roll-film prize for April, viz., a three-guinea camera offered by Houghton & Co. Ltd. every month for the best negative on "Ensign" film. The entries close on the 3rd of each month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.—The annual excursion will be held on Saturday, May 22, 1909, when Farnham and its vicinity will be visited. The chief points of interest will be the castle, the church, Moor Park, and Waverley Abbey. A list of the subjects to be photographed is being prepared, and the party, on reaching Farnham Station, will divide into two groups, each under the guidance of the officers, one party doing the town and the other Moor Park and Waverley Abbey. Special facilities have been very courteously given by the Bishop of Winchester for the castle, and Mrs. Johnston for Moor Park. All particulars as to trains, etc., from the hon. general secretary, Frank F. Wood, 11, Milton Road, Wallington, Surrey.

AT THE "PHOTO-SECESSION" GALLERIES, New York, a series of photographs of Rodin's "Balzac," by Eduard J. Steichen, have recently been on view. The prints, eight in number, are from negatives taken between the hours of 11 p.m. and 4 a.m., with the moon as the only source of light, for which purpose the "Balzac" was removed from M. Rodin's studio and placed in an open field on two nights during the period of the full moon in October of last year. The next exhibition, which opens to-morrow (May 8), will be devoted to a series of paintings by Mr. Marsden Hartley, of Maine.

"PHOTOGRAPHIC CHAT."—The monthly journal, issued by Mr. A. H. Baird, under this title, appears with the current (May) issue in a revised form. It contains a series of personal notes, under the heading "Entre Nous," short articles on "Selection of a Background," and "Weights and Measures." Those interested can have it sent, post free for one year, by sending 6d. to Mr. Baird, at 37 to 39, Lothian Street, Edinburgh.

THE BARTON COMPETITION.—Messrs. Barton Pictorial Postcard Co., 15, St. James', Barton, Bristol, announce that the winners of the free draw of 1,000 postcards are Messrs. Moore and Roberts, printers, Colchester, who receive 1,000 postcards free from their own negatives or print.

THE STRUCTURE OF LIPPMANN HELIOCHROMES.—The translation of the paper by Professor S. R. Cajal, on his experiments on the structure of the Lippmann heliochrome which appeared in the "Colour Photography" Supplement of the "B.J.," has been included in the Annual "Report" of the Smithsonian Institution for 1908, and issued as a reprint from that publication by the Government Printing Office of the United States, Washington.

HOW TO PHOTOGRAPH THE LITTLE ONES.—The following appeared in the Exeter "Express and Echo," but there is no reason to suppose that Mr. Richard Speaight has been induced to subscribe to our West Country contemporary:—"A photographer was having his troubles with a child of eight years whom its mother had brought to the studio for a series of photos. The picture man struggled with the youngster, who wriggled and squirmed and generally made his

miserable for upward of an hour, trying to procure the poses desired by the doting parent. Finally, a happy thought struck the photographer. 'May I suggest, madam,' said he, 'that you leave alone with this charming little girl for a few minutes? I think it, with a little quiet persuasion, I may be able to calm her nervousness.' The mother assented; and when she returned the photographer announced that he was sure of several fine negatives. 'Oh, my,' asked the mother when they were out of the studio, 'what did that nice man, the photographer, say to you when you were alone, that he was able to get the pictures?' 'He said,' answered Dolly, with a quivering lip, "'If you don't sit still, you miserable little worm—you dough-faced little monkey—you, you—don't know what—I'll shake you till you're blue in the face.'" So, mamma, I sat still."

UNFAVOURABLE RECEPTION OF THE ISOCYANINES IN CANADA.—The "National Photo-Bulletin" of Montreal, in its April issue, writes: "Mr. Samuel Edward Sheppard discourses in 'The Photographic Journal' on the optical and sensitising properties of the isocyanines. For the benefit of those of our readers who are interested in our photography we were about to abstract the article. Our efforts were in vain. When we reached the point where the author mentions paramethoxyquinaldineparamethoxyquinolineethylcyanineiodide the photographer demanded a vacation. Consequently we must refer to those who are interested to the original." To which it may be added: "The photographer who only paramethoxyquinaldineparamethoxyquinolineethylcyanineiodide know."

HERE PASSED AWAY, on March 23 last, at his residence, Moorlands, Ingleton, Yorkshire, at the age of 69 years, a well-known photographer, Mr. Joseph Wilkinson. He had formerly large photographic businesses in Burnley, Colne, and Huddersfield. Failing health induced him to select a quiet retreat at Ingleton.

THE HANDSWORTH PHOTOGRAPHIC SOCIETY are holding an exhibition, on May 13, of the Affiliated Societies' competition prints, and send a hearty invitation to members of other societies, and also to photographers generally, to be present on that occasion. Mr. Walter Morgan, who criticised the prints, will deliver a lecture illustrated with lantern slides made from the prints and his sketches. The exhibition will be held at the society's rooms, 20, Soho Road, Handsworth, and will commence at 8 p.m.

Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen,—Will you permit me to point out that Mr. T. S. Hargreaves' experiment, so far as it is detailed by him, gives no practical proof one way or the other in the matter of efficiency? Certainly he has proved that "there is practically no difference in the result, as far as exposure is concerned." Just so. He has proved that the effective exposure is the same, and in my letter appearing in the "B.J.," April 16, I pointed out that, no matter what position the blind occupies between the lens and the plate, this is a constant quantity. His negatives really tend to prove a difference in efficiency, and it is not obvious that the slit takes less time to cross the apex of a light cone than it does to traverse the base; and if the time varies, yet the exposure remains practically the same, is it not proving, right up to the hilt, that efficiency varies?

Personally, I set the utmost value on experiment, but Mr. Hargreaves does not give sufficient data. What aperture did he use? Did he photograph a stationary object or one rapidly moving? If the latter, what was the extent of the movement recorded on the negatives for each position? Of course, with a small aperture and a wide slit, there is very little variation in efficiency, and if Mr. Hargreaves will repeat his experiments, using largest aperture possible, and a very narrow slit, and exposing an object moving so rapidly that a small amount of movement is recorded on the negatives, then the difference in the extent of the blur will be a measure of the difference in time, and by this measurement, together with the equality

in exposure he has already demonstrated, he will have established a practical measure of efficiency. I am sure there are many of your readers who would be most interested to know the result of such an experiment; it might settle the question as to whether there is a difference between the actual and the practical duration.

Referring back to Mr. Salt's letter of April 23, I quite appreciate his contention that, with the blind in a certain position, the light action during part of the time of exposure is very feeble; but I do not think we should be justified in altering our estimate of duration on that account. If, for instance, we fix the shutter blind so as to expose only a band across the plate, and expose by uncapping the lens on such a thing as a black motor-car, with gleaming nickel fittings, with a proper exposure we should find that, while some parts of the car were vignetted off to nothing before reaching the mathematical limits of our band, other parts would be portrayed by a clean cut image right up to the limits thereof. So the amount that could be deemed negligible differs with conditions, varies with different parts of the same subject even. And, further than this, with an actual focal-plane shutter exposure with the slit the same width as the light-pencil where it is cut by the blind, each point of the plate receives a whole series of illuminations, rising to a maximum and falling again; and who shall say that the weakest light, although too feeble to bring about a developable condition by itself, has not, when added to the whole series, done its little bit to upset the equilibrium of Ag Br.? Perhaps Mr. Hargreaves' experiments will throw some light on this.

C. J. STOKES.

52, Winchester Road, Twickenham, S.W.

May 3, 1909.

[We refer again to the focal-plane shutter in an article next week.—Eds. B. J.]

PHOTOGRAPHIC TRADE IN BRITISH COLUMBIA.

To the Editors.

Gentlemen.—In your issue of the 2nd inst. we notice an article by L. Haweis which we cannot pass by without commenting upon, as his conception of the Canadian photographic trade is altogether wrong. We enclose you, under separate cover, copy of our "National Photo-Bulletin," which will show you the position we occupy in the photographic trade. We issue each month 3,000 copies of this journal, which we mail absolutely free to all amateurs in the Dominion. We also have an open subscription list for same, and as soon as names are received they are put on a regular mailing list. We notice one of his complaints, where he says rival goods are frequently in the same hands, and that in being so placed they are not properly handled. We do not agree with this remark, as we find an ever-increasing sale for the products of all the manufacturers who are advertising in our "National Photo-Bulletin."

Again, too, he mentions the discrepancy in the prices of different articles. We would like to point out to you that owing to the very high freight charges the prices of goods must necessarily vary. We cover the whole of the ground in Canada, and have branch houses in all the important cities, thus we are able to place the manufacturers' goods in a far more effective way than a small firm carrying a sole wholesale agency. We employ sixty-seven travellers, and thus the whole of the ground is practically covered at once, instead of taking several months, in the case of the small man. We trust you will find space to publish this letter, as we would like the English manufacturers to know that there is at least one firm outside of the Trust that is capable of doing a very large photographic business in this country.—Yours truly,

J. MATTINSON, Manager,

National Drug and Chemical Co. of Canada, Limited.

34, St. Gabriel Street, Montreal, April 19, 1909.

REMOVING THE FILMS FROM LARGE NEGATIVES.

To the Editors.

Gentlemen.—In reference to the recent paragraph as to the use of large negatives for the making of passe-partout mounts, may I give a little hint which may be useful to some? It is to damp the film slightly with a moist rag. The negative can then be simply peeled off from the edges—rolls off, in fact—with the fingers, whereas hot water means a tremendous lot of trouble in getting away every trace of film.—Yours very truly,

F. NEWELL.

Eastern Photographic Company,

Manningtree, Essex.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

- S. H. Greenway, 27, Abington Street, Northampton. *Photograph, Group of Northampton Town Football Club, Southern League Champions.*
- J. A. Stelling, "Modena," 60, Peckham Road, London, S.E. *Photograph of the Rev. C. E. Pugh.*

CONSTANT READER.—The difference will not be great. We should advise you to choose whatever focus suits you best.

SINGLE LENS OF DOUBLET.—I understand that for those for whom the price of a soft portrait lens is too high the single combinations of some other lenses will give really artistic results in large heads, etc. (1) Could you recommend to me one or two reliable series for this purpose? (2) Do the exposures run into rather a long time compared to portrait lenses? (3) Has a telephoto lens any useful bearing on portrait work—the size is half-plate?—C. H. S.

(1) Certainly a long focus lens is preferable for large heads, otherwise the point of view is not far enough off, but the single combination of a doublet will usually not be larger than $f/12$, which is slow for a portrait lens. As your query suggests you are seeking a lens to give somewhat diffused results, we may advise you to apply to Messrs. A. E. Staley and Co. for particulars of their anachromatic series of lenses. (2) Certainly they do. (3) Not very much. The chief function of the telephoto is to give a large size image of a distant object, with short camera extension. In a studio the subject is near, and the camera extension can usually be anything up to 30in. or 40in., whilst the small aperture of the telephoto is against it.

"CINEMATOGRAPH JOURNAL."—Will you please inform me, through your "Answers" column, who the publishers of the "Cinematograph Journal" are? I have heard of this paper before, but have never seen it on sale, and as I am interested in cinematography should like to know more of it.—L. S. TRUSS.

"The Kinematograph and Lantern Weekly" is published by E. T. Heron and Co., 9-11, Tottenham Street, London, W.

M. F. AND S.—From the shape and appearance of the spots we should say there is no doubt that they are due to dirt on the plates. Possibly chips or flakes of either backing or varnish from developing tank or dark slides.

STEREO FRONT.—Can you kindly tell me where the right and left handed screw described on p. 320 of the "B.J." is to be obtained! —R. J. S. S.

Our screw was home-made with paper dies. If you do not care to go to the expense of suitable taps and dies (costing about 6s.), we should advise you to get some firm such as George Adams, Holborn, to make the screw, or any engineer engaged in cycle or electric works, and most camera-makers could no doubt do it for you.

AMERICAN P.P.A.—Can you oblige by informing if there is a professional association of photographers in America similar to our own? Also, if there is a list of the members published?—PHOTO.

The Professional Photographers' Society of New York State. The secretary is L. Minor Sherow, Ossining, N.Y. We cannot say if a list of members is published.

PRINTING-IN CLOUDS.—As an amateur reader of your valued paper (from which, by the way, I obtain far more useful instruction and information than from other journals), I should be extremely obliged if you could inform me through an article or in the correspondence column of a reliable way for printing clouds into landscapes. On printing out paper I have used with considerable success a method described by you about a year ago, viz., painting over the landscape outline on the print with photopake. This method is obviously inapplicable to carbon and platinotype, and, also, I must say I have not been quite successful even on P.O.P. with complicated outlines such as tree branches against the sky. In such a case the procedure is most tedious and must require much skill to prevent the work showing, and the necessity for repeating the process after each failure makes it somewhat unsuitable for amateurs with limited time at their disposal. Of course, I am well acquainted with the

majority of more or less rough and ready methods of vignetting skies into landscapes, which have so frequently been described, but on what I want information is some accurate method, such, for instance, as is employed by Mr. Whitehead, in whose landscapes not a trace of the method of combination printing employed can be noticed, and whose clouds are continued behind his trees and join up with the horizon in an absolutely natural manner. I should prefer some process which does not involve the making of copies from worked up prints, as I am not cut out for copying, but if this is inevitable I shall have to arrange for it somehow. For platinotype print I have tried tracing the outline of the horizon on grainy paper-mineral, blacking out to a sufficient depth with water-colour and pasting on film side of cloud negative. But I have never in this way succeeded in getting exact registration, as the paper expands and then does not exactly contract to its original position.—JOHN.

The various methods that have from time to time been described are all reliable. They all require patience and some little experience in the working, but that is quickly acquired with a little steady perseverance. If instead of using water colour on mineral paper you employ plumbago (black lead) applied with a stump, there will be no trouble arising from the expansion of the paper. In Illingworth's "Carbon Photography Made Easy" two or three methods of marking in skies in carbon printing are described, and they are quite simple in practice.

RIGHT TO PUBLISH.—Would you kindly inform me if proceedings could be taken against anyone for publishing a photograph in a book or paper that they have not actually taken themselves, and that is not copyright?—C. R. HIDER.

Proceedings could, of course, be taken, but whether they would be successful is very doubtful. However, it would be highly discreditable if you publish another man's picture representing, as being your own work.

EDITH SMITH and Others.—In our next.

OTHELLO.—Certainly it will not become larger. We do not know that it is a peculiarity of Jena glass, but we think it cannot impair the lens.

GLASS FOR STUDIO.—I desire a little information as to which is the most suitable glass for a studio side and top light. We are having a new establishment constructed here, and our architect has ordered Hartley's rolled plate. One of our professional friends here tells me there is a drawback to this sort of glass, but do not know what it is. There is just time for the order of glass to be altered to any other kind if you would kindly name it.—H. F. COOPER.

Hartley's white rolled plate will be very suitable. It obstructs but little light, is not likely to be broken by hailstones, and has the advantage that it cannot be seen through. We should have the glass as ordered.

BATREY.—The two prints—Continental copies of paintings—are toned bromides, as you surmise. They are double transfer carbon prints, made in a special green colour tissue. There is no method that we know of that will yield results like them by toning bromides.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Royal Photographic Society will, in a few weeks' time, make its home at No. 35, Russell Square, where it has secured a lease of more commodious premises. (P. 388.)

In further reference to the correspondence as to the efficiency and speed of the focal-plane shutter, we discuss in an article on page 375 the separate factors which require consideration.

An incident which took place on the making of a flashlight photograph last week very nearly led to serious consequences. (P. 374.)

A Canadian photographer has recently made a specialty of a so-called "pipe-dream" photograph, and has found that the display of specimens in the window led to a deal of local prominence of his studio. (P. 383.)

A method of home sensitising by which black and brown tones are obtained when the paper is treated first in a salt bath and then in hypo is given on page 382.

In the current "Photo-Notes" of the Rotary Photographic Co., Mr. Douglas Carnegie describes a method for setting the plate parallel to the subject when copying in the camera a flat surface, such as a painting or plan. The apparatus necessary is readily made. (P. 377.)

Mr. R. J. Wallace, in conjunction with Mr. H. B. Lemon, has found that the preliminary exposure sometimes recommended when very faint light impressions are to be recorded upon a plate is practically of negligible advantage. (P. 378.)

Methods of machine-etching and the procedure in white-letter processes are mentioned under "Photo-Mechanical Notes." (P. 384.)

Mr. D. W. Gawn describes under "Correspondence" a method of making an electrical igniter for flashlight work. (P. 390.)

We give on page 382 the questions set at the recent examination in photography held annually by the City and Guilds of London Institute.

EX CATHEDRA.

The Dresden Exhibition.

The opening of the International Photographic Exhibition at Dresden, by H.R.H. the King of Saxony, took place on May 1st with every manifestation of enthusiasm. We understand that the exhibition was practically complete in every part on the opening day, a fact upon which the organisers may be congratulated. The official catalogue, a volume of 350 pages, shows that in the department of scientific or technical photography, professional portraiture and amateur or pictorial photography, the exhibition is particularly strong. The collection of professional photography by Americans is very representative of the best workers in the States, and in the amateur section the British collection appears to be the most important. The trade section is chiefly German and Austrian. There are only one or two French houses represented, and British firms appear to have exhibited, though chiefly through their German agents. We gather from the German papers that the design and decoration of the exhibition have been done on most artistic lines, and that each section, even that devoted to commercial articles, has been caused to conform to a certain style. The exhibition appears to have realised the aims of its promoters, and we hope to deal at greater length with its several sections in forthcoming issues.

* * *

Physical Photography.

Dr. Hall Edward's suggestions for the encouragement of scientific photography deserve attention, for exhibitions generally tend to suggest falsely that pictorial work is the most important application of photography. But the scientific applications of photography are more numerous than ever, yet they are not very much in evidence at exhibitions excepting in the form of natural history work. A somewhat important, but very much neglected branch of photography is its use in illustrating curves produced by various kinds of motion. For example, by fixing a bright point on a wheel and exposing while the wheel is rolling, the formation of a cycloid can be illustrated in a most convincing fashion, and by slight modifications various forms of cycloidal curves (such as hypo-cycloids, etc.) can be produced. Lecturers make use of such photographs occasionally, but the general application of the same methods to various curves does not seem to have been worked out, though the task should be a very interesting one. A great deal of work is being done in the photography of physical experiments, but very few of these are in evidence on the walls of exhibitions, excepting when they represent something startling, such as the history of a splash or the flight of a bullet. Such work represents the highest standard of physical photography on account of the difficulties to be

overcome, but there is plenty of less ambitious and less difficult work that is quite interesting enough for exhibition purposes.

* * *

Magnifiers and Fixed Focus Cameras.

The general principle which in theory governs the action of the supplementary lenses, commonly miscalled "magnifiers," is fairly well understood. If a camera is focussed on infinity, and a "magnifier" of 5 feet focal length is attached, then objects 5 feet away come into focus, and similarly we need only substitute a 3-foot lens to bring objects 3 feet away into focus. This simple principle is, however, likely to break down in practice, because the fixed focus camera with which such magnifiers are useful is not likely to be focussed on infinity. If it is to be generally useful without the addition of magnifiers, it should be set to focus on the hyperfocal distance or thereabouts, and when so set the theory of the magnifier breaks down to a very considerable extent. Suppose, for example, we have a camera with a five-inch lens, working at $f/8$, and set permanently to focus on 26 feet, we add a 5-foot magnifier to this and expect objects at 5 feet distance to be in focus, whereas the real distance of sharp focus is somewhere about 3 ft. 9 ins., or 15 inches nearer. It is therefore always necessary to make a practical test when fitting magnifiers, and usually advisable to purchase magnifiers rather longer in focus than the distance required to be brought into focus. In the instance quoted, a 7 ft. 6 ins. lens would be about the right power for the purpose, and a similar, but greater relative increase in focal length would be required for greater distances than 5 ft. Thus a 20-foot magnifier would only bring into focus objects 11 feet away.

* * *

Molybdenum Printing Papers.

The use of molybdenum compounds for the preparation of papers intended for the copying of plans, etc., has recently been patented in Germany by the Neue Photographische Gesellschaft. These papers are "developed," after exposure to light, by means of a ferricyanide which forms, with the molybdo-molybdate produced, an insoluble, stable, highly coloured image. Eighteen grms. of molybdenum trioxide are added to a solution of 20 grms. of oxalic acid in 400 c.c. of water; by crystallisation a mixture of oxalic acid and molybdic acid is produced, which can be coated on paper. For blue tones the developer may contain ferric chloride, potassium ferricyanide, and oxalic acid; for brown tones uranium nitrate; and for red tones copper sulphate is substituted for the ferric chloride. The sensitiveness of ferro-prussiate papers is increased by addition of molybdic acid; thus paper may be immersed in a solution of 3 grms. of molybdic-oxalic acid mixture, 2.5 grms. of potassium ferricyanide, 0.5 gm. of oxalic acid, 1 gm. of sodium chloride, 12 grms. of ferric ammonium citrate, and 3 grms. of gelatine in 100 c.c. of water. After exposure to light these papers are developed by water.

* * *

A Flashlight Incident.

According to a report in the Nottingham papers of last week, the taking of a flashlight photograph in a crowded hall in that town recently was the occasion of an incident which gave rise to something almost approaching a panic. A performance of a theatrical character had been given before an audience composed almost entirely of children, and at the conclusion a flashlight photograph was taken of the final tableau. The flash, however, instead of taking place in an almost noiseless fashion, is stated to have given rise to a loud report and the evolution of volumes of smoke. The sudden rush of performers and spectators to

the exit was fortunately checked by some elders, and no serious results followed. There need be no cause for alarm in regard to the incident, for it is clear, from the account, that no actual harm was done, but the incident is a reminder that every care is needed when handling flash powder among persons susceptible to anything seeming to be dangerous. The explanation of the mishap is probably the use of a larger charge of powder than was necessary, though why, as suggested in the press report, that course should have been adopted in order to secure instantaneous firing it is difficult to understand.

* * *

A Chemical Test for Metol.

According to M. A. Nicolle, in a recent paper in the "Moniteur Scientifique," commercial metol may contain paramidophenol sulphate, which interferes with the keeping qualities of the developer. The following test is described for detecting the presence of this substance: About 1 gm. of the sample is shaken with 3 c.c. of concentrated hydrochloric acid. If after a few minutes the solution is not perfectly clear, paramidophenol sulphate is present. Mineral adulterants, such as sulphides, etc., may be detected by incinerating a portion of the sample; in no case should the ash exceed 0.5 per cent.

THE HYPO-BROMIDE-FERRICYANIDE REDUCER.

A RECENT communication from the laboratory of "Progresso Fotografico," which, we presume, is directed by Professor R. Namias, records the results of trials made of two modifications of the Farmer reducer, intended to give the even reduction afforded by persulphate. The two varieties were (1) hypo and ferricyanide *plus* ammonia and (2) the mixture of hypo, ferricyanide, and bromide described by Mr. Welborne Piper in our issue of April 24 last year. These modified solutions were tried both on plates taken direct from the washing tank and on others hardened with alum. In the case of the unhardened plates it was found that the ammonia formula acted a little more slowly, but otherwise scarcely differed from the normal formula in its selective action on the shadow of half-tone detail. The bromide formula was found to emphasise the contrasts still more, and these results were obtained also with the plates treated in the alum bath. It was noticed that the ammonia both retained its activity for five or six hours, whilst the other two decomposed in a few minutes. It is concluded that the suggested modifications in the Farmer reducer, instead of "softening" the effect, actually tend to increase contrasts. Possibly the results are partly due to the fact that the bromide and ferricyanide formula used was only about one-tenth the strength of the solution described by Mr. Piper. It does not, in ordinary conditions, act as slowly as stated in the report from which we are quoting, and though its effect on gradation is a very doubtful matter it is favoured by many workers on account of its steadiness of action. It has never been claimed that it acted like persulphate, but we were informed some time ago by another experimenter that it gave the same results as the normal Farmer's reducer when fog readings were deducted, while it gave less contrast if the fog readings were included. The latter, of course, ought not to be deducted in tests of this nature.

While on this topic, we may suggest this question of reduction for investigation in an exhaustive manner. It is of little use to compare reaction of various reducers when we do not know the conditions that govern the action of any one of them. Farmer's reducer, for example, seems

to produce many different effects, according as its strength and proportions are modified, further than which it sometimes acts quite differently on old and new negatives. So far the facts available seem to be very fragmentary and difficult of assimilation, while in many cases we cannot deduce anything from them, because the experimenters do not state whether their measurements include fog or not.

THE SPEED OF A FOCAL-PLANE SHUTTER.

THE letters that have appeared in our columns on the subject of the focal-plane shutter show pretty clearly how little the peculiarities of this shutter are understood. In a recent issue Mr. Hargreaves gave the results of what he described as a "practical" test, which, unfortunately, was eminently unpractical as a test of efficiency. All that this test revealed was the fact, previously pointed out by Mr. Stokes in our issue of April 16, that the efficient exposure is the same whatever the distance may be between plate and slit. This can be shown mathematically without the trouble of experiment, and Mr. Hargreaves missed the important point that, though the efficient exposure is the same, yet the efficiency and duration alter. In view of the confusion likely to arise from thus misconceiving the crux of the problem, it will be as well to go more closely into the matter of "speed" in the case of the focal-plane shutter.

First of all, it is evident that many fail to realise what "speed" means with this shutter. This is proved by the various incorrect methods of measuring it that have been proposed from time to time. Many correct methods can be devised for ascertaining the speed of a lens shutter, but very few of these methods are capable of giving even approximately correct results with the focal-plane instrument. The measure of speed with a focal-plane shutter is the time during which light is allowed to reach one infinitely narrow band of the plate, which band is parallel to the slit. If this time is ascertained for a band in the centre of the plate, then we know the time for any part of that area of the plate which is illuminated by the full aperture of the lens; provided, of course, the rate of movement of the shutter-blind is constant.

The factors that govern the speed of exposure are:—

1. Rate of movement of blind.
2. Width of slit.
3. Angular aperture of lens.
4. Distance of blind from plate.

The efficient exposure, which is a matter quite separate from speed, is independent of the fourth factor mentioned, but the important thing in focal-plane work is the duration of the exposure, not its efficiency. We, of course, want the exposure to be as efficient as possible, but we have to regulate exposure by the rate of movement of the object, therefore speed or duration is of first importance. This being the case, the fourth factor must be taken into account together with the others, and any system of measurement that ignores any one of the four factors is quite valueless from a practical point of view. A good many people have tackled the measurement of speed without paying any regard to these fundamental necessities of the problem, hence the whole subject of speed with the focal-plane shutter is much confused. If the speed of a shutter is measured independently of the camera and lens with which it is to be used, there is only one measurement that can be of any use, and that is the speed of the shutter for a plate situated in the same plane as the blind. When that shutter is afterwards fitted to a camera, the variations due to the new conditions must be calculated and allowed for. The only alternative is to measure the speed in the precise conditions under which the shutter is to be used, and this is not a very easy matter. For practical testing probably the simplest method would be to use a special testing camera arranged so that the angular aperture is always the same, and so that the shutter may be mounted at what corre-

sponds to a certain fixed distance from the plate. From the results the speed can be computed for any other distance and for any other angular aperture, or for a plate situated in the plane of the blind.

As an example of the importance of regarding all the four factors mentioned as essential to a speed determination, we may take a case comparable to some extent with that stated by Mr. Hargreaves. He experimented with a blind giving a nominal speed of 1-1,300th sec., and at the two distances of $\frac{1}{8}$ inch and $\frac{3}{4}$ inch from the plate. He did not state either aperture or width of slit, but we will assume the one to be $f/6$ and the other $\frac{1}{8}$ inch. Neither did he state when the speed was 1-1,300th sec. We will, however, first assume this to be the speed with the plate in the plane of the blind. In these conditions, if the blind is moved forward to $\frac{3}{4}$ inch from the plate, the speed is reduced to 1-650th sec., and the efficiency to $\frac{1}{2}$. This means that the effective exposure is the same as before—viz., 1-1,300th sec., while any blur due to movement is doubled. At $\frac{1}{8}$ inch from the plate the speed is 1-1,114th, and the efficiency 6-7ths. The effective exposure is still 1-1,300th, but the speed is 1.7 times the speed at a distance of $\frac{3}{4}$ inch. Again, we may consider the speed to be 1-1,300th at $\frac{3}{4}$ inch. In this case it must be greater at $\frac{1}{8}$ inch distance, and it is in fact equal to 7-12ths of 1-1,300th, or to 1-2,228th sec. When blind and plate are in the same plane the speed is 1-2,600th, which is also the efficient exposure for any position of the blind.

From this it is evident how much depends on the position of the plate relative to the blind when the speed is being ascertained. To say that a given shutter gives a speed of 1-1,000th sec. is quite meaningless, unless we know the exact conditions under which that speed is attained.

The rule that the efficient exposure is the same for any position of the blind shows that we shall get just as much light effect if we move the blind right up to the lens. If the shutter gives, say, 1-1,300th sec. when plate and blind coincide, it will still give the same efficient exposure if the blind is moved up to the diaphragm slot; but supposing our $f/6$ lens to be of 6 inches focal length, the duration of the exposure will be increased (or the speed reduced) to 1-185th sec., with an efficiency of 1-7th. Shutters of this type have been used, but it is obvious that we can do far better than this with the more usual types of lens shutter.

People are in the habit of talking very glibly of speeds of 1-1,000th sec. and upwards, but possibly few realise what such a speed means. If such a speed is really given in practical working conditions with an $f/6$ lens, and with $\frac{1}{8}$ inch shutter slit working $\frac{3}{4}$ inch from the plate, it means that the blind must travel at the rate of 21 feet per second, which is a fairly high speed to be attained with mechanism of the kind commonly employed.

We may add that the vignetting effect described by Mr. Salt in his letter of April 23 need not be considered. The definition of speed we have given fully allows for this effect. We should also mention that Mr. Stokes, in his letter of April 16, was in error in attributing an effect of under-exposure to the low efficiency caused by distance between plate and blind. As he himself has pointed out, the efficient exposure is not affected, and this is, of course, the factor that determines the adequateness of the light effect. For similar reasons the light effect should be fairly uniform over the plate, even though oblique pencils may be vignetted by the lens mount, and the efficiency thereby increased (not decreased, as stated by Mr. Salt) towards the margins of the plate.

It is a simple matter to calculate the effect of varying the position of the slit relative to the plate. We must first ascertain the diameter of the light-pencil in the plane where it is intersected by the shutter-blind, and then, if we divide the slit width by the sum of the slit width and diameter of light-pencil, we get the efficiency. The duration of exposure is

always exactly proportional to the sum of slit width and pencil diameter, while the product of efficiency and duration is the efficient exposure. When the plate is at the plane of the blind the diameter of the light-pencil is nil, and the efficiency 100 per cent. That is to say, the efficient exposure and the duration

are the same. As the efficient exposure is a constant quantity for any one slit and tension, regardless of position of slit, it is very convenient to take the duration of exposure with plate and blind coincident as the basis of comparisons between different shutters.

PHOTOGRAPHY AND OUR ANCIENT CHURCHES.

III.

Screens and Carving.

Many of the larger churches possess stone altar-screens, which are often erections of singular grace and beauty. Wooden rood-screens, though much less common, are still to be met with in certain rural parish churches. They are commonly of oak, and built in two stages, the upper generally consisting of open-work tracery, and the lower exhibiting a series of panels decorated with geometrical designs.

In the churches of the Decadent period the carved woodwork of the pulpit and pews will sometimes repay the visitor's examination, whilst in those of the Perpendicular and Later Decorated periods the oaken stalls intended for the use of the officiating clergy are often of admirable workmanship and design. The *misereres*, or folding-seats, attached to these stalls are, it may be mentioned, frequently ornamented on the under-sides with figure groups of a singularly naïve character. In the earlier churches no such stall-work is to be met with, *sedilia*, or recessed stone seats, having, during the twelfth, thirteenth, and fourteenth centuries, been employed as a substitute. Finely sculptured examples of the latter are still to be seen in many of the churches of the Early English and Decorated periods.

Fonts, Mural Paintings, and Tombs.

In edifices of the parochial type, among the smaller objects of interest likely to form suitable subjects for the camera, the font will commonly deserve particular notice. As a rule, the more interesting examples are those of early origin. The fonts of Saxon and Norman date are of various forms. Some specimens are circular, and ornamented with the well-known chevron moulding, or with knot-work designs of an elaborate pattern. Others, again, are square or polygonal, and exhibit panels decorated with conventional foliage, figures of animals, and sculptured groups representing incidents in Scriptural history. The fonts of the Early English period, on the other hand, are usually plain. Most of the specimens of those of the Decorated and Perpendicular periods are, however, of a more ornate description, and the nature of the decoration of these is almost invariably heraldic.

Mural and fresco paintings, though formerly a common feature of perhaps the majority of our church interiors, are nowadays of very rare occurrence. As the complete obliteration of such vestiges of work of this kind as still remain uninjured is, unhappily, only a question of time, the necessity for our perpetuating by photographic means whatever in the characteristics of the extant specimens seems worthy of preservation will be obvious to all who are interested in early ecclesiastical art.

The churches of Great Britain are particularly rich in monu-

ments of a sepulchral character. Memorials of this kind occur in a variety of forms. The incised grave-slabs of the earlier periods, and the monumental brasses of the fourteenth and fifteenth centuries are, as a rule, owing to their usual position in the pavement of the building, ill-adapted as subjects for the camera. The carved altar-tombs of the Decorated and Perpendicular periods are, on the other hand, specially deserving of the photographer's notice. These are generally richly ornamented with heraldic devices, and support life-sized stone effigies representing the deceased in the armour or costume of their generation.

In certain churches military trophies in the form of helmets, swords, shields, gauntlets, and armorial banners are still to be seen. Relics of this class are, however, now exceedingly rare, and for that reason merit careful record.

Stained glass of early date is also nowadays far from common in ecclesiastical edifices. Good specimens are still to be met with in some of our larger churches, but, unfortunately, seldom in such a position as, under ordinary circumstances, to be readily accessible for the visitor's close examination, or for the employment of the camera.

Among other antique objects of archaeological interest which will sometimes merit particular notice may be mentioned umbries, font-covers, offertory boxes, lecterns, and muniment chests, characteristic specimens of one or more of which will be found in most English churches of the parochial class.

In addition to the ancient tombstones so abundant in many of our country churchyards, lich-gates and churchyard crosses will now and again provide the photographer with striking subjects for the illustration of what may be termed the accessory features of parish ecclesiology.

In conclusion, a few words may be added concerning monastic antiquities. Ruined abbeys and priories are numerous both in England and Scotland, and the vestiges of many of these are of great architectural beauty. The range of buildings attached to a mediæval abbey was usually extensive, and generally included a chapter-house, cloisters or ambulatory, refectory, dormitory, abbot's parlour, guest-house or hospitium, cells, domestic offices, and entrance gate-house. The chapter-houses were commonly of hexagonal or octagonal form. Many fine specimens, chiefly of the Early English and Decorated periods, still exist in a fair state of preservation. The refectories, or conventual dining halls, are also frequently well worthy of the visitor's examination on account of the superior excellence of their architecture. Such of the monastic gate-houses as still exist are, as a rule, picturesque structures, and not infrequently form suitable subjects for the camera.

MATTHEW WILSON.

THE LONDON AND SOUTH-WESTERN RAILWAY Co. have just issued their official guide book for 1909, which is a valuable compendium of information regarding that part of the country reached by this line and its connections, including its steamship services to Normandy, Brittany, etc. In addition to the brief topographical details of the chief holiday resorts, list of golf links, train and boat services, etc., the book contains a comprehensive list of hotels, board-

ing houses, farmhouse and other accommodation suited to the pockets and tastes of all classes of tourists and holiday makers. The numerous illustrations, together with a well printed map of the districts covered, form an attractive feature of this guide, which may be obtained gratuitously on application to Mr. Henry Holmes, superintendent of the line, Waterloo Station, S.E., or for the price of one penny from Messrs. W. H. Smith and Son's railway bookstalls.

A PRACTICAL METHOD FOR SETTING PLATE PARALLEL WITH THE SUBJECT.

[In a competition organised by our monthly contemporary, "Photo-Notes," a prize was offered for a reliable method of adjusting the sensitive plate and a flat subject, such as a painting, in exact parallelism, a condition which is essential to the accurate photographic reproduction of plans, drawings, etc., but is not one which is readily fulfilled by the attachments ordinarily provided on a camera. Cameras built solely for process work are constructed so that the focussing screen (and plate) and copy-board can occupy no relation other than this, or can be put out of this adjustment only by purposely doing so; but whenever an original cannot be placed on the copying easel, as when photographing in galleries, an adjustment of this kind becomes necessary. The following simple piece of apparatus has been designed by Mr. Douglas Carnegie, to whom the first prize in the competition is awarded.—Eds. "B.J."]

The method here proposed for placing the plane of the photographic plate parallel to the plane focussed for is a direct application of the simple laws of reflection at a plane surface. The necessary apparatus (hereafter for brevity called the "paralleliser") is of the simplest character, and its manufacture is well within the capabilities of anyone whose digits are not all thumbs.

another flat strip of wood is screwed on to the slotted piece, so as to bind the pins securely in position. Before screwing up tight care must be taken that the tops of the pins are in accurate alignment. The pin holder (H) is now nailed to the end of the bar, and for purposes of easy identification the top half of the central pin is painted black on the side away from the peep-hole, the whole of the portion of the central pin facing the peep-hole being left bright. The bar itself is now mounted on a tripod by means of a small ball and socket head (suitable ball and socket heads can be purchased for a shilling).

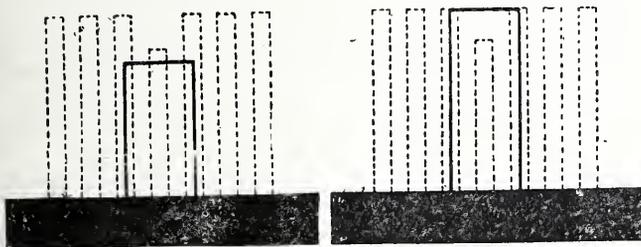

Fig. 1.

Fig. 2.

Fig. 1.—Appearance when the paralleliser is adjusted in azimuth, but not in altitude. (Full line represents the central pin; dotted line represents the mirror images of the pins.)

Fig. 2.—Appearance when the paralleliser is adjusted both for azimuth and altitude.

The Paralleliser.

At one end of a bar of wood 10 inches long and 1½ inches broad, seven pins (P) are fixed in vertical positions, one-eighth of an inch apart from each other. (Fig. 3.) A peep-hole (s), made by boring a hole one-twentieth of an inch in diameter in a piece of sheet zinc (z), is affixed to the other end of the bar. If the refraction of the observer's eye is not normal, a lens of suitable power and sign must be fixed centrally over the peep-hole.

The side of the zinc plate facing the pins should either be painted dead black, or covered with black velvet. The pins I have used

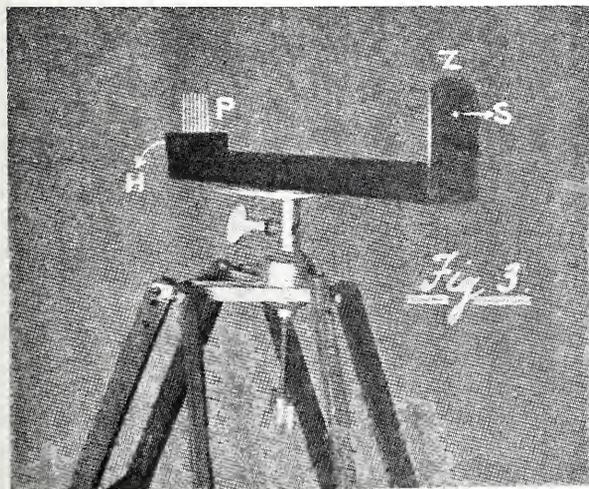

Fig. 3.

are of the large size (1-20th inch diameter) known as "blanket pins." The points and heads of the pins are cut off so that inch-and-a-quarter lengths of uniform diameter are obtained, and the ends are smoothly filed off at right angles to the longitudinal axes. By means of a saw of slightly narrower cut than the diameter of the pins, shallow slots are made in a small strip of wood at intervals of one-eighth of an inch. The pins are pressed into these slots, and

The Procedure.

Suppose the object to be photographed is a picture (P), inclined to the vertical wall on which it hangs. (Fig. 4.) The camera (C) (which should also be mounted on a substantial ball-and-socket head) is set up in front of the picture at such a distance as to give the desired scale of reproduction. It is adjusted so that the focussing screen is as nearly parallel to the picture plane as can be judged

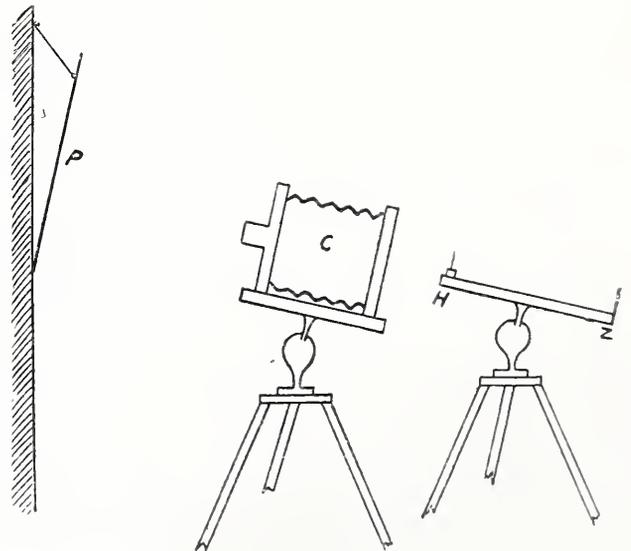

Fig. 4.

by the eye. The picture is centred and roughly focussed. The lens is now unscrewed from its mount, and the focussing screen removed from the back of the camera. The paralleliser (H) is set up as close behind the camera as is consistent with good illumination of the pins, and its line of sight is directed along the axis of the camera. A small piece of patent plate mirror (M) (1-16th inch thick) is stuck flat on the glass of the picture by application of wads of soft wax at the corners. If the picture is not glazed the mirror must be held up against the picture surface by an assistant.

On looking through the peep-hole of the paralleliser the pins and their virtual mirror images will be seen. The paralleliser is now turned in azimuth (laterally) till the central pin centrally overlaps its mirror image, the latter easily recognised by its appearing shorter than the images of the other pins, owing to the black paint with which its upper front half has been treated. (Fig. 1.) The paralleliser is then turned in altitude (vertically), so that the top of the central pin is in perfect alignment with the tops of the images of the other pins. (Fig. 2.) The focussing screen is now replaced, a piece of mirror affixed to its hind surface, and (the ball joint

of the camera having been loosened so as to move smoothly when gently urged) the camera is adjusted on its head till a similar coincidence and alignment to that just described is again obtained on looking through the peep-hole at the focussing screen mirror.

The plane of the screen must now, of course, be parallel to the picture plane. The lens is replaced in its mount, and the picture is finally and critically focussed.

The advisability of using a camera and plate of larger size (*e.g.*, of using a half-plate for the production of a negative of quarter-plate size) will, I think, be clear, for if in the preliminary focussing the image just filled the screen, the final adjustment with the paralleliser would result in throwing some of the image off the plate altogether. It is also advisable that the camera be of the front focussing type.

Rationale of the Paralleliser.

Why, it may be asked, is a peep-hole used on the paralleliser? Would not the pin images be brighter in the absence of such a perforated screen as is recommended? The object of the peep-hole is, firstly, to fix the direction of regard; and, secondly, to give the eye an artificial near point, so that the pins can be distinctly seen at a distance well within arm's length, thus permitting of the manipulation of the camera while looking through the peep-hole. In an ordinary room, and with the size of aperture specified, the images of the pins are usually abundantly bright. (If, owing to the darkness of the room, or to the necessity for placing the parallel-

iser in such a position that the pins do not receive good frontal illumination, the images are too dim for clear discernment, they must be illuminated by a suitably placed lamp or gas flame.) Were the paralleliser not furnished with a peep-hole, then not only would error arise from changes in the direction of regard, but the services of an assistant would most probably have to be requisitioned to move the camera according to the instructions of the observer, and this is neither a satisfactory nor expeditious way of getting an adjustment.

Again, it may be asked, what is the object in having seven pins? There is no particular virtue or magic in the actual number seven, but there is virtue in multiplicity, for the mirror image of a single pin is much further from the eye than the pin itself, and consequently the image appears much smaller than the object. (Figs. 1 and 2.) Since, then, from the nature of the case, the object must overlap its image, the exact adjustment for altitude with a single pin would necessarily be a matter of guess-work. The images of the lateral pins provide a horizontal datum level, permitting of the adjustment in altitude being made precise and unequivocal. If the plane focussed for is a considerable distance away from the camera, it may be necessary to increase the length of the row of pins by adding to their number.

There are other solutions of the problem here attacked, but the one described I have found the most useful and workable.

DOUGLAS CARNEGIE.

ON THE EVALUATION OF THE RECIPROCITY LAW, BASIC FOG, AND PRELIMINARY EXPOSURE.

(A paper in "The Astrophysical Journal," Vol. XXIX., No. 2.)

A CURSORY examination of past photographic literature is sufficient to show the recurrence of similar ideas and methods which have either been discarded as fallacious, or, because of lack of definite scientific investigation, have never advanced beyond a somewhat nebulous stage of development. The systematic and unbiased investigation of these ideas is of the utmost importance, not only in the upbuilding of a firm foundation upon which may be reared the structure of photographic practice, but such investigation is also of major importance to every scientist who records his results by photography.

The work detailed in the present paper was undertaken in the hope of obtaining definite measurable results and shedding light upon somewhat disputed questions.

Primarily, it was concerned merely with the effect of a supplementary "fogging" exposure upon a plate as influencing the recording power of the sensitive film, but, as the work progressed, it was found necessary to investigate also the influence of varying amounts of "fog" upon recorded densities, and likewise the so-called "reciprocity law."

It is usual in all photographic density measurements to subtract from each reading the total amount due to basic "fog,"—i.e., the sum of the absorption of the glass, the gelatine, and the general reduction products in the film. As a usual thing this value is comparatively small, amounting in a good, clean-working plate to about 0.05 (Hurter and Driffield), which is practically negligible except on records of small total luminosity. From causes either inherent in the film—induced by subject or apparatus, or intentionally added (as in the case of a preliminary exposure)—this value may increase in an alarming manner and rise as high as 0.45 or 0.5 H. and D. This is equivalent to 20 per cent. of the highest allowable printing density upon the plate, for when this fog value is subtracted from the various densities, the records are not only in error, but result in anomaly.

As an example of such, the following experiment is detailed.

A Seed "G. E. 27" plate was impressed with a series of preliminary exposures in strips A_1, A_2, \dots, A_8 running parallel to the longer edge. The plate was then exposed in the sector-disc machine and received a second series of exposures B_1, B_2, \dots, B_8 ,

and was developed. Measurements of the plate gave the following density values:—

TABLE I.

No.	Original (Minus Fog).	Original + F_2 .	Original + F_3 .
Fog ¹ ...	0.0105	0.2418	0.5278
10105	.0216	.0094
20105	.0386	.0286
30461	.0700	.0486
41841	.1662	.1038
54327	.3472	.1792
67603	.6110	.4082
7	1.1669	1.0032	.6988
8	1.6443	1.4504	1.1328
9	2.2223	1.9130	1.6634

If now these measurements be plotted in the usual manner against log. exposure, it will readily be seen (Fig. 1) that all of the curves will cross the original curve at a low density-value, so that in the region of higher density these results are utterly false representations of the plate values; for these, while still in the straight portion of the characteristic curve, are shown as of lower density when the incident light-value is increased. The utter falsity of this result may be appreciated by glancing at fig. A, which is a reproduction of a similar negative.

Observation of Fig. A will at once impress the fact that as the increasing supplementary fog value F_n falls upon successively increasing original densities (O_n), the additive effect becomes less and less apparent until it is finally lost, this *extinction point* (so to name it) varying with the relative values of F and O . It is therefore evident that the subtraction of an equal value for this fog, F , from densities, O_n , cannot be considered. To determine this variation was therefore obviously the first consideration.

"Fog" Value with Increasing Densities.

Upon a Seed "27" plate was made a series of exposures to the constant acetylene light, the exposures being so timed that each strip received an exposure increasing by 1.27 times that immediately preceding it, and then developed. When dry the plate was measured

¹ The value of the "fog" on subscripts 3 and 6 equals the value of the preliminary exposure plus the basic "fog" of the original.

in the spectrophotometer at several points along the *length* of the strips in order to determine the evenness of the deposit.² This plate was then used as a transparency, behind which were exposed a number of other plates for fog value determination.

This transparency plate was set up at a distance of 2 metres from the constant acetylene light, and the plate behind and in contact with it received an exposure of 200 seconds. Upon completion of the

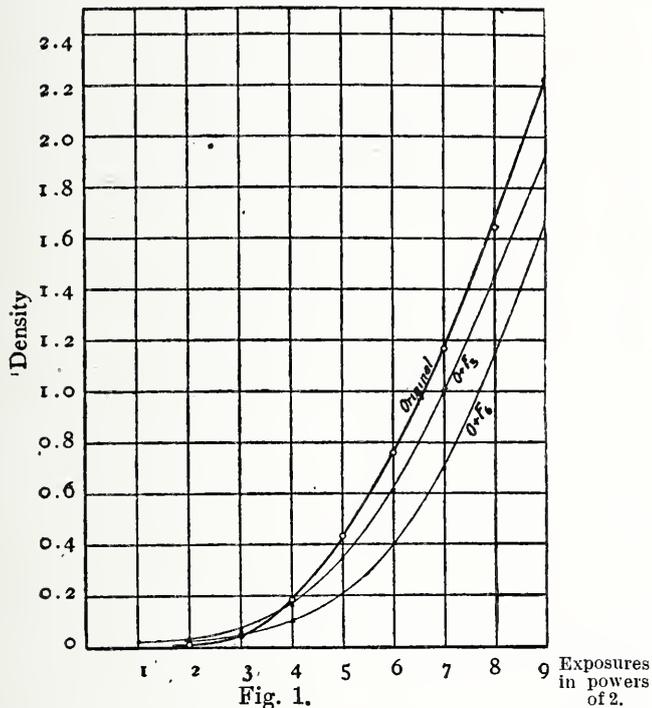

Fig. 1.

exposure the plate was rotated 180 degrees and exposed again for another 200 seconds, and then developed. A large number of such plates was made in the course of the investigation.

Measured densities were then plotted as ordinates against

F₁ F₂ F₃ F₄ F₅ F₆ F₇

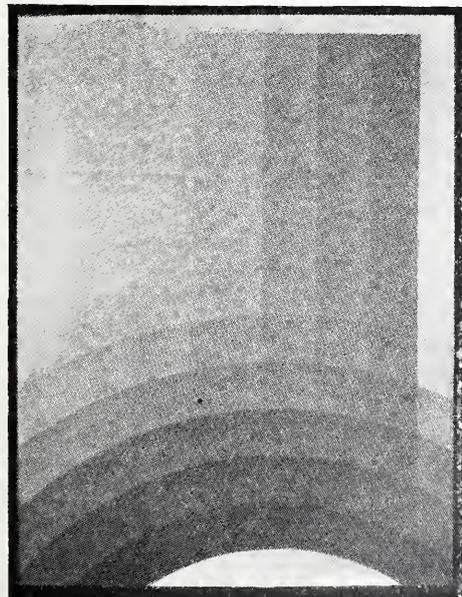

Fig. A.

logarithms exposure as abscissæ, and as the actinic value of the acetylene burner at a distance of 2 metres = 0.15 candle, then

$$\log. E = \log. I + \log. T,$$

where log. T is the value obtained by measurement of the strips on the transparency plate.³ These curves are shown in Fig. 2.

Referring to Fig. B, and calling one series of exposures

Fig. B.

² Owing to the coating inequality of the ordinary commercial plate, it was found necessary to make careful selection before one sufficiently even was found.

³ A series of differently timed crossed exposures made directly to the acetylene light without the interposition of the "transparency" gave precisely similar results.

the original, its successive strips may be designated $O, O_1, O_2, \dots, O_{20}$, while the other exposures may be termed "fogging strips" and designated as $F_1, F_2, F_3, \dots, F_{20}$. It will, of course, result that the graphic illustration of $O, O_1, O_2, \dots, O_{20}$ (which has been protected from any additive exposure) will simply represent the characteristic curve of the plate, while $F_1(O, O_1, O_2, O_3, \dots, O_{20})$ illustrates the change occurring when definite amount of "fog" (F_1) is added to the original series of exposures $O, O_1, O_2, \dots, O_{20}$ (Fig. 2).

In photometric and general scientific work, where it very often occurs that heavily fogged plates have to be measured, the value of the curves should be obvious; particularly in the measurement of relative brightness in such instances as solar disc phenomena, selective spectral intensity, etc.

In use one knowing the value of the "fog" under consideration may at a glance obtain the "minus value" of the same for densities of varying amount. It will be noted that fog-increase values appear to become asymptotic to the straight portion of the characteristic curve.

Gain from Preliminary Exposure.

To determine the value of preliminary exposure with reference to the photographic visibility of light of feeble intensity, the following method was adopted. Exposure was made to the constant acetylene light through a transparency graduated in strips (whose densities advance in arithmetical progression) for a definite length of time and at a definite distance. The plate was next turned through 180deg. and exposed behind the rotating sector disc, the apertures of which advance geometrically. Both exposures were so timed that the developable impression ceased to be visible before exhausting the number of strips. The plate was then developed as usual under constant conditions.

A very large number of plates (Seed "27") were thus made with the light at different distances and behind variously graduated transparencies, but the results in every case simply verified one another.

Fig. A is a reproduction of such a plate as has just been described, and even with the unavoidable loss due to the half-tone process it will be seen that there are arcs showing upon some of the "fogged" sections which are totally invisible upon the original unfogged region. This gain is best noticeable at F_4 , and the gradual disappearance of the effect of the additive "fog" against increasing density of the original is also clearly shown.

All of the plates thus exposed were assembled, and selection for measurement was made of that one which showed the maximum effect of increase. The measurement of such small differences requires the utmost care, and is very trying upon the eyes; ample precautions were taken relative to screening off extraneous light.

The density measures of this plate are shown in Table II., and the plotted values in Fig. 3.

TABLE II.

No.	Original ^a (Unfogged)	Original ^b + Prelim. Exposure.
1	—	0.4938
2	—	.5232
3	0.1588	.5590
4	.2818	.6512
5	.5324	.7646
6	.8306	.9970
7	1.2574	1.3860
8	1.7128	1.8038
9	2.2108	2.2108

It was at first intended to plot the densities of this plate against actual candle-power, but further consideration of the method showed the infeasibility of such a plan, for while it presumably would be true for a certain emulsion evenly coated, yet commercial production does not allow of such a degree of accuracy, and any change in the speed or constitution of the emulsion would necessitate an entirely new determination. We considered it decidedly better, therefore, to plot these densities against exposure ratios in powers of 2 as being the more practical, and also because this method presents uniformity with earlier papers published by one of us.

Considering now these curves shown in Fig. 3, the continuous line represents the original (unfogged), while the dotted line represents the same original exposure, but as influenced by an amount of pre-

liminary exposure giving a density value of 0.3218. It is, of course, understood that this density (0.3218) would appear in practice entirely covering the plate as a "basic fog," and would be representative of the highest transparency thereon. Having a definite measure of this additive fog, we can, by reference to the curves shown in Fig. 2, construct another curve which will represent the true increase or gain in sensitiveness conferred by the preliminary exposure. This curve is shown by the heavy continuous line in Fig. 3.

Just how much has been gained by the method is plainly shown graphically, but is difficult to present in figures. One naturally expects to be able to state in percentages the amount of any change, but in this instance such a method would convey very misleading information, for while with the most careful examination No. 3 was the first exposure to show any trace of development action on the original (unfogged) scale, yet Nos. 1 and 2 showed perfectly measur-

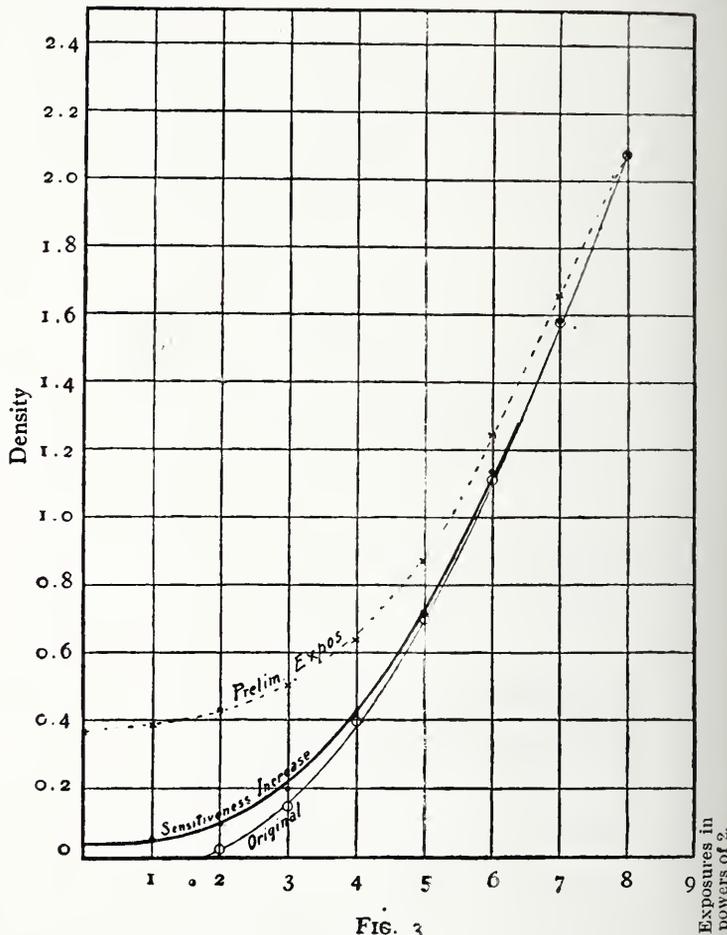

FIG. 3

able differences on the strip preliminarily fogged. The gain could thus be only represented in percentage by "infinity," which is ridiculous. We have considered it better, therefore, to make our deductions from sector exposure No. 3, which gives a density difference of 0.08 (H. and D.). This value corresponds to about 0.2 magnitude on stars near the limit of photographic action—i.e., of a density so low that their impress is but barely discernible on the negative. This gain, as will be seen both from the curve and from Fig. B., is a quantity decreasing with the density—for example, for neighbouring stars giving a density value of 0.4 the gain is reduced to 0.08 magnitude.

From these results it therefore appears to us that there is no practical advantage in preliminary (or supplementary)⁶ exposure, in so far as concerns astronomical (stellar) photography. It is, however, perfectly comprehensible that there may be special occasions (more particularly in long spectroscopic exposures) where the exposures are measured by hours or days, when the slight gain would be well worthy of consideration; ordinarily the "gain" is a negligible quantity, which is in many lines of work offset by the change in gradation curve.⁷ The great majority of workers will naturally hesitate to purposely "fog" their plates for so slight a gain.

⁶ Plates made with supplementary exposure resulted in values similar to those preliminarily exposed.

⁷ This change is shown by the uniformly lower γ of the "fogged" strip, i.e., by a smaller angle between the straight portion and the log. E axis.

⁴ These values represent the actual density, the value of the density due to glass and gelatine having been subtracted, as is usual in sensitometric measures.

⁵ Density of preliminary fog = 0.4512.

Reciprocity Law.

The well-known Bunsen-Roscoe "reciprocity law" states that the product $I t = E$, where I is the intensity, t the time, and E the exposure. Abney was the first to point out that this law did not hold for photographic plates, and further work has since been undertaken upon the subject by English, Schwarzschild, Mees and Sheppard, and others, from which it results that the formula $I t^P = E$ is more in agreement with truth when P is slightly less than unity.

As the matter is of considerable importance from an astronomical standpoint, it was decided to verify these foregoing values upon the plates most generally in use⁸ in astronomical and general scientific work—viz., Seed "27" and Cramer "Instantaneous Isochromatic."

A large number of exposures were made upon these respective plates behind the graduated transparency before mentioned at different distances from the constant acetylene light, and (by means

constant light at a distance of 2 metres. This "constant" exposure may be represented by m . The light was then removed to a distance of 12 metres (=1/36th the original intensity), and four more exposures were given on the remaining portions. As each exposure time was completed, the movable slides protected that portion from further light-action, which, for example, were in some cases

24 minutes (=m)	=P=1.0
35 " 4 seconds	=P=0.905
53 " 48 "	=P=0.816
1 hour 26 " 16 "	=P=0.734
2 " 27 " 52 "	=P=0.663

although varying values for P were given on different plates.

As was anticipated, examination of the plates after development showed that in every case, with the "27," the exponential value

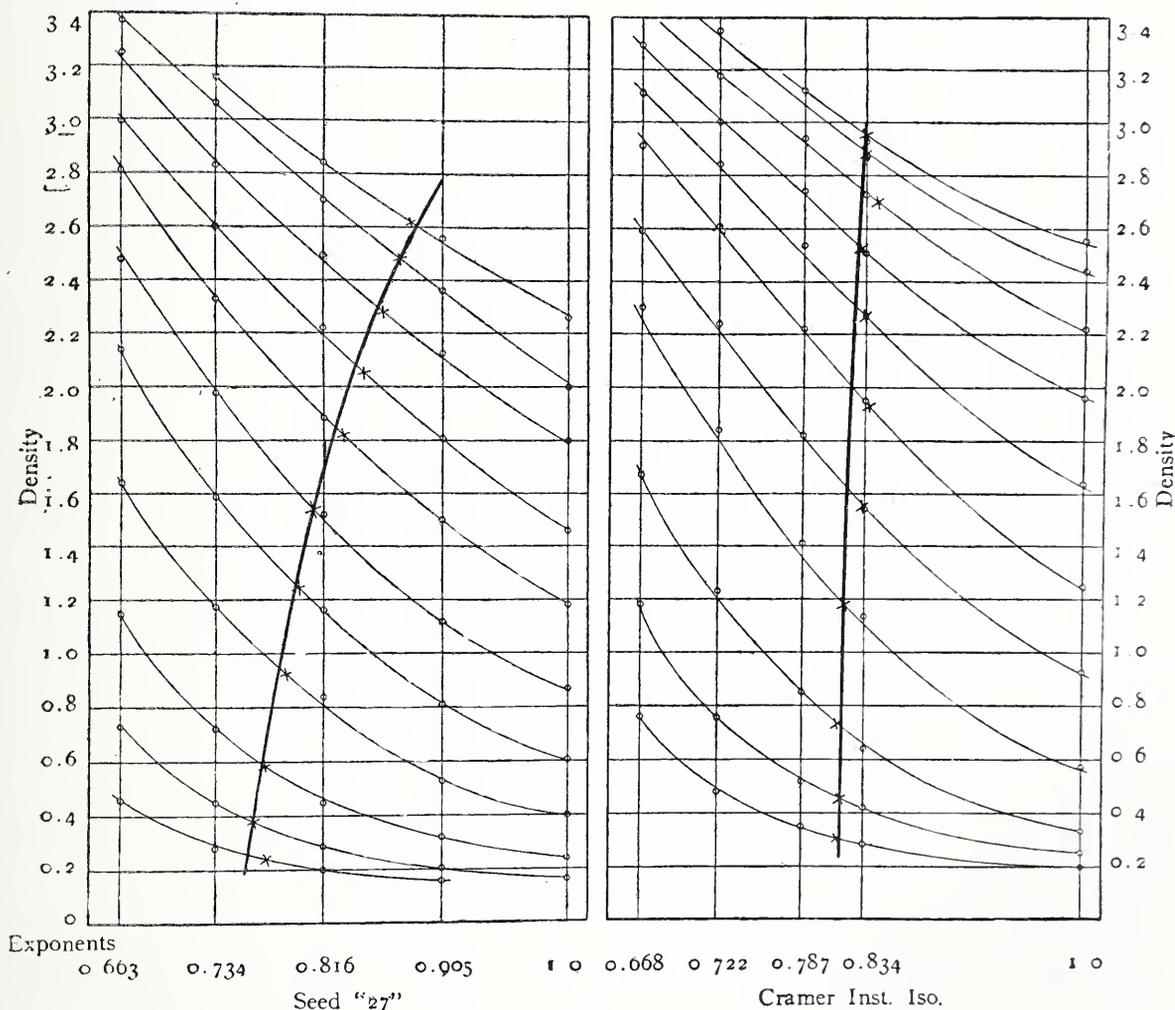

FIG. 4

of shutters) for different lengths of time—i.e., different values of P . From the formula $I t^P = E$ we obtain:

$$I_1 t_1^P = I_2 t_2^P,$$

whence

$$P = \frac{\log \frac{I_1}{I_2}}{\log \frac{t_2}{t_1}},$$

and

$$t_2 = \text{antilog} \left(\frac{\log I_1 - \log I_2 + P \log t_1}{P} \right)$$

In actual practice six separate exposures were made on each plate ("27" and "iso") in the following manner. One portion of the plate was exposed behind the transparency for 40 seconds, with the

varied with the density. With the "iso" plate this variance does not obtain, but remains practically constant even beyond the limit of full printing density. Plotting the measures made from these two types of plates against the true log. E , the crossing of the various curves over m is plainly shown.

If, however, these curves be plotted with density against exponents, we obtain a series of smooth curves which present great interest, for upon each unit we may indicate the density value of m , and, connecting the points, obtain a result which gives directly the exponential value required to reproduce a density of any chosen magnitude. Thus it will be noted (Fig. 4) that with a Seed "27" plate for a density value of 2.6 the exponent value required is 0.88, while for $D=0.4$, $P=0.76$.

In astronomical photography, assuming that for certain stars of n th magnitude an exposure of 60 minutes is necessary in order to obtain upon the film a density of 0.4, then the exposure time neces-

⁸ In the United States.

sary to obtain images of comparable density from stars 1 magnitude fainter would be found as follows:—

$$\begin{aligned} \text{Let } I_1 &= 1. \\ I_2 &= \frac{1}{2.5} \\ P &= 0.9. \\ t_1 &= 60 \text{ minutes.} \\ t_2 &= x. \end{aligned}$$

$$\text{Then } \frac{0 + 0.3979 + 0.9 \times 1.7782}{0.9} = 2.22.$$

$$\text{and } \log^{-1} 2.22 = 166 \text{ minutes} = t_2.$$

For stars of higher density the time is proportionately shorter.

Regarding the Cramer "inst. iso." plate curves (Fig. 4), it will be seen that when plotted in similar manner the exponential curve is practically a straight line with its mean value at 0.83, which is in practical agreement with Schwarzschild, who found when using Schleussner plates $P=0.86$. It is evident, however, that the value for P will vary with plates of identical "brand" if the emulsion be not coated in one operation at the one time. It is also probable that the P value may vary with the wave-length of the incident light.

R. JAMES WALLACE.
HARVEY B. LEMON.

SENSITISING SOLUTIONS FOR PRINT-OUT PAPERS TO GIVE BLACK AND BROWN TONES.

(Some modified formulæ for the making of plain paper are given in a recent issue of "Der Photograph," by Dr. C. Stürenburg, who, in recommending their use, comments upon the preference now extended to printing papers which give the rich brown tone of a mezzotint engraving, and at the same time possess the natural texture of the paper.—Eds. "B.J.")

THESE conditions, it is pointed out, are realisable by the use of a paper which the photographer can prepare for himself with comparative ease, and requires only to fix and wash. The following formulæ and methods of preparation are recommended.

For a paper which shall give a black tone 10 gms. of sodium phosphate and 20 gms. of gelatine are dissolved in 1,000 ccs. of water. To this warm solution 10 ccs. of a 5 per cent. solution of shellac in alcohol are added. The paper to be used is dipped in this warm solution and removed and hung up to dry as soon as the liquid has penetrated it. In place of immersion the solution may be applied with a brush, and the dried paper can be kept for any length of time. In order to sensitise it the following silver bath is prepared:

Silver nitrate	120 gms.
Boric acid	10 gms.
Potass chlorate	20 gms.
Water	1,000 ccs.

The paper is floated on this bath for about five minutes and hung up to dry. Printing takes place very quickly, and the prints are then washed and placed in a plain bath of hypo of 10 per cent. strength, again washed and dried.

A second method (for brown-toned prints) is as follows:—

Soft gelatine	10 gms.
Ammonium chloride	6 gms.
Sodium carbonate	2 gms.
Borax	2 gms.
Sodium phosphate	6 gms.
Potass. bichromate, 10 per cent. solution...	3 drops.
Water	300 ccs.

The above proportions give a deep brown tone. For a black tone only 8 gms. of borax should be taken and 9 gms. of sodium phosphate. For sepia tones the proportions should be borax 15 gms., sodium phosphate 2 gms.

This warm solution is applied freely to the paper by means of a brush, the paper being pinned to a board. After drying, the paper is sensitised in:—

Silver nitrate	15 gms.
Lead nitrate	15 gms.
Distilled water	240 ccs.

Ammonia is added drop by drop to this bath until a slight permanent precipitate is produced. The bath is then exposed to light until the precipitate has settled and is then filtered. The paper may be sensitised by liberal application of the solution with a brush. In its sensitive condition the paper will keep a few days. It may be fairly deeply printed, and the prints then given a few minutes in a 3 per cent. solution of salt, rinsed and fixed in a hypo solution containing 180 gms. hypo per 1,000 ccs. of water. This is followed by the usual washing.

THE CITY AND GUILDS EXAMINATIONS IN PHOTOGRAPHY.

At the examinations held on April 28 and May 1 by the City and Guilds of London Institute, the following papers and practical exercises were set in photography. The number following each question is that of the number of marks given for it.

ORDINARY GRADE.

Written Examination.

1. The following formulæ for development, accompanying each box of plates sent out by a popular maker, is a fair sample of the usual instructions, with British weights and measures. Would you advise any improvement, and, if so, what, in the mode of stating the proportions of the ingredients?

Avoirdupois Weight.

Pyro Developer.

To those who prefer a vigorous negative the following is recommended:—

Sol. 1.	Pyro	1 oz.
	Potassium bromide	50 grs.
	Potassium metabisulphite	50 grs.
	Sodium sulphite	8 ozs.
	Water to make	80 ozs.
Sol. 2.	Sodium carbonate	8 ozs.
	Water to make	80 ozs.

Use equal parts of solutions 1 and 2.

For softer negatives the following may be used:—

A.	Water	16 ozs.
	Sodium sulphite (crystals)	1 oz.
	Pyro	1 oz.
	Citric acid	20 grs.
B.	Water	16 ozs.
	Sodium sulphite (crystals).....	4 ozs.
C.	Water	16 ozs.
	Sodium carbonate (crystals)	4 ozs.

To develop take

A.	1 oz.
B.	1 oz.
C.	1 oz.
Water	8 ozs.

(a) Taking 1 oz. of the first-named complete developer, what would it contain?

(b) What are the contents of an ounce of the second "for softer negatives"? (30 marks.)

2. Given a batch of negatives thoroughly washed and ready to be dried, how would you proceed to dry them, (a) twelve hours being allowed, (b) half-hour only being allowed? In either case, what troubles might possibly occur, and how would you remedy them? (30.)

3. What strength would you recommend for a "hypo" fixing solution for negatives? How would you decide when to remove the plate from the solution? What method would you adopt for freeing it from the "hypo"? (25.)

4. Of what is the film of an average dry-plate of the present day composed? (40.)

5. Explain the action of the developer upon an exposed gelatine dry-plate? (40.)

6. For use in various departments of photographic work, dishes of many kinds of material are purchasable; state what material or materials and what colour or colours you would prefer, and give your reasons for such preference. (30.)

7. If the inside of the bellows of a camera had lost its original dead black appearance and become grey and worn-looking, would any ill-effect be produced when using it? If so, how would you provide against it? In re-blackening the interior of a dark slide how would you proceed, and what materials would you employ? (35.)

8. Having a whole-plate (8½ ins. x 6½ ins.) camera capable of extending to 18 ins., what is the extreme size you could, with it, enlarge a head 1½ ins. from chin to top of head when using (a) an 8-in. focus lens and (b) a 5-in. focus lens? (40.)

9. In the case of a gelatine dry-plate negative badly cracked, but with the film itself not ruptured, how would you transfer the film to another unbroken glass plate? What risks would occur, and how would you combat them? (35.)

10. Some makers advertise lenses as specially valuable on account of their so-called "depth of focus." Have you found, in your own experience, such claim to be well founded? On what does this "depth" depend? (30.)

11. Give formulæ for the composition of a developer and a clearing solution for platinotype printing. (30.)

12. How would the resulting prints on platinotype paper be affected if the paper had been insufficiently protected from the atmosphere for some weeks? (30.)

13. Used in a studio 20 ft. long, what is the longest focus a lens could have so that a full-length standing figure 6 ft. high could be taken for a cabinet size (5½ ins. x 4 ins.) picture, leaving ¾ in. space above his head and ½ in. below his feet on the print? (40.)

HONOURS GRADE.

Written Paper.

1. Give an account of the chemical theory of the formation of the photographic image. State any objections to it which appeal to you. (60 marks.)

2. A lens is made of glass, having a refractive index of 1.52. It is equi-convex, and has a focus of 12 ins. What is the radius of curvature of the two surfaces? (40.)

3. What are the essential principles of sensitometers for three-colour work? (50.)

4. You are given colour screens which are not perfectly plane. By preference where should such screens be placed? Give your reasons. (30.)

5. A good lantern slide has to be made by contact on a fairly rapid lantern plate from a very thin negative. Describe how you would set about making it. (50.)

6. Describe Hurter and Driffield's method of ascertaining the comparative rapidities of plates. Point out anything which militates against the absolute theoretical accuracy of the method. (60.)

7. Name any metallic salts (other than silver salts) which are sensitive to light. (30.)

8. Discuss the advantages or disadvantages of having an instantaneous shutter between the two components of a doublet lens. (40.)

9. Describe the single transfer carbon printing process. (30.)

10. State what you know about flashlight photography as regards time of exposure and ingredients employed to produce the flash. (40.)

11. Give the formula for an acid fixing bath, and state any advantages it possesses over the ordinary hyposulphite bath. (30.)

12. Describe some plan by which you can use with safety plates that are liable to frill. (40.)

Practical Examination.

1. Copy the engraving given you, making the image as large as possible on a half-plate.

2. Dry off the above negative with methylated spirit and take a contact print from it on bromide paper.

3. Print the negative given you on carbon paper, double transfer.

4. Intensify the negative given you.

PIPE-DREAM PHOTOGRAPHS.

AMONG the forms of photograph of a kind to attract attention which have come under our notice of late, the most striking is undoubtedly that devised by Mr. W. R. Barefoot, of the Dixon Studio, Toronto, and called by him "Pipe-dream Pictures." The novelty of the setting and its value as a means of advertising the photographer are best summed up in the expressive phrase applied to it by Mr. Barefoot, "It's a winner."

In response to our request for a print for reproduction and some account of the process, Mr. Barefoot writes as follows:—

"To make a 'pipe-dream picture' you take a negative of a subject you may choose on a white ground. Vignette it in on your

panel sheet of matt-surface paper, and at the same time from a negative of a pipe the required size. Print in that also on the bottom of the same panel sheet of paper. This being done, you develop the print in the usual way, fix and wash, and then dry the print under pressure to keep flat. The smoke effect is now put in by hand, with a piece of absorbent cotton and graphite, and etched out with a rubber to the design you may require. A soft rubber is used for the etching.

"These novelties are very simple and easily made, and when I dressed our Christmas window with them—it being the first appearance of a 'pipe-dream' in photographic form in America—they attracted no small amount of attention from the public."

Photo-Mechanical Notes.

Another Etching Machine.

The patent specification (No. 13,452, 1908) is just published of an etching machine invented by Mr. Holt, the managing director of the works of Messrs. John Swain, Limited, at Barnet. The machine consists of an etching bath, in which the plates are laid in the etching solution. Just above them is arranged a disc, which is caused to rotate by means of a small motor. On the face of the disc are fixed vertically small blades or vanes so constructed that the rotation causes them to make a maximum agitation of the liquid.

The idea would seem to be a combination of those of Concewitz, who whirls the plate in the bath, and Albert, who agitates the liquid by a reciprocating movement. The special claims of this machine are that it is durable and effective, that the desired effect is obtained in a very expeditious, economical, and satisfactory manner; further, that it is silent, and can be run at small cost.

It is well to remember, in these days of etching machines, that the only way to facilitate etching mechanically (the strength of mordant and other conditions remaining the same) is to remove rapidly the reaction products and bring fresh mordant to bear on the metal to be etched. That is the reason why violent shaking of the bath, or violent brushing of the plate, hastens the process. The point, therefore, to be determined is which method of removing these reaction products is the most effective. In copper etching with iron perchloride without agitation, there can be no doubt that face-down etching is better than face-up etching, principally for the reason that the copper chlorides formed sink, and if the plate is laid in the bath face up the reaction products fill up the etched spaces, and if they are then removed by surface agitation the side-spreading action is much greater than it is when the mordant is allowed to act from below, because the chlorides, in the latter case, sink then into the bath and not into the etched spaces, and leave fresh copper exposed automatically. There is no advantage gained by etching in a still bath with zinc face down, because some of the reaction products are gas bubbles, which cling to the surface and spoil the etching unless they are removed. But it is certain that violent rocking of the bath or violent brushing of the plate also increases the width of the etching action in proportion to the depth, and that until some other method is found to be better it is probable that either raining down the mordant or spraying it up will be found superior for both zinc or copper. Comparative tests on different machines, some using agitation of the bath solution, others using spraying methods, have shown, as was to be expected, a greater depth for the same width or a lesser width for the same depth in the case of the spraying machines, while the reverse is true for the other machines. However, there is no doubt that any of the machines so far on the market give superior results to hand-rocked tub-etching.

White-Letter Process.

A correspondent writes:—"Have you at any time given under 'Patent News' or elsewhere details of Baker's 'line-tone' and white-letter process, and if so, could you give me date or number of issue? Failing this could you give me the number of the patents?"

We believe these are secret processés, and we do not remember ever having seen them referred to as patented. The white-letter process is a transposition method, and such "reverses" can be simply attained as follows:—Take a good black impression of the matter desired to be transposed, and immediately dust over it dry oxalic acid in powder, brushing away all powder that does not adhere to the ink. Cover the litho. stone or zinc plate with a thin even film of transfer ink. Place the print in a damping book for a few seconds, and then lay down on the stone, pull through the press with good pressure and remove. The acid has now penetrated the ink and the stone can be gummed up and washed out as usual.

Another method is to dust the ink impression with powdered gum arabic, and lay this down on a stone previously damped with water applied with a clean cloth. Pull through the press, and the gum will adhere to the moist stone. The stone can then be

rubbed up with ink and turpentine, dried and treated in the usual manner, when a "reverse" will be the result. The former method is said to give the sharper results.

PHOTO-MECHANICAL PATENT.

The following patent has been applied for:—

PRINTING.—No. 10,260. Improvements in photo-mechanical printing. Oliver Samuel Dawson, 254A, High Holborn, London.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents have been received between April 26 and May 1:—

HANGING DEVICE.—No. 9,865. Improvements in devices for hanging photographs and other objects. Ivan August Mauritz Larsson, 65, Chancery Lane, London.

BIOSCOPIES. No. 9,876. Apparatus applicable to bioscopes for minimising the risks of fires. Frank Porter and British Bioscope Manufacturing Co., Ltd., 11, Southampton Buildings, London.

EMULSIONS.—No. 9,900. Improvements in photographic emulsions of phosphate of silver. William John Wilson, Paget House, Watford, Herts.

CINEMATOGRAPHY IN COLOURS.—No. 9,912. Improvements in and relating to cinematography in colours. Henry William Hamblin Palmer, 52, Stephens Road, Tunbridge Wells.

FILMS.—No. 9,925. Improvements in photographic films. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

COLOUR PHOTOGRAPHY.—No. 10,059. Improvements in and connected with colour photography. Louis Weigert-Sterne, 77, Chancery Lane, London.

MOUNTING.—No. 10,205. Improvements in and relating to the mounting of photographic and other pictures and the like. James Bert Bowden Bailey, Montague Picton Prout, and Frederick William Emuss, 37, Chancery Lane, London.

VIEWING PHOTOGRAPHS.—No. 10,207. Improvements in and relating to obtaining and viewing of photographic images. Andrew Lincoln Jackson, 18, Southampton Buildings, London.

EMULSIONS.—No. 10,284. Improvements in photographic emulsions. William John Wilson, Paget House, Watford.

PROJECTION APPARATUS.—No. 10,292. Improvements in apparatus for projecting series of luminous pictures. Georg Mewes, 31, Bedford Street, Strand, London.

COLOUR PHOTOGRAPHY.—No. 10,351. Improvements relating to colour photography. Richard Merkel, 17, Holborn, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH MECHANISM.—No. 11,395, 1908 (May 27, 1907). The invention relates to safety mechanism for the prevention of fires in the cinematograph projector, and is based on the fact that celluloid melts before burning and for melting requires heat which arises first from the source which causes the ignition and after by the flame of the already burning celluloid. By pressing the ignited band between two solid parts, such as plates, rollers or jaws, the fire is extinguished; the same result is obtained

when the burning band is freely placed between such solid parts separated the one from the other by an interval which can amount to a seventh of an inch and even more. The parts then exercise at a distance a cooling action on the flame and thus prevent the next point of the band from melting and which otherwise would become ignited. The cooling action is so effective that the fire is extinguished even when the band is in motion between the solid parts; therefore the larger the interval between these parts and the higher the speed of travel of the band, a greater length of the band must be comprised between the cooling parts for ensuring perfect extinguishment; the result is more perfect when the parts are of metallic, good-conductive materials. But, in cinematographic practice when sufficiently good conditions do not exist or when the celluloid is particularly inflammable, the action of the cooling parts causes at least an enormous checking in the speed of the conflagration, enabling an automatic apparatus to separate the ignited portion of the band from the other portion thereof, either by cutting the band or by compressing it before its entrance into the fireproof film magazine; said entrance being simultaneously closed by the same operation of cutting or compressing, and thus all further danger is prevented. Amédée Lertourné, 2c rue Payée, Rouen, Seine-Inférieure, France.

Analecta.

Extracts from our weekly and monthly contemporaries.

A Copying Dodge.

A task I have just had to perform, writes Mr. Ralph Earle, in "Photography and Focus" for May 11, was the copying of a design to which had been attached a water-colour sketch, which had apparently been toned down all over with some wash. Every exposure on the whole thing resulted in either the design being hopelessly over-exposed or the sketch equally hopelessly under-exposed. The sight of a sheet of orange-paper suggested the following dodge to me, and this proved to be an effective solution of the problem. A hole was cut in the orange-paper with a sharp knife and a glass plate as a guide, so that it exactly fitted the water-colour, and the paper was then laid down on the design, with the water-colour showing through the hole. In this condition an exposure of thirty minutes—which experience had shown to be about right for the water-colour—was given. The paper was then removed, without disturbing the other arrangements in the slightest, and a further exposure of two minutes was given to the whole design. The result proved to be quite satisfactory. Black paper or black velvet would perhaps have answered better, but the orange-paper was handy, and seemed to do all that was needed.

FORTHCOMING EXHIBITIONS.

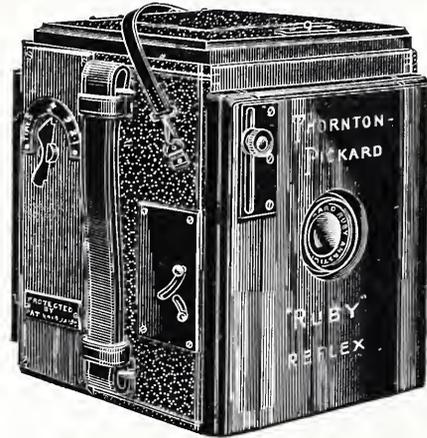

- April 29 to May 17.—Photo Club de Paris. Secretary General, Photo Club, 44, Rue des Mathurins, Paris.
- May 20 to 27.—Malvern Camera Club. Entries close May 10. Sec., J. B. Nickolls, The Exchange, Malvern.
- July 7 and 8.—Canterbury Camera Club. Entries close June 23. Sec., B. J. Fisk-Moore, St. George's Gate, Canterbury.

"OLD COACHING DAYS."—Lovers of Dickens will doubtless welcome this little booklet which gives an account of the early days of "The White Horse Cellar," so familiar to readers of "Pickwick," giving the chief place of departure and arrival for the old time coaches. Two specially interesting features are the eight illustrations in colour, reproduced in miniature from old sporting prints of the period, and the table of fares compiled from old way-bills and other coaching records. The little book has been compiled and published for the present proprietor of this old time hostelry by Messrs. Ward and Co., of 34, Craven Street, Charing Cross, London, W.C., from whom copies may be obtained, price one shilling net.

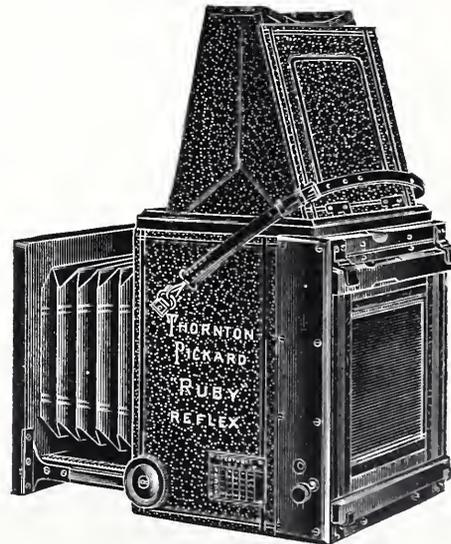

New Apparatus, &c.

The "Ruby Reflex" Camera. Made by The Thornton-Pickard Manufacturing Co., Ltd., Altrincham, Cheshire

The instrument sold under this name is made by the Thornton-Pickard Co. at a lower price than the "Royal Ruby" reflex, which is built with a pull-down baseboard carrying the universal front of the Thornton-Pickard design. This form of construction gives a

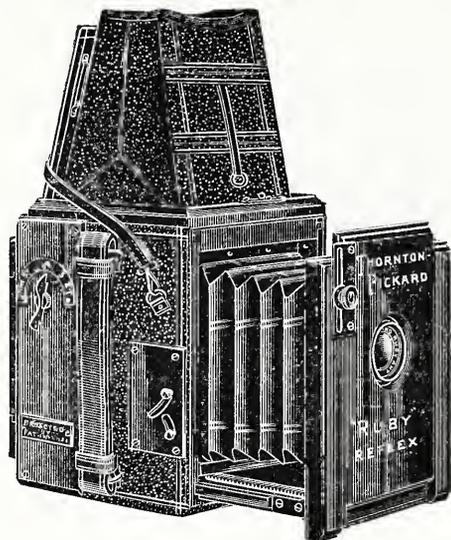

very great range of movement, but in the "Ruby Reflex" the makers supply an instrument which, while possessing a lesser range of movement, can claim to have one advantage over its more expensive fellow inasmuch as it is ready for use without the need of drawing out the front upon its baseboard. The camera is of the single-extension pattern, is provided with a rise-of-front movement, and has the hood instantly detachable for cleaning the ground-glass, two movements which may be considered essential in a reflex instrument. The chief feature, however, of the camera, and one which renders it extremely good value for the price charged for it, is the shutter, which is of quite distinct pattern from any hitherto used

on the Thornton-Pickard manufactures. Its chief claims to commendation, and they are particularly strong ones, are first that it is self-capping, protecting the plate when the shutter is re-wound; that all the speeds are instantly obtained simply by turning the winding-key, and this whether the shutter is set or run down; that setting is done with a very quick wind, only about half a turn of the milled head being necessary; and, lastly, that the construction of the shutter provides for a perfectly taut blind, the aperture in which is locked for each speed and does not vary as the blind runs down. In a reflex camera particularly a self-capping shutter is of the greatest advantage, since it prevents inadvertent re-exposure of the plate, even when the camera is not provided with an automatic return of the mirror to the down position. In the Thornton-Pickard camera this also is done so that the use of the instrument

is reduced simply to the one movement of re-winding the shutter after exposure and placing any plate in position in its dark-slide or by means of a changing box or other device. As the mirror may, however, be instantly locked in the up position so that a clear course is provided from the lens to the plate, the camera serves very conveniently for use on a stand, and here the quickness with which the shutter gives the full opening of the plate and may be thus used either for time or bulb exposures, is an excellent feature of the

arrangements. In giving this description of the mere convenience of the movements we should not do the camera justice if we omitted to say that in smoothness and silence of running the shutter is altogether excellent, and certainly marks an advance, from the point of view of the practical user, in focal-plane shutters. With all this convenience and efficiency the camera in quarter-plate size is priced at only £7 without lens, but with three double dark-slides, or with Thornton-Pickard "Ruby" anastigmat $f/6.8$, the price is £10.

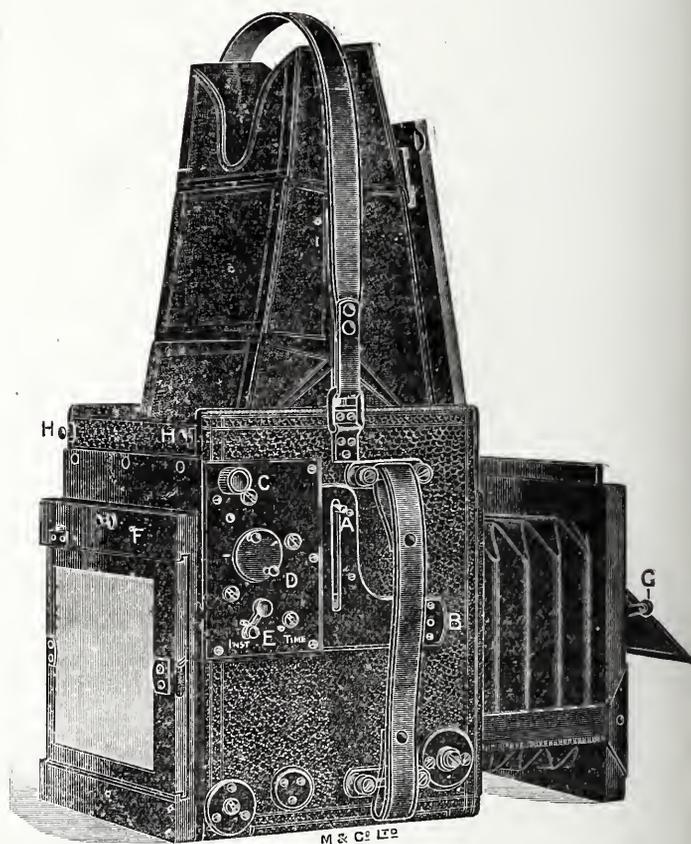

The "Soho" Viewing Mirror Attachment for Reflex Cameras, and new models of the "Soho" Reflex. Sold by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

As everyone who has used a reflex knows, that type of instrument possesses the drawback—we would almost say the one drawback—of requiring to be held in a somewhat low position in order to secure

a convenient view of the ground-glass screen. We have heard of heroic expedients undertaken in order to adopt a more lofty point of view: some photographers have declared their advocacy of holding the camera upside down at arm's-length above the head, in which position the picture upon the screen may be seen and focussed. This method, which, to say the least, is uncomfortable and apt to attract remark, is not one which is likely to come into general use. Messrs. Marion, in introducing a mirror attachment for the hood of the camera, have provided photographers with the means of doing prac-

tically the same thing in a much more convenient way. The mirror may be fixed at the mouth of the hood, as shown in the drawing, and the image formed on the ground-glass observed in it, a plan which, it will be seen at a glance, allows of the camera being held level with the eyes. Such a device has been embodied as a fixture in at least one camera, but this necessitates a hood of special pattern and one less suitable when viewing the picture in the ordinary way. Moreover, the detachable mirror being hinged to the frame by which it is affixed to the hood, the height at which the camera is held may be varied simply by giving the proper inclination to the mirror. It will be understood that it is not claimed for the attachment that the full size of the picture can be seen in the mirror; but a little experience of the accessory shows that very good judgment may be made as to the picture being actually obtained, and focussing may be done just as when the customary position is taken. Messrs. Marion supply the mirror attachment mounted so that the glass is protected when detached from the mirror, and may be carried flat in the pocket or in the camera case. This useful accessory is certain to be much appreciated by users of reflector cameras, inasmuch as it removes, as we have said, the one disability of this type of instrument. The price

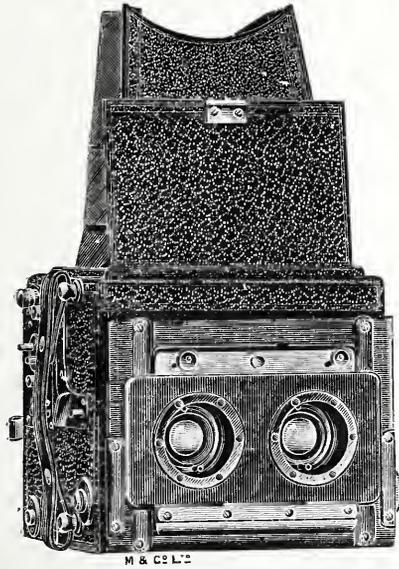

of the attachment covered in leather is 12s. 6d. in quarter-plate size, postcard 13s. 6d., 5 x 4 14s. 6d., and half-plate 16s. 6d.

In the 1909 model of the "Soho" reflex camera, an instrument which has taken its place as a standard of excellent manufacture and moderate price, several improvements have been made which materially enhance the working qualities of the instrument. In the first place, a lever adjustment of the rising front is provided whereby the movement is adjusted to a nicety while the operator has his eyes on the focussing screen. This is a feature of a reflex camera which is appreciated as much as any. Almost equal in importance, though perhaps not so clearly recognised as such by those unused to a reflex, is the ready accessibility of the ground-glass for cleaning purposes. This is now provided in the new model of the "Soho," the hood being hinged to the front and immediately raised releasing a catch. On a dusty day the focussing screen may receive a layer of dust which makes it difficult to secure a sharp focus, and on occasions when the camera has to be used in the rain, drops of water falling and spreading on the focussing screen will again make it almost impossible to be certain of accurate focussing, particularly when using lenses of large aperture. The shutter of the camera has been further modified so that the actual speeds for each width of

slit are recorded and all calculation dispensed with. The prices of the "Soho" reflex thus improved remain the same, and are given in full in a new twenty-page list just issued by Messrs. Marion and Co.

A further new pattern of the "Soho" reflex is one especially made for use in tropical climates. It is made throughout in teak, polished, and bound with brass where necessary, and of course without a leather covering. The hood and bellows are made of best Russian leather, whilst the dark-slides are also of teak and brass-bound in both the solid and book-form patterns. The apparatus is evidently of a kind to withstand the trying conditions of hot, moist, climates, and is issued in the quarter-plate size, complete with lens and three double solid plate-holders, at the price of £17 17s.

The stereoscopic pattern of the "Soho" reflex, introduced some little time ago, is built to take plates $5\frac{1}{2} \times 3\frac{1}{2}$ inches (postcard) size, the stereoscopic division being ingeniously fitted at the back of the camera, so that it is almost instantly removable when using the instrument for single pictures the full size of the plate. The panel

carrying the pair of lenses is similarly quickly removed, and the instrument thus allows of ordinary stereoscopic photography being practised while, at the same time, enabling the user to obtain negatives of the very pleasing shape, from the pictorial point of view, of $5\frac{1}{2} \times 3\frac{1}{2}$ inches. The price of the "Soho" stereo reflex complete with three solid plate-holders and stereoscopic division, and including the mounting of the two lenses, is £14 10s.

New Materials, &c.

THE LUMIERE FILM BLOCK.—By the omission of two letters from the notice of last week we were made to say that: "Separating papers are used between the films." The sentence should, of course, be: "No separating papers are used," etc. The error, we hope, will have been obvious from the context in which the very effective opaque backing and separating pellicles were described.

PHOTOGRAPHIC MOUNTS FOR PROFESSIONALS.—Since in our issue of March 26 we gave a description of current styles of commercial mounts under the title "Mounts and Mounting of To-day," we have had the opportunity of making the acquaintance of still other products than those mentioned in this article. Many of our readers know the work in mount designing and manufacture of Messrs. Witt and Wesley (the British Photo-Mount Co.), who a few months ago moved from the West-End of London to the seclusion of Tottenham, and have there established a factory which is probably unique in this country in its provision of the most modern machinery for mount making. The modern photographic mount, simple as it is in design and effect, calls for a surprising number of operations, and for several of great mechanical nicety, such as the adjustment of a paste-on nearly equal in area to the complete mount. Messrs. Witt and Wesley manufacture only the

high-class mount; the cheap article they leave to others, for they deal almost solely with photographers able to use mounts as good each of their kind as can be made. Their business is chiefly directly with the photographer, and in most cases they make to order; thus they have little stock and the specimens we secured on our visit were mostly those thrown out as not good enough to supply. These, however, sufficed to show the beautiful styles in mountings. Perhaps the most distinctive mounts are those of mounted or plain vellum bearing a tint or copper plate engraving. The latter by their beautiful fineness present an appearance much superior to that of lithography. Messrs. Witt and Wesley make and retain dies for a photographer's exclusive use. In mounts sold as B.P.M.C., of linen texture and two or more tints, the linen effect is very nicely obtained, and the mounted-on tint shows not the faintest sign of an edge owing to the enormous pressure used in affixing it. The result might be by litho so even is the surface, but the tint has the linen surface and presents a better surface for mounting on than a litho tint. In colour tones, too, these mounts include some delightful examples of harmony, and the makers justly point with pride to some in which a plate-mark is put round the mounted tint. Cosways, C. de V., and other mounts are produced of very choice design, and it is clear that no mount is beyond the makers' skill. Messrs. Witt and Wesley evidently take a great personal interest in their business, are ruthless in discarding imperfect mounts, and show in all their work a very nice appreciation of the requirements of refined portrait photographers.

Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, E.C., have also sent us examples of their latest styles in mounts for professional portraits. They include a great variety. Of these the "Mitsi," a Japanese hand-made mount with the mill edges, provides a very handsome style of mounting. A new departure is a mount with a flexible base with a fairly stiff paste-down, allowing of good effects by the ordinary method of mounting. It is invidious to specify particular items where there are so many nice in design and colour, but from the collection before us we may mention the "Greville," a canvas surface, fawn mount with embossed plate-mark; the "No. 2 Cosway," made in cream and white, with impressed plate-mark and natural edges; the "Cambic" portfolio, another of the popular canvas mounts; and the "Ideal" folio, composed of a cover imitating coarse brown canvas containing a "canvas" board with cream tint. Messrs. Butcher would remind our readers that by the absorption of the firm of Chas. Tyler and England Bros., Ltd., they at the same time took over their extensive mount factory, which they have still further improved and enlarged; therefore buyers have the satisfaction of knowing that all their mounts are of British manufacture.

LILYWHITE MEDIUM SPEED BROMIDE CARD.—The Halifax Photographic Co. have just produced a card of the bromide class which is slower in speed than ordinary bromide and gives prints of greater vigour than the "Standard" Lilywhite brand. We found the paper to give excellent and plucky results from negatives of average contrast—negatives about right for P.O.P. printing—and to develop to a fine black colour. The advantage of a card such as this which allows of brilliant prints being made, and of these being then toned by the sulphide process is one which photographers doing much commercial work will appreciate.

MR. ARTHUR S. NEWMAN, formerly managing director of Messrs. Newman and Guardia, whose severance from that firm we announced some time ago, has established himself in business as a scientific instrument maker at Whittington Works, Highgate Hill, London, N., within two minutes of the Highgate Tube terminus. Mr. Newman's long connection with the manufacture of photographic cameras of the highest class—the "N." of "N. and G." signifies Newman—is sufficient guarantee that his skill, we might almost say genius, as a mechanic may be depended upon by his customers. He is prepared to design, construct, alter, or repair cameras and shutters which require such expert skill as his, and the photographer or photographic investigator requiring special apparatus can depend on getting from him a design which is scientifically right, and workmanship which spares no pains to attain reliability. Mr. Newman, having no trade bias, also offers his services to readers abroad anxious in purchasing an outfit to obtain expert advice and supervision of goods purchased by him for them in London.

CATALOGUES AND TRADE NOTICES.

SECOND-HAND STUDIO CAMERAS.—A list just issued by the Sloane Square branch of the City Sale and Exchange, 26 and 28, King's Road, S.W., gives particulars of cameras for studio and field use, to be seen at these West-End premises, where the firm offers a very large choice of apparatus, which is shop soiled or has been little used. The list includes a number of large studio instruments, and those in want of such apparatus would do well to pay a personal visit to the C.S.E. establishment, which is within a minute's walk of Sloane Square.

"MIRAL" REFLEX CAMERAS.—Messrs. F. V. A. Lloyd, Ltd., the well-known photographic dealers, of 15, Lord Street, Liverpool, send us a new list of the "Miral" cameras of Talbot and Eamer, whose sole selling agents they have become. The list specifies the several patterns of "Miral" reflex, the reversing-back and focal-plane models of which particularly are instruments of excellent construction and design. The list is well illustrated with specimens of reflex work with the "Miral."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 15.

United Stereoscopic Society. Outing to Alexandra Palace and Park.
South Suburban Photographic Society. Beginners' Outing to St. Paul's Cray (afternoon).
Southend-on-Sea Photographic Society. Excursion to Hockley Woods.
Kinning Park Co-operative Camera Club (Govan). Outing to Lochwinnoch.
Southampton Camera Club. Ramble to Cadnam.

SUNDAY, MAY 16.

Borough Polytechnic Photographic Society. Outing to Malden.

MONDAY, MAY 17.

South London Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

TUESDAY, MAY 18.

Royal Photographic Society. "Some Ancient Abbeys and Churches of South Essex." C. W. Forbes.
Edinburgh Photographic Society. Ramble to St. Andrews.

WEDNESDAY, MAY 19.

West Surrey Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Southend-on-Sea Photographic Society. "The Camera at Home." E. T. Holding.

THURSDAY, MAY 20.

Handsworth Photographic Society. "A Day in a Trappist Monastery." J. A. Swift.
Polytechnic Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Edinburgh Photographic Association. Ten-Minute Lectures on Favourite Subjects.
South Suburban Photographic Society. "Line and Composition." P. Bale Rider.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 11, the president, Mr. J. C. S. Mummery, in the chair.

It was announced that Mr. James A. Sinclair had been appointed a member of the Affiliation Committee to fill the vacancy caused by the death of Mr. Hector Maclean.

The president announced that after lengthy negotiations the arrangements as to the removal of the society from its present premises had been brought to a conclusion, and the agreement for a lease of No. 35, Russell Square had been signed, and the society would shortly be transferring itself to the more commodious premises at this address. Members were therefore advised that the enlarging room, dark rooms, and lockers at 66, Russell Square must be cleared out for removal by the 22nd inst. With the exception of the secretary's office, the rooms at 66, Russell Square will be closed after June 8.

A gift of a number of photographic reproductions of pictures in the Bridgwater collection had been made to the society by Mr. Walter Bourke. Mr. Bourke, in acknowledging the vote of thanks, commented upon the great value of the collection he had illustrated.

A paper was then read by Mr. Horace Mummery on "The Way We Look at Things," in the course of which the lecturer took a depreciatory view of the present craving among photographers with pictorial aims to produce something which compelled attention.

Mr. Mummery expressed a preference for the results obtained by "straight" photography as compared with those of "control." A short discussion followed the reading of the paper, in which the Rev. F. C. Lambert, Messrs. W. Thomas, Bale Rider, Walter Bourke, and the President took part.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Mr. Charles H. Oakden dealing with "Irish Architecture," on April 30, traced its development from a very early period up to the present day. He showed many very fine slides, illustrating the earliest dwellings extant, the clochans, probably the same as the circular stone houses referred to by Julius Cæsar as existing in Britain at the time of his visit, the cliff castle of Dun Engus, the cahers or camps of Clare, the curious oratories of Gallerus and Kilmahedar; various examples of the round towers and the high crosses were shown with details of the ornamentation and sculptures on the latter, the symbolism of which was explained. Other slides showed the decadence in architecture which took place during the period of the rebellions, also the revival in recent years.

CROYDON CAMERA CLUB.—"In the Solent—Coves Week," formed the title of a capital lecture on the 5th inst. by Mr. F. W. Hicks. It was illustrated by a large number of slides, chiefly depicting varied types of racing yachts and other craft, and it was generally agreed that no better lecture-set had ever been shown in the club rooms. Full of graceful lines, sunshine, and suggestion of motion, the slides amply demonstrated that clean, straightforward photography can be beautiful, true, and delightful, and in subtlety of gradation is unapproached by any other method of graphic expression. The lecture had been preceded by three consecutive expositions on "processes of control," and there is no denying the fact that last week, by comparison, the photographic atmosphere seemed to suddenly clear and become more wholesome. A faithful and well-tried "N. and G." camera had recorded the pictures, Wratten lantern plates translated them, and Mr. Hicks supplied an interesting and breezy narration.

EDINBURGH PHOTOGRAPHIC SOCIETY.—At the monthly meeting, a most interesting paper was read by Mr. Francis Caird Inglis, F.S.A. Scot., on D. O. Hill and his work. The lecture was illustrated by some eighty slides made from original negatives. In addition to these, there were exhibited on the walls about a hundred old calotype prints done by D. O. Hill at the Studio on the Calton Hill, now occupied by Mr. Inglis. Among the portraits shown were Dr. Chalmers; Hugh Miller; Nasmyth, the inventor of the steam hammer; Dr. Knox, the anatomist, who was connected with Burke and Hare; Christopher North; Sir John Gladstone, of Fasque, father of the late W. E. Gladstone; Charles Kirkpatrick Sharpe; George Combe, the phrenologist; the Hon. Stuart Wortley; Lockhart, the biographer of Sir Walter Scott, and several other Edinburgh people of note. A series of most interesting views of Edinburgh about 1844-66, including pictures of the Scott Monument in course of erection, and delightful pictures of buildings now demolished. Mr. Inglis mentioned in the course of his paper that the first calotype taken in Scotland was produced in 1840, and was taken at Rossie Priory, the seat of Lord Kinnaird. The result of the experiment was a blurred and hazy outline of an old lady, who had been kept sitting for twenty minutes in full sunshine. In concluding, the lecturer suggested that a memorial medal be instituted commemorative of one who gave to photography its first artistic impetus in Scotland, this medal to be known as the D. O. Hill Memorial Medal, and to be the blue ribbon of the Edinburgh Photographic Society. The suggestion was unanimously and heartily approved of, and the matter remitted to the Council to form a committee. On the motion of the chairman, Mr. F. J. Duthie, a very hearty vote of thanks was accorded to Mr. Inglis. Messrs. Oliver, McCulloch, Baird, Anderson, and W. D. McKay, R.S.A., were among those who expressed their appreciation, etc.

THE LETO PHOTO MATERIALS CO. (1905). LTD., in consequence of the growth of their business, have removed their London offices and warehouse to larger premises at Roman Wall House, 1, Crutcher Friars, where a large showroom will be fitted up, and specimens of all the well-known "Leto" materials will be exhibited.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The Directors have declared an extra dividend of 5 per cent. upon the Common Stock of the Company, payable June 1, 1909, to Stockholders of record at the close of business on the 18th May.

AFFAIRS OF AN INVENTOR.—In the Chelmsford Bankruptcy Court, held at the Shire Hall last week, Mr. Birt Acres, whose address was given as 47, Cambridge Road, Southend, and formerly of St. Vincent's House, St. Vincent's Road, Westcliff, managing director of a company, appeared for his public examination. In a summary of debtor's statement of affairs, the gross liabilities were set down at £4,544 11s. 7d., of which £3,780 4s. 9d. was expected to rank. The assets were set down as 500 £1 shares in a company, 14 £1 shares in another company, one good book debt £966 4s. 9d., and a surplus from securities in the hands of creditors fully secured (per contra), £2,300; thus showing a considerable estimated surplus.

In reply to the Official Receiver (Mr. C. Mercer), debtor said the petitioning creditor was the Rev. J. K. Wood, Boy's Farm House, East Barnet, and he owed him £118 for money lent in July, 1907, mainly for the purposes of paying the wages of the men of the company and current expenses. He originally commenced business as a manufacturer of celluloid films at Barnet, and his trading returns for the years 1903-4-5-6 were £5,145 5s. 1d., £5,351 15s. 11d., £10,034 10s. 11d., and £11,994 10s. 1d. respectively. He had a cash capital of £100, and two years afterwards removed the business to Nesbit Alley. About 1897 he sold the business to a private company, which was afterwards wound up. Debtor took some machinery as interest in the company, but this was of no value at the present time. He commenced business again at Whetstone, and subsequently obtained land at Wickford on which to erect works that cost £500. In December, 1907, he sold the business with the Wickford premises to a company for £2,540 and £3,496 in shares. He received £2,000 in cash, the remaining £540 being allowed for the purchase of land at Wickford. He received £300 on the turnover in August, 1907, but could not give the date when he received the balance, as his papers connected with the company at Whetstone were annexed. The rates had not been paid and his desk was seized by the bailiff, whom he paid out.

Witness said he received the shares, but Barclay's held 2,000, Stollwerck's 1,000, and the Official Receiver had 500. The works at Wickford and Whetstone were now closed. Mr. McQuitty was practically the company, and he (debtor) was managing director. He did the experimental work of the company at a salary of £600 a year, which was paid up till January 31, 1908. The reason he did not receive the salary after that date was because the funds of the company would not allow of it. He would not accept the statement that he had carried on the Serikon Company without reference to Mr. McQuitty. It was impossible that Mr. McQuitty lost £4,500.

A number of the documents mentioned were perused, and questions asked upon them respecting the formation of companies and the accounts of the company with which Mr. McQuitty was connected. Debtor was ordered to provide a cash account of the £3,950 paid by Mr. McQuitty or the company from August 12, 1907, and the date of the receiving order.—The examination was adjourned.

NEW COMPANIES.

BRYAN AND SPEDDING, LTD.—Capital £500, in £1 shares. Objects: to carry on the business of Chemists, Druggists, Opticians, Dry-cleaning, Photographers, Nature Study Specialists, etc. Private company. Registered Office, 48, Deansgate, Manchester.

TOURIST GUIDE TO THE CONTINENT.—The Great Eastern Railway Company send us a copy of the latest edition of their popular guide book, which, in addition to its usual features, contains particulars of new tours in Holland, Belgium, and North and South Germany, also a chapter on "Tourists' Travel Talk," in English, French, and German. The descriptive account of the places reached by this company's services include such useful items as the time occupied by the journey from one part to another, cost of same, names and charges of chief hotels, etc., and the well printed illustrations and maps add much to the value of the book as a practical guide to the tourist. Copies may be obtained, price 6d., from the Continental Department, Liverpool Street Station, London, E.C., or from the publishers at 30, Fleet Street, E.C., and 12A, Regent Street, W.

News and Notes.

WIMLETON TOWN COUNCIL passed plans on May 5 for the erection of a photographic studio at the rear of 31, St. George's Road, for Mr. P. L. Truckle.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.—The secretary of the architectural section is now Mr. E. N. Pearce, of 35, Lyndhurst Road, Thornton Heath, Surrey.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—An exhibition of Autochromes will be on view at the room of the above society, 9, Eberle Street, Liverpool, from May 15 to 31, between the hours of 10 a.m. and 7 p.m. (Saturdays 10 to 4). Admission will be free.

LILLYWHITE IN NEW ZEALAND.—The Halifax Photographic Co. writes: Will you kindly inform your New Zealand readers that we have now opened a depot at 148, Hereford Street, Christchurch, Canterbury, New Zealand, where a large stock of our material will always be kept? Our agent, Mr. Bennett, will only be too pleased to give all orders sent through him his best and personal attention, and being a well-known photographer we think very much satisfaction will be given. This will be so convenient for our very large circle of New Zealand customers. It is our intention to also open a depot in Australia, and we are at present making arrangements for a depot in South Africa, so that our colonial friends will be well catered for as soon as our arrangements are completed. Until our Australian depot is ready it will be, perhaps, a convenience to our Commonwealth friends to buy from our New Zealand Branch.

CINEMATOGRAPH LEGISLATION.—The Parliamentary Committee of the London County Council reported this week on suggestions submitted to them by the Theatres and Music Halls Committee in connection with the provisions of the Cinematograph Bill, which has been introduced into Parliament in the present Session. The most important recommendation of the Theatres Committee is that the Bill should be extended to include not only cinematograph exhibitions where inflammable films are used, but all exhibitions. They point out that the film is not the only source of danger. There is considerable risk in connection with the arrangements for the illuminant, and the Council when recently revising the cinematograph regulations decided to make no difference as to the restrictions to be imposed where non-inflammable films were used. The Committee also state that if the restrictions were limited only to cases where inflammable films were used it would be more difficult to administer the Act, as in any case where exemption was claimed it would be necessary to test all the different lengths of films to ascertain whether any was inflammable. They also make another point of the suggestion that if non-inflammable films were exempted proprietors of premises where cinematograph displays took place would generally adopt them, and thus would be able to avoid structural alterations, etc., which otherwise could be forced upon them by the licensing authority. These places would also then be exempt from restrictions as regards Sundays, except such as are contained in the Lord's Day Act, and "it is very desirable," says the Theatres Committee, "that all places of public entertainment should be treated in the same way." The Committee's second recommendation is that a penalty should be provided in the Bill for refusing admission to premises where a cinematograph display is carried on, to a constable or officer appointed by the Council. They point out that in the case of unlicensed premises which there was reason to believe were used for cinematograph displays, it would be difficult to prove that they were so used in contravention of the Act if the Council's officers could be refused admission without penalty. The Committee propose that a penalty up to £20 should be imposed under the Bill. Their third and last recommendation is that the aggregate fees for licences paid for any one place in one year should not be limited to £1 as provided in the Bill. They think that each occasional licence will give the Council and their officers considerable trouble, and that a fee of 5s. cannot be considered excessive, whether the licence is for a month or part of a month. The Parliamentary Committee have adopted all these suggestions, and they state that as the scope of the Bill will depend largely upon the regulations made by the Home Secretary, they intend to obtain if

possible, an assurance from him on the matter, so that the Council can consider the regulations before they are finally settled and make representations to Mr. Gladstone thereon if necessary.

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen,—In reply to your correspondent, Mr. C. J. Stokes, in your last issue on the above, I wish to say that my experiments, mentioned in your issue of April 30, were made with a view to test both the exposure and efficiency on rapidly moving objects with $\frac{1}{8}$ in. slit and open aperture $f/4$.

Why I did not mention efficiency in my letter was that I was somewhat in doubt at the time as to whether the efficiency varied or not at the different distances of plate from blind. Since then, however, I have made a long series of tests on rapidly moving objects, and my opinion, expressed in my previous letter, is confirmed as regards exposure, and my conclusion regarding efficiency is that it is slightly less when the plate is furthest away from the shutter, but the difference is so very slight that it can be ignored by the practical worker.

In order to show Mr. Stokes how near alike the results are both in exposure and efficiency, I have posted him two sets of negatives for his inspection, each set marked with a number, and I wish him to point out to your readers which plate in each set has been nearest the slit in the blind.

The negatives are of a man jumping, and were exposed with lens full aperture $f/4$, narrow slit in blind, all other operations being the same throughout, except that one negative in each set was $\frac{1}{8}$ in. from blind and the other $\frac{3}{8}$ in. from same.

I have given the following different exposures on this same subject:—1-300 sec., 1-400, 1-500, and up to 1-1000. I have selected the two sets of negatives which I think are most valuable for the purpose—viz., those receiving 1-500 sec. exposure. These show slight movement of the hands. Below this speed the image is considerably blurred and useless for comparison one with the other, and above this speed are both quite sharp. I may mention that very great care has been exercised in making these experiments, and I have personally seen that lens, shutter, light, plate, object, and developer were all precisely the same in each individual set.

I have instructed Mr. Stokes to forward the negatives on to you with any remarks he wishes to make on same.—The plates marked 1A and 2A have been furthest away from shutter.—Yours faithfully,

T. S. HARGREAVES.

3, King Street, Clitheroe.

[Our correspondent also sends us three prints which, he states, "show the measurement of the actual light rays as they fall on the plate at varying distances from the shutter and were made in the same way as my tests were made with plates, with the exception that the blind of shutter was kept still and the exposure made by uncapping the lens, using bromide paper instead of plates." These prints show the width of the shadow cast by the slit at the two different distances, but we fear the information they give is of no use in estimating either efficiency or duration.—Eds. "B.J."]

To the Editors.

Gentlemen,—Mr. T. S. Hargreaves has kindly sent me four negatives for inspection, these being focal-plane exposures on a young man jumping over a rail. He desires me to express an opinion as to which were exposed nearest the blind, and then send them on to you. This I am doing, together with his letter. I quite frankly admit that the negatives are so much alike that I cannot decide; and as this seems a kind of challenge, I should like to express an opinion, if possible, but it would be a pure guess.

Mr. Hargreaves used a lens working at $f/4.5$ and a slit $\frac{1}{4}$ -inch wide and the positions of the plates were $\frac{1}{8}$ inch and $\frac{3}{8}$ inch from the blind and according to my calculation the efficiency for the two positions would be 90 per cent. and 60 per cent. respectively. The duration of the reciprocal of the efficiency, so the difference in the amount of movement recorded in the negatives should be as 1 to $1\frac{1}{2}$ for 3 points moving with the same angular velocity. Now, how am I to determine two such points in two negatives of a man jumping? His arms and legs are out of the question, their movements being so complex as to defy all mathematical analysis. Quite probably the centre of gravity of a jumper rises and falls with a velocity approximately computable from the known laws of acceleration; it is possibly it would be justifiable to assume that this point of unific acceleration is situated near the bottom button of his waistcoat, but unfortunately the bottom button is covered up by the somewhat indefinite folds of an apron, and this, together with the fact that an athlete has apparently left Mother Earth further behind in one position than in the other, which means that, assuming he left the ground with the same initial velocity each time, the particular point in anatomy under discussion would be travelling at a different rate. Altogether there are so many assumptions to make, and the amount to be measured is so small, that I must refrain from committing myself. An object moving with a uniform velocity across the field of view and with definite lines marked upon it would serve the purpose so much better than a man jumping. I appreciate the trouble Mr. Hargreaves has taken, and his negatives are interesting examples of quick work. I trust he will not think I am trying to unduly force my own opinions, but in a scientific measurement it is necessary to be precise.

CHARLES J. STOKES

52, Winchester Road, Twickenham, S.W., May 10.

[We quite agree with Mr. Stokes that it is impossible to tell anything from these test plates. The object is moving towards the camera, and is at a different distance from it in each case, and the velocity is, of course, a variable quantity. We do not see how an adequate test could possibly be made without proper apparatus designed for the purpose. We have confirmed the calculations of efficiencies and durations given by Mr. Stokes, which are quite correct.—Eds. "B.J."]

AN ELECTRIC DEVICE FOR FIRING A FLASHLIGHT

To the Editors.

Gentlemen.—A correspondent recently inquired what would be a suitable size fuse-wire for the flashlight ignition device described No. 2,554. It depends upon several factors. There is the capacity of the battery, the voltage, the resistance of the circuit, and the quality of the fuse-wire, all having to be taken into consideration. The dry-cells referred to in the article were very small, and the resistance of the whole device was probably fairly high. Under these conditions, an extremely fine fuse-wire would be required. Anyone making the apparatus exactly as detailed would do well to select the finest gauge wire obtainable for the fuse—about No. 30 S.W.G. Any dealer in electrical supplies would have it.

To the present writer it has seemed that the American construction is likely to prove too complicated and troublesome for practical photographers to adopt. Dry cells are short-lived things at best, and soon fail to give a useful current when called upon for continuous work. Then, the fuses are calculated to be costly and anything but simple to make or replace. It would be expensive, too, having to insert a new fuse each time the flashlight was required.

An almost ideal electrically ignited flashlamp would be one in which the current was inexhaustible and the sparking or firing point permanent. Such a lamp is quite practicable. It would consist primarily of a small magneto machine, suitably encased and provided with a hand driving gear. The lamp proper, a small cup of refractory material, would have provision for screwing it a sparking plug as used in motor car engines. A switch and contact for the conveyance of current between the machine and the lamp would then complete the apparatus. Properly constructed, it would be practically everlasting, always ready and effective.

Those who wish to make an igniter of this nature for themselves may dispense with the magneto machine and use an inductor coil and accumulator instead. Let both these be of the auto type, since they are specially designed to give a hot flaming spark.

second-hand, they are to be had very cheaply at any motor auction.

Obtain a piece of slate or a tile and a motor sparking plug. Take two suitable lengths of flexible high-tension cable (i.e., stranded copper wire heavily insulated), connect one to the "B" terminal of the coil and to the top screw of the plug, and the other to the "I" terminal of the coil and to the metal base of the plug. It will be sufficient to bare the wire and wind it around tightly. Take a further couple of lengths of ordinary insulated wire and connect one to the accumulator to the coil—the red or + binding screw of the former and the corresponding + terminal of the latter, and the — of the accumulator to the coil terminal, which may be marked "C," "V," or "E," assuming it to be of French manufacture. Provide a switch in series with one of the last-mentioned wires so that the current may be cut in or out as wanted.

For action, simply lie the plug, with its connected wires, upon the slate or tile. Cover its sparking points with a little heap of talc powder, and it will be ready. On closing the switch, a brilliant spark will pass at the plug and so ignite the magnesium. 17, St. Ann's Road, Harrow. D. W. GAWN, M.I.A.E.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Harvey, Beechville, Wivenhoe, Essex. Photograph of Mr. Jack Humphreys Aeroplane on the River Colne, Essex.
Grewer, 1, Tottenham Street, Great Yarmouth, Norfolk. Photograph of St. Nicholas Parish Church, Great Yarmouth, Struck by Lightning, Showing Public and Arrival of Fire Brigade, April 27, 1909.

DEVELOPMENT.—1. In tank-development will halving the strength of developer and doubling the correct time of development give the same contrast as the full strength developer and normal time? 2. Is there any rule to ascertain the correct time of development from the plate speed? 3. As certain makers give Wynne III. 12 mins. and Wynne 88 12 mins., am I correct in taking these times for any brand of plates with the same speed, and assuming Wynne 45 to require 14 mins.? (Rodinal 1:22, 65 deg.)
-TRICOLOUR.

1. No, it will not. Air dissolved in the water produces irregularities. See the paper by Wratten and Wainwright in the issue of "B.J.," November 15, 1907 ("B.J. Almanac," 1909, p. 579). We believe Messrs. Wratten will send a reprint of this paper on application. 2. No, certainly not. There is no direct relation. 3. Most decidedly not. The times of development for a given degree of contrast vary largely with different plates. Why don't you buy and study the "Watkins Manual" (Watkins Meter Co., Hereford, 1s. 2d.)?

RETOUCHING PENCILS.—I want to know how to tell which retouching pencil to use for thin negatives and dense negatives, as I cannot get it right; the retouching shows more or less. Would be glad to know. Have tried 3, 4, 6 and 3, 4 for thick negatives, and 5, 6 for thin negatives.—E. SMITH.

No. 4 is the usual for thin negatives, and No. 3 when heavier work is required. If for other than portrait negatives, then use Nos. 1, 2, and 3; but the softer the pencil the lighter should be the

touch. The fault probably lies, not with the pencil, but with the medium and the way it is applied—or with the work.

STOPPING OUT SUN.—The studio I am working has a north-west light, and I have great trouble with afternoon sitters through the sun flooding the windows; although I have covered them with tissue I cannot get a brilliant lighting. The only light I can get is a golden twilight, so to speak, which causes very flat results. Can you suggest any coloured paper that would have the effect of white light?—SUNLIGHT.

There is no coloured paper that will give the effect of white light. Possibly the tissue paper you have is not really white. We would suggest that you try stippling the glass over with starch paste, to which a little whiting has been added. It can easily be washed off when the sun ceases to be troublesome.

THE OMNICOLORE PLATE.—Seeing your article on the "Omnicolore" plate in this week's "B.J.," I should be obliged if you would tell me where I can obtain it.—G. H. JACKSON.

From the English agent, Mr. A. E. Dean, 82, Hatton Garden, London, E.C.

POSTCARDS.—When in Scotland last year I took some photographs which I venture to think would sell well as postcards. Can you tell me whether (1) It would pay me better to produce the cards myself if I get any orders on submitting them to the local shopkeepers, and if I do, what is the usual price to ask? (2) Or should I be doing better to try to sell the right to reproduce them to some publisher of pictorial postcards, and if so could you give me the names and addresses of one or two? 3. In either case should I be wise to copyright them?—ENQUIRER.

Your best plan, we should say, would be to arrange for a local sale, that is, if you can find that a demand exists. You could get the cards reproduced in half-tone, collotype, or bromide; but the latter and three-colour cards are the best sellers. Consult our advertisement pages as to firms doing this work. The postcard publishers will not pay more than a guinea a negative for ordinary subjects as a rule. It would certainly be wise to copyright the photographs, as a good deal of copying goes on in this class of trade.

CLIPTO-GRAPH.—If not intruding too much on your valuable time, I take liberty to write you a few following lines which you will take into your kind consideration and it shall be great favour if you will let me know the instructions about it. I beg to state, that by reading the page 296 of the "Graphic" of the 6th March 1909 I have come to know that "clipto-graph" is an Italian invention a thief can not enter the room without disturbing one of the wires, and the machine then turns towards the point where the disturbance arises. Sets fire to a magnesium light, rings an alarm bell and takes a snap-shot of the intruder." I now therefore under instructions request your honour to be good enough to let me know the names and address of such company who may supply me the said machine (camera) complete with magnesium light and I shall feel obliged if you will secure his price-list if possible with full particulars regarding the said machine. Further I beg to state that it shall be great favour if you will kindly let me know the price of the said machine.—MAHAREJI RANCHOHO, Cutch, Bhuj, Bombay, India.

We are sorry we do not know the address of the maker, nor even whether the instrument has yet reached the commercial stage. Many pieces of apparatus of this class never go further than the patent specification of the inventor.

AMIDOL.—I am rather interested in chemistry relating to photography, and would much like to know whether you could inform me as to the composition of amidol. I have never seen its composition mentioned in any chemistry book I have come across.—E. E. WALKER.

Amidol is diamidophenol—C₆H₃ OH NH₂.

COLOURING PRINTS.—1. I have several military photographs (P.O.P.) which I have to colour in oil. I should be much obliged if you will kindly inform me whether the prints have to be prepared in any way before colouring? 2. Also if any preparation for water colouring?—HENRY ASHDOWN.

1. No preparation is required. 2. Again, none is necessary.

POLISHING GLASS.—1. By cleaning the glasses with "Bluebell" metal polish I find I get better gloss and less trouble in stripping post-

cards, etc., from glasses when glazing same. Is there any danger to permanence of P.O.P. prints by doing this? 2. Also please say best medium preparation for unbleached calico to be painted with flatted oil?—RISH.

1. We do not know the composition of the polish named. But we should think it would not have any injurious effect, unless it should contain a preparation of mercury. 2. After the fabric is strained on the frame, give it a coating of common size as sold at the oilshops. That is the only preparation that is required. The size must be melted and applied warm.

LENSES FOR COLOUR CAMERA.—Please advise me in your correspondence column where I can procure three lenses mounted for three-colour work as described in last "Colour Supplement" of the "B.J." as used by Andre Cheron and Sydney Young?—H. E. BLACKBURN.

Any optician would supply lenses in specially thin mounts for this purpose. We know of none on the market. We advise you to address a leading optical firm in your country.

AUTOCHROME AND APERTURE.—(1) I am working the Autochrome process with success by Watkins' method, exposing by meter and developing by his time developer. When the method was simplified and a new developer put on the market (Quinomet) a few weeks ago I tried it, but every time I tried a plate a patch of what to me appeared fog appeared in the middle of the plate. On reading this week's "B. J." (May 7), "Colour Supplement," page 40, in article on redevelopment of Autochromes, 13th line from top, solarisation is mentioned. Is that the fault of the enclosed plate? How is it caused, and what is the remedy? I may state that immediately following exposures giving that defect and developed by Quinomet, I give exposures similar in every way, but develop with Watkins' time developer and have never once got that result. It does not matter if it is under- or over-exposed, it comes just the same. The example I enclose is developed for $3\frac{1}{2}$ mins. at 65 degs., reversed and re-developed, not intensified. I have outlined the faulty spot with ink; it should contain brilliant roses at that particular spot. (2) Having bought a portrait lens, also a 12in. R.R. without any stops, I am going to make them myself out of sheet brass. It is for use in Autochrome work, and I must have stop apertures correct enough to work with the Watkins meter. I am not clever enough to work it out in a proper way, so would it be near enough if I focussed for infinity, which I find is exactly 7in. for the portrait lens from the slot in tube to the focussing screen? Should I divide this into 8, 7, 6, and 4 parts and make the aperture of stops to above for F8, F7, F6, F4, or should I measure from the back glass to the screen? Kindly let me know how I should proceed.—THISTLE.

(1) We do not see how the change of developer can account for the appearance. Are you sure that the effect is not due to a reflection of some foreground object in the front of the vase? With regard to solarisation, the abstract referred is not quite clear. The phenomenon might occur owing to bad over-exposure in the first instance, but our experience of it is confined to the effect produced by over-exposure prior to second development. The effect on your plate is not unlike that produced in this way. We are sorry we cannot give a more definite explanation of the trouble, but we can only suggest that it is far more likely to be due to some fault in manipulation than to the use of any particular developer. (2) Your method will give only approximately correct stops. They will all be a little too large. The measurement must, of course, be taken from slot, not from back lens, but the slot measurement is not necessarily correct. We should advise you to get a dealer to supply the stops. They will not cost much, probably less than the value of the time you will spend in making them, and they will be more accurate than your home-made ones are likely to be.

ARTIFICIAL LIGHT.—We are thinking of opening a branch studio, but find the place is so situated that it is impossible to obtain a good light. Would you be kind enough to give us the information we require, viz., what is the most useful electric light on the market for taking portraits from C. de V. to 12 x 10?—McNAMARA AND SON.

If the portraits are head and shoulders, or, say, three-quarter length, only one arc lamp of the enclosed pattern will be sufficient

with a reflector, or two arcs for groups. See our advertisement pages for announcements as to the Westminster, Jandus, and other arcs.

MINIATURE PAINTER.—(1) D. Brucciani and Co., Ltd., 254-258, Goswell Road, London, E.C. (2) Try Mrs. C. H. Dighton, 11, Bessborough Street, Westminster, or Miss Ramsay, Stoke Villa, Private Road, Honor Oak, S.E.

"BUSINESS."—Some makers, both of plates and papers and of apparatus, will not supply you if you sell below the standard price. That is the only restriction.

ARTIST.—The affairs seem to be somewhat complicated, and we should hardly like to express a very definite opinion. We should say, however, that you are entitled to full wages, not exceeding two months, prior to the bankruptcy. If more than that is owing, you will stand in for that with the other creditors, and will be paid by "C." If "C." or the purchaser of the business, agreed to continue you as their employee, you must look to them for your wages.

DAMAGED LENS.—I have a portrait lens by — offered to me very cheap. It is about $3\frac{1}{2}$ in. in diameter and 12in. focus. There are two chips in the back lens, one of which is about $\frac{1}{4}$ in. and the other not quite so large. Will you please tell me if these damages will prevent good picture being taken with the lens if it is well stopped down?—G. DOWNES.

The chips will make no practical difference in the performance of the instrument. The places should be covered with black varnish to avoid reflection. The only effect of the slight injury will be an almost imperceptible loss of light, nothing more.

COST OF STUDIO.—I propose erecting a studio for professional work on the top of the house. A small portion of the present roof will have to be removed and a staircase made to it. Will you please tell me the probable cost if the studio is made 25ft. long and 12ft. wide?—T. WARDELL.

We cannot. Sometimes the alterations, staircase, etc., come to more than the studio itself. Your best way will be to get out the plans of what is required, and then obtain an estimate from a local builder.

LANTERN SLIDES.—I want to make a few lantern slides from half-plate negatives, and I find that my camera is not long enough to permit the lens they were taken with being used. The only other lens I have is a quarter-plate R.R., $5\frac{1}{2}$ in. focus. Could that be used? I ask the question because I have heard that the same lens as the one used in taking the negative is the best for reproducing it.—AMATEUR.

The quarter-plate will answer the purpose quite as well as the half-plate one, and with it your camera will probably be of sufficient length.

O. P. Q.—We are sorry to tell you that you have no remedy, notwithstanding that you bought the business and all the copyright negatives. From what you say, we assume that the copyright in them was not legally assigned to you by your predecessor. That should have been done. As it is, although the negatives are your property, you possess no copyright in them. It would be useless to waste money by taking action.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

A preliminary first report on the Dresden Exhibition gives a description of the fine accommodation provided and of the general character of the exhibition. (P. 396.)

The R.P.S. makes an announcement with regard to a change of premises (p. 399). We comment on the importance of this step on page 393.

We reprint a paper by Paul Thieme, describing a form of apparatus for measuring shutter speeds. (P. 397.)

The first portion of a valuable paper on “Absorption Spectra,” by S. H. Wratten and C. E. Kenneth Mees, is reprinted on page 399.

The report of the National Photographic Record Association and an account of the annual general meeting appears on page 402.

An exhibition of child pictures has been opened at the galleries of Speight, Ltd., New Bond Street. A review appears on page 403.

“The Optician” utters a warning with regard to the injurious effects of strong light on the eyes. (Pp. 394 and 402.)

The Summer Exhibition of the Royal Society of Painters in Water-Colours is reviewed on page 394.

Our Patents Column includes one by Carl Zeiss, covering a new and important method of producing lenses with non-spherical surfaces. (P. 404.)

The programme of the Photographic Convention is given on page 401.

Our Correspondence Columns include letters upon Photographers’ Assistants, Focal Plane Shutters, Flashlight, and other interesting topics. (P. 410.)

The important question of “sale rights” is dealt with in “Answers to Correspondents” and in an “Ex Cathedra” note. (Pp. 394 and 412.)

EX CATHEDRA.

The R.P.S. Change of House.

The announcement made in the “Photographic Journal” of the early migration of the R.P.S. from 66, Russell Square, to No. 35 on the opposite side, marks an important stage in the history of the Society. It is no easy matter to find premises of a kind suited to the purposes of such a Society. Moreover, the end of a lease means dilapidations, therefore the members of the R.P.S. are very much to be congratulated upon the providential circumstances that have given them all the accommodation they can require with no increase of rent, and with a very material prolongation of lease from eleven to thirty years. These advantages have been acquired in consideration for surrendering the lease of No. 66, which house is required for other purposes, and the fact that it should have been so required at the present time almost looks like an intervention of Providence. Regrets will no doubt be felt at leaving the old house, with its historical memories and pseudo-historical associations with the Sedley family, and the ever memorable Becky Sharp; but in truth, in spite of its statuary, painted ceiling and palatial style, the old house has disadvantages. It is rambling and inconvenient in many respects, and the new one is planned in a more accommodating fashion. The dark-rooms will be reached by one staircase going down instead of three going up to the roof. The meeting-room will no longer be L-shaped, and worrying to speakers who never know which corner to speak into. Several extra rooms will be available if required. A studio will be provided, while last, but by no means least, the new house is on the quiet side of the square where motor-buses are not a perpetual nuisance. Possibly the announcement of the move will come as a surprise to some members who may have forgotten the preliminary notice given at the Annual General Meeting, but those acquainted with such delicate proceedings as the negotiation of leases will know that they cannot be conducted in public. Those who have brought the negotiations to such a successful and advantageous issue deserve the hearty thanks of the members generally for obviating what might have been a very disastrous state of things a few years hence. The odds against such an opportunity occurring again would have been immense, and the chances are that the compulsory move and incidental expenses—which would have been very large—would have seriously crippled the Society.

* * *

A “Rogues’ Gallery.”

Captain Cuppers, of the “Kaiser Wilhelm II.,” and the officers of the North German Lloyd, confided to a Plymouth correspondent a new method which they state they have adopted to warn passengers against ocean gamblers. It is the posting of

photographs in the first-class smoking-room. As warnings printed in various languages in big black type seem to be of no avail, the system of framed photographs of men whose methods are so well known that there can be no mistake will be installed. The photographs of the gamblers with their various aliases attached will be framed, and it is believed that no gambler whose face is pictured will dare to set his foot on the steamship that is so decorated. As the project was suggested only last week before the "Kaiser Wilhelm II." sailed for Plymouth, there was no time to introduce it on that voyage, but next trip passengers will probably be able to amuse themselves inspecting the "Rogues' Gallery." The express ships of the line will be first equipped, and if this proves a success all others will have the interesting bureaux of faces for travellers to scan.

* * *

Royal Society of Painters in Water-Colours.

The Summer Exhibition of this society is now open, and is worthy of the reputation of its forerunners. Picture-lovers turn always to the shows of this society in the sure and certain hope of seeing

the finest examples of water-colour pictures that this country produces. It stands head and shoulders above all other exhibition societies, and affords a finer show than the single room devoted to water-colour at the Royal Academy. The work of W. Eyre Walker is in itself a liberal education, for he gives us not only fine and noble subjects in landscape, with charming colour and pictorial qualities, but nature pure and unalloyed by convention also. The President, Sir A. Waterlow, is also a worker who never disappoints. His "River Path" (63) is particularly fine. The delicacy and masculinity of Robert W. Allen; the romantic dreams of Albert Goodwin; the richness and expansiveness of H. Hughes-Stanton; the popular charm of R. Thorne-Waite, all are here as usual. Only in a few cases must one regret the presence of works where the artist's motive and point of view seem to be at fault. Mr. J. Walter West is growing niggley and losing strength of design; Mr. Walter Crane begins to be downright amateurish, while Mr. Walter Bayes gains nothing by his aggressive pen outline. But there is no need to complain of such trifles where we have the set-off of such masterly work as Geo. Clausen's "Mill at Dusk" (261)—a monumental achievement—and such promise as Mrs. Laura Knight's "In the Orchard" (163), to say nothing of beautiful things by H. Clarence Whaite, David Murray, Robert Little, Rose Barton, E. J. Sullivan, Alfred Parsons, and others.

* * *

Sole Right to Photograph.

Pageants seem to be the order of the day just now, and it is very general for the committees that get them up to advertise for tenders for the sole right of photographing them, and in this way the profits of the show are somewhat increased. In some instances, the photographer who gets the concession makes a fair profit by it, and at the same time gets a good business advertisement if he is a local man—that is, if his pictures are good. Sometimes, however, he loses by the transaction, or, at least, to some extent, by his work being forestalled by enterprising outsiders who have got their pictures on the market before he has issued what he may have taken. Some who tender for these so-called "sole rights" seem to be under a misconception as to what they consist in, as evidenced by a correspondent we reply to this week in the "Answers" column. It must not be imagined that he who pays for the sole right can prevent other photographers photographing the scenes if they get the opportunity, and using their pictures for any purpose they may like. All he gets for his money is spe-

cial facilities and privileges in doing his work within the enclosed area, but they do not extend beyond that. Anyone can photograph the spectacle outside without hindrance, or even inside if it can be done surreptitiously. In most of these pageants the ubiquitous Press photographer is present with his hand camera, and if he manages to get within the enclosure it does not take him long to obtain what he wants, provided he is not observed. When he has secured his negatives the pictures appear in the papers next day, and the concessionaire can get no redress either from the snapshotter or the paper for which he works. As there is no copyright in the scenes themselves, the Copyright Act does not apply in any way whatever. What the one who buys the sole right should do is to see that a camera is not used in the grounds, and in this the committee should assist him. One sometimes hears that the sole right to photograph churches, ruins, and the like has been accorded to a certain local photographer, and no others are allowed to take pictures of them. In the case of interiors and enclosed grounds the owners can, of course, prevent cameras being used, if they are seen, by treating the parties as trespassers, and ejecting them by force, if necessary. But if they have already secured their negatives there is no law that will prevent the pictures from being published, even if they were obtained surreptitiously from private grounds. This is also the case with, say, the interiors of churches. If a person unobserved has obtained a photograph there is nothing to prevent him publishing it or making any other use he likes of it.

* * *

Photograph of a Ghost.

In the far West of England superstition still prevails to a great extent amongst a certain portion of the population. We read in the "Standard" of Saturday last that great excitement has been occasioned at Barnstaple by the appearance (alleged) of a ghost in an old disused burial-ground, and that large numbers of people have visited the place in the hope of catching a glimpse of the mysterious apparition. An enterprising photographer in the locality, according to the report, has turned the thing to a profitable account by photographing the ghost—"though nobody knows how or when"—and publishing picture postcards of it, which are said to be having an abnormal sale. The picture is thus described: "By the side of one of the tombs, as if rising from it, is a white apparition, but no form can be seen, whether man or woman." This photograph will no doubt be looked upon by many credulous people as a confirmation that the ghost actually exists in the same way as spiritualists look upon so-called "spirit photographs" as confirming spiritualism. It just occurs to us that it is quite an easy matter for a photographer in a district where superstitions prevail to make a little profit, and at the same time have a little fun to himself. All he has to do is to, say, photograph an old ruin or a churchyard under a dismal aspect and introduce a ghost or spirit by any of the well-known dodges. If the picture is given a night effect so much the better. Having secured his negative, all he has to do is to circulate a rumour that a ghost has been seen hovering about the place at night—such rumours quickly spread in places where credulity reigns. Considerable excitement is soon created, and then is the time for him to publish his postcards.

Effect of Light on the Eyes.

An article which we reprint from "The Optician" draws attention to the damage the eyes are likely to sustain by allowing strong light to fall directly upon them. The warning is a very necessary one to many who work with arc and other powerful lamps, for familiarity breeds care-

lessness, and the danger is often not realised until the damage is effected. Even the light of burning magnesium is capable of working mischief, and though the effects produced by a short exposure to it may soon wear off, yet it is not safe to submit the eyes to the strain repeatedly. By practice one can become accustomed to gaze at a powerful artificial light, and this is just where the danger comes in. We have known cases where the incandescent gas-light worked havoc owing to the direct observation of the naked mantle, and we have also known a lantern operator to be incapacitated for some weeks owing to giving too much close attention to an unsteady arc lamp in the course of an evening's exhibition.

SUN TROUBLES IN THE STUDIO.

As is not unusual at this time of the year, we have received several letters from correspondents asking the best way of stopping out the direct rays of the sun from the studio. There are few studios upon the roofs of which the sun does not shine for some portion of the day at some seasons of the year, and as it approaches its zenith it is a little more troublesome to deal with than when it is lower, unless one has a very perfect arrangement of blinds and screens. To meet the trouble now under notice, some have outside arrangements in the form of a large screen of sail-cloth that can be hauled up when the sun is giving trouble and let down when not required. Others have a permanent wooden hoarding, which slopes over the top of the studio and does not interfere with the proper lighting of the inside of the building, while it shuts off the direct rays of the sun from the highest portion of the roof. Although these appliances meet the trouble to a very great extent, there are times—when the sun is at its highest altitude—when they do not achieve all that could be desired. They are, too, often costly to erect, by no means sightly when seen from the outside, and are sometimes really dangerous during exceptionally high winds, unless they are very substantially fixed in the first instance.

We may now consider some of the methods of dealing with the direct rays of the sun from the inside of the building. One well-known way is by stippling the glass, on the under side, with white paint. This is very effective, but it is attended with some disadvantages. On long exposure to light, the paint is likely to become discoloured and acquire a dirty yellow tint, which, of course, very materially impairs the actinic quality of the light that passes through it. As the sun is usually a source of inconvenience only during a few months in the year, the obscuration is needed only for that period; at other times it is not only not wanted at all, but is really injurious by stopping out light that may be useful. Furthermore, it is a troublesome and messy work to clean paint off at the end of the summer season, or whenever it is no longer required.

A plan which is equally efficacious is to stipple the glass over with starch paste, mixed with a little common whiting. A bowl of starch paste, somewhat thinner than is generally used for mounting prints, is prepared, some whiting added and thoroughly incorporated with it. This mixture is applied to the glass, which should be previously cleaned, by dabbing it on with a fair-sized piece of sponge. Instead of starch, flour paste may be used: one is just as good as the other. A little Prussian blue, ground in water, as sold at the oil shops, may be added to tone down the glare of the white, though it serves no other purpose. As just said, this is equally as good as paint, while it has the advantage that it can be easily washed off if it becomes dirty, or at the end of the sunny season. It may happen, with some studios, that it is only about midsummer that the sun reaches the glass, and then only on a few panes at the ridges. In this case these few panes may have brown paper pasted over them or stuck

on the sash bars, or temporarily attached to them by drawing pins. Tissue paper pasted on the glass answers well, as also if merely attached to the sash bars with paste. The disadvantage of the latter method is that the paper, being thin and only attached by its edges, is liable to get accidentally torn, when it becomes very unsightly.

Another way of subduing direct sunlight is to have two or more light wooden frames (covered with tissue paper) at hand for use when the sun is causing inconvenience. If these are provided with a couple of screw eyes on either side, and the latter threaded on wires, strained tight along the roof of the studio, they can be pushed backward or forward by a long rod as occasion may require, or they may, if more convenient, be hinged to the ridge of the studio and pulled up by cords close to the sash bars when required, or left to hang down when not in use. These frames need be but temporarily fixed; they can be then readily removed.

Although tissue paper answers the above purposes very well, tracing papers or tracing cloths answer better. They are not so easily torn, do not hold dust and dirt as does the tissue paper, and when they get dusty the dust can be lightly brushed off without causing discoloration. Another advantage of tracing linen is that it can, if desired, be attached to rollers and used as ordinary blinds. Thin muslin, white or light blue, may be used instead of either of the above materials, and can, when no longer required, be washed and put away for another season. When this material is chosen the wooden frames may sometimes be dispensed with, rings being merely stitched along the long edges of the fabric, and these threaded on wires strained horizontally along the roof. Such curtains can simply be pushed forward or backward by means of a light rod.

In the foregoing we have been more particularly dealing with the sun on the roof of the studio at this season of the year. It may happen, however, that although it may not reach the sitter or the camera, it may cause trouble in other directions; for instance, when it shines on the sides of the studio or on the lower portions of the roof glass. The effect then is often that there is an apparent haze between the camera and the sitter. When this is the case it is impossible to obtain a brilliant image on the focussing screen, and, as a consequence, all negatives taken under these conditions will be poor and flat, and lacking in the usual brilliancy. This apparent haze is caused by dirt on the glass, and it is curious that that which is on the outside seems to have a greater effect than that which may be on the inside, but the two together, of course, increase the haziness. In these conditions, if the glass, outside and in, be cleaned, the haze will be got rid of, or at least be reduced to a very great extent; a thin muslin curtain, or better still, a good size screen, covered with muslin, that may be moved about as required, will do the rest. In an ordinary way, dirty glass causes no inconvenience beyond stopping out a certain amount of light; but when the sun is shining direct upon it, as we have just shown, trouble may arise in other ways. It is impossible in one article to give such directions as will meet all cases, because the aspects of studios, their forms, and their surroundings differ greatly, but sufficient has been indicated to enable anyone with ordinary intelligence to apply what has been said so as to meet all trouble arising from the sun at its present high altitude.

PIPE DREAM PHOTOGRAPHS.—We hear from the Tress Company, 4, Rathbone Place, London, W., that they are now prepared to supply a film negative to enable the photographer to print the "Pipe Dream" design and use any of his own negatives. They send two specimens, which are in every way similar to the design devised by Mr. Barefoot, and reproduced in our last issue. The price of the negatives is 2s. 6d. each.

THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT DRESDEN.

A FIRST IMPRESSION.

THE 300-page catalogue of the Dresden Exhibition, to which reference was made under "Ex Cathedra" last week, showed that the organisers in Germany and their commissioners in other countries had brought together a very large collection of exhibits. It was possible from the catalogue alone to form a fairly accurate judgment of the extent to which the Exhibition can claim to be representative of the present position of photography, or rather, of its many branches, as well as to allocate the share taken by the various contributing countries. International the Exhibition certainly is; representative, too, of the modern developments of photography, of the photographic industry, and of the many applications of photography in science and education. As was inevitable, Germany is the largest and most important contributor in nearly every section, and the Exhibition affords a demonstration of her activity in the manufacture of photographic apparatus and materials, and of her patience in the scientific uses of the camera, but most of all of her powers of organising and arranging such a vast collection as this. Before saying a word as to one section of the Exhibition, it is necessary to digress for a moment and explain the conditions under which the Exhibition is held.

The park wherein stand the buildings of the Exhibition lies scarcely a mile from the centre of Dresden. Exhibition or no exhibition, it is a place of popular resort, a lung of the city, where of an afternoon or evening one may listen to good music, drink good Saxon beer, and sit with one's friends in an outdoor restaurant about the size of Trafalgar Square. The chief building is a stone palace beside which our own National Gallery would look small. Exhibitions have been held there before, and will again; and thus the interior, though greatly altered for the photographers, is specially suitable for the effective display of pictures and other objects. Apart from Dresden being the seat of the photographic industry—four of the largest houses in the trade are there—the organisers of the Exhibition have thus the enormous advantages, first, of a *locale* whither the 500,000 people of Dresden are accustomed to wend their way, and, secondly, of a building lending itself in every respect to the purposes of artistic display. Great were the opportunities, but greater still is the superb way in which every detail of the organisation has been carried out.

Imagine a building with a frontage as long as that of the Law Courts in the Strand. The central main entrance admits first to a circular vestibule, straight through which we come into the main hall, round which a broad decorative gallery has been built for the present year. Right and left of this hall stand two quadrangular series of halls, the full height of which in most cases has been reduced to about 15 ft. by a velarium, which also gives the most perfect lighting on the walls. In order to give an idea of the area thus afforded, it may be said that this series of velarium-lit rooms would, at a moderate estimate, amount to fifty such galleries as that in which the Royal Photographic Society hangs its pictorial section each year at the New Gallery. Here lay the opportunity of the organisers to achieve the direst failure or to give a demonstration of consummate skill in the furnishing and hanging of picture galleries. We think any visitor will concede that they have afforded the latter; and, without intending a back-handed compliment, we would say that the manner of the Exhibition takes equal rank with the matter. To explain this it is necessary to particularise.

Each room or salon of the great series we have described has been specially provided with both floor and wall coverings, both

of which in each case are chosen with regard to (1) the pictures to be hung on the walls, (2) to each other, and (3) to the coverings used in adjoining rooms. These plans were carried out under the direction of artists, to whom and to the craftsmen in carpeting or wall-decoration profuse acknowledgment is made in the catalogue. In most rooms the pictures are arranged in panels or are placed not more than two deep. In either case it is usual to run a deep plain frieze round the room, and to break up the area of the walls with pilasters. All this has been done with a most wonderful regard for colour harmonies; less frequently for colour contrasts. We learnt, however, in reference to this latter principle of decoration, that it was thought advisable in furnishing so many rooms, the contents of which were, in the main, similar in kind, to employ quite distinct schemes of colour for adjoining rooms, in order to avoid or disperse a feeling of monotony on the part of the visitor. Thus, where a colour scheme of light grey for the walls, buff for the pilasters, and dark grey for the floor will be found in one room, the next will perhaps have a floor covering of warm ochre, and the walls of a further room will be covered in bluish-green. The fabrics used throughout for the floor are of similar kind—a hard, coarse cloth, which allows of the most comfortable walking, and relieves the visitor of much of the fatigue accompanying the spending of a day in picture galleries.

The weather being cool at the time of this first visit, the unwarmed galleries were a trifle chilly; in the height of summer they will probably be pleasantly cool. When we have added that no single salon is without some article of furniture, such as a settee, a cabinet, or one or two chairs of nice design, perhaps a pot of flowers or a wreath of evergreens, we have perhaps said enough for the present as to the æsthetic mounting of the Exhibition and may proceed to give a brief impression of the collections which have been brought together.

The first two things that impress themselves on the visitor who makes a preliminary tour of the whole Exhibition—this will take an hour, even if one does not halt at all—is, first, the large representation of the German photographic trade. A large "Industrie Halle" accommodates the many firms who are thus bringing their manufactures before the public in ways of which we shall speak later. It would seem that not a single German house of any standing is absent, and many have gone to great expense in fitting up very elaborate installations, exhibitions, or bureaux. The second salient feature is the comprehensiveness of the sections devoted to the scientific applications of photography, in particular to photogrammetry, criminology, and medicine. Perhaps the next most prominent feature to the eyes of an English visitor is the size and number of the sections devoted to topography. The scenes and customs of their own and other lands evidently have an importance in the German mind which, if it exists in our own, does not find expression in our photographic exhibitions. Frankly, the exhibits in many cases are "just photographs," and often of not a very high order of merit; but they have a great interest for the public, are regarded as of educational value, and in some instances, notably that of Austria, do possess really great pictorial merit. Sir Benjamin Stone's photographs are the only ones in this section relating to England.

Of amateur and professional photography there is a great deal. Perhaps one sees so much of the former here that the many salons of it at Dresden do not impress us as they will the Germans. A small number of American, English, French, and

Austrian workers appear as the "Internationale Vereinigung der Kunstphotographen," in comparison with which sonorous title of a body specially called into existence for this occasion the name "amateur photography" of the other sections sounds poor indeed. The exhibits in both sections cannot be considered in the short space of this first impression. Of professional photography the Americans make a great show, though they have crowded their walls unnecessarily. The section in its own building devoted to photo-mechanical work is also most

representative, both of Germany and Austria, and evidently displays the most modern achievements of the reproductive crafts.

This brief first impression must suffice for our readers until in the immediately forthcoming issues the collections can be adequately reviewed.

English exhibitors will probably be glad to hear that sixty attendants keep watch upon the exhibits. This is exclusive of the 180 trade stalls, which have their own attendants.

ON THE MEASUREMENT OF THE SPEEDS OF INSTANTANEOUS SHUTTERS.

(A paper in "Photographische Mitteilungen.")

I.

THE object of the present communication is firstly the description of a method devised by the author for the measurement of the times of exposure given by instantaneous shutters, and secondly the comparison of this method with others usually adopted. The first experiments were made by means of an intermittent source of light obtained by the rotation of an ordinary ventilator in front of a Nernst lamp, the source of light being photographed through the ventilator by means of a moving camera. There is thus obtained on the negative a series of points from the number of which the time of exposure is calculated. For exposures as short as 1-1,000 of a second, namely, those given by the focal-plane shutter, the ventilating fan was not found to serve; it was necessary to replace it by a screen provided with a series of slits giving about 3,000 light-impressions per second. Under these conditions the movement of the camera and the release of the shutter at the right moment gave great difficulties. These have been overcome by rotating the plate in a stationary camera at the same moment as releasing the shutter. The author preferred this method to that just mentioned, for the reason that there was thus obtained in a very simple way an intermittent point impression of light in each instance lasting for the same time. A screen was divided into equal sectors, a slit of wedge shape made in each sector, and each slit given a slight radial shift. There thus results a screen of the form shown in Fig. 1. If this screen is placed in front

together in the slit as many points of light as there are slits in the screen. Obviously, it is only necessary to photograph the slit *b* in the ordinary way with the fixed camera in order to obtain from the number of points of light a measure of the time of exposure.

This is the principle of the method of measuring, and it only remains now to describe the most advisable arrangement of apparatus and its degree of accuracy. It is well to use a screen with 60 slits. When this is the case the time which one slit requires to come in front of the stationary slit is expressed by the following simple equation:—

$$\text{Duration of one point of light in seconds} = \frac{1}{\text{No. of rotations of screen per minute.}}$$

$$\text{or } t = \frac{1}{N}$$

For driving the screen an electro-motor is best, as it is easy to get it to run up to 3,000 revolutions per minute, the screen being attached direct to the shaft of the motor. The motor should not be smaller than 1-10th horse-power, and, preferably, should work with direct current for the sake of constancy of speed. A resistance is attached to the motor, allowing of the number of revolutions being adjusted to as low as 200 per minute. For ascertaining the speed of the motor there can be used either one of the ordinary revolution counters or a so-called tachometer, which is coupled to the shaft of the motor, and indicates directly on a scale the number of revolutions per minute. The Frahm's speed indicator, depending on a resonance method, is also very suitable. Direct indicating apparatus is preferable, for the reason that small motors may have their number of revolutions reduced by the ordinary counter, though probably only to some few per cents.

The illumination of the fixed slit must be both uniform and bright. The most simple arrangement is to direct the apparatus to a window so that the bright sky can be photographed through the slit. If an artificial source of light is to be used, the best for the purpose is an incandescent gas burner, placed close behind the rotating screen, or a condenser fitted with a Nernst or arc lamp, as for ordinary projection. A ground glass screen is placed on the side towards the rotating screen. The operator must remember that he cannot very well have too strong a light, since, at the highest speed of the motor, its action lasts for only 1-3,000th of a second. This is so short a time that the most sensitive plates and warmed developer are necessary to secure satisfactory density.

Figs. 3 and 4 show a convenient arrangement of the plate apparatus. Fig. 5 is a diagram of the resistance. A is the

Fig. 1.

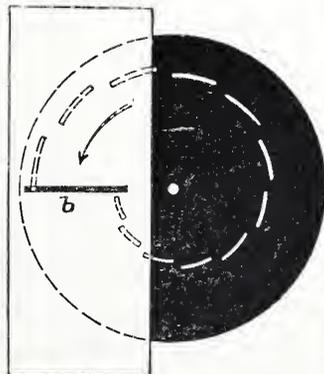

Fig. 2.

of a fixed stop provided with a slit *b* in the direction of a radius of the screen (see Fig. 2), and the screen then slowly rotated in the direction of the arrow, there appears in the slit a point of light moving from left to right, the eye being directed through the stop and screen towards a bright background. The point of light seems to make its appearance to the left, and to disappear to the right. On quickly rotating the screen there are seen to-

“anker,” F the field of the motor, W the resistance, S the fuses, D switch, K terminals.

In using the apparatus a rough idea is first obtained of the times of exposure to be measured. Assuming that a focal-plane shutter is being examined, this will be from 1-5th to 1-1,000th of a second. The greatest speed of the motor, working at 3,000 revolutions per minute, will thus indicate for each point of light 1-3,000th of a second. The greatest number of light-points which can be formed is 60, corresponding to the 60 slits in the rotating screen. If the screen be given a second revolution, this series of points appears a second time, but is not visible on the plate, as one series covers the other. An exposure which shows all 60 points is therefore not practicable; the highest number that can be obtained is 59—that is to say, with the speed of revolutions of 3,000 per minute one can measure exposures as long as 59-3,000ths of a second. For longer exposures the slower speed of 200 revolutions per minute is employed, and times down to 59-200ths of a second thus measured. Supposing that for the sake of accuracy the smallest number of points of light to be obtained is 10, then with 200 revolutions per minute, we can measure 10-200 = 1-20th of a second. Between 200 and 3,000 revolutions the motor can be worked also at 1,000 revolutions per minute, equivalent to recording exposures as long as 59-1,000ths and up to 10-1,000ths = 1-100th of a second. The whole range of the shutter is thus covered.

As to the accuracy of measurements there are two values to be determined from which the time of exposure is calculated, (1)

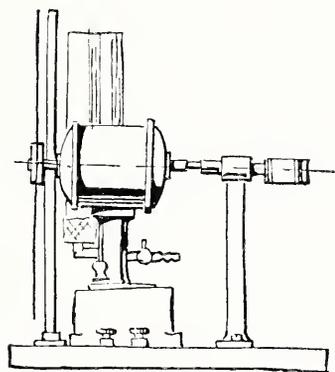

Fig. 3.

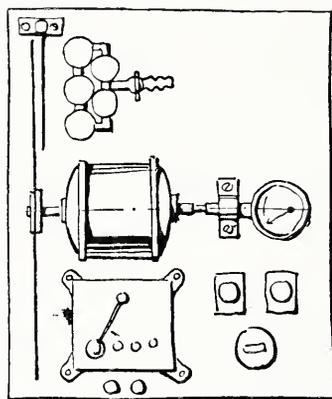

Fig. 4.

the speed of the motor, and (2) the number of points resulting on exposure. The number of revolutions per minute of the motor can be recorded with such accuracy that failures on this score are excluded. The light-points on the plate are further quite accurately counted, but it is necessary to discover to what degree these points of light accurately represent the time of exposure.

In the formula already given, $t = \frac{1}{N}$, it is assumed that a slit of the rotating screen illuminates the radial fixed slit during 1-60th of a revolution. This, however, is not absolutely the case, since the rotating slits, in order not to deprive the screen of its solidity, must be made shorter—in fact, by one-quarter of their ideal length—so that each slit corresponds with only 3-240ths of a revolution of the screen, whilst 1-240th remains for the interspace between two slits. If we now assume that an exposure has given two points of light, and notice from Fig. 6 the path which the rotating screen must at least have followed, it is at once seen that in any case the distance A must be reckoned as more than 1-240th of a revolution: we may assume at least 3-240ths. The path b may also be put down at 9-240ths, as also in this case only two points appear on the plate. It is, however, a special case in which b would so come that only two points appear. On making one or two further exposures with the same speed of shutter there would very probably be three points. If this is the case, the path has certainly become

greater than 7-240th of a revolution—that is to say, the action has taken place through the full length of slit No. 2, but only through one-third of their respective lengths in the case of slits Nos. 1 and 3. This will be shown in the exposure by the fact that the middle point will be of strong density, whilst those on the two sides are weak only. From the two values 9-240ths and 7-240ths the mean 8-240ths is 12½ per cent. in error, and therefore not sufficiently accurate. By choosing the conditions so as to obtain 5 and 6 points there is obtained a maximum of 21-240ths and a minimum of 19-240ths—that is to say, a mean of 20-240ths corresponding to an error only of 5 per cent.—quite accurate enough for the purpose. If 10 points be taken as the minimum number, and the control test is found to give 9, the mean of the two observations gives 36-240ths of a revolution, and a maximum error of only 2½ per cent. Tabulating these three results we get—

Points.	Revolution, mean.	Error, per cent.
2 and 3	8-240ths	12½
5 and 6	20-240ths	5
9 and 10	36-240ths	2½

It will thus be seen that the lowest number of points obtained on several controlled tests gives without further calculation the number of 60ths of a revolution which the screen has made during the exposure. Calling this lowest number of points z,

the time of exposure in seconds is $t = \frac{z}{N}$

For the shortest time of exposure of 1-1,000th of a second which

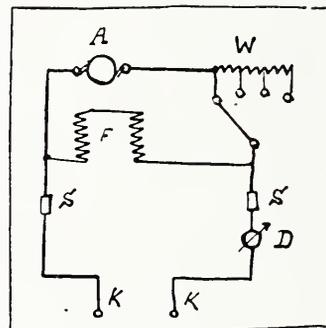

Fig. 5.

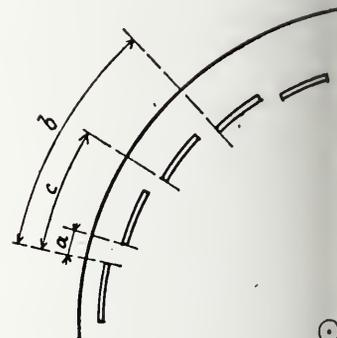

Fig. 6.

we have to measure 3 and 4 points would result according to this formula. That is to say, we can measure these shortest times with a degree of accuracy of 10 per cent., quite sufficient for practical purposes. If the speed of the motor was raised to 4,000 revolutions per minute, the accuracy would be within 6 per cent. Actually, it is not, however, necessary to measure the time of exposure of 1-1,000 directly, as will be seen from the following

These times of exposure correspond with a width of slit of 2 to 3 mm. If this width is doubled the time of exposure will be doubled, for even with those shutters in which the alteration of the width of slit involves a simultaneous alteration of the tension of the spring, there is in the case of the very small widths of slit such slight change in the tension that there is an exact proportion between the width of slit and the time of exposure. If we therefore make measurements up to 1-500th of a second using 6 to 7 points, and obtaining an error no greater than 4 per cent., we can calculate smaller times of exposure accurately from the narrower width of slit.

It will have been seen from the foregoing that the method is extremely simple in use, and gives very exact results; all that is necessary is to control the speed of the motor and to count the points obtained. Measurement of the image, necessary in most other methods, is dispensed with. The apparatus, having been once installed—it does not require much space—allows of the testing of any shutter in any camera without any previous preparation. The method is specially suitable for focal-plan

shutters, since the series of points which is formed parallel to the slit of the shutter possesses a diminishing extension in the direction of the movement of the shutter, so that any correction for the movement of the spindles is not necessary, as will be seen in an example to follow. In a later portion of the pre-

sent paper the results of testing a number of shutters will be given, from which it will be seen that there are considerable departures from the figures given in tables of focal-plane shutters or marked on the instruments themselves.

PAUL THIEME.

THE ROYAL PHOTOGRAPHIC SOCIETY.

CHANGE OF PREMISES.

THE following notice appears in the May number of the "Photographic Journal":—

In November last the Council was asked to exchange the Society's present house for one at No. 35, Russell Square. Inquiries were made and it was found that the house at No. 65, Russell Square, adjoining the Society's premises had been let on a building lease, and that proposals had been made to rebuild No. 67 on the other side of the Society's house. Apart from the serious damage likely to be done to the foundations of a very old house by these building operations, it was obvious that they would seriously hamper the Society's work and cause great inconvenience to the members.

The Council accordingly entered into negotiations with a view to obtain for the Society a suitable home, and at the same time to secure by an exchange of leases some permanent advantage for the Society. After prolonged negotiations the Council has entered into an agreement by which the Society will secure a lease of No. 35, Russell Square, for thirty years in exchange for the present lease, of which eleven years only have still to run. No. 35, Russell Square, having been built at a later date than No. 66 and being in a sounder state, will cost less for upkeep than the present premises. It offers better accommodation and in a more convenient way than the Society now enjoys. The rent will be the same as that which

the Society is at present paying. No. 35 will be put into a thorough state of repair inside and out, and so thoroughly redecorated that little expense for these purposes will be incurred by the Society for many years.

A studio will be provided in addition to the dark rooms, enlarging room and work room. The meeting room will be as large as the present one and of better shape; more and better library accommodation is provided and there are several rooms in excess of those at No. 66. The dark rooms, enlarging room and work rooms will be in the basement, and the studio will be over the basement, at the back of the house.

The agreement provides that the Society will pay no part of the costs in connection with the exchange of leases, the fitting up of the new house, and the removal of the Society's goods and furniture.

The dark rooms, enlarging rooms and work rooms at the Society's present house will be closed to the members after Saturday, May 22, but the remainder of the house will remain open till the close of the session on June 9, when the removing operations will be begun. The alterations will be pressed forward with all speed, and the date of the opening of the new house will be published in the "Journal."

ABSORPTION SPECTRA.

(A paper read by Dr. Mees before the Royal Photographic Society, and reprinted from the "Photographic Journal.")

THE connection between the colour of an object and its absorption spectrum must always be of considerable interest to those who have to deal with photographic matters, and the specific branch of it with which this paper is concerned—namely, the absorption of various organic dye stuffs—is of especial importance for the preparation of filters. Our laboratory has now devoted a considerable amount of attention to obtaining convenient methods for recording the absorption spectra of dyes, and some of the recent dye stuffs which we have obtained not being well known, it seemed to us that it would be useful if we were to publish a *résumé* of our more recent work on this subject, showing our experimental methods and the more interesting spectra which we have photographed.

A coloured substance may be defined as one which does not equally transmit all the constituents of white light, but which removes some of these constituents and appears to the eye to be coloured by virtue of the excess of the remainder. When such a coloured substance is examined in the spectroscope the absorption of some of the colours causes a black band to appear in the spectrum, and this is what is known as the absorption band of the substance in question.

An absorption band may be either sharp or shallow, but inasmuch as many absorption bands are broad, embracing a considerable portion of the spectrum, it is usual to use the sharp and shallow terms with regard to the *edges* of the bands, since many bands have one edge sharp and the other edge shallow. Rhodamine B, for instance, has an absorption band which stretches from 5,800 to 4,700. The edge of this at 5,800 is very sharp, while that at 4,700 is shallow and gradual (Fig. 1). That is to say, we pass very rapidly at 5,800 from a position of almost complete transmission to one of almost complete absorption, while at 4,700 the transmission is gradual, and a great change of colour takes place between the position where the transmission can be considered as reasonably complete, and that where it is nearly nothing.

Methods of Recording Absorption Spectra.

There are three main methods of recording absorption spectra. The first, by far the most accurate and most important, is the spectro-photometer. There are, indeed, only two objections to the spectro-photometer:—

1. That it is a comparatively slow method, *i.e.*, that it takes a considerable amount of time to measure the absorption spectrum of a dye.
2. That its use is limited to the visible spectrum.

The spectro-photometer consists in the first place of a spectroscope, usually fitted at the eye-piece with a narrow slit, which enables any

Fig. 1.

Dye wedge Rhodamine B.

particular portion of the spectrum to be isolated, and with a method of turning through the spectrum so that it is known which portion is being employed at any time. The field of view is divided horizontally into two portions, so that two spectra are observed, and it is necessary, if accurate measurements are to be made, that the two fields should be as near together as possible. One of these spectra is formed by the beam which is passed through the dye solution to be measured, the other is a beam which has not suffered any absorption, but of which the intensity can be diminished in a known manner. The spectro-photometer shown, and which we have chiefly

used, is the Huefner spectro-photometer, a full description of which has already appeared in the "Photographic Journal" for July, 1904 (Figs. 2 and 3).

In this instrument the upper beam passes through the absorption cell, which is arranged so that the top half only contains dye solution, the lower half being filled by a block of glass. The lower beam passes through the polarising nicol C. Both beams together after dispersion pass through an analysing nicol. The turning of this analysing nicol darkens the lower polarised beam only, and the

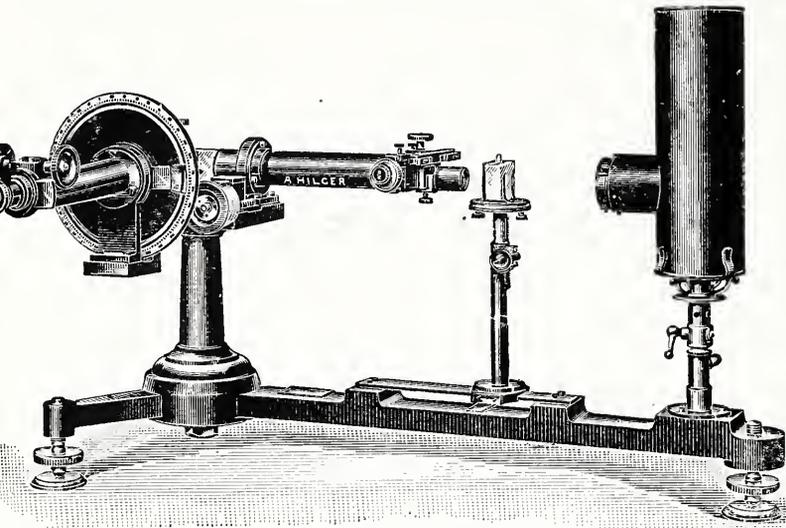

Fig. 2.

degree of darkening can be calculated from the angle through which it is turned. In order to make a measurement of an absorption spectrum, the lower half observed in the eye-piece is equated to the top half, a very narrow ocular slit being used, so that only a small portion of the spectrum is observed at a time, and the measurements so obtained are plotted against the wave-length of the light employed. The units of absorption chosen may conveniently be opacity logarithms, which are known in absorption work as extinction coefficients, and have the advantage that they are directly propor-

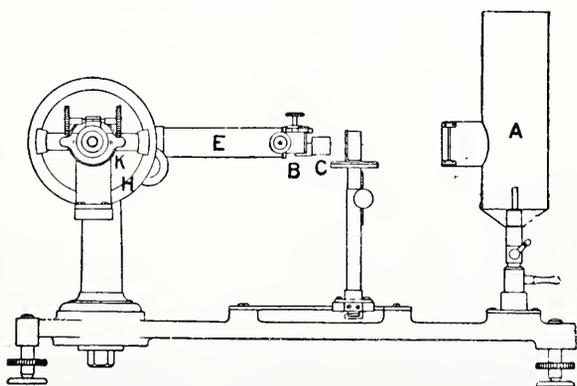

Fig. 3.

tionate to the weight of substance employed. The curve shown is the absorption curve obtained in this way for a 1 in 6,000 solution of potassium permanganate (Fig. 4).

This spectro-photometric method of recording absorptions is undoubtedly the most accurate, and in many ways the most satisfactory method which can be employed. It gives an absolute measurement independent of the light sources used and proportional to the mass of dye in solution. It can be used for the correct analysis of an impure dye. Suppose, for instance, that we have a commercial sample of methylene blue to use, and we wish to know the percentage of methylene blue contained in it. This can only be done chemically by a long and complicated analysis, but if we obtain a pure sample of methylene blue, either from another source or by purification of a small quantity of our sample, measure the density at a given point in the spectrum for a standard concentration, and then measure the density of the impure sample in the same concentration, the proportion between the densities will give the degree of purity of our sample.

But spectro-photometric methods of obtaining absorption bands have one great objection, they are comparatively slow, and while this is of no importance in research work, although it is to be noted that no long series of carefully measured absorption curves of dyes have yet been published, it is a great disadvantage when it is necessary to obtain a reference collection of the absorptions of as many dyes as possible. In order to prepare a great variety of filters for all purposes, we have made a careful study of the available dyes, and have obtained absorption spectra by the methods shortly to be described, of nearly 300; neglecting only those which seem to be

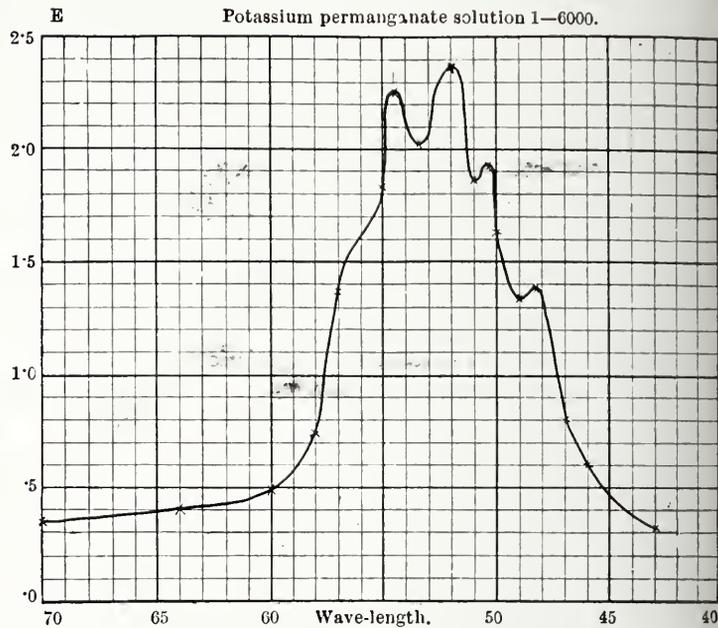

Fig. 4.

quite unsuitable for any purpose which was likely to interest us at present. We are hoping before long to publish these in some form, and we are only bringing before the Society to-night types of the absorption curves given by different groups of dyes, as we find that little has been published on the subject, and some curves which we have to show may be new to practical workers. We have purposely extended these observations as far into the extreme red and ultra-violet as possible, our spectrum being limited by about 8,000 on the one side and 3,500, where light is cut off by glass, on the other.

In order to obtain this great range it is, of course, necessary to use a photographic method, and there are three photographic

Dye wedge.

Black wedge.

Fig. 5.—Xylen red.

methods which can conveniently be employed for this purpose:—
 (1) One may take a series of photographs with increasing dilution of the dye; (2) One may take a series of photographs with a constant concentration of dye but an increasing thickness of the cell; (3) One may take a series of photographs with a constant concentration and constant cell thickness, but with a varying exposure. These three methods will all produce different results, though (1) and (2) are nearly equivalent to one another. (1) is a very slow method, and it would probably be quicker to use a spectro-photometer.

(2) and (3) though quicker are still slow if carried out as described. But if in method (2) instead of using varying thicknesses of cell we use a cell of which the thickness varies throughout the length, that is to say, a wedge-shaped cell placed in front of the slit so that the thickness of the layer of dye solution in front of the slit varies from end to end of the slit, the method resolves itself into taking only one or possibly two photographs of each dye. Method (3) is inferior to the other two methods, as it involves the interpretation of the photograph of the plate curve. It is, however, a convenient way of examining the absorptions of coloured films and finished filters. In order to carry it out rapidly, the black wedge which

ally absorbing dyes, was first inserted, which caused the plate to give an even spectrum from 7,300 to 5,200, after which it rises to the blue-violet maximum of the plate. Two cells containing a 1 in 100,000 solution of mandarin orange, and a 1 in 300,000 para-nitrosodi-methyl-aniline solution sufficed to subdue this blue-violet maximum, so that when a black wedge spectrum was taken of the plate through these screens it was found to be even in height from 7,300 to 3,800; falling off from 7,300 gradually to 8,000, and from 3,800 to 3,500, where the glass absorbed, and it ended. (Fig. 7.)

With this arrangement it was found that to get sufficient density upon a plate, an exposure of five minutes was required, and except

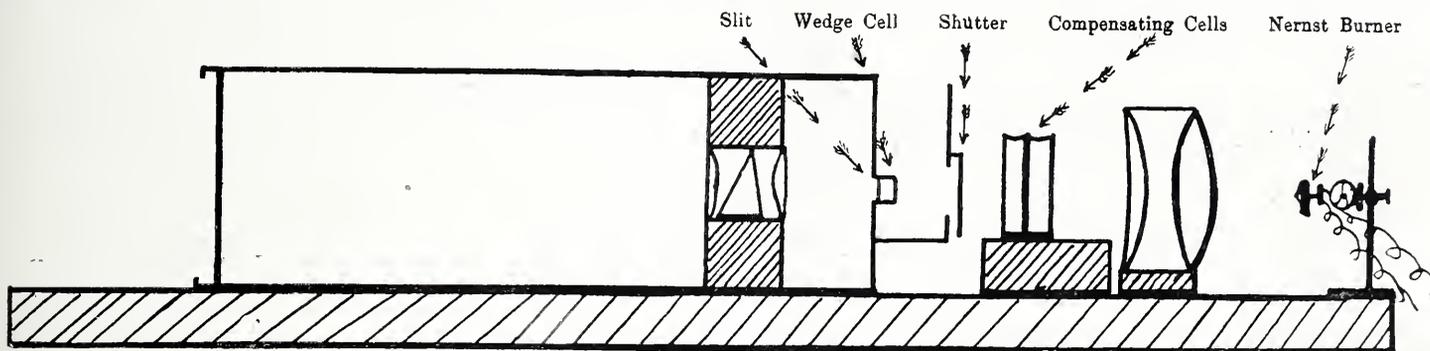

Fig. 6.

we have before described is used in front of the slit spectroscope, so that the intensity of light falling upon the slit varies from end to end of the slit. Fig. 5 shows the results obtained by methods (2) and (3) for a solution of xylen red.

The Apparatus Employed.

The apparatus employed consisted of a modified Tallent Spectrograph fastened down to a board, and with a scale in front of the plate. This scale in front of the plate makes it impossible to measure the density of the negatives, but as we do not wish to measure the density of the negatives, that does not matter. In order to obtain great light intensity, which is necessary because of the screens which are to be used, a Nernst lamp is placed parallel

Fig. 7.

Black wedge of screened plate.

to the horizontal slit, and a large condenser focusses an image of the filament upon the slit of the spectroscope. The width of the slit is about .2 mm. (Fig. 6). In front of the slit was fastened the wedge-shaped cell containing the dye solution.

The plates used were plates which are made specially for spectroscopic purposes, and which we call Spectrum Panchromatic. These plates have a very intense red-sensitiveness which spreads into the infra red, so that with long exposures they can be used up to 8,000 A.U. A blue screen empirically adjusted and made of gradu-

ally absorbing dyes, was first inserted, which caused the plate to give an even spectrum from 7,300 to 5,200, after which it rises to the blue-violet maximum of the plate. Two cells containing a 1 in 100,000 solution of mandarin orange, and a 1 in 300,000 para-nitrosodi-methyl-aniline solution sufficed to subdue this blue-violet maximum, so that when a black wedge spectrum was taken of the plate through these screens it was found to be even in height from 7,300 to 3,800; falling off from 7,300 gradually to 8,000, and from 3,800 to 3,500, where the glass absorbed, and it ended. (Fig. 7.)

Properties of Dyes which Render them Suitable for Filter Making.

Except in the rare case of special compensating filters, it is usually required that a filter should absorb as completely as possible the region which it is required to absorb and transmit as completely as possible the region which it is required to transmit. The degree to which a dye will do this depends mainly on the sharpness of its absorption band. The edge of an absorption band which is towards the red end of the spectrum is nearly always sharp, and such dyes do not absorb light other than that in their absorption band proper. A red dye having an absorption band in the yellow-green, or a yellow dye having an absorption band in the blue, are bright dyes transmitting the red or green and red portions of the spectrum completely, but if the absorption band faces the other way, as in the blue and blue-green dyes, it will generally be more gradual, and there will be a great absorption of the portion of the spectrum which should be transmitted. This is well shown in the case of the tricolour filters. The red tricolour filter will transmit about 75 per cent. of the incident red light, but the best green filter only about 35 per cent. of the incident green light, and a blue filter only about 16 per cent. of the blue light. When examining dyes for use with filters, the great object is to choose those which have the sharpest possible absorption and the least residual absorption in other portions of the spectrum.

S. H. WRATEN.

C. E. KENNETH MEES.

(To be continued.)

THE PHOTOGRAPHIC CONVENTION AT CANTERBURY IN JULY.

THE Handbook of the forthcoming meeting of the Convention at Canterbury in July, under the Presidency of Mr. H. Snowden Ward, is to hand, and judging from its contents conventioners should have an enjoyable and profitable time during their visit to that ancient and historic city. The Mayor, the Cathedral authorities, the Committee of the Chamber of Commerce, and the Canterbury Camera Club have all given their hearty co-operation, and everything gives promise of a very successful gathering. The headquarters of the Convention during the week will be at St. George's Hall. The following is the programme of arrangements:—

MONDAY, JULY 5.

Morning.—Members of the Camera Club will attend at St. George's Hall to conduct parties to places of interest in and around the city.

Evening at 8.—Reunion. The proceedings will open with a few words of welcome by his Worship the Mayor, Mr. F. Bennett-Gold-

ney, after which the President, Mr. H. Snowden Ward, will deliver his inaugural address. At the conclusion of the Presidential address Mr. and Mrs. Ward will be At Home to members and friends, after which the annual general meeting will be held.

TUESDAY, JULY 6.

Morning, at 9.30.—Excursion by brakes to Patricxbourne, Wingham, Wickhambreaux, and Fordwich, all of which possess interesting old churches, and the last-named a unique town hall.

Evening, at 8.30.—A lecture entitled "Canterbury and Its History" will be given by Mr. F. Bennett-Goldney, F.S.A., followed by a meeting of the new Council.

WEDNESDAY, JULY 7.

Morning.—Visit to the Cathedral, where the Rev. Canon Moore, D.D., on behalf of the Dean and Chapter, will hold an official reception at 11 o'clock.

Afternoon, at 3.—His Worship the Mayor, Mr. F. Bennett-Goldney, and the Mayoress will give a garden party at their residence, "Abbots Barton," at which the official Convention group will be taken by Mr. H. B. Collis at 3.30.

Evening, at 7.—The annual dinner at the County Hotel.

THURSDAY, JULY 8.

Morning, at 9.39.—Excursion by train to Rochester, which is particularly rich in objects of archaeological and historical interest, many of the former dating back to Roman and early Norman times. The cathedral, castle keep, and Eastgate House (now the museum), will possess special interest for students of architecture.

Evening, at 8.30.—A paper will be read by Mr. C. Welborne Piper, followed by a paper by Mr. C. H. Bothamley entitled "Some Aspects of Photographic Record Work."

Friday, at 9.40.—Excursion by train to Rye and Winchelsea. Rye is full of objects of interest, amongst which may be mentioned St. Mary's Church, with its ancient clock, the monastery, the Town Hall,

and the Ypres tower. Many fine views may be obtained from the harbour and the east and west cliffs. In Winchelsea, which is little more than a village, the chief objects of interest are the old church, the Court Hall, and the three gates; the surrounding country also is very picturesque.

Evening, at 8.30.—A paper will be read by Capt. Owen Wheeler on "High-power Telephotography," followed by a lecture by Mr. F. Martin Duncan on "Colour Photography Applied to Natural Science."

SATURDAY, JULY 10.

The last excursion of the Convention of 1909 will leave Canterbury by train for Maidstone at 9.40, where conventioners will be met by members of the Maidstone Camera Club, who will act as guides to the various places of interest in and near the town.

The handbook contains a list of the hotels and apartments where accommodation may be obtained, also a list of photographic dealers and dark-rooms in Canterbury, and other places visited.

INJURIOUS EFFECTS OF STRONG ILLUMINATION UPON THE EYE.

From "The Optician and Photographic Trade Journal."

ALTHOUGH everybody knows, or ought to know, that the eye should never gaze directly at an unprotected electric arc or incandescent filament, this rule is constantly broken by placing such lights where their rays fall directly on the eye; and we may attribute, in part, the injurious effects of direct radiation to the invisible ultra-violet rays or those that fall beyond the violet of a solar spectrum.

Although this invisible light provokes no sensation, it by no means follows that it is without physiological action, and we may inquire whether its effects on the eye may not be injurious. One has an instinctive apprehension of this when he thinks of the mercury-vapour lamps, sources particularly abundant in ultra-violet rays. We are reluctant to admit that their unnatural light is in conformity with the rules of hygiene.

In these conditions is it not to be feared that the continuous action of the ultra-violet rays emitted by our usual sources of light may present serious danger? Messrs. Schanz and Stockhausen have been trying to clear up this question by a study of electric arc and incandescent lamps. The former emit ultra-violet light in abundance, and the two physicists attribute to this fact the ophthalmia often caused by arc lamps. Again, after having shown that the crystalline lens of the eye is made fluorescent by the ultra-violet rays, they state their belief that this phenomenon may at length render the lens opaque and thus cause cataract. Incan-

descent lamps using metallic filaments are also sources of ultra-violet light, although they are less rich in it; and it is only fair to say that the glass of the bulbs and shades absorbs a notable part of the ultra-violet light.

But, it will be said, the sun's light, the ideal of all artificial illumination, is not without ultra-violet rays. Indeed, it is much richer in rays of this kind than arc or incandescent lamps. Should we conclude that the dangers of which we are warned by Messrs. Schanz and Stockhausen are imaginary? By no means. The solar light is rich in ultra-violet rays, but it is dangerous to receive it directly. No human eye is able to look steadily at the sun, and it is logical to attribute to the ultra-violet radiations a part of the disastrous results of such an act. The light that reaches our retina has been previously reflected and diffused in a thousand ways. It contains but a feeble proportion of the dangerous elements. On the other hand, in the case of artificial sources of light, we often receive their rays directly, and their continued action may, therefore, be injurious.

The conclusion to be drawn from these investigations is that it is important so to arrange our electric lamps that it will be impossible to see the arc or the bright filament directly; and in our interior installations we must use, as far as possible, indirect illumination, by reflection and diffusion of the light on large surfaces.

NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

THE annual meeting of the above association was held at 4 p.m. on Tuesday, May 18, when the members and visitors enjoyed the hospitality of Sir Benjamin Stone at the Midland Grand Hotel, St. Pancras. The secretary read the report, which we reprint below, and then the President gave his annual address. This was partly devoted to a consideration of the progress of photography in general, as evidenced in the Dresden exhibition, at the opening of which Sir Benjamin was present. He described the English pictorial exhibit as representative of a large number of well-known exhibitors, but so overweighted with meaningless pictures as to lose all attraction. In consequence of this, he said, the room is nearly always empty, while the scientific section is much appreciated. The record exhibits in particular being peculiar to England attract much attention. Sir Benjamin concluded his address by strongly urging the organising of a similar exhibition in England. After the adoption of the report the Rev. F. C. Lambert moved the following resolution:—"That considering the ever-increasing uses of photography, the Government be urged to establish a photographic department where technical instruction may be obtained, and where historical photographs of passing events, customs, and other matters of interest may be

secured, indexed, and stored for public reference." This was carried unanimously and the meeting terminated, after the president, council, secretary, and treasurer had been re-elected for the next year and the customary votes of thanks had been passed. Among the numerous speakers were Major-General Waterhouse, Dr. Mills, and Messrs. John Spiller, G. A. T. Middleton, and G. A. Storey, A.R.A. Mr. Spiller suggested that possibly the first purely record photograph ever produced was one made by himself on May 8, 1860. In any case this was the first photographic record made by the War Department of shot marks on armour plates. The report of the Association is as follows:—

The Council of the National Photographic Record Association have now the pleasure of presenting their eleventh report, and although our own society has not received as many prints as we might have wished, it must be satisfactory to all interested in the subject to know that record work is being carried on vigorously by many photographic societies throughout the country, and that valuable prints are being deposited in many local and central museums and public libraries, and available for public reference.

Since our last report we have received 189 prints and 334 nega-

tives, from most of which we hope to be able to obtain prints for the collection, making the total number of prints received 4,367.

The President, Sir J. Benjamin Stone, has contributed 50, including a series illustrating an old custom in Lichfield—The Sheriff's Ride; a set of the old Gateways and Walls of York—St. Mary's Abbey, York; an Ancient Cross and Stocks at Ripley, and other photographs from Worcestershire.

Mr. G. Bingley has forwarded 39 prints including a set of Ludlow Castle, Glastonbury Abbey and the old George Hotel, Stokesay Castle, Wenlock and Buildwas Abbey.

From Mr. Welch, of Belfast, we have received 22 of his celebrated Irish photographs, including some studies of the people and their houses, and various views of some of the ruins of the old churches.

Mr. H. W. Fincham has forwarded 27 prints, including views of Walpole House, Chelsea, and 4, 5, and 6, Cheyne Walk, and some of St. John's Gate, and St. John's Church, Clerkenwell.

Mrs. M. Powles has favoured us with views of Littleham Church, Devon, and Dunning Church, Perthshire.

Mr. Brace has secured an interesting record of a part of the old London Wall, unearthed when making an excavation in America Square, Minorities.

Miss Niblett has again contributed some prints, including a set of Compton Wingates, where four sovereigns are reported to have stayed, viz., Henry VIII., Elizabeth, James and Charles, also some views of the Scilly Isles.

The Hon. Secretary, 25 of the Essex churches, including Thaxted, Great and Little Samford, Great Leighs and Bradfield, and the old Moot Hall at Thaxted.

The Council are much indebted to Mr. G. H. Fowler Jones, who has forwarded 334 negatives, taken by his late father, Mr. George Fowler Jones, architect, York. They are of particular interest, first from a photographic point of view, as Mr. Jones was a friend of Fox Talbot, and worked with him occasionally, and as the negatives date from the year 1843 down to 1904, they practically form a history of photographic progress, but they are also interesting as records, comprising as they do views of Kirkham, Kinloss, Melrose, Muckross, Dunblane and other abbeys, Cawdor, Conway, Craig Miller, Lilleshall, Urquhart, and other castles, and many of the churches and interesting buildings of Yorkshire and the North.

The London County Council have set a good example to other municipal bodies by making a collection of photographs of interesting old houses and other buildings in their district that have to be removed for street improvements, and the prints are stored in the library of the County Hall, Spring Gardens. With regard to work being carried on by other societies, the premier society, the Survey Society of Warwickshire, President, Sir J. Benjamin Stone, Hon. Sec., George Whitehouse, continues to do splendid work in the county, and they now have a large and important collection at the Central Reference Library, Birmingham. The Photographic Survey and Record of Surrey, H. D. Gower, Hon. Sec., have received 456 prints during the year, making a total of 2,381, which are preserved at the Town Hall, Croydon, under the charge of the chief librarian, J. Stanley Jast, Esq., and it is particularly gratifying to find the public are appreciating the value of the collection, as 1,215 references to the prints were made last year. This year their annual excursion is arranged for Saturday, May 22, to visit Barnham and the vicinity, a part of the county practically unrepresented in their collection. The Survey of Sussex under the Presidency of the Duke of Norfolk, J. C. Stenning, Esq., Hon. Treasurer, are getting together a good collection of photographs, which are deposited in the Public Library, Brighton. The Photographic Survey of Essex, V. Taylor, Hon. Sec., have now a considerable collection, which are deposited at the Essex Museum of Natural History, Stratford, and the societies of Kent, Leicester, Worcestershire, the North Middlesex Photographic Society, Edinburgh and District, and many others are making good progress.

By special invitation the National Photographic Record Association have arranged and forwarded to Dresden for the important photographic exhibition now being held there, a series of photographs illustrating the record work being done in this country, and the Council are indebted to the London County Council, the Survey Society of Warwickshire, and of Surrey for having lent a selection of their prints, and also to Messrs. Welch, G. Bingley, H. W. Fincham, and the Hon. Secretary, who have also contributed. The President,

Sir J. Benjamin Stone, has also exhibited a large collection of his well-known photographs of old customs, and was by special invitation of the King of Saxony, present at the opening of the exhibition.

We regret to have to record the death of Mr. Hector Maclean, a gentleman who had taken the greatest interest in our Association, and was an enthusiastic supporter of record work generally, and only a week before his death he took the chair at the meeting of the Photographic Survey of Surrey and gave an address upon the work being done. In it he referred to the deplorable destruction of so many grand old structures during the 19th century and suggested that possibly many photographs were in existence taken before works of restoration were commenced. In 1851, with the advent of the collodion process, there was an immediate expansion of the art of photography, and the same time was the commencement of the period of church restoration, and he took the opportunity of appealing most earnestly to all men of intelligence, who are interested in the country, to rummage amongst their portfolios and albums, and those of their friends, for old photographs of persons, places, and things. This appeal we most cordially endorse, and would again urge all interested in the history of our country to have another search amongst their old photographs and negatives, as it is well known that not only is there very much valuable matter hidden away in private collections, but also that there still remains a large number of negatives that have not even been printed from.

In conclusion, the Council would wish to draw attention to the fact there are two classes of members of the National Photographic Record Association, one whose qualification shall be a contribution of not less than six prints per annum, and another class who qualify by a subscription of 10s. per annum. At the present time we should be glad to have some additional subscribers, as we have to find means for printing some 250 from the negatives presented to us by Mr. F. Jones, in addition to our ordinary expenses.

Warm thanks are again due to Mr. George Scamell for his continued assiduity in directing the work of the Association, and for his additional contributions, which now form a considerable portion of the British Museum Collection.

FAIR CHILDREN.

UNDER this title an exhibition has been opened at the galleries of Speaight, Limited, in New Bond Street. A one-firm show of professional photographs, at a charge of one shilling to the public, is something new in photography, and the promoters are, at any rate, putting what is known as commercial work upon a footing hitherto occupied entirely by photographs of pictorial pretensions. We congratulate them upon the idea, as well as upon the results they show. The handsome gallery is tastefully decorated and hung, and the pictures are in most cases worthy of attention, from the pictorial standpoint alone.

Messrs. Speaight are famous for their child-pictures, yet, for our own part, we are not a little grateful for the mothers that sometimes come in as mere supports. They fill this rôle with artistic, as well as domestic, grace.

"The nobility and gentry" of the world are figured in profusion, Mr. Richard Speaight having visited Germany, Sweden, and Spain for commissions which are the distinguishing points of this aristocratic collection. Nevertheless, it must be admitted that the most successful works are those which are in reality more frankly pictures than likenesses. Such are the charming "Children at Play," two nude figures contesting for a basket of flowers, which the taller holds high over head; "Richard Langford Speaight and his Mother," a well composed, airy interior, where the mother plays a spinet and the child plays on the floor; also "Ave Maria, Gratia plena," a little girl kneeling at prayer, with head bent low and hands together. Some of the likenesses are also remarkably full of the pictorial feeling without which a portrait is often an arid performance. For example, the way in which the Crown Princess of Sweden holds up her lively baby is quite in the manner of Reynolds. "John, son of Mrs. Ernest Pitman," recalls a Hoppner by reason of the costume of the boy. The old-established "family group" occurs only once or twice. In most cases the children play naturally with skittles, or fish-bowls, or "teddy-bears"; but where the mothers are included the posing is always feelingly managed, and the composition tastefully managed. As to the quality of the prints, one can scarcely speak too highly.

They all have a fine, quiet richness, without any undue forcing, and their old-world air is carried out happily in the mounting, with hand-drawn and hand-lettered mounts and appropriate frames. There is also a collection of exquisitely worked miniatures, the natural flesh tints of which may be taken for granted when it is understood that they are the work of Mrs. R. Speaight, whose reputation is well founded.

Photo-Mechanical Notes.

The Residues in Wet-plate Work.

In a little book published by Mendel, called "Traitement des Résidus Photographiques," per L. Mathet, there is given the following simple method to recover the silver from residues in wet collodion work, a plan that might be adopted by any photo-engraver to his profit. The used fixing baths, and also the drippings and first washing waters from developments, are collected in a vessel, and there are then introduced some pieces of copper sheet, the surfaces of which have been previously very thoroughly cleaned. The silver will be thrown down by the copper in the metallic state. From time to time, say every two days, the copper is scoured with a hard brush to detach the silver veneer from the copper surface. When the vessel is full all or part of the supernatant liquid is syphoned off and further solution added and treated in the same way. When it is judged that there is sufficient silver collected, it is separated from the liquid by filtering on a closely woven cloth. After washing and drying the deposit can be further treated, fused, or converted into silver nitrate, or, what is probably better, may be at once sent to the refiners.

Improvements Relating to Photographic Printing Apparatus.

Three patents, Nos. 23,684, 23,690, 23,701, 1908, have been granted to William Carl Huebner, of 32, Laurel Street, and George Bleistein, of 197, Main Street, both of Buffalo, New York State, U.S.A., for improvements in apparatus by means of which prints can be made on litho stone or metal plates, sensitised to receive a photographic image from either a negative or a positive. It is claimed that the apparatus enables the print to be made with great certainty and accuracy in a very expeditious and inexpensive manner; and, moreover, several prints may be made on the same or different portions of the same surface exactly where required without any difficulty. With the great increase now being made in the use of photo-lithography there should certainly be room for some apparatus to enable the print or prints to be quickly and satisfactorily made on the stone or plate.

Collotype for Amateurs.

In reference to our recent paragraph respecting the Procédé Cello, M. H. Calmels writes, taking exception to the opinion of our contributor that this process is not one by which a professional photographer would make much money. That, of course, is only a matter of opinion and of local circumstances, but we ourselves feel that if only a few prints are required a pure photographic process will be the most economical, all things considered; while if very many prints are required from an occasional job it will be more economical to place the work with firms making reproduction their special business. If there are continuous jobs of such a character, of course the photographer may be advised to install a proper plant, but then he would rely on "Collo." M. Calmels is mistaken when he says it does not pay to work collotype in the ordinary way for less than 1,000 prints. We can assure him he will not have the slightest difficulty in placing orders for as many jobs as he likes for 500 prints per subject. M. Calmels is also ungenerous, as well as in error, in supposing that our contributor reviewed his book without having read it.

FORTHCOMING EXHIBITIONS.

May 20 to 27.—Malvern Camera Club. Sec., J. B. Nickolls, The Exchange, Malvern.

July 7 and 8.—Canterbury Camera Club. Entries close June 23. Sec., B. J. Fisk-Moore, St. George's Gate, Canterbury.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between May 3 and May 8:—

PROJECTION SCREEN.—No. 10,541. Improved screen for optically projecting on to in an illuminated room. William Cecil Jeapes, 85, Tulse Hill, London.

ANIMATED PHOTOGRAPHY IN COLOURS.—No. 10,542. Improved method of producing moving pictures in natural colours. William Cecil Jeapes, 85, Tulse Hill, London.

CINEMATOGRAPH-PHONOGRAPH.—No. 10,543. System for producing synchronism between talking-machine and moving-picture machine. William Cecil Jeapes, 85, Tulse Hill, London.

COLOUR PHOTOGRAPHY.—No. 10,611. Improvements in three-colour photographic processes. Rodolphe Berthon, 7, Southampton Buildings, London.

PANORAMIC PICTURES.—No. 10,669. Panoramic pictures. Edward Nelson White, 33, Cannon Street, London.

COLOUR PRINTING.—No. 10,716. Method of printing in natural colours on paper, cardboard, wood, ivory, or porcelain. Sir Louis Augustus Gordon, Bart., 9, Pall Mall, London.

CINEMATOGRAPHS.—No. 10,859. Improvements in and relating to cinematographic effects. Horald Dorman Patterson, 1, Queen Victoria Street, London.

ACETYLENE GENERATORS.—No. 10,880. Improvements in and relating to acetylene gas generators and like containers. Ernst Arthur Nier and Johan Michael Ehmer, 322, High Holborn, London.

FRAMES.—No. 10,908. Improvements in the manufacture of photograph frames. George Moore, jun., Prudential Buildings, Corporation Street, Birmingham.

FOLDING STEREOSCOPE.—No. 10,916. Folding stereoscope for viewing with natural colour effects stereoscopic photographs that are printed in sheets. Gilbert Dyas, 9, St. Mary Street, Dublin.

CAMERAS.—No. 10,922. Improvements in or connected with the adjustment of photographic cameras. David Borland Russell, Catkin Avenue, Rutherglen, Glasgow.

MOVABLE BATHS.—No. 10,928. Improvements in movable baths for photographic and similar purposes. Iliffe and Sons, Ltd., and Thomas Bush, 18, Hertford Street, Coventry.

CAMERAS.—No. 10,938. Improvements in cameras. Joseph Somers Goodwin, 40, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable; price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

A METHOD OF PRODUCING LENSES BY SUBSIDENCE.—No. 3,444. 1909 (February 12, 1909). The invention relates to the manufacture of glass lenses, which have only one spherical surface, whilst the other one is a non-spherical surface of revolution, the axis of which passes through the middle point of the spherical surface. Under lenses are also to be understood those bodies of revolution which are to be silvered on one surface, so that this surface may act as a reflecting surface. The expression spherical surface is intended to include the special case of a plane surface.

A proposal has already appeared in the American Patent Specification, No. 4,786, of overcoming the difficulty of manufacturing a non-spherical surface in the kind of lenses described, by first of all producing a lens of deviating form with two spherical surfaces and thereupon transforming this primary lens into one of the desired form by subsidence by heat, the mould surface being spherical and differing from the spherical lens surface to be produced only in the algebraic sign of the radius. As far as the dimensions of the primary lens are concerned, its thicknesses at the vertex and at the margin are not at all or inappreciably different from the

respective thicknesses of the final lens; its two radii, however, have to be suitably selected. A closer investigation of this process shows that the eligibility of the two radii is insufficient to produce lenses at will with a spherical and a non-spherical surface of revolution, even though only profile curves be admitted for the surface of revolution, the radius of which increases or decreases steadily from the vertex to the margin.

This known process is therefore in the present invention developed so that the calculated or otherwise prescribed profile curve of the surface of revolution can be realised with greater approach to accuracy than heretofore. If obtaining the spherical surface of the final lens immediately by the mould be dispensed with, and the course be rather to produce the final spherical surface after subsidence by grinding, the radius of the spherical mould surface offers itself as a third eligible element. Four forms of the new process can be differentiated, according as, on the one hand, the mould surface be concave or convex, and, on the other, as its radius be shorter or longer than the radius of the final spherical surface. In two of these four cases—namely, a convex mould surface of enlarged radius and a concave mould surface of diminished radius, producing the final spherical surface by grinding can only be carried out when the thickness at the vertex of the primary lens has been correspondingly enlarged. In the other two cases the marginal

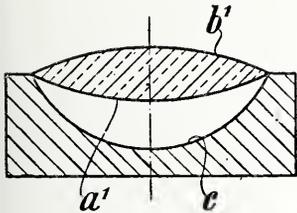

Fig. 1

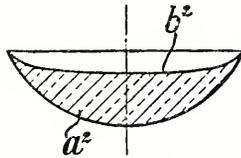

Fig. 2

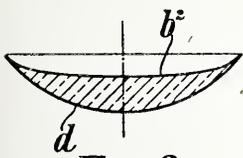

Fig. 3

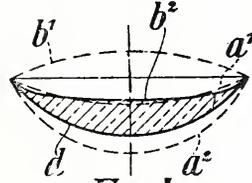

Fig. 4

thickness of the primary lens must be correspondingly greater than that of the final lens.

In the drawings two examples of the new process are illustrated, in Figs. 1 to 4 the production of a collective meniscus by means of a spherical mould surface, and in Figs. 5 to 8 the production of dispersive menisci with the aid of a duplex mould, the two mould surfaces of which are made after the same non-spherical surface of revolution.

Fig. 1 shows a symmetrical double convex lens, the surfaces a^1 and b^1 of which are spherical, as the primary lens laid upon a mould with concave spherical mould surface c . The result of the subsidence is shown in Fig. 2. A meniscus is the outcome, the upper surface b^2 of which closely approximates to the prescribed non-spherical surface of revolution, whilst its lower surface a^2 corresponds exactly to the spherical mould surface c . The lens has now to be ground, in order to replace the surface a^2 by the final spherical surface d , which, as shown in Fig. 3, is weaker convex, so that the final lens, d b^2 , with equal diameter, and with the same marginal thickness, zero has a smaller vertex thickness than the primary lens a^1 b^1 . In Fig. 4 the changes undergone by the lens are given at one view.

If the primary lens had been already given the final vertex thickness and the mould surface the weaker curvature corresponding to the final spherical surface d , grinding would have been saved, the known process mentioned in the first paragraph above only being applied. It is, however, easily seen from Fig. 4, that in this case a non-spherical surface of revolution would have resulted, the profile of which had differed from that of the surface b^2 by a smaller vertex radius and a slower reduction of the radius towards the margin of the lens.

In the example, according to Figs. 5 to 8, two similar primary lenses, each with two spherical surfaces of infinitely large radius, are contained in a glass plate with parallel plane surfaces e^1 and f^1 . This plano-parallel plate is, according to Fig. 5, laid upon a mould having two similar, concave, non-spherical surfaces of revolution, g g , and may be held firmly in position at the margins by a frame (shown in dotted lines). After subsidence the plate has

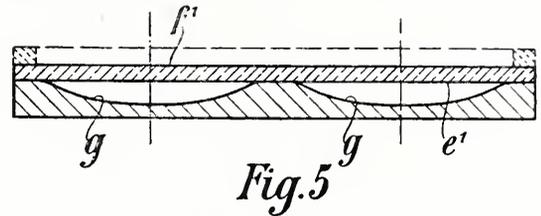

Fig. 5

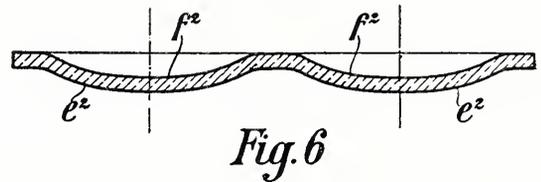

Fig. 6

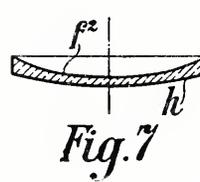

Fig. 7

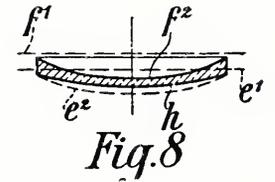

Fig. 8

taken up the form represented in Fig. 6, in which it contains two lenses, each with a final non-spherical concave surface, f^2 , of prescribed profile, and a similar convex surface e^2 , which is immediately produced from the concave mould surface, g . Fig. 7 shows the cut-out lens, after in place of the surface e^2 the final spherical surface h has been produced by grinding. In Fig. 8, as in Fig. 4, the steps in the development of the lens are represented again at one view. Carl Zeiss, Carl-Zeiss-Strasse, Jena.

SYNCHRONOUS CINEMATOGRAPH AND TALKING MACHINES.—No. 11,333. 1908 (May 25, 1908). In order to obtain an exact combined action or synchronism in the production of living pictures and in the reproduction of voices, either singing or speaking, it is necessary that both apparatus should run perfectly equally. The devices hitherto employed for attaining this object were mostly constructed by an electric contact apparatus being inserted between the talking machine and the reproducing apparatus or cinematograph. This arrangement has, however, the drawback that in the case of fluctuations in the current an irregular running of the two apparatus easily arises; on the other hand, interruptions in the working frequently arise, which can only be removed with a comparatively large expenditure of time, even by a skilled mechanic, who is not always available, so that serious interruptions arise in the representations. By reason of the great distance between the two apparatus the operation in common of both apparatus by means of a flexible shaft is also inadmissible, and again the separate parts of the shaft make more or fewer revolutions, so that a uniform rotation at both ends of the shaft cannot be attained.

By the arrangement which forms the object of the present invention the drawbacks hereinbefore mentioned are avoided in a simple manner, the adjustment taking place by means of two indicating devices provided with indicating parts which are clearly visible, one of which devices is operated by the operating mechanism of the talking machine and the other from the cinematograph or reproducing apparatus operated by hand. For the purpose of producing the synchronism or equal running, the operator of the cinematograph has only to take care that by a suitably rapid rotation of the operating crank of the reproducing apparatus he brings the indicating part of the respective indicating device into constant coincidence as regards the actual position of both parts with those of the indicating apparatus operated by the talking machine.

In the operating-room there is a reproducing apparatus (cinematograph) the film feed drum of which carries a chain or cord wheel or pulley on a prolongation of its shaft. By means of a

chain or, if preferred, a band, cord, or the like, a shaft provided with a chain pulley is operated, on which shaft a worm is provided, which worm is in engagement with a worm wheel. On the shaft of the latter there is a pointer and dial, provided with divisions or marks. The pointer, with the arrangement belonging to it, is preferably arranged in the inspection aperture or peep-hole, through which the person operating the cinematograph observes the picture.

On the stage facing the operating chamber there is the projection surface or screen, near which the second indicating device is so arranged that it may be easily observed by the person operating the cinematograph. The operating mechanism of the talking machine, erected in proximity to the stage, has a long shaft or the like, which, under the intermediary of a worm gear, rotates the operating shaft of the indicating mechanism. On the operating shaft a non-transparent disc is mounted provided with a radial slot, the periphery of which disc is surrounded with a number of slots provided in a disc corresponding to the number of the marks or the like, of the disc. In the interior of the indicating mechanism one or more sources of light are rays which penetrate to the outside through the radial slot and the smaller slots, and may be seen by the operator in the operating chamber. The slots round the periphery of the disc may be replaced by dark lines, dots, or other markings.

The non-transparent disc, which constantly rotates during the running of the talking machine, informs the operator in the operating-room, through the illuminated radial slot, constantly as to the extent of the forward movement or progress of the plate or roller of the talking machine. The speeds of rotation of the disc and the pointer are so attuned by a suitable selection of their operating mechanisms that the uniform running of the reproducing apparatus and talking machine necessary for the exact demonstration of the pictures is obtained when the indicating mechanisms of both indicating apparatus always have the same uniform relative position in their axes of rotation. In order to obtain and maintain the uniform running it is thus only necessary for the person operating the cinematograph to rotate the crank of this apparatus at such a speed that the angular velocities of the indicating mechanisms are constantly the same.

In place of the radial slot a black pointer might also be employed, which rotates in front of an illuminated surface, or a white pointer illuminated from the front, which pointer rotates in front of a black surface.

Instead of giving the indicating mechanisms a rotary motion they may also move in a straight line or be arranged so as to rock, in which case the marks or slots must be correspondingly arranged in a straight line and a circle respectively; they may, however, also be entirely omitted. The respective movements of the parts may be obtained by a suitable selection of the operating mechanisms without further difficulty. Heinrich Bayer, 4, Sturmstrasse, Nuremberg, Germany.

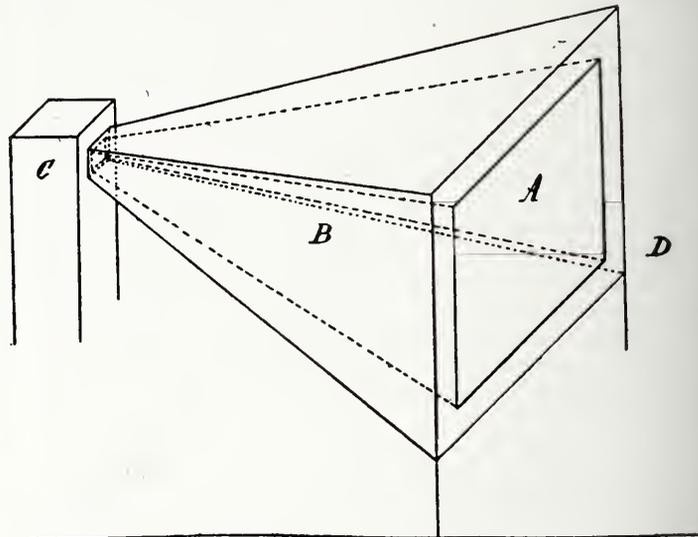

LANTERN PROJECTIONS VISIBLE IN FULL LIGHT.—No. 27,376. 1908 (December 16, 1908). The invention relates primarily to an improved process of obtaining, on a suitable screen, stationary or moving projections visible in full light, that is, in a lighted room or even in the open air in diffused sunlight; this process avoids the drawback of being obliged to darken the room or theatre, and does away with covers, reflectors, illuminating combinations, etc., arranged in the room.

Behind the projection screen a dark chamber is formed, in which the projection is directly effected, and of which the screen forms the front face separating this dark room from the spectators. According to the invention the projection is made by means of a lantern placed outside the projection chamber, which has an orifice through which only the luminous rays projected from the lantern can pass. The projection screen is constituted by a sheet of dull glass or its equivalent, the unpolished face being turned towards the spectators. As this translucent screen only receives light from behind according as the parts of the images projected are more or less clear, these appear very visibly on the front face, notwithstanding the lighting of the screen from the front. In certain cases, for limiting the quantity or the intensity of light coming from the front into the dark chamber through the translucent screen which constitutes the front wall, it is advisable to double the projection screen at the side next the spectators by a slightly

smoked sheet, which only slightly weakens the intensity of the white lights, and improves the projection.

The annexed diagram illustrates the means for carrying out the invention.

The screen A, of transparent but dull material, lined or not with a slightly smoked glass sheet, constitutes the translucent front face of a dark chamber B, whose other, opaque, faces are formed either by a darkened cabinet, or by bellows or other casings, or

in any other manner: the lantern placed at C projects the images on the screen A, which makes them visible to the spectators situated at D.

This device thus enables the spectators to be in full light, the dark chamber alone sufficing to give the projections the necessary strength. Antoine Jacques Michel Poch (engineer) and Prosper Jacques Pierre Poch (banker), of 16, Boulevard Saint-Denis, Paris, France.

New Trade Names:

ALLIANCE (LABEL DESIGN).—No. 312,008. Photographic dry plates and films and all other photographic goods included in Class I. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers, and films. April 5, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Soft Water and Lead Pipes.

The following note appears in "Photography and Focus" for May 18: "That the pipes through which it is conveyed may contaminate water is well known. Many photographers have traced black spots on their prints to particles of iron in the water, particles derived from the metal pipes through which it has been supplied. It is not so generally known, perhaps, that while lead or 'compo' pipes will serve very well for hard water, they are not suitable for soft water, which dissolves the metal and rapidly corrodes them. The explanation of this is a curious one. Hard water contains sulphates and carbonates, which soon form a protecting crust on the inside of the pipes, this crust consisting of lead carbonate or lead sulphate or both, which salts are insoluble in the water. Soft water, on the other hand, contains air, which forms lead oxide on the inside of the pipes, which oxide, being slightly soluble in the water, is dissolved, leaving a fresh surface of the metal to be attacked. It is well to bear this fact in mind in settling upon the pipes for the water supply of the dark-room."

Art and Photography.

Photographers must needs learn about art (says a writer in the "Bulletin of Photography" for May 5) both inside and outside their studios. What we mean by that is that photographers, as a

rule, even those who are known as artistic photographers, are too apt to study art through the one eye of their cameras instead of studying it through the two eyes in their heads. They get so used to the photographic rendering of certain effects of colour, light, and shade that they forget to look at them with the eyes of an outsider, and get to regard the photographic rendering as right because the lens and camera produce it so. It would be well for every photographer who wishes to keep ahead to join some art class or school and study art independently of photography, as well as studying those books which are devoted exclusively to art photography, and to learn to look at it from an outsider's point of view.

This advice will, we know, be particularly irksome to those who always want to go the quickest way to work, and who, unless they see some immediate advantage in it, will not care to try it. But there is no short or royal road to knowledge, and experience must be gained by long and often irksome effort.

Orthochromatic Plates in the Studio.

One can easily understand (writes Mr. Charles R. Ogilvie in "Camera Craft" for April) that a better rendition of flesh tones and shadows therein will result from the use of colour-sensitive plates. White drapery and flesh tints will retain in the negative their relative values. The steps of gradation will be greater, and, of course, more roundness secured. Slight, almost imperceptible, patches of yellow or red, such as are present in almost every face, do not come out as spots of soot in the negative. They are rendered as the eye sees them, barely perceptible. The retouching is minimised accordingly. Different fabrics have their individual depth of tone. Velvet looks as such, not as if it were a metal surface with strong highlights and coal-black shadows. Still another great advantage lies in the uniform good results with any reasonable exposure. An ordinary plate and short exposure gives a certain result, because some colours are rightly exposed, while others have been sadly under-timed. With the correct colour plate every shade and colour takes the benefit of the latitude of the plate uniformly.

New Books.

"Observing and Forecasting the Weather. Meteorology without Instruments." By D. W. Horner, F.R.Met.Soc., etc. Second edition. Price 6d. net. (Witherby and Co., London.)

A second edition of this book is before us, and though it contains nothing of a photographic nature, yet there is much in it useful to photographers. The weather is certainly a matter of moment to them, and they will find a perusal of Mr. Horner's little treatise both interesting and profitable. It contains several good photographic illustrations of snow, frost, and fog effects, the frontispiece, "Above the Fog in Long Mynd," forming a very striking picture.

"Barnet Handbook." No. 4. "Barnet Ortho Plates and their Use." (Messrs. Elliott and Sons, Ltd., Barnet.)

Messrs. Elliott and Sons, Ltd., send us a copy of their latest handbook, No. 4, entitled "Barnet Ortho Plates and their Use." This is a brief and clearly written little booklet on orthochromatic photography, coupled with a price list of plates and screens, its object being, as stated on front page, to help beginners by telling them how to avoid mistakes, and how to select and use the right kind of plates. Dealers are supplied with a stock of these books for distribution among their customers, while a copy will be sent direct to any applicant on receipt of stamp to cover postage.

PHOTOGRAPHIC TRADE IN BRAZIL.—All the best known brands of photographic dry plates are finding a market in Sao Paulo. Although the total demand for this class of goods is not yet very heavy, by judicious pushing and advertising new brands easily find a sale here. An Austrian representative came out recently and did very well. The trade is principally in the hands of German importers, wholesale and retail, although of late some of the Italian firms are also introducing these articles on their own account. So says the Austro-Hungarian Consul at Sao Paulo. But surely the majority of the best known brands of photographic dry plates are of English manufacture, in which case it is pertinent to ask how it happens that the trade is principally in the hands of German importers.

New Apparatus, &c.

Studio Furniture. Sold by Messrs. O. Sichel and Co., 52, Bunhill Row, London, E.C.

Messrs. Sichel are introducing studio furniture of Chippendale design, and send us photographs of a chair and settee, the latter of which we reproduce. The price of the settee is £4 4s., while the

Chippendale Settee, £4 4s. 0d.

chair (which is of the same pattern) is £2 12s. 6d. These should form handsome accessories in the studio, where commonplace furniture is very inappropriate.

New Materials, &c.

"Cascafoam." Manufactured by the Cascade Manufacturing Company, and sold by Kodak, Limited.

This product is described as a photographic stain-remover, and a trial shows it to be remarkably effective in its action upon stains of various descriptions, whether on dishes and measures or on the hands. It is put up in tins with airtight, close-fitting covers, and is in the form of a paste of a soapy nature. When applied with a cloth or flannel—using warm water if the hands are the subject of the cleansing operations—the stains rapidly disappear. In a very short time some of our measures presented a most abnormal appearance of perfect cleanliness, and we fully appreciated "Cascafoam" as a most welcome addition to our dark-room equipment.

"Klimax" Dry Chemicals. W. Butcher and Sons, Limited, Camera House, Farringdon Avenue, E.C.

These are a series of developers and toning baths packed in a new and very convenient manner. Each carton holds three cubical packages, each of which contains the materials for making up a definite quantity of solution. On pulling a tab the cubes appear one at a time, so there is no difficulty in manipulating the carton in the dark-room. The chemicals are in powder form, not compressed tightly, but only to an extent sufficient to make the bulk conveniently small; they therefore dissolve very readily. They are very efficiently protected by two wrappings of paper and one of tin-foil. Metol-quinol, pyro-soda, and hydroquinone cartons are sold at 6d. each, and gold-toning and fixing cartons at 9d. Each cube makes about 4oz. of solution of normal strength.

Sanders' Green Stain. Messrs. Sanders and Crowhurst, 71, Shaftesbury Avenue, London.

Messrs. Sanders and Crowhurst have put upon the market a dark green stain, which anyone can apply to his own camera and tripod if he wishes to attain an inconspicuous dark finish similar to that of the Birdland camera. The colour produced on quite white wood is a very dark "invisible green" admirably suited to apparatus used by naturalists. The stain is strong, and one application with a stiff brush is almost sufficient, while two we found to give as dark a finish as we desired. It is stated that the stain will stand rain

and sea-spray without running. An obvious use for the stain is to be found with picture frames, and for them the colour is a very good one. The price is 1s. per bottle, postage 3d.

"Hydroquinone Special." E. Merck, 16, Jewry Street, London, E.C.

We have received a sample bottle of this brand of hydroquinone, which for purity of colour and for fineness and regularity of crystals leaves nothing to be desired. The name of the manufacturer is a sufficient guarantee of the quality of the preparation, the introduction of which is welcome, in view of the important part that hydroquinone plays in photographic development.

CATALOGUES AND TRADE NOTICES.

THE CITY SALE AND EXCHANGE, of 90 to 94, Fleet Street, London, E.C., have just issued an up-to-date catalogue, which is abundantly illustrated, of the apparatus, materials, and accessories which they are prepared to supply, amongst which they include the principal makes of cameras, lenses, shutters, enlarging apparatus, tripods, etc. It is impossible to describe the list, which runs to over 300 pages, in detail, but it would appear to include practically everything that the photographer, be he amateur or professional, can need for his work, and copies may be obtained post free on application to the above address.

The same firm also send us a copy of their spring list of bargains in new and second-hand goods, in which a quantity of first-class apparatus is offered at prices considerably below the original cost. This also may be obtained on application to the above address.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 22.

Handsworth Photographic Society. Excursion to Wootton Wawen.
Hackney Photographic Society. Outing to High Beech.
Southend-on-Sea Photographic Society. Visit to Epping Forest.

MONDAY, MAY 24.

Cripplegate Photographic Society. Annual General Meeting.
Southampton Camera Club. Demonstration of the Use of the Club's Enlarging Lantern. C. M. Cooper.
Marylebone Pres. Church Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

TUESDAY, MAY 25.

Royal Photographic Society. "Toning Bromide Prints." Henry W. Bennett.
Hackney Photographic Society. Negative and Print Display by G. Capper, W. A. Hensler, A. J. Linford, J. Linley, W. Rawlings, and W. H. Witts.
Kinning Park Co-operative Camera Club (Govan). Club Meeting.
Wallington Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

WEDNESDAY, MAY 26.

Sale Photographic Society. L. and C. P. U. 1909 Portfolio.

THURSDAY, MAY 27.

Handsworth Photographic Society. Demonstration—"Passe-partout Mounting." A. E. Cope.
North-West London Photographic Society. Portfolio Night.

ROYAL PHOTOGRAPHIC SOCIETY.

LANTERN meeting, held May 18, Mr. Furley Lewis in the chair. Mr. C. W. Forbes lectured to a crowded audience on "Some Ancient Abbeys and Churches of South Essex." A large number of slides testified to the industry of the lecturer, and proved that the ground covered by him is very rich in churches of a more than usually interesting character and history. The lecturer's comments kept up the interest in the subject, and doubtless the district described will soon be popular with other photographers, who will profit by Mr. Forbes's example.

MANCHESTER AMATEUR PHOTOGRAPHIC ASSOCIATION.—A crowded meeting of members was held on May 11 to see Mr. C. F. Inston, F.R.P.S., hon. secretary of the Liverpool Photographic Association, give a demonstration on oil printing. The demonstrator first gave a brief outline of the process, and then proceeded to produce several pictures by its means. He showed clearly to what a large extent the work is under the personal control of the manipulator and how printing in oil permits to a greater extent than any other photographic process the expression of the worker's own artistic individuality. The prints produced and the specimens exhibited on the

walls showed Mr. Inston to be a thorough master of his subject, and the audience followed his remarks with the keenest attention, and expressed an earnest hope at the close that it would not be long before they had the pleasure of welcoming him again to Manchester.

Commercial & Legal Intelligence.

DIVIDENDS.—Notice of intended dividends are given in the case of (1) Edgar Wilkinson, 1, The Arcade, Norwich, photographer. Proofs to be lodged with Mr. E. H. Hawkins, 4, Charterhouse Square, E.C., on or before May 25. (2) Mrs. F. P. Brown (carrying on business under the name of Mrs. F. W. Brown), Liphook, Hants, photographic chemist, etc. Proofs to be lodged with Mr. W. F. J. Hunt, Cambridge Junction, High Street, Portsmouth, on or before May 26.

A first and final dividend of 2s. 7½d. in the pound has been declared in the case of Walter George Lewis, photographer, 1, Seymour Street, Bath. This dividend will be payable at the office of the Official Receiver, 26, Baldwin Street, Bristol.

A dividend is to be paid in the case of Joseph Harriott, photographer, 10, Chapel Street, and 15, High Street, Warwick. Proofs must reach the Official Receiver (Mr. C. J. Band), 8, High Street, Coventry, by May 29.

DISPUTED ORDER.—At the Manchester County Court, before his Honour Judge Parry, Messrs. Lafayette, Limited, photographers, brought an action against Mr. Franz Bohem, Consul for Honduras in Manchester, to recover nine guineas, the price of two dozen photographs. Mr. Dehn appeared for the plaintiffs, and Mr. Oppenheim for the defendant. The plaintiffs' case was that the defendant ordered a dozen photographs of himself and a like number of his wife, and that he had declined to pay for more than half the number. The defence was that only half the number charged for was ordered. During the hearing of the case a question arose as to a conversation over the telephone, and the Judge said some day the Court of Appeal would have to decide what was evidence in regard to such conversations. Judgment was entered for the plaintiffs for the amount claimed, with costs.

NEW COMPANIES.

C. MITCHELL AND Co., LTD.—Registered May 1 by McKenna and Co., 31-4, Basinghall Street, E.C. Capital £60,000, in £1 shares (20,000 Preference). Objects: To adopt an agreement with L. O. Johnson and to carry on the business of advertisement agents and contractors, photographers, photographic and general printers, stationers, lithographers, etc. Private company. The first directors (to number not less than two nor more than five) are L. O. Johnson (permanent governing director and chairman), J. Strong, and W. Wellsman. Qualification of ordinary directors, one share. Remuneration of L. O. Johnson, £250 per annum. Registered office, Mitchell House, 1 and 2, Snow Hill, E.C.

TALBOT AND EAMER MIRALS, LTD.—Registered April 21. Capital £1,000, in £1 shares (650 Preference). Objects: To acquire the business carried on at 54, Seel Street, Liverpool, as Talbot and Eamer; to adopt an agreement with M. M. Robertson and to carry on the business of photographic manufacturers and dealers, opticians, photographers, etc. Private company.

AN HOSPITABLE ORDER.—According to the "Dewsbury Reporter," Lord Egerton of Tatton has issued orders to his cottagers not to supply refreshments. The notice sent out is a remarkable one—viz.: "Lord Egerton of Tatton will not permit any cottagers to receive any person, whatever, into their cottages for the purpose of the sale or consumption of any refreshment. Any cottager infringing this rule will get instant notice to quit. After reading this notice you will return it signed as an acknowledgment of your agreeing:—I agree to abide by the regulations contained in this notice." This notice affects the whole of the village of Rostherne, which is close to his lordship's home, and which in the summer time attracts thousands from various parts of Lancashire and Cheshire, and the Manchester district in particular. The object of this strange proceeding is not apparent, but evidently photographers must be prepared for a period of total abstinence in the village of Rostherne unless they elect to carry their own refreshments.

News and Notes.

CAMERA REPAIRS.—The Tella Company inform us that they are now making a speciality of camera repairs, which are conducted at their own works, where the Tella Reflex is made. They state the average time for repair work will be two days.

THE QUEEN'S GIFT-BOOK PHOTOGRAPHS.—The interesting photographs which appeared in Queen Alexandra's Gift-Book have now been reproduced, by special permission, in the form of picture post-cards, in photogravure, on plate-sunk mounts. The prices of the cards are 2d. each, or the complete set of forty-six cards, 7s. 6d. With each complete set is presented a full-length autograph portrait of her Majesty the Queen, in photogravure, size 11in. by 8½in. Messrs. A. V. N. Jones and Co., 112 and 113, Fore Street, E.C., have published the cards and the portrait.

THE CINEMATOGRAPH OUT OF DOORS.—A novel entertainment—a cinematograph performance by daylight and in the open air—was given on the 14th inst. for the first time in the grounds of the Middlesex Hospital. The idea of the entertainment is to provide a little diversion for the more able-bodied of the patients, but owing to the cold weather it was thought inadvisable to take the sufferers out of the building. Nurses and medical students were therefore invited to see the animated picture display, which will be repeated before its intended audience when the warm weather returns.

ANOTHER CANVASSING FRAUD.—At St. Rollox Police Court, Glasgow, William Bell, a middle-aged man, was sent to prison for fraudulently collecting money from householders on the pretext of booking an order for photographs. He presented cards bearing a close resemblance to the business cards of Mr. Drummond Shiels, Jamaica Street, the name, however, being mis-spelt "Shields." There is some reason to fear that others are engaged in this swindle, and Mr. Shiels wishes it to be known that no person on his staff is empowered to collect money away from the studio.

THE YORKSHIRE UNION.—The tenth annual meeting of the Yorkshire Photographic Union was held under clouded circumstances, due to the death of the president, Mr. Charlesworth, of Sheffield. The meeting, at the rooms of the Leeds Camera Club, was presided over by Mr. W. Bagshaw, J.P., Batley, one of the vice-presidents, and he asked for more enthusiasm on the part of the societies. Every society should have an annual exhibition, as it was a real stimulant to the members to do work, and when the time came for a greater exhibition, or a request from the Union for some fixtures, the nucleus was there.

YE OLDE NAPIER.—Ye Olde Napier Tavern, High Holborn, an old building standing on the site of a chapel, and lately the headquarters of the London and Provincial Photographic Association, was practically destroyed by fire early in the morning of May 14. The flames spread so rapidly that the occupants had to rush out into the street in their night apparel. Messrs. Henekey's wine shop adjacent was threatened, and the people sleeping in the rooms above were roused by the firemen and took refuge in neighbouring houses. The roof of the wine building caught fire, but was quickly put out, and little damage was done. While working inside the Napier Tavern Superintendent Gosling and Fireman Cook were hurt by falling wood.

A PHOTOGRAPHIC LOAN EXHIBITION.—We see from the "Eastern Daily Press" that the Castle Museum Committee at Norwich have accepted on loan from the Norwich and District Photographic Society a selection of the prize prints which won the East Anglian award at Ipswich. The collection includes the work of Mr. and Mrs. Edward Peake, the former of whom won the affiliation plaque for 1909. Mr. W. L. Clutterbuck is also represented, with numerous other workers. These photographs are hung on a temporary screen, which has been placed in the water-colour rooms. The museum is open free to the public from 10 a.m. till 5 p.m. every day, with the exception of Tuesdays and Fridays, when a charge of 3d. is made. The museum is also open on Sunday afternoons from 2.30 until 5 o'clock.

INTERNATIONAL PHOTOGRAPHIC CONGRESS.—An International Congress of Applied Photography will be held in Dresden in July, 1909. The Committee of Organisation includes Prof. Miethe, of Berlin; Prof. Eder, of Vienna; and Prof. Luther, of Dresden. The lectures to be delivered on all branches of applied photography, while of

scientific character, will be adapted to general comprehension. Since the International Photographic Exposition at Dresden from May to October, and the jubilee of the University of Leipzig the latter part of July, will bring many visitors to Saxony, the Congress will probably attract attendance from all over the world. The Society for the Promotion of Travel will afford all possible assistance and information to those attending the Congress. Explicit information on all points concerning the Congress may be had from Dr. H. Weisz, Dresden—A., Winckelmannstr., 27.

RIVER POLLUTION BY PHOTOGRAPHIC WORKS.—At the meeting of the Thames Conservancy on Monday the River Purification Committee reported that a notice was served on the Uxbridge Rural District Council in respect of the pollution of the Frays River by the effluent from the settling tanks and filters constructed to deal with the trade refuse from the Rotary Photographic Works at West Drayton, and by the discharge from a 12in. surface water drain situated immediately above the filters. On the expiry of the notice on November 12 last it was found that certain measures had been taken with a view to dealing with the pollution, but as these were ineffectual proceedings were instituted against the Council. An adjournment of the summons was granted, however, pending a meeting between the Council's surveyor and the Conservator's chief inspector.

THE BOLT COURT SCHOOL.—We learn from the "City Press" that, in a report to the Education Committee, the Accommodation and Attendance Sub-Committee state that on various occasions they have had under consideration the question of the unsuitability of the accommodation now provided for the L.C.C. School for Photo-Engraving and Lithography. The present buildings in Bolt Court, which are rented on a yearly tenancy of £300 by the Council from the City Parochial Foundation, are cramped, likely to be very dangerous to life in the event of an outbreak of fire, and altogether quite unsuited for continued use as a technical institute. They have considered the merits of various sites and buildings, and have come to the conclusion that the existing site is by far the most suitable. It is situated in the centre of the photo-process trade, and the position of the school is now very well known to employers. Further, the cost of erecting a new school on the site would be very little more than the cost of a building on any other site in the same locality. It may be possible to arrange with the freeholders, the central governing body of the City Parochial Foundation, to acquire the whole of the site at a price which the Council could be advised to accept. The estimated cost of erecting a suitable building on the site would be about £20,000. The Sub-Committee have been instructed to report as to the steps necessary to acquire the site for the erection of new premises.

A MAGIC PORTRAIT (?)—The "Daily Chronicle" records the following, naïvely commenting that the facts are remarkable, and the interesting phenomenon will probably arouse much interest in photographic circles:—

"Quite unconsciously a Kentish Town lady has taken a portrait of herself without the use of a camera.

"What apparently happened was this. The lady, wearing an ordinary pair of spectacles, was reading the other evening about the hard lot of Mr. Milton Wellings, the composer, whose famous song, 'Some Day,' is fraught in her own case with many painful memories.

"Behind her, on the table, was a small paraffin lamp, which threw a light over her right shoulder. As she read, a tear stood in each eye. Almost simultaneously the lens in the line of the lamplight became blurred. She thereupon removed her spectacles—to find the blur an excellent snapshot of herself in profile.

"The lady has been interviewed by a representative of the 'Daily Chronicle,' and the spectacles have been submitted to a well-known oculist for examination. He was unable, however, to express any definite opinion as to the process by which the picture appeared on the right lens. He suggested that tears may have trickled down the lady's cheek on to the lens, and that in wiping it she had unconsciously caused the formation now upon it.

"In regard to this suggestion, the lady declares emphatically that no tears trickled down her cheek, and that she made no attempt to wipe the lens. Moreover, when she is wearing the spectacles there is an appreciable space between her cheek and the lower rim of the lens, so that it could not catch any falling tears."

Apparently the mystery is not yet solved, at least not to the satisfaction of the lady.

Correspondence.

- We do not undertake responsibility for the opinions expressed by our correspondents.
- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

"ANOTHER ETCHING MACHINE."

To the Editors.

Gentlemen,—I notice in your journal there is a slight error in your account of "Another Etching Machine"—viz., it is the invention of my son, Harold Holt. I enclose you the specification, which kindly return at your convenience. I should be glad if you will be kind enough to correct this statement in your next issue, and oblige.—Yours, etc.,

W. HOLT.

May 14, 1909.

PHOTOGRAPHERS AND THEIR ASSISTANTS.

To the Editors.

Gentlemen,—As I believe that the topic of this letter will prove of interest to many photographers and their assistants, I hope you will grant it the hospitality the correspondence columns of your valuable paper afford.

A friend of mine had the misfortune to personally answer an advertisement for "a good retoucher who could take charge of studio when necessary," and after having satisfied the manager of the firm as to his qualifications, he was offered 30s. a week on condition to work from 9 a.m. to 9 p.m., and every alternate Sunday.

When my friend had recuperated from the shock, he ventured to opine that this would mean literal slavery, and that he would not accept such terms for double the salary; so the manager good-naturedly smiled and said that they could get all the hands they wanted, and before long "even the best assistants will be glad to work for us under these terms, for in whatever district we establish ourselves no other photographer can exist very long—he must either pack up or get broke."

For obvious reasons, my friend did not want to have his name published; therefore I have undertaken to write this letter, and I hope that every photographer's assistant, and even some employers, will think it nigh time to do something that will prevent these sweaters from exploiting the poor assistant and from ruining the fair trader.—Yours, etc.,

A. REDMOND,

Process Photographer's Assistant.

4, Mildmay Grove, N.
May 14, 1909.

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen,—A perusal of your valuable and very complete article on the "Speed of a Focal-plane Shutter," in last week's issue, certainly seems to confirm my original remark that the subject in all its bearings is undoubtedly complex. I read that the definition of "speed" given fully allows for the vignetting alluded to in my letter of the 23rd ult., but I do not see how this can be the case. Mr. Stokes points out that the extent of such vignetting, practically speaking, cannot be considered apart from the luminosity of the object photographed. Quite so. If there is anything at all in the point raised, then for equal "speeds," as defined by you, there may be variable amounts of blur purely dependent upon variation in brightness of a rapidly moving object.

I note that you state that "the light effect should be fairly uniform over the plate, even though oblique pencils may be vignetted by the lens mount, and the efficiency thereby increased (not decreased, as stated by Mr. Salt) towards the margin of the plate." Please accept my thanks for the correction, which unfortunately loses some of its force owing to the fact that I never made the statement alleged, or in any way dealt with the particular point raised.

The paragraph, as it stands, is somewhat ambiguous, though its meaning is evident. It is also a little paradoxical. No doubt the efficiency of the shutter increases under the conditions given, as the slit traverses the margins of the plate. It logically follows that the more the oblique rays are obstructed by the lens barrel the higher the efficiency of the shutter. If the rays were altogether stopped,

from a purely mathematical standpoint would it be unreasonable to assume an efficiency of 100 per cent?—Your faithfully,

Sanderstead, Surrey.

E. A. SALT.

[We fear we do not quite follow the argument with regard to the vignetting effect. The case we considered was that propounded by Mr. Salt in his lecture ("B.J.," page 289). Here it is evident that the point F is reached by light for a time equal to that required for the slit to travel twice its own width. For only one moment is F exposed to the full aperture of the lens, and for all the rest of the time it is reached only by light that is cut down by vignetting. This affects efficiency, and is, of course, the factor governing efficiency, but we cannot admit that it has any practical effect on duration. With regard to Mr. Salt's second point, we were certainly under the impression that he made this suggestion in his lecture, but our memory seems to have been at fault, for which we apologise. As to his last point, we do not think his assumption at all unreasonable. There would, of course, be no light, but that is another matter. We are not, however, prepared to enter in a discussion that involves the consideration of the infinitely small.—Eds. "B.J."]

CHROMIUM INTENSIFICATION.

To the Editors.

Gentlemen,—I note in your issue of March 26, page 252, "Chromium Intensification." I would point out, as a result of some experiments I made some considerable time ago, that the degree of intensification obtainable appears to depend very largely on (a) the amount of washing before development, (b) the composition of the developer used. Prolonged washing before redevelopment gives but slight intensification. Rinsing for a few moments before redevelopment gave the greatest degree of intensification.

The hydroquinone metal developer gave less intensification than the pyro soda, but doubtless by varying the composition of these developers different results will be obtainable. Over-exposed and under-developed negatives which are thin and unprintable can be rendered crisp and contrasty by this method. By a variation in treatment, negatives can be (a) reduced, (b) reduced in contrast using the same solutions. I am of opinion that staining is caused principally by imperfect washing before bleaching—i.e., trying to bleach negatives which have not been well washed.—Yours truly,

Rue des Alpes, La Tour-de-Peilz.

EDGAR SIMPSON.

May 13, 1909.

SUNLIGHT IN STUDIOS.

To the Editors.

Gentlemen,—As an old reader of your paper for the last thirty years perhaps you will excuse me taking the liberty of writing to you on a subject which I see very often in the column "Answers to Correspondents"—"How to stop the sun in the studio." We are not all able to get studios with north light. My studio is built due east, so I have the sun to contend with every morning. I tried all kinds of dodges, but I found with a great many of them that I lost a certain amount of light which is very valuable in the evenings. But I am glad to say that I have overcome the difficulties by adopting the following method. I generally buy a quire of the best white tissue paper, threepennyworth of castor oil, and half-pint of petroleum. For use I take equal parts of each. Get all the papers ready laid on each other, after having cut them to the size required, then brush them over with the above solution. But before putting it on the glass see that it is clean, and also gum the edges of the glass so that the paper will stick. This method gives a very transparent paper and no loss of light, and also the papers will keep white for the whole season. I have adopted this method now for years and find it answers all that is required.—Yours truly,

D. G. THOMAS.

25, Chester Street, Wrexham.

AN ELECTRIC DEVICE FOR FIRING A FLASHLIGHT.

To the Editors.

Gentlemen,—I was interested in reading Mr. D. W. Gawn's letter in last week's "Journal," p. 390. I refer particularly to the latter part of same, where he recommends a sparking-plug for igniting flash powder. I am able to say that the ideal plan is splendid, but it will not work. About a month ago I was commissioned to photograph a large dramatic group of amateurs. I had the same idea in every detail as Mr. Gawn, but I happen to possess a small motor

car, so that I had all the appliances at hand. I hunted up a spare sparking-plug and coil and a four-volt accumulator, and connected them up with the switch exactly as Mr. Gawn suggested in his letter, and, having flash powder, I put some around plug and switched on, but there was no powder ignited. I could see a good spark. I could also see the powder had been driven away from the points of plug into a hollow around same. I then took the plug and dipped it into small heaps of the powder; it would not allow the powder to be anywhere near it. I then disconnected the coil and put in a fuse wire in circuit with the accumulator with a switch. I then put a rather large heap of powder covering the fuse wire, and switched on and found the fuse was burnt off, but none of the powder ignited. I tried again, and found that if I passed my finger over the top of fuse wire so as to leave the top of the wire exposed to the atmosphere, it would explode the powder every time.

I have no doubt Mr. Gawn is a good electrician, but I do not think that he has tried the experiment he recommends, or he would have found a surprise.—Yours, etc.,

JOHN BELL.

Frome.

May 18, 1909.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

E. Saville, 1, Schofield Street, Mexborough, Yorkshire. *Four Photographs of Win. Hague, known as "Ian" Hague, Champion Boxer.*

H. Greenway, 27, Abington Street, Northampton. *Photograph of the Northants Cricket Club and Australians.*

EXCELSIOR.—You cannot do better than apply to the firm you mention, who manufacture the particular substance. The address is Messrs. Hopkins and Williams, 16, Cross Street, Hatton Garden, E.C. We cannot give you prices, but they will no doubt do so by return post.

STAINED NEGATIVE.—We should be greatly obliged if you could tell us of any method of getting rid of stain on plate enclosed herewith. It is several years old, and mark is due probably to its not having been washed sufficiently.—**PERPLEXED.**

We think that yours is probably the true explanation of the stain, and fear that the case is hopeless. Bleaching in potassium bichromate and hydrochloric acid, followed by redevelopment, will sometimes improve matters, but in this case the negative has been retouched, and any chemical treatment will possibly ruin it. We suggest that retouching is the only remedy.

STEREOSCOPY AND AUTOCHROMES.—1. I have been taking Autochromes with a little stereoscopic camera, size 107mm. by 45mm. Is it necessary to cut the plates and reverse the two pictures right and left, and, if so, why? The picture opposite the right eye is the one taken with the right lens, and that opposite the left eye the one taken with the left lens, and I concluded, therefore, that cutting the plates and reversing the pictures was unnecessary, especially as the pictures, being taken through the glass, are, on the film side, each in itself correct as regards right and left. On looking at the views so taken in an ordinary stereoscope—the lenses of which are, of course, more widely separated than the lenses of the little camera—the images blend and only one is seen. But I am puzzled by the appearance presented by the planes of the view. The objects in the middle distance stand out in relief in front of the objects in the foreground. I should be much

obliged if you will be good enough to tell me in the "British Journal" why this is and how it may be avoided. 2. I use, for developing, the Lumière Company's new Quinomet formula, and find it an inconvenience to work out for each degree Centigrade the alterations in the total time of development called for by variation of temperature. Can I use the Watkins time developer with the same results as the Quinomet, and can it be used for the second development as well, and if not, can rodinal? 3. A friend who works Autochromes tells me that he *always* intensifies. My positives, erring probably on the side of under-exposure and possibly under-development, are quite strong, and do not seem to need any intensification. Would not intensification add to the already sufficient strength, or would it improve the colours also? 4. I am a bad hand at flowing varnish over a plate, never having been in the habit of varnishing my negatives. Ridges form on the plate when I flow over it the Lumière Company's varnish. Can I apply, with a brush, celluloid dissolved in amyl acetate, in what proportions, and with what kind of brush?—**TIRESIAS.**

1. The mistake you have made here is a very usual one. The uncut stereoscopic Autochrome corresponds to an uncut transparency printed direct from a stereoscopic negative, and it shows pseudoscopic relief in just the same way. In a properly cut and mounted stereo slide you will find that the two images of a near point are closer together than those of distant points, but if you apply the same test to the uncut print you will see that the near points are farther apart. This is the cause of the effect. If you want to avoid cutting it is a good plan to expose two lantern plates side by side and then mount the two in proper relative positions on a cover glass. 2. It seems to us that the working out of the variation is no more difficult with the Quinomet developer than with any other, but you might use the Watkins thermo-indicator with Quinomet to save trouble. To do this you must find the right time for one temperature by experiment, and then use the scale to adjust for variations. The developers you mention can certainly be used, but the Quinomet being especially adapted to the plate will probably give more satisfactory results. 3. The Autochrome plate, as now made, does not always require intensification, but in our opinion the early plates were always the better for it. Intensification brightens colour as well as adding to the strength. 4. We prefer the celluloid dissolved in amyl acetate to any other varnish. It must be made with amyl acetate only, no spirit being added. There is no need to worry over proportions. Make a thick syrup by adding cut-up films to amyl acetate, and then for use thin down with more amyl acetate until of convenient consistency. It can be applied with a brush, but flowing is best. This varnish does not give ridges very readily, as it dries rather slowly. If a brush is used it should be a big soft camel-hair brush. It can be cleaned in spirit, but after cleaning it must not be used again until the spirit has completely dried out.

DUPLICATE NEGATIVES.—I have several negatives—half-plate—of churches in Cornwall. I wish to sell duplicates of them. What price is reasonable to ask? I should make the duplicates by reversal process, so that only one plate is required.—**NEG.**

A reasonable price would depend a great deal on the quality of the negatives, which would probably not be very high if they were made by a reversal process. Your question is one that you should be better able to answer than we are, as you know the cost, the subjects, and the possibilities of sales.

PHOTO-MECHANICAL PUBLICATIONS.—Would you be kind enough to state, in the valuable columns of the "B.J.," names of a few weekly and monthly papers or journals on photo-mechanical, photo-lithography, or half-tone work?—**INQUIRER.**

The following list should meet your requirements:—"Process Engravers' Monthly," 6d., Dawbarn and Ward, Ltd.; Penrose's "Process Work," monthly, 1s. per annum; "Modern Lithographer," monthly, 4s. per annum, published by the proprietor, at 119-125, Finsbury Pavement; "American Photo-Engraver"; "The Engraver and Electrotyper" (American); "The American Inland Printer" also publishes every month a page of photo-mechanical notes; French "Le Procédé," published by H. Calmels, 150, Boulevard du Montparnasse, Paris; German "Zeitschrift für Reproduktionstechnik," 16s. per annum.

FLASHLIGHT.—We find there is a practically smokeless powder for flashlight being used, and as we have tried most on the market

which are not smokeless, and have a difficulty in finding the powder in question, we shall be glad if you can assist us.—**ENQUIRER.**

We cannot tell what particular powder you refer to, as there are so many "practically smokeless" powders. We do not know of any powder that is absolutely smokeless, and it is quite impossible for us to say which of the numerous powders available gives the least smoke. Perhaps some of our readers can help you. But why not make direct inquiries of those you know to be using the powder in question.

RETOUCHER.—Your retouching is merely second-rate, lacking in modelling and general finish; but a few postal or personal lessons from a really skilled teacher would soon make a great improvement in your work, and enhance your value as a retoucher.

S. T.—1 and 2. Yes, by Oscar Hermann Stendel, Dornblüthstrasse, Dresden. No. 10,051, 1906. See "B.J.," November 9, 1906. 3. The only complete list will be the Abridgments published by the Patent Office at 1s. per volume. Five volumes of this publication cover about twenty years. For thirty years back you want the last seven volumes. You can obtain them by writing to the Patent Office.

REFINING SILVER AND GOLD.—We find the pure silver, as sold in the market, contains traces of copper, and the gold of silver. We shall feel obliged if you will kindly inform us the method of removing these traces and getting the metals chemically pure for photographic purposes, through your valuable journal.—**S. M. AND SON, India.**

To remove the copper from the silver dissolve in hot dilute nitric acid, filter, and then precipitate the whole of the silver by adding more copper. Copper wire twisted into a spiral may be put into the solution and left until no more dissolves. The wire will require brushing occasionally to remove the silver that adheres to it. Afterwards let the silver settle and pour off the blue solution of copper nitrate, fill up with water, stir well, allow to settle again, and then decant off the water, repeating this series of operations until the water contains no trace of copper. The remaining residue should be pure silver. The gold can be treated by dissolving in hot nitric and hydrochloric acid and filtering off the yellow solution which contains the gold only. About three parts of hydrochloric acid to one of nitric will be required, but the best proportions vary with the relative amounts of gold and silver present. The gold can be recovered from the solution in the form of powder by precipitating with iron, or the solution can be evaporated down until it crystallises. The gold chloride thus obtained should be dissolved in distilled water, and recrystallised if it is to be used for photography.

SOLE RIGHTS.—We are applying for the sole photographic rights on the occasion of a Royal visit in June next, and we should like your opinion on the following points:—1. Would the sole right preclude papers such as the "Mirror" or "Graphic" sending down men for pictures? 2. Would it stop amateurs from sending snapshots (we presume we cannot stop them using hand cameras) to the papers? If they do so, whom could we recover compensation from—the paper or the amateur? 3. Again, if any pictures not taken by us are published in, say, postcard form can we claim the copyright or compensation, or would all these matters have to be fought out between ourselves and the committee? 4. Some of the papers, such as the "Stockbreeder" and similar journals, send their men down with small cameras with which they take the prize stock, these being used to illustrate the next issue. Can we stop this kind of thing if it is done whilst the show is on, if we have the sole right? 5. What would you consider would be a reasonable price to offer? There will be, of course, the usual snapshots of the proceedings with the Royal party in them, and possibly an arranged group. There would be a demand for postcards, and also copies of the groups, besides the press illustrations.—**LEGAL.**

1. It would not preclude the papers sending men down, and it would rest with the authorities and you to prevent them from obtaining the photographs. 2. No. If they succeed in securing pictures they will have the right to send them to the papers if they think fit. You will not be able to obtain compensation from either the one or the other, as, although you may get the "sole rights," there is no copyright in the scenes. 3. As just said, there is no copyright in the scenes, so you cannot claim compensation under the

Copyright Act. Unless you can show that the committee were negligent in not preventing the pictures being taken we expect you will get nothing. 4. Only by preventing them by obstruction or otherwise from using their cameras. 5. You can certainly better estimate the value the concession would be to you than we can. We do not reply to correspondents by post. See also page 394, where we deal with the same subject.

STORING RAIN WATER.—I lately bought a galvanised iron cistern (new), and after a thorough scrubbing, filled it with clean, clear rain water. After standing a week or two I find the water clear, but a copious heavy flocculent deposit on the sides and bottom. Would you kindly tell me if you think this is due to any chemical action? I enclose a specimen of the deposit. When wet it is of a blue-grey colour and is fairly heavy. Is the clear water likely to be unfit for photographic use?—**W. C. C.**

The cleanliness of rain water depends on the manner in which it is collected, and it looks as if your water has taken up some impurities on the way to the cistern. If these impurities have been precipitated by the metal of the cistern, then the clear water left is probably quite good enough for use, though the cistern may be damaged. We should clean out the cistern again, using water only for the operation, and then refill. If the water supply is quite clean possibly the effect will not occur again. If it does, we should test the water. A well galvanised cistern should have no effect on clean water, but it can easily be attacked by impure water, and if the zinc coating is eventually destroyed you will have trouble with iron spots, etc. You can prevent any such effect by painting the cistern with a good bath enamel, but this will, of course, not help to purify the water.

LENS FOR COPYING.—Would you kindly advise me what kind of a lens I should require for ordinary copying purposes, say for enlarging from C.D.V. to cabinet?—**BEGINNER.**

A good rectilinear or (preferably) an anastigmat of 7in. or 8in. focal length should do all you require.

O. BAINES.—We are not sure that plain salted paper as used in the days of old is an article of commerce at the present time, though papers giving results similar in appearance are on the market. Failing to get it ready salted, the formula you enclose would be as good as any if used with Saxe paper.

LENS.—Not long ago I bought a lens at a pawnbroker's for 10s. It bears the name of J. H. Dallmeyer. The back glass is larger than the front one, and between the two there is a much smaller one. It gives a very sharp image on the focussing screen, but not so brilliant as my R.R. by the same maker. Can you tell me anything about this form of lens, and what purposes it is made for, as no one who has seen it can enlighten me on the point. The diameter of the back glass is about 2½in.—**HANTS.**

The lens is the old form of triplet, and is a very useful instrument. We are not sure that it is made now, as it was superseded many years ago generally by the Rapid Rectilinear, which has a larger aperture, and, consequently, is quicker acting. The aperture of the triplet is about $f/10$, while that of the R.R. is $f/8$. On reference to an old price list of the maker's, we see that the lens with back glass the same size as yours has a focus of 15in., and is intended for 12 x 10 views.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Dresden Exhibition. The first part of the review of the scientific section of the International Exhibition at Dresden commences on page 417, and deals with the exhibits relating to teaching, the detection of crime, balloon and military photography, and the use of the camera by librarians, in scientific laboratories, and for illustrative purposes.

The section of photographic chemistry in the Congress of Applied Chemistry, which opens to-day (Friday), meets under the presidency of Sir William Abney. About thirty papers are down for reading. (P. 412.)

A note on the method employed at the National Physical Laboratory for the measurement of both efficiency and speed of shutters appears on page 414. A description of the method is shortly to be read before a learned society.

A note by Mr. W. Thomas on page 421 describes the simplest and best way of removing the wrappings from a box of plates when the latter have to be re-packed after exposure.

The conclusion of a recent paper by Dr. C. E. K. Mees and Mr. H. Wratten appears on page 422. In it are described the properties of the principal dyes used in making light-filters for orthochromatic and three-colour photography.

Two further methods of preparing screen-plates for colour photography, in neither of which registration is necessary, are described under "Patent News." (P. 425.)

Among other topics in "Photo-Mechanical Notes," an alternative method of placing the back of the camera parallel with an original when working away from the "process" studio is given. (P. 425.)

A recent paper before the Royal Dublin Society by Mr. E. E. Fournier d'Albe deals with the method of making positive copies direct from drawings, etc., by utilising the light reflected from the original on the lines first adopted by the late Mr. Hort Player. (P. 420.)

Mr. Gustav Dietz, in "The Camera," suggests how a lens of short focus and very large aperture may be usefully obtained from one of such longer focus by means of a couple of supplementary glasses. (P. 414.)

Some of the many matters which go to make the studio of the photographer comfortable and attractive in appearance are dealt with in an article on page 416.

EX CATHEDRA.

The Chemical Congress. As already announced, the meetings of the International Congress of Applied Chemistry made a formal commencement yesterday, but business begins in earnest to-day (Friday). The meetings of the photographic and photo-chemical sections are held in the physical lecture theatre of the Imperial College, South Kensington, being held from 10 to 1.30 to-day (Friday), and from 10 to 1.30 and from 4 to 6 on Monday and Tuesday next. It is intended to take the more technical papers in the mornings and lectures of more general interest in the afternoons. Mr. Chapman Jones, the secretary of the section, informs us that some thirty papers are to be read, and the meetings should prove of exceptional interest. On Saturday morning the members of the section will visit, at their individual choice, either the Bolt Court School of the London County Council or the Regent Street Polytechnic, by invitation of Mr. A. J. Newton and Mr. Howard Farmer respectively.

* * *

Effect of Washing with Chromium Intensification. In our last issue a correspondent, Mr. Edgar Simpson, referred to the fact that in chromium intensification the amount of density gained is very little if washing is too prolonged before re-development. This we also have found to be the case, and the reasons for it seem to be somewhat difficult to understand. As the result of very much prolonged washing plates have been known to become quite undevelopable, and this complicates the matter somewhat. To a certain extent the diminished intensification may be due to the decomposition of the chromium compound upon which the effect of intensification mainly depends; also, if the washing is conducted in the light over-exposure or "solarisation" may, and probably does, tend to prevent subsequent development. Lack of density may then be due either to a change in the chromium deposit or to incomplete development. These two factors, however, do not appear to be sufficient to explain all the facts observed. We understand that the phenomenon in question has recently been investigated in connection with another process, and that the results, which will shortly be ready for publication, show a third cause of a very unexpected nature. Possibly when details are available further light will be thrown upon the intensification problem.

* * *

Cinematograph and History. It has been recently affirmed by a promoter of an exhibition that "There is no limit to the possibilities of the cinematograph as an educational factor." He is no doubt quite right if desirable and undesirable possibilities are taken together. When one considers the difficulty of reconstruct-

ing episodes of history so as to eliminate the anomaly, the anachronism, and the solecism, there seems to be some demur as to the statement that it will be easier to make clear to a child's mind the story of Magna Charta if it is shown on the screen while the teacher is explaining it. In the first place, the cinematograph is nothing if without action in its pictures, and action full and free at that. We can imagine all the actors and supers in the display doing their best according to their lights in this direction, and if a little educational enthusiasm be allowed for the operator who puts the film through, we can imagine, further, a lively knock-about scene between John and the barons which would afford the youngsters much more delight than precise information. Our writer instances also such episodes as King Alfred "seen actually burning" the cakes. That promises some effective by-play for the old lady whose hospitality and pastry was abused. But really, is this history? Do not children fasten on to this and similar incidents quite disproportionately already, and is there any need to spend time and energy upon such amusements? History is something more than a string of tales, nine-tenths of which are unauthenticated. But enthusiasm knows no bounds. "The boy stood on the burning deck," it is stated, "is merely a phrase as it stands. On the cinematograph film the incident becomes an example of heroism." Well, in our humble opinion this is a case where the least imaginative child could make more of the "mere phrase" than he could of a bioscope presentment of such an obviously faked-up scene, which would certainly either send him into fits of terror, or else invoke the barbaric glee of Guy Fawkes Day.

* * *

The Uses of Supplementary Lenses. As a general rule, supplementary lenses are only used for the purpose of varying the focal length so that we may obtain sharp images of near objects with fixed-focus cameras, or larger images of distant objects when the camera is a focussing one. In the one case we add a lens to shorten the focal length, and in the other one to lengthen it. Incidentally, such an addition must cause the f value of the aperture to alter, but this alteration is seldom taken into consideration; that is to say, we seldom add a supplementary lens for the express purpose of altering the relative aperture. In "The Camera," Mr. Gustav Dietz suggests that at times this alteration of aperture is a very useful feature. He points out that if we add a 16-in. lens to both back and front of a 9½-in. lens working at $f/6.8$, then the focal length is reduced to about 4½ in., and the aperture increased to $f/3.5$, or thereabouts; and he gives excellent examples of photographs obtained with this very rapid combination. It is obvious that the use of supplementary lenses for this purpose may at times be very advantageous, therefore the effect produced upon aperture is one not to be disregarded. The corrections may be disturbed to a certain extent, but in the examples given there is little fault to find with the definition. Any way, it is better to put up with a little loss of definition if the only alternative is no result at all, which may easily be the case if the light is bad and the exposure very short. In the case quoted, the increase of rapidity is 3½ times, which, of course, may make just the difference between a passable and a useless result.

* * *

Wood Engravings. Photography has practically killed hand-engraving. Photogravure, to all intents and purposes, has taken the place of line as well as mezzotint engraving for the reproduction of paintings, while process blocks have superseded wood-engraving for book illustrations and similar purposes. It may be interesting to our readers to know that a fine collection (proofs) of wood-engravings, printed on India paper, by the Brothers Dalziel, has been presented by Mr. Gilbert

Dalziel to the borough of Hampstead. There are some 250 of them, and they will form a permanent exhibition at the Hampstead Central Public Library in Finchley Road, where they can be seen by anyone. Many of the present generation have but little conception of the excellence to which wood-engraving was brought by our best men, and they will do well to pay a visit to the collection of prints now at Hampstead. Artists much regret that photogravure has killed line-engraving as well as mezzotint-engraving, for there is no gainsaying the fact that there is an excellence and charm about a fine line-engraving, or in a mezzotint, of a painting that we do not get in even the best photogravures. Yet the old engravers have died off, and there are none to take their places, simply because, in face of the perfection to which photogravure has been brought, the future prospect was not sufficiently encouraging to younger men. The way that the works of the old engravers are prized at the present time is evidenced by the prices they realise at auction sales. Will photogravures in the distant future ever fetch anything like such sums?

* * *

Measuring the Efficiency of Shutters. It is often stated that what we want to know with regard to a shutter is the efficient exposure, not merely the duration.

This is not always the case, as we pointed out recently when referring to the focal-plane shutter, but, still, a knowledge of the efficiency is often a very desirable thing. Unfortunately, however, it is not an easy thing to determine accurately, excepting in special cases. We can measure the duration pretty easily, but unless we assume a constant rate of movement for the shutter, and a shutter aperture of simple and invariable shape, we cannot measure the exact efficiency without indulging in complexities. At the National Physical Laboratory the method employed appears to be the only one that can give accurate results. The area of the aperture is measured at definite intervals of the exposure, and from these measurements the efficiency is calculated. Obviously this is not a simple operation. For practical purposes, however, we do not want to compare shutter with shutter, but different settings of the same shutter with one another, and, therefore, the simpler methods commonly adopted, such as Mr. Salt's method, for example, are often capable of giving very useful information. In some cases the assumption of uniform speed is quite warrantable, as, for example, in the case of a focal-plane shutter with narrow slit, and then we can arrive at a near approximation to the truth with a minimum of calculation. But when dealing with a lens shutter with an opening of irregular shape the matter becomes very complex, and so also does the method of measurement. We understand that full details of the N.P.L. methods will be published before long, and the description will doubtless form a very valuable addition to the literature on the subject of shutters.

* * *

Some Stereoscopic Matters. We see that in a contemporary Mr. W. I. Chadwick criticises some of the statements in "Stereoscopic

Facts and Figures," given in the "Almanac." First the one "use light or dark mount according as subject is lighted from front or back." He advises dark mounts in all cases, and remarks that according to our advice, "as the majority of subjects are lighted from the front the mostly light coloured mounts are to be used." But we do not agree that the majority of subjects are lighted from the front, and do not favour the general adoption of light mounts any more than he does. We have, however, found that in some cases light mounts give a distinctly better effect than dark ones, and consideration of the conditions led to the advice we gave. A stereoscopic

view is essentially realistic, and any small matter that looks not quite reasonable spoils the effect to some extent. As a rule, the mount is visible, and the effect produced is that of looking at the subject through an aperture in a screen. If the object is a near one photographed indoors, and is strongly lighted in front, perhaps by a window behind the operator, an actual screen existing between the subject and the camera will also be lighted in front, and if we use a very dark mount an anomalous effect is produced that is often disturbing. To us the dark mount only gives a quite satisfactory result when the existence of a dark screen is perfectly natural, and the abbreviated rule we gave is a very useful guide to deciding upon the right tint of the mount. With a number of general outdoor subjects the dark screen is perfectly reasonable, for many of these views might easily be views seen through an open window, but with others it is not reasonable, and then the safest course is to select a tint that will satisfactorily accord with the lighting of the subject. The other criticism needs little reply. It is that we are wrong in stating that the horizon should be opposite the centre of the eyes. In nature this is the only level that it can occupy, and, therefore, any other position is unnatural. It does not follow that it must be in the centre of the picture at all. We regret to see that Mr. Chadwick deprecates the adjustable front. Apparently, he thinks it unnecessary, because nature has not provided us with an adjustable interocular distance, but this happens to be one of the reasons why it becomes necessary in the camera. With it the use of the camera is extended, and also greatly facilitated. Instead of being an added complication it is really a simplification; moreover, it renders some work possible that is impossible without it.

* * *

Red, Yellow, and Blue. It seems curious that it should be necessary nowadays to write a book for the express purpose, as set forth on the title-page, of correcting the "commonly held theory" that red, yellow, and blue are the primary colours, yet from a note in "The American Printer" we learn that such a book, by J. Arthur H. Hatt, has just appeared. We read that the book is intended especially for artists and students, architects, colour printers, decorators, and costume designers, but we presume that it is not suggested that all these various workers are still in the dark ages with regard to the primaries. They are not so in this country, at any rate, and we have, of late years, often been agreeably surprised to find how generally the true facts with regard to the primaries are known. No doubt this advance in general knowledge can be attributed in no small measure to the teachings of the photographic press, which has insisted upon the truth of the matter for a very long time. The scoffers who were so numerous twenty years ago seem now to be almost extinct in this country, and if they still flourish in America we can only suggest that it is high time they were either converted or extinguished.

* * *

Artist Judges. At a recent exhibition we are informed that an artist judge officiated, no photographer being appointed to assist him. This may have been only an experimental arrangement, but it does not strike us as particularly wise to ignore photographic judges altogether. Photographers seem very apt to forget that there are so many ways of making pictures, that the results can only be judged by those who have not only full cognisance of all the ways and means that were at the disposal of the producer, but also a practical knowledge of the limitations that served to guide him. Each method of picture-making requires a special apprentice-

ship, has special possibilities and limitations, and without understanding the details peculiar to the method it is impossible to arrive at a fair judgment. It is a very difficult thing to find the ideal judge, but we certainly think a skilled photographer with a theoretical knowledge of pictures forms a better judge than a skilled painter with only a theoretical knowledge of photography. Possibly, as things are, it is best to have judges of both kinds, for the average photographer's knowledge of pictures is usually very elementary. He has picked it up in odd moments, whereas the painter has devoted years of thought and observation to acquiring it. Possibly the judge selected at the exhibition referred to is as skilled a photographer as he is an artist, in which case he must, of course, be an ideal judge; but such a combination is so very unusual that we may be pardoned for assuming the contrary as more likely to be the case.

* * *

Single Lenses for Portraiture.

Some persons seem, notwithstanding all that has been written on the subject, to be under the impression that to take portraits successfully a portrait lens must necessarily be employed. That is not so, as portraits can be taken with any form of lens whatever. Anent this subject a correspondent—a professional portraitist—writes: "Seeing an answer to one of your correspondents a few weeks back, in which you say that a landscape lens 4in. in diameter and 20in. focus could be used for groups out of doors on 12 by 10 plates, and that if the fixed stop were enlarged it would still yield fair definition, having had by me a similar lens (by A. Ross) for many years and never used by me, I thought I would try it for large heads in the studio. I managed to get out the fixed stop, and made some cardboard ones, with openings equalling $f/11$ and $f/8$ and smaller to fit in its place, and fixed the lens on a 12 by 10 outdoor camera, as my studio camera is only a whole-plate one. On trying it with the $f/11$ stop I was surprised at the definition it gave, and its depth of focus. On the 12 by 10 plate I can get $3\frac{1}{2}$ in. or 4in. heads better than I can get $2\frac{1}{2}$ in. ones with my —'s whole-plate lens. I shall now make a feature of large portraits, which I have hitherto been unable to do on account of the cost of a portrait lens for the purpose, etc." We merely quote this letter to show that costly portrait lenses are not actually necessary for large portraiture. Large portrait lenses are necessarily expensive, and the advantage of them is their rapidity in action, but it is found in practice, in order to get the different planes of the picture in focus (depth of field), they have to be considerably stopped down, hence their great rapidity is much discounted. Sometimes with large portraits, in order to get the necessary depth, the lens has to be stopped down to $f/8$ or $f/11$; then, of course, it is no more rapid than a single lens with a similar aperture. The front lens of a portrait combination does not differ much, if anything, from the old form of landscape lens, and may be used for the same purposes. Anyone who has, say, a whole-plate portrait lens can use the front combination for about 12 by 10 pictures, as it has somewhat more than double the focal length of the entire combination. It may be mentioned that many of the late Mr. Valentine Blanchard's figure studies were taken with the front combination of a French portrait lens, and, by the way, by the old wet collodion process, which was exceedingly slow as compared with gelatine plates. It may also be mentioned that all the earlier pictures of the late Mrs. Cameron were taken with an old Ross landscape lens: the stop was entirely removed, and the lens used without any stops at all, but the definition under these conditions was not such as would satisfy portrait photographers or their customers.

NEATNESS IN THE STUDIO.

TAKING it all round, we are inclined to think that the photographic studio is the most difficult place imaginable to keep clean and tidy. Do what you will, the general effect after taking a few sitters is more reminiscent of a rag shop than the most important room in a presumably artistic establishment. Certainly, public opinion rather expects untidiness in such a place, but a lady client in an expensive dress would much prefer cleanliness, whilst orderliness is essential if operating is to be conducted with any degree of comfort and despatch. When one is obliged to store canvas conservatories that rival Kew, palatial palaces, and weird woodlands in one and the same place, as well as broken balustrades, stone steps, garden seats, oak settles, several varieties of chairs, not to speak of the amount of space occupied by small headgrounds, reflectors, and stone, the general effect is bound to be somewhat incongruous. Try as one will, it is impossible to carry out the theoretical idea that a studio should resemble an ordinary room. To secure the most pleasing results, both in the sitter's expression and subsequent order, every effort should be made to make the studio as inviting as possible. Many people are affected to a remarkable extent by their surroundings, and most are more susceptible than usual when visiting the photographer's, for even now our craft is still tinged with the mystery of the unknown.

It is essential that the general scheme of decoration be extremely reserved and subdued, and as harmonious as possible. A bold scheme, however pleasing it would be in a private room, with a carefully selected suite of furniture, would appear merely as a discord when so many varying articles are collected within it. The usually advised grey walls we do not care for: they are too cold, and likely to prove quite out of keeping with any upholstery. It may, however, be necessary to use this colour if the studio is narrow and reflected light essential. When a free hand can be taken, a green or a brown scheme appears to us to be much more cheerful and has the advantage that drapery, curtains, etc., can easily be obtained to match. To make a studio at all presentable every opportunity of securing repetition should be taken in order to give the general appearance a feeling of unity. Variety there will be and to spare without seeking for it. If the walls are plaster, a good matte paper, devoid of pattern, should be used with perhaps a quiet stencil for frieze. Many studios have matchboard partitions; than which nothing looks worse. They are, however, remarkably easy to treat, since anyone of average intelligence can apply a fabric wall-covering, skirting-board, and picture rail to such an amenable base. The art canvas in various colours supplied at about 1s. 8d. per yard of 52in. wide may be stretched and tacked in position, or the fabric hangings sold under various fancy names and prepared for pasting on the wall may be used. They are only 36in. wide and more expensive per yard, but we find them very much more durable and really easier to hang. If the ordinary art canvas is used, it is essential that the matchboard be first papered over, preferably on both sides of the partition, with some cheap paper; ordinary brown will do. If this is not done, dust will work through the joint of the boards and make dark streaks on the canvas. The doors and other woodwork should be painted a shade darker than the wall-covering, but never have the doors picked out in two shades.

Floor covering is another important item. Without any hesitation we recommend a good linoleum. It is easy to keep clean, castors on the various accessories run easily on it, dropped chemicals will not affect it, if good it is extremely durable, and, lastly, thoroughly artistic designs can now be had. Cork carpet is very warm and elastic to

the tread, but we find the colours apt to become dirty and degraded in parts. We do not care for perfectly plain, self-coloured floorcloths, since they are monotonous and show the dirt badly. Any bold pattern is to be avoided, especially geometrical and floral designs. A small indefinite pattern of a slightly darker or lighter shade than the ground are quite inoffensive; but, as a general rule, at the risk of being called over the coals by the purists for advising an imitation, we cannot conceive a more admirable material than inlaid linoleum in simple parquet designs. Of course, a real parquet floor is the height of one's ambitions, but very few photographers are in a position to, or would be justified in, having one laid. When selecting a design, it must not be forgotten that parquet patterns are innumerable, and that the majority are unsuitable for photographic purposes. One or two small rugs will be required to break up the floor space, and if of an almost plain design will be useful for interiors. Here, again, we prefer to match the general colour scheme rather than employ Oriental rugs, rich as they appear to the eye, but totally unsuitable for inclusion in a picture.

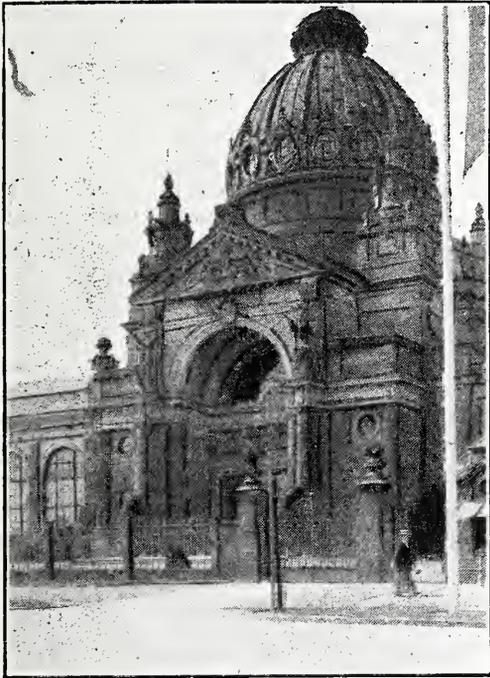

The skylight blinds are usually black, and this from practical motives is advisable. Any other curtains, however, should be in a plain, unpatterned material of the prevailing colour. In place of the usual black camera cloth, we have one made out of the same fabric as our curtains.

The trite old saying, "A place for everything and everything in its place," should occupy a prominent position in that imaginary spot known as one's mind's eye. It will often be found that orderliness and neatness take the place of muddle merely by changing about the usual position of accessories: this stool will go under that chair, this chair under that table, and so on. It is foolish to keep any unused lumber; its room is of greater value.

Backgrounds are perhaps the most insistent sign of photography in the studio, and too often their general appearance brings them into undesirable prominence. One of the first moves in the improvement of the studio should be some neat and compact system of storing the grounds. For headgrounds, experience persuades us that for simplicity and utility a headground stand of the kind described by Mr. Foster Brigham in the "B.J." for December 15, 1905, p. 989 (see "B.J.A.," 1907) cannot be beaten. The roller scheme described in the same place is also about the neatest method for large grounds. The rolled-up ground does not look particularly pretty, however, and we find it adds to the appearance if a wide piece of moulding, preferably on the same level as the frieze moulding, is fixed in front of them to hide them when rolled up. Grounds on stretchers are ungainly and very frequently an eyesore, owing to ragged edges, crooked rows of tacks, and bare white stretcher or stretcher edges showing. The two latter defects are overcome by painting the frame before stretching the background, and the two former by tacking three-quarter inch black tape over the lines of tacks and cutting off any ragged edges of background not covered with a sharp knife. After executing these permanent aids to neatness, the more frequently-needed attentions of the char-lady should not be forgotten. The floor should be washed at the very least once a week, whilst the upholstery should be brushed, and the camera, furniture, and ornaments dusted every day. Above all, do not leave lying about stray negatives, printing frames, prints, drying racks, mounts, blotting paper, or any of the innumerable articles connected with the manipulative branch of the work. Of course, some studios are obliged to use the studio as a general workroom, but some scheme should be devised to keep such signs of one's business as unobtrusive as possible.

THE DRESDEN EXHIBITION.

IN continuation of the general survey published in last week's "British Journal of Photography," we proceed to deal with the exhibits in more detail, although the size of the collec-

Entrance to Exhibition Palace.

tions in many cases makes it compulsory to select for mention only a few items of especial interest. In some sections, too, particularly those devoted to pictorial and record photography,

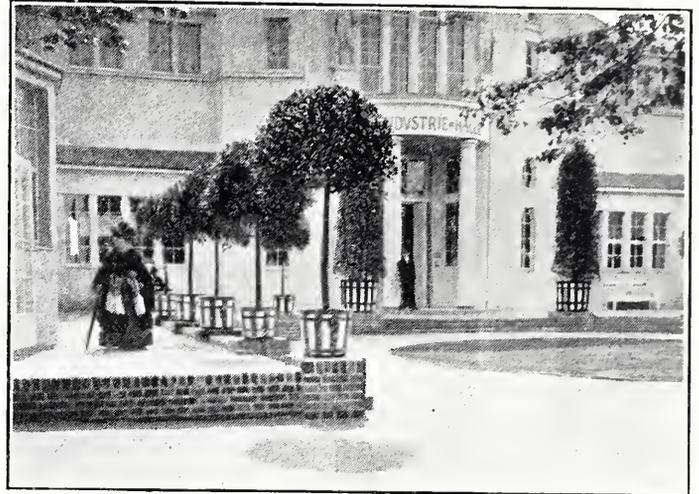

In the Exhibition Grounds.

any detailed review would be most unprofitable, on account of the number and sameness of the photographs, and it will be sufficient and of greater service in these instances to describe

THE SCIENTIFIC AND TECHNICAL SECTIONS.

Undoubtedly the chief interest of the Exhibition is centred in this section, which is divided into seventeen different departments contained in as many rooms, or rather more, for several of the collections occupy several separate galleries. The whole section is housed in communicating rooms in the centre of the left-hand quadrangle of the main building, and is thus bordered by the galleries containing the works of amateur photography.

the general character of what is shown. As we have already said, the chief interest of the Exhibition is centred in the scientific and technical section, and we shall therefore first deal with the seventeen sub-sections into which this large collection is divided. While a detailed description may give some idea of the labour of the organising committees, it cannot describe

The Entrance to the Trade Galleries.

the great excellence of the size, arrangement, and mounting of the whole Exhibition. One or two photographs here reproduced may perhaps give some suggestion of the scale upon which things have been done at Dresden. They show the main entrance to the building in which the scientific, amateur and professional, exhibits are arranged, the front of the large hall or series of galleries specially built to accommodate the 186

The Restaurant in the Exhibition Grounds.

trade exhibitors, and also give two glimpses of the very pleasing garden grounds and restaurant which intersect the various buildings.

The following are the sub-divisions of the section:—

- | | |
|---------------------------------|-----------------------------|
| 1. Teaching and instruction. | 10. Astronomy. |
| 2. Research and experiments. | 11. Colour photography. |
| 3. Botany. | 12. Press photography. |
| 4. Zoology and anthropology. | 13. Mineralogy and geology. |
| 5. Detection of crime. | 14. History of photography. |
| 6. Bibliographical photography. | 15. Photogrammetry. |
| 7. Physics and chemistry. | 16. Balloon photography. |
| 8. Pathology. | 17. Military photography. |
| 9. Meteorology. | |

Of these sub-sections those dealing with the detection of crime, with photogrammetry, and with pathology were by far the largest and most interesting and important. Sub-section No. 1, devoted to the teaching of the principles of the graphic arts, deserves, however, a very special reference, since it provided an exhibition of great popular and educational character. We will, therefore, first refer briefly to it, for we hope to deal more adequately with it in a later issue.

"Press-Button" Science Teaching.

In a room opening out from that in which the pictorial work of the "International Vereinigung" is shown there is a sound of light-running motors: the whirr of the wheels is just enough to remind the observer of the American photographs that Art is not everything. Tracing it to its source, we find forty-four separate cabinets, each measuring about 20 inches high, 12 inches wide, and 12 inches deep. They have the look of those boxes in which, at railway stations and other places, the public is offered the inspection of twelve pictures reputed to represent gay life in Paris. But the contents of the Dresden cabinets are of a different order. Each of the forty-four contains the apparatus for a demonstration of some basic fact of photography or vision in such a state that pressure on a button, or turning of a handle, allows the observer to perform the experiment himself. Brief printed directions are affixed to each cabinet, and state not only the mode of using the apparatus, but succinctly explain the fact to which it is related. We spent a most interesting hour in examining the contents of all the cabinets, and propose in a later issue to describe the manner in which this series of experiments has been given popular form. We may select two examples to show how the Germans have contrived to make, say, phenomena of the eye interesting. Cabinet No. 4 is to show the contraction of the iris of the eye when in strong light. On applying one's eye to the peep-hole, the reflection of it is seen in a mirror. In accordance with the instructions, a button is pressed and a second incandescent lamp caused to illuminate the eye. The iris is then seen (in the mirror) to contract. No. 6 illustrates the falsity of impressions received by one eye. On looking through a small circular peep-hole (large enough for one eye only), there is seen what appear unmistakably to be three solid white cubes and one pyramid. On pressing a lever, a shutter falls back, both eyes come into play, and it is instantly seen that the apparently solid bodies are hollow paper shells, really the halves of the figures they seemed when viewed with one eye. The difference is most startling, and although every cabinet does not contain so pretty an illusion as this, the whole series affords a very instructive exposition of elementary facts of light and colour. Perhaps the most eloquent testimony to the cleverness of Dr. Goldberg and his students at the Leipzig School of Graphic Art, where the models were made, was the interest with which ladies and children were seen to make the tour of the cabinets.

Photography in the Detection of Crime and in Municipal Legislation.

Three large rooms are required to accommodate the collections brought together in this section under the superintendence of Herr Koeltigg, head of the Dresden Police Service. In a brief introduction (page 62 of catalogue), Herr Koeltigg refers to the growing use of the camera in making records of railway accidents, in the prevention of these latter by the detection of defects in materials, by recording nuisances caused by smoke, etc., and in many other ways in which the German proverb, "Die Sonne bringt es an den Tag," assumes a new meaning. The majority of the exhibits illustrate the use of photographic methods in the registration of criminals and suspected persons, and in the detection of crime. The Police Service of St. Petersburg show a collection of photographs illustrating the method employed in registering the features of persons with the object of their identification at any time—a task with which no doubt the police authorities in Russia constantly have their hands full. In addition

to the verbal particulars, the Russian form of identification includes the prints of the four fingers and thumb, and photographs of the face, full and profile, and of the whole figure, three in all.

The most interesting exhibit is that of the Service de l'Identité Judiciaire, of the Paris Police Department. The details of the elaborate system worked out by M. Bertillon are here shown. Basing the classification of faces first on the shape of the nose, it is explained how the three large classes of faces are those

in which the nose is straight (1),

in which the nose is concave or retroussé (2),

in which the nose is convex, broken, or hooked (3),

each of which is divided into five other sections, according to other features. One photograph shows a class of French police officers receiving blackboard instruction in making a mnemonic note of the features of a person on these lines. An album showing faces arranged according to this system supplies a most impressive indication of the thoroughness of the French methods.

Examples are also shown of the Bertillon method of preparing from a photogrammetric negative a plan of the scene of a murder. The employment of the finger-print system is illustrated by a series of photographs, the first of which shows the scene of a murder in a café. A half-drained glass stands on the table, and the next photograph is of the impression of a finger on the side, which impression, in comparison with one in the police records, is shown to identify the suspected person. Similar examples are shown by the Imperial Police Department of Vienna. The exhibit of the Berlin police "Präsidium" shows the enormous scale upon which the work of this department is done. The headquarters of the police authorities include a huge chemical laboratory devoted to criminal investigations, whilst the photographic department installed in the same suite of buildings comprises a studio and other work-rooms equipped for the making of photographic records of criminals. The table whereon the finger-print impressions are taken is shown, as is also a full-size camera and tripod used in photographing the position of a body as found by the police. The tripod is a solidly constructed apparatus which permits of the camera being pointed vertically down upon the body from a height of twelve feet or so. One leg is therefore built as a ladder, and the photographer thus enabled to mount to the focussing screen. The outfit is issued commercially by the Dresden firm H. Ernemann and Co., and appears to be somewhat largely used for such specialistic purposes. The Berlin police also exhibit photographs from hand-camera negatives showing bookmakers and pickpockets engaged in their occupations. Another photograph represents a travelling studio, which can be drawn on wheels to the scene of an accident or crime, and a photograph thus made of a subject which could not be removed to the permanent studio. Part of the Berlin exhibit also is a model of a court of justice, showing a projection lantern being employed for the purpose of describing facts to the jury or judge.

Unofficial exhibits are found in the third room devoted to this section. Dr. Jeserich, who was a pioneer in the use of photography in detecting forgery, identification of blood-stains, of human hair, etc., shows a large number of photographs and photo-micrographs, many going back for a number of years. Dr. Popp, a professional "detective chemist" of Frankfort-on-Maine, shows photographs illustrating the use of photographic and microscopic methods, and the town of Dresden shows numerous photographs recording municipal improvements.

Balloon Photography.

This is only a small section, the chief exhibitors being the Military Geographical Institute of Vienna, the Saxon Society for Aerial Flight, Dresden, and Sir William Lockyer, who sends four photographic enlargements of views taken from a balloon of South Kensington, the East End of London, and Roehampton. The chief exhibit in the section is an actual projectile or rocket camera constructed and shown by Maul, of Dresden, and designed

to allow of photographs being taken at much less cost and with much greater expedition than can be secured by the use of a balloon. The apparatus consists of a stout iron stem about twenty feet in length, carrying a camera, and discharged into the air from a vertical framework of about the same length as itself, the whole outfit being capable of transport within reasonable distance by two men. On being shot into the air by an explosive contained in a lower chamber, the "rocket" rises to a height of about 500 yards, and a parachute attached to it then allows of its slow and safe return to the earth. Apparently the camera is provided with mechanism which causes the exposure to be made at the maximum height of the projectile. The photographs taken with it show that it is capable of very practical results, and we were informed that it was the intention to obtain by its means pictures of the exhibition grounds at intervals during the summer.

Military Photography.

The chief exhibitor in this section is the Imperial Military Technical School of Charlottenburg, at which establishment extensive use has been made of the principle of photographing bullets, etc., in their flight by the use of the electric spark as devised by Professor C. V. Boyes some years ago. The Charlottenburg experimenters, however, have carried out their researches on a very comprehensive scale. They have devised what is described as a ballistic cinematograph, by means of which a large number of exposures may be made in very rapid succession—that is to say, at the rate of about 5,000 per second. With this instrument they investigate not only the flight of bullets, but also the stages of the firing of different types of guns, the photographs, which are, of course, shadow pictures (no lens is used), showing every stage of the action which takes place in the breech of the gun, and thus allowing of the most exact and valuable comparisons being made between different types of instruments of warfare. In the case of the series (No. 388) of the firing of a self-loading pistol there are 370 separate pictures, each of the full cinematograph size, and taken at intervals of 1-5,000th of a second. A number of other photographs, each measuring about 8 by 5 inches, and being, presumably, enlargements from the smaller negatives, show the various stages of firing in the breech of a pistol. The same apparatus has also been applied to the measurement of the speed of shot from a gun, also to showing the discharge of unburnt particles from a gun, and the different manners in which the bullet emerges from the barrel of the gun. Messrs. Krupp have several exhibits showing the application of photographic methods to the testing of guns, including one descriptive of a method of measuring the angle of fall of a distant projectile in its course from a gun. Three cameras are used, provided with electric release. The middle one is fitted with a sensitive film mounted on a rapidly rotating drum, and the three successive exposures at a very brief interval of time serve to show the amount of drop of the projectile.

A number of other exhibits in this section are connected chiefly with the engineering industry, and consist for the most part of photographs of apparatus during manufacture or under test. The German Admiralty exhibit a fine number of photographs showing the stages in the building of a battleship, and the Imperial establishment for the Testing of Materials show photo-micrographs illustrating the methods of testing steel and other materials for defects of manufacture.

In this section, too, is a small exhibit by the Baese Photo-sculpture Co. It consists of medallions, frames, etc., produced in somewhat shallow relief and in different scales of enlargement. It suggests that the method, which now dates back to some three or four years, is being successfully used for commercial purposes.

Bibliographical Uses of the Camera.

This section, though not large, is of interest from the fact that similar uses of photography for purposes of public in-

struction are little heard of in this country. It is produced under the direction of Professor G. Krumbacher and Herr K. W. Wolf-Czapek. It represents a collection of specimens of apparatus illustrating the uses of photographic methods in preparing reproductions of ancient deeds and documents, and in other ways multiplying originals which, on account of their rarity or value, cannot be generally placed at the disposal of the public for consultation. The most usual method of reproduction appears to be the making of a single negative copy on bromide paper directly in the camera, the white-on-black copy of a document being quite as serviceable for purposes of consultation as a positive facsimile. Two models of cameras suitable for making these copies are shown, in both cases being fitted with a roll-holder taking a spool of negative paper sufficient for fifty whole-plate exposures. The cameras are the work of Ernemann and Wünsche respectively. One is so built that the original may be laid flat upon the horizontal board or table, and the camera, which is held vertically, pointed down upon it. The operator can take a lofty position on the stand of the camera, which necessarily is of substantial construction, and, by actuating a winch-screw, can raise or lower the original in relation to the lens. It would appear from the references to apparatus of this kind in the catalogue that they are extensively used in public libraries in Germany. Of the exhibits Professor Krumbacher contributes an example of the zyklograph, an instrument for obtaining a flat complete photographic representation of the design of a vase at one exposure, the vase being automatically rotated so as to present the whole area of its design to the lens (No. 191).

In an exhibit by the Hof- und Staats-Archiv of Vienna there are some specimens of reproductions of ancient MSS. in which advantage has been taken of the gum-bichromate process to secure a facsimile copy of the original—the first instance we can call to mind of any industrial use of the gum process. One exhibit of Professor Krumbacher consists of photo-micrographs of a tiny portion of text (a line subject) reproduced by different processes—namely, collotype, half-tone, photo-zinco, and Spitzertype. It is seen that the finest "resolution" is that given by the zinco line-block, the Spitzertype block coming next, whilst the collotype has its definition much broken by the grain of the plate, and the half-tone more so still by the structure of the screen. For comparison with these photo-micrographs are actual reproductions of handwriting in the four respective processes (No. 191).

Professor Gradenwitz and E. Pringsheim show a series of transparencies explanatory of the means taken to decipher by a photographic method the writing of palimpsests. A negative, A, is first made on an isochromatic plate with a yellow screen, receiving a full degree of exposure, and developed so that a somewhat flat negative is obtained. This gives the older writing as rather weak, and the newer as stronger. A second negative, B, is made on an ordinary plate, and developed to full strength. In this the older writing is stronger, and the newer weak. From this second negative a vigorous positive transparency, B¹, is made on glass. A and B¹ are placed together in the camera, when the older writing is very plainly seen, the newer almost disappearing. A negative, C, is then made from this combination of negative and positive, and used for contact prints or collotype plates.

Photography in Physics and Chemistry.

The use of the camera in investigation of chemical and physical subjects does not provide a large section. One of the most interesting exhibits is that of Professor O. Wiener, illustrating the use of a photographic method in recording the diffusion which takes place between two liquids over a period of time. The image of a fine slit about 10 cm. in length is cast by a lens through a cell containing the liquids on to the sensitive plate. The diffusion of the liquids causes a gradual distortion of the image of the slit, and a series of exposures made upon one plate serves to record the progress of the diffusion.

Press Photography.

Under the direction of Herr August Scherl, proprietor of the German newspapers "Die Woche" and "Der Tag," and of other publications which have led the way in Germany in the direction of using ample illustration, a very large amount of illustrative matter is crowded into a small space. Many of the frames contain perhaps one hundred photographs, and the two galleries, therefore, of the press photography section represent an enormous volume of illustrative material, which in every case is of a high order as regards quality. Most of the photographs are of events of the day, or of portraits of people in the public eye, and the collection is quite international in its character from the fact that the exhibits come not only from Germany, but from London, Paris, New York, Spain, Norway, Italy, Holland, and other European countries. The collection shows the firm hold which photography has taken in the illustration of newspapers. The

two most interesting exhibits in the section are, first, that by Dr. Neubronner, of Cronberg. This consists of the actual tiny cameras which, attached to carrier pigeons, are used to obtain photographs during the flight of the birds. The actual negatives measure only about $1\frac{1}{2}$ inches square, and, to judge from those exhibited, are not of a very high order of definition, inasmuch as the enlargements, about 6 inches square, are rather more diffused in definition than would be usually exhibited. The results, however, are a tribute to the ingenuity of the inventor, who, we noted, had devised a stereoscopic carrier pigeon camera. The telegraphic transmission of photographs by the Korn method is represented by a complete working installation, the actual production of a telegraphed picture being demonstrated twice weekly in the exhibition. A number of reproductions showing the photograph before and after being telegraphed by the Korn method forms part of this exhibit.

(To be continued.)

ON PHOTOGRAPHY BY REFLECTION UNDER CONTACT.

[In the following paper, recently read before the Royal Dublin Society, the author describes the process of printing by contact from opaque positives, which he appears to have worked out without knowledge of what had been done by the late Hort Player. The paper is accompanied by a supplemental plate, showing the satisfactory reproductions obtained in this way of line subjects.—Ed. "B.J."]

In the usual methods of contact photography, a copy is taken of the original or negative by allowing light to pass through the latter on to a sensitive surface. The resulting picture is due to differences in opacity in the various points of the original or negative.

The new method to be described consists in transmitting the light in the reverse direction, and producing a picture, not by differences of opacity, but by differences of reflecting power in the original.¹

The obvious objection to such a method is that the sensitive film, being exposed to a uniform incident illumination coming through the back of the plate, will be uniformly "fogged"; and the resulting positive will be marred by a brightness which invades and partly obliterates all the dark portions. If this difficulty can be overcome, we obtain a method of copying any flat picture or design without a camera; and we avoid the difficulties of distortion, curvature of field, chromatic and spherical aberration, flare, astigmatism, and lack of uniformity of illumination, which beset all but the best lenses, and which cannot, in practice, be simultaneously reduced to a negligible amount.

When the original to be copied has no half-tones, it is possible, by suitable exposure and development, to eliminate the fog entirely. The general principle is to employ exposures and developers which in ordinary photography "suppress the detail in the shadows," or, in other words, confine the developed image to those portions which have received the maximum illumination. In copying a line-drawing, a page of print, or similar full-toned matter in this manner, the areas of maximum illumination are those which are illuminated by the incident light *plus* the light reflected by the white paper. The areas in contact with the black portions of the original are only illuminated by the incident light *plus* the small proportion reflected by the black ink. The incident light greatly exceeds the reflected light in amount; and the difference in illumination relied upon to produce the necessary contrast does not, in most cases, exceed 5 per cent. With this small margin of additional illumination it is found possible, however, to obtain a contrast in the negative

amounting to as much as 40 or 50 per cent. Once this is obtained, the negative may in turn be used to produce a transparency in which the contrast is further increased by a second application of the same treatment. Workable lantern-slides are obtained in this manner; but much better results, comparable to the best lantern-slides obtained with the camera, are secured by two additional reversals, to which the same principle is applied.

Instead of making a number of successive reversals, the fog may be eliminated by reduction and subsequent intensification. Howard Farmer's reducer (potassium ferricyanide and hyposulphite of soda) dissolves away the fog more than the full-tone if sufficiently concentrated. The negative is intensified with mercuric chloride and silver nitrate.

The best results are obtained with slow plates of the "photo-mechanical" class, and the developer used was the following:—

No. 1.—Hydroquinone	80 grs.
Potassium metabisulphite	120 grs.
Potassium bromide	10 grs.
Water	10 ozs.
No. 2.—Caustic potash	200 grs.
Water	10 ozs.

Equal parts of both solutions are mixed.

The best fixing agent is potassium cyanide, on account of its solvent action on thinly deposited silver. But I used the ordinary "hypo" bath.

Other Applications of the Process.

Excellent paper negatives are obtained with rapid bromide papers, and also with gas-light papers.¹ On printing positives from them in the ordinary way, the grain of the paper negative disappears, as it is automatically compensated by the grain within the paper which gave rise to it. Printing-out papers also give negatives which can be used for printing positives on bromide paper without previous toning and fixing. But the exposure has to be very long.

Bichromated gelatine plates give a good relief by this method, and, unlike the usual printing with bichromate, the more insoluble portion of the gelatine is nearest the support, whether glass or paper. Direct positives may be obtained either by over-exposure (fifty times), or, better, treating ordinary plates or

¹ Such a reflection process was devised in 1897 by J. H. Player (see "The Photographic Journal," 1897, p. 222). He used bromide paper, and transmitted the light through a green glass. He "could not succeed with plates." It is said (*ibid*) that positive copies of maps were for some time made in the French army by contact with Ilford process plates, but no details are given.—E. E. F.

papers with a 10 per cent. solution of potassium bichromate, and exposing them for the period usual in bichromate printing. The action in this case is as follows:—The bichromated gelatine which receives the reflected light is rendered more insoluble than that which adjoins the black areas. Only the latter, therefore, absorb the developer; and the whole film being “fogged,” a direct image of the black portions results.

The Active Agent.

The very striking results obtained with bromide paper are attributable to the double absorption undergone by the incident light in penetrating the developed film and returning to the eye of the observer. There appears to be in reality nothing but a purely optical effect. The suggestion was somewhat obvious that some radiation from the pigment of the original, usually, perhaps, intercepted by a slight thickness of air, might inhibit the reduction of the silver salts. This, however, is rendered very improbable by the following observations:—

1. On impregnating paper with sugar, glycerine, mercuric chloride, uranium nitrate, and various other substances which do not produce a visible effect, it is found that paper so treated has the same photographic action as the original paper.

2. The gradation of colours is found to be the same as that obtained with the camera.

3. Red has no special inhibiting action. On applying this process to a deep red paper printed with black lettering, a faint negative was obtained, in which the black printed whiter than the red. Had red light exerted any inhibiting action, the fog should have been reduced, and the red should have appeared whiter in the negative.

In applying the process described to black and white originals, certain advantages are gained over the ordinary methods with the camera:

1. The reproduction is of the exact size of the original;
2. The sharpness of definition is only limited by the size of the silver grain in the plate;
3. All differences in the angle of reflection of light by the original are avoided, all the effective light emerging at right angles to the surface.

This last circumstance places at our disposal a delicate and accurate method of comparing the reflecting powers of surfaces for vertical incidence. It consists in mounting the surfaces in the same plane side by side, and exposing a plate with its film in contact with both. If the surfaces are large enough, a slight gap may be left between the sensitive film and the surfaces to be tested, so as to eliminate photographically active radiations or emanations from the surfaces.

E. E. FOURNIER D'ALBE, B.Sc., A.R.C.Sc., M.R.I.A.

PACKING PLATES EXPOSED ON TOUR.

THE usual way is to cut or tear open one end of cover-paper and draw out the box. This is all right when the plates are to be exposed and developed straight away, but if it be intended to replace them in the box after exposure, and keep them secure pending future treatment, then tearing open the cover-paper is all wrong; it makes a clumsy, untidy mess, and when work is being done in the dim light of some strange dark-room, to replace the plate-box inside the remains of the cover-paper is not always an easy thing to accomplish.

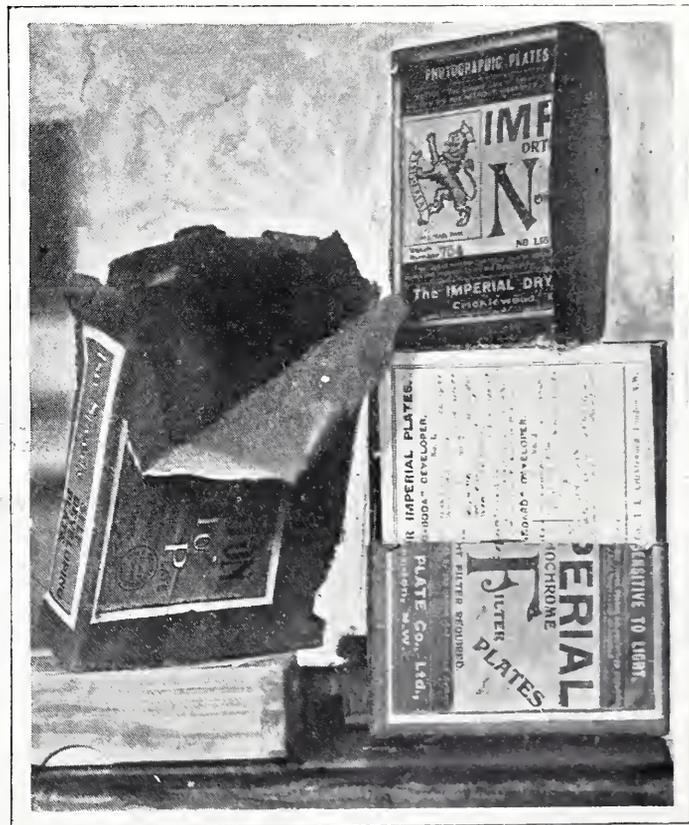

The Best Way to Open a Plate Box.

Take the unopened box as received from the dealer, and with a sharp knife make a clean cut right round the middle of the package. When this is done, the two halves of the cover-paper will quite easily slip off each end. Then, when it is required to re-pack the plate-box away securely, all that is necessary is to replace the two halves of the cover, when a piece of adhesive paper, such as used for binding lantern slides or passe-partouts, stuck round where the cut was made, will join both cover parts together, and the plates are as secure and safe from injury as when first received from the makers.

The illustration shows the two methods, the left-hand side being that of a box opened by tearing the cover; that on the right being the other method described.

As regards the plates themselves, quite the safest plan is to put them face to face and wrap tightly round in the brown paper originally packed in. They are then quite safe once inside the box and the outer covering fastened with gummed paper as described above. Since adopting this plan I have not had a single accident with plates packed on holiday tours.

W. THOMAS.

THE ENSIGN ROLL FILM COMPETITION.—Mr. A. C. R. Righi, Woodlands Hotel, Darjeeling, India, is the winner of the Ensign roll film competition for May. Houghtons Ltd. offer a three-guinea camera every month for the best negative on “Ensign” film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of “Ensign” film.

THE WAKEFIELD PHOTOGRAPHIC SOCIETY has recently made several changes in its constitution. The meetings are held as heretofore in the Church Institute on Fridays at 8 p.m., but the office of president is now filled by Mr. J. H. Chaplin and that of secretary by Mr. G. W. Johnson, to whom communications should be addressed at Lindale Villas, Newton Hill, Wakefield.

ABSORPTION SPECTRA.

(A paper read by Dr. Mees and Mr. S. H. Wratten before the Royal Photographic Society, and reprinted from the "Photographic Journal.")

II.

The Absorption in Special Regions of the Spectrum.

The first region in which absorption may be required is the extreme red and infra red, from 8,000 down to 6,500. We have, indeed, been very urgently requested to make a filter which absorbed from 8,000 to 7,000, but did not absorb the red proper

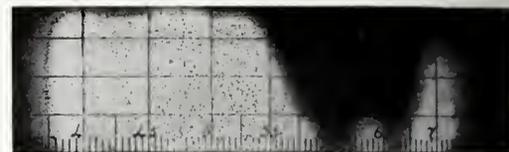

absorption than the common variety; toluidin green, Hoechst, toluidin blue, which is a permanent dye absorbing the extreme red, and not absorbing ultra-violet or violet, and which has just been put on the market by the Hoechst Dye Works; and the still later filter blue-green of the Hoechst Dye Works. Unfortunately the attempt to obtain a dye which had its maximum above 7,000 was a

Victoria blue $\frac{1}{2000}$.

Rapid filter blue $\frac{1}{1000}$.

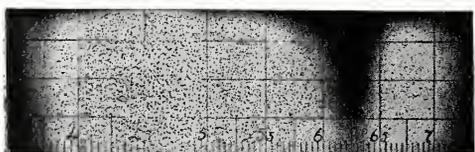

Toluidine blue $\frac{1}{1000}$. Red end only.

Filter blue-green $\frac{1}{1000}$. Red end only.

Patent blue $\frac{1}{1000}$.

Erioglaucin $\frac{1}{1000}$.

Methyl violet $\frac{1}{1000}$.

Rhodamine 6 G $\frac{1}{1000}$.

Uranine $\frac{1}{2000}$. Blue end only.

Monobromo-fluoresceinate of sodium $\frac{1}{1000}$.

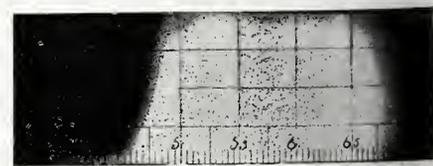

Tetraiodo-fluoresceinate of sodium $\frac{1}{1000}$.

Rose bengal $\frac{1}{1000}$.

β Naphthol-di-sulphonic acid $\frac{1}{2000}$. Blue end only.

Picric acid $\frac{1}{1000}$.

Fig. 8.

below 7,000, and that request was really the commencement of this series of observations.

In order to investigate the matter, the ordinary compensating filters were removed and a special compensating filter composed of methylene blue at first, and later of toluidin blue, together with the red tricolour filter, was used in order to enable us to work satisfactorily fully up to 8,000 A.U. The dyes investigated were naphthol green, both the commercial variety in which the hydroxyl and sulphonic acid groups occupied the second and seventh positions, and another variety given us by Dr. Koenig, in which the groups are in the second and sixth positions; this last having less blue

failure. All the dyes named have their maximum about 6,700 to 7,000, except toluidin blue and green, where the maximum is lower still. Much the most satisfactory of the green dyes is the new filter blue-green, which has only a slight absorption in the violet.

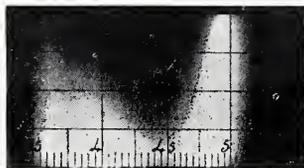

For making blue filters, toluidin blue is of great use, although its shallow absorption, like that of toluidin green, renders it less useful than if it had a sharply cut band. In the extreme red, methylene blue has a unique absorption, showing a double absorption band, of which the stronger member has a maximum at 6,800, while the weaker has a maximum at 6,100. Unfortunately, methylene blue is very sensitive to heat, like auramine, and while it is

fairly permanent to light, it cannot be trusted because of this sensitiveness to heat. Indeed, methylene blue is almost the only dye which we would always avoid, on the ground of permanency, if it were possible to do so. The patent blue series, which were originally Hoechst dyes, give a most valuable series of sharp absorptions in the red. One of the members of these series, erio-glaucin, made by Geigy, of Basle, is particularly noteworthy for its single sharp absorption band, with its maximum at 6,250. The Hoechst red-absorption dye naphthaline green, has a very bright and sharp absorption, but of course has the disadvantage that it absorbs the extreme violet and ultra-violet. Its curve is not as sharp as erio-glaucin.

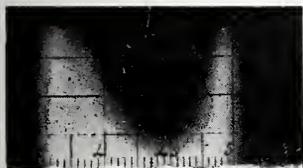

The difficulty of the next group of dyes, those absorbing the spectral yellow and orange regions of the spectrum, is that they are nearly all basic dyes, and as basic and acid dyes cannot be used together, and as, moreover, basic dyes frequently give much trouble with gelatine, it is better to use acid dyes if possible. We have now succeeded in almost completely eliminating basic dyes from our filters. These blues, as they may be called, comprise the Victoria blues, which are the sharpest-cut of them, and of which there are a great many varieties, the methyl violets, which are of but small use, owing to the superiority on the one side of the Victoria blues and Patent blue series, and on the other the rhodamines

and rapid filter blue Hoechst, which has the advantage of being an acid dye and quite permanent, but is of very shallow cut. The methyl violets can be well replaced in filter making by the acid violets, which are of even sharper cut in the deep red, and are much easier to work with.

For the absorption of the green proper, there are two groups of dyes of the same chemical type:—the fluorescines, which are acid, and the rhodamines, which are basic. Fluorescine itself, or uranine, absorbs only the blue-green, and as the molecule is weighted by the addition of chlorine, bromine and iodine atoms, the band moves towards the yellow; so that the heaviest member of the group, rose bengal, has a sharp band with a maximum at 5,600. Rose bengal is still probably the best dye for the red filter in tricolour work. It is not quite permanent any more than most of the dyes which have been discussed, but it will stand full daylight and sunlight for three months, which is all that can be asked of any filter except possibly an orthochromatic filter.

Of the rhodamines, rhodamine B is the only one in general use, though very many varieties are made, the others do not seem to offer advantages over the corresponding fluorescines. But there is one dye which can be taken as belonging to both the rhodamine and fluorescine groups, and which has only recently come to our notice, which we consider of the greatest possible importance. This is xylen red from Hoechst. It is both an acid and a basic dye,

works perfectly with gelatine, and will mix with the acid dyes, It has the sharpest absorption band towards the blue which we know, and makes a very nearly perfect complementary-to-green dye.

Mandarin orange has an absorption band in the same position as uranine, transmitting the extreme violet, but the only yellow dye absorbing the violet satisfactorily and still transmitting the ultra-violet, is Wood's para-nitroso-di-methyl-aniline. Tartrazine has the defect of not completely absorbing ultra-violet, but still it absorbs a great deal. Filter yellow K completely absorbs the ultra-violet except in dilute solution, in which case picric acid is better, though this cannot be used for making orthochromatic filters, as it rapidly goes brown on exposure to light. For the absorption of the ultra-violet from 3,900, aesculine is the only known substance, but if the extreme ultra-violet from 3,600 to 3,000 only need be absorbed, beta-

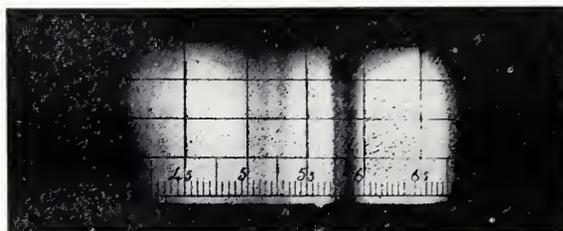

Fig. 9.
Didymium glass absorption.

naphthol-di-sulphonic acid is a more satisfactory substance, and does not darken in light nearly so quickly.

In order to make a filter which transmits the ultra-violet but does not transmit the visible spectrum, it is necessary to use para-nitroso-di-methyl-aniline with blue-violet dyes, and unfortunately these blue-violet dyes always strongly absorb the ultra-violet, the rhodamines and xylen red having an absorption band there. In order to avoid this difficulty we have obtained from Schott and Genossen, of Jena, some of their blue uviol glass, which is extremely transparent to the ultra-violet; by cementing the film between two pieces of this glass, a satisfactory ultra-violet filter can be prepared.

Special Absorptions.

A useful filter is a piece of didymium glass, also obtainable from Messrs. Schott and Genossen, as the absorption bands from this are very narrow and sharp, and can be well used for roughly scaling or setting spectroscopes (Fig. 9). The band in the yellow will also

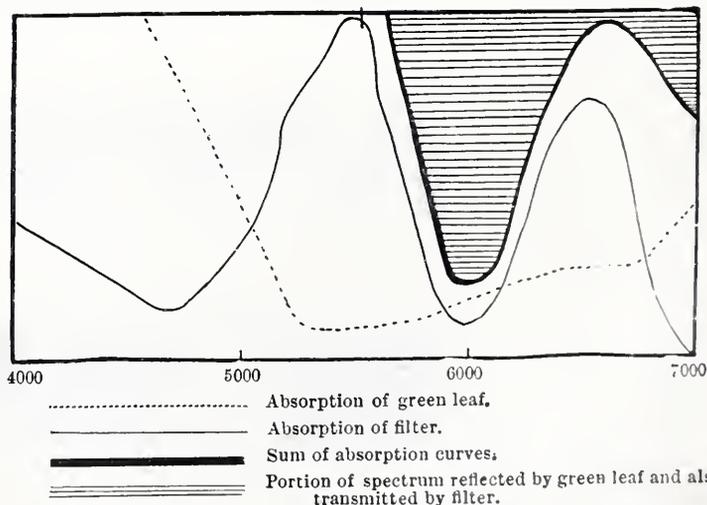

Fig. 10.

completely remove the sodium and mercury yellow lines, and a filter made by cementing a strong yellow film between two pieces of didymium glass of a thickness not more than 1 cm. will transmit only the green line, and this almost undiminished, in a mercury lamp. In this way the most powerful monochromatic light source that we know can be obtained.

We have prepared a number of interesting filters having double-banded absorptions and transmissions. One which we prepared some time ago had the interesting effect that while it was either a black or a green filter, it made the green of trees and grass appear red.

The filter was one which had two transmission bands, one in the red, one in the blue-green, there being a strong absorption band in the yellow-green, and the depth of the two transmission bands was modified until the whole filter appeared black when looked at, the red and blue-green bands balancing each other. Now the green reflection from a leaf has in it very little blue or blue-green; it consists of the central green and yellow-green of the spectrum, and of a considerable amount of orange. The yellow-green and central green are absorbed completely by the filter while the orange is

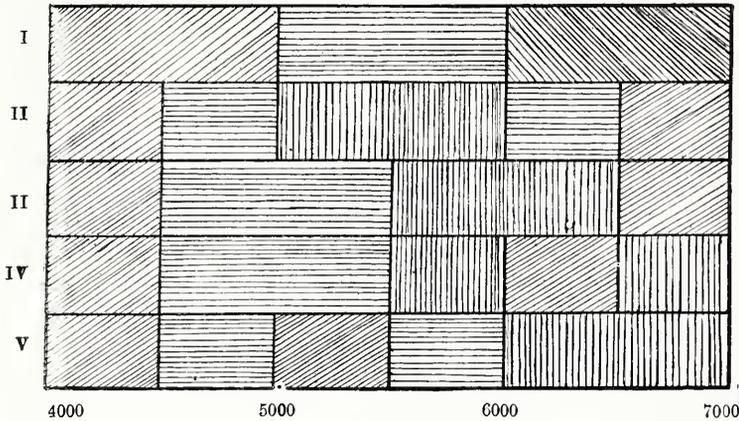

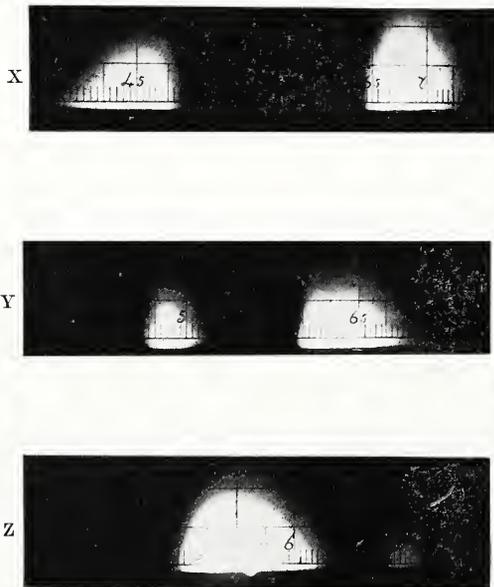

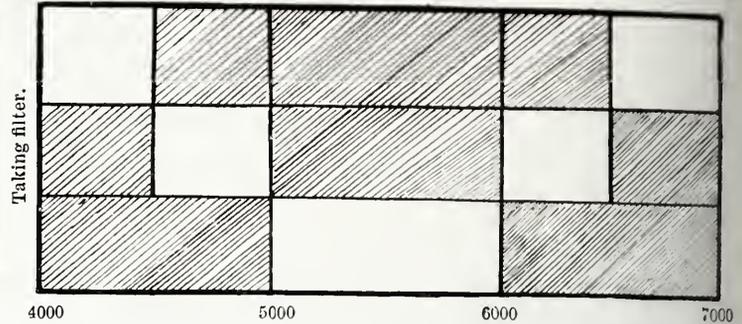

Fig. 11.

transmitted, so that although the filter may be black or even green to the sky, yet green leaves will appear orange brown through it (Fig. 10).

Another piece of work which as an exercise in absorption work has been of interest, has been the cutting up of the spectrum into tricolour filters in other ways than those usually employed. Fig. 11 may make this clear. Consider a spectrum extending from 4,000 to 7,000. For normal tricolour work this is split into three portions extending from 4,000 to 5,000, 5,000 to 6,000, and 6,000 to 7,000. This is shown on line 1. Line 2 shows us another method

have called X, comprises the whole of the spectrum from 6,500 to 4,500, and is consequently light green. The complementary to the second one, the plum coloured filter which we have called Y, has

two absorption bands, one extending from 4,500 to 5,000, and the other extending from 6,000 to 6,500. It is a whitey-green in appearance by daylight, and bright green by artificial light. The third

Fig. 12.

filter is central green, and its complementary is magenta. This filter we called Z.

We have prepared these filters as actual filters, and have photographed the spectrum through them, Fig. 13, and having explained their composition, we think it would be a useful exercise for those

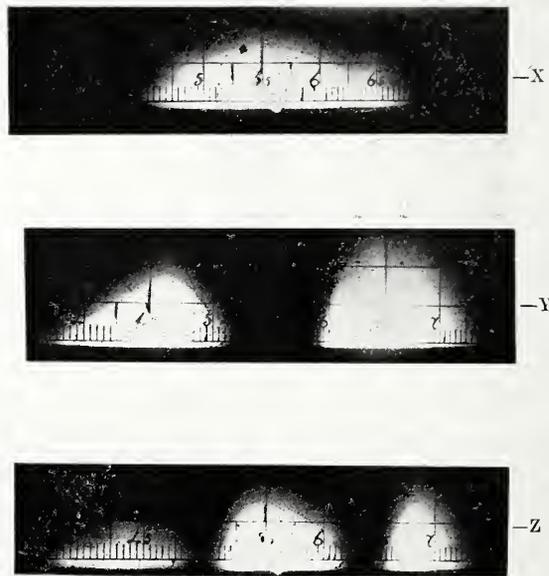

Fig. 13.

of splitting up the spectrum, and the three filters there are (1) identical with our former green filter from 5,000 to 6,000; (2) a filter which transmits from 4,500 to 5,000, and also from 6,000 to 6,500, and is a kind of plum colour; (3) one transmitting from 4,000 to 4,500 and also 6,500 to 7,000, a purple filter. Figs. 3, 4, and 5 show some suggested other methods of splitting up the spectrum. The method just discussed in line 2 has been more completely worked out. In Fig. 12 the upper diagram shows in its clear spaces the light transmitted by its taking filters, and the lower diagram shows the corresponding printing colours. It will be seen that the colour complementary to the methyl violet coloured filter, which we

who think that they understand three-colour work to try to work out the effect of photographing a chart of mixed colours by means of these three colours, and printing them in their complementaries. We may point out one conclusion, which will be found to be borne out in practice; this is that since the filters are symmetrical about the centre of a spectrum, they will not distinguish a red from a blue, and consequently all deep reds will appear of the methyl violet shade, and so will all deep blues, while bright blues and scarlets will appear as magentas; but the exercise is an interesting one for various colours, and can be safely left to our readers.

In concluding this paper, we hope that even if these later sug

gestions as to eccentric sets of tricolour filters, or filters which make things appear in their wrong colours are not considered useful, they may be taken as corresponding to those mathematical puzzles of which mathematicians are occasionally guilty; while the more serious discussion of the values of different groups of dyes in the earlier portion of the paper may be of use to those who are interested in the work.

S. H. WRATTEN.

Photo-Mechanical Notes.

The Ascertainment of Parallelism.

As stated in the article published recently, the photo-engraver, to whom parallelism is essential, is usually provided with a camera and a copy-board that cannot be other than parallel; but it not infrequently happens that an operator has to photograph pictures with an ordinary camera away from the studio, and then he is in need of some such apparatus as that devised by Mr. Carnegie, and described by him. But I fear this would be regarded by the average operator as somewhat complicated in use, and so he provides himself with something that answers the same purpose, albeit not quite so accurately. This consists of a metal pointer (hung on a knife edge, and so swinging freely) on a small board, the edge of which is perfectly straight. At the bottom of the pointer is a small adjustable indicator. If the edge of the board is placed against the picture the swinging metal pointer will drop vertically, and the indicator can be moved until it corresponds to the position of the pointer; now the board is taken and placed vertically on the ground glass of the camera, when the camera is tilted or the back swung until the pointer reaches the same position as the indicator. A home-made apparatus can be used by taking a piece of stout cardboard with a true edge and inserting at the top in the centre a piece of thread with a small lead weight attached. Place the straight edge against the picture and make a pencil mark on the card when the plummet has come to rest. This can now be used at the ground-glass. This method conveniently ensures vertical parallelism; to ensure horizontal parallelism a compass is used. In the instruments sold for the purpose this is mounted on a square piece of wood, and the case covering the needle which carries a mark at north and south, can be rotated so that the two marks can always be brought opposite to the two points. After placing the edge against the picture and allowing the needle to come to rest, the case is rotated—and fixed when the marks come opposite to the needle ends. Now the compass is taken to the back of the camera, and the camera turned until the needles again come opposite to the marks, care being taken that N. is kept to N. at both picture and camera back. Of course, any ordinary compass can be used, supposing it is mounted in a square mounting, and the readings noted or indicated by an ink spot on the glass. Unfortunately, the compass sometimes fails when working in the neighbourhood of powerful arc lamps.

A. J. N.

Reproductions of Academy Pictures.

The annual flood of half-tones reproducing the Royal Academy and New Gallery pictures serves to show both how far we have gone from, say, ten years ago, and how far we have yet to go before even the moderately critical can be satisfied. Finer screens are used, and the printing is better, but comparison with the original pictures will show that there is nothing like the same improvement in the truthful rendering of the luminosity of the various colours, and the subtle tones of the artist are often sadly to seek. Worse than all, the sometimes baleful work of the fine etcher, in his efforts to brighten up the block, leads to the absolute ruin of the artist's intention. Thus we have in mind a delicate nude study in which the fine etcher has heavily outlined the figure and stopped out the eyebrows, the nipples, and even the fold in the abdomen, so that the accentuation of these mere suggestions of the painter made the reproduction grotesque. Certainly we have improved, but until it is possible to reproduce a picture without fine etching (unless done under the express instruction of the artist), we cannot be said to have improved sufficiently.

Another Transposition Method.

Where photo-litho transfer paper is in use, an easy and satisfactory transposition method is available if the matter is printed in good solid impression either from stone or type on to the sensitised paper. The

paper can then be exposed to light, rolled up all over with transfer ink, and developed in the usual manner. The result is that where the impression was, no insolubilisation has taken place, and the ink will wash away there, leaving the design in black and white. This can then be transferred to stone or zinc and printed from, giving a very sharp reverse.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between May 10 and 15:—

CINEMATOGRAPHS.—No. 11,045. Improvements in cinematograph apparatus. George Bennett Bowell, 40, Chancery Lane, London.

CINEMATOGRAPHS.—No. 11,132. Improved cinematograph film-feeding mechanism. William George Barker, 55, Chancery Lane, London.

THREE-COLOUR SCREENS.—No. 11,147. Improvements in three-colour screens for photography and the process for their manufacture. John Bamber, 33, Cannon Street, London.

APPARATUS.—No. 11,250. Machine for colouring cinematographic films. Reginald William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes, Cinématographes, et Appareils de Précision, France.

CAMERAS.—No. 11,546. Improvements relating to cinematographic cameras. George William Curtiss, 31, Bedford Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SCREEN-PLATES FOR COLOUR PHOTOGRAPHY.—No. 9,044, 1908 (April 25, 1908). The invention relates to the making of a fine mosaic screen-plate. A thin film of a suitable vehicle (e.g. collodion), mounted upon a suitable carrier (e.g. a glass plate, or a sheet or film of waterproof material), is first uniformly dyed all over with a suitable dyeing agent, say of a red colour. A solution of a protective agent or resist consisting of indiarubber, guttapercha, bitumen or paraffin wax, dissolved in a suitable solvent, for example, naphtha, is then applied in the form of spots so as to partly cover the film; the colour from the exposed portions of the film, that is to say, those portions not covered by the spots of protective material, is removed, by dissolving out or bleaching the colouring agent, and the exposed portions of the film are dyed with another colouring agent, say of a blue or blue-violet colour. Then another set of spots of protective material of the kind mentioned are applied to the film so as to cover a further portion of its surface, the colour is again removed from those portions of the film still not covered by the second application of the protective material, and then the remaining exposed surface of the film is dyed with a third colouring agent, say of a green colour, the spots of protective material being finally removed by a suitable solvent in such a manner as not to disturb the multi-coloured film. Usually only the three colours mentioned are necessary. Excess of colouring agent is washed off after each application of dye to the collodion, e.g., by water. In this way there is produced a film comprising an immense number of fine closely arranged coloured spots that are in contact with one another so as to leave no clear spaces between them and none of which overlap others. The film of collodion applied to the glass plate or other carrier may be dyed previously to being applied to the carrier. In some cases, as protective material of the kind mentioned does not materially interfere with the coloured spots or the transparency of the screen, it need not be removed.

Each of the two first mentioned colours can be dissolved out of the collodion film, as set forth, by agitating the coloured and partly protected film in a liquid which will not dissolve the protective material used—e.g., in alcohol—or the colour can be removed from the film by bleaching it—e.g., with a solution of a bleaching agent,

for example, chlorine, or acid or alkali, as may be found advantageous.

The spots of protective material can be applied in various ways. Preferably they are applied in the form of a fine spray produced, for example, by an aerograph spraying machine of the kind now commonly used by artists and others. By this means spots of protective material of extreme fineness can be deposited upon the film, resulting in the production of a colour screen composed of an infinite number of closely arranged coloured spots.

The application of a protective agent or resist in the form of a fine spray, as set forth, constitutes an important feature of the present invention and can advantageously be adopted in any method of forming colour screens wherein it is required that a protective agent or resist shall be deposited upon a film or surface in a finely divided condition.

The protective material used must, of course, be one not soluble in the solvent used for the dyes, or in the liquid that may be used for bleaching the exposed portions of coloured film. Also, the solvent used for removing the protective material, when such material requires to be removed, must be one which will dissolve the spots of protective material without affecting the multi-coloured collodion film below the same. By using indiarubber, gutta-percha, bitumen, or paraffin wax, dissolved in naphtha, and alcoholic or aqueous solutions of aniline dyes as the colouring agents, the above requirements are complied with.

Colour screens produced as described can be coated, as usual, with a sensitive film, a film of protecting material, for example, indiarubber or varnish, being first applied to the coloured screen, if desired. George Sydney Whitfield, of the Paget Prize Plate Co., Ltd., St. Albans Road, Watford, Herts.

SCREEN PLATES FOR COLOUR PHOTOGRAPHY.—No. 21,840, 1908 (July 23, 1908). The process of localised dyeing which is employed consists in allowing the dye, after parts of the surface have been coloured and dried, to act so briefly in the subsequent dyeings that the previously coloured areas are not affected, but only the areas which are uncoloured and exposed to the dye are coloured. The process is based on this fact, not upon methods of partial insulation or application of a resist. Hitherto if, for instance, a strip of celluloid is partly immersed in a red concentrated colouring solution (e.g., rhodamine), and the surplus colour adhering to the surface be washed off with water and then allowed to dry, a red strip intensely coloured to half its extent is obtained. If this strip be immersed in a green alcoholic dye solution (e.g., malachite green), and left therein for a long time, then washed and dried, it is noticed that the part formerly uncoloured appears green, whilst the part dyed red has also strongly absorbed the green colour and has thereby become discoloured.

The colouring, however, takes place quite differently if these strips, according to this improved process, be only left a few seconds in the second green dye solution, and then rapidly immersed in water, with the object of immediately interrupting the action of the alcoholic solution. In that case only the part of the celluloid which has remained uncoloured becomes intensely coloured, whilst the part of the surface which was first coloured red remains unchanged.

This action may be explained by the colour or dye which has dried on the surface from the first colouring acting initially as a resist or insulation against the action of the second colouring.

As in this example an alcoholic dye solution acts for a short time on celluloid and as its duration of action is interrupted by immersion in water, a liquid in which the celluloid does not absorb colour, surfaces consisting of gelatine, casein, and the like, which are adapted to be coloured in a watery solution may be differently coloured according to the same principle, after a sufficiently short action. It is only necessary to interrupt the action of the watery colouring solution at the right time, which is possible by immediate immersion in alcohol or squeegeeing off or absorbing the surplus colour.

An example of carrying out this process is, for instance, the making of celluloid sheets which are intended to have, for instance, in a red frame, green transparent writing with blue initial letters. Transparent celluloid is printed with the desired text in printers' ink, placed in a cold saturated alcoholic solution of rhodamine B, whereby the parts not covered by the print, that is to say, the

framing or border, are dyed, whilst the places covered by the printers' ink, which form the letters, are not coloured. The celluloid is then immersed in water in order to remove the excess of colouring solution and dried in any suitable manner. The printers' ink which forms the small letters is removed and the surface exposed for about two seconds to the action of a cold saturated alcoholic solution of malachite green and then immediately placed in water and dried as before. By this means the small letters exposed are coloured green without the already red coloured border being affected, whilst the printers' ink of the large letters insulates the ground or foundation.

The large letters are now also to be coloured blue. This is done by removing the printers' ink from the large letters also, whereupon the sheet without any protection of the previously exposed parts is immersed for about a second in a cold saturated alcoholic solution of a blue dye, for instance, spirit blue, and immediately placed in running water and then dried. The result is that now the large letters which alone remained bare are coloured blue, without affecting the red and green colours.

Another example is afforded in the production of multi-coloured screens. If a two-coloured screen is to be made, celluloid, for instance, is printed with a fine series of lines, immersed in a cold saturated alcoholic solution of rhodamine G, whereupon only the exposed lines are coloured but not those which are protected by the printers' ink. After drying, the printers' ink is removed, for instance with turpentine oil, whereupon the transparent celluloid is laid bare. By immersion for two or three seconds in a second differently coloured dye solution, for instance a cold saturated alcoholic solution of crystal violet, the bare transparent lines are coloured in a second colour, without its being necessary to insulate in any way the previously coloured lines, so that the first coloured lines take on no further colour.

In order to make three-colour screens, the process is adapted particularly in combination with the process described in Patent No. 21,839 of 1908, the following method being preferably adopted. A fine system of lines is impressed by means of a copper matrix in transparent celluloid, in such a way that the depressions form a third of the total area. The raised part, as described in the specification just mentioned, is rolled with printers' ink, thus only coating it, whilst the interstices remain free. After insulation of the rear side of the sheet, it is placed in a cold saturated alcoholic solution of crystal violet.

Only the depressions are coloured, whilst the raised portions remain uncoloured. After washing and drying, the printers' ink is removed and a second series of lines is impressed at right angles to the direction of the first. The printers' ink roller is again passed over the sheet, and when it is immersed in a cold saturated alcoholic solution of malachite green, the raised parts remain uncoloured, because only the depressions are exposed to the action of this dye solution. The application of this improved process commences at this point.

Whilst formerly no importance was attached to the period of action of this second alcoholic dye solution the period of action is now reduced to a minimum. This minimum is dependent on the concentration and the nature of the dye solution, on the depth of the relief and so forth, but in general only extends over a few seconds. Therefore this second dye solution is only allowed to act about three seconds, and thereby depressed lines are only coloured in the places which have remained transparent, while where the blue points cross these impressed exposed lines no colouring takes place. The printers' ink is then removed and without any insulation of the printed side, it is exposed to the action of a cold saturated alcoholic solution of rhodamine G, but only for one second. By this means only the remaining third which has remained free, is coloured intensely and brilliantly red whilst the two other already coloured parts remain unaffected.

The necessary photographic intensity of the colours is sufficient in spite of the short period of action.

By the application of pressure and heat, the separate colours are then brought into one plane and so a complete screen mounted in celluloid is obtained. Vereinigte Kunstseidefabriken A.G., Kellstedt, near Barmen, Germany.

PROJECTION APPARATUS.—No. 24,621, 1908 (November 15, 1907). This invention relates to an improved optical projection apparatus.

of the kind adapted for the projection of views on opaque bodies such as photographs or engravings. Such apparatus usually comprises as its essentials two lamps which throw converging rays, either by means of reflectors or condensers, on to the view which is then projected by suitable combinations of lenses.

The present invention consists in improving the details of such an apparatus; for instance, the lamp holders and condenser supports, which are removable and adjustable, and the relative dimensions and shape of the casing whereby a more convenient construction is attained.

The claim is for the improved optical projection apparatus constructed in plan in the form of a right-angled triangle with each of the angles cut away to produce short sides, two of which are constituted by doors for the introduction of the lamps and the other has a covered aperture opposite which the view to be projected is slidden. Albert Leveque, 13, Rue des Ursulines, Tourcoing (Nord), France.

New Trade Names.

AUTOCHROMES LUMIERE (DESIGN).—No. 306,657. Sensitised films and plates for use in colour photography. Société Anonyme des Plaques et Papiers Photographiques. A. Lumière et ses Fils, 21, Rue St. Victor, Lyon-Monplaisir, France, manufacturers. October 3, 1908.

B. M. AND Co.—No. 310,589. Alkalies used in manufactures, photography, or philosophical research. Brunner, Mond, and Co., Ltd., Winnington, Northwich, Cheshire, alkali manufacturers. February 17, 1909.

Reflex Suggestions.

I think that there can be little doubt (writes Mr. J. Milton Watson in "The Amateur Photographer and Photographic News" for May 25) that the average worker directs his attention chiefly to landscape work and portraiture, for which high speeds are impossible, and to such a reflex camera, with a simple focal-plane shutter giving merely low speeds, would be a great boon and much appreciated, for a slow-speed shutter ought not to call for such intricate mechanism, and should be cheaper to make than one that combines both high and low speeds. Messrs. Adams and Co. have made a preliminary announcement of the appearance of a new focal-plane shutter, which is to be fitted to their new Studio reflex, working merely to about 1-100th of a second, and giving time, bulb, and slow automatic speeds. Could not this be fitted to the Videx? And cannot Messrs. Newman and Guardia, Marion, Watson, and the Thornhill-Pickard Co.—to mention no others—give us a similar slow-speed shutter fitted to their cameras? I am sure that a well-made high-speed instrument, fitted with such a shutter, would have many purchasers, especially were the camera priced at not too high a figure.

One other suggestion. There is a large number of camera users who prefer to work with roll-films for touring to save weight and trouble. I do not know that there is a single roll-film reflex on the market, while a detachable roll-holder is to me a nuisance. And surely the reflex camera, above all others, is most peculiarly suited for use with roll-films, seeing that, as a rule, it is not possible to focus for each exposure on the ground-glass of ordinary film cameras. A roll-film reflex with closed back would probably only mean an addition of, at the most, an inch to the present length of the camera, and such an instrument would be of inestimable benefit for touring. The absence of dark slides would mean decreased weight and cost.

A good specification for the ideal tourist's camera would be: Reflex, revolving back, for use with roll-film, but capable of being adapted for use if required with dark slides, low-speed, focal-plane shutter, with a speed capacity of from 1-10th to 1-100th of a second, time bulb, and automatic slow speeds of $\frac{1}{2}$, $\frac{1}{4}$, 1, 2, and 3 seconds, long double extension, good rack rising and double swing front.

New Materials, &c.

The "Sanzol" Green Toner. Made by H. Edmund and Co., Ezra Street, London, E.

This is a new toning solution for bromide and gaslight prints, which on trial we find to work excellently. The toner is put up in a carton containing a couple of 2 oz. bottles, sufficient solution to make 36 oz. of toning solution. The print is soaked in water, ten minutes' soaking being advised for prints that have been made some time before toning, and is then immersed in the toner for times from seven to ten minutes, according to tone required and strength of print. No apparent difference is produced in the toning bath, but when the time is up the print is washed in five changes of water and then immersed for two minutes in dilute hydrochloric acid, 2 per cent. strength, when the green tone at once appears. A final washing for fifteen minutes in seven changes of water completes the process. We found that brighter greens were produced by more prolonged immersion in the acid, and it appeared that the final tone depended to some extent on this time, though the instructions did not suggest this. Very prolonged immersion in the toning bath had a similar effect. The process can be repeated if desired, if the first tone is not bright enough. Ten minutes' toning and two minutes in the acid give a dark, quiet, and very pleasing green of the terra-verte or reseda variety. Longer toning gives a yellow green tending to an olive, while after several repetitions a distinct blue is reached in the light tones, the shadows remaining olive. The process gave no trouble whatever, and worked with great certainty, and those who find a use for green toned prints can be strongly recommended to try this new introduction. The cartons, containing two solutions, cost 1s.

CATALOGUES AND TRADE NOTICES.

SECOND-HAND CAMERAS.—The City Sale have just issued from 54, Lime Street, London, E.C., a large quarto 16-page price list of second-hand cameras, including many reflex and other hand-cameras, stand instruments, and a large selection of studio cameras and lenses. The list, which is sent free, describes an immense variety of apparatus obtainable at sale prices.

SOME BUSINESS MAXIMS.—The new "list of charges" just issued by Messrs. Raines and Co., and the subject (on another page) of a few words of merited appreciation, contains, scattered through its pages, quite a number of brief paragraphs, each with some kernel of suggestion for increasing or solidifying your business:—

We do not believe it possible to create more than one reputation. A business, whether that of professional photographer or that of trade enlarger and printer, can have but one reputation—that for quality or that for cheapness.

The Raines "Service" stands for quality, and it believes that quality is the professional photographer's best policy. Cheapness is the province of the "Twelve for a shilling—sit to-day, ready to-morrow" man, and the photographer desirous of maintaining or creating a sound business can no more compete both on quality and price than he can mix oil and water.

We are frequently asked by middle-class photographers how can they best compete with their neighbour who is offering bromide enlargements at ridiculously low prices. Our invariable reply is: Do not attempt to do so by showing enlargements that afford any opportunity for comparison of price. Show something completely different.

The taking of photographs may be an art, but the selling of them is purely a business matter, and the importance attached to a window display by the most successful houses of business in every line to-day is such that the photographer cannot afford to neglect any opportunity of attracting the attention of the passer-by.

Many of our customers are ordering, on an average, a miniature every month. When it is realised that a tactful receptionist can equal this in any middle-class studio the desirability of having a specimen for her to show is at once seen.

Meetings of Societies.

WEDNESDAY, JUNE 2.

Edinburgh Photographic Society. Forty-Ninth Annual Meeting.

THURSDAY, JUNE 3.

Bideford Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 25, Dr. Evershed in the chair. Mr. H. W. Bennett read a paper on "Methods of Toning Bromide Prints," in which he described a number of variations of the sulphide toning process, made with the object of securing a considerable range of colours. A number of questions on details of these methods followed the reading of the paper, and a vote of thanks was passed to Mr. Bennett at the conclusion of an instructive evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held on Thursday, May 20, Mr. W. R. Stretton being in the chair, Mrs. Kitty Human gave a lecture upon the photography of "Flowers and Still Life." The lecturer described the various methods which she used to take the flowers in their natural gracefulness, and first named that of laying the blooms upon a sheet of glass and taking them with the camera pointing downwards. This method, she said, was very handy for some subjects, as it placed the background a little out of focus, but it had the drawback that it very often gave reflections which were very troublesome, and led to the spoiling of many plates unless great care was used. For flowers which had a long stalk she recommended a strip of good stiff lead, about two or three inches in width, and folded into a series of S's, or a glass funnel turned upside down and the bloom inserted into the narrow end was very useful when treating single blooms; also a jar filled with fine sand would be found of service, and would hold a variety of blooms in almost any position. The long narrow vases, that are now so easy to obtain, were most useful for flowers with long stalks, whilst hanging plants were best photographed in their pots, hanging from a cord across the room, in front of the background; this meant long waiting for the flowering plant to find its level. For backgrounds it was found that nature papers were all that could be desired. The various shades of greys and browns were the most useful.

As regards plates, the lecturer was a firm believer in orthochromatic plates; they were absolutely essential for flower photography. It was advised to cut the bloom overnight if one desired to get the best results, and after arranging them to let them stand for a short time before making the exposure. Only by this means could one be sure of not having movement in the result. Flowers always tended to turn to the light, even after they had been cut for some time. Another point was to handle the blooms as little as possible; by no means should any attempt be made to force them into a strained position.

The lecture was illustrated by means of about a hundred and twenty slides, and a most hearty vote of thanks was accorded to Mrs. Human.

COLOUR CINEMATOGRAPHY.—It is only when the sun shines brightly that "Kinemacolor," or the art of bioscoping animated scenes in the actual tints of Nature, is practicable. Thus, when the fine weather came, three weeks ago, Mr. Charles Urban at once sent out his camera-men, and on Wednesday last Mr. Alfred Butt, as holder of the exclusive exhibition rights in London, introduced several new military and rural subjects, and particularly some remarkable views of the Alpes Maritimes, into the programme at the Palace Theatre. Usually regarded as a winter subject, the Alps of plashing waterfalls and snow-capped mountains sparkling in the sun provide new charms to unaccustomed eyes.

Commercial & Legal Intelligence.

LOSS OF A PHOTOGRAPH.—At the Gateshead County Court, last week, Thomas Collins, miner, of Shields Row, claimed from Harris Bell, picture framer, Redheugh Terrace, Gateshead, the sum of £5 or the return of a photograph, which plaintiff had entrusted to defendant, through his agent, to be framed. Plaintiff said it was a large photograph in respect of which he claimed. It was a picture of his three brothers and sister, and was taken in South Africa and sent to him. Its loss was irreparable, as two of his brothers shown on the photograph were killed during the South African war. Defendant's canvasser was handed the picture to be framed, and it was not returned. Mr. Lambert said he could not deny that his client had received the picture, though defendant had failed to trace the photograph or the canvasser to whom it was entrusted. He submitted that its value was greatly overstated, because the court was only entitled to take into consideration its actual value, and not the sentimental value attached to it by plaintiff.—His Honour Judge Greenwell said it was difficult to fix the value of the photograph, but certainly plaintiff was entitled to something for its loss. He gave judgment for 50s., with costs.

SHOP HOURS ACT.—Amongst the ten prosecutions from March 12 to May 5, inclusive, under the Shop Hours Act, 1892-1904, reported to the London County Council this week, was a case of a photographer in the West of London, who was fined the costs of the summons, viz., 12s. 6d., for employing a young person ten hours in excess per week; for failing to exhibit a legal notice the defendant was further fined 5s. and 2s. costs.

CINEMATOGRAPH PROFITS.—Although the Biograph Theatres, Limited, was registered as recently as October 9, 1908 (to acquire the privately owned cinematograph business), it is already able to present a substantial list of theatres open and running. This is the natural result (writes the *Financial News*) of the rapidly expanding popularity of this class of business, which exactly meets the public taste for something light and pretty. The theatres at present open are:—

Theatre.	Situation.	Seating capacity, about.
1. Parkhurst	Holloway Road	560
2. Bijou	Kilburn, N.W.	160
3. Electric	Rye Lane, Peckham	450
4. Picture Palace	Wandsworth, S.W.	380
5. Picture Palace	Hornsey, N.	420

Of course, it must be understood that as these theatres are filled and emptied as often as seven or eight times daily, the real daily seating capacity is equal to the number of seats multiplied by the number of performances. The company is pursuing a progressive policy, and is opening on the 24th inst. a theatre in Wilton Road, Victoria, with a seating capacity of 450. This building, so it is said, will be the finest and most luxurious of its kind in London. Further sites are reported as acquired at Lewisham, Clapham Junction, and Kilburn, and structural additions are being contemplated at the Holloway and Wandsworth Theatres which should increase the seating capacity of the entire group of theatres from 2,000 to 4,650. Negotiations are also understood to be proceeding for the acquisition of other convenient and suitable sites, so that it is anticipated that within a year this company will have from 15 to 20 of these theatres and halls open in and about London. The five theatres, with 2,000 seating accommodation, have for the last three months, according to the official figures, shown average receipts of £325 3s. per week, or 3s. 3d. per seat. At the same ratio 4,650 seats should give £755 12s., and as experience shows, so the company says, that the half of this amount will more than cover the working expenses, the profits, when these new theatres are opened, are calculated at about £377 per week—equal to nearly £20,000 per annum. The further sites which are being negotiated for the erection of theatres will have an additional seating accommodation for about 2,000 persons. By this means it is hoped that by the autumn another £325 gross per week should be taken, or a total of about £1,080 per week, which represents, allowing for 50 per cent working costs, a profit at the rate of £28,000 per annum. But before that period sites for the erection of other theatres will have

been acquired; so that a further upward readjustment of the figures is talked about.

The practical administration of the company is under the control of Mr. G. W. Grant, the managing director, who has had a wide experience of this class of business in America. Cinematograph pictures have been shown now for the past ten years in London at the Palace, Empire, and Alhambra, and are still attracting the same interest as at the outset.

AN APPRENTICESHIP QUESTION.—At the Epsom County Court, last week, David Knights Whittome, photographer, Sutton, claimed £75 damages against Emily Louisa Cranston, grocer, Cheam, for breach of covenant in respect of an apprenticeship indenture, dated October 26, 1907, under which defendant covenanted plaintiff that her daughter, Emily Helen Cranston, should serve plaintiff for three years, from January 1, 1908.

Mr. Addington Willis appeared for plaintiff and Mr. Robinson for defendant. Mr. Willis said that plaintiff was a photographer in a high class of business, and was photographer to the Royal Family. The breach of covenant consisted in defendant's daughter absenting herself from her master's service. Mr. Robinson stated that the defence was that her absence was due to illness. After hearing the evidence his Honour said he considered it a pity matters had reached such a stage, and at his suggestion the parties had a consultation. As a result of this, Mr. Willis said the action would be withdrawn, each side would pay its own costs, and the daughter would go back to plaintiff on the following Monday.

LEGAL NOTICES.—A dividend is to be paid in the case of Joseph Sharples (trading as the Romanus Publishing Co.), 54, Church Lane, Marple, Cheshire, photographer and publisher. Proofs should be sent to the Official Receiver, Mr. A. C. Proctor, 23, King Edward Street, Macclesfield, by June 5.

A Receiving Order, dated May 19, has been made in the case of Alfred Chapman Blades, photographer, of 50, Queen's Road, Hastings. The petition was filed by the debtor himself on the same date. He has been adjudicated bankrupt.

News and Notes.

THE RAINES SERVICE.—The 1909 "list of charges" which Messrs. Raines and Co. have just issued is more than a price list. It is a demonstration of what this enterprising firm is able to do. It has become a recognised principle of modern business that one does not go far wrong in judging a firm by its ability and discretion in advertising, an argument which may be fallacious where all advertisement help is supplied from an outside source, but is certainly true in the case of Messrs. Raines, the whole of whose advertising, stationery, etc., emanates from the management of the works itself. Therefore it is only common sense to argue back from the evident pains and trouble taken by Messrs. Raines in advertising, catalogue-making, etc. (which can be seen every week in the "B.J.," and by writing to Raines for the present list), to similar pains and trouble taken in enlarging and printing. We know that the methods are the same in the two cases, that the Raines business puts a sustained standard of quality first on its agenda, and for that reason has earned the confidence of innumerable photographers for their work in enlarging (in bromide, carbon, and platinotype), in finishing, printing, and framing. We could point to several new styles and specialties for photographers in the present list, but we prefer to let our readers study these for themselves, as they can do from the very well arranged pages. Enough that we emphasise the thoroughness and reliability of the "service" which Messrs. Raines are rendering.

PHOTOGRAPHY AT THE L.C.C.—The Establishment Committee of the London County Council report that the financial results of the year's working of the new system whereby the photographic work of the authority was undertaken by the chemical, etc., department, was satisfactory, and justified a continuation of the present methods for one year, at the end of which time permanent staff arrangements would be considered. The services of Mr. A. E. Lane at £200 with

one assistant at 35s. a week, and a boy at 12s. a week, are to be retained accordingly for another twelve months.

ROYAL PHOTOGRAPHIC SOCIETY.—Out of seven applications for admission to the Fellowship of the society the following three candidates were elected:—J. Willis Grundy, John Maddison, and George Edward Thompson.

HAROLD BAKER, LTD.—At the annual meeting of this company, held on May 1 last, a dividend of 5 per cent. was declared.

"TRAVEL AND EXPLORATION."—The June number of "Travel and Exploration" contains articles on the two chief centres of interest in Turkey during the recent crisis. Captain F. H. Shaw contributes a chatty description of Constantinople, which has left imprinted on his mind "a picture of domes and minarets, of tiny booths and horrible cripples, of squalor, filth, and—most pronounced of all memories—the ubiquitous, mangy, wholly unpleasant dogs"; while Captain Arthur F. Townshend, formerly British Military Consul at Mersina, tells the story of a journey over the Anti-Taurus from Adana, supplementing his narrative with an account of the places that figure most prominently in the reports of the recent massacres. In Captain Townshend's opinion a massacre is hardly likely in Mersina, situated as it is on the coast with a large population of foreigners, including Consuls of nearly every European Power. On a previous occasion when a massacre was feared the fellaheen inhabiting the neighbouring districts, who are not really Moslems, announced that if it took place they would come to the help of the Christians. The result was that nothing occurred. Other contributors to the number are Colonel Sir Thomas Hungerford Holdich, who discusses the work that still remains open to the explorer in Central Asia; Dr. Oscar Bongard, who accompanied the German Colonial Minister to South Africa last year, and now gives an account of the tour, in which he warmly acknowledges the courteous assistance everywhere extended to the travellers by the British authorities; Mr. A. G. Adshead, who writes from Canada in reply to a previous article in which was set forth the dark side of a British emigrant's experiences in Canada; and Mr. G. D. Abraham, who tells the story of some climbs in the Alps. There are over a dozen full-page illustrations on art paper, and a number of maps.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.—The annual excursion of the above association to Farnham on Saturday, the 22nd inst., proved a success both from point of numbers attending and also the amount of work accomplished. The number of members putting in appearance at Waterloo allowed advantage to be taken of reduced fares and reserved carriages. Arriving in good time at Farnham, the party divided into two main groups—one going on to Waverley Abbey, Stella's Cottage, and Moor Park. The day was a tropical one, tempered by a breeze, and also a thirsty one into the bargain. A good number of plates were exposed by this contingent, numbering some fifty. The second party visited the castle, which had been placed at the disposal of the members by his lordship the Bishop of Winchester, and a good deal of work was done here, over seventy exposures being made on the exterior and interior parts of architectural portions, etc. The church and town were not so extensively done as could be wished, but as the survey secretary was accused at tea of accomplishing much useful work in recording the picturesque courtyards of the numerous inns, etc., it may be an incentive for members to take advantage and complete this phase of work, which is extremely interesting on a hot summer day, at some future period. The members and delegates represented the following societies: The Croydon Camera Club, the Croydon Natural History Society, the Geologists' Association, the Battersea Field Club, Surrey Archaeological Society, Sutton Photographic Club, Waddon Camera Club, Farnham Field Club, and the Aldershot Camera Club, who co-operated, much useful information being given by their hon. secretary, Mr. D. Morrison, to whom the association owe their thanks. The total number of exposures made in all were some 130. High tea was taken at Daracott's, 7, West Street, Farnham, at five o'clock, the catering being excellent, while Mr. Ed. A. Hale, photographer, of 25, The Borough, placed his five dark-rooms free at the disposal of the association for changing plates. Thanks are also due to the numerous residents and friends interested in the work of the survey for much useful information that was so freely given and made use of.

Correspondence.

RESTRICTIONS AT ROSTHERNE. To the Editors.

Gentlemen,—It was with some surprise that I noticed that you had been carried away with the sensational statements that have recently appeared in the Press respecting the action of Lord Egerton of Tatton, and I am sorry that my old and esteemed "Journal" should have been a party to the general clamour, for there is in this case, as in most cases, two sides to the question, and, so far as I have seen, the various papers have only given one side.

I am told by residents and tenants that Lord Egerton is a kind and considerate landlord, and a gentleman who would go out of his way to perform a kind action; that, so far from desiring to prevent the public from enjoying the beautiful country, he would make considerable sacrifice to permit of it. No action of his lordship can prevent the public from using the lanes and the highways, or from taking photographs if they wish to do so, and I am quite certain that he would be the last person to desire to do it. The beautiful park which he owns has been thrown open for years past to visitors. The reason for his lordship's action at Rostherne is, I am told, perfectly justifiable, and quite as much in the interests of his tenantry as in his own—perhaps more so—for a certain portion of those persons who have visited the village on Sundays in the past have behaved in a most unbecoming manner. They have broken down branches of trees and hedges; have harassed the cattle; have invaded the villagers' gardens and helped themselves to flowers; have been very noisy; and have sometimes molested the women folk going to or from church, and have frequently been guilty of conduct which one cannot repeat in print. I have not actually seen the objectionable conduct at Rostherne myself, but I have frequently been told about it by my friends. I have, however, witnessed it in adjoining parishes, and it is of a nature and character that makes one ashamed to think that his countrymen should be guilty of, and I am perfectly certain that you, Gentlemen, would be the last to uphold.—I am, yours faithfully,

J. BUXTON PAYNE.

Newcastle-on-Tyne,
May 21, 1909.

TRADE, PROFESSION, AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen,—A short time ago you answered a query, "Whether photography was a trade or a profession." In your issue of the 30th ult. were reproduced some examples of advertisements used by photographers which smack strongly of trade, and that not a very dignified one.

In the current issue of your paper Mr. Redmond, after recounting the "unfortunate" experience of a friend, concludes with the hope that "assistants and employers will do something to prevent sweaters ruining the fair trader"; the professional element does not appear to enter into Mr. Redmond's calculation. I fear that the hope expressed by this gentleman is a forlorn one. To hope for a better state of things is delightfully easy, but to suggest any practicable means of improving the "trade" or a plan which can even give any reasonable expectation that Mr. Redmond's hope may be realised is a very difficult task.

I have been a reader of the "B.J." for over thirty-five years. I do not mean by this that I have merely been supplied with a copy. *I have read it*, so that I have had ample opportunity of observing the changes which have taken place in the photographic world during that period, and it appears to me that in attempting to answer the question, "How has photography reached its present deplorable condition?" your correspondent's query must be carefully considered.

If I remember rightly, the view indicated by you was that if and "when the point was raised in a court of law—I had almost written justice—it will probably be held that, as practised by one person, photography is a profession, as practised by another a trade." With such an established precedent I should not be inclined to quarrel, but with the decisions based upon it I am not at all sure that I and a large number of your readers would feel disposed to agree. Who or what tribunal will trace the line of demarcation? Assume for a moment that such a tribunal existed, and I see no reason why it should not, there would be no need to appeal to courts of law.

Those who claimed to rank as professionals, and could make good the claim, might be registered as such, and be entitled to append to their names the magic letters M.S.P.P. Would it materially assist their proud possessors? I think not. In many instances it would have a contrary effect, as probable patrons would anticipate higher charges. Nothing would, in my opinion, be gained by distinguishing the sheep from the goats if the goats were allowed to graze in the sheep's pastures. Only legislation can prevent them doing this, and there is not the remotest possibility of any intervention from that quarter. Nor do I see how it can be consistently asked for.

Submitting one's anatomy to the camera is not attended with any risk which can affect the subject to the prejudice of the State, and so far as I am aware, in every case where any particular class enjoys exclusive rights or privileges they have been granted (at least ostensibly) in the interest of the community at large.

A registered plumber notifies by his business card and stationery that he is such. Does this assist him? Alone it would have exactly the same effect as the photographers' M.S.P.P., *but* the powers that be step in with the fiat "only capable plumbers (of which registration is evidence) shall be employed," and the tinkers are excluded. But, as I have already said, this is not designed for the plumbers' interest, but for the welfare of the State. An incompetent plumber makes bad joints, sewage escapes, epidemic and deaths ensue, State suffers. Dentists, chemists, doctors, parsons, lawyers are all covered by the same argument, within which it is not possible to include a photographer, be he an artist in its true sense or a maker of sticky-backs at 3d. per dozen. Each class must work out its own salvation if such a thing be possible or desirable.

Without cohesion assistants and employers are equally powerless, and I should like, if I may, to express the opinion (with a faint hope that someone will enable me to alter it) that, so far from anything being done to put a stop to "sweaters ruining fair traders," that competition will become keener every day. If this competition were confined to excellence of productions, or even to lowness of price, I for one would not complain; but it is not. Competitors of a class seem to vie with each other as to who can frame the most misleading and untruthful advertisements, or who can hoodwink the public most successfully. As an example, I enclose an advertisement which appeared in our local paper, by which you will see the advertiser claimed the exclusive right, "as maker," of no less than five photographic processes, and also that "best results" could only be obtained at his studio. This art photographer a few days before the issue of this advertisement sent to the chemist for a box of plates. The messenger left them on the counter. When the "operator," who had been canvassing with 16in. by 20in., came in the art photographer had opened the package and was carefully examining the plates in broad daylight, no doubt with the object of ascertaining whether the glass was strong enough to bear the strain of receiving an impression of his original and artistic ideas. I also enclose two circulars which were issued concurrently with the advertisement, which I think you will consider unique in art photography, and should settle once and for all the question asked by your correspondent and put to the blush the feeble efforts you recently published.

A friend of mine in the medical profession once told me that before attempting to combat a disease he endeavoured to ascertain all he could of the patient's history and habits, the commencement, duration, and general symptoms of the complaint, the suspected cause, and with these data in his possession to trace the diagnostic symptoms; and, assuming that the complaint had not reached the chronic stage, to proceed to the remedy. May I, in the interest of photographers who read the "B.J.," treat photography as a patient in very poor health, on the lines suggested by my medical friend?

PLAYFAIR.

SUN IN THE STUDIO.

To the Editors.

Gentlemen,—Regarding the recent article on "Sun in the Studio," I tried tracing paper and cloth for a year or two, but abandoned both in favour of ordinary ground glass, which I keep cut in lengths of about 32in., and slip in under the ordinary glass on small wooden catches and supports. They can be put up or taken down in a few moments; never tear, are easily cleaned, and do not need renewing.

—Yours truly,

W. MACFARLANE.

339A, High Street, Cheltenham.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. Bolton, 51 and 53, Byrom Street, Deansgate, Manchester. *Photograph of an Oil Painting by Moriano Miguel: Salome, the Daughter of Herodius.*
- R. Rushton, Park Hotel, Blackpool. *Six Photographs of Views of Portuguese Earthquake: Five of Benavente and One Samora.*

SPOTS ON POSTCARDS.—I should esteem it a favour if you can tell me cause of the white spots on the enclosed postcards. These cards are treated in exactly the same way every week, in batches of about 350, but once in a while a batch will turn out as per enclosed. They are all right (to all appearances) in the final washing, and the spots appear when drying on the ferrotypes, and I should like to know the cause, so that we can guard against it in future.—E. E. E.

We are afraid it is impossible for us to do more than guess, particularly as you do not give us any idea of the source or quality of the cards. If you are paying a low price for the cards it is likely that you will experience occasional bad batches. Any maker can make good emulsion at times; the excellence of the best makers consists in maintaining a high quality all the time.

COPYING BY REVERSAL.—I have just tried to make a negative from a negative by the same process as the reversal of the plate in the Autochrome process. I obtained a good contact positive first. I then rinsed for 30 seconds and placed in a reversing solution, and took out into daylight. In the first case the image vanished (almost) in about 60 seconds; in the second case it began doing so in about the same time. I took out, rinsed, and re-developed in daylight, but got nothing. Where was I wrong? How can the Autochrome process be used for making a negative from a negative?—S. H. C.

The Autochrome method is not suited to ordinary plates. It can only be used when the film is very thin. For other methods see "B.J." for October 23, 1908.

BAS-RELIEFS.—I should feel much obliged if you would kindly inform me if there is a process for producing bas-relief portraits by photography, such as could be cast in plaster or wax, and if such a thing has ever been produced commercially. I have offered to me the patent rights of a process for producing these, and the specimens shown me are fairly high in relief, said to be produced by photographic means. The invention comes from abroad, and it is supposed to be original; but as I have a vague recollection of something of the kind being produced a few years ago I should be much obliged if you could tell me if I am correct or not, and if such a process, if existing, is a patent.—READER.

You are quite right. There is no novelty in bas-relief portraits produced by photography. Several methods of making them have been patented and described in past years, but they have not proved of any commercial value. We believe the Baese patent process is being commercially worked with success, but we know of no other.

DYES FOR COLLODION.—A matter which is arousing much interest in Great Britain is the introduction of dyes (presumably aniline) for slide colouring. Unvarnished dry plate slides present no difficulty. But wet plate slides do. In fact, one may say it is practically impossible to use these dyes on them. Could you kindly say what medium should be used to enable the dyes to be easily manipulated? I believe that most wet plate slide makers use a spirit varnish, and it is, therefore, necessary to bear this in mind.—JAPANALDYE.

The coal tar colours sold for tinting gelatine pictures are not suitable for colouring varnished collodion slides, as the aqueous solution does not penetrate the varnish as it does the gelatine film. Transparent oil colours are generally used for the purpose. It is possible that if coal tar colours were dissolved in alcohol they might be used, but we have not tried them. You might try coating the collodion pictures with a thin, warm solution of gelatine while wet, and tinting on the film when dry with the ordinary colours. The gelatine might absorb them, and the slides could be varnished afterwards.

BALLEY AND FLOWER.—We should recommend the Illustrations Bureau, 12, Whitefriars Street, E.C. We do not know anything of the other firm.

PROFESSIONAL.—There is no book on bromide and gaslight emulsions. The information on these subjects is somewhat jealously guarded by those who are using, and have used it, for trade purposes. You might obtain assistance by advertising for it.

BROMIDE.—We should say the card is on a collodion paper, toned by the usual gold and platinum method.

GEO. ALLEN.—Presumably you are intending to photograph in the camps during military manoeuvres, in which case you should apply to the commanding officer for permission.

N. GREEN.—It is not our business to say where specimens of work may be purchased. All we can suggest is that you apply to some printing firm, to whom you may be able to give some orders.

SHUTTER SPEEDS.—I shall be greatly obliged if you will kindly answer me the following questions. One paper has not had the courtesy to reply at all. I have an Ernemann camera, two shutter type, 9 x 12 cm., and the speed of the focal-plane shutter is marked as follows:—Spring tension 1-12, slit regulated in millimetres.

Spring.	Slit (width).	Speed.
1	50 mm.	1/25
6	50	1/40
12	50	1/50
12	40	1/65
12	30	1/90
12	20	1/130
12	15	1/180
12	10	1/260
12	5	1/520
12	2½	1/1000
12	1	1/2500

- (1) The full opening of the slit is 8 cm., the full width of the plate. What would be the speed with this slit and the spring tension 1?
- (2) How can I calculate intermediate speeds? (3) Do you think the last three speeds on the table can be anywhere near correct? There is so little difference in the width of the slit, and the tension is the same for all. Moreover, it is a very difficult matter to adjust the slit from 2½ mm. to 1 mm.; this is done by the aid of a mm. rule at the edge of the blind. (4) Is it possible to get an exposure at all through a 1 mm. slit, f/6.8 lens used? (5) What is the width of slit, say on a Goerz camera, at its shortest exposure? (6) My lens is a ——. I am informed that these lenses are not as fast as they are marked. Is this so? (7) The above lens is mounted in a Koilos shutter (bought in Germany), and the stops are marked f/4.6, 6, 12, 24, 48, 96, 192. How can a f/6.8 lens work at stop f/4.6 and f/6? When the stop marked f/4.6 is in use, it is (the iris) open at full width of lens, but as soon as you move to the next stop, f/6, the iris closes slightly. (8) Are these stops the English standard? If not, please give equivalents. (9) Which is the better for a ½-plate enlarging lantern—a 8½in. R.R. — lens, f/8, or a 7½in. — anastigmat, f/5.5?—MANCHESTERITE.

(1) We cannot estimate this without more particulars. The diameter of the light pencil, where intersected by the blind, is essential, and this, of course, depends on aperture of lens and also on distance between blind and plate. (2) See our leader of May 14. With any given tension and aperture the duration is proportional to sum of widths of slit and light pencil. (3) If one speed is correct the others should be nearly so. (4) No doubt it is possible, given enough light, but for ordinary subjects a much faster lens would be required. (5) Cannot say definitely without one at hand to measure. Usually the smallest slit is about 1-16in. to ¼in. in the average shutter. (6) The measured aperture is generally about f/7, but the lenses pass a great deal of light, and may be considered in practice to be as rapid as others of the same type: possibly more rapid than some. (7 and 8) It cannot. Are the stops marked

as you say— $f/4.6$, etc.? If marked simply 4.6, 6, 12, etc., the marking is on the Stolze system, and the numbers give the relative exposures. That is to say, No. 12 requires twice the exposure necessary with No. 6. No. 6 on this scale is equal to $f/8$, about; No. 24 is therefore $f/16$, and No. 12 is $f/11$. The Stolze scale of marking is frequently found on Continental lenses. (9) The anastigmat is, of course, preferable, on account of its greater rapidity and better connection. Both are rather short in focal length for enlarging from $\frac{1}{2}$ -plate; but if they will cover a half-plate perfectly in the camera they should serve. With this proviso the R.R. should be very serviceable, if cheapness is essential.

POLICE PHOTOGRAPHY.—I should be much obliged if you could give me any information as to the methods adopted by the police of photographing finger prints, such as marks made on furniture by burglars.—**PHOTOGRAPHER.**

See the review of the Dresden Exhibition on another page. One section in the review deals with this subject.

CORRECTION OF OVER-EXPOSURE.—In the Colonial Number, March 26, on pages 229-230, you give a formula for rectifying over-exposure. Enclosed are two negatives, one being given five seconds' exposure, which is about right, the other forty seconds. My difficulty is that the latter still appears insufficiently fixed, though in the hypo bath an hour. Is this whitish appearance harmless? I may say the hypo bath contained a small quantity of potass metabisulphite.

—**EXPERIMENT.**

The negative is quite fixed. The fog only shows that the developer was not quite enough restrained. Possibly the plate will print fairly well, but it could be improved by clearing with Farmer's reducer and then intensifying.

ENSYNA.—(1) Will you please say in the "B.J." whether, in your estimation, the new paper, "Ensyna," is as safe for a professional to stake his reputation on as other silver papers? And (2) how I can single transfer to opal, using a solid background, and leave a specified even border of bare opal around it.—**H. W. GAULD**, (Manitoba, Canada).

(1) Yes. We should say that prints on Ensyna are as stable as any other silver paper. (2) Simply fix a cut-out mask on the negative the shape desired, which will protect the border. It is a good plan, after the backing of the tissue has been stripped off, and the gelatine is dissolving, to wipe away with a piece of sponge the coating round the masked border. This will ensure its being perfectly white.

CARBON QUERIES.—Would you kindly enlighten me on the following? (1) What is the action of ammonia in the carbon sensitising bath? I have looked up manuals on the process, but have not come across a statement as to the why and wherefore of the ammonia. (2) Could you give the name of the brush used by carbon printers for softening down vignettes while the print is on the temporary support? (3) Would you give a formula for making adhesive tissue from ordinary tissue paper?—**R. S.**

(1) The ammonia is simply to neutralise any acid there may be in the bichromate of potash, thereby enhancing its solubility and keeping qualities. (2) An ordinary flat camel-hair brush, if any at all is used, is the best. (3) Those who supply the tissue commercially do not publish the formula they employ. However, a solution of shellac in methylated spirit will answer very well. As the tissue is sold at so low a price we think you will find it more economical to purchase than to make it.

ROE McMAHON.—We have heard that there is to be a photographic section, but inquiries both by letter and in the grounds within the past few days have failed to obtain any information about it.

MACFARLANE.—1. There is no book on the use of electric light for portraiture. 2. It is usual to have two lamps for full-length figures and groups. 3. All four are excellent lamps. 4. The use of the arc light when once it has been fitted up is a simple matter.

CINEMATOGRAPH FILMS.—1. Would you be kind enough, through the medium of your valuable journal, to give me the address of any firm from whom I could purchase dyes for cinematograph film colouring? 2. Is there any means of avoiding the shiny surface given to the emulsion side of the film after reduction by ferricyanide and hypo? I enclose a sample of same subject reduced and not reduced.—**OLD PHOTOGRAPHER.**

1. For hand-colouring you might try the Bertha dyes supplied by the Vanguard Manufacturing Company, Maidenhead. 2. No, we

do not see that it is possible to avoid this, as the reducer naturally dissolves away the silver in the upper layers of the film.

DETERIORATED FRAMES.—Will you kindly give a formula or recipe for a brilliant reviver of photo. frames, principally of oak? After I exhibit enlargements in my window the colour and brilliance of the moulding is replaced by a dry and faded appearance, and I want to be able to rub them up before dispatching to my client.

—**W. H. WARREN.**

Without knowing what the moulding has been polished or varnished with, or even if it is polished at all, it is impossible to say. If, however, it has been polished it is possible that any of the polish revivers sold at the oil shops would be useful. If the wood, say oak, has its natural surface, and has become dirty or discoloured, fine glass paper will make it look like new. If the wood was stained on its natural surface it may be rubbed down with glass paper and then restained the same colour with the wood stains sold by the oilmen. Stephens' stains are good, and there are a good variety of them. An excellent "reviver" for woodwork is made up by the Vanguard Company, and should be cheaper than any home-prepared composition.

POSTCARD REPRODUCTIONS.—Recently a certain postcard publishing house requested me to send some of my studies, with terms for "rights of reproduction." I sent a number of subjects, of which twelve were selected. I subsequently dispatched transparencies to copy from, with accompanying invoice, which was worded as follows: "To rights of reproduction, as postcards, of twelve photographs." They objected to the phrase "as postcards," and requested me to alter invoice "according to previous arrangement," meaning thereby that I was to give unlimited rights for a small fee I refused to admit that I had agreed to grant licence unconditionally, although I had responded with specimens of my work to their invitation given in general terms, and pointed out that in invoice I had only been particular in defining the rights I was selling, and, if objectionable, they had the option of rejection. They, however, refused to withdraw from their contention, and in consequence I cancelled all rights on any terms, asking them to return the transparencies. These I have not received back, nor any reply. Do you consider they would be legally entitled to reproduce my subjects, as I think the transaction was abortive?—**CYCLOPS.**

We should say that the correspondence leaves no doubt whatever that you do not accept the firm's conditions (or they do not accept yours), and therefore they have no right to reproduce the photographs.

WATER CHARGES.—My printing is done at a small private house in the suburbs. I paid the water rate for years at the usual rate for houses of this rateable value. When the Metropolitan Water Board took over the supply an inspector called and saw the premises and what they were used for, and he said that the water in future would have to be paid for by meter, as it was used for business purposes. A meter was fixed, and I now find that the water rate is rather more than three times what it used to be. Am I really legally bound to use the water by meter, as it is only a small private house?—**AQUA.**

The size of the house is of no moment. As the water is used for business purposes the Board has the power to charge according to the quantity consumed, i.e., by meter.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

M. Robert Demachy contributes a very interesting review of the Salon of the Paris Photo-Club. (P. 435.)

A further instalment of the review of the Dresden Exhibition deals chiefly with the sections of photogrammetry and photographic research. (P. 437.)

A large number of papers were read in the photographic section of the Congress of Applied Chemistry. A general report of the proceedings appears on p. 439.

A Congress of photography is to be held at Dresden from July 11 to 15. (P. 433.)

We call attention to the opportunities of shop window display which are offered by the reflex camera. (P. 434.)

Some notes on the practical methods of preparing photographic groups from separate portraits of a large number of persons appear on p. 434.

A very simple method of making portraits by double printing with natural backgrounds is described in an article by Mr. H. M. Taskard, who recommends the result as an attractive and saleable form of portrait. (P. 441.)

The parallelism of plate and object, chromium intensification, photographic copyright in America, and the question of photographers' competitive methods appear under "Correspondence." (P. 446.)

Under "Photo-Mechanical Notes" reference is made to the use of mercury-vapour lamps for process work. (P. 443.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

The colour section proper at the Dresden Exhibition is reviewed in a short article on p. 41, but the best colour exhibits are scattered in other parts of the exhibition.

Some account of recent experiences with the "Omnicolore" plate appears on p. 42.

Dr. W. Scheffer has examined a screen-plate made by a modification of the Warner-Powrie process. He draws attention to the remarkable diffraction figures obtained when examining a bright source of light through a screen-plate. (P. 43.)

A recent note by Jan Szczepanik deals with the varnishes suitable for the protection of the Autochrome film. (P. 48.)

The use of a projection screen of metallic surface is the subject of an article by Dr. Hans Lehmann. Such a screen permits of much more brilliant projections, but the number of possible spectators is somewhat limited. (P. 44.)

EX CATHEDRA.

M. Demachy on Pictorial Photography of the Day.

The review of the Salon of the Photo-Club of Paris by M. Robert Demachy which appears on another page will be found to contain some most refreshing comments on present-day tendencies in pictorial photography. The occasions on which M. Demachy addresses himself directly to English workers are, alas! all too few, and therefore it is well that we emphasise one passage of his article, in which he laments the tendency in much work of the present day, towards strangeness of arrangement at the expense of qualities which artists in other media have held to be of first importance. We have all of us here had the opportunity of watching the hectic efforts to employ the camera in producing pictures which should possess this quality of strangeness, however else they were deficient. M. Demachy, in words of mild, perhaps amused, remonstrance, points out how many workers appear to have followed in the steps of those whose only god is pattern, certain assemblage of lines, and who have therefore put away from them perspective, tone-values, and atmosphere. Whilst so much is written glorifying these works as triumphs of art, it is comforting to hear M. Demachy's frankly declared preference for the older yet fresher and saner conceptions of art.

Photography at the Chemical Congress.

The photo-chemical section of the International Congress of Applied Chemistry held its meetings under the presidency of Sir William Abney at the Imperial Technical College, from May 28 to June 1. Among those from abroad who attended the meetings were Professor Luther, Dresden; M. Seyewetz, Lyons; M. L. P. Clerc, Paris; Professor Namias, Milan; and Herr R. Jahr, Dresden. The papers, numbering in all about thirty, touched upon many subjects. Sir William Abney, in a brief introductory address, dealt with the application of photographic methods for quantitative measurements of physical phenomena, and illustrated his suggestion that more might be done in this way by reference to measurements of fluorescence recently made by him. The results obtained by the eye agreed with those recorded by the plate, and justified the statement that when proper precautions were taken the photographic measurements could be depended upon. The other papers dealt with comparisons of developers, the preservation of sulphite solution, the latent image, plate speeds. Dr. Mees read a report on the present condition of sensitometry, Mr. A. J. Newton on etching methods, Dr. S. E. Sheppard on colour chemistry, and Mr. W. Gamble on acid resists.

A Congress of Photography at Dresden.

It is announced that an international congress of photography is to be held at Dresden from July 11 to 15, when papers relating to the more scientific branches of photo-

graphy will be read. Among those who have promised to take part in this congress are Dr. Miethe, Professor Dolezal, Professor Schaum, Dr. von Röhr, Professor Namias, Dr. Panconelli, and others. The time of the congress is one very convenient for paying a visit to the Dresden Exhibition, and doubtless those who may think of going to Dresden will be glad to make their visit the opportunity of meeting with many of the leading personages in photography on the Continent. The arrangements for the congress are in the hands of Dr. H. Weisz, 27, Winkelmannstrasse, Dresden.

* * *

The Reflex Camera in the Shop Window.

From all we hear, the reflex type of camera is proving a very ready seller even at the prices which must be paid for the least expensive instruments. In conversation with the head of a leading firm of general dealers the other day we were told that their sales in reflexes represented the larger part of their business in hand-cameras, and that we can well believe, seeing that the advantages of the reflex are now so widely appreciated. Whether the possible business to be done in reflexes is as clearly recognised by the dealer may perhaps be doubted, and our object in now writing is to pass on a suggestion of our Berlin contemporary "Photographische Industrie," to the effect that much more could be done by the dealer in the way of window demonstrations of the facilities provided by the reflex type of camera. It would not be difficult to arrange a camera so that the full-size focussed image on the ground glass could be seen from the street, whilst the accuracy obtainable with the reflex in arranging and focussing the subject equally lends itself to demonstration by means of an exhibition of negative and enlargement side by side. We believe that among purchasers and users of hand-cameras there is a general feeling of dissatisfaction with the cheaper descriptions of camera, and the dealer may therefore be well advised in taking steps to turn the preferences of his customers reflexwards.

* * *

Chromium Intensification.

Mr. Edgar Simpson, writing again on this subject in our correspondence columns, makes several comments with regard to the conditions that govern the intensification obtained, but it occurs to us that some of his suggestions are made in ignorance of the results obtained some time ago by Messrs. Piper and Carnegie. These investigators pointed out that the most important controlling factor is the proportion of acid present in the bleaching solution, and that Eder's original formula (which Mr. Simpson appears to use) was not adjusted to give the most powerful effect. For general use they advocated a solution containing 10 grs. bichromate and 5 minims hydrochloric acid to the ounce, while the most powerful intensifier of practical service contained 5 grs. bichromate and only 1 minim acid to the ounce. They also pointed out that the product of bleaching is developable without exposure, and that redevelopment could be retarded or prevented by an excessive exposure. This, however, applies only to the exposure prior to redevelopment. If the plate is only exposed during development the retarding effect does not occur. The effect of over-washing, we hope, will be explained shortly, for we understand that work bearing upon it has recently been carried out. The effect of the composition of the redeveloper is rather mysterious. Some developers certainly seem to give greater density than others, but it is still doubtful if this is not simply a matter of time of development. Amidol seems to be one of the best redevelopers and hydroquinone one of the most ineffective. In some recent work we, however, found Rytol used in twice the ordinary strength for negatives give very good results indeed. There

seems to be no doubt that the intensification depends to some extent on the nature of the original image. It seems probable that this affects the second cause of intensification pointed out by Messrs. Piper and Carnegie—that is, the increase in bulk of the silver particles due to the retention of undeveloped silver compounds.

BUILT-UP GROUP PHOTOGRAPHS.

The following article is suggested by a query which a correspondent sends up this week, instead of replying to which in the usual column, we may deal with it here, inasmuch as what will be said may be of service to other readers as well as to our inquirer. The latter wishes to produce a group containing the principal members of an important club in his district similar to one he has seen of leading members of the Royal College of Surgeons with the hall of the college as a background. We happen to remember this particular picture very well, as we do several others of a similar type, though we cannot say much in their favour so far as their artistic merits are concerned. They are sometimes termed "patchwork" pictures, and that is by no means an inappropriate name for them. Some of them contain most glaring incongruities. In some one sees a figure lighted from one side, while the one next is illumined from exactly the opposite direction. The figures, in many cases, are looking in all manner of different directions, and the poses of some are little short of ludicrous in reference to the *tout ensemble* of the picture. In most instances these incongruities are due to the fact that the portraits had to be obtained from quite different sources and were not specially taken for the work.

Incongruities in this class of picture are not entirely confined to photography, for we have in mind as we write two or three paintings from which expensive engravings have been produced in which they prevail. One in particular is the well-known picture of the "Waterloo Banquet," in which the late Duke of Wellington is depicted as addressing the guests, not one of whom are looking in the direction of their host, while the larger proportion have their backs to him. Another is one of a cricket match, in which the persons in the foreground, representing the leading cricketers of the period, all have their backs toward the players, and are seen not to be taking the slightest interest in the game. The main interest in pictures of this type is the portraits and nothing more. Our readers are quite familiar with similar productions of more modern date than those referred to, and they are not less incongruous. However, without saying more from the art side of these pictures, we shall now give a few hints as to how they are produced.

We will now consider the type of the photograph mentioned by our correspondent, and what will be said will apply to such works generally. In the first place, a suitable background is required, usually some scene which the persons depicted are intimately associated with. A sketch of good size is made, or a photograph of it is taken and enlarged, say to thirty inches or larger, for it is well to have it on as large a scale as convenient. In making this enlargement, or sketch, some attention must be paid to the size of the portraits to be stuck upon it, so as to get as fairly good perspective as possible in the circumstances. In making the background from a natural scene or building, it is well to take the photograph in a very subdued light, so that there are no pronounced shadows from any particular direction, as then it will the better blend with portraits which may be lighted from different directions. The enlargement should be somewhat dark, and if it is a little fogged so much the better, as the details should not be strongly pronounced, or

they will detract from the portraits. It is then mounted on stout cardboard. If the portraits are taken expressly with a view to the production of the picture, they can, of course, be all lighted one way, and then the work is comparatively plain sailing. However, we shall assume that, as is usually the case, prints from different sources have to be utilised. If they can be obtained unmounted so much the better; if not they must be soaked off their mounts.

The next step is the arrangement of the figures in their best positions. In this no definite instructions can be given, as all must depend upon the nature of the picture and the number of persons to be included. In any case, the most important personages should be given the most conspicuous positions, such as in the foreground or centre of the picture. It is a good plan to arrange the portraits roughly on the background picture and see the effect. In arranging them, attention should be paid to their size. If they have been obtained from various sources some may happen to be larger or smaller than others. In this event the larger ones should be placed nearest to the foreground and the smaller behind them, as their faults in perspective will be less conspicuous. In all cases a good amount of foreground should be left in front of the figures.

When the arrangement has been decided upon, the portraits should be numbered on the back and similar numbers put on the places they are to occupy in the finished group. The next thing is to rearrange the figures neatly in their final places and secure them, temporarily, there with a touch or two of indiarubber solution in the centres, leaving the edges loose and free. Then, when all are fixed, the overlapping portions of the portrait pictures are cut clean through down to the mount with a sharp pen-knife, and the pieces set free removed. In doing this part of the work, judgment must be used as to where the cuts are made. If it can be avoided they should not be

close round the head, but a little of the background of each included. When all the portraits are trimmed, they are taken off and the adherent rubber removed, and that is easily done by lightly rolling it off with the finger. The prints are then ready for final mounting on the background, and if the trimming has been neatly done they will fit together like the parts of a child's dissecting puzzle, and the numbers on the back will be a guide as to their relative positions.

As a mountant, one should be employed with as little water in it as possible, so as to avoid any undue expansion of the paper. Very thick starch paste is suitable if it is applied thinly, and the print is quickly got in its place and at once well rubbed down. When the whole of the prints have been mounted, should any fine lines be seen at the junctions they must be touched out with water-colour. The picture is then rolled or hot-pressed, when all will be flat and even. The picture is then ready for copying to the size or sizes desired.

It will probably be found, when the portraits have been obtained from different sources, that in the reproduced negative they are not all of equal printing density, arising from their not all being of the same tone or depth in printing. In that case the thinner ones must be backed up with one or more thicknesses of thin mineral paper, so that they equalise with the others; or matt varnish, tinted or not as occasion may require, may be applied to the back of the plate and then scraped away round the edges of that particular figure.

As we have already said, pictures of this kind can never be looked upon as being in any way artistic productions. Yet they sometimes prove tolerably remunerative to the producer, and that is the object he may be assumed to have in view when spending the time generally required for these productions.

THE PARIS PHOTO-CLUB SALON.

EXACTLY 479 pictures have just been shown at the Cercle Volney, in whose beautiful gallery the Paris Photo-Club has found for its annual salon what we have reason to believe will be a permanent home. The room is all that can be desired. It has been expressly built for the club exhibitions of oil paintings and water colours, and is also used for theatrical purposes; a well-fitted stage occupies one end of the gallery. As in past years, the aspect of the exhibition would be quite excellent if the jury had not accepted so many pictures. Three hundred frames would have allowed the hanging committee to give proper spacing. As it is the walls are crowded. Yet more than half of the pictures sent in have been rejected. But the Photo-Club committee is responsible for a hundred or more pictures brought in by invitation—thirty pictures by the Photo-Secessionists, six by Mr. Arbuthnot, six by Mrs. Barton, five by Mr. Mortimer, two by Mr. Job, six by Mr. Keighley, etc., etc. It was a wise as well as a courteous step to take, but this outside contingent added to the number passed by the jury has made up a rather big total.

If one has the patience to examine the large number of pictures sent in by the French photographers a very marked advance will be noticed at once. The sympathies of the French, who, as a rule, use the Rawlins process and the "dépouillement" papers such as the Fresson and Aitigne, lean without doubt towards classical composition and classical rendering of Nature. No low-toned pictures like those of Mr. Keighley, for example, will be found amongst their work. There will be instead a long scale of gradation, sometimes extending from pure white to pure

black. And it is for this reason that platinotype, bromide and similar processes have been abandoned over here in favour of those methods by which extreme notes can be secured without necessary loss of intermediate gradation. The results are not always successful, but the same may be said of many of the pictures shown at the Grand Palais. At any rate, there are no glaring faults nowadays, and no exasperating cocksuredness. The French are trying to learn, and many of them are learning, with true modesty, what we photographers have to be taught before our work can be taken seriously. Amongst the best contributions on the French panels we notice those by Major Puyo, MM. Michaud, du Breuil, de Montgermont, de Singly, Ch. Thermitte (the younger son of the famous painter), Hachette, Le Bégue, Manry, Mussel, etc. All these gentlemen, with the exception of M. Le Bégue, have shown oil prints.

Belgium is well represented by M. Misonne and Dr. Cardyn. Hungary by M. Féliédi and M. Haranghy Gyorgy. Holland by M. de Jonge, Portugal by Mme. de Magalhaës, Spain by M. Ramiro, Germany by Mlle. Malda Schönberg; Denmark by M. Louis Schow, Russia by Dr. Vlodimir Kirchner: to the English well-known names already mentioned we will add those of Mr. Crooke, Mr. Warburg, and Miss Warburg. The level of the English pictorialists is always high, and Mr. Arbuthnot's work enlivens the gravity of the British school with a dash of American pick-me-up, which is not without flavour.

The Photo-Secessionists have sent thirty-four pictures, which have been hung together round the leader, Mr. Steichen. Mr. Steichen's big frames are black and his prints, also dark, are

mounted on dark grey paper. His followers have chosen light mounts, and the effect of this close companionship is not such as the hanging committee would have preferred. But the rules of the association are most stringent, and we have followed them obediently.

Mr. Steichen's style is well known, and his six pictures are excellent examples of his original talent. I inadvertently used the word *followers* just now when I mentioned the relationship between Mr. Steichen and the Photo-Secessionists. The term is ill-chosen, for though Mr. Steichen and the Secessionists now belong to the same creed—that of pure and uncorrected photography—their methods and their results differ. For if Mr. Steichen shows manifest personality, the twenty-eight platinum prints that frame his central panel seem, on the contrary, to have been printed by one and the same operator, though they are the children of nine different authors.

In most of these there is an absolute disregard—or is it contempt?—for those qualities which are considered of paramount importance by artists in other mediums—so absolute indeed that some of the pictures require a certain amount of study before it is possible to understand the relative positions of the objects therein suggested. But one notices amongst this representative collection a general and hopeful effort towards originality of composition. Perhaps the effort is too noticeable in some cases, while in others all important factors have been sacrificed to pure strangeness of arrangement. Still, the American school is very young, and it will no doubt outgrow the exuberance natural to its youth.

Has the Photo-Secession been influenced by a certain school of painting, whose disciples aim solely at the production of decorative patterns, whose ideal is the Persian rug design, and

which stoops rarely to portraiture because the human frame is too common for its taste? So much so that values and atmosphere are put aside so as to produce absolutely flat patterns, retaining only the projected form of natural objects on one plane. Such methods of rendering Nature are far removed from the French conception of art—so far removed that I suppose that my opinion on the subject is unfairly biased. Yet I must say that I prefer the old-time methods used by certain unsophisticated artists, who have been dead a long time, it is true, but who have left a name behind them.

For the first time Autochrome transparencies have been admitted to the Photo-Club Salon. A hundred plates of different sizes, ranging from 18 by 24 cm. down to 6½ by 9 are shown at the Volney, and this well-chosen collection has attracted universal attention. The Volney Club is mainly composed of painters, and the verdict of the community on Autochrome work promised to be interesting. Unhappily it has not been by any means favourable. On the side of the lay public, visitors are interested, astonished and often enthusiastic, but their enthusiasm goes towards glaring colours, the two or three plates which have found some favour with the painters being overlooked by them. On the whole the result is rather discouraging for autochromy—from an artistic point of view. Artists complain of a general untruthfulness in the rendering of colour, and particularly of the absence of necessary touches of complementary colours in the shadows, which they say are of the same colour as the lighter portions. They find no vibration, no life in the colours, though vivid, probably because of the monotony of the colour areas. This unfavourable verdict has been quite unanimous on the part of the painters, as far as I have been able to ascertain.

ROBERT DEMACHY.

THE DRESDEN EXHIBITION.

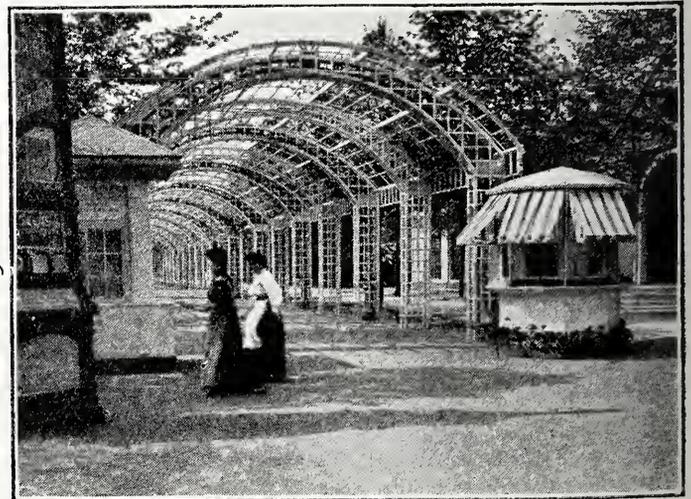

II.

In accompaniment of a further article reviewing the International Photographic Exhibition at Dresden, some few words ought to be said of the attractions of Dresden other than those photographic ones which, during the present summer, are pro-

colony than any other town in Germany. Few towns of its size can offer the resident a similar area of streets planted with trees, and set on either side with villas or blocks of flats standing in garden grounds. We say "streets," because these verdant

The Entrance to the Cinematograph Theatre in the Exhibition.

A Main Avenue of the Exhibition Grounds.

minently advertised on the electric cars in the Saxon capital. Dresden is emphatically a comfortable and pleasant place of residence. Without the grandeur of Berlin or the commercial bustle of Frankfort-on-Main, it has attracted a larger English

thoroughfares branch off in all directions in the very centre of the town. A walk of some ten minutes from the latter takes the visitor to the Royal Palace in the heart of the old part of the town, close to which are the world-famed picture galleries

and the picturesque Bruhl Terrace, a lofty promenade overlooking the Elbe, which here runs through a somewhat deep valley, on the heights of which are many picturesque resorts. Apart from the exhibition, a couple of days can be quite profitably

spent in seeing things in Dresden which rank with the chief treasures of London or Paris. There are plenty of good hotels and a greater number of pensions than are usually to be found in German towns.

THE SCIENTIFIC AND TECHNICAL SECTIONS.—II.

Photo Surveying and Measurement.

In this section a most complete collection of exhibits illustrating the application of photography to the measurement of buildings, districts, heights, distances, etc., has been brought together by Professor E. Dolezal, of the Vienna Imperial Technical School, and Editor of the "Archiv für Photogrammetrie." Professor Dolezal has drawn largely upon his own collections, and his arrangement of the exhibits, and also of the entries in the catalogue in historical order, makes this section of especial value. As Dr. Dolezal points out in a brief introduction, the methods by which, with the aid of a lens of known focal length, the measurement of natural objects and distances may be carried out, are now of increasing importance. The surveyor uses them, particularly in countries which it is difficult to traverse; the topographer of mountains employs them; they are of value to the architect; they are used by the meteorologist in determining the height, speed, and direction of clouds, whilst extensive use is made of them in navigation and for military purposes. The development of stereo-photogrammetry has still further widened the sphere of this important branch of applied photography. One of the earliest examples of photogrammetric practice is that of Colonel Laussedat (No. 367-3), of the village of Buc, made in the year 1860, which shows the front and side elevation of a church obtained from the photographic negative taken in perspective. An early example of a complete panoramic record is that of Chevallier, of the Castle of Pierrefonds (No. 367-4). With this instrument an image in the shape of a narrow ring was obtained round a somewhat large central disc. A further example of the early French work is that made by Javary and Galibardy, in which the map of a whole valley was prepared from photographs made from three separate stations. Among the drawings of instruments representing the French photogrammetric methods are those of the cameras of Laussedat and Javary, Chevallier, Mangin, and Rousson, with the cylinder of Moessard, the photo-theodolite of Gautier, and the photo-tachymeter of Mailhat, of Paris (No. 367-6).

In illustration of the development of photogrammetric methods in Italy, the drawings of instruments shown by Professor Dolezal include a diagram of Porro's panoramic camera, Salmoiraghi's photo-theodolite, and a photograph of Rocha's photo-theodolite.

The exhibit of the Royal Institute for photogrammetric work in Berlin (Königl. Messbildanstalt) contains some interesting examples of the work which has been carried on for many years past by Dr. Meydenbauer in the way of recording in the most exhaustive manner the chief buildings and monuments in Prussia. The special instruments for this purpose are made in the workshops of the Institute, the photographs being taken on plates 40 x 40 cm., 30 x 30 cm., or 20 x 20 cm. Since the establishment of the Institute 13,000 exposures have been made of about 1,100 buildings in 231 different places. The negatives are taken with three specific purposes: (1) for the making of draughtsmen's plans of the building; (2) for the recording of architectural details on a larger scale; and (3) of preparing ordinary perspective views which, when considerably enlarged, are suitable for wall decorations and for educational purposes. The examples shown of these three branches of work carried out by the Institute include as subjects the Town Hall of Bremen, for the record of which 96 negatives were made, 40 x 40 cm.

The drawings shown of the German photogrammetric instruments include those of Gust Heyde (Dresden), Breithaupt

and Son (Cassel), Wiechert, constructed for cloud photography, Schilling (made by Gunther and Tegetmeyer, Brunswick), Professor C. Koppe, as used in German East Africa, in addition to those of Dr. Schlichter (made by L. Tesdorpf, of Stuttgart), and of Professor Meydenbauer, Professor Laas.

Drawings are also shown of the stereo-photogrammetric outfits constructed by Messrs. Carl Zeiss for various expeditions: among the instruments being the well-known "Stereo-Comparator."

Among the exhibits of the Austrian society for photogrammetry, Vienna, are several frames showing plans obtained by exposures made from a balloon, the photographs representing the various views being embodied in the plan of the district thus obtained. Among other Austrian work are two examples of the method used by Jaffé, of Vienna, for the making of panoramic photographs of interiors of buildings. Two negatives are taken, each at a narrow angle, and combined together to form a panoramic photograph of the building, the result being much more satisfactory than that obtained by taking the same amount of subject with a wide-angle lens. (375.)

Professor Dolezal also shows prints and diagrams illustrating the method of measuring the speed and direction of movement of a cloud by taking two negatives one within a short interval after the other, the conditions being so arranged that the reflection of the cloud in water is used for the computation (No. 369-19). In another set of photographs and diagrams a somewhat similar method of recording the height and direction of movement at two successive exposures is obtained by including in the negative the shadow of the cloud (No. 369-48). Professor Dolezal's collection of drawings and photographs of the Austrian photogrammetric instruments include those of S. Starke, Dr. A. Schell, Colonel Harth (all of which are made by Starke and Kammerer, of Vienna), Baron von Hübl, Dr. Dokulil (made by R. and A. Rost, of Vienna). Other instruments are the meteorograph of Dr. Rheden (made by Ressel, Vienna), the photo-theodolite of Pollak and of Steiner (made by Lechner, Vienna), and the meteorograph of Dr. Köstersitz.

A very interesting exhibit is that of Hauptmann Scheimpflug (Nos. 376-21 to 35), which shows the reconstruction in a correct form of photographs taken at too wide an angle or with the plate tilted out of the proper position of parallelism with the vertical planes in the subject. In No. 38 of the same collection is shown the plan made of the Vienna Prater from two balloon negatives, the inclination to the horizontal of the lens axis being about 45 deg., the focal length 12 cm., and the height of the camera about 1,400 metres. The further exhibits of Scheimpflug show the making of a complete panorama from balloon negatives and the maps prepared from these latter. The only exhibit representing the work of England in photogrammetry are drawings of the instruments of Bridges-Lee, Dallmeyer, and Warren de la Rue, in addition to the stereo instruments of Fourcade (made by Troughton and Simms).

Sweden shows a few results of photogrammetric surveying, and photographs of the camera of Axel Hanbury and that of Eckholm for cloud measurements.

A small collection of actual photogrammetric instruments is exhibited, namely, those of Dr. Th. Dokulil (made by R. and A. Rost, Vienna), and that of Dr. A. Schell (made by Starke and Kammerer). Both of these are stereo instruments. There is also the Zenith camera of Schnauder (made by Toepfer of Potsdam) and the photo-theodolites of Dokulil (made by Rost),

Pollak (made by Lechner), von Hübl (made by Rost), and Koppe (made by Günther and Taegetmeyer).

Perhaps the most comprehensive series of photographs and plans showing the results of photogrammetric work are those sent by the Canadian Department of the Interior and by the Coast and Geodetic Survey of the United States. The former includes plans and photographs showing the survey of the Selkirk range carried out by Arthur Wheeler.

Research and Experiment.

In this section, arranged by Herr K. W. Wolf-Czapek, are collected a number of exhibits chiefly consisting of examples of technical processes relating to emulsion-making, developers, etc., which have latterly been the subject of papers in the German photographic Press. Thus Dr. Lüppo-Cramer shows a number of illuminated transparencies made with emulsions of various silver salts. That prepared with silver cyanide gives a fine blue-black positive transparency of great vigour which suits the subject—an Alpine scene. Emulsion prepared with mercuric iodide gives an image of good black tone though somewhat weak as regards density. Images are also shown in photo-chloride and photo-iodide, the former of brown colour. The photo-bromide allows of the making of direct positives on short exposure: particulars of the emulsion are announced to appear in "Photographische Korrespondenz." The transparencies on silver iodide in gelatine are of excellent brown colour, whilst those of the photo-chloride in gelatine are black, and those of silver sulphocyanide in gelatine, purple-brown. Dr. Lüppo-Cramer also shows examples of the "development" of X-ray latent-images by exposure to ordinary light. A very educative exhibit is that of Professor Luther and Dr. H. Weisz, of Dresden, showing the effect of development, intensification, and reduction on negatives of various character: in each case a positive transparency printed from the negative which has been treated gives a clear idea of the effect produced in each instance. An exhibit of Otto Mente on the production of halation in relation to the time of exposure and the thickness of the film is also interesting. Dr. Scheffer shows photo-micrographs of sections of the film of plates showing the action of various reducers and intensifiers, whilst other exhibits are those of Dr. B. Homolka relating to development with indoxyl, of Dr. E. Goldberg of apparatus for the study of the moiré effect in the half-tone process, and there are also some very interesting stereoscopic photographs of diseased eyes taken by Professor A. Elsching, of Prague. An apparatus for the testing of shutter speeds is also shown in this section by Dr. R. Birkhauser, of Berne. There were no printed particulars of the apparatus, but apparently the basis of the method is a rotating plate containing 250 perforations arranged round its edge. It would seem that the number of these apertures which is visible in a mirror when the rotating screen is viewed through the shutter affords a measure of the speed of the latter. Two large frames contain actual filters, and measurements of the amount of light transmitted thereby are shown by Dr. Karl Stockhauser and Dr. F. Schanz. They show the variations in the percentage of light transmitted ranging from 80 per cent. to 35 per cent., and include a greenish-coloured filter prepared by the exhibitors under the name of "Euphos," the percentage of light transmitted by which is stated to be from 75 to 85 per cent.

The History of Photography.

This is one of the smallest and weakest sections of the exhibition, and but for the contribution from the collection of Professor H. Krone, of Dresden, would be a very poor collection indeed. As it is there are many duplicate exhibits relating to a given process, whilst on the other hand many advances in

photography in the past are unrepresented altogether. The Imperial School of Graphic Arts in Vienna send an exhibit chiefly devoted to process work, as does also the Imperial Photographic Society, also of Vienna. The only contribution directly illustrating the share taken by England in the development of photography is that of the Autotype Company, consisting of the first carbon print and a series of portrait carbon prints of midget size made in the seventies of the last century. This section of the Dresden exhibition compares very unfavourably with the historical collection brought together at the 1898 Crystal Palace exhibition of the Royal Photographic Society.

Meteorological Photography.

Types of clouds and of lightning flashes compose the chief portion of this section. Those of the former subject by Mr. C. P. Butler are of cloud studies taken in a mountainous district of South India, and, apart from their scientific value, are pictorially interesting. Another very interesting photograph by Mr. Butler is the enlarged photograph of an exploding meteor. Types of the higher and lower clouds and of cloud movements are shown by George A. Clarke of the Aberdeen Observatory, and the cloud photographs also shown by A. G. von Obermayer, of Vienna, are excellent specimens of beautiful technical photography applied to this purpose. Sir William J. Lockyer shows photographs of "black lightning" and of various types of clouds. Of another character, but equally interesting in its way, are the photographic records of magnetic disturbances exhibited by Stoneyhurst College, Blackburn. Dr. Vaughan Cornish shows a number of his well-known photographs of wave and ripple formations in Nature. Lightning photographs are also shown by J. Howden Wilkie, Paul Georgi, and Professor Walter. Of particular interest from the meteorological standpoint are the photographic records of barometer readings, shown by Professor Toepler. The photographs show the great delicacy of the recording instrument, 130 millimetres on the print corresponding with one millimetre of pressure of the mercury barometer. Mr. John Tennant contributes a few stereoscopic photographs of clouds made with a telephoto lens, which supply a very effective idea of the size of cloud structures.

Botany, Zoology, and Anthropology.

Professor Naumann, in his introductory comments to this section in the catalogue, emphasises the great—even indispensable—services which photography renders to students of botany, and particularly in the fields of the geography and biology of plants. But, as he somewhat caustically adds, the photographs must be such as to allow the student to see, not to guess, the details of the subject. In the case of photographs showing the habitat of plants the surroundings require to be depicted in proper perspective and with satisfactory detail. A lens of long focus is usually necessary in such cases. Where the details of a plant are the subject proper of the photograph the use of a short focus lens which dwarf objects beyond the plant is indicated, and an artificial background is often desirable. Dr. Naumann puts in a plea for the use of orthochromatic methods in botanical photography. In the sub-section dealing with the physiology of plants one very interesting exhibit is a series of five photographs showing the unfolding of the night-blooming cactus, *Echinopsis Eyriesi*, by B. Haldy. H. Ritter von Guttenberg shows photo-micrographs of the organs of sense in plants. Among photographs grouped under morphology and classification of plants a very fine series is shown by the Imperial Botanic Garden, Dresden, each plant being recorded by a general view, photographs of details and photo-micrographs of parts of its structure. The Sächsischer Heimatschutz, a society for fostering local study, exhibits a comprehensive series of photographs of trees indigenous to Saxony. The flower

studies of Walter Köhler call for special mention. They are life-like reproductions taken in an ordinary room. Dr. Rodman contributes photo-micrographs of pollen and diatoms, and Arthur Smith stereoscopic photographs of diatoms.

The most interesting section is, to a photographer, that devoted to the geography of plants, the first place in which should certainly be accorded to J. Ostermaier, of Dresden, who shows a very large series of plants of Central Europe, in every case representing the subject in its natural surroundings. The series includes an interesting set of Alpine plants growing above the snow-line. In every instance there is mounted with the monochrome photograph a colour print in the shape of a multi-colour lithograph prepared by the firm of Neuke and Ostermaier. The whole exhibit is a model of its kind. As fine technical photography as any in the section is that of G. Horace Macfarland, who sends a few photographs of American plants and trees. Mr. Macfarland shows a refined taste in the mounting and lettering of his prints which is rarely to be noticed in so-called "technical exhibits." A very fine series of plants photographed in the neighbourhood of Dresden is that of J. Hartmann. In the section devoted to the diseases of plants the photographs are chiefly of great interest to botanists and horticulturists, and show the very great value of photographic records even better perhaps than do other sections.

The exhibits relating to zoology group themselves into photo-

graphs of animals and photo-micrographs of animal organs and tissues. The first group includes a great deal of work such as has been done in this country for some years, particularly in illustration of the types and habits of birds. The English workers represented are R. B. Lodge, one of whose photographs is a most realistic photograph of an eagle preying upon the dead body of a horse, and F. Martin Duncan, who exhibits a number of animal photographs, including those illustrating the protective mimicry practised by insects. J. T. Roberts shows some very good photographs illustrating the life history of the spider and frog respectively. Dr. Hutchinson contributes colour transparencies by the Sanger-Shepherd process of butterflies. The photographs of birds shown by R. A. J. M. Tepe call for special mention, as do also those of insects and reptiles by Walter Köhler. A large series of very good studies of many animals is shown by G. E. F. Schulz as transparencies. The set of coloured slides by J. Bolle, illustrating the life history of the silkworm, are highly educative, and would be more so if it had been possible to employ a method of colour photography for their production.

The anthropological section is not a large one, but contains a good deal of ethnographic interest, and more than enough to show how indispensable the camera is to the modern explorer. In several instances the quality of the work shown is much below the standard of what should be accepted in these days of dry plates and simplified photographic methods.

PHOTOGRAPHIC CHEMISTRY AT THE CHEMICAL CONGRESS.

THE meetings of the Congress of Applied Chemistry, which have been held during the past few days, have brought to South Kensington the leading authorities and investigators in every branch of technical chemistry. In the section of photo-chemistry, of which Sir William Abney was president and Mr. Chapman Jones secretary, the foreign members who attended and read papers included Professor Namias, Professor Seyewetz, Professor Luther, M. L. P. Clerc, and Herr Richard Jahr. In a brief presidential address Sir William Abney welcomed the foreign members, and expressed the hope that many of the questions relating to photo-chemistry would be helped towards a settlement by the papers and discussions. He then gave a short résumé of experiments in which photography had been applied for the measurement of the fluorescing power of certain dyes, as the result of which it could be stated that when due precautions were taken the photographic method was a reliable substitute for eye observations. The papers read on Friday, May 28, were as follows:—MM. A. and L. Lumière and A. Seyewetz, recorded the results of experiments made to compare the reducing power of the principal developers and the means afforded by them of increasing or reducing the degree of contrast in negatives. They found that as regards the rendering of faint exposures any developer of the series examined was as good as another. The bodies experimented with were pyro, hydroquinone, metol, adurol, edinol, metol-hydroquinone, metoquinone, and hydramine. Of the various methods for obtaining a lessened degree of contrast during development simple dilution with water served for all except hydramine; those least sensitive to such dilution are hydroquinone, metol-hydroquinone, metoquinone, adurol, and edinol. Addition of sulphite of soda to the extent of three volumes of 5 per cent. solution is effective for lessened contrast in the case of developers such as diamidophenol which work with alkali. The addition of further alkali for the same purpose is best applied to pyro, metol, and hydroquinone. Increased temperature leads to lessened contrast only in the case of hydroquinone and adurol, other developers showing

very little difference in this respect. In the case of all the developers the most effective means of securing greater contrast was found to be by addition of bromide. Those which best lend themselves to this means are pyro, hydroquinone, adurol, glycin, and eikonogen.

Professor Namias read a note on the advantageous addition of boric acid to the diamidophenol developer, which was thus rendered much more sensitive to the restraining action of bromide. With boric acid in the developer the time of development may be reduced to less than one-half the time which would otherwise be necessary for a given addition of bromide. The boric acid also serves to keep the developer from oxidation, and to prevent any action upon the screen.

A further paper by Professor Namias dealt with the oxidation of sulphite in solution alone or in mixed solution with developers. It was found that addition of caustic alkali retarded the oxidation of the sulphite, whilst carbonated alkalies increased the rapidity of oxidation. Bisulphite of soda was without effect. When hydroquinone was mixed with the sulphite, caustic soda was found to accelerate oxidation, carbonate of soda less so. In the case of the developers hydroquinone, glycin, and metol, it was found that both the sulphite and the developer oxidised more slowly when present together in the solution than when in separate solutions.

M. L. P. Clerc read a paper on pyramidol developer* which consists of the neutral sulphate of diparaphenylamine. The developer can be made up either with sulphite only or with a caustic alkali. When the quantity of the latter corresponds only to that necessary for the liberation of the diparaphenylamine by neutralising the sulphuric acid the development is little more rapid or energetic than when the pyramidol is used in neutral sulphite solution. When the alkali is used in quantity to saturate the hydroxyl groups a very energetic developer is obtained. A solution of pyramidol made up with dilute acetic

* Prepared by the Brugg Chemical Co., Aargau, Switzerland.

acid containing a considerable proportion of glycerine forms a physical developer suitable for the development of faintly printed P.O.P.

Professor Namias also read a short note on the use of thiocarbamide in gold-toning baths. He recommended the use of oxalic or lactic acid for use with the thiocarbamide; in place of the latter the allyl-thiocarbamide could be used, and gave an equally permanent toning bath.

Professor Namias further described a method of converting transparencies into a condition in which an image consisting of a basic dye was formed, as in the diachrome process of Dr. Traube. The developed transparency was bleached with a solution of lead ferricyanide, the bleached image consisting of the ferrocyanides of lead and silver. The latter was removed by a suitable solvent and the remaining lead ferrocyanide converted into sulphate, which latter acted as a mordant of the basic dye and could always be removed, leaving only the dyed image, by means of a bath of hypo.

The session of Friday concluded with two other papers, one by L. H. Friedburg relating to the making of prints by reflected light from an opaque original on the lines of the Playertype. The author's experiments confirmed the theory of Dr. R. A. Reiss that the action was due to the various reflective powers of the different parts of the original. A note on the action of the ammonium persulphate reducer was read by J. Hertzbergs.

On Saturday morning visits were paid by members of the Congress to the Photographic School of the Regent Street Polytechnic, where, by invitation of Mr. Howard Farmer, arrangements were made to take Autochrome portraits of the visitors, and to the L.C.C. School of Photo-Engraving, Bolt Court, where Mr. A. J. Newton had arranged for demonstrations of photo-engraving processes.

The Monday session commenced with a paper by Dr. Lüppo-Cramer describing some very interesting phenomena relating to the latent image produced by light, Röntgen and other rays. The author showed that the latent image in a gelatine emulsion plate caused by the X-rays might be developed simply by exposure to light. He had sent with his paper plates which contained such latent images, and on exposure of the naked plates to an arc light a reasonably strong image made its appearance in a few minutes.

A note on the reversal of the photographic image by Wilder D. Bancroft described experiments leading to the conclusion that when a sensitiser (reducing agent) is present in the film during exposure the increased intensity of the silver image masks the reversal. When an oxidising agent is present a check is put on the production of density and a clearer reversal is obtained.

The most interesting part of Monday's proceedings were those relating to the sensitometry of photographic plates, which subject was introduced by a paper by Dr. C. E. Kenneth Mees in the form of a report on the present methods. The author briefly reviewed past systems of measuring plate speeds from the days when plates were marked as so many times wet plate to the modern use of the H. and D., Scheiner, and other methods. He briefly described the apparatus employed for making rapid sensitometric measurements, such as were necessary for a plate factory both for ordinary and colour-sensitive plates.

A further short paper by Mr. F. F. Renwick brought forward two very interesting points relating to the accurate sensitometric measurements of plates. He showed that in the case of ordinary plates—that is, those not sold as colour-sensitive—the sensitiveness of the different parts of the spectrum might nevertheless be such as would affect the densities obtained by exposure to an artificial source of light to a very considerable extent sufficient to lead to quite misleading values of speed being obtained. A further cause of discrepancy was shown to be due to the use of intermittent exposure, such as that obtained with a sector wheel and a continuous exposure by time. The paper was offered

as a preliminary to a full account of the experiments to be published shortly.

Sir William Abney said he was very glad to find a practical photographic chemist pointing out the inaccuracy of the intermittent method of exposure. He himself had been preaching the unreliability of that method for many years. The error was particularly marked when dealing with slow plates, and he strongly emphasised the necessity of sensitometric measurements being passed upon exposure for continuous periods of time. The effect of the scatter of light in measuring densities was also a source of differences which had to be allowed for. Dr. Mees pointed out that he had made measurements of the limits within which the sector method of intermittent exposure might be made with due accuracy. Dr. S. E. Sheppard remarked that the intermittent method might become particularly inaccurate when desensitisers were present in the plate.

A further paper was read by Mr. F. W. T. Krohn, in which he suggested an international method of marking the speed of dry plates, the suggestion being the use of a description of slow, rapid, extra rapid, etc., for plates coming between certain limits of speed. Mr. Krohn's paper detailed a number of the precautions which require to be taken in obtaining comparable measurements of plate speeds. Arising out of the discussion, Sir William Abney proposed that an English committee should be formed to draw up a report of the most advisable methods of sensitometry for presentation to a forthcoming meeting of the Congress. He suggested that the Council of the Royal Photographic Society should be asked to take up the matter.

A paper on the sensitiveness of Eder's solution (of mercuric oxalate) was read by Dr. C. Winther, in which it was shown that small quantities of ferric chloride solution caused a variation of the sensitiveness from 1 up to 12,000. Other papers read during the session were on the latent image and its development by H. Reeb, the action of temperature on the sensitiveness of plates by A. Popovitsky, and on the action of sensitisers in relation to the silver bromide in emulsion plates by S. de Prokoudine-Gorsky. A note by Maximilian Toch related to the photo-chemical deterioration of oil paintings.

Tuesday's proceedings related largely to photo-mechanical work. Mr. A. J. Newton read a paper on the present methods of etching used in photo-mechanical processes, and Mr. W. Gamble on acid resists employed as a means of etching in relief and intaglio on metals and glass or in photo-lithographic processes, as also for the protection of vessels holding etching solutions. Mr. Charles W. Gamble contributed a paper on the cause of variations in the sensitiveness to light of mixtures of colloid bodies with bichromates. A paper on methods of preparing agar-agar for use in the making of photographic emulsions was given by W. F. Cooper, W. H. Nuttall, and G. A. Freak. The paper described the preparation of agar emulsions and the chemical precautions necessary in preparing them. Other papers down for reading at the morning session included one by R. M. Reichenbach on photographic films of nitro-cellulose and a note by J. Ramos suggesting a discussion of methods of photo-relief.

At the afternoon session a paper by Professor W. N. Hartley described experiments made with the object of discovering the diactinic properties of organic substances available as mounting materials for microscopic objects, and to be used as liquids for immersion lenses constructed of uviol glass or quartz. The paper gave the best solvents for a metastyrol mounting material, together with the refractive index of each for the D line, the solubility of metastyrol in each liquid, together with other data necessary for employing the liquids for high power immersion photo-micrography.

The other papers were as follows:—MM. A. and L. Lumière and A. Seyewetz read a note on the simplified method of developing Autochrome plates, and of the system to be followed in con-

nection with it for the compensation of errors of exposure; Mr. Howard Farmer gave an account of the reproduction of Autochromes by means of three-colour typographic printing, detailing the methods to be taken for securing diffusion when preparing three colour-sensation transparencies from the Autochrome. A

paper by Capt. W. J. Stomm was also on the agenda. It dealt with the various colour screen-plates now upon the market. The last paper was that by Mr. R. Vincent on a simple and effective method of preparing collodion emulsion for trichromatic process work.

STUDIO PORTRAITS WITH NATURAL BACKGROUNDS.

Not a few portraitists at the present time, more especially those at seaside and other pleasure and health resorts, are doubtless considering if there is anything in the way of novelties that they can utilise in such a way as will, either directly or indirectly, attract business to their establishments during the coming holiday season. In some places this is but of short duration, but it is really a local photographer's harvest, as very frequently during this brief period his receipts exceed the takings of all the other portion of the year put together. Therefore many will be glad of any practical hints that may be likely to increase those returns.

It has been somewhat a matter of surprise to me that photographers in places such as I have now in mind make so little use of local scenery as backgrounds to their portraits. Everyone who spends a few days' holiday away from home makes a rule of sending friends picture postcard views of the places they visit, but portraits of themselves, with the view as a background, would be far more highly appreciated. We are quite aware that some few photographers have had such backgrounds painted from photographs they have supplied, or may have painted them for themselves, but the numbers of them are not great. When this has been done the backgrounds have been limited to one or two, so that there is no great variety for sitters to select from. This has been largely due to the cost of the backgrounds, also to the fact that these painted scenes are not all that could be desired. They show that they are painted properties and nothing more—and have a stagey look.

There is, however, a quite simple method that has more than once been referred to in these columns, of producing portraits in the studio with backgrounds taken direct from nature. This, of course, is done by double printing. Now double printing is looked upon by some as being troublesome and difficult work, and requiring considerable skill in order to avoid the juncture of the two printings from showing in the finished picture. That, however, is a fallacy, at least so far as the present procedure is concerned, for if the method to be described is followed the thing is reduced to mere child's play, and can be done by the ordinary printer without any previous training being necessary. It must not be assumed that, simple as the way is, these pictures can be produced at the price of cheap postcards. It is only suitable for portraits of the better kind—say, cabinets. For such pictures considerably higher prices could be obtained beyond the usual ones—say, fifty or more per cent. The method is as follows:—

In the first place a fair stock of negatives of the different scenes that may suggest themselves to the photographer as being of interest to sitters should be obtained. The present is the best time in the whole year for securing them, as the foliage is thin and delicate in tint. In taking the views some little consideration should be given with regard to the amount of subject to be included, so that it will suitably accord with the portraits. It is well, for convenience sake, to take the background pictures on plates somewhat larger than are to be the final pictures, as then different portions can be utilised to suit the subject. Many photographers already have a good stock of negatives of local scenery which they publish. These may well be brought in for our present purpose.

In taking the negatives they should be fully exposed, as if under-exposed the shadows would be too strong and heavy in the portrait picture. In the development they should be made fairly vigorous, but not too dense, otherwise the background will appear much too pronounced. Having got our negatives, and it is well to have a good number of them so that sitters will have a good variety to select from, I will now describe the way the work is carried out.

The sitter, who should be in walking or outdoor costume, is posed in the studio, and here care must be taken that the lighting of the figure is in unison with the landscape that is to be used. It goes without saying that if the sitter were lighted from one direction and the landscape or seascape from the opposite, the thing would be little short of ludicrous. The sitter must be posed before a very light, though not white, plain, or shaded from the bottom background, and taken in the ordinary way. The reason why a quite white background should not be used will be referred to later on. A grass mat will make a suitable foreground if the background is to be a landscape or woodland scene, and one of baize will serve for a seascape.

The prints are made in the ordinary way on *albumen* or *collodium* paper, when the portrait will of course show against a very light grey background. The printed figure is then painted over with gamboge—only a very thin coating is necessary. This work does not take long, as a girl after a very little experience can do a dozen, with single figure, in less than that number of minutes. On this print the view negative is printed, and not too deeply. All the little extra work is now completed, and the print is toned and fixed in the ordinary way. In washing out the silver from the paper, before the prints are toned, the gamboge is entirely dissolved away and leaves no trace of stain behind, and toning and fixing proceed as usual. Gelatine P.O.P.'s are not suitable for the work, for the reason that the gamboge would be absorbed by the gelatine, and would, with most of them, show a yellow stain when the picture is finished. It is for these reasons that either albumen or collodium papers must be employed, as with them there is no such trouble.

It was mentioned just now that a quite white background should not be used for the sitter. If it were, the landscape, when printed, would be too pronounced as well as inartistic, and thus greatly detract from the portrait part of the picture. Furthermore the light grey tint, while subduing somewhat the force of the landscape, gives an atmosphere between the sitter and background, and conveys the idea that it is a distant scene. It goes without saying that incongruities must be avoided. Indoor furniture, for instance, would look ridiculous in a picture with a natural landscape or seascape background, though outdoor accessories, such as stiles, gates, etc., may sometimes be used with advantage, if employed with judgment.

From what has been described above it will be seen that the production of portraits in the studio with backgrounds taken direct from nature is a very simple affair, and that such pictures cost no more, beyond a slight extra trouble, than those made in the usual manner. If portraitists in such places as we have in mind were to make a feature of these pictures, and well advertise them in the locality, they would no doubt find the thing

remunerative as well as being a means of attracting attention to the studio. For these pictures much higher prices than those for ordinary portraits could be obtained, and these prices might further be enhanced by giving the customer the option of having

different backgrounds from which to select. No extra trouble is involved in producing a dozen portraits each with a different background than in making them all with one.

H. M. TASKARD.

OXALATE DEVELOPMENT FOR PAPER AND FABRICS COATED WITH IRON AND SILVER SALTS.

[In the following article, from the "Bulletin of Photography," attention is drawn to the uses of the silver-iron or Kallitype process of printing. It cannot be claimed for the oxalate developer that it is a new prescription in this process, since it is directly derived from the allied platinum process. An oxalate developer has not been used largely for Kallitype papers, and it may be doubted if it can prove more satisfactory than the mixture of borax and Rochelle salt usually employed.—Eds. "B.J."]

At the present day there are a number of different preparations of various iron salts for the coating of paper with a sensitive surface, and changing the colour of the deposit by an after-toning with the salt of some other metal. The Kallitype process and the blue print process are all capable of being varied to give different colours, or they may be toned to secure the colour desired. It is not at all certain that many of these substitution colours can be relied upon for lasting qualities, or, in other words, they cannot be considered permanent, or of even resisting the effects of the atmosphere, dampness, and light. The blue print, which consists of cyanide of iron, if kept dry, is one of the most permanent products of the iron salts.

The prints that appear to be the most fadable, made with the salts of iron, are those where the image is produced by some organic body, forming a component part of the sensitiser with the iron salt, particularly gelatine. In the case of platinum paper, the use of the iron salt is to secure such an image that, by the altered chemical condition in changing a ferric salt into a ferrous, more or less in degree, is the cause of the platinum salt, which is in combination with the iron in the sensitive coating, giving up the platinum when brought in contact with a free oxalate in solution. In this case the iron salt is employed only to produce a provisional image, and becomes eliminated in the acid clearing solution and after washings, leaving a beautiful image in platinum. In the process given here the iron salt acts in much the same way, only that an image in silver is produced instead of platinum also by development, which image can be toned before fixation in gold or platinum, or both, not only upon paper but upon such fabrics as sateen or any kind of cotton goods, but not upon silk. A photograph upon silk made according to the formula here given does not possess the brilliancy that is possessed by the same method upon sateen or any kind of cotton goods. The image upon silk appears to be sunken into the material, and a thin, washed-out appearance upon the surface. Some qualities of note-paper are well suited for this process, but the best paper is that kind that is used for photographic purposes; they can be used without any previous sizing.

Having obtained a few feet of Steinbach paper, or any other good make, cut into pieces about 8in. wide and 2ft. long, note the back of the sheets by a lead pencil mark, then prepare the following sensitising solution:—

No. 1.	
Distilled water (hot)	4 oz.
Citric acid (crystals)	1 oz.
No. 2.	
Distilled water	8 oz.
Ammonio citrate iron (green crystals)	1 oz.
No. 3.	
Distilled water (hot)	4 oz.
Nitrate of silver	1 oz.

Each of these solutions should be mixed in amber-coloured glass bottles, shake the contents well, so that the crystals all dissolve, then pour No. 1 into No. 2, shake the mixture, then add No. 3, and shake the mixture vigorously.

The mixing and using can be carried out by gaslight of feeble intensity, or an oil lamp or an incandescent electric light, if not more than sixteen candle-power. This mixture must be filtered through a tuft of absorbent cotton, pressed lightly into the neck of a glass funnel. As soon as this has been done, pour some of the solution into a glass tumbler, place the tumbler in a saucer; this will catch

any liquid that may become spilled. Lay the sheet of paper back down upon a sheet of glass, and brush the surface carefully all over, using a 2in. camel's hair brush mounted in rubber (a metal-mounted brush must not be used; it will cause the silver to precipitate in a black powdery mass). When the sheet of paper has been evenly coated it may be dried by any convenient source of heat—a gas stove is well suited—by suspending the sheets above the flame, over which is placed a piece of perforated tin plate. When dry, the paper must be coated again and suspended by the opposite end to the last coating. As soon as dry, the paper can be cut into suitable sizes and kept under pressure in a printing frame, or it may be rolled up and kept in a tin case, the same as platinum paper. The printing may be done by direct sunlight, in diffused light, or by arc light. Some sateen should be prepared and dried at the same time, and dried in just the same way, only the middle of the fabric should be sensitised, if it is intended to print a vignette or oval.

Printing the Image.

Take any suitable negative; place it in an ordinary printing frame; lay the piece of sensitive paper upon it and expose to the light. The progress of printing can be examined by a weak light just the same as ordinary printing-out paper. As soon as the print is about half done, remove it from the frame, place it aside and print a piece of fabric the same way. A test can now be made by development.

Oxalate Developer.

Dissolve in hot water the following and use it at a temperature of 160 to 180 deg. Fahr.:—

Potassium oxalate	6 oz.
Water (hot)	50 oz.
Oxalic acid	1 dram.

Place about 20oz. of this in a clean enamelled tray; keep the temperature even; then dip, without stopping, the paper print into this; development will take place instantly; a brilliant red-brown image will result. Place this into cold water; take the printed fabric, dip that into the hot developer, then, in an instant, a strong image will appear. Place this also into cold water. Print all that may be required in the same way. Develop and wash in two or three changes of water, then place the prints, two or three at a time, into an ordinary gold and borax toning bath; the quantity of gold must be only half the amount used for ordinary toning, and the older the bath the better. Watch the change of colour; only a faint change must take place. Now wash the prints in two changes of water and fix in a plain hyposulphite of soda bath, consisting of 3 oz. of hyposulphite of soda to 20 oz. of water. The fixing will be complete in five or six minutes. The prints must now be well washed and dried. They can then be trimmed for mounting, or, if the paper is very thick, allowed to remain without mounting.

The fabric will present a beautiful blue-black image, very brilliant. It will be well on the surface and half-way into the fabric. This class of print can be well dried, and will lie quite flat if squeezeed upon a ferrotype plate, or it may be wrung nearly dry and ironed between a clean folded towel or a piece of washed-out muslin, and finally by passing the warm flat iron over the surface of the print. This class of print can be washed with soap and water, rinsed in clean water, and ironed at any time. In fact, prints made upon sateen, 14 x 17 say, from a negative 11 x 14, either portrait or view, when

stitched along each side and mounted between two rollers, finished at the ends with an acorn or heavy brass-headed nail, and silk cord attached for hanging against the wall, form a fine piece of photographic tapestry, unique in appearance and novel in style, while the paper prints can be secured in colour from a deep brown to a rich violet.

The sensitising solution will keep in good working order for a year or longer, while the sateen and prepared paper will also keep good for several months if kept dry and away from actinic light.

A. J. JARMAN.

AN ARGUMENT ABOUT SHOWING PROOFS.

(A Note in "The Bulletin of Photography.")

THERE is quite a difference of opinion among photographers as to where is the better place to display proofs—whether to get the customer to come to the studio and there show them, of course; or to mail the proofs to the sitter's home. There is no question that the photographer, from an artistic point, vastly prefers the customer's presence at the studio, but there is also another matter of great importance to be reckoned with—orders. At the studio the pictures can be shown as the artist wishes them—proper order, proper light, amid proper surroundings, and, greatest of all, with suggestions and comments that, if followed, will result in a selection that will be highly creditable to the photographer. On the other hand, has a photographer the right to show proofs that, when finished, will not do him credit? We think not. He has his own interests to look after as well as those of his customers. Grant, for the sake of argument, that it is not policy to show proofs that are not satisfactory to the photographer. Then, why should he hesitate to send proofs by mail where there is no professional help to make a selection?

It is certainly less trouble for the photographer, if selection can be made without his help. There is an argument raised by some that if the selection of proofs is left in the hands of the customer's whole family—which is the case when they are sent by mail—that nobody is suited, and the only result is a resitting. If this is the case and the photographer doesn't dare show proofs without a line of talk by himself—why then, he had better close up his studio and learn a trade.

The question now narrows down—where are the larger orders coming from: home proofs or studio proofs?

At the studio the photographer may and may not, by showing the good points of several proofs, talk the customer into ordering more than he had originally intended. The chances are that if there is an increase it will be very slight. Now, let us see what happens when the proofs are sent home.

Placing proofs in the hands of the customer makes his friends and family the judges—they are not all suited with any particular one, and it takes several poses to satisfy them; and, what's more, every one of the family and all of the friends want a picture; so the customer, to keep peace, instead of ordering a single dozen of one kind, orders copies of several poses, with a grand total of, say, two dozen.

Photo-Mechanical Notes.

Mercury-Vapour Lamps in Process.

A year or two ago there was a considerable boom in mercury vapour lamps, but at that time the lamps were not so satisfactory as to make their adoption in any way economical. They have, however, latterly been much improved, particularly with regard to the glass tubes, as these can now be obtained of English manufacture of guaranteed life, and also in regard to the method of lighting. Lamps are now supplied which light merely from the switch, or have an automatic tilting device. These improvements greatly simplify the use of the lamps, and supposing they could be made of a suitable shape and on a suitable holder to stand close to the copy, they would seem to be a much more perfect form of illumination for black and white copies than arc lamps. The cost for current

is about the same when placed at the same distance as an arc, which being a point source must be some little distance away, but the mercury vapour lamps not being a point light source, and moreover, not anything like so hot as the arc, can be placed very much closer to the copy, thereby shortening the exposure. This makes them really cheaper than the arc in cost of current, and, of course, there is no expense for carbons. Provided the glasses do not break, there is practically no expense at all in running other than the current cost. We hear of one large photo-engraver in England who has adopted them throughout, and finds the saving in his electric light bill has amply justified his action. Of course, it must not be forgotten that they are absolutely unsuitable for any sort of copying except black and white, as the light consists only of narrow regions of green, blue, violet and ultra-violet, and most coloured objects copied under them would, of course, be very incorrectly rendered, so far as colour values are concerned. But black and white originals can be produced, because when an ordinary plate or wet collodion is used the only light having any effect on it is the ultra-violet, violet and blue; the black absorbs all the light to which the plate is sensitive, while the white reflects it, and therefore correct tone values will be obtained.

The L.C.C. School of Photo-Engraving.

The report of the Bolt Court School for the season 1907-8 has now been published by the London County Council, and, as in previous years, contains a large number of examples of students' work. The report of the Principal, Mr. A. J. Newton, shows that the total number of individual students was 626, as compared with 567 in the previous session. The increase is due to students in the new classes for stationers and paper-makers. Among the specimens of line and half-tone plate-making, photogravure, etc., contained in the report is one very interesting example of three-colour printing on a matt-surface non-loaded paper. This paper has been produced by Messrs. Dickenson from rag fibre of the highest class which is thoroughly washed. After bleaching to remove all perishable residues from it, a very durable paper, capable of giving a durable impression, is thus produced, whilst the lightness and agreeable surface of the paper cause one to hope that Mr. Newton and his colleagues at Bolt Court can convince the printers and publishers of the advantages of such papers on æsthetic and hygienic grounds.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between May 17 and 22:—

APPARATUS.—No. 11,846. Improvements in apparatus for treating cinematograph films after exposure. Leo Kamm, 27, Powell Street, Goswell Road, London.

DRY-MOUNTING.—No. 11,872. Improvements in metal folders for use in connection with the dry-mounting of photographic prints or the like. George Wilson Morgan, 121, West George Street, Glasgow.

REFLEX CAMERAS.—No. 11,993. Improvements in or relating to photographic cameras of the type known as reflecting or reflex cameras. Arthur Lewis Adams, 24, Charing Cross Road, London.

FILMS.—No. 11,994. Improved film for use in cinematograph apparatus and the like. Austin Edwards, 23, Southampton Buildings, London.

CAMERAS.—No. 11,995. Improvements in and connected with magazine cameras for photographic purposes. Ernest Stones, Birkbeck Bank Chambers, Southampton Buildings, London.

SHUTTERS.—No. 12,105. Improvements in focal-plane shutters for photographic cameras. Herbert George Chessher, trading as Tella Camera Co., 51, Basinghall Street, London.

DEVELOPMENT.—No. 12,120. Means for determining the relative times of development of photographic plates or films for different

temperatures. Alfred Watkins, Birkbeck Bank Chambers, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 12,141. Improvements relating to cinematographs. Charles West, 9, Warwick Court, Gray's Inn, London.

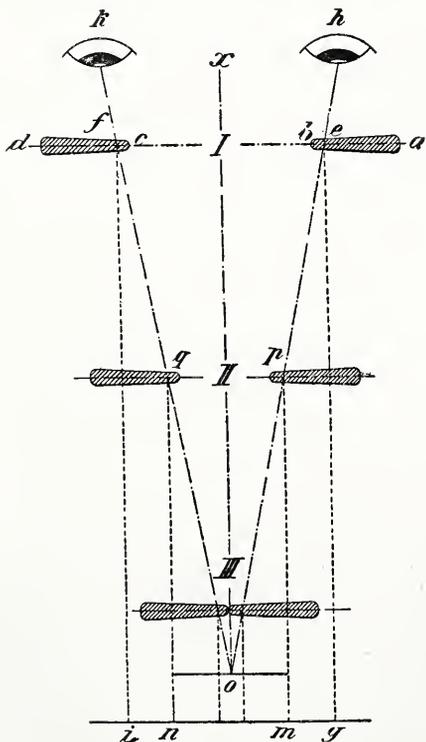

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STEREOSCOPES.—No. 9,507, 1908 (May 1, 1908). The invention relates to a stereoscope in which, whilst the distance between the eyes and the picture is fixed, the eye prisms can be adjusted in various ways to the pictures alike as regards their distance from the eye and the picture and their distance from one another, enabling pictures of any size to be observed with the same stereoscope. The manner in which the prisms have to be put farther from the eyes and nearer to each other for the purpose of observing pictures which are unusually small will be seen from the following observations.

In Fig. 1 of the drawing the prism position I is that which is taken in an ordinary stereoscope with ordinary pictures. k and h are the points occupied by the eyes and $c d a b$ the prisms with the corresponding points $e f$. o is the middle point of the picture carrier, and q and i are the middle points of two stereoscopic pictures of ordinary size. The distance $q i$ is equal to the distance $e f$. The rays proceeding from q and i are refracted at e and f so

that they reach h and k , and consequently the two eyes see the points q and i at o coinciding at the point of intersection of $h e$ and $k f$. Thereby o and likewise the whole picture appears stereoscopically. If now it be desired to cause two smaller stereoscopic pictures, the middle points of which are m and n , to coincide optically, all that is necessary is to adjust the two prisms so that the points e and f take the positions p and q (prism position II.). These points p and q are the intersection points of $h o$ and $k o$ with the points m and n that are parallel to the central axis $o x$. The rays $n q$ and $m p$ are now refracted again to k and h and appear as previously to the eyes as if they came from o . Thus the double pictures again coincide.

The prism position III. is the limit to which the eye pieces can be put nearer together until they touch.

In these observations it is assumed that the distance between the picture and the eye remains the same, which is ample for practical purposes. In this manner, with a stereoscope that is arranged so that the prisms can be adjusted between the picture and the eye and with regard to their distance apart, pictures of the most varied dimensions may be observed, without the necessity of cutting them apart.

It is also desirable that the picture carrier should be somewhat adjustable, in order, as with an ordinary stereoscope, to make the pictures accessible to different long and short sight eyes. By the adjustment of the prisms between the eye and the picture, moreover, the area of vision—which represents the sum of all the rays reaching the eye through the prism framing—is reduced so that in any case nothing more than the picture itself is seen, and no more relief effect can be obtained than is due to the refractive positions of the two images. Karl Lenck, 154, Friedrichstrasse, Berlin NW 7, Germany.

New Trade Names.

MANUL.—No. 311,544. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives, but not including substitutes for camphor and not including any goods of a like kind to substitutes for camphor. Max Ullmann, Thalstrasse 16, Zwickau, Saxony, Germany, printer, March 22, 1909.

F. AND B. (DEVICE).—No. 311,726. Films bearing photographs for use in cinematographs and like apparatus. Foulsham and Banfield, Ltd., 49, Old Bond Street, London, W., Photographers, March 26, 1909.

New Books.

"Photography for the Press." By the Editors of "The Photographic Monthly." London: Dawbarn and Ward, Limited. 1s. net.

A third edition of this manual, written for the guidance of the press photographer chiefly in matters of policy and business, reaches our table. Its aim is to offer advice to those taking up illustrative photography, either seriously as a business or as a means of putting a little money in their pockets. The writers lay stress on many points in which those unversed in the ways of the press and of publishers may be in the dark, and this part of the book should thus save the beginner from many disappointments. But perhaps the most useful section is the directory of illustrated newspapers and magazines, in reference to each of which details are given as to the time up to which illustrations can be accepted, the class of print preferred, the block space usually to be filled, etc. There is also a list of agents in business to place photographs, etc., with the press. "Photography for the Press" continues to be a manual from which many useful hints may be taken.

"Photographisches Reise-Handbuch." By F. Wentzel and F. Palch. Berlin: Gustav Schmidt. 3Mks.

This is a treatise on photography exclusively from the point of view of those who use the camera as an accessory to travel or touring. The choice of apparatus is therefore advised on this basis, the authors discussing the selection of apparatus for such serious accompaniments of exploration as photogrammetry and balloon photography. The second portion of the work concerns itself with the most suitable methods in various departments of tourist photography, and with the expedients to be adopted in the development of plates and films.

"CAMERA WORK," No. XXVII., Alfred Stieglitz, New York.—We are bound to say that the last number of this pioneer magazine lacks some amount of that art and beauty which it makes such strenuous efforts to secure. It is just possible that, in the enthusiasm of the chase, as a chase, the quarry itself is overlooked at times. For example, the two "experiments" contributed by Messrs. Stieglitz and White may have been very interesting to their makers; but for the public at large they are surely of no interest of any sort. We are not told precisely the objective of

these experiments; but if mere nebulosity were the end in view, the attempt appears to have been highly promising. Of this group of work "The Torso" is by far the best. It is a nude study that was shown at the last Salon in London. The series of prints by Herbert G. French have that rich quality that seems to be the birth-right of any print capable of being reproduced in photogravure. American photography is characterised either by light and airy nothingness or else by an all-over hopeless blackness through which a glimmer of an image struggles to the front. Mr. French's are in the latter category. Granted this inherent characteristic, however, they may be pronounced in excellent taste and possessing much charm of design. The letterpress gives nothing out of the way this time except an amusing tirade against American Indifference, by Benjamin De Casseras. This might have been written by a Britisher, but for the fact that no Englishman would give himself such licence of expression in a book making claims to refinement.

Dew Apparatus, &c.

A Stand for Specimen Prints. Made by Houghtons Ltd., 88-89, High Holborn, London, W.C.

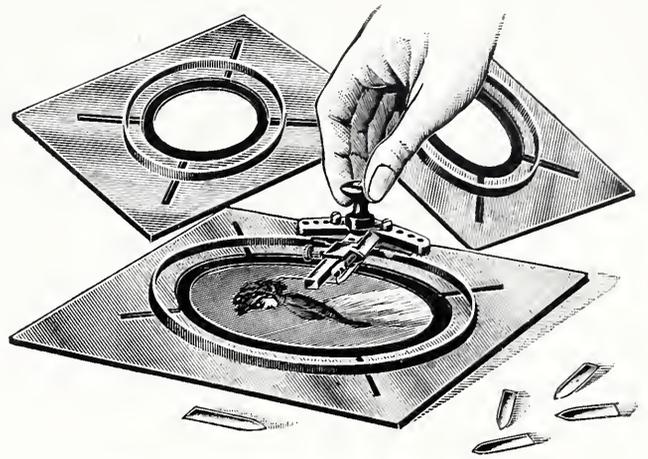

A portfolio, which is also a handsome article of furniture, is now being supplied by Messrs. Houghtons, of the design shown in the drawing. The stand is made in oak, and takes a set of boards, each 24 x 20 inches, thus allowing of the display of a large number of prints without the necessity of overcrowding. The stand measures about 2ft. 3in. in width by about 3ft. 6in. in height, the top folding flat

when the apparatus has to be put on one side. Mounted on castors, so that it is readily moved into any part of the reception-room, the stand should prove a profitable investment, since it allows customers to inspect the photographer's work for themselves; in fact, the open construction of the portfolio provides a temptation to turn over the contents, which the majority of persons cannot resist. The price is £22s., that of suitable art mounting boards, 24 x 20 inches, being 6s. a dozen.

A TRIMMER FOR CIRCLES AND OVALS.—An apparatus for trimming prints to oval or circular shape is now being introduced to photographers by the Adhesive Dry Mounting Company, Ltd., 27 and 28, Fetter Lane, E.C. The apparatus consists of a series of metal plates,

on which is a raised rim. On this moves the carrier of the cutting knife, the travel of which can be modified so as to give ovals of various shapes and sizes. The apparatus is strongly made, and

should provide a ready means of trimming prints to the now popular oval shape, a description of print which has largely superseded the circle in photographic portraiture.

CATALOGUES AND TRADE NOTICES.

CAMERAS, TRIPODS, ETC.—The catalogue just issued by the Camera Construction Co., Eagle Works, Durham Grove, Hackney, London, N.E., is one of particular interest to the professional photographer for the reason that it is mainly devoted to cameras, repeating backs, and other apparatus for studio use which are the actual manufacture of the company. Studio cameras are made in several patterns at remarkably moderate prices; studio stands figure also in some considerable variety, and among other apparatus of interest are the firm's enlarging easels, background stands, and rapid bromide printer. The list is very fully illustrated with actual half-tone reproductions of photographs of the company's specialties.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 5.

Edinburgh Photographic Society. Ramble to East Linton.
United Stereoscopic Society. Outing to Cobham.

MONDAY, JUNE 7.

Southampton Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

TUESDAY, JUNE 8.

Royal Photographic Society. Ordinary Meeting.
Hackney Photographic Society. "Portraiture." C. Wille. Council Meeting.
Kinning Park Co-operative Camera Club (Govan). Club Meeting.

SOUTHAMPTON CAMERA CLUB.—Mr. C. M. Cooper gave a lecture and practical demonstration on making enlarged prints before the above society last week, in the course of which he recommended the use of a negative of medium density which would not only give good gradation in the enlargement, but also minimise the exposure in making the prints. As regards focussing, he advocated an open aperture in the lens of the enlarging lantern, and also, if possible, to have the film side of the negative nearest the illuminant owing to getting sharper detail in the resultant print. To obtain the correct exposure, the use of a trial strip of bromide paper was suggested upon which various exposures could be made, and the largest stop should be inserted in the lens. He then demonstrated the use of the club's enlarging apparatus and fully described its use. Several excellent prints were made and developed. The demonstration was excellent, and many useful and practical hints given. A vote of thanks to Mr. Cooper brought an interesting evening to a close.

Commercial & Legal Intelligence

OBSTRUCTING A FACTORY INSPECTOR.—Charles Dereske, photographer, of East Street, Derby, was fined 10s., and ordered to pay the costs, £1, for obstructing Mr. F. J. Parkes, H.M. Inspector of Factories, in the execution of his duty. Defendant pleaded guilty. The Inspector said he visited the defendant's premises on March 22, with an assistant, and asked to be allowed to see the workroom. Defendant declined to admit them or to answer any questions. He (witness) had visited some 50,000 factories and workshops during his official experience, but had never been so contemptuously treated before. Defendant said he had been in business since 1880, and had never understood he came under the Factory Act. He had nothing to conceal.

NEW COMPANIES.

PERFECTO FILMOGRAPH COMPANY, LTD.—Capital £100, in £1 shares. Objects: To carry on the business of manufacturers of photographic materials and apparatus, and of apparatus for exhibiting pictures, music-hall and theatre proprietors, etc. Private company. Registered office, 10, Market Street, Chorley, Lancs.

Correspondence.

CHROMIUM INTENSIFICATION.

To the Editors.

Gentlemen,—Referring to my previous letter and to your note this week on chromium intensification, from observation of various plates intensified by this means, I think the degree of insolation the plate has received (exposure) has also a considerable influence on the amount of intensification obtainable, and also the steepness of gradation. I have no means of accurately measuring the densities, but for those who have the problem should have some interest. It is not improbable that some similar effect (I do not refer to chemical action) takes place within certain limits in intensification, as in printing in gum bichromate.

An over-exposed and rather flat negative, such as would yield a good gum print when intensified by this process, would yield a vigorous negative suitable for silver printing. It will, however, be noted that the low densities (corresponding to the shadows) have only been slightly intensified, and the high-lights have been very considerably built up. It will be noted that in the considerably over-exposed negatives greater intensification has been obtained, but the steepness of the gradation seems less than in previous cases (this I have judged by appearance and not by measurement), and that after a certain point the half-tones in the high-lights become clogged and are not distinguishable from the high-lights.

I have not been able to obtain any appreciable, or, I might say useful, intensification, with under-exposed negatives. The films (kodoid) do not seem to be affected in the same way as plates (Lomberg, Agfa, Chromo, Isola, and Wratten panchromatic).

All my experiments were made with a bleaching solution of the same strength (Eder's formula), and I did not vary the amount of bichromate in the bleaching solution. I therefore came to the conclusion that the degree of intensification was limited in the first instance (1) by the exposure the plate had received; (2) by the amount of washing after bleaching; (3) on the composition of the re-developer; (4) the manner and composition of the first development may have some influence; (5) that the gradation or steepness depended on the amount of exposure. I have obtained this constantly during these last four years, and the results appeared to be from the same cause in every instance.

I may note that the reducing was always done in the dark-room, and the re-development commenced there also, but often enough con-

tinued in the light of an ordinary room, even close to the windows, without any apparent difference being noticeable, though I have never made any experiment to test this. If, however, the action of the light does stop development it might be a useful means of stopping the intensification at a given point.—Yours truly,

Rue des Alpes, La Tour-de-Peilz.

EDGAR SIMPSON.

May 29, 1909.

[We refer to this letter under "Ex Cathedra."—Eds. "B.J."]

PARALLELISM OF PLATE AND OBJECT.

To the Editors.

Gentlemen,—I was much interested in your articles on "Parallelism." The method I use is as follows:—On the focussing screen is drawn a small circle, exactly centred on the axis of the lens. On the middle of the picture to be copied I place, or have held, a mirror. When I can see the reflection of the lens in the centre of the circle I call the camera correctly placed. I should be glad if you would inform me whether this method is correct or not. Q. S.

[So far as we can see it should in theory give quite correct results, but we have tried similar methods, and have at times found great difficulty in observing the image of the reflection of the lens upon the ground glass.—Eds. "B.J."]

PHOTOGRAPHIC COPYRIGHT IN AMERICA.

To the Editors.

Gentlemen,—In your recent issue of May 7, on page 360, in an article on "Photographic Copyright," appears the following statement:—"Photographers in the United States, chiefly through the tireless energy of Mr. B. J. Falk, have secured clauses in a Bill (which becomes law on the forthcoming 1st day of July), the effect of which will be to improve in some degree the unsatisfactory state of things which has prevailed in the past—." In next column, on same page, the article further states: "Mr. Falk, who has taken on his own shoulders the burden of pressing for a full recognition of photographers' rights—."

Both these statements as they stand do a great injustice to a man who has laboured with me most untiringly, most ably, and most self-sacrificingly for fair copyright protection to the photographer.

This man is Mr. Pirie MacDonald, who, as my fellow-delegate, appointed by the Photographers' Copyright League of America, has done most important work on behalf of the photographic cause. He was not only present, but he made his presence felt, at every meeting of the Copyright Conference, convened by the Librarian of Congress, and composed of delegates representing the various interests affected by copyright, and he attended all the public hearings at Washington before the Congressional committees, who were engaged in drafting the new law. During all this period, which extended over four years, he never once shirked his duties and responsibilities as delegate, and paid no heed to the loss which his own business affairs suffered. His speeches before the Joint Senate and House Committee did much towards securing for us the benefits of the new statute.

I feel certain that you will agree with me that no fair account of the recent copyright struggles of American photography can be complete without due recognition and full credit being given to Pirie MacDonald, and in that spirit I would most respectfully ask you to mention in your esteemed Journal the facts above enumerated

—Very truly yours,

B. J. FALK.

14 and 16, West 33rd Street, New York.

May 21, 1909.

[We gladly publish Mr. Falk's letter, and we hope Mr. MacDonald will accept our expression of regret that we should have failed in acknowledging his share in the recent copyright struggle. We have so often had to refer to Mr. MacDonald in association with work for the general good of photographers that we may be sure he will acquit us in this instance of any desire to fail in justice to him.—Eds. "B.J."]

TRADE, PROFESSION, AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen,—When I wrote the letter which appeared in your issue of the 21st ult., I merely intended to call the attention of those

interested to the unfair demands of a clique of sweaters and their aughty boasts.

In the current issue of your paper I see that "Playfair" has covered a big space to show in what haphazard manner he has chosen is non-de-plume, and how inconsistent he is with his own assertions.

He declares that my hope of something being done, etc., is a *forlorn one*, and proceeds to carefully consider "How photography as reached the present deplorable condition" in forty-five lines of most irrelevant matter; but he finishes the paragraph with "Each class must work out its own salvation, if such a thing be possible or desirable!"

But in order to prove how *forlorn* the hope was that I expressed he starts the next paragraph with these words: "Without cohesion assistants and employers are equally powerless," etc.; and another thirty lines of equally irrelevant matter with the forty-five mentioned above.

I will only add, for "Playfair's" benefit, that the word "trade" as, besides the synonym "commerce," also that of "craft," and if he had been true to his pseudonym he would not have attributed the first-named meaning to my statement.

In conclusion, I wish to say that if photographers' assistants would have a few conversations on the subject with intelligent bricklayers they would find out more practicable ways and means to their salvation than either I or even "Playfair" could tell them of. I hope (again) that somebody with a little influence will take the initiative to bring about the formation of a photographers' assistants' protecting league, and remain, with best wishes for the trade (profession) of photography, not the "commerce of photographs," yours every respectfully,

A. REDMOND.

4, Mildmay Grove, N.

June 1, 1909.

Answers to Correspondents.

- *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

V. Ranford, 136, High Road, Lee, S.E. Photograph of C. W. Gardiner of Lewisham, Winner of "Evening News" Marathon Race, 1909. Photograph: Group of C. W. Gardiner, A. Fuller, and A. W. Bush.
Lander, The Cooper Art Studios, Medical Hall, High Street, Canterbury, Kent. Photograph of the Rev. S. Gee. Photograph of the Rev. T. Rae.
J. Scott, 38, St. Barnabas Road, Cambridge. Photograph of Capt. Cook's Memorial in St. Andrew's Church, Cambridge.
A. MacKenzie, 62, North Parade, Belfast. Photograph of a "Full Weight" Tea Window.

QUERIES.—(1) What focus do you recommend for cabinet busts to produce results without distortion when a good length of studio is available? (2) Is any real advantage gained by having a lens of 14in. to 18in. focus work at $f/4$ over one at $f/5.6$ for cabinet work?—A. MARSHALL.

(1) One of 14in. or 15in. will be a very suitable length, as then pleasing perspective will be obtained. (2) Yes, in the point of rapidity, but nothing more. (3) No, not a sharp and crisp image with the full aperture. If that is desired, the lens will require to be considerably stopped down.

OLD LENS.—Is a lens marked "Valantin Opten Ex Cont tre des ateliers de Mr. Lerebours, Paris," of much monetary value and use for cabinet heads? It is about 3½in. in diameter. Stops fit in front. Are these reliable?—F. NEWELL.

From the description we should say that the lens was made

some fifty or so years ago. It is impossible without examining it to express any opinion on what it will do. We may tell you, however, that it has but little market value, but it does not follow from that that it may not be a useful lens. You had better try it by taking two or three negatives, and if it answers your purpose you can get central stops fitted to it. They are better than front ones.

W. H. WARREN.—Frame-makers specially catering for photographers can supply you. See advertisements in each week's Journal.

ROBIN HOOD.—(1) As good in optical effect as others, and, of course, occupying less space. (2) Yes; the effect is the same. (4) For 12ft. picture you require a 10in. lens; for 15ft. an 8in. (5) Can be used on both types of current; the lamps are not efficient when used on current of high voltage, 200 to 250, and then afford a very constant and high power light. (6) A good anastigmat of $f/5$ or so aperture, or a portrait lens covering the lantern slide or plate.

COPYING PLANISCOPE.—Can you oblige me with a few hints as to using Griffin's copying planiscope (1½in. internal diameter of lens hood planiscope), with a No. 4 Cartridge Kodak (5 x 4)? I find a good deal of difficulty in focussing accurately when copying small pictures and preventing linear distortion.—ERTHU.

If distortion is produced it is due to the supplementary lens upsetting the corrections of the original one, and we do not see any way of preventing this effect. It is, however, probably at a minimum for some one particular scale of reduction, which you might find by trial. If you cannot secure good focus with the aid of a focussing glass and an oiled screen a similar cause may be suspected. But possibly you have forgotten to stop down the lens. You cannot expect good focus at full aperture when the focal length has been shortened by a planiscope, as the relative aperture is much increased.

SKETCH.—From your letter we do not gather the kind of picture you mean by "sketches." If you will be good enough to send us an example or a fuller description we shall no doubt be able to help you. Certainly such a bleaching method as you suggest might be used, but we do not know that it is. The best bleaching agent would be a mixture of iodine and potass cyanide, which totally removes the image.

TOP LIGHT STUDIO.—I have at my disposal a small, narrow studio, the roof of which, also one end, is wholly composed of glass, but no side light is available. Will you kindly inform me, through the medium of the "Journal," how best to compensate for this defect to give good results.—A. E. L.

Such a studio will be difficult to work in so as to obtain the best results. If it were of good size the case would be different. Without knowing the actual dimensions the only suggestion we can make is that you somewhat subdue the top light and utilise the end light to soften the shadows; also use reflecting screens for the same purpose.

VARIOUS QUERIES.—(a) Can you tell us the address of a firm of automatic machine makers who make postcard slot machines? (b) What is the quickest method of obtaining rough proofs from 12 x 10 negatives? If with a thin sheet of celluloid between bromide paper and wet negative, where can a few sheets of same be obtained (usual houses do not stock)? (c) What is the most suitable material for front of flashlight cabin? Is there any ready fireproofed translucent material on the market? (d) Can you describe method of transferring signatures to negatives so as to give name in white on finished print?—E. E. E.

(a) Most of the large dealers supply automatic printing machines for postcards. But possibly that is not what you want. We know of no machine for postcards like those used for small direct positives. (b) From Fallowfield's, Charing Cross Road. (c) We think not. However, you can make it for yourself by soaking thin muslin in a strong solution of tungstate of soda. (d) The simplest way is to use the indiarubber type letters, made for the purpose. They may be had from any of the large dealers or from Messrs. Richford, Snow Hill, E.C.

PERMANENCY.—(1) Certainly, the results are fully as permanent as those of other processes. (2) Yes, you are right in your suppositions.

PLATES AND SCREEN.—I should be much obliged if you would give me the benefit of your advice on the following subject:—(1) I am taking photographs of birds' nests and eggs, mostly situated

amongst crags; therefore there is not much foliage—i.e., green. Is it an advantage to use Wratten's panchromatic plates and screen, K 111, or will ordinary Ortho plates be satisfactory? (2) What lens do you advise for the work?—G. E. C.

(1) Such a panchromatic plate and screen are really necessary for the correct rendering of the colours of the eggs, or of many of them, though for the general work of landscape photography an orthochromatic plate and filter are sufficient. (2) A decent R.R. lens should give you much better results than those you send, though the negatives in some cases have not been sharply focussed, or the camera has not been held steady at the time of exposure. If you would give us some information as to the camera, lens, aperture, etc., we might be able to assist you further.

DEVELOPER.—Some few years ago I saw the following formula recommended in the columns of your Journal as an excellent developer for focal plane shutter: The formula was:—

A.—Pyrogallol	1 oz.
Citric acid	1 oz.
Sodium sulphite	5 ozs.
Water to make	50 ozs.
B.—Sodium carbonate	12½ ozs.
Water to make	50 ozs.

Equal parts of the two solutions to be mixed for use.

Will you kindly give me full information regarding this developer? (1) It was highly recommended as a developer, in which "all the speed of the plate was allowed to do its work." Can you recommend it for this purpose? (2) If I make up the above quantity will it keep indefinitely? I do not do a great deal of focal-plane work, and want a developer which will keep. I have been informed that the above will not keep. Please give full particulars on this point.—W. J. HUGHES.

(1) It is a good pyro-soda formula, but we should prefer to add water to it when developing exposures which have been very brief. Half strength will be better. We think you would do better with a developer of pyro and metol, say the Ilford formula given on page 857 of the "Almanac," or one of the single solution developers, such as the Ilford Company's "Certinal," with which there is less tendency to obtain harshness than with pyro. (2) The solution will certainly not keep indefinitely. It would most likely keep in good condition for a couple of months.

TONING.—Is there any chemical or chemicals that will develop or tone a pure bichromate print into a black and white, like a bromide?—F.

If by a "pure bichromate" you mean a carbon print, there is, of course, none. But cannot you make your meaning clearer?

CAXTON.—We have not heard of cases where amidol has been the cause.

A. C. TAYLOR.—So far as we know, there is not. You might apply to Mr. Cooper, at the Research Laboratory, Watford.

AMMONIA SOLUTION.—Would you kindly let us know, in the columns of the "B.J.," the amount of water which must be added to 1 oz. of ammonia, .880, so as to make the density .920?—A CONSTANT READER.

Roughly, the 1 oz. must be diluted with water to make 1½ ozs.

MILDEWED PRINT.—I have a valuable photogravure or engraving of a picture, called "Solitude," after Sir F. Leighton, which has got damp and is covered with white mildew spots all over. Will you kindly tell me in the next issue of the "B.J." how to remove or obliterate these, as the picture is useless as it is?—SHAW.

Mildew spots can sometimes be rubbed off with bread. When they cannot the print should be treated by immersion in a solution of bleaching powder, or preferably one of hypochlorite of soda (eau de Javelle). The formula for this is given in the "Almanac," p. 782. If the picture is a valuable one we should advise you to place it in the hands of a competent print restorer, as plate paper is very tender and not easily handled while wet, and it is necessary that the bleaching agent be thoroughly removed, or the paper will become very rotten in a short time.

PORTRAIT TROUBLE.—Will you be so kind as to inform me how I can obtain good portraits on light backgrounds? Hitherto I have been using dark grounds, and my lighting on these has been very good; but on the light grounds the face, hands, and figure generally appear to sink into the background, making a flat inky effect, although I have developed them up well. What I want

is to produce the flesh nearly as light as the ground so as to get a sketchy effect. At present I am using a Marion P.S. 250 plate, and it is essential that I should work at this speed, so if you can explain this difficulty I should feel so obliged.—TEXO.

As we see by your letter heading that you are a professional photographer, we should have surmised that you would have had no more difficulty in getting good results with a light background than a dark one. It is simply a question of lighting the background, and the sitter. You should bear in mind that portraits taken before a light background require quite as full, if not fuller, an exposure as when taken with a dark one; possibly you have been giving less. Slower plates than those you are using would lead to stronger contrasts, but more will depend upon the lighting.

APPRENTICESHIP.—Two years ago we took an apprentice for three years. He was to have 5s. a week for the first year, 7s. 6d. the second, and 10s. for the third. He has turned out a good hand, and knows his work well—indeed, is now of great service to us in the business. Last week he told us that unless we gave him 10s. a week more (that is, double what he is receiving now) he should leave and get a better place. On our reminding him he could not do that, as his apprenticeship would not be at an end for another year, he replied that he knew that, but in a fortnight he would be twenty-one, and then he should go unless we paid the wages he required. Will you please tell us what steps we should take under the circumstances?—J. J. and Co.

The only thing you can do is either to pay the young fellow what he demands, or to let him leave. An apprentice, however long he may be bound for, is not bound to serve after he has arrived at the age of twenty-one.

THE MARRIAGE of Dr. C. E. K. Mees to Miss Alice Crisp took place on Tuesday last at Croydon. Dr. and Mrs. Mees were the recipients of many letters and telegrams of congratulation. They left by an afternoon train for Paris en route to Switzerland.

AN ALTERATION IN OFFICE HOURS, somewhat on the lines of the much-talked-of Daylight Saving Bill, is being introduced by the C. P. Goerz Optical Works, Ltd., of 1-6, Holborn Circus. Until September 30 next, the office hours will be from 8.30 to 5 o'clock, and on Saturdays from 8.30 to 1.15; and an arrangement has also been come to by which each member of the staff will be absent one Saturday out of every four, so that he may obtain the benefit of a week-end.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATIONS OF THE U.S.A.—In reference to your printed question in a May issue of the "Journal," Mr. L. Minor Sherow, of Ossining-on-Hudson, U.S.A., writes that as he is not familiar with the workings of the British Photographers' Association, he cannot say that the American Association is of a similar character. There is a Professional Photographers' Association in America, but there is no list of the members published that he knows of. Regarding the Professional Photographers' Society of the State of New York, Mr. Sherow states that there is no printed list of the members, but he will be glad to send a list of the members to anyone desiring the same.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

We draw attention in an editorial article on page 451 to the merits and demerits of the two systems on which the great majority of reflex cameras are made, namely, that in each the mirror is raised by hand on making an exposure, and that in which a spring is used for the purpose.

In reviewing the professional photography in the Dresden Exhibition we note the notable strides made during the last few years by German professional workers. The exhibit of American professional photography is an extremely complete and interesting one, and shows the tendency to produce a uniform output of a highly finished form of photograph. (P. 453.)

Many ways in which a professional photographer, without spending a halfpenny, may make himself and his work known among the people of his town are suggested in an article, "Sociality as an Aid to Business," on page 452.

The Blackpool Bench of magistrates have ruled that photographers who make and sell photographs on the beach are pedlars and must take out a licence. (P. 465.)

A useful accessory, serving to attach cameras of the turntable pattern to a baseboard when using them for copying, etc., is described in a note on p. 460.

Mr. G. Watmough Webster describes the many useful repairs which may be done with a new commercial cement. (P. 456.)

At the R.P.S. on Tuesday evening Captain Owen Wheeler gave a most useful address on the practical methods of telephotography. An abstract of the paper and a report of the discussion which followed appear on p. 463.

A camera is now being used in America for recording the speed of motor cars. Two successive exposures are made at a known interval of time, the difference in the size of the image of the moving car serving as the basis of the measurement of speed. (P. 458.)

A correspondent draws our attention to an "outfit" for photography being sold at the price of one farthing. (P. 450.)

The photographic section of the International Exhibition now being held at Shepherd's Bush is reviewed on p. 459.

Intensification of negatives, reduction of bromide prints, and telephoto calculations appear under "Correspondence." (P. 465.)

The realistic reproduction of the texture of carpets is mentioned under "Photo-Mechanical Notes," where also a short *résumé* of the papers on process work at the recent Chemical Congress is given. (P. 458.)

A recent table by Drs. R. Luther and H. Weisz aims to give the equivalents of the various systems of plate-speed numbers. (P. 457.)

EX CATHEDRA.

Parallelism of Plates and Object.

A correspondent last week suggested another solution of the problem how to set the plate parallel to the object. He drew a circle on the focussing screen exactly centred on the axis of the lens, and then held a mirror against the object. When the reflection of the lens could be seen on the ground glass in the centre of the circle he assumed the adjustment to be correct. In commenting on this method we stated that as far as we could see it should in theory give quite correct results, but further reflection shows that in practice the result would not of necessity be quite correct. The test does not guarantee in any way that the focussing screen is absolutely at right angles to the lens axis, though it does ensure the subject being so. Therefore it does not necessarily secure parallelism between plate and subject. This suggested solution, that seems so plausible at first sight, is a good proof of the very tricky nature of the problem. A little consideration will show that the plate might be inclined very considerably from its proper position without the decentring of the lens image becoming apparent. This might be a serious source of error in the case of a centre swing adjustment to the back.

* * *

Sharp Definition in Enlarging.

Good definition in enlarging depends on several conditions beyond that of the use of a well corrected lens, but we have serious doubts as to the validity of a condition suggested by a lecturer when recently addressing a provincial camera club. According to the report, the speaker stated that sharper detail is obtained when the film side of the negative is nearest the illuminant. We can see no reason why this should be so, while there is at least one very good reason for assuming the contrary, that is the interposition of a sheet of glass not usually of the best quality between film and projecting lens. Possibly the lecturer is accustomed to place a diffuser between the light and the negative, in which case there is something to be said for his argument. Diffusion may and often does disturb definition when the diffuser is not in contact with the film, but with the ordinary lantern, in which a condenser without any diffuser is relied upon, our experience is that the lecturer's advice is wrong. Good focus depends far more than is often suspected upon the proper adjustment of the light, for the image projected upon the screen is to a certain extent an image projected by condenser and lens working together. As has been pointed out before, a beam of light projected by a condenser is subject to violent effects of spherical aberration. A proper adjustment of the light means that the projecting lens is correcting the aberration due to the condenser, and it is only when this condition is fulfilled that perfect focus is secured. Hence the necessity for careful readjustment of the light when the

scale is altered. If a negative is put into a lantern that is properly adjusted and the light is then shifted from its one right position, not only does the illumination become defective, but the definition is damaged, sometimes to a surprising extent.

* * *

Turntable Clamp.

The majority of modern cameras are now fitted with turntables, which are at times a source of great inconvenience when we do not want to use the camera on its own tripod. If, for example, we wish to fix it on a copying stand we cannot screw it down in the ordinary way with a tripod screw, neither can we very well hold it down with weights. Various elaborate devices have been put upon the market from time to time for filling up the turntable space, while sometimes a separate baseboard, with side clips to hold the camera, is used. All these contrivances are, however, clumsy, expensive to purchase, and troublesome to fit up, and of late we have got over the difficulty in a much simpler fashion. We simply took a piece of flat brass bar, long enough to fit over the baseboard of the camera, under the bellows, and in the centre of it riveted a screw boss to take a camera screw. The bar is only long enough to rest on the upper edges of the turntable ring, while the underside of the boss is nearly flush with the bottom of the turntable. The camera is put upon the support arranged to receive it. The bar is dropped in over the turntable, and then a camera screw passed through the support and screwed tightly into the boss holds everything as firm as can be wished. The contrivance fulfils its purpose perfectly, and can be carried about quite easily in the pocket.

* * *

Farthing Photography.

When some year or two ago we drew attention to the means provided for the practice of photography at a total cost of one halfpenny, we thought we had tapped the very bottom of cheapest photography. Not so: a correspondent sends us a "farthing packet," which is now sold by toy and fancy shops to children at half this price. It consists of a quarter-plate negative and two pieces of ferro-prussiate or "blue" paper, the "printing frame" being the negative itself plus two bent strips of metal by which the paper is held in contact with it. Those who have wondered what becomes of stocks of old negatives may be interested in hearing that the one in this farthing packet was evidently taken in the regular way of business. It is varnished, and bears the name of the sitter, the number 87,369, and brief particulars of the order. So far as we know, such purpose as this represents the only commercial use which is made of disused negatives, and apparently even in these remote fringes of the photographic trade the competition of the lower-priced article is being felt. In this matter some of our readers may be glad of our opinion, which is, that the higher price represents a better return for the money. We advise those in doubt not to look at the outlay, but to fix on the halfpenny outfit.

* * *

The Borders of Stereoscopic Views

A matter with regard to which there seems to be many differing opinions among stereoscopic workers is the presence of a visible border or frame around a stereoscopic view. We have often seen large views bigger than the standard size advocated on the ground that with them no portion of the mount is visible around the subject. For our own part we are inclined to think the visible border is an advantage in several ways, but admitting that there may be cases in which it may be advantageously dispensed with, a patent specification, published in our issue of June 4, offers some interesting suggestions. This patent covers a special form of stereoscope, in which

the lenses are adjustable, not only as regards their separation, but also with respect to their position between the eyes and the slide. The advantages claimed for this arrangement appear to be that small images can be more readily made to combine, though the reason for this is not stated, and that in all cases we can arrange matters so that the borders of the images are not visible. The latter effect can, however, be produced with an ordinary stereoscope by simply holding the instrument farther from the eyes and readjusting the slide until the image is sharp. The view thus obtained is bounded by the lens margins which are not in focus, and the effect appears to us to be far less pleasing than that of the clear sharp-cut margins given by the mount. So far as we can see, the method covered by the patent will give similarly indefinite boundaries and be just as unsatisfactory. We fear that if the mount is to be invisible there is no satisfactory expedient that will take the place of large pictures, but for our own part we feel no wish whatever to abolish the effect of the mount, which with proper trimming can be utilised to add greatly to the effect produced by the slide.

* * *

The Standard Photometric Unit.

It is interesting to note that America, France, and Great Britain have come to an agreement with regard to the adoption of a standard photometric unit, the one selected being the Harcourt pentane lamp, as used at the National Physical Laboratory. This involves no change on the part of the French standard, the bougie decimale, which is exactly equivalent to the pentane standard, but the American standard candle has to be reduced by 1.6 per cent. to make it agree. The German Hefner unit is equivalent to 90 per cent. of the new standard, and it is to be hoped that before long Germany and all other countries will fall into line with those that have entered into the agreement with regard to the pentane standard, which came into force on April 1, 1909. Of course, this standard applies more particularly to the gas and electric industries, and has only an indirect bearing on photographic work. Still, it is of some importance to photographers, who frequently have to employ a standard light for experimental and testing purposes.

* * *

Finding the Exposure.

A writer in a contemporary advocates a simplified method of ascertaining exposure the foundation of which is the assumption that the correct exposure for $f/22$ is equal to the time required for the meter paper to darken to a 1-16th tint. The speed of the plate is assumed to be between 180 and 200 (presumably Watkins numbers), and for very fast plates the exposure is halved, while for slow plates it is doubled. The idea, apparently, is that the amateur who is not sufficiently intelligent to be able to match two tints in the ordinary way will nevertheless be able to determine quite easily the time when the paper just begins to darken. We can hardly confirm this from personal experience, and we should much prefer to take the quarter tint. In any case, however, we do not see any advantage in the method described. If the user of the meter can ascertain the 1-16th tint or match the quarter tint, he surely must have sufficient intelligence to turn the dials and read off the exposure required. He gains little by assuming all plates of the "rapid" variety to be between 180 and 200 Watkins, for some of them are nowhere near those numbers. One "special rapid" plate, for instance, is listed as 90 only. It is not always safe to guess the speed as 180 or 200, and if the true speed is known the photographer may as well use his meter properly as not. In the absence of a meter there is, however, something to be said for another method suggested for outdoor work in fine weather: that is, to give one second at

f/32, or an equivalent exposure at any other aperture. Such a method is, of course, directly opposed to all the teachings of the meter advocates, but in the absence of any accurate knowledge it forms a very useful guide, though usually we have to modify the time a little in accordance with our previous experiences.

* * *

Storing Rain-water.

A few weeks ago a correspondent sent a query with regard to a deposit formed in a galvanised iron tank filled with rain-water. He sent us some of the deposit, which, in the dry form, is a very fine grey powder, and on analysis it appears that it consists of zinc carbonate and soot. The rain-water was therefore not quite clean, and was also strongly aerated with carbonic acid, which is generally the case. Such an action, though usual in lead tanks and pipes, is not, we believe, very common in galvanised iron tanks. At any rate, we have seen many such tanks used for rain-water which have shown no sign of the trouble. In the case of our correspondent's tank, he cleaned it thoroughly by scrubbing before use, which operation no doubt caused a fresh zinc surface to be exposed to the action of the water. In a sense the water was no doubt purified by the action of the zinc, but the deposit formed is very likely to lead to trouble in photographic work, and it would be as well to prevent it by a coat or two of good bath enamel, paint, or japan. The carbonic acid present in the water is not likely to be detrimental in any way, while the soot can be removed by filtering. It is a common mistake to suppose that rain-water is pure water. It is free from the salts that produce hardness in other waters, but carbonic acid and soot are generally contained in it, while a smoky atmosphere will often add sulphuric acid and other impurities. When it is collected for photographic purposes care should be taken to provide a proper separator that will automatically reject the first rush of water from the roof, for in this portion the greater part of the dirt is found.

SYSTEMS OF REFLEX CAMERAS.

DESPITE the very great number of types of reflex camera upon the market—and there must be in all some thirty reflector cameras—one feature may be selected as a means of dividing the instruments into two classes. This is the device by which the mirror is raised and the plate exposed. In the larger number of cases the mirror is not provided with any spring or other mechanism for automatically raising it, but, when the exposure is to be made, pressure upon the lever outside the camera first of all raises the mirror into the "up" position parallel with and close to the focussing screen, and when this has been done, actuates the shutter. We may call this the "hand" method of mirror-release in contradistinction to the second system, namely, the one used on the fewer number of more expensive instruments, the mirrors of which are provided with springs. On the shutter-release in this case being pressed, the effect is to cause the rise of the mirror and then immediately afterwards the release of the shutter. The sequence of these two operations is independent of any skill or intervention on the part of the operator; simple pressure upon the release automatically raises the mirror and releases the shutter. Those whose experience in reflex cameras is limited may be in doubt at first glance as to which of these methods is the preferable. Neither can be said to possess an unmixed advantage over the other, but a consideration of their respective merits and demerits will, we think, show the balance of advantage from the practical point of view to rest with the second or automatic method.

Obviously, as the mirror in the case of the hand adjust-

ment is not provided with any actuating spring, it falls immediately after exposure by its own weight, covering the plate again and dispensing with the necessity of re-setting. These two points are certainly of advantage since the first makes one movement the less when preparing the mirror for a second exposure, whilst the fact of the plate being automatically covered after each exposure makes impossible the accidental fogging which may be caused in reflexes of the other pattern as a result of re-setting the shutter while the mirror is still up. To set against these two advantages, however, is the fact that a certain amount of force has to be exercised in raising the mirror, and therefore the conditions are not those most favourable to making an exposure with the maximum of steadiness. Not that this matters very much when a fairly high speed of shutter is employed, say anything over 1-50th of a second, but when employing speeds of 1-5th, 1-10th, or 1-15th of a second, which are often very advisable, the greatest steadiness in holding the camera becomes a matter of importance. Even in high-speed work, the automatic method of release has this advantage, that the time between the pressing of the release and the actual making of the exposure is constant, depending not in any way upon the operator, but upon the mechanism of the camera. On the other hand, when the mirror is raised by hand, the personal equation comes in, and an operator may depress the lever more quickly at one time than another, thus tending to irregularity in obtaining a moving subject correctly on the plate.

A study of these considerations should, we think, convince those who employ a reflex either for slow or rapid work, that of the two methods the "automatic" is preferable on the whole. As has been stated, it is true that the advantage of the automatic covering of the plate after exposure is of importance in practice. In the case of some cameras with this form of release, means are taken against the accidental re-exposure of the plate by winding the shutter with the mirror "up," in the form of a locking device, which requires the mirror to be put down (shielding the plate) before the shutter can be re-wound. An alternative method of securing the same degree of safety of the plate is to make the shutter a self-capping one, so that the only time at which light passes through the blind is during the actual exposure. Some constructors of reflex cameras do not appear to have realised this particular advantage of the self-capping blind. Assuming, as we think should be done, that the method of raising the mirror by hand is less advantageous than automatic raising by spring, the particular reason for adopting the self-capping shutter should be that it provides a means of dispensing with the locking device just mentioned. With such a shutter it will not matter, as regards the safety of the plate, in what order the re-adjustment of the camera for a fresh exposure is made; the mirror may be put down first or the shutter may first be wound; in either case no light can possibly reach the plate.

There is still a further respect in which the hand-raised mirror compares disadvantageously with the mirror raised by a spring. In cases where a low point of view has to be taken (when the reflex is held in its normal position about level with the waist), it frequently happens that parts of the subject cannot be included, owing to some obstacle in the foreground. A common instance is when a view is being taken near to a row of railings, or when photographing a procession from a public stand or other place where the heads of people in front may come in the way. In such circumstances as these a camera of the reflex type may be held at arm's length above the head in an inverted position, and the picture on the ground glass examined by looking up into the hood. This gives a view-point some two feet above the level of the eyes, and allows of photographs

being taken which would be impossible by any other method. But if a camera of the type in which the mirror automatically falls after exposure is used for this purpose, it is obvious that in the inverted position the mirror will fall parallel to the ground glass—that is, into what is usually called the “up” position, and cannot be used in this way unless a special latch is provided to keep it in the normal pre-exposure state at an angle of 45 deg. to the lens axis. We believe there is at least one camera in which this automatic latch is provided, the act of raising the mirror putting the latch out of action without special intervention on the part of the operator. In the case of

the mirror raised by a spring, no such accessory means are needed, and this type of camera is one which, in this respect also, may claim to be of more universal use than that in which the mirror is raised by hand.

In the above notes we are speaking, of course, entirely from the point of view of the user of a reflex. There may be considerations of ease of manufacture which have been overlooked, but makers of reflex cameras have shown themselves so competent to deal with a variety of mechanical problems that it is not too much to say that less importance may attach to considerations of difficulty of manufacture than to those of expediency and practical usefulness.

SOCIALITY AS AN AID TO BUSINESS.

Of the personal note in professional photography not more has been written than will be. Individuality is the key of success, and nothing succeeds like it. It would be easy to show how, in one form or another, this principle of individuality permeates all human effort and achievement; but here it will be sufficient to remark the army of imitators of his work with which every master of our craft (and, indeed, of any craft) is surrounded, and almost invariably to the advantage of the master. The pupil rarely outvies the master in his own line; indeed, if the pupil excels at all it will be seen to be not in servile reproduction, but in a method of the disciple's own: restatement rather than reduplication—a step forward sometimes, but a step aside as well.

But there is another sort of personal note which, although it does not touch technics, is perhaps of even more importance to every professional photographer according to his *métier* as a business man, and that is the personality, not of the man in relation to his method of work, but of the man and his work in his relation to those to whom he looks for practical support.

Granted, for instance, that what you do not know about photography is not worth knowing, that your composition is noteworthy, that your technique is without fear or reproach, that the finished article as it reaches your discriminating clients is not less perfect than the bloom on the dainty cheeks of your expensive lady receptionist who hands it to them; I say, granted all this—and this, dear brethren, is almost too much for most of you!—how is it again, for instance, that the “Bon Accord Boudoir and Button Co.” round the corner, which metaphorically sat down at your elbow eighteen months ago—you can hide it from yourself no longer—does a trade you never did—does, in fact, a good deal of that trade which was once your own, and that will never be yours again?

I will tell you. The manager of the B.A.B.B.C., Mr. Horatio Darkslyde, is something less of a photographer than yourself, it is true, but that is not of much consequence, since you yourself are so exceptionally endowed: removed from the general rut of men, and enjoy an eminence from which you can command an uninterrupted view up and down your principal street—and hardly further. But Darkslyde, if he is less of a photographer than yourself, is also something else besides. He is (more instances) a useful tenor in the local Christchurch, he is a member of three local athletic clubs and one social, he is an enthusiastic and therefore much-sought-after mover at bazaars, he is the best Punch-and-Judy man the Mothers' Guild Waxwork Show ever had. He is, moreover, many things besides, for does he not write to the local paper on “stray cats,” “broken lamp-posts and roadways,” “the borough council”?—in short, anything, so long as he gets his name into print at least once a week. In fact, it pays him better to employ an operator, two printers, and seven lady assistants, besides receptionist, and stay out and enjoy himself, rather than to sit at home and grumble at the weather as you do.

As for yourself, do you ever go to church o' Sundays. Never. Sometimes. Often. But have you ever attended public worship as a principle of business? Will you deny that, if you always attended church, business would result? Neither one way nor another? What about that choir group you had such a hard job to prevent Darkslyde getting last year, and—shall I write it down?—that this year you never got at all? I quite understand that you consider church work should be divided evenly—that Darkslyde should have his fair share; but do not for a moment believe you are to share if you do not support the vicar. You know very well that Darkslyde got the order for all the booths at the recent bazaar. And then, what happened only last June when you wrote the vicar for a complimentary sitting? The vicar—busy man!—could not possibly spare the time—with apologies. Darkslyde, of course, got to hear of this, and, like a wise Mahomet, forthwith went to the mountain and photographed him in his vicarage study, as well as all the other members of his family, and the servants in the hall, and Rufus in his kennel, and the coach-house!

Frankly, this is scarcely exaggeration, because Darkslyde knows his business.

To be exclusive—to do the “high-art fake,” as Henley has it—requires conditions which also must be exclusive. Your style and personality must dominate your clientele to the extent of eccentricity, if need be; but dominate it it must if as a business man you are to dispense with all the social tricks which are well known to bring business. It is the old story of the purveyor of luxuries starving in his lair. The most ruinous form of self-indulgence is to ply a trade at the expense of your bile, and there is only one recipe for a full larder in these days of strenuous competition—that is, you must get out and hustle because, mind you, when it is all boiled down there is no “Bon Accord Boudoir and Button Co.” but in the social personality of Mr. Horatio Darkslyde.

In short, the successful photographer must be, and always is, something more than a photographer. Every good operator in the country will testify that to be lacking in tact and social accomplishments is to court disaster. Once under the skylight, child and adult must be humoured. For, after all, what is your objective but the choice of your sitter's expressions, not merely the most characteristic, nor necessarily the most pleasing, but a happy combination of the two; and it is far more needful for the photographer to command the social adroitness which will induce this elusive regard than for the portrait painter, who can attend to drapery when the features of his client are contrary and get busy with the expression when the opportunity offers, or at a pinch, when the sitter's back is turned, by recollection. Hence, the photographer needs to make his opportunity, where his brother of the brush can afford to wait; and in order to do this no amount of photographic technics can help, except in so far as photographic conditions must exist, not so much for the

capturing of the expression as for the subsequent practical reproduction of it once captured.

Besides, who is there who has not heard the remark: "Oh! don't go there; he is such a disagreeable man!" And what proportion of real success is there in the portraiture of the operator whose temper is uncertain? Or, at any rate, what are the prospects of a pleasing likeness commanded by the operator with a surly manner?

A model photographer's establishment should run like the front wheel of a new bicycle lubricated for the first time—that is, without a sound of the works. Everything should go as smoothly as receptionist, operator, rules, armchairs, and clean-

liness can make it. Even the till should be padded, though this will not be necessary in the case of payment by cheque.

But the effort must come from without. The man who can coax the business along through social channels is he who is going to make the money. This does not mean that photography is to be his one topic of conversation outside; on the contrary, it means that photography shall be the last theme of conversation he shall be dragged into discussing—apparently.

Finally, let your personality so irradiate your social acquaintances that they may be convinced of your good work before—and after—they see and have paid for it.

L. T. J. H.

THE DRESDEN EXHIBITION.

III.

A SERIES of twenty galleries, several of them lofty and spacious halls, accommodates the section devoted to professional photography, the chief arrangements for which have been in the hands of Professor G. Emmerich, of Munich. The division of the exhibits is into countries, and the representation of the various nations is as follows:—Germany, by 65 exhibitors; Switzerland, by 29; Holland, by 21; America, by 40; Sweden, by 7; France, by 3; Italy, by 2; Finland, by 6; Denmark, by 4; and Norway, by 1. Professor Emmerich, who cites these figures in his introduction, points out that the Austrian photographers show their work in the special Austrian house, but he goes on to say that the works of British professional photographers are shown together with those of amateurs in the amateur or pictorial section. He surely cannot have closely looked at the British amateur section, where, as a matter of fact, out of nearly a hundred pictures there are about a score by workers actually engaged in professional photography. These in every instance are the men who are in the habit of sending to exhibitions here work which in a good many instances is nothing like that which they do in their business. It was the expressed intention of the sub-committee which had charge of this section to include professional work. It has, however, included the work of the few of the professionals who are most akin to the amateur in their methods. Professional photography as practised by the most prominent members of the profession in this country is not there at all, a fact which requires to be stated, as Dr. Emmerich's note on page 135 of the catalogue may imply that it is.

German Professional Work.

At a first brief glance it is easy to see the rapid strides which portrait photographers in Germany have made during the past ten years or so. There is evidence in every direction of the production of work of a very individual character. It is easy to see that many photographers have been powerfully influenced by artists who are not photographers. Such influence was bound to make itself felt in the direction of unconventionality, for, if it is anything, German art is imaginative even to the point of the grotesque and the bizarre, terms which might be quite fitly applied to some of the professional exhibits. However, commercial considerations would appear to exercise a not unhealthy influence upon the photographers, and it is noticeable that the most extreme and unconventional work is not that of the acknowledged leaders, such as Erfurth, Grainer, Raupp, not to forget the ubiquitous Herr Dührkoop, who, let him deny it as he may, is less German than his contemporaries. But among the smaller men, those who appear to be beginners just embarking on a career of professional portraiture, one sees signs of the most positive discontent with the commercial type of photograph. That dissatisfaction in these instances takes all kinds of freak forms—of strange lightings and posings and prints of queer colour or tone—and the desire to get away as far as possible from the evidently despised "good photograph," as a middle-

class woman of forty-five would understand that term, is shown in the profound gloom of prints, which might be the most sinister productions of the gum-process. We doubted if the makers of such as these were really photographers in business for themselves, but we were assured that no amateur, or even photographer's assistant, might exhibit. We do not wish to suggest that there is a preponderance of this sort of thing: it occurs only in the cases of the smaller exhibitors, and among these may be found plenty of originality which does not run to eccentricity, and some which in its pleasing light tones and airy effects stands out among the more usually sombre scales of tones. Thus Amalie Eva Schroer, of Hamburg (No. 420), is very nice in her choice of light and dark tones, though she, like many another, apparently cannot resist the temptation to

A Group of Galleries in the Professional Section at the Dresden Exhibition.

pop in a landscape or two. Another lady photographer, Elisabeth Hecker, of Munich (No. 434), shows very versatile taste in her eleven portraits of women, dressed and undressed. Munich supplies by far the most interesting work. The work of Frau Dr. Stephanie Ludwig (No. 437) and of the brothers Lützel (No. 438) is very varied, original, and pleasing, and technically above reproach. Next to them are photographs by Ernst Müller, of Dresden (No. 438), whose portraits and landscapes show great originality. Another Dresden photographer, Bruno Wiehr (No. 442), has some notably good portraiture, among which is a portrait of Herr Karl Weiss, the general secretary of the exhibition, upon whose shoulders has fallen the bulk of the work of organisation. There being a general tendency to subdued tones, especial mention deserves to be made of two gems of brilliant indoor lighting by E. Wolleschak, of Naumburg (No.

454). One is of children in school, and the other might be called "When poverty comes in at the door, love flies out of the window."

Another exhibitor whose work reaches a high standard is Hans Bender, of Bremen (No. 455). A large number of prints, all portraits, all of a style, and all technically excellent, are shown by Max Gluer, of Oppelm (No. 445).

Between the galleries containing the above works and those in which are larger collections by individual photographers is an ornate chamber, decorated and furnished in gold, containing photographic portraits of European crowned heads, that of King Edward VII., by Mr. E. O. Hoppé, being the only one which we could not discover. Beyond the fact that the portraits are of very distinguished persons, and are very richly produced and framed, no special interest attaches to this collection.

Grainer, Dührkoop, Smith, Ruf, and Erfurth.

Of these separate collections, which are housed in the spacious alcoves radiating from a central chamber, a photograph of which is reproduced above, one comes first to that of Herr Dührkoop. There are fifty-five portraits, few of which we can remember to have seen before. The tireless Dührkoop seems to forget about the portraits of last year: he has made probably a thousand more since then, and certainly the collection—though every print is admirable—has the look of having been made up with what there was at hand at the time, which is perhaps as high a compliment as can be paid to any photographer.

The work of Herr F. Grainer, of Munich, is distinct in style from Dührkoop's. Perhaps it may be called more unconventional. In many instances a natural background is used, with very good effect. One very striking example of the photographer's liking for the uncommon is No. 9 in the series, in which a man is shown looking down into a dark space which occupies about one-third of the print. But Grainer's technique is so fine that one may pardon occasional indulgences of oddness such as this.

A much larger number of prints is shown by Frank Eugène Smith, painter and instructor in the the Photographic School at Munich, a photographer better known here and in America as Frank Eugène. They are almost all fine character portraits, mostly of artists. One of a boy standing at a door (No. 20) is one of the very best. A fair number of the prints are extraordinary considered as professional photography. They are not the best, and we should have thought more of Mr. Eugène Smith's work without the nudes, such as the studies of Adam and Eve, which he drags in at the tail-end of his collection.

Theodor Ruf, of Freiburg, exhibits less than twenty prints, but every one is technically a fine piece of work, with much expression of character in the sitter. One group—of surgeons engaged on an operation—is a triumph in its way, though no one can commend the photographer for choosing such a repulsive and gruesome subject unless for some surgical purpose.

Another large collection is that of Hugo Erfurth, of Dresden, whose work is big and powerful—qualities which it secures by sacrificing delicacy and harmony. The effort to produce something which will fairly "knock" the spectator twenty yards away seems too obvious in a large proportion of Herr Erfurth's work, clever as it undoubtedly is. It leads him to portraits in rough, brutal tones, though, from other prints done on a quieter scale, it would seem that the work actually given to the average sitter is not of so aggressive a type.

These six one-man shows complete the German professional section. Though one or two well-known names are absent, notably that of Perschied, the section demonstrates how very keenly many of the German professionals are devoting themselves to the development of their art as an art. A number, it would seem, have succeeded in proving that art can pay. But even with those who make no particular claim to be "individual," a most notably advanced standard of work is apparent.

Switzerland and Holland.

These two countries are represented by prints to the number of 131 and 72 respectively. Those of Switzerland include almost as many landscapes as portraits, which latter are not above the standard of a good studio likeness such as can be seen in almost every town. The work from Holland is scarcely more distinguished. A large proportion consists of figure studies and landscapes, the only legitimate portraiture of outstanding merit being that of P. Clausing Jun, of Haarlem.

American Professional Work.

There is no doubt that the section which will attract the English visitor most is that of the American professionals, since the names alone, Hoyt, Garo, Goldensky, Core, Pierce, Mock, Strauss, Falk, and Macdonald, are as well known to photographers in this country as in America. And interesting the large collection is, though in a different way very likely from that intended by its contributors. The 286 portraits have been brought together by Mr. Pirie Macdonald and Herr Dührkoop, the latter's acquaintance with the American workers dating back to the St. Louis Exhibition. It would seem that, without a single exception, the collection contains the work of the acknowledged leaders of portrait photography, in addition to which it shows, for the first time in Europe, portraiture by new men which bears comparison with the productions of the leaders, and in some instances possesses qualities absent from that of the best-known studios. The first thing which cannot fail to strike the student of this section is the absolute sameness of all the prints by a given exhibitor. That applies to the lighting, and to the kind of print, and to the mounting as well, and it can be observed in the case of most, though not all, of the front rank of American professionals. The style may be altogether different from that emanating from the studio a year ago; but, to judge from the photographs at Dresden, the American method is to evolve a certain form of print—as distinctive as you like—and to adjust the methods of the studio to turning out that particular form as effectively as possible. Obviously that should be a sound commercial system to work on, so long as it does not fail in retaining customers. But apparently the directors of the studios are wide awake to the necessity of changing the kind of print before the public has tired of it. In almost every instance, the American work represents a high degree of re-touching: in this, as in other respects, it is most finished and admirable, and the set of prints by each exhibitor leaves one in no doubt as to the style favoured; and the display of a dozen or more portraits all as like as pins in style creates the idea that the makers are able to reduce the details of their production to a system which turns out a product of a certain type with machine-like regularity. This is not to say that the American photographs do not show many excellent and individual features: they do, but the family resemblance between each print of one group cannot fail to impress the visitor.

The ten photographs by Mr. Dudley Hoyt are all of women, richly gowned ladies of imposing appearance—or made to look so by Mr. Hoyt. In every instance the space of the print is admirably filled by the subject. There is not an example of the dropped appearance of a figure which one often sees. One cannot suggest how much better the result would have been had a figure been so much to the one side, for the reason that the portraits admit of no improvement in the manner of accommodating the size and form of the image to that of the final print. Mr. Hoyt adopts a strong style of lighting. His prints are all large ovals with narrow oval border a little darker in tone, and around this a square-cornered tint of a little lighter tone, the whole actually printed on a white plate-marked paper.

Frank Scott Clark, of Detroit, shows photographs only of women and children, in which good use is made of dark Romneyesque backgrounds and strong lighting to show the sheen of silk skirts. The mounting is in the Cosway style.

George M. Edmondson, of Cleveland, shows five superb ex-

amples of what must be at home portraits, though very beautiful lighting has been secured. The three prints by George E. Tingley, of Mystic, Conn., are in much nicer schemes of multiple mounting than we are accustomed to see here, except from workers like Mr. F. H. Evans.

A professional worker of whom we have not previously heard is Eugene R. Hutchinson, of Chicago, whose portraits show a highly developed sense of the massing of tones. The photographs are not large, but they are as strong and full of individual character as anything in the section. Mr. Hutchinson uses diffused focus with reserve, and thus avoids the over-re-touching which most of the American photographers consider necessary. It is a pity that Mr. Hutchinson should think it well to adopt the "Photo-Secession" trade-mark of art—the round globe. He introduces it into two of his portrait studies. Both they and the others show the maker to be capable of such fine work that we should be sorry to see him stooping to these tricks of method.

The people who would appear to be favourite sitters of Mr. Elias Goldensky, of Philadelphia, are not those who are beautiful. His photographs show people of character, most of them old people, in every case drawn by Mr. Goldensky with his accustomed regard for harmonies of tone and colour.

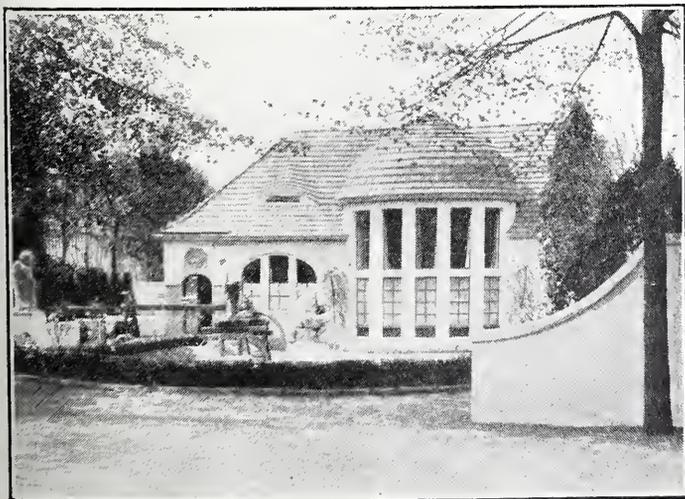

The work shown by Garo, of Boston, is quite up to the standard of this photographer. The portraits are nearly all of women, are printed in a rich sepia, and are of the superb technique as regards lighting of the face and dress, which is characteristic of this studio.

Mrs. Käsebier's five frames are quite out of the common. They are titled "A Japanese-Tissue Print," "A Gum Print," "A Bromide Print," "A Gum-Platinum Print," "A Platinum Print." This little demonstration of Mrs. Käsebier's command of these processes is at the same time a very good testimonial for the bromide process. The bromide print is of remarkably rich black tone, and reproduces the muslin and silk of the sitter's dress most admirably. Mrs. Käsebier's portrait of Mr. Alfred Stieglitz is a striking likeness.

E. B. Core ("Papa" Core to all the "boys" in New York State) shows ten of the portraits of children which have made him and his studio famous. And delightfully spontaneous they are in pose and expression. When a collection of photographs typical of the work of American studios was shown at the house of the "B.J." some time ago, Mr. Core's portraits attracted

PROFES IONAL EXHIBITS IN THE STUDIO HOUSE.

In a building specially erected in the grounds, close to that of the photographic trade, a number of exhibits of professional

The Studio House. The window to the right is that providing the light in the model studio of Herr Hugo Erfurth.

more notice than any, not only for the natural appearance of the little sitters, but for the force and strength of the prints. They were vigorous black prints, the background in which was white as a rule. All the pictures at Dresden Mr. Core has printed in sepia on a cream paper, though he gets an equally big effect.

The veteran Joseph Byron, of New York, is represented by four large prints, associating him, as ever, with flashlight photography. H. H. Pierce, of Boston, is another of the men with a very distinctive style of his own. All his portraits are in somewhat dark tones, and are mounted first with a narrow and lighter border, next to which comes a broader and much lighter band, the back mount being dark. The technical quality of the series is of the highest order, and the only criticism which can be made is that the sameness of the style becomes marked when a number are shown together.

The last remark applies with even more force to the portraits of men by Pirie Macdonald. Nearly thirty of them are hung in rows, all of panel shape, and in every case "framed close." As there are but two sizes of frame, and as the full thirty are arranged symmetrically, the impression made is not that which Mr. Macdonald's fine work deserves. In expression of character these heads of men stand by themselves in professional photography. Their author, like the volatile Dührkoop, is a man "with a way with him," a great and interesting talker, and an observer of men, one with a nice sense of humour, and powers of discovering his sitter's characteristic traits. We would like to have seen his portraits shown in a way which offered more inducement to study each individually.

It may be our imagination—we think not—but in no portraits do we seem to discern the suggestions of the photographer so plainly as in those of Mr. Strauss, of St. Louis. There is not one face among the dozen or so that looks dull or uninterested. It would appear that Mr. Strauss is determined they shan't. Some seem mildly to disapprove what is going on; some women seem amused; children have the appearance of liking it immensely. Of the photographic qualities of the portraits, it is only necessary to say that they are beautiful examples of lighting and printing—no less so are those by other Americans—but it is not easy to find quite the same air of moderated animation elsewhere. Only the sitters' friends can say if this is the making of the portraits. Mr. Strauss's success suggests that it is.

PROFES IONAL EXHIBITS IN THE STUDIO HOUSE.

this latter, by which the illumination of the sitter is provided, is seen in the first illustration on this page. The studio is with-

The Studio House from the grounds, showing the small model lean-to studio.

photographic interest are brought together. The chief of these is the model studio of Herr Hugo Erfurth. The bow window of

out top light, but is of lofty proportions, about 15 or 16ft. in height. The furnishing is done in various tones of green, and

the furniture and decorations are very tastefully selected to harmonise with the floor and wall coverings. The studio is fitted with reception and dark rooms, and is in regular use. A special type of studio stand, designed by Herr Erfurth, and constructed by Ernemann, carries a full-size camera. The stand is built in the form of a couple of uprights supporting between them a horizontal baseboard, on which rests the camera. This arrangement allows of the camera being raised up and down within a considerable range, and of being brought quite close to the floor :

screw adjustments also allow of its being tilted up and down. Various other small rooms within this building contain examples of frames, mounts, and backgrounds for professional workers, also of arc lamp installations—the "Jupiter" and "Regina" lamps are shown—and there is also a model daylight lean-to studio of the kind made and supplied by the firm of G. Zimmermann, of Stuttgart. Other rooms contain examples of blinds and curtains for studio use, and of such apparatus as dry-mounting machines, trimming machines, washers, etc.

REPAIRING APPARATUS—A FIND.

In a recent number of the well-known scientific periodical *Nature*, the Editor, in reviewing a work on practical physics, called the author to task for not mentioning a comparatively new addition to laboratory aids—a cement possessing properties widely different from those of the ordinary "liquid glues," and others with a common main basis of gelatine. It occurred to me that I should be equally to blame if I failed to bring before my brother photographers a personal experience extending over several months with this new material, which I look upon as a veritable "find." The cost of breakages among the many and various utensils, dishes, measures, storage jars, et hoc genus omnes of a photographer's plant, forms a serious item in his yearly expenses, and any method of minimising it is to be welcomed. This new cement is sold under the name of "Cementium," and even a sixpenny tin of it goes a long way. It is utterly unlike the well-known sticky pastes or liquids we all know so well, for, strange as it may appear, although its qualities as a cement are so admirable, it is not sticky, and, more, it stands both fire and water. There is no fear of a slight smear on the fingers causing them to adhere to the article under repair, and, perhaps, pulling it to pieces again, and instead of, as in the ordinary way, using as little of it as possible, Cementium should be laid on fairly thickly, and the broken edges only lightly pressed together. I take it to be composed of a solution of water-glass holding in suspension some fine silica, though really it does not matter, for the stuff is cheap enough, and the makers have, no doubt, gone to sufficient trouble to hit upon the exact proportions and strength of its constituent parts. It is sold in tins which, when open, disclose a watery fluid with a thick white deposit. Before using it has to be stirred up with a piece of stick till it becomes of the consistency of thick cream. It will then stick together anything except india-rubber, vulcanite, celluloid, and blacklead. When dry, and fairly set, it gradually hardens and becomes like stone; the maker's name of "liquid china," is by no means far-fetched. Its actual great usefulness to the photographer will be shown by a recountal of my own experiences with it. (I may here say that I have found the makers quite ready to give advice when any one finds himself face to face with a difficulty in its use.)

My first essay was with a 15 x 12 "porcelain" dish, which my laboratory assistant had rendered useless by knocking a piece off one corner. I pieced the corner on with Cementium, gave it a week to set, and then put it into use. It lasted three months, solutions being put into it every day, and then it came apart. I wrote to the makers, and they pointed out where I could improve my method. I rejoined the pieces, and it is now, after four months' use, apparently as firm as ever. The makers sell what they term a "hardening solution," which, after a few days' drying, should be painted over the join, and so expedite the process of hardening after drying. It may be said that to wait a week or two after a repair is too long a time to be practicable. But this is only necessary when there is much handling of the restored article. Otherwise, at the expiration of a day or two the article is fit for use.

This experience was so satisfactory that I proceeded to test another remarkable property possessed by Cementium, which is neither more nor less than building up a missing part! Another similarly broken dish had been put aside as useless, for not only was the corner broken away, but, when it came up for repair, a piece was missing, and a triangular gap extending half an inch from the margin was left. The first step was to mend as far as possible. This was done, and a day given for hardening; then the thick cream was taken up, with a

pointed stick only, and allowed to drop into the triangular gap. It lends itself beautifully to the work, and remains where it is placed. The gap was gradually filled up above the level of the margin, and put aside to dry for a week. Then the superfluous material was scraped off with a penknife and rubbed down level with sandpaper, and afterwards painted over three times with the "hardening solution," and the whole put aside for a fortnight to get thoroughly set. At the end of that time one was only just able to scratch the built-up portion with a penknife, so hard had it become, and the dish has been in constant use for months.

The next article to repair was a small atmospheric gas burner, one of the feet of which had been knocked off and lost. An old brass gas socket was found, and just the right height. Cementium was used to fasten it, and it is now in regular use, and has been for months, and is quite firm, though often nearly red-hot.

There was a thermometer with milk glass scale enclosed in an outer tube, which latter had got broken, the thermometer stem fortunately being intact. The outer tube was cut off level; an old negative was cleaned off, and narrow strips cut off it. These were joined at the edges by our "find," and made into a neat square tube, which I slipped over the thermometer stem till it reached the outer tube, and then secured in its place and made air-tight by a thick dose of Cementium. A little packing was placed at the opposite end of the square tube to keep the thermometer stem from shaking; a small final piece of glass was cut to fit the end and Cementiumed on, and a neat thermometer of square section, far superior to its original condition, as it did not roll about when put in the platinum developer, was the result. One mistake was made: sufficient time was not allowed for the material to dry out, and, in consequence, moisture condensed inside, and sometimes obscured the mercury column for a few seconds. The remedy is obvious.

A Japanese tea-pot—the best vessel possible for use in varnishing—had the spout end, on the under side, broken off, and so was rendered useless. The broken part was built up with Cementium, and the spout is as good as ever.

A test-tube on foot had the foot broken off. It was fastened on, and for months has been in daily use, and, though kept suspended from hooks by the foot, it remains firmly attached. Another such tube had half the foot broken away. A disc of glass was cut with a diamond, and fastened on with a plentiful supply of Cementium. It has now a more secure base than ever, and is in constant use.

More as an experiment, I repaired a glass 2oz. measure which had been broken into seven pieces. These were carefully put together, all "at one sitting," allowed to dry for a week, and then painted over with "hardening." The measure has since repair been constantly used for several months.

Two Winchester quart bottles had stoppers broken and useless; in one only the ground part that enters the bottle was left; in the other the top half was broken off, and the stopper could not be used. The latter was quickly cemented with Cementium. The former required a new head entirely for it to be of any use. A thick layer of Cementium was laid upon it till it became top-heavy. Two days were allowed for drying, and then a final layer was added. In another two days, having set hard, it was shaped out with a penknife, smoothed down with glasspaper, and given a fortnight in a warm corner to dry out. It was then treated with hardening solution, and for many months has done duty in guarding a store of distilled waters, been removed and replaced scores of times, and still remains a perfect stopper, with a model handle.

A large window-pane of hammered plate had had a stone thrown through it. An old negative was cleaned and fastened over the hole, and, though exposed to wind and rain, is now, six months after, faster than ever.

I may add that the makers sell also a material of putty-like consistency for filling up, in cases where putty would ordinarily be used; it seems excellent. I have only used it for one purpose. In my printing-room are a series of Doulton-ware sinks connected to the waste-pipe by leaden pipes joined to the sink by a socketed end filled up with putty. In one the putty had become loosened and washed away. The new material was used to replace the putty, and answers admirably.

In conclusion I may say that I consider the sixpence I first spent on Cementum one of the best investments I ever made.

G. WATMOUGH WEBSTER, F.C.S.

A DAYLIGHT DEVELOPING APPARATUS.

FROM "Popular Science Siftings" we learn that a novel daylight developing apparatus of a portable kind has been devised by Mr. E. H. Smart, a gentleman known in London art circles. It is capable of separately developing one or several plates or films, and a single plate may be readily examined without running off the developer. The apparatus consists of two chambers, one containing the developing bath, and the other sliding with relation to the first and provided with red glass panels acting as an inspection chamber. This inspection chamber is also provided with means for raising a plate out of the developing bath.

The light-tight tank is sufficiently large to receive the plate or plates. When the tank is constructed to receive several plates it may be divided by partitions into a number of separate compartments. Each compartment is provided with a draw-off tap, or with an aperture and stopper. Each plate is mounted in a carrier or slide, which has a hook or an aperture or ring at the upper part by which it may be raised from its developing compartment.

The developing tank is covered at the top and sides with an inspection cover, made of light-tight material with suitable panels at the sides, made for instance of red glass, or it may be made entirely of red transparent celluloid or glass. This inspection cover slides over the outside of the tank and fits this latter in a light-tight manner. It has one or more funnels in its top, which is or are so constructed as to admit liquid to the various compartments but not light.

The top of the inspection chamber is provided with one or more internally projecting hooks, which may be rotated from the exterior to engage with the hook or ring at the top of the slide when it is desired to lift a plate by sliding the inspection chamber upwards.

The plate or plates to be developed are each mounted in a slide or carrier, and inserted into the tank, and the top of the inspection cover is placed in position. These operations are performed in the dark or in a dark room. The tank is then taken into the daylight and developer is poured through a funnel into the compartment or compartments containing the plate or plates. After a short time the inspection cover is lifted, carrying with it one of the slides, with a plate therein, which is examined by looking through the red panel. If necessary some of the liquid may be run off and more or other developer may be added. When the plate is sufficiently developed the developer is run off and water is allowed to run through the tank.

A NEW STUDIO, designed by Mr. Drinkwater Butt, F.R.P.S., is now being erected on premises forming part of the estate of Lord Willoughby in the Market Place, Spilsby, Lincs, for the occupation of Mr. T. Bundock, B.Sc., who, on completion, will open a high-class photographic business therein.

LOST.—On Whit Monday, May 31, a No. 3 Folding Pocket Kodak camera, with spool of twelve films (eleven exposed), opposite the Gables, Bull Lane, Gerrard's Cross, Bucks. The Kodak was left on the bank by the roadside opposite, and was picked up while owner was in the garden of the Gables. Reward offered for return to Goadby, 54, Woodfield Crescent, Ealing, London, W.

A TABLE OF PLATE SPEEDS.

ALTHOUGH comparative figures drawn up with the object of enabling a plate-speed reading in one system to be converted into another may very frequently be misleading, some rough indication is occasionally of service, and tables for this purpose have been compiled in the past by various writers. Possibly, however, none have been quite as complete as one recently published in the "Photographische Rundschau" by Drs. R. Luther and H. Weisz, who comment upon the desirability of plate-speed numbers, which stand in a simple ratio to the exposures required. Thus, a plate of Watkins speed No. 5 requires double the exposure of a plate of speed number 10. The authors suggest that the most simple and correct unit for plate speeds would be a plate of such sensitiveness that on an exposure of one candle-metre-second—that is, an exposure of one second at one metre distance from a standard candle—a just developable image would be obtained. The absolute sensitiveness would thus be measured by the number of times a given plate was more sensitive than the unit plate; or, by the number of plates that could be exposed, one after the other, so as to give a developable image in one candle-metre-second. The absolute sensitiveness is thus a reciprocal of the minimum exposure for developable image or "schwollenwert" (as the Germans call it) in candle-metre-seconds.

The following table is given by the authors for the systems of plate-speed numbers in use in this country and on the Continent, or occurring in photographic literature. The numbers are only approximate, as the bases of the different systems do not permit of a strictly exact comparison. The table is drawn up so as to give the equivalents of the twenty degrees of sensitiveness adopted in the Scheiner system. The numbers of the first and second columns are exact within 1 per cent. Those of the Warnerke scales are given to one-tenth of a degree, whilst those of the H. and D., Watkins, and Wynne systems are rounded off to be exact within 1 per cent. The formulæ serving for a conversion of the different systems are as follows:—

1. Warnerke (less transparent—21) x. 1193=(Scheiner—11) x. 1053.
2. Warnerke transparent=Warnerke less transparent+3.
0,1193 (Warnerke transparent)
3. Hurter and Driffield= $\frac{1}{8,908} \cdot 10$
(Warnerke transparent—7,9615).
I.e. =1,3162.
4. Watkins=2 H. and D.
5. Wynne=9.057 $\sqrt{H. \text{ and } D.}$

Minimum light value in candle-metre-seconds producing developable image.	Absolute light-sensitiveness.	Degree Scheiner.	Degree Warnerke.		H. & D. Actinograph number.	Watkins plate number.	Wynne F. number.	Chapman Jones scale.	Unit number suggested by Schmidt-Eder's "relative sensitiveness."

Whether the two different scales of the Warnerke instrument run above 25 degrees in actual practice has not been ascertained. In England the ordinary use of the Warnerke number applies to the transparent scale, whilst in Germany, as a rule, the Warnerke degree implies the instrument with less transparent scale, although

some use is also made of the other scale, for example, in the widely distributed "Agfa" exposure table.

It will be seen that the relation of the different systems to the Scheiner system becomes much more simple if the 1:100 interval of the Scheiner system be divided, not into 20, but into 21, degrees, giving 20, instead of 19, intervals. Further, the making of the characteristic curve on the Scheiner system is greatly simplified by this change. It is a matter for congratulation that marking according to the Scheiner system appears to be becoming more general. The marking of plates also with the absolute sensitiveness might be done with advantage, not as a substitute for the Scheiner number, but supplementary to it.

AN AUTOMOBILE SPEED-RECORDER.

THE "Photo-Era" reports that the first conviction in the U.S.A. of an overspeeding motorist by means of an automobile speed-recorder,

A Specimen Photograph made with the Automobile Speed-Recorder.

involving no measured "road-trap" or the use of a stop-watch, was secured April 30, in the Roxbury District Court, when the speed-

recorder, which is the joint invention of Dr. Herbert T. Kalmus and Dr. Daniel F. Comstock, instructors at the Massachusetts Institute of Technology, had its initial test before a judge. It won so signal a victory that this new method will probably supersede all others in use at the present time. With this device all an officer has to do is to step out behind a receding car which he thinks is going too fast, aim his instrument at it, and press a lever on the side of a small box which resembles a camera. This box is about 7 x 7 x 3 inches over all, and, in reality, consists of two cameras, one above another, with a single plate covering both lenses. Suitable mechanism is provided, so that when the operator presses the release lever a picture of the moving body is taken automatically by one of the lenses, and, approximately one second later, another picture is taken by the other lens. These two pictures appear on the same plate, as shown in the accompanying reproduction.

Immediately in front of the plate is a chronograph, so placed that it casts the shadow of its hand on the plate. The mechanism, which is put into operation by the lever which the operator moves, first starts this chronograph, and, after an extremely short interval of time, makes the first exposure. This watch is started in such a position that a shadow of the hand appears on the picture taken by the first exposure. Approximately one second later, the hand of the chronograph has passed through an arc of 180 degrees, and, consequently, casts its shadow upon the second picture. The time between these two exposures is definitely and accurately known from the position of these two shadows on the plate. This furnishes a complete record of all that is needed to calculate the velocity of the moving body—in this case the moving automobile.

If the size of the image and the distance of the image from the lens are known, the distance of the object from the lens may be calculated by simple laws of arithmetic. This may be done for the object in each of its positions, as shown on the plate. That is to say, the length of the wheel-tread of the image is measured directly on the plate by means of a carefully made steel scale, if necessary with the aid of the microscope. The size of the object is regarded as the standard width of this tread, which is a known constant for any given automobile. The distance of the image from the lens is experimentally determined by the focal length of the lens, and the distance of the body from the lens, which is desired, is a simple function of these first three qualities. The difference between the distance thus indicated for the first and second positions of the object is the distance that the moving object has moved in the time indicated by the chronograph; hence the velocity is known with a high degree of accuracy.

Photo-Mechanical Notes.

Process Work at the Chemical Congress.

In the photographic section of the Congress process work came in for its full share of attention, though nothing very new was brought forward. Mr. A. J. Newton's paper was chiefly interesting for the slides, showing magnified examples of comparative etchings by hand rocking and by various machines. The author showed the amount of side spread, and M. Clerc, in the discussion, pointed out that in a still-etched copper plate etched face downwards, the spread sideways was equal to the depth at the edge of the resist, so that if a point at this edge was taken as the centre of a circle, the amount of side spread and depth could be shown growing with the radius of the circle. With the machines this condition did not hold, and a greater depth than side spread was obtained, the figure around a point on the edge of the resist being an ellipse rather than a circle.

Mr. W. Gamble, in dealing with resists, pointed out that one of the best of them—namely, dragon's-blood resin—was always accompanied by considerable earthy matter, in some cases as much as 40 per cent. But he was doubtful whether the purification was sufficiently advantageous to justify the cost; some etchers find that even the best of the current commercial samples are more troublesome to work than those not so pure.

Mr. Chas. W. Gamble, in his paper on gelatose, pointed out that, when considering the sensitiveness of bichromated gelatines, insufficient attention had been paid to the condition of the gelatine itself, which had an enormous effect.

Mr. Howard Farmer's paper on Autochrome reproduction was illus-

trated by half a dozen capital half-tone reproductions of Autochromes. Such examples as these should prove to photo-engravers that there is a very large field of work open to them in this direction.

The Reproduction of Carpets.

We have recently had submitted to us some very fine reproductions of Turkey and Persian carpets, in which the imitation of the pile and colouring was quite remarkable. They were stated to be done in Germany at a price incredibly low. However, we know of at least two firms in England doing such work, with results quite as good as the samples submitted. The secret lies in the paper, which is one known as "flock"; it is sold in rolls of about ten yards long by 40 inches wide, at prices from about 11s. per roll to 15s., according to the quality of the pile or flock surface. The printing on to this paper is done only from flat tints; the ink must be very fluid and a considerable quantity carried in order to saturate the pile with colour. The colours are generally applied from relief blocks, though it is asserted that the printing can also be done lithographically. Naturally, the method is only of use to illustrate materials having a pile texture, but for that purpose the results are more nearly facsimile than would be possible in any other way.

PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

PRINTING.—No. 12,214. Improvements in and relating to photo-mechanical printing. Carl Richter, 345, St. John Street, London.

Exhibitions.

THE PHOTOGRAPHIC SECTION AT THE IMPERIAL INTERNATIONAL EXHIBITION.

IN accordance with announcements which have been made, a section devoted to photography is to be found in the exhibition now being held at the grounds at Shepherd's Bush. It is housed in a series of five galleries in what last year was the Fine Arts Palace, a building standing on the right after passing through the Fountain Court from the Wood Lane entrance. This year fine and applied art meet in these spacious galleries. In addition to the paintings and statuary, there are a large number of commercial exhibits of carpets, furniture, etc. The photographic rooms are found immediately on the right on entering the palace. On their walls are displayed photographs derived from a variety of sources. A number of professional photographers make a good display of their work. Photographic societies to the number of a dozen or more send collections representing the work of their members; there are also a number of prints sent by individual workers, presumably by payment of a certain sum per frame, a method of exhibition making of which we felt compelled to disapprove in an earlier reference to the proposed exhibition. In addition to these, the work of photo-engravers, particularly in the three-colour process, nearly fills one room. We were informed that several stalls representing the photographic trade would be found in this section, but at the time of our visit, on Tuesday last, nothing could be seen of them. There is thus produced an exhibition which certainly contains a good deal of excellent photographic work. Its defect in the section made up by the work of amateur photographers is that it contains a good deal that does not deserve to be exhibited. This was an inevitable result from the somewhat promiscuous method of bringing the collections together, any photographic society that liked having apparently been given the opportunity to exhibit and to send any photographs it chose. The result, however, is interesting to any photographer making a study of such methods of producing an exhibition, and it must be said, too, that many of the pictures call forth expressions of approval from the lay public which inspects them. A few pictures may be singled out as worthy of special mention.

Among those shown by the Borough Polytechnic Society are "A Winter Afternoon," by A. C. Buckham; "The Village Tavern," by W. Page; "Evening Mists," by E. H. Roberts; and "The Rivulet," by Paul Carden. In those of the Woodford Photographic Society, W. L. F. Wastell shows a charming bit of landscape "On the Moselle"; another pleasing piece of work is "At Eventide," by

B. E. Stacey. Among the pictures of the South Essex Camera Club one very good piece of work is "The Outfall," apparently made in the precincts of a sewage works, but we were unable to discover the author's name. Among the prints of the Doncaster Camera Club the best are "On the Moors," by F. A. Jordan, and "Gooseberries," by W. R. Napier. The Wallington Camera Club's exhibit contains some very charming studies of children by W. Prout, one of the cleverest of which is entitled "Marbet." The prints of the Wimbledon Park Photographic Society had no authors' names on them, but two of woodland scenery, Nos. 297 and 384, represent very good work. The Ealing Photographic Society contains a very effective landscape by E. H. Atkinson, entitled "Misty Mountains." Two other prints, "In Cold Winter's Grip," by A. Richardson, and "Hound Tor, Dartmoor," by T. W. Bartlett, are worthy of mention.

From these we come to the exhibit of the Society of Night Photographers. Most of the prints must be considered in the nature of experiments in this fascinating field of work. About the only two which can profess any pictorial quality is one by A. H. Blake of a terrace or embankment on which are grouped three figures, and another of trees under arc light printed in rather bright greenish-blue. The photographic section of the Eastbourne Natural History Society contains two examples of the clever work of Ellis Kelsey, one of a motor car with lamps lighted at dusk and another entitled "When Lights Gleam Through the Mist." The exhibits of the Glasgow and West of Scotland Photographic Society have no names on them, but we would mention No. 172, "A Snow Scene," and two of John Hepburn's genre pictures—one of a boy undergoing the tortures of a hair cut, which is very comic, and another entitled "The Lesson." The South London Photographic Society shows a good deal of very excellent architectural photography, particularly from C. H. Oakden, E. Pady, and E. R. Bull. Among the exhibits of the Oxford Camera Club, No. 376, "A Flemish Canal," by G. Aitchison, may be mentioned. Among those of the Shropshire Camera Club, Nos. 104, 106, and 107, the two latter very fresh and airy renderings of seashore and sky. The Wearside Photographic Circle's two best prints are Nos. 183 and 198, the latter by H. Bradwell.

By far the best collective exhibit is that of the Postal Camera Club, the work in which is deserving of a much better place and more adequate display. Most of the pictures have become familiar in exhibitions or by reproductions in our contemporaries. Arthur Marshall sends one of his essays in coloured oil; J. M. Whitehead the familiar "Silent Guide"; Aubrey Harris the delightfully humorous "Darning Lesson," Bertram Park the portrait of G. A. Storey and a very charming study of a head and shoulders. Miss Brenda Johnson shows her Diana in the glade, Oscar Hardee "Isabella en Jan Wilden." This list does not by any means exhaust the contents of this section, which presumably has been got together by the secretary of the Postal Camera Club, Mr. J. C. Warburg.

Other societies represented are the Belmont Camera Club, Battersea; the Everton Camera Club; the Rotherham Photographic Society; and the Acton and Chiswick Camera Club.

Among the process exhibits the greatest display is that of John Swain and Son, Ltd., who show a large variety of three-colour work, and stages in the making of a sheet of three-colour prints. Messrs. André and Sleigh likewise show a number of reproductions of works of art in three-colour, and Messrs. Carl Hentschel, Ltd., exhibit not only specimens of their "Colourtype" process, but also show quite a large collection of books of travel, etc., illustrated in colour by them.

Among the professional exhibits, the leading place both as regards the work shown and the manner of its display is taken by Langfier, Ltd., 23a, Old Bond Street. The portraits include those of military and official personages, a larger number of fashionably dressed women, and some very dainty examples of child portraiture. All these are arranged round the walls of an alcove specially built to take them. Next to this exhibit is one by Roe McMahon, of Dublin, whose photographs of a number of types of Irish girls are offered for use as postcards or show cards. Two large spaces are taken by Messrs. Wakefields, 64, High Road, Chiswick. They consist entirely of photographs of motor cars, a branch of work in which the firm has specialised with much success. Mr. F. A. Swaine, 106, New Bond Street, has a panel of his portraiture, chiefly full-length portraits of women done in the vignette style with a background very lightly sketched in. Keith Danuatt, of Haslemere, has a variety of portraits on a light grey background placed within a white frame, the whole

result being very pleasing. The Mattype Studio, 30, New Bond Street, shows its characteristic work in sepia portraits. Miss Agnes Jennings, 10, Charles Street, Haymarket, shows a collection of portraits free from the customary accessories of the studio. Stephanie Maud, 25, Harrington Road, South Kensington, exhibits photographs only of children. Miss Ellen Macnaghten, 83A, Gloucester Road, South Kensington, shows work chiefly very delicate and charming coloured prints. Mr. William Gill, of Colchester, conveys a very strong impression of his work by showing simply one large carbon photograph—a portrait of a mother and her little boy. Copies of paintings are exhibited by Paul Laib, 95B, Drayton Gardens, South Kensington.

At the time of our visit the photographs by individual amateur photographers were in course of hanging, and it is therefore not possible to refer to them, but from casual examination of some of the frames it would not appear that they call for special mention.

Analecta.

Extracts from our weekly and monthly contemporaries.

The Autochrome under the Microscope.

Mr. E. Senior, writing on the above subject in "Photography and Focus" for June 8, gives the following particulars regarding the dimensions of the Autochrome film. "The following figures, from a number carefully ascertained by various methods, may be taken as closely approximate:—

Thickness of the combined films, 0.09 to 0.10 mm. (about 1-250 in.)	
Thickness of the layer of varnish fixing the starch grains to the glass.....	= 0.05 mm.
Thickness of the layer of starch itself.....	= 0.02 mm.
Thickness of the varnish separating the starch from the emulsion	= 0.01 mm.
Thickness of the emulsion itself	= 0.02 mm.
Total	0.10 mm.

The emulsion appears to be a gelatine one of rather a fine grain, the particles measuring about 0.0014 mm. in diameter. . . . The films from which the sections were cut were embedded in paraffin, and the sections mounted in balsam for examination."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between May 24 and May 29:—

PHOTO-RELIEFS.—No. 12,302. Process for obtaining photo-reliefs. Carlo Baese, 77, Colmore Row, Birmingham.

CINEMATOGRAPHS.—No. 12,374. Improvements in cinematographs. Leo Kamm, 27, Powell Street, Goswell Road, London.

APPARATUS.—No. 12,571. Improvements in cinematographic and photographic apparatus. Paplo Audouard and Alberto Lleo Claudio Baradat, 27, Chancery Lane, London.

DEVELOPMENT.—No. 12,605. Improvements in developing machines. Magnus Niell, 88, High Holborn, London.

PHOTOGRAPHIC PENDANTS.—No. 12,629. Method to fix photographs in lockets without the use of metal mats. Thomas Able, 44½, Frederick Street, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SHUTTERS.—No. 18,922. 1908 (September 9, 1908). The invention

relates to a method of actuating an inside single-flap photographic shutter by means of a flexible wire cable (as used on bicycle brakes) and a rack and pinion motion enabling the operator to act and control the shutter at a distance and also to see that the shutter operates, as all the mechanism is fixed in view outside the camera. Fig. 1 shows pinion A and rack B, with spring C to keep shutter

Fig. 1.

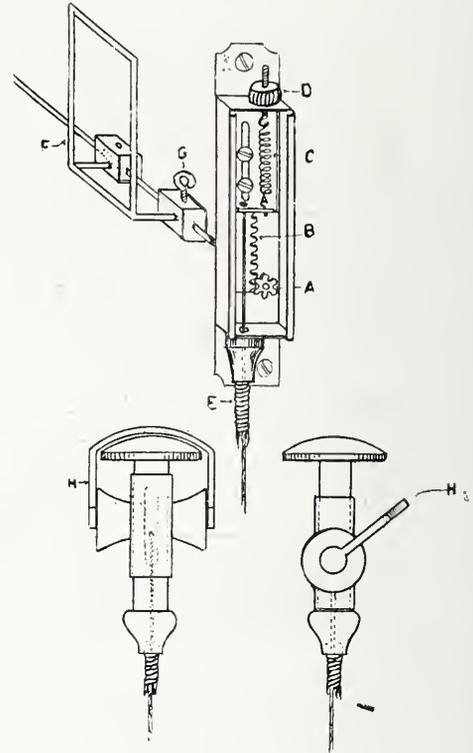

Fig. 3.

Fig. 2.

closed, and hold cable taut; D is nut for adjusting spring; E, flexible wire cable; F, frame for shutter, to be covered with any light stopping material; G, set screw to fix shutter frame on spindle of pinion A. Fig. 2 shows push ready to act and held in position by the spring C, Fig. 1. Fig. 3 shows push compressed, with bridge piece H in position to keep shutter open when required. Charles Henry Rott, 17, Orange Street, Swansea.

CINEMATOGRAPH MECHANISM.—No. 4,534. 1909 (February 24, 1909).

The invention consists of an improved form of mechanism for imparting an intermittent movement to the photographic film in a cinematograph camera of the kind in which the driving pins are given a positive movement into and out of the perforations in the photographic film. The object is to reduce the number and weight of the moving parts so tending to produce increased steadiness in the picture. Use is made of a rack and pinion operated by a single grooved cam to move the pins into and out of the perforations in the film; a crank and connecting rod impart the vertical movement to the film by means of a slide carrying the necessary driving pins. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London, N.W.

The following complete specifications, etc., are open to public inspection, before acceptance, under the Patents Act, 1901:—

COLOUR SCREENS.—No. 18,744, of 1908. Manufacture of screens for use in colour photography. Dufay.

POWDER PROCESS.—No. 7,932, of 1909. Photographic powdering process. Rieder.

New Trade Names.

B.B. (DEVICE).—No. 311,416. Bioscopes, their accessories and component parts, all being goods included in Class 8. The British Bioscope Manufacturing Company, Ltd., 11, Long Acre, London, W.C., bioscope manufacturers. March 17, 1909.

New Materials, &c.

Enlargements Framed and Unframed. Made by the Tress Co., 4, Rathbone Place, London, W.

Two new styles in enlarged photographs just being issued by the Tress Co. are the "Vandyke," a sepia enlargement placed under an oval cut-out and framed in a polished rosewood frame of 1½ in. width.

The "Vandyke"

The measurement of the framed picture over-all is 24 x 15½, and the result presents a most tasteful appearance. The price from print or negative is 7s. 6d.

A further line of unframed enlargement, made under the title of the "Academy," includes an oval or circle sepia print mounted on a canvas art board which is attached by the two corners to the back mount. The size of this latter is 15 x 12, and the price of the

The "Academy."

enlargement from either print or negative is 2s. 3d. The Tress Co. have just issued a large illustrated circular showing a number of their specialties in mounts, frames, and accessories.

DILOS FRAMES.—A very handsome frame for 20 x 16 enlargements has just been introduced by J. Epstein and Co., Rupert Street, Bristol, under the name of the "Dilos." The frame is of 5½ in. width, and of very striking design. It is issued complete with glass and backboard at the very moderate price of 54s. per dozen.

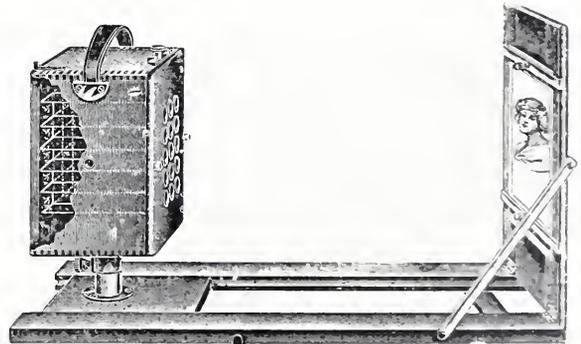

NAMES ON PRINTS.—In reference to the inquiry of a correspondent last week, we have inspected with much interest the celluloid "Name Films" made for photographers by the Autotype Company, 74, New Oxford Street, London, W.C. They are films of such thinness that their interposition between the negative and the paper does not affect the sharpness of the print, whilst the opacity of the lettering gives a perfectly white title on the print. The Autotype Company charge 5s. for writing name and address, photographing and supplying the film, subsequent films 5s. per dozen. They also supply from stock films bearing in neat lettering the words, "Rough Proof Only," at a price of 5d. each. This serves the very useful purpose of checking the practice of those sitters who seek to obtain photographs on the cheap.

"CROWN" MOUNTS.—The Crown Manufactory, Rotherham, sends us examples of several new mounts of theirs, among which we may name the "Melton Portfolio," a dark brown board with embossed plate-mark enclosed in brown folder with tissue. This sells at 9s. 6d. per 100 post free. The "Emboda" is a linen-surface mount with grey embossed border for print and round the edges. Price 6s. 6d. per 100. Another very neat mount is the "Oceana," a white board of figured surface, with sunk ornamental border round print. The price for cabinet prints is 5s. 6d. per 100. The Crown Manufactory offer to send sample selections of their mounts (returnable post free) to any photographer.

New Apparatus, &c.

The "Royal Mail" Stamp Camera and Easel. Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

A fixed-focus stamp camera which Messrs. Butcher have supplied for the making of "stamp-photo" negatives is now issued by them with an easel and baseboard, which allows of a cabinet or carte-de-visite photograph being copied without any focussing being necessary. The baseboard carries a sliding piece, to which the camera is attached, and it is necessary simply to bring this piece opposite the cabinet or C.D.V. mark in order to obtain a copy of the required size. A single exposure then gives fifteen copies of the original on

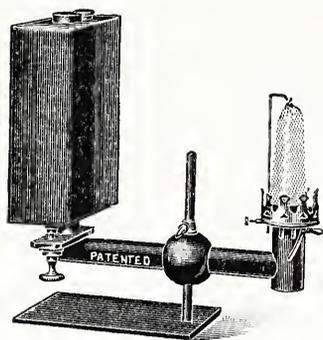

the quarter-plate negative. The easel is provided with a pair of springs which hold the photograph flatly to the surface, and at the same time allow of it being quickly placed centrally on the board. The apparatus folds flat when not in use, and the complete outfit of camera, easel, board, and one dark slide is supplied for £1 15s. Border negatives to be used in printing the "stamp-photos" are obtainable in a variety of designs at a price of 1s. each, complete with three of the necessary masks. Messrs. Butcher also supply ordinary P.O.P. for printing from the negatives, ready perforated after the method of postage stamps.

The "Petrolite" Enlarging Lamp. Sold by Albert J. Garrad, Southampton House, 517, High Holborn, London, W.C.

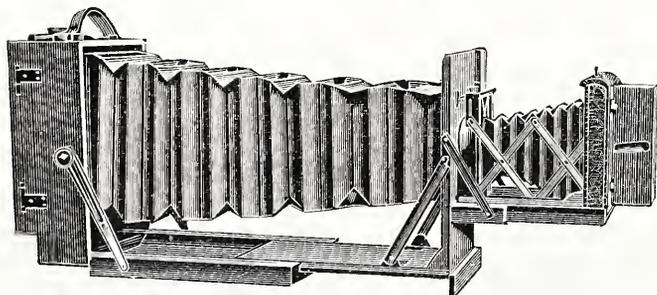

A new self-contained incandescent light for the optical or enlarging lantern has been designed by A. J. Garrad, by whom it is sold under the above name. The lamp burns petrol (motor spirit), and is of such very simple construction that it is difficult to see how any mishap

can occur with it. It consists of a saturator, placed, as shown in the drawing, at the back of the burner, that is to say, outside the lantern. The saturator is a metal chamber, supported through its centre on a pillar of about $\frac{3}{4}$ in. diameter, which communicates with the burner. The interior of the chamber is filled with an absorbent material, which is charged by filling it with petrol, allowing the latter to remain for a minute or so and then drawing off the excess.

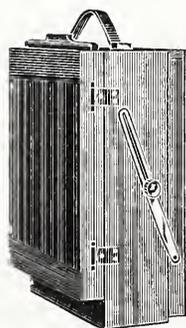

The action of the apparatus is thus to provide the burner with a current of air saturated with petrol, giving a very intense incandescent light without aid of a pump and in a very small space. One very great advantage of the lamp is that by means of the screw beneath the tank the light can be turned quite low. One charge of petrol suffices for a light of six hours' duration, at a cost of about one penny. As regards safety, the saturator can be taken off its pillar and a light applied to it; the only result is to inflame the traces of vapour in the tube. These features of the lamp should, we think, strongly appeal to those enlarging by artificial light, since even when gas is available, a light of this kind, which allows of the enlarging lantern being placed anywhere, is the most convenient, whilst the light given by it is a very great improvement on the ordinary incandescent burner. The price of the "Petrolite" lamp, complete with burner and mantle, but uncharged, is £1 10s. 6d.

AN "N. AND G." ENLARGER FOR "SIBYL" NEGATIVES.—A folding enlarger of very convenient pattern has just been introduced by Messrs. Newman and Guardia, of 17 and 18, Rathbone Place, London,

W., purely for use with their "Sibyl" cameras. The illustration shows the manner of using the apparatus, the "Sibyl" being simply placed on the outside board of the enlarger and a light-tight joint

made by the special mounting provided by the latter. The enlarger is made for both the $3\frac{1}{2} \times 2\frac{1}{2}$ and quarter-plate "Sibyls" to give a print of half-plate or whole-plate in each case. The prices are from £3 5s. to £4 5s., and the apparatus, which is instantly folded after

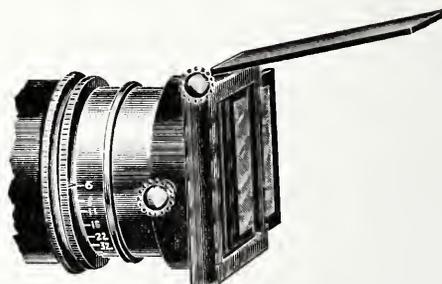

use, allows of large photographs being very quickly and easily made from the negatives of the "Sibyl."

AN ACTINOMETER of somewhat novel pattern has been introduced by Messrs. W. Butcher and Sons, under the name of the Primus "Photo-Meter." It consists of the usual graduated scale, running from 1 to 24. The scale, however, is duplicated, the two series of tints being placed side by side on a narrow strip, measuring about $1\frac{1}{2}$ in. x $6\frac{1}{2}$ in.

This allows of the following convenient method being employed:—A piece of P.O.P., the full size of the actinometer plate, is placed in the frame, and at the same time a piece of similar paper placed behind the negative, to be printed in carbon or platinotype. Both are exposed to light, until it is seen that the P.O.P. under the negative is printed to the necessary depth. The spring mask of black metal on the front of the actinometer frame is then pushed over from one strip of tints to the other, the carbon tissue placed behind the negative, and the two frames again put out to print. This time the printing of the negative is controlled by the actinometer, printing being continued until the two halves of the P.O.P. strip in the latter show the same numbers. The apparatus is neatly made, and costs two shillings.

A SCREEN-HOLDER WITH FLAP.—A little accessory which will need no recommendation to orthochromatic workers is shown in the illustration. It is a holder for a light filter and a flap shutter in one. The colour-screen is slipped into the frame of the holder, the flap of which is very lightly mounted, and is raised by the milled

knob seen in the figure. A second screw adjustment allows of the holder being firmly attached to the lens hood. As supplied by the designer of the holder, Mr. Albert J. Garrad, Southampton House, High Holborn, London, W.C., the price is 9s. 6d. in quarter-plate size, 10s. 6d. in 5 x 8, and 12s. 6d. in half-plate.

CATALOGUES AND TRADE NOTICES.

WHAT CAN BE DONE WITH A HAND-CAMERA.—A new book of photographs just issued by the C. P. Goerz Optical Works, Ltd., 1 to 6, Holborn Circus, London, E.C., provides a most admirable demonstration of the capabilities of the modern hand-camera of the highest class. The subjects are taken indoors and out, in rapid motion, such as jumping horses, ski sports, and in bright and dull light. They include also portraiture, landscape, etc., all done with one or other of the Goerz series of cameras—the Goerz-Anschütz folding, the Goerz folding reflex, Pocket Tenax, and Vest-Pocket Tenax. The text of the book gives much really useful advice on the selection of a hand-camera, and the booklet well repays study. It is sent post free.

AT THE LIVERPOOL B.P.A., Eberle Street, Dale Street, Liverpool, an exhibition of photographs by members of societies affiliated to the P.P.S. is being held. The prints are a selection from the 1908 competition, and may be seen until June 21 from 10 to 7, except on Saturdays, when the hours are from 10 to 4.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 12.

Handsworth Photographic Society. Excursion to Old Hill.
South Suburban Photographic Society. Excursion to West Wickham.
Kinning Park Co-operative Camera Club (Govan). Outing to Balloch.
Hackney Photographic Society. Outing to West Drayton.
Worthing Camera Club. Outing to Amberley.
Birmingham Photographic Society. Excursion to Warwick.

SUNDAY, JUNE 13.

Borough Polytechnic Photographic Society. Outing to Guildford.

TUESDAY, JUNE 15.

Hackney Photographic Society. Short Lectures by Members. (Excursion Committee Meeting.)

THURSDAY, JUNE 17.

Chelsea and District Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.
Handsworth Photographic Society. Short Papers on Holiday Photography by Messrs. Collins, Grove, Teague, and others.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, June 8, the president (Mr. J. C. S. Mummery) in the chair.

Captain Owen Wheeler read a paper entitled "The Practical Side of Telephotography," a subject which he introduced in the first place by referring to the question of cost. Assuming that an amateur had got a good lens and a good camera, which could be used on a tripod, a £5 note would enable him to do a great deal of very good work in telephotography. The lecturer showed a 5 by 4 folding camera, with which much of his own work had been done up to seventeen and eighteen magnifications. It was simply a hand-stand camera of good construction not specially built for extra rigidity. As regards the tripod, the best advice he could give was to use one for a camera two sizes larger. At full extension a supporting strut for the front of the camera was certainly an advantage. He showed one in which the strut took the form of an extra leg, which supported the lens tube of the telephoto mount directly from the ground. The strut was the design of Mr. A. J. Garrad.

Coming to methods of telephotography, Captain Wheeler pointed out that the two systems on which a variety of work might be done were (1) to keep to one negative attachment and obtain the different magnifications by varying the camera extension, or (2) to adopt one or two camera extensions and obtain the various magnifications by means of a series of negative attachments. His own practice convinced him of the superiority of the latter system. It provided the means of securing a fully covered plate on all scales of magnification, and it reduced the necessity of long camera extensions, thereby removing one cause of failure in telephotography—that of the vibration of the apparatus. His own series of negative attachments had foci of $2\frac{3}{4}$, $2\frac{1}{4}$, $1\frac{3}{4}$, and $1\frac{1}{8}$ inches, this series allowing him, with the 5 x 4 camera which he showed (of extension about 15 inches), to secure telephoto negatives of magnifications from $3\frac{3}{4}$ to 14 or even up to 17.

As regards focussing, the use of a long hood or screen on the front of the lens lightened the task of the telephotographer. A large focussing cloth, a good magnifier, and a fine screen were the three essentials to getting sharp focus. Some preferred to cement a microscope cover-glass to the focussing screen, but he found that rubbing the ground glass with lanoline answered his purpose. One secret of focussing was to give plenty of time; the eye did not quickly discern the faint image on the screen. In the subsequent discussion Captain Wheeler confirmed the advice of another speaker to focus by separating the positive and negative of the telephoto, not by moving the ground glass or the lens front as a whole. A focussing hood over the ground glass was a drawback to a camera for telephoto work: the hood was useless as a screen, whilst it prevented the convenient use of a magnifier.

As regards the rule for exposure, Captain Wheeler preferred not to pronounce absolutely definitely, but his experiments led him to conclude that the theoretical rule that the exposure was proportional to the square of the magnification held good, provided that the photographer realised the altered conditions in telephotography,

whereunder a subject which would be reckoned as distant when using an ordinary lens came under the heading of "near object" or "strong foreground" in the case of telephoto work. Captain Wheeler pointed out the advantages of the orthochromatic screen for doing telephoto work under conditions of haze which would render good negatives impossible without it. For haze due to heat—a state of things which was described as a "boiling atmosphere"—there was no remedy, and in such weather the telephotographer might as well stay at home. In his own work Captain Wheeler had found that there was no very practical advantage in using a positive lens of greater aperture than $f/4.5$, $f/3$, and similar apertures. A very interesting series of slides, most of them consisting of comparative examples of subjects photographed with the ordinary lens and with the telephoto at various magnifications, were then shown, and illustrated the gain in vigour due to using a hood on the lens, as also the remarkable sharpness of definition secured in the negatives even at a magnification of twenty or thirty diameters. Captain Wheeler concluded his lecture by showing a few examples of instantaneous telephoto work.

In the discussion which followed Mr. Edgar Clifton said he must admit that Captain Wheeler had thoroughly made out his case for the lens hood. He had never seen better high-power telephotographs; at the same time he wished to emphasise the fact that for average purposes the most useful telephoto lenses were those of quite moderate power giving magnifications of three, four, and five diameters—that is to say, carrying on the greater focal length which a worker got from the use of the half-lens of his doublet. When opticians first introduced the telephoto they appeared to have gone on the principle that photographers could not have too much of a good thing, and devoted themselves to providing lenses of the higher powers. As regards the methods of telephotography, his experience was that those people who took a telephoto lens and used it just like any other, without worrying very much about theory or aperture calculations, actually got the best results. As regards the calculation of the magnification, and therefore of the exposure, he recommended the use of a piece of tape attached to the camera and marked off in divisions each equal to the focal length of the negative attachment. Allowance being made for the projection, if any, of the negative lens into the camera, the tape, if attached to the camera front, would show the magnification being employed. Focussing in telephoto work was more rapid and actually much more certain when done by racking the lens mount—that is, separating the tele-attachment from the positive lens—than when using the rack and pinion of the camera. The depth of focus in the latter case was so great that one was never certain whether the best focus was obtained, whereas in the other method either there was focus or there was not, and with a little skill the most exact focus was secured in this method, which resembled using the coarse adjustment of the microscope when focussing that instrument. As regards exposure, Mr. Clifton emphasised the fact that the theoretical rule of exposure proportional to the square of the magnification was only correct if account was taken of the distance of the object. One great advantage of telephoto work was in making full-scale photographs of small articles, such as ornaments, small boxes, etc., a species of photography which was frequently necessary for catalogue illustration. When a lens of ordinary focus was used the view-point which had to be taken was so near to the object that correct perspective was impossible, and he had had a case brought to his notice quite recently in which a whole series of such photographs had to be practically redrawn before they could be used for catalogue purposes. A similar instance had occurred in the use of the camera in a museum where it was required to take photographs of fossils, bones, etc., for record purposes or for exchange with other museums. Here, again, the bad perspective due to a near view-point when using an ordinary lens had led the authorities to condemn photography as useless. They had altered their opinion on employing a telephoto lens allowing of a distance of 14ft. or 15ft. from the object being taken up.

Mr. H. A. Sanders asked what was the shortest exposure which Captain Wheeler had been able to make in telephoto work. The reply was 1-150th of a second at five or six magnifications.

Mr. W. A. Furse, in reference to the tape method of indicating magnification, pointed out that it would not be accurate in the case of negative attachments which were moved by the pinion of the telephoto tube. He had seen such telephoto lenses, and he thought

that an engraved telephoto tube showing magnifications was a preferable method.

Mr. Madden pointed out that the graduations on the lens mount applied only to objects at infinity.

Mr. Ernest Marriage said that in his experience the figures for magnification on telephoto lenses were most fallacious; he had found that they were in error to the extent of three or four magnifications. In reply to a query, Mr. Marriage said that he had made instantaneous tele-photographs to a fair number using a reflex camera giving exposures of about 1-30th or 1-40th of a second.

Mr. C. F. Lan-Davis, in reference to instantaneous work, pointed out that there was no necessity to consider that an aperture which by calculation appeared to be very small prevented rapid exposures being given.

Mr. G. E. Brown pointed out the effect which telephoto lenses might be expected to have on hand-camera construction, fixed-focus telephoto objectives of comparatively large aperture providing considerable focal length without the need of double extension of the camera.

Mr. McIntosh remarked upon the advantage which might be taken of the telephoto principle by using a negative spectacle lens behind the ordinary rectilinear or triplet objective. A hearty vote of thanks to Captain Wheeler concluded the business of the evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held May 27, Mr. R. Beckett in the chair. Mr. Woodland showed plates that had been fixed one half in daylight and the other half in the dark-room, the experiment having been suggested by the fact that at a prior meeting one of the members had called attention to the fact that one of the plate makers had in the handbook issued by them said that no white light should be allowed to reach the plate until after fixation was complete. The plates that were fixed in the dark room had no sign of any stain, whilst those that had been fixed in white light showed a considerable amount of stain of a dirty yellow nature. The plates used were of a speed of about 60 Wynne, and had been developed with a pyro-soda developer.

On these plates being passed round, Mr. Teape produced and passed round five plates that had been fixed, half in the dark-room and half in the daylight. These had had a washing after development of from six minutes down to a mere rinse, and the one-half then placed in the fixing bath in the dark-room and the other half carried into the daylight, and placed in a fixing bath in the light. Upon examination it was found that neither half showed any sign of stain, and, in fact, had the two halves not have been marked it would not have been possible for any members to have said which was which. These plates were of a speed of about 200 H. and D., and were developed with rodinal.

The results led to a long discussion, and as the plates were of as near as possible the same speed the only decision that could be come to was that the developer made the difference, because, as was pointed out, it could not be the washing, as Mr. Woodland had given each of his plates a washing of fifteen minutes before fixing.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Members and friends, to the number of twenty, under the leadership of Mr. W. F. Slater, spent the Whitsun vacation at St. Ives, Hunts. The immediate neighbourhood of this old-world town is rich in material for the pictorial landscape photographer. Plenty of work was found at Hemingford Grey, Hemingford Abbots, Houghton Mill, and Holywell, as well as in St. Ives. It would be difficult to say who was the more surprised at the chance meeting of the president of the R.P.S. and a party at Holywell, but Mr. Mummery's hearty wishes "For a good bag and a successful outing" were no surprise to anyone who knows the genial president of the R.P.S. The party were well catered for at the White Horse, and secretaries of other societies would do well to consider St. Ives when arranging their programmes.

LONDON TOPOGRAPHICAL SOCIETY.—His Royal Highness the Prince of Wales has expressed his desire to become a member of the London Topographical Society, and, at the request of the President of the Society, Lord Rosebery, has signified his pleasure to agree to the wish of the Council to become Patron of the Society.

Commercial & Legal Intelligence

LEGAL NOTICES.—A first dividend of 8s. in the £ is to be paid in the case of Edgar Wilkinson, photographer, carrying on business at 1, The Arcade, Norwich. The dividend is payable on June 17, at the offices of Messrs. Poppleton and Appleby, 4, Charterhouse Square, E.C.

Notice of intended dividend is given in the case of Arthur Sager, photographer, carrying on business at the Studio, Church Street, Keighley, Yorks. Proofs must be sent to the trustee, Mr. W. Durrance, 12, Duke Street, Bradford, by June 19.

Geo. Richard Knight, dealer in photographic apparatus, 63, Castle Road, Southsea, who failed in 1904, is to apply for his discharge in bankruptcy on July 8, at Portsmouth.

An order of adjudication, dated May 28, has been made in the case of Moss Wright and Joseph Heaney, trading together as Wright and Heaney and Mossherne, photographers, at 608, Attercliffe Road, Sheffield. Debtors filed their own petition on the same day that the Order was made.

News and Notes.

THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—The awards in 1909 Slide Competition were as follows:—Plaques: H. Creighton Beckett (S. London P.S.); Rev. O. H. Fenton (Devonport C.C.); James Shaw (Manchester A.P.S.). Plaque in Scientific Section: Geo. H. Rodman, M.D. (Richmond C.C.). Certificates: 1, South London P.S.; 2, Manchester A.P.S.; 3, Belfast Y.M.C.A.C.C.

MR. FREDK. HOLLYER is exhibiting, during June and July, his platinotype reproductions of the works of Mr. G. F. Watts, R.A., O.M., including the pictures in the Tate Gallery, and the portraits in the National Portrait Gallery. These may be inspected at Mr. Hollyer's Studio, 9, Pembroke Square, Kensington (Earl's Court), daily from 10 to 6.

MR. W. A. SIMS, who for some years past has been with the Rotary Photography Co. as manager of the Photographic Paper Department, has joined the firm of Kosmos Photographics, Ltd., of Letchworth, as commercial manager. The company is shortly putting bromide, P.O.P., and other papers on the market, its London office being at 131, Fleet Street, E.C.

AT THE LAST MEETING of the Leyton District Council it was resolved that a whole-plate photographic outfit, for taking photographs of damaged tramway cars, etc., be purchased by Councillor Matthews, with the tramway manager.

FLASHLIGHT ACCIDENT.—At a meeting at Penzance, last week, Mr. Vaughan Paul took a flashlight photograph of the speakers on the platform for Press purposes. Under one of the balconies was placed a pair of high steps, on the top of which rested the camera. When the powder was ignited at the moment of exposure Mr. Paul received the full effect of the flashlight in his face, which was blackened and considerably injured, the eyes swelling to a great extent, and the moustache and eyelashes being burnt off.

THE NEW ENGLISH ART CLUB.—We must congratulate this band of artists upon their removal to the Suffolk Street galleries, which, gloomy and barn-like as they are, nevertheless surpass in fitness and convenience the back-attic arrangements recently adopted. The show is larger than usual, and fuller of good things. But, alas! the tares continue to grow with the wheat. The mid-Victorian craze is still an obsession. We find Philip Connard affecting the costumes of the sixties and the lustre chandeliers of that period; but the painting of the white interior and its distant figures would be successful enough were it not for the enormous proportions of the nearest lady. Henry Tonks, too, adopts the same bygone fashions in his painfully contrasted scheme of blue-greens and crimson, which appears to us a gross exaggeration of a truthful firelight effect. Prof. Fredk. Brown's portrait of himself is not flattering. At least, our personal knowledge of him denies this brick-red monotony of flesh

tint. A. E. John sends one of his supreme jokes in paint which only make us sad and sick. It is a pleasure to turn to such well-motived work as Gerard Chownp's flower paintings, the exquisite harmonies in which should be studied by all who are experimenting with colour-plates. Sydney Lee sends some fine landscapes, the difficult "Alpine Solitude" being the most remarkable on account of the "looking down" point of view. As to Wm. McTaggart's attempts to paint motion, we can only regard them as the *reductio ad absurdum* of realism. To paint children in the manner of planet "tracks" such as the telescope gives is obviously to give up altogether that *suggestion* which is Art's sweetest charm, and instead to force upon the eye and brain one of their most painful experiences in optical operations. The antithesis is in Prof. Holmes's stagnant forms, iron-bound with an aggressive outline—a recent development we much deplore in his hitherto poetical work. Sargent's sketches and many other delightful things we have no space left for, much as we should like to record our praise of them at length.

"THE AUSTRALASIAN PHOTO-REVIEW," our Melbourne contemporary, published by Baker and Rouse Proprietary, Ltd., has somewhat enlarged the size of its pages with its April issue. In matter and production it continues to offer remarkably good fare to its readers. The issue before us contains one chapter of a series on night photography, some interesting photographs by Paul Cinquevalli, and many good illustrations. Its news items and answers to correspondents show it to be closely in touch with photographic happenings.

ARE BEACH PHOTOGRAPHERS PEDLARS?—The Blackpool Bench of magistrates has ruled that photographers who make and sell photographs on the beach are pedlars, and must take out a licence. Recently a deputation from the Blackpool Professional Photographers' Association waited on the Chief Constable, and the co-operation of various public men was also enlisted in a crusade against the injustice of the summer invasion by all sorts and conditions of men with cameras. One of these itinerant photographers, Christopher Charles Arnold, a young man, was ruled by the magistrates to be a pedlar without a licence, and was fined 5s. and costs.

Correspondence.

- *• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

REDUCTION OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—In "Ex Cathedra" for April 23, speaking of reduction of bromide prints, you state that any method of partial bleaching followed by fixing is only equivalent to the familiar Farmer's reducer. I believe you are referring to the use of iodine; but, as Farmer's reducer is mentioned, the remark would be taken to include the separation of the bleaching and fixing in that also.

I have shown by experiment, and considerable use, that such is not necessarily the case; and in an article in "Photography and Focus" on October 6 last gave details of working. May I refer you to that article? The absolutely essential feature of the process is the extreme weakness of the bleaching solution. The working bath is:

Potassium ferricyanide (5 per cent. sol.)	5 drams.
Sodium chloride (10 per cent. sol.)	5 drams.
Water	20 oz.

The slight bleaching takes from 3 to 8 minutes, according to reduction required. In the shorter time there is scarcely an apparent change before fixing. A few experiments on spoilt prints being the easiest way of determining the action. The prints, after well rinsing in several changes, are fixed in a plain hypo bath, say an ounce to the pint.

A mixture of the weak bleached and hypo baths, even with a

less amount of hypo, has not the same result by any means. By the method I advocated the shadows are reduced even more than the high-lights (with bromide paper), a result, I believe, not previously attained either with Farmer's or the modified Farmer's reducer. Nor is there any fringe of colour in the lighter half-tones, a result not unfrequent with the Farmer's reducer.

I did not see any extract in the "B.J." of my article, nor was any mention of the process in the "Almanac."

The paper used was Kodak bromide. I regret that I had not time or opportunity to experiment with a variety of makes. Out in South Africa one has not the convenience or possibilities of those at home.

—Yours faithfully,

HAROLD SMITH.

Eloff Street, Johannesburg,

May 17, 1909.

[We would point out that Mr. Smith's formula is a very different one from that which we criticised. He has only 1 part ferricyanide in 640 parts of water, while the procedure to which we took exception was the use of a ½ per cent. iodine solution in an exactly similar manner. Mr. Smith's method is safe enough, but numerous others which have been advocated are undoubtedly unsafe.—EDS. "B.J."]

TRADE, PROFESSION, AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen,—I have read through my letter again, and I stand by every point—each is germane to the questions under consideration. If your readers will dissect my letter they will find the following components:—

That the photographic trade is in a deplorable condition.

That this condition is due largely to the competition by persons with no knowledge of the "craft," and no appreciation of the art side of photography, who embark in the "craft" to make money—somehow, anyhow—and to do this "exploit the poor assistant."

That unless remedial measures can be employed there is every prospect of the situation becoming worse instead of better.

That without cohesion assistants and employers are equally impotent.

That the subject, so far from being one easily disposed of by a bricklayer, is an exceedingly complex one, and would have to be dealt with in the manner indicated by my simile (the patient).

That there was no hope for legislation, for the reasons I gave.

Mr. Redmond may be—I have no doubt he is—very enthusiastic in his friend's cause, which, by the way, is also his own; but I cannot help thinking that his friend might have selected an advocate with a more evenly balanced mind from amongst the bricklayers, upon whose counsels Mr. Redfern places so much reliance. If photographers' assistants could at will stagnate the industries of the country, or even a limited area, there might be something to learn from the trades union artisan, but their "modus operandi" is an open book.

Thanking you in anticipation for the insertion of this letter, and awaiting with curiosity a report of the proceedings at the proposed somewhat incongruous gathering together in solemn conclave of bricklayers and photographers' assistants, I remain, etc., FAIRPLAY.

TELEPHOTO CALCULATIONS.

To the Editors.

Gentlemen,—In your issue of April 23 an interesting article on "Telephotography," by Dr. Edmund J. Mills, appeared. In the course of this Dr. Mills discusses the question of exposure, and points out the correct rule, namely $\left(\frac{m \times l}{n \times l}\right)$ for two magnifications, *m*, *n*, for calculating exposures in enlarging where a fixed lens system is used. This rule, in fact, applies to all cases in which different sizes of images are obtained by varying the distances of image and object from a fixed lens. A useful trial and error method of obtaining telephoto exposure time is also laid down.

Dr. Mills then seems to suggest that this rule can be used for comparing the exposures with a positive lens, and with the combination of this positive and a negative to form a telephoto lens.

"Magnification" with a telephoto lens is, however, used to denote the ratio of the size of image given by the combination to that given by the positive alone, and not to the actual magnification compared with the object. In this case, therefore, the rule does not apply, as the system is not a fixed one, and Mr. Dallmeyer was right in stating that, theoretically, the time of exposure depends on the square of the magnification. When comparing, therefore, exposures with the positive only, and with different images produced by the telephoto lens, keeping the distance between lens and object fixed, the rule of the square of the magnification should be adhered to. For distant objects it has been found by all workers that this rule gives considerable over-exposure, but the explanation of this would seem to be rather in the chemical action of the atmosphere. Of course, if the telephoto lens be fixed, and different sized images obtained by altering the separation of lens and object, the formula given by Dr. Mills applies.—Yours faithfully,
C. L. D.

HOSPITALITY FOR THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—The members of the Royal Photographic Society may have the use of the M.P.C. Photographic Society's dark-room during the period of removal from 66 to 35 Russell Square. Application to the church caretaker is all that is necessary.

E. MARKWELL, Secretary.

Marylebone Presbyterian Church Photographic Society, Upper George Street, W.

INTENSIFICATION.

To the Editors.

Gentlemen,—In your last two issues I noticed Mr. Simpson's letter and your remarks re the effect of *prolonged washing*, prior to intensifying with chromium. I have several times come across a singular phenomenon in using the bichloride of mercury intensifier, and I should be glad to have your opinion as to the cause. The two prints enclosed are from negatives that were allowed to dry after the usual develop, fix, and wash; then placed in a grooved washing tank with water flowing in freely, and, I think, equally for an hour. On one you will see small thin streaks, on the other quite broad ones; neither appears till after they are placed in the ammonia to blacken throughout, but, once there, appears irremovable, making this method, as it appears, *also the chromium*, somewhat *risky*. Are these streaks the result of the *kind* of washing? I may add that the intensifier is composed only of mercury bichloride and water, as I have found the addition of hydrochloric acid has a tendency to cause reticulation of the film. Apart from these occasional streaks, it works all right, but these elements of uncertainty would be better gone, as they usually appear when least wanted, like other obnoxious things.—Yours,
PROF.

[The marks on the prints sent us are not unlike those which result when mercurial intensification is applied to imperfectly fixed plates. It is difficult to see how one hour's washing can have any ill-effects on an ordinary developed negative, though it is often detrimental to a bleached image. Possibly some of our readers have had experiences which will throw some light on this washing problem.—Eds., "B.J."]

THE HEIGHT OF THE CAMERA.—As a rule little attention is paid to the height of the camera by the average operator; the height of the camera is governed by the height of the operator. If he is a tall man, his camera will be high. If he is a short man, his camera will be low. What he should do is to raise and lower his camera after closely studying his subject's features. A short nose will appear more so if the camera is lowered. To lower the camera makes a low forehead appear lower. A long nose appears to an advantage when the camera is lowered, but a long neck looks like a "rubber neck." The operator should use judgment in the raising and lowering of his camera, for it is a feature of his work that will "make or mar a pretty face."—"Professional and Amateur Photographer."

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the

PHOTOGRAPHS REGISTERED:—

B. Hughes, 28, Patrick Street, Cork, Ireland. Photograph of Mrs. Desmond Humphreys (Rita).
C. E. Weale, 3, Victoria Road, Tamworth. Photograph of the Wilnecote United Football Team.
G. A. Dean, 14, High Street, Rugby, Warwick. Photograph of the Rev. H. A. James, D.D., Head Master, Rugby School.

PETER L. KIDD (Dorchester, Mass, U.S.A.)—From Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C.

STEREOSCOPIC PROJECTION.—Can you inform me where to get particulars of magic lanterns for showing stereoscopic pictures on the screen, and of the coloured eye-pieces necessary for looking at these pictures? Are these lanterns made so that various-sized slides can be used, or must one size be adhered to?—WM. ZIMMERMAN.

So far as we know, no special lanterns are made. If they are, Messrs. Newton and Co., 3, Fleet Street, E.C., are the people most likely to be the manufacturers. The dyes as recommended in our columns ("B.J.," November 6, 1908) by Dr. König are obtainable from Messrs. Fuerst Bros., 17, Philpot Lane, E.C.

THE "B.J. ALMANAC."—I have seen from time to time in the "British Journal" references made to the "British Journal Almanac." Will you kindly let me have particulars as to price and contents, as I do not see it advertised in the "B.J.," as I am desirous of purchasing one if the particulars suits me.—J. W. C. COGAN.

The "Almanac" is published each year on or about December 1. That for the current year appeared December 1 last. The whole edition of 25,000 copies was sold out before that day, but you may perhaps be able to get a copy by inquiring at local dealers'. The total size of the book is over 1,000 pages. Price 1s. net.

STRIPPING WITHOUT HYDROFLUORIC ACID.—Will you tell me how to strip a 1-1 plate negative and stretch to 10 x 8 without hydrofluoric acid? The restrictions against hydrofluoric acid are so great and the acid so bad to keep in the dark-room that I would be obliged for the above information.—J. H. S.

We should advise you to try the use of 5 per cent. solution of ammonium fluoride, to which is added strong sulphuric acid in the proportion of 10 drops per ounce, in place of the hydrofluoric acid. Our experience of other methods is that they are less certain than that given on page 792 of the "Almanac," and really the inconvenience in handling the acid is not a very serious obstacle to its use. One other method which has been recommended, though we cannot speak from our own use of it, consists in laying the plates for ten minutes in a cold saturated solution of carbonate of soda, drying it without washing, and then immersing it again in the soda solution. We advise you to try this or the other method on a waste negative or two before applying it to one of value.

AUTOCHROMES.—I find enclosed in "Work" of April 24. Do you know if anybody has tried the experiment on this side of the Atlantic? And what is a "dilute solution"?—"Experiments with Autochromes by immersing the plates after exposure and before development in a dilute solution of potassium meta-bisulphite for thirty seconds to destroy the colour-sensitiveness, were related by Dr. Drake-Brockman to the Cleveland Camera Club. It was then found that the first development could be done with comfort,

using the yellow light usually used for working with ordinary bromide paper. The meta-bisulphite solution must be used in absolute darkness, and the dark-room light not turned up until after the plate is placed in the developer. If more contrast was required in the finished transparency, he immersed the plate, before development, for thirty seconds in thirty minims of a saturated solution of potassium bichromate added to about 5oz. of water."—TINSIA'S.

You are in error in supposing that the suggestion comes from America. Dr. Drake-Brockman resides at Middlesbrough, and he first described his method in the "Colour Photography" Supplement to "The British Journal of Photography" for October 2, 1908, to which we would refer you. The meta-bisulphite was used in 3 per cent. solution for 30 seconds.

UTOMATIC MACHINES, ETC.—1. We want the address of a firm of automatic penny-in-the-slot machines who do make or would make such a machine for selling postcards. (Such machines are in use on railways, etc.) 2. Can you describe method of transferring signature (our client's own written signature, not printing titles) to negatives so as to give facsimile of writing in white on finished print?—EASTMAN AND SONS.

1. Try George Salter and Co., 101, Leadenhall Street, E.C., or Godfrey Bros., 3 White Lion Street, Pentonville, N. 2. The best plan would be to reproduce the signature in black in a clear ground on a celluloid film and place between negative and printing paper. You could do this on thin film, such as Kodoid, or the copy could be made by the carbon process. The Autotype Co. make a special line of the latter method.

LENS QUERY.—Can you kindly give me any information of a lens which I have the offer of buying, as regards price, covering power, age. I believe it is about 6in. or 7in. focus, in a focussing mount, sold as a portrait lens, No. 3,638, made by Fredk. J. Cox, 22, Skinner Street, London.—F. A. Thain.

F. J. Cox was not a maker of lenses, but a dealer in photographic materials some forty years ago. The lens is probably one of the old quarter or half-plate ones of French make. It has really no market value at the present time. You had better try it and see what it will do. It is impossible for us to say what it will cover.

STUDIO QUERIES.—I am having a new studio built. It is to be of brick, size 33ft. 9in. x 16ft. 6in., with rooms on ground floor and studio on first floor, with north-west light, which will be practically unobstructed by any buildings within, say, 100ft. on N.W. side (glass side), and 30ft. S.W. side. I beg to enclose the proposed plans for your inspection, and any improvements you can recommend I shall be pleased to know. I enclose stamps for return of plans. Being an old reader of the "Journal" I would feel greatly obliged for your advice re above, also enclosed questions:—1. What amount of glass in studio 33ft. 9in. x 16ft. 6in. would you recommend? 2. What width of opaque wall should be from back end S.W. to glass? 3. What width sections for glass on roof and sides? 4. What style of framing for glazing, wood or iron sash bars, and the best method for fixing glass in same? 5. What kind of glass most suitable for all-round work, fluted, rough-rolled, ground, frosted, or plain glass, worked with blinds which could also be covered with tissue paper if required? 6. Do fluted and ground glass obstruct much more light than plain? if so, state at what percentage. 7. Would it be necessary to fix blinds with ground or fluted glass (as I have always used them with plain glass), and would the above glass diffuse any strong sun towards the evening? 8. I shall be taking at S.W. end of studio; or would you advise placing sitters at the N.E. end? 9. Would you recommend having a small portion of glass on opposite side of roof (facing S.E.); if so, how much?—W. NEWARK LEWIS.

1, 2, and 3. About 6ft. 6in. at either end may be solid, and the rest glass. You will then be able to work either end. If you elect to use one end only, the same amount may be solid and about 13 or 14 glass. 4. Stout iron sash bars and good ordinary putty. 5. White-rolled plate will be best for the roof, as that will resist hail-stones. Fluted or plain glass for the sides. The former will prevent the sitters being seen from the outside if the studio is overlooked. 6. Practically fluted glass obstructs no more light than plain. Ground glass stops out but little light, if kept clean. 7. Yes, blinds will be necessary. Just the same as with plain glass;

but the rolled plate in the roof will render it somewhat less troublesome. 8. We should advise the studio being glazed so as to use both ends, so that sitters may be lighted on either side as occasion may require. 9. Not necessary if the studio be worked as just suggested. The plans have been returned to you.

BROMIDES.—I am puzzled as to the veiling of bromide during development. You could only see a dim outline on looking through, and developing by that method. The image was bright enough. They fixed out very fair. I am wondering as to cause; perhaps under-exposure. It is a semi-matt. I never had the experience before.—BROMIDE.

Your information is too meagre for us to do more than guess, but it would appear that the developer was exhausted, or contaminated with hypo.

DEFECTIVE POSTCARDS.—I enclose a postcard. Will you kindly tell me the cause (or causes) of the failure and of the back being stained? It is one of a new lot that I got recently, and most of them are defective. The other card, of a cottage, shows another defect which many have, but not the staining of the back. If you will kindly tell me if it be my fault or that of the cards you will greatly oblige.—J. E. GUBBINS.

The particulars you give are so scanty that we really cannot suggest causes of trouble. If these are self-toning cards it would seem likely that the cards are at fault. Possibly stale.

CINEMATOGRAPHY.—(1) Could you recommend any books on cinematograph projection, electricity, etc., relative to animated pictures? I am thinking of taking up the business this coming season, and should like to read up some useful information before taking a few practical lessons. I want a book that avoids terms that are not really understood by novices. I understand the "handle-turning" part. It is the electrical part and the lenses required for varying distances between bioscope and screen, etc. (2) What class of material is best for a screen?—ANIMATED PHOTOGRAPHER.

(1) We should advise you to get "Animated Photography," by Cecil M. Hepworth (Hazell, Watson, Viney, Ltd., 1s.). You would also do well to study the "Kinematograph Journal" each week. (2) The material usually used is stout sheeting, with a coating of zinc white.

RIGHT TO PUBLISH COPIES.—I have been asked to print many postcards of late vicar of Church. Letter asking for permission from photographer who took this photograph having been returned "address unknown," should I be safe in doing these prints to sell for benefit of the church?—E.

Certainly not. If, as is most probably the case, the copyright is the photographer's, the fact that you do not know where he is does not give you the right to take his property.

BACKGROUNDS.—1. Would you kindly tell me through the "Journal" [the best way to get an intensely black background on a soft negative. Is there any method of blocking out or bleaching the film? I use a dark ground, but cannot get it a nice black, only with a very hard negative. 2. Is it quite safe when bromide-printing at night to give prints a good rinse, dry them and thoroughly wash next day? I often have to do that, and wondered if it would affect permanency.—J. S.

1. If the outlines of the negative allow of it the best way is to make a transparency, block out this and from it make a second negative. But that is making the best of a bad job; if you want to get a dead black ground, the best plan is to pose the sitter before a dark space, e.g., the doorway of a completely darkened room. 2. It is not the best plan, but if the fixing be very thoroughly done the prints ought not to suffer. We should not advise a regular practice being made of it.

WINDSOR CASTLE. (1) Can you tell me if the State apartments of Windsor Castle have been photographed? (2) Whether any special permission is required to use a camera on days when they are open to the public? (3) If so, who are the proper parties to apply to for it? (4) Whether any permit is required to photograph the castle from the outside?—TASMANIAN.

(1) The State apartments of the castle have been photographed over and over again, and the pictures published. (2) Yes, certainly it is. (3) From the Lord Chamberlain's Department, Windsor Castle. Written application should be made some days before you desire to do the work. (4) None, if the camera is used from outside the

castle grounds. If you wish to take photographs from the inside of the grounds, open to the public, you will, no doubt, be able to obtain verbal permission to do so from the Inspector of the Castle at the time of your visit.

PHOTOGRAVURE PLATES.—I am anxious to make some experiments in photogravure, but I am in a difficulty about the cost of the copper plates. What I want are about the half-plate size, and, on inquiry at one or two of the houses that supply printing materials, I find that the prices are exorbitant as compared with the present price of copper. As I must be prepared to spoil a number of plates the cost is, with me, a serious item. Can you give me your advice in the matter?—W. CROWE.

Messrs. Penrose and Co., Farringdon Road, make a speciality of copper plates for photogravure and like purposes, and we should advise you to get their prices. You must understand that the cost of plates for engravers' purposes is due to the workmanship in their manufacture rather than that of the raw copper.

ECONOMY.—A hypo bath that has been used for fixing P.O.P. prints may be used for fixing negatives. But one that has been employed for fixing negatives should not be used for fixing prints, or trouble may be expected. Surely hypo is cheap enough to render it unnecessary to stint its use in the way you propose—particularly if the stability of your work is of any consideration whatever.

OPERATOR.—There is no law that will compel an employer to let an assistant take specimens of portraits he may have taken of sitters during his employment. It is usual to let an operator have a few on his leaving, so as to enable him more easily to obtain another engagement, but that is done as a matter of grace, and not because he has any legal rights with regard to them.

STUDIO ROOF.—Can you please tell us how we can make the roof of our studio completely watertight? It is an old one, and we have had a lot of trouble with it during the past two or three years. It seems as if when one place is repaired, leaks appear in others.—C. A. R. R.

This is a query that a local builder after seeing the place can answer better than we can. It is not an easy matter to make a neglected studio roof thoroughly watertight. However, if the place is in the bad state described, the best thing to do will be to scrape or "hack" out the whole of the old putty on the upper side of the sash bars and apply a couple of coats of thin paint—the first liberally applied—when it is dry to re-putty the work and afterwards repaint. It is possible, as the studio is old, that the sash bars give with a strong wind and thus cause the putty to crack. In this case they should be strengthened. This may be done by a couple of bars of "T" iron, fixed horizontally, inside, and screwed to the sash bars.

AJAX.—We cannot tell you a "suitable strength," to employ, inasmuch as gelatine is quite insoluble in absolute alcohol. Your friend has, no doubt, made a mistake in the translation of the formula into English. Possibly acetic acid and not alcohol was what was given in the formula, as gelatine is soluble in that.

STAINED PRINTS.—Can you tell me the cause of the stains on the enclosed prints? They are not due, I am sure, to their being imperfectly fixed. You will notice that the whites of the vignette are somewhat fogged and are not, as they should be, pure white.—C. SIMMONS.

The "stains" and impaired whites are due to the prints having been toned in too strong a light. That is proved by two of the prints sent being marked where they were overlaid by others while in the toning bath.

THINNING VARNISH.—I have the best part of a pint of negative varnish that has become too thick to use, through the cork being left out of the bottle. Can you please tell me how to thin it so as to make it useable?—W. BRYCE.

We cannot tell without knowing what kind of varnish it is. If it is a spirit varnish it must be thinned with methylated spirit. If a celluloid one, it can be thinned with amyl-acetate, or acetone, or a mixture of the two. Should it be a dammar varnish benzole will be the proper thing to use.

BUCKLED PRINTS.—I shall be indebted to you if you will be good enough to help me out of a difficulty. I mount certain of my pictures on special mounts by attaching them only at the edges with the cement. They are perfectly attached and are quite flat at first.

After a day or two they become buckled in the middle, though still secure at the edges. The reason that the prints are not cemented all over is that the mounts used for these particular pictures are very costly, and, with care, we can take rejected proofs off and use the mounts again. Any hints will be greatly appreciated.—A. G.

The only suggestion we can make is that the prints were over-dry when they were cemented to the mounts. If they were abnormally dry when they were mounted the paper would be in its most contracted state. Then when it regained its normal condition it would expand again and become more or less buckled. Try keeping the prints in a cool and rather damp place for a few hours before they are mounted. That will probably overcome the buckling trouble.

DISCOUNTS.—Will you please tell me the largest discount that manufacturers allow off plates and paper? As I am an amateur, and get nothing for my work, I want to get my material at the lowest possible price?—J. C. J.

We cannot say what the largest discount is that manufacturers allow, and they are probably not all alike. As you are neither a dealer nor a professional photographer, we do not see that you should be allowed any, except, perhaps, a small cash discount. Why should you?

CYANIDE OF POTASSIUM.—I want a little cyanide of potassium. I have applied for it at three dealers, and they all tell me that they do not keep it, and that I shall not be able to get it. I only want about an ounce or so for some experiments. Will you kindly say where I should be likely to get it?—CYANIDE.

This salt is one of scheduled poisons under the Pharmacy Act, and is only allowed to be sold in small quantities by pharmaceutical chemists. Any pharmaceutical chemist who makes a feature of photographic materials will doubtless supply what you require. According to the Act you will have to be introduced by some one who is known to him; but, as a rule, chemists neglect this, so long as the poisons book is signed by the purchaser.

DISHONEST CANVASSER.—Some months ago a man, who seemed to be a respectable one, applied to me for a berth, saying that he was very hard up. He said he would canvass for me as agent, on commission only—that is, if he did no business he would get no pay. To this I agreed on condition that he rendered an account every Saturday night. He did very well up till just now. He has now left without notice and is working for another photographer a mile or two off. I now find that he has been taking money which he has not accounted for to me. Also that he has taken deposits for pictures to be made at ridiculously low prices—ones that will not pay me. I have seen the fellow, and threatened him with the police for embezzling unless he settled up at once. He laughed at me, defied me, etc. Will you please tell me what to do? Of course I shall not take the pictures at the price he has agreed for.—A. L.

It seems to us that as the man was not paid a salary he was not a servant, and therefore cannot be charged with embezzlement. You appointed him as your agent, so that you can only sue him in the County Court for what money he may owe you as such. We expect you will have to take the portraits at the prices the man contracted for, as a principal is bound by agreements that an appointed agent may make.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Dresden Exhibition.—We review this week the sections labelled "Amateur Photography" by the Dresden authorities, and devoted to exhibits claiming pictorial merit. Of these, the "International Union of Art Photographers" provides by far the most interesting sub-section. The twenty-eight other rooms devoted to pictorial photography prove rather tiring, though the Dresden executive has done everything possible, in the way of hanging and furnishing, to relieve the monotony. (P. 471.)

We commend to all teachers and demonstrators of photography the description of the devices of Dr. E. Goldberg shown at the Dresden Exhibition for presenting the elementary facts of photography, light and colour, in a way which impresses them upon the mind even of the non-scientific person. (P. 476.)

Dr. D'Arcy Power, in "Camera Craft," has described a convenient form of vertical enlarging camera. To save shifting the shelf or easel bearing the sensitive paper, he alters the focus of the lens by means of a supplementary glass. (P. 475.)

A method of converting a bromide into a pigment print by brushing over it a mixture of casein and pigment has been patented. The process is based on the ozobrome method. (P. 480.)

Intensification markings and the speed numbers of plates are topics dealt with under "Correspondence." (P. 486.)

A little-used method which may often be applied with advantage for the improvement of negatives is the subject of an article on page 470.

A hint to fine-etchers and a new device for checking the type-height of blocks are items included in "Photo-Mechanical Notes." (P. 480.)

EX CATHEDRA.

A Possible Window Attraction.

The other afternoon, when spending an hour or two in the side-shows of the Earl's Court Exhibition, we came across one which suggested possibilities in the ways of an attraction for a photographer's shop window. We do not expect to find it taken up down both sides of Baker Street and Bond Street, but in many small towns a business which caters for middle-class people might do worse than provide something which, photography apart, would excite wonder. The attraction is for night time only, since the illumination must be confined to two "line-o-light" lamps placed one on either side, and quite close to the wall or panel to which the exhibit is attached. This consists of a relief made in "plasticine," or any convenient material, in such a way that a different picture is seen according to whether the lighting is from the right or left. The change results from the fact that under a lighting falling across the surface of the relief from a source close to it, the shadow side of each ridge of the subject is really invisible, though the mind, by suggestion, appears to see there the appropriate detail. Thus in the case of a portrait the two halves of the face can be made to represent different persons, a race-horse is convertible into a cart-horse, and other equally astonishing effects are easily secured.

* * *

Formula or No Formula.

While there are many photographers who seem to be impressed with the idea that great virtue rests in some particular development formula, there are a few photographic writers who go to the opposite extreme and denounce formulæ as worthless. One such writer in a contemporary states, in italics, that "the formula does not matter." This dogma is just as misleading as the opposite idea, for the only information it conveys to the beginner, who takes instruction very literally, is that it does not matter how we proportion the ingredients of the developer so long as the necessary ones are all in. The real fact, of course, is that formulæ do matter, and while our knowledge of the science of development is not yet complete enough to enable us to determine the ideal formulæ, yet it is well known that we cannot depart very far from certain proportions without getting into trouble. The fallacy in the statement that "the formula does not matter," is as great and misleading as that involved in the further one, that if exposures are not correct no developer will put them right. Such dogmatic statements only contain a grain of truth which is too perfectly concealed to be of any value, and if they are interpreted literally and as baldly as they are written, the result is quite at variance with well-known facts. It is a good plan to impress upon the beginner the great importance of correct exposure, but there is no need to back up the advice by the assertion that all the formulæ in the world

will not save an incorrectly exposed plate. If it happens to be over-exposed there are several well-known methods of saving it, and the photographer gains nothing, and may lose a good deal if kept in ignorance of this fact.

* * *

Cheap v. Free Enlargements.

We note that in a neighbourhood that has recently been infested with free portrait swindlers a local dealer is advertising his willingness to supply 15 by 12 enlargements from prints or negatives for three shillings each, and frames of the same size for another three shillings, the total cost being, therefore, less than one-third of the amount that the itinerant swindler tries to extract from his victims. The dealer in question being well known in the neighbourhood, there is no longer any great field open to the free philanthropist, whose victims will now be limited to those who imagine that "free" means no cash payment. Hitherto this gentleman has done the greater part of his business with the little more intelligent class who know they are not being dealt with honestly, and yet think they are getting good value for their money. They will now, no doubt, jump at the chance of getting the same value for one-third the money, in which case the strange canvasser with his free offer will lose their custom and a proportion of his own profits.

* * *

Stains in Chromium Intensification

Sometimes when a plate is put through the chromium intensification process the final result shows brown stains, especially where fingermarks existed on the original. These stains, particularly when due to the existence of grease on the negative, are easily removed if the plate is first soaked in a solution of sulphite of soda and hydrochloric acid, and then rubbed with a wad of cotton-wool. The slighter stains will rub off immediately, while the stronger ones will yield to two or three applications of the solution. Incidentally the solution will slightly reduce the intensification obtained, and for this reason it is better to soak the whole plate than to merely apply the solution locally. The reduction is, however, not very great in any case, unless a great deal of acid is used, and three or four drops in two ounces of 5 per cent. sulphite solution are usually quite enough. Sulphuric acid will no doubt serve, though it so happens that hydrochloric is the only acid we have actually used for the purpose. It is, of course, better to prevent rather than to cure the stains, and they will not appear if the negative is thoroughly cleaned before intensification, and the film is not touched between bleaching and redevelop-ment.

LOCAL INTENSIFICATION TO ANY DEGREE.

It is not uncommon for us to receive inquiries as to the intensification of negatives from which it is evident that the real object of the inquirer is to produce very considerable local treatment of the negative, rather than a general intensification. Often in such cases it is intended to take a very large number of prints from the negative, and therefore some little trouble in securing the most perfect conditions at the outset are of no consideration. The dusting-on method, now little practised in this country, affords a means of attaining this end which those who have not practised it will, perhaps, fail to put at its proper value. One great advantage of it is that the change in the negative, if not thought perfectly satisfactory, can be destroyed, and the operation started afresh. The method is simple in practice, and may be said to be quite a mechanical one. It may here be as well to explain what this process is, for the benefit of those who are not conversant with the principle upon which it is based. If a

plate be coated with a bichromated colloid, which is of a somewhat tacky nature, it is greatly modified by exposure to light. Thus if we coat a glass plate with, say, gum arabic, mixed with a little glucose, honey, or the like, plus a bichromate, and dry it, a pigment brushed over as a fine powder will adhere evenly all over. If, however, the plate be exposed for a while to light the character of the colloid will be altered, and the powder will not take at all. With this brief explanation, it is easy to see that if certain parts are protected, as by exposing through a negative, that another negative can be directly obtained, and this process has been largely used, though not so much here as on the Continent, for producing reversed negatives for collotype and similar processes. With this little preamble, we will now describe the method of working the process for our present purpose.

In the first instance it will be well to varnish the negative to be dealt with. This is not really necessary, but it is a wise precaution to take, because if in coating the back of the varnished negative a little of the mixture gets on the front it can easily be wiped off, whereas if it is not varnished the negative film would be liable to be stained by the bichromate. The back of the plate must be made thoroughly clean, otherwise the mixture to be applied would not flow evenly over it, and an even coating will not be obtained. As regards formulæ for the powder process, very many have from time to time been published, but so far as our experience has gone with them they are all workable. The following are two which are reliable and easily prepared:—

- A.—Gum arabic 4 drams.
- Glucose 10 drams.
- Honey 2 drams.
- Water 10 ozs.

When dissolved, add alcohol 1½ drams.

- B.—Ammonium bichromate 1 oz.
- Water 10 oz.

For use, add one part of A to two parts of B.

The second is a one-solution mixture:—

- Dextrine 2 drams.
- Sugar candy 2 drams.
- Ammonium bichromate 1 dram.
- Water 8 oz.

The solutions when mixed with the bichromate will keep good for a few days only; but if the bichromate be kept separate they keep for weeks.

The back of the negative, being thoroughly clean, is flowed over with the sensitive solution, drained, and then dried before the fire or over a spirit lamp. Only a very thin coating is required, so that the plate should be well drained before it is dried. While the plate is still warm it is laid on a piece of thoroughly dry black velvet or black paper, and exposed (face upward, of course) to light for a few minutes. After the exposure the plate is again warmed and allowed to rest for a short time. It is scarcely necessary to say that this, like the preparation of the plate, must be done in a very subdued light. When the plate has become cold, if the negative has to be generally intensified all over, a little fine plumbago—that sold for electrotyping purposes is the kind to use—is lightly dusted over with a flat camel-hair brush, when it will be found to take on in proportion as the light has not acted on the coating; that is, the lights will take the colour freely, while the shadows will hold but little, and the deepest ones none at all, as in them the tackiness of the film has been practically destroyed by the action of the light. A word of caution will not be out of place here. It is that only a very thin deposit of plumbago is necessary, as it obstructs far more light than would be suspected by the novice.

Supposing local treatment is required, then the plumbago is applied (with a camel-hair pencil) only to those parts that require strengthening, while the other portions are kept clear of the powder. Should the detail in the shadows be too weak to print well, the powder should be applied to those parts and kept away from the denser portions. If the lights only want more vigour, the plumbago is applied only on them. In this way there is immense scope for converting an inferior negative into a really good one, and with advantage that, if the first essay is not quite satisfactory, the work can all be cleaned off with a damp rag and the plate re-coated. Although the work is on the back of the negative, it serves its purpose quite well, while it does not require such nicety in the manipulation as if it were on the film side.

With regard to the exposure, all must necessarily depend upon the light and the density of the negative. But there is great latitude in this matter. If it is found when the powder is first applied that it takes too freely, it shows that the plate has been insufficiently exposed, or that the film is in a too moist condition. Still, it may generally be made right by warming it before the fire so as to drive off some of the moisture. If, on the other hand, the plumbago does

not take kindly, it shows that the exposure has been too long; but that can usually be remedied within very wide limits. What we do in this case is to put the plate in a damp place for a quarter of an hour or less, so that it can absorb more moisture. The same end may be attained by gently breathing on the plate; but when that is done the powder should not be applied for a few minutes afterwards, so that the moisture may become evenly absorbed by the film. If it were applied at once brush-marks would probably be produced. It will thus be seen that the successful working of the powder process depends entirely on the hygroscopic condition of the film.

When the work is finished, the superfluous powder is removed lightly with a broad camel-hair brush; but the plates should be well warmed beforehand, otherwise there might be sufficient moisture in the film to cause some of it to stick. The work being completed, it only remains to fix it. This is done by simply exposing the back of the plate to a strong light—sunlight is best—for an hour or so. This will harden the film, and so destroy, permanently, its tackiness. There is no necessity to remove the bichromate, as the film is so thin its presence will not appreciably retard the printing.

THE DRESDEN EXHIBITION.

IV.

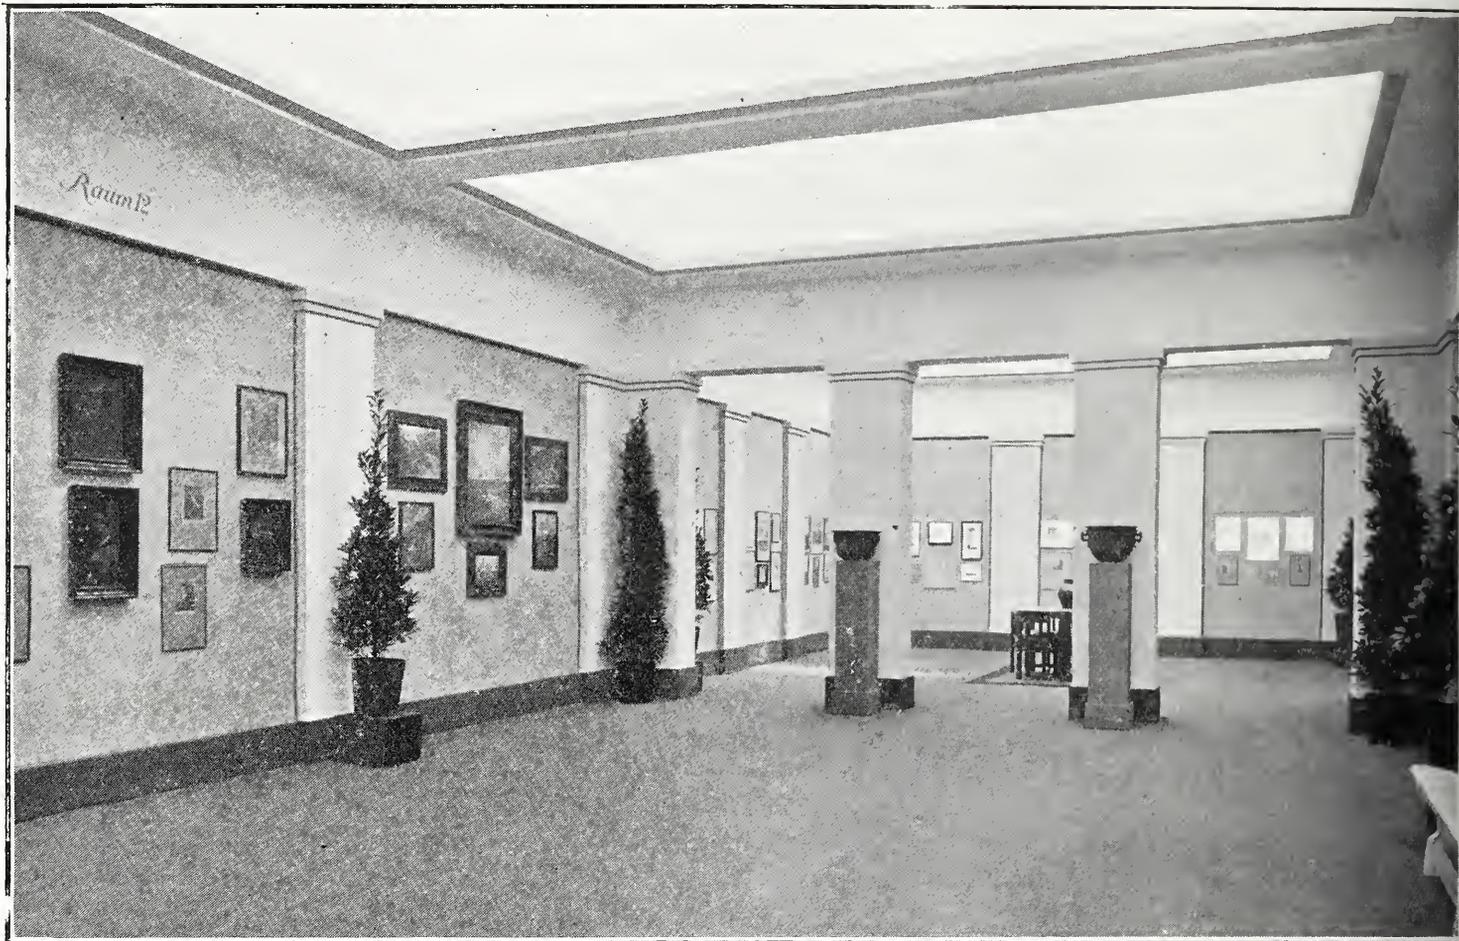

As we wrote in the first article on the Dresden Exhibition, the most striking feature of interest within its many galleries is the one to be found and studied in all of them—namely, the art of arranging and mounting a whole series of collections of photographs. That impression remains one of the most persistent of those formed, and, on that account alone, a visit to the exhibition comes near to being an education for those who may be entrusted with the duties of supervising the display of photographs for public inspection. And, unfortunately, it is a feature of an exhibition most difficult to describe. The photographs which we reproduce in this issue will give some idea of the details of arrangement, furnishing, and lighting, but they cannot convey the niceties of tonal harmonies and contrasts practised throughout with great skill. In every instance these arrangements were in the hands of artists working in conjunction with the executive of the exhibition. Very likely the result in every case would not commend itself to our English ideas of what is fit and proper, but, as already pointed out, in some instances almost vivid contrasts between floor-covering and those on the walls have been adopted in order, as it were, to administer an æsthetic tonic to the visitor making a conscientious tour of the galleries. This explanation, which is quite seriously given, would seem to amount to the damning admission that the photographs themselves do not provide the jaded observer with sufficient variety, and, frankly, no truer criticism than that could be passed on the pictorial

sections of the exhibition. It is not particularly comforting to be told that the sensation of weariness produced by series of "photographic pictures" supposed to be the pick of pretty nearly every country in the world requires to be—and may be—dispelled by offering to the eye an expanse of ochre carpet below a saffron frieze. We will not say that the plan of the German decorators has this result, but we cannot disguise the fact that there is the need of some tonic (or should it be balm?) more potent than contrasted tones of arras cloth. If ever a cult or a craft suffered by being presented in too liberal a measure, the so-called pictorial photography of the present day has suffered at the hands of the Dresden organisers. Granted—there is no reason to do otherwise—that they erred with good intent. Their aim was manifestly at a highly comprehensive demonstration of what photography could do in the hands of people of cultivated taste; but they carried a system of classification and sub-division according to place or country to a foolish excess, with the result that the larger number of the photographs have no other result than to make you very tired, and to cause you to take a solemn vow never to go to another world exhibition of pictorial photography. Years ago, in the early days of the pictorial photograph, Sir William Abney declared that one out-of-focus photograph produced in him an absolute sensation of nausea. If Sir William Abney should visit the galleries of "amateurphotographie" at Dresden—

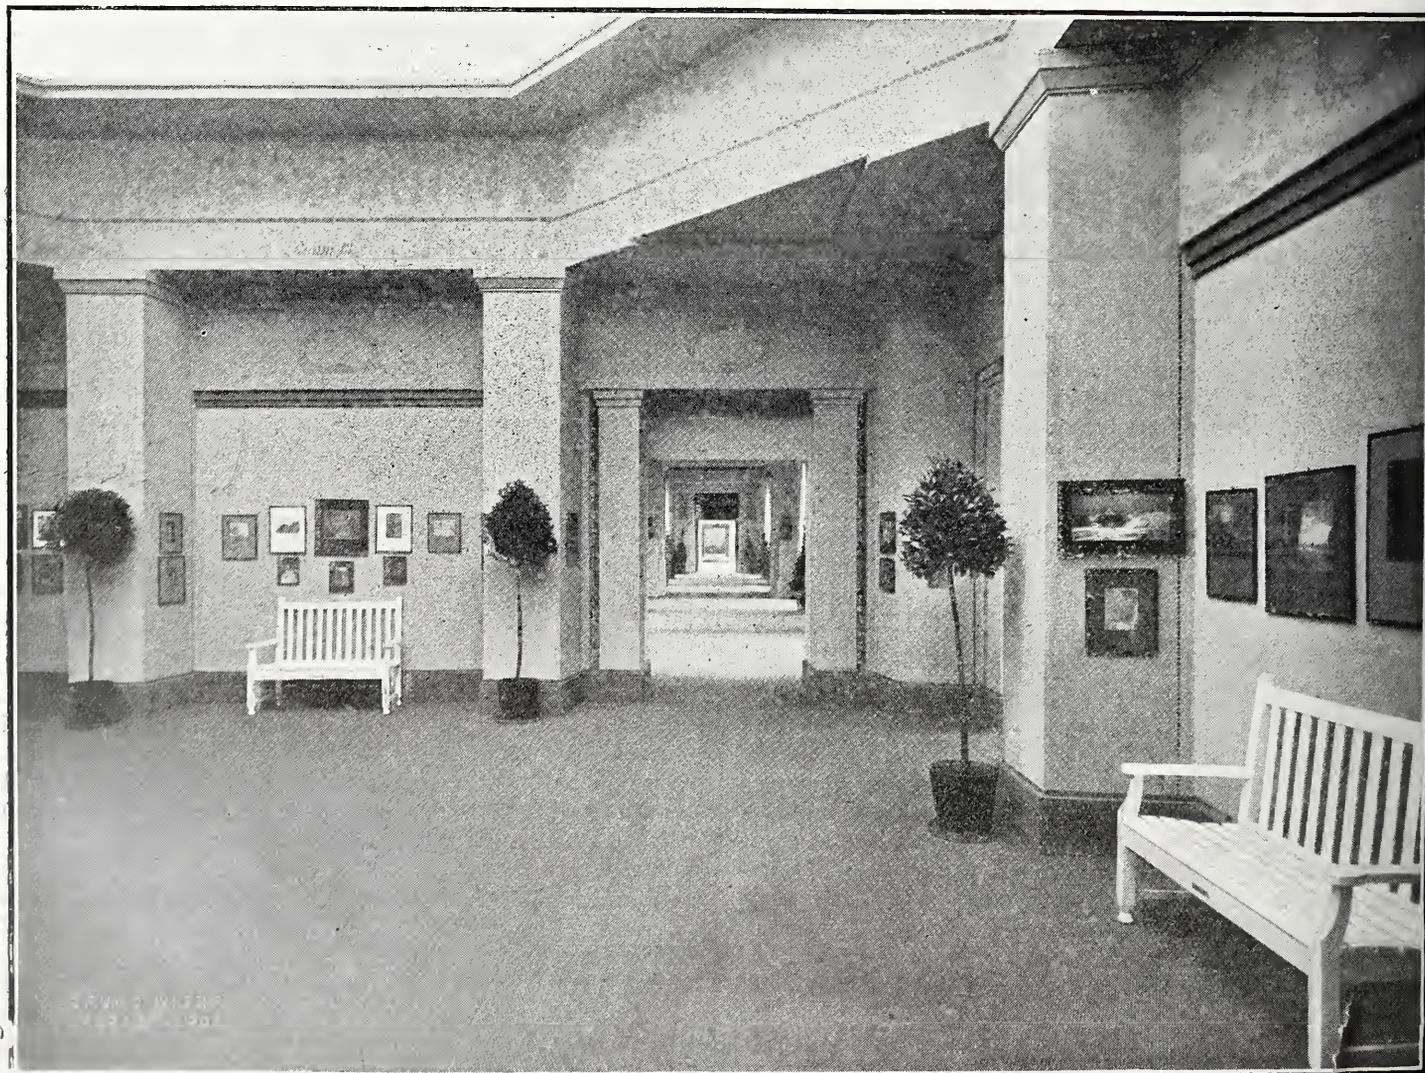

THE AMATEUR PHOTOGRAPHY SECTION.

We have written above of the general impression obtained on conscientiously studying the contents of the twenty-nine separate apartments in which the work of the amateur photographers are collected, but it would be most unfair to dismiss this section of the exhibition in this perfunctory way, particularly as at least one sub-section deserves to be excepted from the general criticism: we refer to that of the so-called "International Union of Art Photographers" (Internationale Vereinigung der Kunstphotographen). In the catalogue this body stands next to the section devoted to photographs by royal personages, including the King of Saxony and his sister, the

Princess Mathilde, some of whose photographs are of very nice technical quality. In the arrangement of the galleries, however, the International Union has the place of honour. Its works are shown in a room of noble proportions, where the 200 pictures are hung with plenty of space between them. As we pointed out in a previous issue, the largest exhibitors are E. J. Steichen and Clarence H. White. A. L. Coburn, Alfred Stieglitz, and Heinrich Kühn come next. Other American workers are Mrs. Brigman with 8 pictures, F. Holland Day with 5, W. B. Dyer with 2, Frank Eugene with 13, H. G. French with 4, J. T. Keiley with 6, and G. H. Seeley with the same number. J.

A general view of the larger of the two galleries in which the English pictorial work is shown.

On each side of the corridor are five separate small galleries containing German pictorial work. The gallery occupying the foreground contains the American amateur section.

Craig Annan (8) pictures, George Davison (5), and A. von Meyer (8) are the three English members of the Union. R. Demachy, with 10 oil prints, is the sole French member, if we except A. Personnaz, who exhibits 10 landscapes amongst the Autochromes, whilst Austria is further represented by F. V. Spitzer, of Vienna.

The larger proportion of the collection is thus the work of the Americans, and a curious emphasis is given to the fact in the catalogue by the insertion after the title of each picture by F. Holland Day, Keiley, Steichen, Stieglitz, and White of the date of its production. As the catalogue number immediately follows, the result is something of an embarrassment when going round the walls, but, presumably, one's compensation for the trouble is the interesting retrospective view thus afforded of the progress of these workers.

So much for the composition of the International Union. We hasten to add that the contents of its gallery tower above the other pictorial collections largely because of Steichen, White, and Kühn, the bigness and certainty of whose work impresses on one the mastery of his art possessed by each author. Although these men may at times scandalise us by their insubordination in the matter of art-discipline, in the long run they usually prove themselves to be the pioneers of work and ways that widen and enrich pictorial photography. If a large exhibition, even of good things, be a surfeit, it must become tiresome; and the new idea, the daring method, the outrageous motive will stand out in our impression as a welcome landmark—an oasis of interest in a desert of level merit. We dare not say that such works need not be good also. Original though they may be, they must not fail to bear the impress of single-heartedness and a conviction that artistic impulses alone have prompted them. Mere bids for popularity that are nothing else simply emphasise our worst impressions of an exhibition.

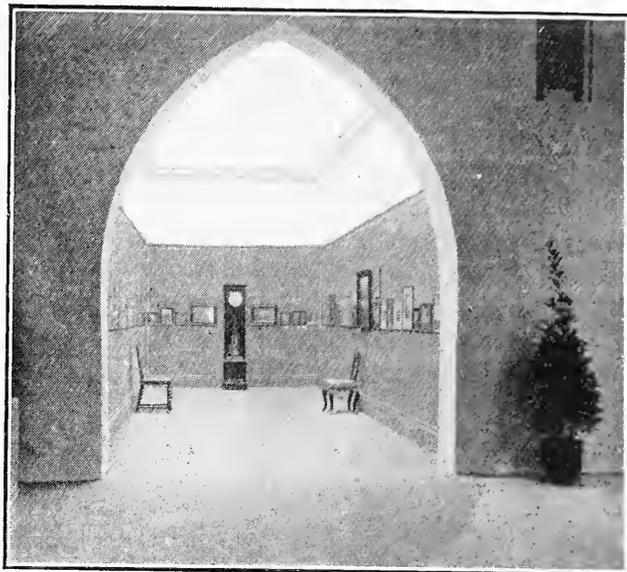

The nude studies of Miss Annie Brigman are, we think, too ambitious in their literary interest. She is too anxious to tell a story, with the result that her figures are combined in an uncomfortable way with various natural objects, and the legitimate interest of nude studies—namely, beauty of form and modelling—is dissipated in far-fetched ideas of the romantic, where nudity seems to be forcibly imported. Much of Mr. Coburn's work suffers from a similar striving. His faculty of beauty-perception seems to become atrophied at times when he produces Flip-Flaps, or selects disorderly lines and ugly masses simply because everybody before him has rejected them. The inclusion of such examples in an international exhibition cannot enhance his reputation among people who are able to judge.

The few works by H. G. French have distinction and novelty also. They are decidedly the result of a purely personal approach, and appear to be independent of that sheep-like discipleship which degrades much work of the romantic and poetic class. Mr. French is his own master, and his work is a great support to the International section. Robert Demachy also is *sui generis*, but in another way. His work is incompatible with the American products surrounding it. As oil prints these pictures require to be seen in a class with others of their kind, where their painter-like qualities would not clash with the smoothness of the photographically derived prints.

Passing through the collection of the International Union, one comes upon a long corridor on each side of which are five separate small galleries containing the work of the German amateurs. These are subdivided so as to give a separate representation to workers in Dresden, Leipsic, Saxony, Berlin, Hamburg, Bavaria (there is a separate section for Munich), Rheinland, and Westphalia, and, lastly, various parts of Germany. The result of this necessarily large representation of amateur work is, we fear, not to the advantage of the German workers, since work which has outstanding merits has to be looked for among a great many prints which are scarcely de-

serving of a place in an exhibition such as this. Any detailed criticism of these many pictures would, we think, serve no useful purpose, but we may make a note of some few pictures of special merit, and thus do some service to those in this country who may be anxious to secure a representation of German pictorial photography at exhibitions here.

Otto Ehrhardt in a print "Weisses Schloss" contributes an imposing rendering of a lofty castle standing among trees. Dr. Kuhfahl in No. 721-39, "März Stimmung an der Elbquelle," gives a fine version of a storm in the snow. J. Ostermaier, whose excellent work in flower photography we have already alluded to, shows in No. 727-52 a very pictorial treatment of a glacier stream. The portraits by R. Renger-Patzsch (730-56) are of large heads of children, and are technically beyond

One of eight small galleries containing German pictorial work.

reproach, whilst they portray the subjects free from the appearance of staring at the camera. In the section of the Berlin workers the three exhibits by W. von Gloeden are by no means the best by this accomplished worker. The Hamburg exhibits, arranged by Herr Ernst Juhl, are naturally interesting, since they include a selection of work, old and new, from the Hofmeister brothers and H. W. Müller. Photographers in Bavaria scarcely seem to have done justice to the many natural beauties of this part of Germany. Two prints which stand out for their charming rendering of landscape scenes are "Sommernachmittag," by Alfred Erdmann (No. 851-3), and "Sommerlandschaft" (No. 860-28), by Albert Mayer. Among a number of prints by workers scattered in different parts of Germany there is one which is a perfect triumph of indoor photography, entitled "Raucherkathe" (No. 873-21), by Andreas Rohwer; it is a view of a workroom lighted by one little window, near to which a figure sits at work. Landscape predominates through these collections, and apparently the German amateur workers have not devoted themselves so much as in France and England to portrait and figure studies. The title of one figure study (No. 761-22) by Elsa Gysac struck a note of humour. It is "Missstimmung" (bad temper), and shows a mournful-looking man waiting while a girl does up her hair preparatory, apparently, to the two emerging together from the front door of their house which stands open.

Next in order of tour through the exhibition comes the English section, the arrangement and hanging of which have been very carefully done by Mr. E. O. Hoppé, who has adopted a scheme of tones for wall and floor covering which are quite English in their note of quietness. Most of the pictures, it need hardly be said, have already been seen in the exhibitions here, and the first impression which is made by the collection is the freshness and charm of the landscapes by the late Horsley

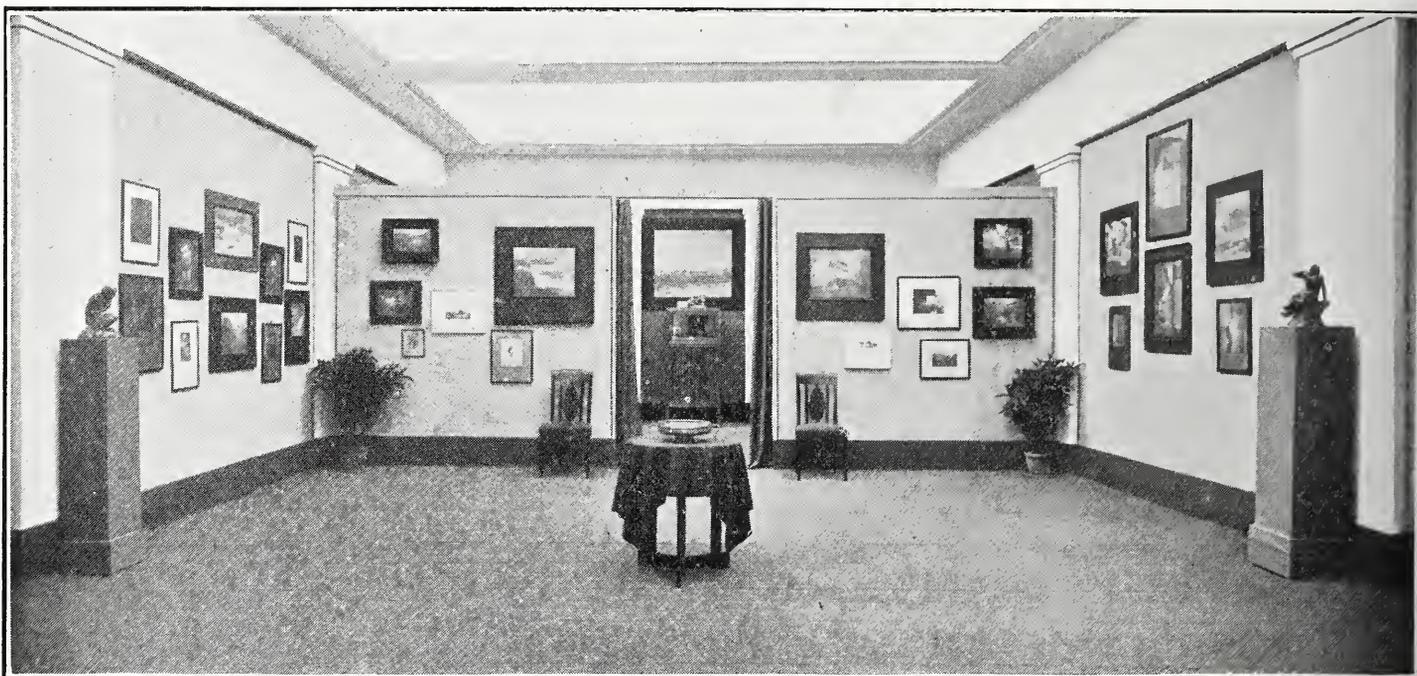

Hinton; these, not only from their size, but from the evident certainty with which the author has translated impressions which appealed to him, take the leading place upon the walls. As regards its representation of other workers the English section fairly completely represents the work of exponents of pictorial photography of this country, not only those regularly sending to exhibitions, but also workers whose pictures are usually seen only at the annual exhibitions of the Linked Ring.

Opening out of the second gallery accommodating the English work is a small collection of pictures collected under the heading in the catalogue of "Englische Lehranstalt für das künstlerische Kamerabildnis und für die wissenschaftliche Photographie," which we may translate as "English school for technical and scientific photography." The exhibits are the work of the scholars and the teaching staff, the chief contribution from the latter being a series of portraits by E. O. Hoppé, and of photographs of natural history subjects by F. Martin Duncan. There are also one or two of the well-known pictures of A. H. Blake, and two of the even more familiar sea subjects of F. J. Mortimer. The work of the students is represented by photographs by Grete Back, Russell Burchall, W. Fells, Chs. Rolph, and C. Wille.

it represents the work of the Italian amateurs. In fact, it is self-evident that it does not, for it includes among some five-and-twenty photographs, mostly of very mediocre quality, only one example of the charming work of Guido Rey. Another Italian worker, Edouarda Garrona, of Turin, whose pictures on the few occasions on which they have been shown in this country have merited the highest praise, is not represented at all, and it would therefore be unfair to make any adverse criticism of Italian work which on the face of it does not represent the best of which workers in that country are capable.

The sections devoted to work of amateur photographers in Budapest and Switzerland do not call for any special remark. Those from the former source indulge the taste for two-colour effects which appear harsh and discordant—to English eyes, at any rate. The subjects are usually landscape and street views of natural beauty, as well as of portraits of ladies of somewhat ample proportions. Of the Swiss photographs all that may be said is that they represent beautiful or pretty subjects and at the same time excellent technical photography. The only one which we could select for mention is a fine study of clouds and landscape by Adolf Gurtner.

Only two workers contribute the section representing Belgium,

Part of the second gallery allocated to the English pictorial work. Through the central doorway is the exhibition by students and teachers in the English school for pictorial and scientific photography.

So far as we can learn, the exhibit represents the first public announcement of this London school of photography, of which we had heard in a semi-private way, and even now the Dresden catalogue does not name the address at which the instruction is given.

America.

Mr. F. R. Fraprie has brought together in this section over 100 examples of the pictorial work done in America by workers outside the charmed circle of the Photo-Secession. The works which appealed most to us were those—and there are quite a number of them—of winter landscapes, in the rendering of which several workers—J. Chislett, J. H. Field, and W. A. Scott—show that they have taken to heart the lesson set in this branch of work first by Rudolf Eickemeyer, jun. "The Snowy Hillside," by Mr. Field, is quite after the manner of Eickemeyer. Other workers who may be mentioned are D. H. Brockins, C. F. Clarke, and E. J. Keller.

Italy.

We cannot say very much for the collection got together by Ernesto Baum, of Rome. We should be sorry to think that

but one of them is L. Missonne, whose work we have seen and admired at past exhibitions of the Royal Photographic Society. The work of photographers in Finland certainly shows a certain character common to most of the exhibits; the taste seems to be almost entirely for evening effects of lighting or for winter subjects, in both cases the strangest colours being selected for the prints.

From Denmark, Sweden, and Holland only a very few prints are sent, to the number only of between sixty and seventy for the three countries. Workers whose pictures show notable merit are A. and D. Duckert, Niels Fischer, and Carl Frederiksen (all of Copenhagen), Nils Bagge and Hugo Beyer, of Stockholm, and W. T. C. Hoffman, of Amsterdam.

Russia.

By far the most interesting pictorial work is that from Russia, and particularly the figure and character studies by S. A. Lobiwikkoff, of Wiatka. He has taken as his subjects types of peasant life, which are treated in the simplest manner against a background which is almost plain or with one or two rude

articles of furniture included in the subject. In most of them there is a note of pathos from the very wretchedness of the sitters, whilst in the case of one or two of the portraits of children there is an air of comicality which appears quite natural to the subjects. Among a collection sent by the Amateur Photographic Society of Kiev one more ambitious subject by W. Ruszejky deserves to be mentioned. It is entitled "Grief," and represents a mother holding her head in her hands whilst a

sewing machine with a child's frock in it stands idle by the side. One last small gallery in the amateur section is devoted to a very interesting historical collection of silhouettes and miniatures, passing from which we come into the Austrian house, specially built by the Austrian Government, and including in its galleries not only amateur and professional work, but also process and trade exhibits, some description of which must be postponed to another occasion.

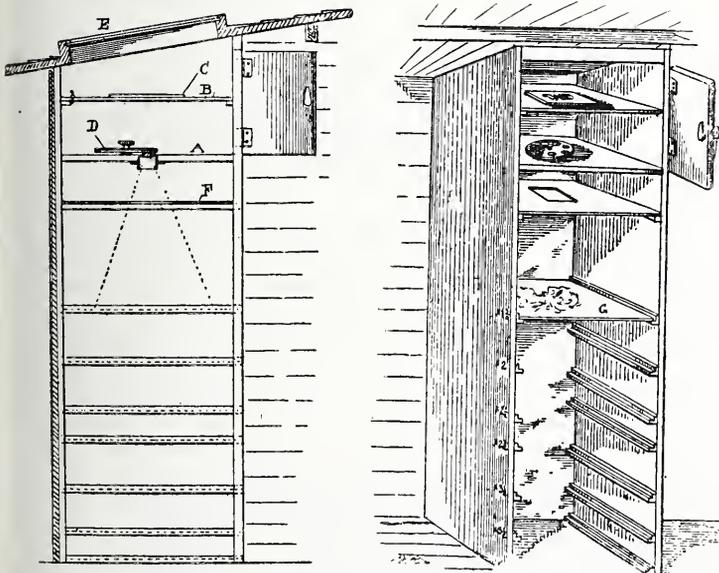

A NOVEL METHOD OF ENLARGING.

[Enlarging cameras built vertically have been designed on many occasions in the past, but have been found to possess drawbacks, chiefly that of the difficulty of moving the various parts in relation to each other. The device of using lenses of different focal lengths described by Dr. d'Arcy Power in the following article from the current issue of "Camera Craft" removes this drawback, and will no doubt allow of the vertical system being adopted more frequently.—Eds. "B.J."]

It sounds almost preposterous to announce anything new in enlarging, which is probably the most written-over topic in photography. Nevertheless, the method I am about to describe, and have successfully used for two years, does not appear in the text-books, and I have not met with it in my reading. This is my excuse for describing it.

The Vertical (Skylight) Enlarger.

I have used all kinds of enlarging apparatus, from a box with a pin-hole to massive and complex apparatus suggestive of a deadly compact between the higher mathematics and applied mechanics; but, for all the purposes for which I use enlarging, nothing has given me such satisfaction as my present arrangement. It arose out of my necessities, which were conditioned

by my environment. In other words, I had to enlarge quarter-plate negatives to various sizes up to 14 x 17 without having a large camera or much room in my workshop. My dark-room was located in the attic immediately under the slanting roof. A horizontal apparatus of the usual type would have taken up too much room. I overcame this objection by cutting a small skylight, E in sketch, in the lowest part of the roof, about six feet from the floor; and this I boxed in on three sides. On the fourth side, that looking directly into the room, I closed in the upper part with a light-tight door, immediately level with the lower edge of which is a shelf (A in the drawing), closing in the upper part of this long cupboard. This shelf has an opening in its centre into which my lens board accurately fits. Eight inches above this shelf is another, B, with a central opening to take a 7 x 5 plate or carrier, or, as I now have it, a sheet of plate glass. The cupboard below the lens is

grooved at the sides to take a movable shelf, G, at any desired level. This is nearly all there is to it; it is simply a long box, with a skylight forming its one end and the floor the other, enclosed as described. How is it used? We take, say, a quarter-plate negative, shown at C, and place it on the glass shelf above the lens and close the door. Its image is projected on the floor, fifty-six inches below, seven times enlarged, 22 x 30 inches; but you say: "I don't want that enlargement; I want an 11 x 14, about three times the size of the negative." All right; we put the movable shelf in a groove at twenty-eight inches, and we have an image of the size desired, but it is all out of focus; the lens needs moving nearer the camera which our simple arrangement does not permit. But, if we drop an ordinary plus spectacle lens over our seven-inch enlarging lens, we change its focal length to six inches, which gives a three-fold magnification at twenty-four inches. Do we only need a two-diameter enlargement, we use a plus two spectacle lens, the paper being placed sixteen inches below the lens. So with all other enlargements. Half a dozen unground periscopic spectacle lenses, which cost only a few cents apiece, will cover all ordinary requirements. They can be kept loose in a box on the lens shelf and slipped over when wanted, or mounted on a disc which can be rotated over the lens. Now, in practice, most of us work at more or less fixed sizes. We use 4½ x 3¼ or 5 x 4 or 7 x 5 plates, and we enlarge on 10 x 8 or 15 x 12 bromide paper. It is a very easy matter to find the supplemental lens that shall exactly give our usual enlargement; and, having marked it, and also marked the groove in the enlarging cupboard where a test slide gives a dead sharp image, we never have any more focussing troubles.

The Saving in Space.

From the construction of the apparatus, neither lens, negative, nor paper can ever fall into different planes, the commonest fault in horizontal enlarging apparatus. The work of printing enlargements is by this means actually more rapid than printing by contact from a negative. There is nothing to do but put the movable shelf in the groove marked for the required enlargement, slip the similarly marked supplemental lens over the enlarging lens, close the door, and, with the usual yellow cap on the lens, adjust the bromide paper (it does not need pinning), remove the cap, expose for necessary time, and develop. The total space taken from your dark-room is only the size of the largest sheet of bromide you are likely to use, in my case, 17 x 14. The cost of the apparatus (you use your camera lens) is, outside of the cost of the small skylight, little more than the price of the spectacle lenses.

Facilities for Vignetting, etc.

But these are not the only advantages. It offers ideal facilities for modifying the print, double printing, and the like. A sheet of plate glass can be slipped into a groove at any desired

height above the print, and thereon a mask arranged that shall accurately cut out or hold back any desired portion; according to the distance this is placed from the paper, so will the line of demarcation be soft or hard. Secondly, all forms of enlarging apparatus are troubled with reflected light when the whole of the image is not taken up by the paper. With this form, every superfluous ray can be cut out by the simple device of introducing between the lens and the paper a piece of cardboard, F in sketch, with a rectangular hole cut out. My plan is to keep such a piece of board permanently in position just under the lens, at D; the aperture is large enough to permit the projection of the largest sized image; when a smaller image is thrown on the screen, the opening is diminished to the size of the part to be printed by narrowing the opening with two pieces of cardboard cut in the form of L squares and used to enclose the portion desired. I never have degradation from reflected light. Let me further point out that, if you are about to enlarge only part of a negative, you are able to place this part over the centre of the lens, thus securing the best definition. The negative-bearing shelf being of plate glass enables you to place the negative in any position, and also to make use of various devices for printing enlargements with toned mount effects.

The Optical Equipment.

Finally, let me give a few hints as to the enlarging lens and spectacle lenses to be used. Be it first understood that, if the principal lens be of short focus, say five inches, the ratio of enlargement rapidly increases, so that at a distance of fifty inches from the negative the image would be magnified eight diameters; whereas, with an eight-inch lens, the same distance would only give a magnification of four diameters. To obtain eight diameters with this lens would require a total

distance from the negative of eighty-one inches. Now, the covering power of a five-inch lens is less than that of an eight-inch, so that, if enlargements are to be made from large negatives, it may not suffice. Whatever lens is used, place as near the negative shelf as may be required to give the largest enlargement you are likely to need. It will be some guide to give you my own arrangement, which, if of limited capacity, is all I need.

My lens is between seven and eight inches focal length. It is fixed about forty-two inches above the floor and about eight and one-half inches beneath the glass negative shelf. It projects a sharp image on the floor magnified four diameters. Fastened by a nail to the negative shelf is a freely rotating disc, home made, of stout mill-board, carrying seven perforations, one open, the others closed by periscopic plus spectacle lenses of denominations given below, and each lens is plainly marked with the magnification it will give. The grooves for the bromide shelf are correspondingly marked. They are as follows:—

Lens.	Distance to paper shelf.	Magnification.
7-inch lens alone.....	41½ inches	4 diameters.
7-inch lens plus 0.12 spectacle lens...	38 inches	3½ diameters.
7-inch lens plus 0.25 spectacle lens...	34½ inches	3⅓ diameters.
7-inch lens plus 0.50 spectacle lens...	29 inches	2¾ diameters.
7-inch lens plus 1.00 spectacle lens...	26½ inches	2½ diameters.
7-inch lens plus 1.25 spectacle lens...	21½ inches	2 diameters.
7-inch lens plus 2.00 spectacle lens...	16½ inches	1⅔ diameters.

These distances and magnifications could all be obtained by calculations based on the foci of the lenses, but I have little confidence in the statements of manufacturers, and always prefer to determine such questions by trial.

H. D'ARCY POWER.

DEVICES FOR THE AUTOMATIC DEMONSTRATION OF FACTS OF LIGHT, COLOUR, AND PHOTOGRAPHY.

When first reviewing the general features of the International Exhibition of Photography at Dresden we referred in appreciative terms to the section arranged by Dr. Goldberg, of the Leipsic School of Graphic Arts, in which means were provided for teaching or demonstrating in a very simple way a large number of the principles on which vision, photography, and colour photography are based. In designing these the evident aim has been to arrange matters in such a way that, while the manipulation should be of the simplest kind, so simple, in fact, that a moment's inspection of the printed directions sufficed to tell the visitor what he had to do, yet practically every exhibit is in the nature of an experiment by which the observer is caused to see for himself that such and such a phenomenon takes place instead of simply taking it for granted from a diagram or printed page. Such a method of cultivating the observing powers of the student is expected in class instruction, though we fear that in many instances the less laborious use of diagrams and lantern slides is made to take its place. This is less excusable, since in a

class it is easy to arrange experiments of this kind to be performed by students under the teacher's direction. The task which Dr. Goldberg and his assistants have had before them for the Dresden Exhibition was one much more difficult, and therefore one cannot but praise the most ingenious arrangement by which each separate experiment is arranged within the space of a cabinet of about the same size in each instance (about 20 x 12 x 12 inches). The interest which these arrangements have for everyone studying photography themselves or engaged in teaching it to others leads us to give a translation of the description of each experiment, and to supplement it, where necessary, with one or two diagrams showing the device employed in certain cases for demonstrating the particular fact.

In each case the fact which the experiment is designed to demonstrate is first stated, and underneath it are given the directions for the performance of the latter. To this plan we will adhere in describing the series.

* * * * *

* * * * *

1. *The Eye.*—The human eye is very similar to the photographic camera. Like the camera, the eye possesses a lens, sensitive plate, a stop or diaphragm, focussing arrangement, etc. (Diagram showing an enlarged sectional drawing of the eye with those parts corresponding to the different portions of a camera.)

observe the writing at the back of the cabinet. Midway between the peep-hole and this writing is a fine piece of net, which, while the eye is fixed on the writing, is scarcely noticeable. Now fix the eye on the net, which will then be seen sharply, whilst the writing will disappear. In the case of old people this mechanism of the eye works badly, and the experiment will not succeed in such cases.

2. *Accommodation of the Eye.*—The lens of the eye having a relatively long focus, objects very near to the eye appear very un-sharp. In order, therefore, to obtain sharp focus the eye is provided with an arrangement which alters the focal length. In this way the eye can bring into action a lens of greater or less focus, and thus with the same "camera extension" perceive sharply an object which is either near or distant.

3. *Explanation of the Mechanism of Accommodation.*—In order to explain the accommodation of the eye the following experiment is made:—Two lenses of different focus are fitted to a camera of fixed extension. The object consists of two electric lamps, placed at different distances from the lenses (corresponding with the writing and the net in Experiment 2). With one lens one lamp is obtained

Experiment.—Place the eye close up against the peep-hole and

sharp, with the second the other. It is impossible to get both lamps sharp at the same time.

Experiment.—Move the lever on the outside of the cabinet so as to focus the image of the lamps on the ground glass screen.

4. *The Diaphragm of the Eye.*—The eye possesses an excellent automatic arrangement for protecting the sensitive film from over-exposure. For this purpose a small stop comes into operation on too strong a light affecting the eye, whilst, when the eye is exposed to weaker illumination, the stop is enlarged.

Experiment.—Bring the eye as near as possible to the peep-hole of the cabinet. The reflection of the pupil (stop) of the eye is seen in a mirror. On now pressing a button the second lamp is brought into operation, strongly illuminating the eye. The instant contraction of the stop (iris) of the eye is very plainly seen.

5. *Halation of the Eye (Irradiation).*—Despite its many mechanical devices, the eye camera has also many drawbacks. For example, halation is very strongly marked in the eye.

Experiment.—Place the eye to the peep-hole and look at the filament of the lighted electric lamp, which appears much thicker than it really is, in consequence of irradiation. Now press a lever, which lets down in front of the lamp a grey screen. It will be seen that the filament now appears of its natural thickness, due to the lessened illumination.

6. *Chromatic Aberration of the Eye.*—The lens of the eye as an optical instrument is in some respects greatly excelled by the modern photographic lens. The eye-lens possesses practically all the defects of a bad cheap lens. One of the most marked is chromatic aberration, that is, the incapacity to focus two different colours sharply at the same time. When an attempt is made to do this, the eye from habit suggests that the colours are in different planes, and a "plastic" effect of semi-relief is thus obtained.

Experiment.—Some lettering is printed in deep red, on a deep green or blue paper. The letters appear to stand out from the paper, owing to the fact that the eye cannot focus both lettering and ground at the same time, and the different coloured rays thus appear to proceed from surfaces at different distances.

7. *The Blood Vessels of the Eye.*—The surface of the sensitive plate in the eye is covered with a network of blood vessels, which interferes with the vision, although the effect is not recognised, since persons have become used to it from birth.

Experiment.—Bring the eye as near as possible to the peep-hole and place it so that the white in the eye is as strongly illuminated as possible. This is done by means of a small mirror in the cabinet. There is then seen by the eye the phenomenon recalling the representation of rivers on a map. If this experiment does not succeed the first time, repeat it, as some practice is necessary.

8. *Blind Spot.*—The sensitive plate of the eye also suffers from many defects. There is in the eye, for example, one rather large area which is lacking in sensitiveness (the blind spot). Persons

FIG. 1

Fig. 1.

have become so unconscious of this defect that the experiment for showing it requires some practice and care.

Experiment.—A small white disc and a much smaller square are mounted on a board, which can move to and fro in a direct line from the peep-hole. Fix the right eye perfectly steadily on the white circle and move the lever so as to cause the board to approach the eye. At a certain place, without the eye being removed from the circle, the small square disappears. On turning the lever further the square again makes its appearance. If the experiment does not succeed it should be repeated, with slight inclination of the head.

9. *Seeing with One Eye.*—When only one eye is used, objects

appear, not in relief, but flat, just as an ordinary photograph is flat, as compared with a stereoscopic print. Usually persons do not notice this, since the forms of objects have become fixed in their minds.

Experiment.—At a short distance from the peep-hole are placed several cardboard shells, or hollow figures, in the shape of half cubes. The peep-hole is large enough for both eyes, but is covered by a plate with an aperture in it for one eye only. Look through this first, and the objects will appear to be perfectly solid cubes. On pressing the lever, so as to allow both eyes to be used, the objects will instantly be seen in their true character, that of hollow shells (one of the most effective of the experiments).

10. *Colours in Twilight.*—Characteristic colours exist only while the coloured objects are sufficiently strongly illuminated. With reduced illumination the "saturation" of the colours quickly falls off to nothing, even while the illumination is sufficient to allow of the outlines of the object being recognised.

Experiment.—Turn the lever slowly so as to gradually reduce the illumination down to the point of extinction. It will be seen that whilst an inscription in writing at the back of the cabinet can still be read when faintly illuminated the different colours of the letters and the ground have completely disappeared, all appearing more or less dark grey. (We did not find it possible to obtain this effect.—Eds. "B.J.")

11. *Small Differences in Brightness.*—A very small difference in brightness between two areas can only be recognised when the areas

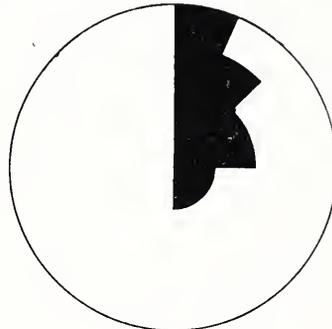

Fig. 2.

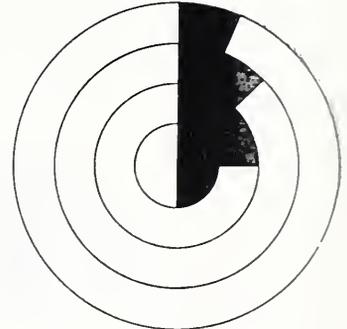

Fig. 3.

are quite close against each other. Even a very thin black line is sufficient to obliterate the differences.

Experiment.—At the back of the cabinet are mounted two cardboard discs marked in black, as shown in Figs. 2 and 3, the only difference between these being the continuous black circles, which in Fig. 3 separate the different annular spaces. The two discs being rotated by actuating a motor, the different annular tints do not appear the same in each. In those of the disc shown in Fig. 3 the areas appear equal in depth, whereas the different gradations of tone are clearly seen in those of Fig. 2.

12. *Colour Contrast.*—Where the grey area comes against a coloured one the grey obtains by contrast a colour the complementary of that of the area opposed to it.

Experiment.—A rod is placed in the cabinet in front of the peep-hole, and can be illuminated either by a white and a red light or by a white and a green light, the shadows due to the two lights being thrown on a screen at the back. It will be seen that in the case of the red and white pair of lights the grey shadows of the rod appear blue-green, whilst in the case of the green and white illumination the shadows appear red.

13. *Complementary Images.*—By tiring the eye for a given colour by allowing it to gaze steadily at it for some time, it will see in its place, when the colour is suddenly removed, a patch of the complementary colour.

Experiment.—Close in front of a white screen at the back of the cabinet a blue disc is placed, mounted so that it can instantly be put on one side by the outside lever. On looking at this for about a minute and then pressing the lever a pale yellow spot is seen on the white wall behind.

14. *Rotating Discs.*—If a screen is slowly rotated in front of the eye, the eye can distinguish the different parts of the screen; for example, the spokes of a wheel. With a greater speed of rotation these separate impressions disappear and the eye sees only a disagreeable flicker. With still greater speed the flicker disappears, and the

eye experiences the sensation of viewing a uniformly illuminated screen. The speed with which the disc must rotate in order not to show flicker is dependent on the strength of the light. The stronger the light, the greater the speed must be. In strong light this will be about 40 revolutions per second; in weak light about 20.

Experiment.—A disc in front of the peep-hole has drawn upon it a series of radii like the spokes of a wheel, and is illuminated by one lamp. On pressing a lever the disc is rotated by a motor, the speed of which can be increased until the flicker disappears. The speed of the motor can be read on a dial. On increasing the illumination by switching on another lamp the flicker re-appears, and to get rid of it the motor must be further accelerated, the nearly doubled speed being registered on the dial.

15. *Instantaneous Photography of Moving Objects.*—In cinematography the wheels of a carriage often show the appearance of turning backwards. The following experiment explains this curious phenomenon:—A rotating disc is observed through a similarly rotating disc placed in front of it. If the front disc is rotating more slowly than that behind, the latter appears blurred (slow shutter, rapidly moving wheel). When the speed of the two discs is the same that behind appears stationary. With a greater speed of the front disc, that behind appears to turn first slowly forwards, then slowly backwards. Finally, if the speed of the front disc (as in the shutter of the cinematograph camera) be twice as quick as that of the hinder disc (corresponding to the wheels of the carriage) all parts of the latter appear doubled.

Experiment.—The handle outside the cabinet regulates the speed of the motor, and allows of the appearance of the hinder disc being observed with different rapidities of the front disc.

16. *Intermittent Illumination.*—When light is broken into intervals so short that no effect of flicker is obtained, the eye obtains the total

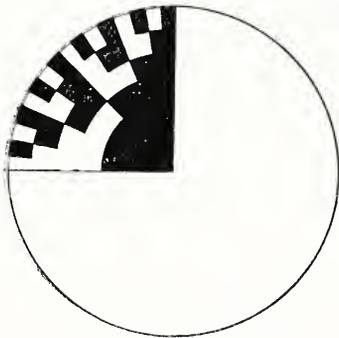

Fig. 4.

impression of the light, so that it is immaterial how often the light is interrupted.

Experiment.—By means of a disc having sector markings on it the light is interrupted about 40 times per second by the solid portion of the disc near to the centre, whilst the black portions near to the circumference of the disc interrupt it about 1,000 times per second, the total volume of light being the same in each case. On turning the disc by the motor the area is seen to be of uniform illumination from centre to circumference.

17. The rotating disc allows of very subtle differences in illumination being shown. In this way it can be seen how much stronger one light must be than another, in order that the difference is perceptible to the eye. It must be remembered that it is not the *difference* between the lights, but the ratio between them as regards strength, which is the factor in the case.

Experiment.—On turning the disc with a motor, grey rings are formed upon it as the result of the black sector marking. Although seven different rings are formed on it, only five can be actually seen in good lighting. On reducing the strength of the light these five rings remain visible (the fifth only weakly), as the ratio of the light intensities of the rings and of the white ground remains the same in all strengths of light.

18. *Properties of Colour-Tone.*—So far the experiments have dealt only with mixtures of black and white, but the rotating disc also shows the properties of mixtures of colours. Colours are mixed, and are altered in three separate ways:—First, a colour can be altered in tone without affecting its other characteristics. Thus colour can pass by imperceptible changes from red to blue, giving all the tones

between the two, such as purple and violet, the brightness and "saturation" of the colour remains the same.

Experiment.—A rotating cylinder is provided (as in Fig. 5) with alternating wedge-shaped regions of red and blue which

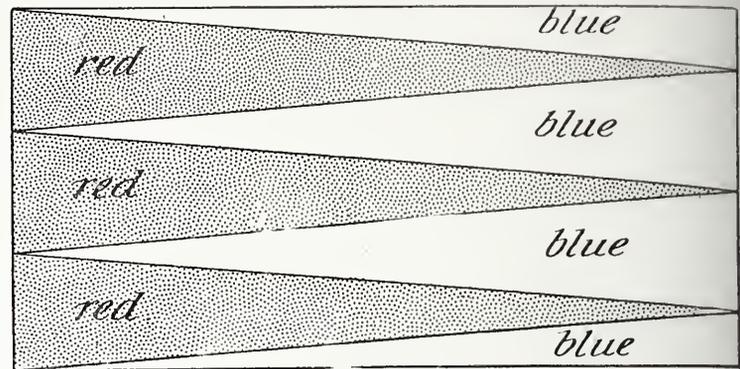

Fig. 5.

run the length of the cylinder. When this latter is rotated the mixtures of these colours in different proportions can be seen along the length of the cylinder.

19. *Properties of Colour-Brightness.*—The brightness of a colour depends upon its admixture with black or white. A colour may pass into black or white without alteration of its tone. The saturation

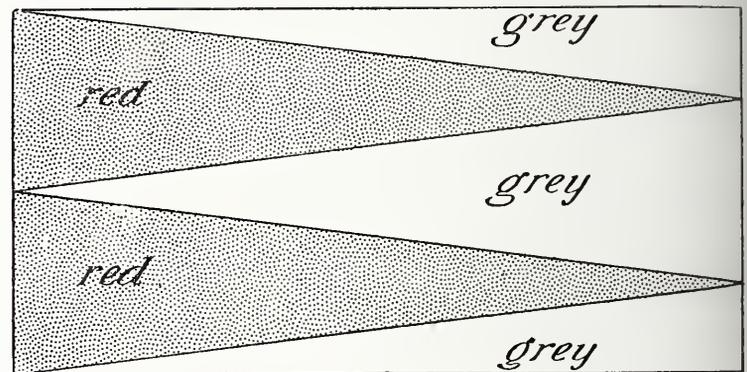

Fig. 6.

thereby sinks to zero, since black and white, as also grey, are quite unsaturated.

Experiment.—A cylinder is marked (as in Fig. 6) with wedge-shaped areas, alternating with similar areas of grey, both of which run the length of the cylinder, the latter being rotated by pressing a motor switch on the outside of the cabinet. The gradual alteration of the brightness of the colour due to admixture with grey is seen.

20. *Properties of Colour-Saturation.* (Degree of "purity.")—A

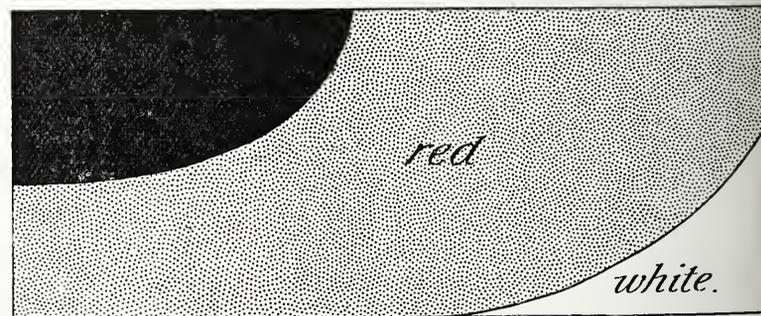

Fig. 7.

colour may be gradually changed into grey of equal brightness without its tone and brightness altering.

Experiment.—A cylinder, mounted as in Nos. 18 and 19, is provided with red, black, and white areas (as shown in Fig. 7). The rotating of the cylinder gives the various degrees of saturation of the red colour.

21. *Difference Between Black and White.*—It is most difficult to define the difference between black and white. It is said that a body is white when it reflects the whole of the light, but this is not correct;

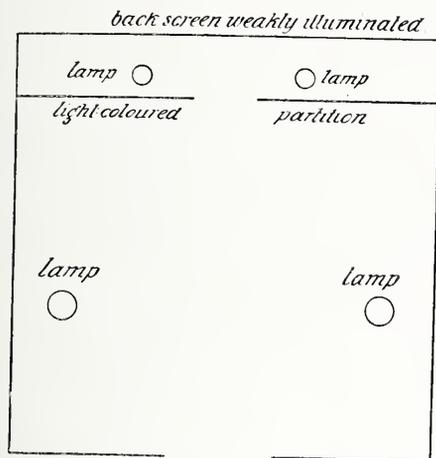

Fig. 8.

one and the same substance with the same illumination appears black or white, according to its surroundings.

Experiment.—Midway between the peep-hole and the back of the cabinet is placed a screen faced with a medium tint, with a central circular aperture in it. The back of the cabinet is somewhat feebly illuminated by lamps A and B, so that on looking into the peep-hole there is seen a white disc on a dark ground. On pressing the switch of lamps C and D, placed between the peep-hole and the mid-way screen, the hole itself appears perfectly black, whilst the screen looks white, a reversal of the previous conditions.

22. *Absolute Black.*—Thus, whilst the previous experiment shows that it is very difficult to say what is white and what is black, it is easy to affirm that no absolute black surface exists. Even the most dead-black can be made to look white in comparison with the absolute blackness of space.

Experiment.—A rather large aperture, about four inches square, is made in the front of the cabinet, the inside of which is lined with black velvet. A piece of black paper affixed to the outside wall of the cabinet appears perfectly black, but when held against the opening of the dark chamber the latter is seen to be very much darker.

23. *Different Kinds of Colour Mixture.*—In mixing colours there are two distinct methods. A mixture of colour sensations may be allowed to take place in the eye itself, or the mixture may be first made and the result thereof allowed to affect the eye. The first

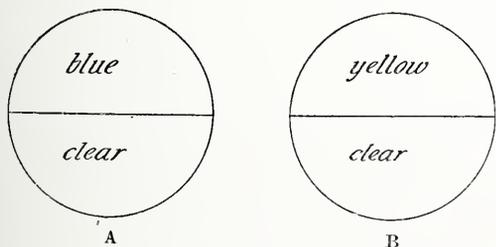

Fig. 9.

method is that known as "additive," the second as "subtractive." Almost all the most recent methods of colour photography are founded on one or other of these methods of mixture. The difference between the two will be seen from the following experiment.

Experiment.—Two pairs of discs, of the form shown in A and B (Fig. 9), are mounted together on the one axis. Pair No. 1 is so mounted that the blue occupies one full half-circle, the yellow the other, without overlap. In the case of pair No. 2 the blue and yellow semi-circles wholly or partially cover each other. On looking through the peep-hole and putting in action the motor which rotates both pairs of discs, it is seen that the light from pair No. 1, consisting of the two complementary colours, blue and yellow, mixes in the eye and produces white. In the case of pair No. 2, the mixture takes place before the light reaches the eye. The action in the first case

is additive. In the second case, the nearer of the two plates subtracts the light transmitted by the first.

24. *Additive Mixture of all Colours.*—The first and most important law of additive mixture is that all colours mixed in equal proportions give a result in which there is no colour.

Experiment.—A disc is provided with sectors of the different colours, the result of rotation being simply to give a uniform grey.

25. *Primary Colours in Additive Mixture.*—It can be shown that all possible colours can be prepared from three only. It is almost

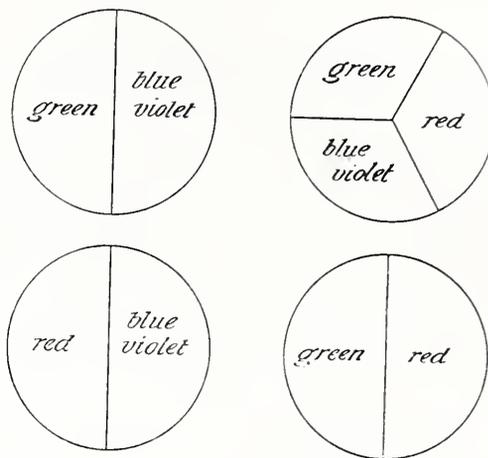

Fig. 10.

an invariable rule in additive mixture to take orange, green, and blue-violet as the three primary colours.

Experiment.—Four discs are mounted so as to rotate together on touching the switch of the motor. The colours on the discs are shown in Fig. 10. The disc with orange, green, and blue gives white, whilst the primary colours in pairs give additive colour mixtures. An important characteristic of the mixed colours is that they are appreciably more whitish than the primary colours.

26. *Primary Colours in Additive Mixture.*—In the choice of three primary colours one is not tied down to orange, green, and violet: any other group of three colours which splits up the spectrum may

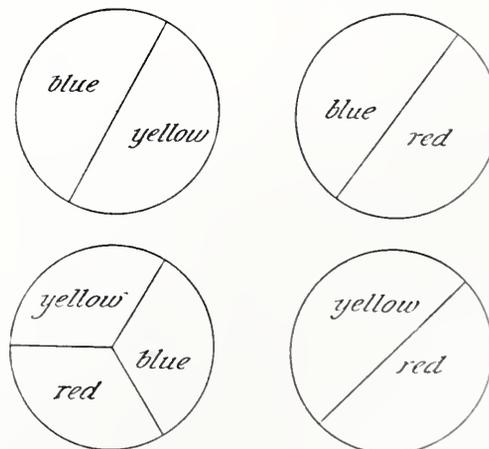

Fig. 11.

be chosen as a primary system, but in other cases the mixed colours are seen to be distinctly more whitish than in Experiment 25.

Experiment.—The four discs rotated from a single motor, as in Experiment 25, are made up with yellow, red, and blue as the primary colours. These three together give white, whilst yellow and red give an orange, blue, and red-violet, and blue and yellow-green. The green with this choice of primaries is much too whitish.

27. *Colour Mixture by Defective Vision of the Eye.*—A method of colour mixture, which is of importance in colour photography (screen-plates), depends on the incapacity of the eye to see perfectly sharply. If a series of lines or dots be placed so near together on a surface

that the eye cannot distinguish them the result is no longer that of the separate lines, but mixture (additive) takes place of the different colours.

Experiment.—A plate ruled with coloured lines, to the number of about 100 to the inch, is placed in an aperture of the cabinet and illuminated from inside. Examined closely, the separate green and red lines can be seen. At a distance depending on the sharpness of vision, the plate appears brownish-yellow, due to the mixture of green and red.

(To be continued.)

Photo-Mechanical Notes.

Measurement of the Height of Blocks.

Blocks as supplied to printers are often not exactly type-high and the machine-minder has to spend considerable time in underlaying them until he gets them right by repeated trials. A machine applying micrometric measurement to this end has now been placed on the market, and should prove exceedingly useful both to blockmakers and printers. The block, which may be any size up to 15 in. in one direction and any length in the other, is laid on the bed of the machine, and a spring released. This brings a bar into contact with the block. The bar controls a pointer which indicates on a scale exactly how much the block is above or below type height. This scale could be marked in any unit desired; in the machine sold to printers it reads so many sheets of paper of a certain thickness. Thus the machine-minder after placing his block on the measurer knows instantly that he must take so many sheets of such paper to bring it to type height and no time is wasted. The machine is sold at £3 10s., by Morton and Co., 32, Emerald Street, Theobald's Road, London, W.C.

Labour-Saving in Process Work.

There is no doubt that the introduction of the etching machine is affording opportunities for economies in labour, sometimes in unexpected directions. It has always been felt that the etching staff might be affected, but now several firms are finding that it is more economical and more satisfactory to have any large spaces deep etched in the machine instead of routed out. Now this will not necessarily affect much the man who did the routing, because the same man usually does the mounting also, though it will affect this sort of labour in large-scale businesses where the avoidance of a considerable amount of routing may give the opportunity of dispensing with, say, one man's services. But nearly all routed work has to be "scorped" round by an engraver, either before or after routing; if before, to make an outline to guide the router, if after, to remove any burr formed by the tool, or to cut away close to the work where the routing tool has been unable to approach. This work being no longer necessary, the engraver has been dismissed. In another department the very great improvement of late years in the character of the dot negative is also affecting the etcher, in this case the "fine-etcher," many of whom are finding their services no longer necessary. On the other hand, the preparation of the original before reproduction is becoming increasingly common, and photographs can nearly always be "touched up" with advantage before being placed on the copy board. This is a direction to which the fine-etcher should turn his education. He must be able to draw, but then a man should not be a fine-etcher without knowing how to draw well, and he must realise that there is a good deal to learn before his efforts are likely to be satisfactory, but it appears to be worth while, since this is a field that is increasing, while fine-etching is undoubtedly decreasing.

THE "FINANCIAL NEWS" HOLIDAY NUMBER, which was presented with the ordinary issue for Monday last, contains a quantity of useful information in concise form for the tourist, whether at home or abroad, including such practical items as routes, fares, names of chief hotels, etc. Two large-size maps—one of Great Britain and the other of Central Europe—add considerably to the value of the publication.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between June 1 and 5:—

FILM-PACKS.—No. 12,932. Improvements in photographic film-packs and films therefor. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

FILM-PACK ADAPTORS.—No. 12,933. Improvements in adaptors and camera backs for photographic film-packs. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

PLATE ADAPTORS.—No. 12,934. Improvements in adaptors and camera backs for photographic plate-holders and film-packs. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

CINEMATOGRAPHS.—No. 13,030. Improvements in cinematograph cameras and projectors. Leo Kamm, 27, Powell Street, Goswell Road, London.

CINEMATOGRAPH-PHONOGRAPH.—No. 13,031. Improvements in synchronism between cinematograph projectors or cameras and talking machines. Leo Kamm, 27, Powell Street, Goswell Road, London.

SHUTTERS.—No. 13,032. Improvements in cinematograph shutters. Leo Kamm, 27, Powell Street, Goswell Road, London.

LENSES.—No. 13,170. Improvements in or relating to the manufacture of lenses. Alfred Julius Boulton, 111, Hatton Garden, London, for the Bausch and Lomb Optical Co., United States.

RACKS.—Improvements in supporting racks for use in photography. Edgar Delacourt Smith, 15, Coniston Road, Muswell Hill, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CASEIN-PIGMENT PRINTS FROM BROMIDES.—No. 19,297, 1908 (September 14, 1908). The invention relates to the preparation of carbon or pigment prints from bromides or other silver prints by contact without exposure to light, somewhat as in Manly's Ozobrome process.

According to Manly's Patent No. 17,007 of 1905, the reduction of chromates by silver images has been already used for manufacturing pigment pictures by means of gelatine pigment paper. The process is said to be also suitable for pigmented gum printing. No good results have been, however, obtained with pigmented gum up to the present, whilst the first method is intended to be carried out with the use of a finished pigment paper. When using casein as a colloid, casein in any shape, the so-called curd, which is usually insoluble in water, or acid or alkaline solutions of the same are mixed with colours which do not make the casein more insoluble. While casein is, as a rule, insoluble in cold water, means are known to make it soluble. The colours which are used should not be such as those derived from metals, which render the casein quite insoluble in water.

The mixture is put on by means of brushes or a roller, on a silver print either fixed or unfixed, whereupon the latter is left to dry and placed with the casein coating in a solution of ferricyanide of potassium and bichromate, to which can be added for accelerating the action a halogen salt of the alkalis, e.g., potassium bromide. The silver reduces the ferricyanide of potassium, and the ferrocyanide produced reduces in its turn the chromate, which renders the casein insoluble in hot water, to which could also be added slightly alkaline salts. After all soluble pigment casein is dissolved, the silver compounds are removed by hyposulphite of soda, whereupon the fixing salt is washed out and the pigment picture is finished.

The appearance of the pictures differs considerably from that of

the gelatine pigment pictures. They have not the reflections in the deep shadows which often have a very disturbing effect. According as dissolved or undissolved casein is used, the appearance of the picture is different; when the latter is used the pictures have the appearance of photo-engravings.

If it is desired to produce pictures in several colours, two processes can be used.

The separate casein colour mixtures are put at the desired places on the picture to be converted into a multi-coloured one, and after the picture has been completely covered with a layer of casein paint or colour it is treated as described; or the whole picture is first covered with pigment-casein of the predominating colour, and the process carried through up to the fixing. The casein mass is again wiped or rubbed off from the still moist picture at the places which are to have a different colour. This can be done very easily, although the casein mass is only slightly sensitive to a jet of water. The remaining mass is preferably hardened with alum or other tanning substances, and left to dry. After the drying the converted silver picture is treated in the exposed portions with any desired developer, and after the latter has been washed off, the process is repeated with other colours.

The proportions in which the colours can be mixed with casein differ considerably. They depend first of all on whether it is desired to put the colour on by means of a roll or by means of a brush. For rolling on, the casein must be of greater consistency than for putting on by a brush.

It is also possible to add other colloids, such as gum-arabic, fish-glue, gelatine, etc., if it is decided to affect the solubility or the spreading capacity. The casein colour mixture can be, of course, also diluted to such an extent that it will be possible to let the silver picture float on the liquid.

The following is an example of carrying out the process:—

250 gms. of pressed-out curds are thoroughly ground with 50 to 60 gms. of water-colour, the mixture is spread uniformly on a previously hardened bromide print. After the drying the picture is left for ten to fifteen minutes in a bath of solution consisting of 10 gms. bichromate of potassium, 10 gms. of ferricyanide of potassium, and 10 gms. of potassium bromide in 1,000 gms. of water, then the picture is placed into water of 105 to 125 deg. F., to which can be added a small quantity of alkaline salts, such as, for instance, oxalate of potash, bicarbonate of soda, etc., in order to get the lights clearer. When alkaline casein solution is used, the picture partly develops in the bath of chromate. If desired, a small quantity of an organic acid—for instance, 0.5 to 1 gm. of citric acid—can be added to the chromate bath. After complete development, the fixing is done in hyposulphite of soda (1:10), the latter is washed out, and then, if necessary, a 5 per cent. alum bath is used for hardening.

The possibility of making the casein, or the mixture of casein with the metal salts, insoluble in hot water, in the manner described, is not the only possible method. Another method when starting from a silver picture is as follows:—

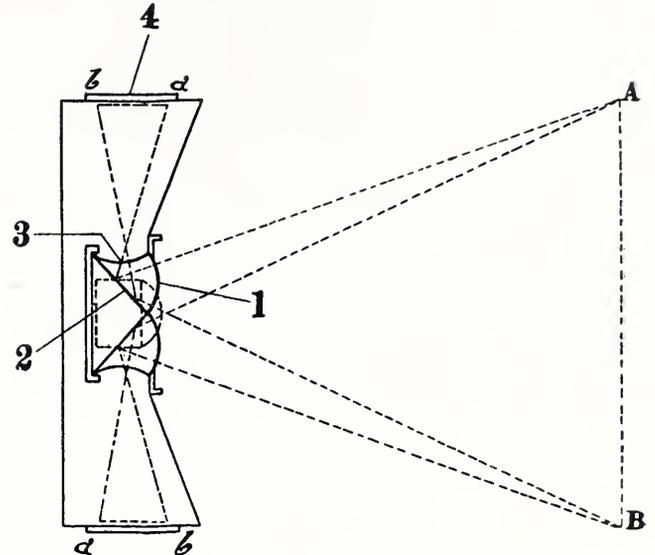

A silver picture is left in a bath of a 5 to 10 per cent. solution of ferricyanide of potassium until it is completely bleached. The ferricyanide salt is washed out, and the picture covered with casein pigment mixture. After the drying, the picture is placed into a bath of a solution of, say, 2 gms. of potassium bromide and 2 gms. of bichromate of potassium in 100 gms. of water for ten to fifteen minutes, then it is washed with warm water and fixed with hyposulphite. A J. Boulton, for Neue Photographische Gesellschaft, 27, Siemens Strasse, Steglitz, Berlin.

LENS FOR COLOUR PHOTOGRAPHY.—No. 27,793, 1908 (December 21, 1908). The present invention relates to a photographic objective composed of two, three, or more objectives of a prismatic triangular form, of which one face receives the rays of light from another face acting as a front lens, directing them towards the third face, which acts as a back lens.

In this manner three distinct images of the same object are formed on the three sensitive plates placed at the three sides of the apparatus, or on a photographic film placed round the three sides.

In the drawing showing a section of the objective described above, 1 is convex face of the prismatic objective; 2, plane face of the prismatic objective; 3, concave face of the prismatic objective; 4, sensitive surface.

These prismatic objectives cut in the same way (one face being plane and the other two having a curvature such that their combined refractions at the entrance and exit of the rays produce the effect of a convergent meniscus) are placed one beside the the other in the same frame so that the distance between their optical axes is less than two centimetres. The rays emitted by the object A B, entering the prismatic objective by the convex face 1, are totally reflected from the plane face 2, and are refracted by the concave face 3. These rays then form a real image on a b, and at this place is a sensitive surface 4.

This objective could also be composed of two prismatic triangular objectives as described above, and of an ordinary photographic objective, this latter forming its image in the back of the apparatus.

It is needless to say that the foci of the three prismatic objectives are exactly the same, and that they give three identical images, allowing exact superposition. It is already known to employ a mirror, and triangular prisms serving as a convergent lens, arranged in such a manner that one of the faces being plane, the two others have a curvature such that their combined refractions at the entrance and exit of the rays produce the effect of a convergent meniscus. Moreover, it will be understood that no novelty is claimed for this kind of prism, but only the disposition one by the side of the other of three similar prismatic objectives, so as to form three images in a different sense, as well as the utilisation for three-colour work of prismatic objectives arranged in this manner. Société Anonyme, La Photographie des Couleurs, 24 Courte rue de S'Hapital, Antwerp, Belgium; Joseph Sury, Wyneghem, Belgium; and Edmond Bastyns, 29, Rue des Tanneurs, Antwerp.

DEVELOPING ROLL FILM.—No. 11,162, 1908 (May 22, 1908). It has heretofore been proposed as described in Boulton's (Blair's) Patent Specification 5,504 of 1893 to manufacture a flexible apron for supporting a photographic film, the apron being provided with transverse wooden slats having raised edges between which the film

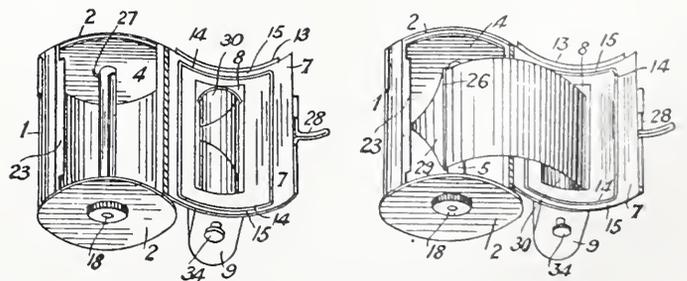

Fig. 1.

Fig. 2.

rests for the purpose of preventing contact between the coils of the film when rolled up with the supporting apron. Also as described in Fiedler's Patent, No. 14,714, of 1902, to manufacture a celluloid apron provided with raised corrugated rubber edges. Also as

described in Thompson's (McCurthy's) Patent No. 21,243, of 1899, of a casing in which a photographic film is placed, to be therein developed and treated without the use of a dark-room and without the necessity of opening the casing during the various steps of developing and fixing.

The object of this invention is to carry out all the operations in and relating to the development of photographic films in the form of daylight-loading spools (so-called roll films) by daylight or by any actinic light, without the employment of a separate dark chamber or box for transferring the exposed film to the developing reel or flexible apron. The developing chamber, in conjunction with the removable spool box, forms a suitable transferring chamber.

The following is a suitable form of apparatus for carrying the invention into effect:—There is provided a chamber, box, or casing of metal or other suitable opaque material (and preferably of a cylindrical shape), with closed ends which are fitted with small holes for the inlet and outlet of air and liquid, these holes being trapped so as to prevent the entry of light. This chamber is provided with a lateral opening, covered light-tight by a hinged door. This door has an aperture which can be covered when required by a spool box adapted to receive the spool of exposed film to be treated as it comes from the camera. This spool box is adapted to slide over or otherwise cover the aperture in the hinged door, so as to exclude the light. Within the chamber is provided a flanged reel with spindle which can be rotated from the outside of the chamber. The film is wound on a flexible apron with thickened edges of rubber or other suitable material having longitudinal ribs,

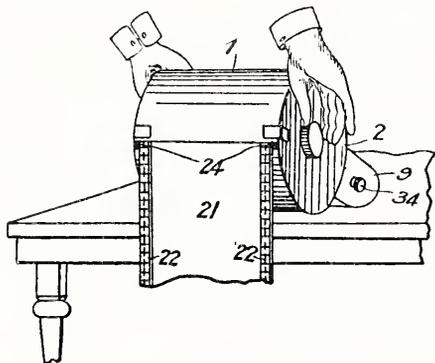

Fig. 3.

the apron itself being made preferably of celluloid; the thickened edges are by preference attached to the apron by stitching along the depressed centre of each thickened edge. The apron can at one end be clipped or otherwise attached to the reel spindle and coiled round it together with the film. The thickened edges of the apron keep the sensitive surface of the film from contact with itself and with the supporting apron, as is well known. Within the chamber or casing is provided an inner portion of a wall bent to the curve of the outer wall, and between the two there is a space or channel. This inner wall extends from end to end of the chamber, and, in conjunction with the ends of the chamber, forms a light trap, the space or channel between the two walls also forming an aperture for the passage of the flexible apron.

In using the apparatus the method consists in first attaching the loose end of the film to its black paper wrapping, then placing the spool in a spool box, which closes an aperture in a door hinged to the casing; next drawing the end of the black paper through the aperture, attaching the end to a reel spindle in the casing, rotating the spindle till the "stop" mark appears on the black paper, passing the end of the film apron into a circular inner channel in the casing, attaching the end of the apron to the spindle, closing the door, rotating the reel till the whole of the film has been drawn into the casing and wound on the reel, removing the spool box, and, if desired, sliding a lid over the aperture in the door, and immersing the casing and its contents in the developing fluid, the parts being so constructed that light is excluded during changing and development. James Wyndham Meek, 32, Albert Road, Stroud Green, London, N., and David Brown Thomas, 119 and 120, Finsbury Pavement, London, E.C.

CHEAP ENVELOPE PLATE-HOLDERS.—No. 10,555, 1908 (May 15, 1908). This invention relates to improvements in photographic plate-

holders of the class wherein holes are provided in the plate tray which engage with pins on the adapter or camera for retaining the sheath when the envelope shutter is withdrawn for exposure, and stops on the envelope cover to prevent the complete withdrawal of the envelope from the casing.

Plate-holders of this class being destroyed after use, in order to render them commercially practicable they must be of very cheap construction. The invention consists of a particular construction and arrangement of the plate-holding tray and removable envelope, which, while being easy of manufacture, will be light-proof and efficient in use.

Fig. 1 is a perspective view of a back of camera designed to accommodate the plate-holder, with a plate in position ready for

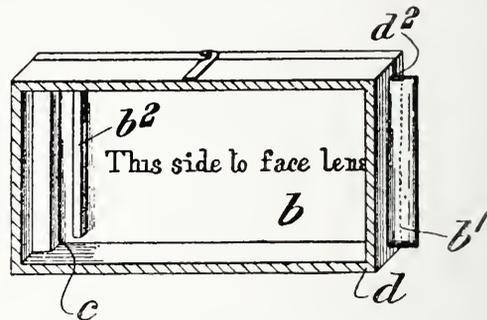

Fig. 1.

exposure and view from the front of the camera, while Fig. 2 is a view of Fig. 1 with a corner broken away and the plate shown exposed.

In these drawings *a* designates a shallow tray of stiff light-proof paper or cardboard with its ends closed by wooden or other stiff members *a*¹, and the plate is arranged in this tray with its sensitive surface uppermost. To accommodate the plate-holding tray *a* there is provided an envelope *b* of light-proof paper or cardboard, and the closed end *b*¹ of this envelope may be stiffened and rendered light-proof by means of an inserted piece of material *b*¹ glued or otherwise fixed in position, or in folding the envelope simply the thicknesses may be glued together.

Upon this envelope it is proposed to give an indication as to which side is to face the lens of the camera so that the plate will be exposed with the sensitive side facing the lens.

At that end where the open edge of the envelope meets the end

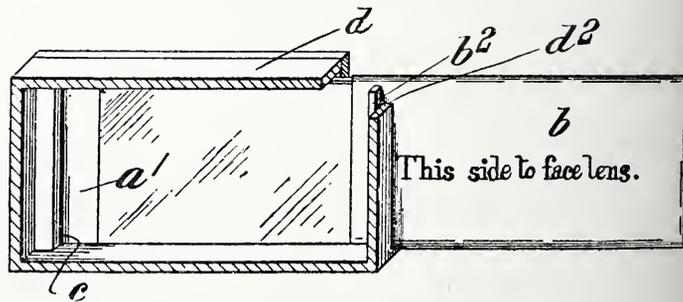

Fig. 2.

of the tray carrying the plate is arranged a felt or other strip *c* so that the open end of the envelope will be embedded in this strip, and thus obviate any danger of light entering. The inner preferably wooden end *a*¹ of the plate-carrying tray *a* is provided with a small hole or recess, or several such holes or recesses *a*³, and in operation these holes engage on a pin or pins, *d*¹ in the camera *d*. When the plate in its holder is arranged in position the camera is closed up and the closed end *b*¹ of the envelope *b* projects outside the camera.

In order to prevent the envelope being drawn too far, a projection *b*² is provided, which engages with the wall of the camera, through a slot *d*² in which the envelope passes. After the plate has been exposed the envelope is again pushed in, when the plate can safely be removed for development.

It may be found necessary to provide the plate-carrying tray

with ledges or lips to obviate any liability of the plate falling out of position when the envelope is drawn off. Robert Marriner Painter, 21, Preston Road, Brighton, Sussex.

New Trade Dames.

ILFORD ALLIANCE (LABEL).—No. 312,008. Photographic dry plates and films and all other photographic goods included in Class 1, but not including glycerine. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers, and films. April 5, 1909.

Analecta.

Extracts from our weekly and monthly contemporaries.

Placing Plate and Subject Parallel.

In the issue of "Photo-Notes" for June the method devised by Mr. Montague Troup for securing the parallelism of plate and subject when photographing a painting or other original is described as follows:—

A white metal tube, six inches long, $1\frac{1}{2}$ inches in diameter, and not less than 1-16 thick, is fixed at right angles to the centre of a piece of blackened board six inches square and one inch thick. To each corner of the board a piece of narrow tape is attached, and this completes the apparatus. For the sake of portability the tape is made detachable, fitting over a short piece of inner tube permanently fixed to the board.

To use the instrument it is placed against and in contact with the object to be photographed, as near the centre as possible, and the four pieces of tape are fixed with pins to the edge of the frame or board, stretching them tightly, so that the tube stands at right angles to the object. The camera is then set up and the image brought to the size required.

On looking at the screen the instrument will show as a white tube with a black centre, standing forward on a black border.

As long as the screen in the camera is not truly parallel to the object we shall see the white tube elongated on one side, but as soon as the camera and object are truly parallel the front edge of the tube will show as a true white circle, with a black centre and black background. The entire operation is very simple and takes no time to complete, while the instrument can be made out of the simplest materials.

Ozobromes in Colour.

Writing on the above subject in "The Amateur Photographer and Photographic News" for June 15, Mr. W. Ermen says:—"Let us suppose that we have an open landscape, in which there is a blue sky with white clouds, green hills, water, ships, and beach. Make a good bromide print of this, and after washing thoroughly, rinse in dilute formaldehyde and allow to dry. The sand, and any other portion of the picture which is wanted yellow, is carefully washed over with a brush just moistened in ozobrome stock solution until bleached, and the print then flooded with water, so that the excess of solution is washed off without damaging the rest of the print. The whole print is next treated with marine blue ozobrome tissue, which gives us the landscape all in blue, except the sand, which is left bare of pigment.

The print must now be dried again, to enable the newly deposited gelatine to stand the next processes.

When quite dry take a fine camel-hair pencil, just moistened with a strong developer, and go over all the portions of the print that are required black, such as the hulls of ships or rocks. With a weaker developer clouds may also have their shadows slightly emphasised.

For the production of greens we proceed in the same manner, only using sodium sulphide solution of the ordinary toning strength. The yellowish tone of this combines with the blue pigment deposited to give just the dull green required for grass. The tone of green can be modified at will by varying the amount of sulphide applied, and can be shaded off to the blue of the distance without any difficulty.

Finally, the yellow sand is got by painting the portions of the print which were bleached before pigmenting.

The finished print is finally fixed in hypo after a slight washing to remove the last traces of developer and sulphide.

The introduction of other colours into our print offers no difficulty. Suppose that in the print which we have already discussed we wish to bring out a red sandstone wall running over the hill. Those portions of the print reserved for red are protected by a preliminary bleaching. The print is then manipulated as before, but instead of fixing after sulphiding, the reserved portion is redeveloped instead of the rocks and the ships. The print is then washed and rinsed in formaldehyde, and dried to harden the pigment layer. The ozobrome manipulation inserts red pigment on all the developed portions. A slight reddish tint may show on other light portions of the paper, but this can be scrubbed off without fear of disturbing the underlying blue pigment, which not even boiling water will remove. Further layers of colour can be put on to any portion of the unsulphided portions by redeveloping as before, after drying with formaldehyde. The last stage is always the blackening with developer where required followed by fixing.

One word of warning. If the sky is reserved by bleaching, with the object of putting on the blue layer last of all, the pigment tissue must not be allowed to remain too long in contact with the print, or else the sky will come out much too dark. I expect that this is due to the insolubilising action of developer left in the paper, which is subsequently oxidised by the ozobrome solution."

New Books.

PHOTOGRAPHY WITH SMALL CAMERAS.—Just as many people are debating in their minds the expediency of replacing the cumbersome outfit by a slim pocket-camera, the "Photo-Miniature" appears with a very useful manual of photography with the small camera. Therein is pointed out the advantages of this type of instrument as regards depth of focus and certainty of action. The writer confines himself to cameras in the British and American markets which take a plate or film less than quarter-plate size, and those who would become acquainted with the recent great advances made in pocket cameras can have no better or practical source of reference. The monograph further describes advisable methods of developing, printing and enlarging such small negatives. The number (No. 97) is obtainable in England from Messrs. Dawbarn and Ward; in America from Tennant and Ward, 122, East Twenty-fifth Street, New York.

CATALOGUES AND TRADE NOTICES.

ILFORD GOODS.—A full catalogue of the plates and papers, and photographic accessories for use therewith, has just been issued by Ilford, Limited, and will be sent post free to any applicant. It very conveniently specifies the materials manufactured by the firm, and will be useful both to dealers and users on account of the full list of all the sizes, from small to large, in which an Ilford plate or paper is supplied from stock. The prices are very cleverly displayed for rapid reference, a point for which a dealer, who has often to turn to a list in a hurry, will bless the Ilford Company.

ROSS CAMERAS AND LENSES.—A new list just issued by Messrs. Ross, Limited, from 3, North Side, Clapham Common, London, S.W., gives details of the latest manufactures in lenses and cameras, among which latter is the new "Panros" camera, with its new focal-plane shutter of most convenient adjustment. The list, as also one of binoculars, telescopes, etc., is sent free.

THE WESTMINSTER PHOTOGRAPHIC EXCHANGE, LTD., in issuing the 1909 edition of their comprehensive catalogue, have evidently spared no effort in endeavouring to make it of value to intending purchasers of photographic apparatus or accessories. The 240 pages are well illustrated, contain up-to-date particulars of the apparatus, etc., at present on the market, and certainly confirms the company's claim that they are prepared to supply "everything photographic." The list before us deals exclusively with new goods, but the Westminster Exchange also make a specialty of second-hand apparatus, lists of which are published periodically. Those in need of anything photographic cannot do better than obtain a copy of

this new catalogue, or, if in London, visit the company's premises at either 119, Victoria Street, Westminster, S.W., or 111, Oxford Street, W.

"A HOBBY FOR YOU" is the title of an illustrated price-list of the photographic apparatus and accessories supplied by Messrs. A. E. Coe and Son, of 32, London Road, Norwich. A perusal of the booklet, which is tastefully got up, shows that Messrs. Coe fully realise the requirements of the present-day photographer, and tourists visiting or passing through Norwich would do well to note the fact that at the above address they can replenish or add to their stock of photographic materials. Particulars of a number of electrical specialties are also included in the list.

PHOTOGRAPHIC MACHINERY.—The well-known firm of August Koebig, of Radebeul, Dresden, manufacturers of photographic manufacturing machinery, have just issued a large new catalogue fully describing the various types of machines made by them for the coating, drying, cutting, etc., of plates and papers. This new list is in German, but Messrs. Koebig inform us that they are shortly issuing an English edition, which will describe their well-known machines in the necessary detail.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 19.

Birmingham Photographic Society. Excursion to Haughmond Abbey and Woods.

SUNDAY, JUNE 20.

United Stereoscopic Society. Outing to Botolph-Clydon.

MONDAY, JUNE 21.

South London Photographic Society. "The Eye and the Camera." Dr. A. R. F. Evershed. Monthly Competition—(Prints.)
Southampton Camera Club. "Radiography." W. P. Purvis.

TUESDAY, JUNE 22.

Kinning Park Co-operative Camera Club (Govan). Club Meeting.
Hackney Photographic Society. Negative Retouching. "The Improvement of Bromide Prints with Meglip." S. Woodhouse.

WEDNESDAY, JUNE 23.

Worthing Camera Club. Outing to Shoreham.

THURSDAY, JUNE 24.

Handsworth Photographic Society. "Flower Photography." A. A. Major.
Sale Photographic Society. Sale Portfolio.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday June 11. Present, Messrs. H. A. Chapman, J.P. (Swansea), Lang Sims, Gordon Chase, A. Mackie, A. Ellis, W. Illingworth (Northampton), S. H. Fry and C. S. Skillman; Mr. Lang Sims, President, in the chair.

The hon. secretary reported that the Association was dealing Elliott, had been summoned to give evidence before the House of Commons Committee on the Berne Convention for Tuesday, June 15.

A long discussion took place upon the commission charged by certain press agencies, and it was finally agreed that the hon. secretary should communicate with a number of agencies inquiring their terms, the information to be available to members.

The hon. secretary reported that the association was dealing with two important infringements of copyright cases on behalf of members. In one of the cases it had been found necessary to place the matter in solicitor's hands.

In reference to the usual summer recess it was agreed that no meeting of the committee be summoned for July or August, and that a meeting be called in September only if the business required it.

Mr. W. Illingworth proposed that the meeting day of the committee be altered from Friday to Thursday in order to give country members greater opportunity for attending, Thursday being the early closing day in the majority of the towns, where the members were resident. After some discussion the proposition was carried. This decision will not affect the members' meetings, the dates of which are fixed by the rules.

It was further agreed that the meetings take place at 6.30 instead of heretofore at 6 o'clock.

Sundry accounts were passed for payment, and various matters discussed relating to the business matters of members.

HACKNEY PHOTOGRAPHIC SOCIETY.—On the 8th inst. a lecture on portraiture was given by Mr. C. Wille, who showed, by precept and example, that artistic portrait work is to be done at home with simple apparatus. The lecturer gave full details of his own methods, and the examples he showed proved such methods to be successful. Exposures were made in a room lighted by one window, and many variations of lighting were obtained by altering the positions of the sitter and camera relatively to the window. Mr. Wille advocated direct work for portraiture, as he thought that enlarging destroyed the tone quality, particularly in the high lights, so whole-plate was the smallest size to work at. The focus of the lens should be a long one, and supplementary negative lenses were useful to lengthen the focus of an ordinary lens. The lens aperture should be large, $f/5.8$ at least, as great depth of focus was not required, the lecturer being satisfied to get the nose and eyes of the sitter in focus. He gave a full exposure, which in his case ranged from 15 seconds upwards. He rarely gave less than 15, and sometimes gave as much as 25 seconds. He found that in such long exposures slight movement of the sitter did not matter, and the long exposure produced a better and more natural expression. These and many other points in Mr. Wille's lecture produced a long discussion, at the close of which the lecturer was accorded a hearty vote of thanks.

Commercial & Legal Intelligence.

A first and final dividend of 2s. 0½d. is to be paid to the creditors of Florence Pattie Brown, photographic chemist, trading as Mrs. G. W. Brown, Liphook, Hants.

NEW COMPANIES.

BIOPTICS, LTD.—Registered June 4, by J. G. Dalzell, 76, Victoria Street, Westminster. Capital, £1,000, in 950 ordinary shares of £1 each and 1,000 deferred shares of 1s. each. Objects: To carry on the business of photographers, manufacturers of and dealers in photographic cameras and materials and cinematograph films, proprietors of cinematograph exhibitions, etc. Private company.

J. WAGNER, LTD.—Capital, £500 in £1 shares. To acquire the business of a photographic paper manufacturer and printer, carried on by John Wagner, at 122, Beulah Hill, Upper Norwood. The first subscribers are: J. Wagner, Mrs. H. Wagner, and E. Wagner, all of 122 Beulah Hill, Upper Norwood, S.E. The first directors are J. Wagner and Mrs. H. Wagner (both permanent; special qualification, fifty ordinary shares). Qualification of ordinary directors, ten ordinary shares. Remuneration, one guinea each per meeting. Registered office: 122, Beulah Hill, Upper Norwood, S.E.

GEVAERT, LTD.—Capital, £5,000 in £1 shares. To carry on the business of manufacturers of and dealers in photographic materials, etc. The first subscribers are: L. Gevaert, Boulevard Leopold 168, Antwerp; P. Koep, 35, Rue d'Edeghem, Vieux-Dieu, near Antwerp; and C. J. Miller, 7, Rathgar Avenue, West Ealing Private company. The first directors are: L. Gevaert and P. Koep. Registered office: 26-7, Farringdon Street, E.C.

THE HACKNEY PHOTOGRAPHIC SOCIETY'S annual exhibition will be held from November 10 to 13 next. Full particulars will be published later.

MR. CHARLES H. HORTON writes that, owing to increasing trade he has removed his showrooms from 21, Lower Park Row, to larger and more commodious premises at 2, Christmas Steps, Bristol to which address all communications should in future be addressed. In addition to developing, printing, enlarging, etc., Mr. Horton makes a specialty of architectural and engineering photography for the purposes of catalogue illustration, and the buyer of picture post cards also will here find a large selection of views of Bristol and other places of interest.

News and Notes.

THE PARTNERSHIP between Messrs. F. R. Griffiths and A. J. Walmsley, exhibitors, manufacturers, and exporters of cinematograph goods and appliances, 1, 3, and 5, Cecil Court, Charing Cross Road, W.C., and trading as the New Bioscope Trading Company, has been dissolved.

DRESDEN EXHIBITION.—Messrs. Thomas Cook and Son, Ludgate Circus, London, E.C., send us a circular of fares to Dresden, and of tours in Germany, in which the visitor to the International exhibition may also visit Berlin, Leipsic, Nuremberg, Cologne, Wiesbaden, and other German towns.

MR. HAMMOND HALL, late editor of the *Daily Graphic*, has accepted the editorship of "Hazell's Annual" in succession to Mr. Wm. Palmer, who, after seventeen years' service, has resigned in order to devote himself entirely to his work as managing director of the Beds Times Publishing Company, Ltd., and editor of the *Bedfordshire Times*.

THE CURRENT ISSUE OF "CAMERA HOUSE JOURNAL," in addition to particulars of Messrs. Butcher's seasonable novelties, contains an article entitled "Di-chromic or Natural Colour Stereo-transparencies," which claims to be a new method of making colour photographs in which two colours only are employed. Full working directions are given, together with a list of the necessary materials and their prices for use with various makes of cameras.

ROYALTY UNDERGROUND.—Though many photographers have taken portraits of Royal personages, it is not often that they have the experience which recently befell Mr. John H. Coath, F.R.P.S., of Liskeard, by whom several negatives of the Royal party who recently visited Cornwall were taken at the bottom of the Phoenix mines, 1,000 ft. underground. The making of an excellent group negative under these conditions is a feat upon which Mr. Coath may be congratulated, as those who have seen the photograph reproduced in several of the illustrated papers will have recognised.

FREE PLATINOTYPE DEMONSTRATION.—The Platinotype Company are giving a demonstration of this beautiful process on Wednesday evening, June 23, before the South Suburban Photographic Society, at their headquarters, Plough Hall, High Street, Lewisham. By arrangement with the Society, any photographer interested, amateur or professional, will be welcomed at the meeting, and every facility will be afforded the inquirer who wishes to keep himself abreast of the latest developments. There will be no charge for admission, which can be obtained on presentation of business or private card. Professional photographers in the South London district may be advised to take a note of this fixture.

A CHINESE SHOWCARD is one of Messrs. Butcher and Sons' latest novelties, and is designed to illustrate the use of their popular cameras in China by the Chinese. The card, which measures about 20in. by 30in., is printed in colours, and depicts Chinese figures and landscape scenes, some of the former being in the attitude of posing for their portraits whilst others are manipulating the cameras. Although originally produced only for the Chinese market, Messrs. Butcher have now issued a limited edition for dealers at home, and those who have not yet secured one of these attractive advertisements should apply to Messrs. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

PHOTOGRAPHIC METHODS OF IDENTIFICATION.—Among the doctors attached to the French detective service (writes the "English Mechanic") there is some difference of opinion concerning the advisability of abandoning the present method of identification of prisoners—by finger-print—in favour of a new method, devised by an Italian professor, Dr. Tomassia, in which identification is proved by means of photographs taken of the veins on the back of the hand. Professor Tomassia bases his method on the observation that no two persons have the veins on the back of the hand so much alike as to allow room for confusion—less, indeed, than with finger-prints. The prisoner's hand is held downwards for several minutes, or the pulse at the wrist is restrained, and the veins are then photographed. This photograph, Professor Tomassia says, will always be available for explicit proof, whereas criminals now understand that

with an ordinary razor they can operate on their own hands without much pain or inconvenience, and may change the pattern of the finger-print beyond chance of identification. To burn the fingertips is more painful, but perhaps even more effective. On the other hand, as Professor Tomassia points out, only a serious and dangerous operation can modify the veinal system.

FIELD WORK FOR BEGINNERS.—The second of the series of beginners' outings arranged by the South Suburban Photographic Society will take place at Monk Wood, Epping Forest, on Saturday, June 26. As before, friendly assistance will be offered to beginners in the selection of a subject, as well as in matters of exposure, lighting, etc. Members and friends will meet at Liverpool Street Station, and travel by the 2.41 train to Loughton. Non-members are invited to join this outing.

CAMERAS FOR THE TROPICS.—The London Stereoscopic Company, Ltd., are now holding in one of their studios at 106-108, Regent Street, W., an exhibition of photographic apparatus supplied by them for use under trying climatic conditions, such as those of the tropics. In addition, an interesting collection of photographs is shown from negatives made in all parts of the world. The majority of these are 15 by 12 or 12 by 10 enlargements from very small negatives, and show the very excellent results to be obtained from the small negatives. The apparatus includes a number of examples of the company's products in the way of folding cameras, made in teak, with extra brass binding and bellows of Russian leather. The tropical model of the Goerz-Anschütz folding focal-plane camera is represented by one or two of the actual instruments, and some illustrations of fine work done with them. The Stereoscopic Company's "Vesca" pocket camera is supplied not only as a single instrument, with or without a detachable film roll-holder, but as a complete outfit, including folding fixed focus-enlarger, changing tent, chemicals, etc. The whole forms an ideal photographic equipment of the smallest bulk and weight, yet capable of giving first-rate results. Reflex and telephoto cameras also figure in the collection, a visit to which cannot fail to show the pains which the Stereoscopic Company have taken in the production of apparatus for the tourist in all quarters of the globe. The exhibition is open from 12 to 4 until July 4, and the features of the apparatus are courteously explained by a representative of the company.

TESTING PHOTOGRAPHIC SHUTTERS.—At a recent meeting of the Physical Society a paper on a new method of measuring the speed and efficiency of photographic shutters by Messrs. A. Campbell and T. Smith, of the National Physical Laboratory, was read by Mr. Smith.

A vibrating beam of light falling through a narrow slit on to a moving plate serves to measure the time. This beam is obtained by reflecting the light of a Nernst lamp from the mirror (area 50 sq. mm.) of a vibration galvanometer actuated by a current of fixed frequency (say 100 to 500 vibrations per second) obtained from a microphone hummer. The use of the vibration galvanometer, in which the amplitude is enormously increased by resonance, greatly facilitates the measurements.

When the total duration of exposure only is required, the vibrating beam of light is passed through the shutter, tracing a sine-curve on the moving plate. The duration of exposure is immediately found by counting the number of ripples recorded on the plate. Ten records of the various speeds of a shutter can be taken side by side on one 5in. x 4in. plate in one minute. The accuracy of the method was found to be within .0001 second (one ten-thousandth of a second), at the highest speeds.

When the efficiency, in addition to the duration of exposure, is required, the method adopted is essentially that of Sir Wm. Abney, but the time measurements are made with the vibrating beam of light instead of a screen. The sine-curve now extends over the length of the plate, and serves as a continuous time record, and is to be preferred to any intermittent method of measuring the time. A slit is placed in a diameter of the shutter-opening as close to the shutter leaves as possible, and an image of a line source of light is made to fill this slit. By means of a concave mirror an image of this slit is formed on the plate by the side of the vibrating beam of light. As the shutter opens, the length of the slit through which light can reach the plate increases, and the record on the plate gives the length of the slit, which is opened at every instant of time. Measurements are then taken of the area of the shutter aperture and

sponding to a number of lengths of the slit-opening. Combining these records the area of the shutter aperture at every instant of the exposure is obtained, and by integrating this area with respect to time the equivalent exposure at full aperture and the efficiency are calculated.

Mr. Baker expressed his interest in the method, which he said was the most satisfactory yet produced. It was difficult to say exactly what to call exposure. In photographing moving objects it was advisable to use as the effective time the time during which the central eight-tenths of the shutter was open.

Mr. Duddell said the method was an ingenious one for determining the efficiencies of shutters. He suggested that by using an arc it might be possible to reduce the size of the mirror and thus work at higher frequencies. Instead of using a slit it might be better to use a short focus cylindrical lens.

Mr. Campbell, referring to Mr. Duddell's remarks, said that with a Nernst lamp it was possible to obtain high frequency curves showing very little tendency to tail off.

Correspondence.

TELEPHOTO CALCULATIONS.

To the Editors.

Gentlemen,—May I point out that in the letter printed to-day on page 465 there is a mistake? The formula should be $\left(\frac{m+1}{n+1}\right)^2$.

Yours faithfully,

C. L. D.

THE SPEED NUMBERS OF PLATES.

To the Editors.

Gentlemen,—On reading the report of the Chemical Congress in your issue of the 4th inst., I note with interest the papers that were read on sensitometry, and the proposition coming from Sir William Abney, and it looks now as if something will be done towards standardising plate-speed marking.

Although most of the plate makers have adopted the H. and D. system, the results obtained by different makers are really too absurd. I enclose the results of tests of three different makes of plates for your observation. The tests were carried out under the following conditions: A Chapman Jones plate tester was placed in contact with a 175-line ruled screen, the screen being next to the plate and set at the usual working distance and exposed to the light of two Cooper Hewitt tubes reflected by a sheet of white blotting paper. The distance from the reflector, diaphragm and exposure were identical in each case, development 7 minutes with hydroquinone at 65 deg. Fahr.

No. 1 was marked H. and D. 15; No. 2, H. and D. 80; No. 3, H. and D. 95. Result: No. 1 is practically 50 per cent. faster than No. 2, and No. 3 is $2\frac{1}{2}$ times faster than No. 1, or to put it another way: If the H. and D. 80 is correct the 95 ought to be marked 320, and the 15 should be 120. All these tests are borne out by actual exposures on copies for half-tone negatives, so I can only repeat that the so-called H. and D. speed marking is absurd, and that the whole question seems to be in a state of hopeless muddle. It is difficult even to find two makers who give the same ratio between Wynne and Watkins.

Following a paper on exposure, which I gave before the Handsworth Society in March last, a resolution was drawn up calling attention to the present state of speed marking, and sent to the R.P.S. with a request that the matter be taken up seriously to endeavour to bring about a standard. A reply was received to the effect that the makers had already been approached, but that they each stood by their own rendering of the system, and that there was little hope of anything being done. So at the quarterly meeting of the Midland Federation on April 29, it was resolved to approach all the other Federations with the object of bringing pressure to bear from all quarters upon the R.P.S., and failing any

good result to endeavour to bring about some concerted action with the makers direct. I mention this simply to show, if this were necessary, that the movement is likely to have the heartiest support from all classes of photographers.

There is much to be said for the suggestion of Mr. F. W. T. Krohn of marking plates as slow, rapid, etc., when coming between certain fixed limits of speed, but the makers must be induced to use the same methods of arriving at these limits or we shall not be any better off than at present where one maker uses H. and D. 300 for the same speed of plate that another maker will mark H. and D. 150, or thereabouts, and many others dropping in between with various figures, and for what are for all practical purposes the same speed of plate, because everyone knows that fractional differences in speed are of no account whatever.—Yours faithfully,

E. A. BIEMANN.

[In the prints sent by our correspondent, 13 is just readable in No. 1, but not in No. 2. In No. 3 the highest readable number is 15. We give these data in place of reproducing the prints since differences of this kind are apt to suffer alteration in the course of blockmaking and printing.—Eds., "B.J."]

TRADE PROFESSION AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen,—I am very much surprised to see with what eel-like dexterity, "Fairplay," alias "Playfair," is trying to extricate himself from the scrape, but I am confident that the readers of your esteemed paper who will take the trouble to "dissect" his letter which appeared in your issue of the 28th ult., and compare it with my two letters of the 21st ult., and 4th inst., will probably agree with me that his words in the current issue are (politely speaking) hardly justified by the facts of the case. It strikes me, however, that I am perhaps too severe with "Playfair," and, after all, he is probably no more guilty for misrepresenting facts than a squinting person is for looking askint.

In that case I do not see what benefit the photographers' assistants will reap from this controversy, and since the modus operandi of the trades union artisan is not endorsed by "Fairplay," I would propose that, whilst "awaiting with curiosity a report of the proceedings at the proposed somewhat incongruous gathering together in solemn conclave of bricklayers and photographers' assistants," he should proceed to treat photography according to his simile—i.e., as "a patient in very poor health."

But before starting on this medical research it would be advisable, I think, that he provide himself with a good treatise on logic and carefully study the chapter on the construction of syllogisms, for this may help him to correct his squinting mind's eye.

May he act on my disinterested advice and thus enable us to soon peruse the first part of his medical thesis; meanwhile I hope some photographers' assistants will satisfy "Playfair" with the report of the proceedings, etc., and I remain, with best wishes for the realisation of some sort of union, yours very respectfully,

A. REDMOND.
4, Mildmay Road, N.

INTENSIFICATION MARKINGS.

To the Editors.

Gentlemen,—Although I have intensified probably many hundreds of negatives with mercury, both with and without hydrochloric acid, I have never to my recollection had any trouble of the kind stated by "Prof." I have, however, when washing the bleached plate under the tap, found that the "whirl" or vortex, caused by the flow of water, leaves a circular patch of different density, and sometimes of a slightly brown colour. As this patch always disappears on blackening I have never troubled about it, but it may bear some relation to the markings complained of. I have always understood that a very thorough washing is desirable between the mercury and the ammonia, though in an emergency I have given only ten minutes without any apparent detriment.—Yours faithfully,

D. BERLIN.

To the Editors.

Gentlemen,—In the "B.J." of this week I noticed a letter from "Professional" concerning streaky marks on plates intensi-

ed with mercury bichloride. I also have experienced them, but with continued circular rubbing with a tuft of cotton-wool immersed in a solution of iodide they always disappear.—I remain yours truly,
W. E. BURNETT.
Eversfield House, 5, East Cliff, Dover,
June 13, 1909.

Answers to Correspondents.

* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

G. Busby, 122A, Chepstow Road, Newport, Mon. Photograph of the Freedom of the Borough of Newport, Mon., being conferred on His Lordship, the Right Hon. Viscount Tredegar, June 9, 1909.

CASE (Swansea).—Certainly; there is no reason why you should not sell any photographic articles.

NEMATOGRAPHY.—Will you, through the medium of your columns, refer me to a good practical work dealing with the cinematograph? I especially desire some information with regard to the electrical details and operating.—F.

We should advise you to get "Animated Photography," by Cecil M. Hepworth (Hazell, Watson, Viney, Ltd., 1s.). You would also do well to study the "Kinematograph Journal" each week.

L.—18s. to 25s. Dark-room assistant.

"TRUE TO SCALE" PROCESS.—Having used the "true to scale" process with very indifferent success I should be greatly obliged if you would clear up the following. I used the "B.J." formula No. 1, and made up evaporation loss after, and still it was far stiffer than the usual office ink hectograph pad. Is this too stiff? If you could give me the action that takes place between the print and the jelly it would be easier to know in which direction to look for the cause of failure.—HECTOGRAPH.

So far as we know, no satisfactory explanation of the process or of the action of the iron salt has yet been given. We know of none. Evidently the effect is produced by insolubilising the gelatine in the line of the drawing. If the graph is too stiff you need only add a little more water to the composition. It should be a little stiffer than the usual hectograph office composition.

LENS QUERY.—I have a lens with the name "Vogel, Philadelphia, U.S.," and number "5,379" upon it. It has a small lens in the centre which is removable. As it is, its focus is 10½in., with the smaller (or between lens) out it is only 4½in. focus and only covers quarter-plate. The front lens alone is 7½in. focus, while the back part used alone is 15in. focus and covers half-plates well and sharp. In fact, it seems best of all. Can you tell me for what this lens was originally used and its market value, and about what would be its present worth? 2. Of late we have unconsciously been using potass. sulphocyanide instead of ammonia sulphocyanide for toning P.O.P. prints. Can you tell us the difference, and say if the one would do as well as the other for purpose named?—J. A. K.

1. From the description we should say that the lens is the old form of triplet. That lens was designed for such work as is now done with the rapid rectilinear, but it was much slower. It has

no market value now. 2. The difference is that the one is a potassium salt and the other an ammonium one. It is the latter that is usually employed for toning P.O.P. If you find the other answers your purpose there is no objection to its use.

BROMIDE.—Bromide would not give you surface veil; on the contrary, it would tend to density more deeply seated in the paper. We advise you to change the developer, say, to hydroquinone; and, if that does not remove the trouble, the paper.

RIGHT TO NEGATIVE.—I have been doing a quantity of 12 x 10 enlargements for a canvasser. He brings me any old photograph and I produce the enlargement finished. He now asks me for the negatives. I have refused, as I naturally think they belong to me. He says he has only to demand them to get them, as it is trade work.—RETOL.

Let him demand them. In no circumstances where a photographer supplies prints, etc., can any claim be made to the negatives by the customers, not even if, for special purposes, negatives have to be made and separately charged for. The negatives are your property, to be used for your customer.

PHOTOGRAPHING SILVER CUPS.—1. What is the means generally adopted by the most successful workers in the photography of silver cups and trophies? I have seen photographs in which the plain surfaces are quite free from reflections, although they had obviously not been frosted. 2. Can a flashlamp (magnesium and permanganate) be satisfactorily fired by the discharge from two motor bicycle accumulators, each of 10 amp. hours capacity, and if so, what gauge wire should be used for heating purposes? 3. What is the relation between the weight of flash-powder employed and the area to be illuminated? How much of the average powder distributed into two equal heaps at different points would be required to make a satisfactory exposure on a group, say, 20ft. wide and 30ft. distant from the camera, F.6 being employed?—D. W. (Oxford).

1. The only way is to be careful in the lighting so that there are no reflections from the plain surfaces in the direction of the lens. Direct front light should be shut off. Usually the surface is slightly dulled, say by pouring some ice-cold water into the vessels a moment or two before exposure, a film of moisture condensing on the outside. 2. You will find information on the subject on pp. 390 and 410 (May 14 and 21 last). 3. We should advise you to obtain a work by F. J. Mortimer, "Magnesium Light Photography" (Dawbarn and Ward, 1s.); but we would say that the colour and illumination of objects render any rule for the quantity of flash-powder apt to prove misleading.

FINGER-PRINT PHOTOGRAPHS.—Will you kindly inform me the details of process for taking copies of finger-prints before photographing them? I am at present taking the matter up, but cannot get information how the impression is taken from the object before the plate is exposed. What would be the procedure (1) for taking impression from glass; (2) from black surface, such as a cash-box; (3) from ruby surface, such as mahogany chair? I have obtained a satisfactory impression from the hand upon paper, so any process you can give me for the comparative transfer will be greatly welcomed.—JAS. DUNNING.

We do not think that, as a rule, any attempt is made to transfer the finger-print from the original object. It is photographed direct, using suitable filter-screens and colour-sensitive plates, and adjusting the lighting so as to show up the mark as much as possible. For advice as to suitable filter-screens you should consult Messrs. Wratten and Wainwright, who can supply screens for any special purpose.

HYPALUM TONING.—Will you kindly inform us through the "B.J." if a zinc tank would answer for hypo-alum toning of bromide cards, and if not, what material tank should be made of?—TANK.

Zinc would only withstand the hot bath for a time. A tank of enamelled iron or porcelain should be used.

PHOTOGRAMMETRY.—Kindly give me simple formulæ for calculating (a) distance of object—viz., house or town. (b) height of same, with lens of given focus, the corresponding light of image on screen and distance of screen from central stop, when focussed, being known. (c) is there a method through using two lenses—viz., whole and

single combination, knowing differences of focus and image?—**PROGRESSIVE.**

(a and b) The ordinary law of conjugate foci will give these dimensions. Subtract focal length of lens from the distance between plate and lens and divide the difference into the focal length. The result is the proportion of object to image and also of distance of object to distance of image. The most accurate method is to focus sharply on infinity and then measure the extra extension of the camera when focussing on the given object. Thus, suppose the focal length to be 6 inches and the extra extension $\frac{1}{4}$ -inch. Six inches divided by $\frac{1}{4}$ -inch, equals 24, therefore the height of the object is 24 times that of the image, and the distance is 24 times the distance of plate from node of lens. This method cannot be applied if the extra extension is so small as to be unmeasurable, and in such a case we cannot suggest a method. (c) We do not know of any method, based on the factors you mention, but one might perhaps be devised. The safest method of all in practice is to place a scale or rod of known length against the subject and photograph this with it. The scale of reduction is then clearly indicated.

DEFECTIVE NEGATIVE.—I would be much obliged if you can point out any error on the enclosed negative and a remedy for the blotchy surface. The plate is developed with metol-hydroquinone and fixed in hypo, 1 lb. to 40 ozs. water and alum $\frac{1}{4}$ lb. I seem to have most of my negatives coming blotchy this last few days, and should be glad if you will point out where I have gone wrong. I may say I have been taking photos this last five or six years and have not experienced anything like this before.—**NEGATIVE.**

Nothing can possibly be done to remedy the marks, as the gelatine is partly destroyed. It looks very much as if the plate had been treated with hot water. In any case, your fixing bath is twice as strong as it should be, and the alum should be left out. If you get the same effect with weaker fixing bath and solutions at normal temperature you had better refer the matter to the plate makers.

OLD NEGATIVES.—We have a quantity of old negative glass, and, wishing to dispose of same, would be pleased if you could furnish us with the address of a buyer.—**M McNAMARA AND SON.**

Chas. Bowen, 58, Grove Road, Holloway, N.

JEWELLING TINSEL.—Can you oblige me with the name of a firm who supply tinsel for jewelling postcards? They used to advertise in your columns, but apparently do not do so now.—**C. TESLA.**
Reinemann and Co., 7, New Zealand Avenue, London, E.C.

PORTRAIT LENS.—I have lately bought a second-hand lens, which was advertised as Dallmeyer's L.B. extra quick acting patent portrait lens, $f/3.15$. When I test the same I find it is 6 in. focus, and the diameter of the front glass is only $1\frac{3}{4}$ in., and it is, therefore, working at $f/3.4$. In Dallmeyer's list the L.B. is described as 2 in. diameter and works at $f/3$. The lens I have bought is only engraved J. H. Dallmeyer, 4307, London. Is it a genuine Dallmeyer lens, and should I be justified in returning it as falsely described?—**P. SYKES.**

Your calculations are quite correct, and a 6 in. lens must be at least 2 in. in diameter. Your best course will be to submit the lens to Messrs. Dallmeyer, who can at once give you definite information. If they state the lens is not genuine you can then send it back and demand the return of your money.

FIXING-BATH.—I would like to try the alum-hypo fixing-bath No. 13 given on p. 5 of your volume for 1908, but as the strength of the sodium acetate solution is not given, I am at a loss regarding this constituent of the bath. What should the strength of this solution be?—**RED PINE** (Ontario, Canada).

There was an error in the formula. The latter should read:—

Chrome alum	24 grs.
Hypo	$1\frac{3}{4}$ ozs.
Sodium acetate	80 grs.
Water	7 ozs.

REVERSED PAPER PRINT.—Some days ago I had occasion to make a bromide positive print, and used some old paper—it had been lying about several years—and an ordinary negative. On developing a paper negative was produced instead of a positive. Can you inform me the reason of this?—**S. W. WILKINSON.**

We have at times heard of this phenomenon, though we have no reason for putting it down to the age of the paper. In the case

of negatives on films (on which it most commonly occurs, in our experience) the most probable cause appears to be exposure to actinic light during an early stage of development, though we doubt if that could give rise to a print which showed as a negative instead of a positive on the surface.

W. Cross.—From your description the apparatus is the ordinary bar burnisher, and if in good condition should answer its purpose.

F. F.—You can use fluted glass in place of ground. It will transmit a little more light, but ground glass, if kept clean, is equally satisfactory.

POSTCARDS.—May I beg to ask if you could tell me, through the columns of the "B.J.," where I can obtain postcards (from my own negatives) similar to the one enclosed. I often take negatives of local events and require to produce postcards in a fairly large quantity to retail at one penny each, and any photographic postcards produced by actual photography cannot be produced (as you know) at anything like one penny each. If you will carefully look at the enclosed postcard it seems a sort of lithographic ink about the same colour as a P.O.P. tone, and then varnished over, and I should be very glad if you could name me any firm that does this work. (2) A studio 24ft. long by 12ft. wide by 12ft. high, facing north (glass side), and to use both ends. Would you please state the distance required (opaque) from beginning of glass to background, both at top and side?—**NODYARG.**

(1) The print sent is a photograph glazed by being squeegeed on a glass plate. It is not a mechanical print. If you refer to the index of advertisers in the "Almanac" you will see the addresses of several who produce postcards for the trade. (2) About 5ft. top, at either end, and 4ft. at the sides will be good proportions to be opaque for that size studio lighted from the north.

SCHOOL PHOTOGRAPHY.—We are sure that many photographers will re-echo the opinion expressed by a recent correspondent of the "School Guardian" in reference to the annoyance caused by itinerant photographers. "School Manager" writes:—

"I beg to draw the attention of school managers and educationists generally to the increasing exploitation of our schools by itinerant photographers for purposes of private profit.

"In one of the schools with which I am connected no fewer than four applications for permission to enter the school-room have been received from various photographic companies within the last month.

"In each case the privilege was sought on 'educational grounds,' which, on inquiry, proved to be (1) selling photographs to children, (2) printing photographs in a journal published by the photographers.

"In addition, I am informed by a fellow-manager in the South of England that one firm is making further profit by disposing of the rights of copyright, which I understand belong to the owners of the schools.

"As the taking of photographs undoubtedly entails great interruption of school work, and as all legitimate requirements for school purposes are already adequately supplied by local photographers, it is sincerely to be hoped that, in the true interests of education, the evil indicated may be promptly suppressed by the various local authorities."

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

An ingenious use is made of the telephoto principle by Dr. H. Harting who employs a very low-power telephoto lens in front of the ordinary objective as a means of focussing on various distances. The attachment amounts to the provision of a whole series of "magnifiers" by simply altering the separation between the negative and positive of the attachment, the focal lengths thus produced being equal to the distances of the object photographed. (P. 492.) Some editorial notes on this new method and on the matter of exposure in telephoto work appear on p. 490.

Messrs. Speaight are inviting photographers to their Bond Street galleries before the close of the present exhibition of "Fair Children," lately reviewed at great length in the daily and weekly Press. (P. 504.)

A German photographer has patented the use of a black mirror placed before the sitter in a dark chamber, which also contains the camera. The device is employed to allow the sitter to see himself at the time of being photographed, the camera and the photographer being both hidden from view. (P. 502.)

"Impressionism," "Free Sittings," and the "Speed-numbers of Plates" are treated, among other topics, under "Correspondence." (P. 505.)

Some hints on the colouring of photographs by Miss Elsie Debenham appear on p. 491.

THE DRESDEN EXHIBITION.—We review on p. 496 the trade section of the exhibition, in which are 181 separate stalls or galleries, the majority by German firms.

The conclusion of the description of the apparatus shown at Dresden for the explanation of elementary facts of photography and colour appears on p. 499.

Sir Cecil Hertslet draws attention, in a letter on p. 505, to the assistance which the Board of Trade is now giving to British exhibitors. In connection with the International exhibition to be held at Brussels next year a Royal Commission has further been appointed to assist English firms. (P. 505.)

A further instalment of the paper on the measurement of shutter speeds by Herr Paul Thieme makes particularly clear the very different results obtained with a focal-plane shutter when measuring speeds by methods involving the photography of an object moving in a circle. (P. 493)

It is necessary to correct a recent statement in reference to the action of reducers on the sulphide-toned prints. Both iodine-cyanide and acid bichromate will reduce the sepia image. (P. 489.)

The prospectus of the Photographic Salon now published gives the names of the Organising Committee. A Selecting Committee is to be formed from members of the Linked Ring. (P. 489.)

EX CATHEDRA.

The Photographic Salon. In the prospectus of the seventeenth "Photographic Salon," the Linked Ring, for the first time in its history, announces to the public the constitution of an "organising" committee composed as follows:—

MALCOLM ARBUTHNOT,	GEORGE DAVISON,
WALTER BENINGTON,	CHARLES H. L. EMANUEL,
REGINALD CRAIGIE,	F. J. MORTIMER.

The names of the committee, in conjunction with the avowal on the entry form that "careful consideration will be given to all pictures submitted," will do much to restore confidence in the management of the Salon. Evidently the events of last year are not to be repeated, and although the Linked Ring would have done well, we think, to have effaced the memory of last year's brusque disregard of its supporters, by giving the names of the members of the actual selecting committee, it has done the next best thing in making it known that a committee will be appointed from among the members. The last day for receiving exhibits at the gallery, 5A, Pall Mall East, is August 30, from 10 to 6. Messrs. Selfridge will receive, deliver, and return exhibits, in which case packages must reach them on August 26 at latest. The prospectus of the Salon may be obtained, as usual, by application to the Hon. Exhibition Secretary, Mr. Reginald Craigie, at 5A, Pall Mall East.

* * *

Permanency of Sulphide Tones. Mr. H. W. Bennett in his lecture at the R.P.S., while touching upon this question, stated that he had tried the effect of various reagents on toned prints, but

found that in no case could he affect the print without first destroying the paper support. He also quoted a paper previously read before the society, in which, according to Mr. Bennett, "it was stated very definitely that it was found quite impossible to reduce to any appreciable extent the sulphide-toned print without first destroying the paper." We are unable to trace this paper and can only find a communication by Mr. Harry E. Smith (June, 1907) on the subject of reducing toned prints, in which no such statement appears. In any case the idea is so erroneous that we feel obliged to correct it. Mr. Smith mentioned several reducers that work very satisfactorily, while it is now well known that a number of the reagents that are used to bleach ordinary bromide prints will attack toned prints almost as readily. Bichromate and hydrochloric acid is a familiar example, and so also is an iodine solution, as pointed out by Mr. Starnes. We do not, however, see that the application of any such solutions can be any test of permanency. The great cause of trouble with silver prints is the action of sulphuretted hydrogen, and this naturally can have no effect on a print that is already

sulphided. We have not, as a matter of fact, met with any instance that suggests impermanency in sulphide-toned prints. Chemical tests are almost useless as tests of permanency because the conditions are not parallel with those under which the prints are kept. Even the fact that simple hot water will dissolve the image might be taken to suggest impermanency if the other reactions indicated anything at all. The use of mercury as a bleaching agent does not seem to suggest possibilities of fading, for the final result is no doubt as proof against the action of sulphuretted hydrogen as the sulphided silver image. The precise nature of the compound formed is, however, certainly a rather doubtful matter.

The Sixth American Salon of Pictorial Photography.

A new president of the American Federation of Photographic Societies has been appointed in the person of Mr. G. W. Stevens, director of the Toledo Museum of Art, by whom the Federation should be greatly helped in its work of organising and circulating an international exhibit of pictorial work. We learn from the secretary, Mr. C. C. Taylor, of 3223, Cambridge Avenue, Toledo, Ohio, that the forthcoming Salon will be held in the art galleries and institutes of Pittsburg, Buffalo, Chicago, Indianapolis, Detroit, New York, Boston, St. Louis, St. Paul, Milwaukee, and other cities of the United States, and it is hoped that ample representation will be obtained from England. Mr. H. Snowden Ward has consented to act as commissioner.

* * *

Parallelism of Object and Plate.

This problem seems to have aroused much interest of late, both in our columns and those of our contemporaries, and it seems to form a most effective trap for the unwary. The last suggestion we have seen made is that plate and copy must be parallel if all four corners of the plate show maximum sharpness at full aperture. Setting aside the facts, first, that depth of focus renders it difficult to determine "maximum sharpness," excepting with very large apertures, and, second, that it is difficult to use the essential focussing magnifier near the corners of the plate, it is obvious that this condition of equal sharpness can easily be obtained when object and plate are at quite a decided angle with one another. If the axis of the lens is not exactly at right angles with the object, and the test does not in any way ensure its being so, then sharp focus in all four corners can still be secured by inclining the plate in an opposite direction to the object. This well-known fact has evidently been overlooked by the writer who has suggested the method referred to. Up to the present only two or three of the methods that have been proposed have proved to be accurate and scientifically sound, and these are all more or less unfamiliar and unusual, though the problem is a very common one. It has been tackled and solved in practice somehow or other by numberless workers, but apparently it is the all-powerful "rule of thumb" that has been their guide.

* * *

Diaphragm and Focal-Plane Shutters.

A writer in a contemporary suggests that an $f/8$ lens on account of the depth of field it gives will best serve the purposes of the average amateur, and then asks—Why set this lens in a diaphragm shutter which reduces its already low intensity to that of an effective $f/11$? Why not fit a focal-plane shutter which will enable us to use the full intensity of the lens? This writer is evidently impressed with the old fallacy that a focal-plane shutter has an efficiency of 100 per cent., while he is also underrating the possibilities of diaphragm shutters. It is suggested

that the ideal camera for the ordinary amateur is one with a shutter accurately timed up to 1-100th second, and, as things are at present, we believe that a modern diaphragm shutter will fulfil this writer's ideal as well as any focal-plane shutter. He asks for a cheap focal-plane shutter, but we should be inclined to think that one costing much less than a "Compound" or "Koilos" shutter, to mention two only of the diaphragm shutters available, would be a thing to be avoided. A focal-plane shutter that is not thoroughly well made and adjusted may be a most troublesome and inconvenient piece of apparatus. We have had some experience of cheap shutters of this pattern and have also discovered the difficulties of adjusting them. A good shutter is a most essential adjunct to the camera, and if the focal-plane variety is preferred then a good shutter can never be a very cheap one. On the other hand, it is possible to make excellent diaphragm shutters at a very low cost, and for moderate speeds these patterns are as serviceable and reliable as can be wished. In fact, if a large enough shutter is selected we consider the diaphragm likely to be preferable to the focal-plane, for moderate exposures at any rate. The usual fault is that a desire for undue compactness leads makers to fit the lens in the smallest size shutter that will take it, whereas the proper course is to use the biggest shutter that the camera will take, and disregard the smallness of the lens. Very high efficiency can be obtained in this way even with the short exposures.

SOME TELEPHOTO MATTERS OF CURRENT INTEREST.

CAPTAIN OWEN WHEELER's paper on "The Practical Side of Telephotography" which he read at the R.P.S. recently gave rise to a most interesting discussion, especially with regard to the subject of exposure. Theoretically, it can be shown that exposure should always vary with the square of the magnification, or that it should be equal to the exposure required by the positive lens alone on the same subject multiplied by the square of the magnification. The accuracy of this rule has often been questioned, but with, we think, very little reason. Those who spoke at the meeting, including the lecturer, supported the rule, but with certain qualifications, and it is just on this matter of qualification that ideas seem to differ. Our own view is that the rule is correct without any qualification, if it is interpreted literally, and that the troubles commonly met with arise from a misapplication of the rule. In other words, the worker often fails to ascertain correctly the exposure required by the positive lens used alone. He almost invariably over-estimates it, and the error being multiplied becomes a very considerable one with the telephoto exposure.

The telephoto lens, of course, only covers a very small angle, and only includes a very small portion of the most distant part of the much more comprehensive view included by the positive lens used alone. In ordinary conditions, exposure with the positive lens is not regulated for insignificant distant objects, but for the view as a whole. A small distant building is ignored, because if we regulated exposure by it the rest of the picture would be badly under-exposed; yet this small distant building is probably the only thing we intend to include in the telephoto view, and it should therefore be the only thing considered when estimating exposure. From this it is evident that in estimating exposure in telephotography we must throughout consider only those portions of the subject that will ultimately appear in the telephotograph. This is just where the mistake is usually made. The exposure for the positive lens is estimated just as if an exposure is to be made upon

the whole view included by that lens, instead of upon the very small portion of it that is destined to appear in the telephotograph.

There is another source of error in regard to exposure that was not referred to at the meeting. The rule quoted assumes that the diameter of the effective aperture of the lens system is the same with the telephoto combination as with the positive lens alone. That is to say, if the positive lens has an aperture of one inch, as in the case, for example, of a six-inch lens working at $f/6$, then the telephoto combination, whatever magnification it gives, is also working with a one-inch aperture. Another rule is based upon this assumption; this is, that the f number of the telephoto combination is equal to that of the positive lens multiplied by the magnification. As a matter of fact, the assumption is liable to break down when large aperture positives are used, for it sometimes happens that the negative lens acts as a diaphragm and stops down the positive lens very considerably. Quite recently we noted this effect in the case of a new telephoto lens that passed through our hands, and it is conceivable that it may very readily occur when various negative lenses are used in combination with the one positive in the way advised by Captain Wheeler. It is not a defect in any way, but it is very necessary that the operator should know whether the stopping-down effect occurs or not, as otherwise he may be very far out in his estimates of exposure.

It is quite possible that unnecessarily rapid positive lenses are often used in telephoto combinations. If the negative lens will not transmit all the light that passes

through the positive at full aperture, it is obvious that a lens less rapid, and therefore cheaper, positive should be equally serviceable.

Another matter of interest touched upon by Captain Wheeler was the use of the camera at a fixed extension and the production of various degrees of magnification by changing the negative combination, fine focus being, of course, obtained by altering the separation of positive and negative combinations. This is a course in favour of which there appear to be strong arguments, for a fixed extension may be a matter of considerable advantage from the point of view of rigidity. The "Adon" lens is an example of a telephoto combination especially intended for use with cameras of fixed extension, but in its case the degree of magnification is very severely limited, and it is perhaps most often used by itself in the same way as an ordinary telephoto lens. The mention of the "Adon," however, reminds us that its principle is made use of for a quite different purpose in the new focussing adjunct described by Dr. H. Harting in an article a translation of which we give on another page. Dr. Harting suggests the use of what is virtually a very low-power "Adon" solely for the purpose of securing sharp focus on near objects with fixed-focus cameras. His idea is really that of a "magnifier" constructed on the telephoto principle, and therefore of adjustable focus. Its magnifying power being very small, it will, of course, be ineffective as a telephoto lens, much as it resembles one, while on the other hand the "Adon" has too much magnifying power to be generally useful for simple focussing purposes.

A FEW HINTS ON THE COLOURING OF PHOTOGRAPHS.

By colouring I do not mean merely tinting, which is just a wash over the picture with different colours. To obtain a bright, fleshy result you must work up and strengthen the shadows and half-tones.

I would like my readers to examine a person's face in a good light; and many who have not done so before will be surprised to find the varied tints in the face. To be a good colourist you must observe where these different tints occur.

I recommend sepia plat as the best to work on; for smaller heads and miniatures, ivory, carbon, or bromide, the colour must be sepia or brown: never use a black foundation. There are a few things to be remembered. Do not try to cover a large space with a small brush. For 12 x 10 use No. 6 to 8 brush for washing, and No. 2, 3, or 4 for finishing and putting in cheek colour, lips and eyes. Never put the brushes to your mouth, and remember to hold them as loosely as possible; it is so easy to get into the habit of clutching the handles. Keep blotting-paper by you, and use it if you have too much colour in the brush. You must also have some perfectly clean water.

Avoid the use of Chinese white and gum, except when the picture is at fault and needs more sparkle. If the print is too dark, you may use a little gum in your colour for the shadows.

To wash (which is to be done first) colour should be mixed in the best medium as regards strength, and used freely. With a large brush, wash the colour from left to right, then back again to left, dragging the colour along, each time coming lower. Of course, your print must be slanted so that the colour naturally drains downwards; this applies to the background in particular; in the same way wash the face, then the hair and drapery. When this is quite dry the background will want another wash. The face should look a little too dark at this stage; now put some shadows in the hair, do the eyes, put some colour on the

shadows in the drapery, and a few touches of purple, red, and sometimes yellow may be added into the background. Very carefully wash the pink in cheeks, and do the lips. The shadows in the face must now be washed over with shadow colour.

It is necessary to start finishing after all this has been done, but do not stipple; fill all the little spaces with a fine brush, and slight touches in a cross-hatching style, which is done by holding the brush slightly sideways, not using much colour, and keeping your brush fairly dry. Join up all shadows and half-tones, leaving the lights; this has the effect of drawing it all up together and making it appear lighter.

Mark the pupil and the line over the eye *slightly* with any dark colour, almost black; the eyebrows must also be coloured according to the hair, but never alter the shape, and keep them soft.

The following colour suggestions will be found useful:—

Complexions.

Dark.—Venetian red and Roman ochre with a little rose madder.

Fair.—Scarlet vermilion or light red with pink madder and Indian yellow or yellow ochre.

Shadow Colour (for deeper tones).—Indian yellow or Venetian red or rose madder, each colour to be used separately according to complexion.

The neck must be greyer in tone than the face, and slightly pink on the collar-bones.

Arms and hands must be of a pinkish hue, also elbows.

Hair.

Always try to have a piece of hair to use as a guide: do not pick out the hairs separately, but put the colour in masses.

For Brown Hair.—Lights, purple hue; shadows, sepia.

For Grey Hair.—Mix a little cobalt or French blue with sepia.

For Golden or Flaxen Hair.—Roman ochre and sepia. A little scarlet may be added.

For Auburn Hair.—Lights, little neutral tint and lake; burnt umber for shadows.

For Chestnut Hair.—Lights and very dark shadows, slightly

purple; general colour, burnt umber and lake. Sepia may be added.

For Red Hair.—Venetian red and lake, or burnt sienna, not very red.

For Black Hair.—Indigo, lake, and gamboge, mixed, makes nice black; or use lampblack modified with lake or indigo according to shade desired.

ELSIE DEBENHAM.

FOCUSSING BY MEANS OF A LOW-POWER TELEPHOTO ATTACHMENT.

[In an article published in the current issue of "Photographische Rundschau," Dr. H. Harting draws attention to the advantageous use which can be made of an attachment to the lens whereby objects at different distances may be focussed without the provision of any moving part in the camera, saving only some convenient device by which a very small degree of separation may be given to a low-power telephoto attachment placed in front of the ordinary lens. He points out the advantage of this method in the case of small fixed-focus cameras. The following translation gives a description of the optical conditions which require to be fulfilled in making use of this system in practice.—Eds. "B.J."]

In the case of most hand-cameras sharp focus is secured by moving the lens in relation to the ground glass. Either the lens is a fixture on the front of the camera and the latter is moved by rack and pinion or other means, or the lens-front is kept at a constant distance from the plate and the lens itself is movable within the necessary range. In by far the greater number of cases this latter system takes the form of the well-known focussing-mount. There is, however, a further method of securing sharp focus at different distances, namely, that in which the course of the rays is somewhat altered. This system of focussing is adopted in the Cooke focussing lens. In this system of three lenses the first is mounted so that it can be moved to very small extent, and the focus thus thrown back behind that of the lens in its normal state, the middle and back lenses remaining in their places. This method of focussing has not come very greatly into use, probably because the definition may be very slightly impaired when the optical system is thus disarranged. There are, however, many cases

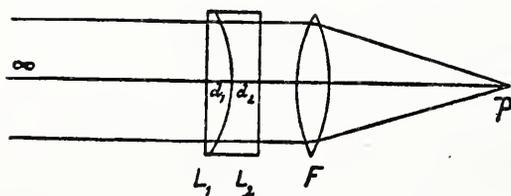

Fig. 1.

in which the ordinary focussing-mount cannot be used; for example, a diaphragm shutter is practically incompatible with a lens mount of this description, whilst, on the other hand, in the case of very small cameras, a movable lens-board has drawbacks from the point of view of rigidity, whilst still again the cost of either form of movement cannot be adopted in cameras sold at the lowest prices. On these various accounts there is something to be said for the supplementary lens as a means of focussing. These have already been used in the form of single lenses of focal length equal to the distance of the object which it is desired to bring into sharp focus. They are usually issued in sets, the particular lens being chosen according to the distance of the object. For example, a lens of two metres' focal length mounted on the front of the ordinary objective, which is placed in focus for objects at infinity, will bring objects at two metres' distance into sharp focus on the plate. But a much preferable plan is to have one optical attachment which will allow of sharp focussing at whatever distance

the object is from the camera, and will further dispense with a collection of separate lenses. Such an attachment is here described.

In Fig. 1 it will be seen that there is interposed in the path of the rays falling upon a lens F a plate having parallel sides, but composed of the two lenses L_1 and L_2 , L_1 being plano-convex and L_2 a plano-concave. Both lenses being formed from the same glass, they will, when in contact, have the effect only of a flat plate of glass of parallel sides. Therefore the focus will be set back only one-third of the total thickness of the plate, that is, one-third of $d_1 + d_2$, and this set-back the focus will be less the further the object is from the camera. When the object lies at the optical infinity for the particular lens, the rays falling upon the plate pass through it in straight lines, without refraction, and there is no alteration in the position of the focus.

If, however, the two lenses L_1 and L_2 are given a slight separation d , the effect of the two is no longer that of a flat parallel-sided plate. Calling the focal length of the two lenses

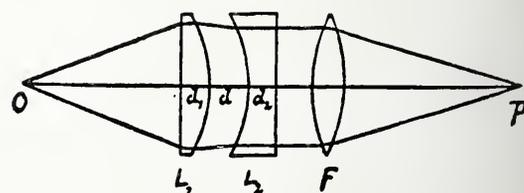

Fig. 2.

f_1 and f_2 the equivalent focal length of the combination will be given by the formula:—

$$(1) \quad \frac{1}{f} = \frac{1}{f_1} + \frac{1}{f_2} - \frac{d}{f_1 f_2}$$

It will be sufficiently accurate for the present purpose to take the lenses L_1 and L_2 as infinitely thin, and to take d their separation. Assuming f_1 and f_2 to be equal, we obtain the equation:—

$$(2) \quad \frac{1}{f} = \frac{d}{f_1^2} \quad \text{and} \quad fd = f_1^2$$

The combination of the lenses L_1 and L_2 thus corresponds with that of a telephoto combination of which the position has the same focal length as the negative; that is to say, the ratio of positive to negative is 1. It will thus be seen that by altering the separation we can obtain any value for the focal length F of the system of the two lenses.

Let O be a point which is to be sharply focussed, the separa-

on d between the lenses L_1 and L_2 thus requires to be chosen so that the focal length of the combination is equal to the distance of the point O . O lying in the front focal point of the system L_1 and L_2 , the rays which emerge from L_2 are parallel, and are brought to a focus in the usual way at P , the focal extension of the camera remaining unaltered. For example, if O is one metre from the lens, the focal length F must have the value of one metre, which is secured by choosing the requisite separation, d . The smaller the separation the greater the action of the front lens L_1 , and therefore the smaller its curvature may be. With d , 20 millimetres, and the object at one metre distance, we have:—

$$f_1 = \sqrt{20,000} \text{ mm.} = 141 \text{ mm.}$$

The corresponding radius r is obtained from the equation:—

$$r = (n - 1) f_1$$

When n is the refractive index. If the very transparent borosilicate glass No. 0.144 of the Schott Works, with the refractive index No. 1.51, is used:—

$$r = 0.51 \cdot 141 \text{ mm.} = 72 \text{ mm.}$$

Distortion is in no case so great that the efficiency of the lens suffers by the addition of this supplementary attachment so long as the lens is not used at too great an aperture and of medium focal length. For the same reason the thickness of the two lenses is kept small, so as to prevent the absorption of light by the glass rising to an appreciable quantity. Still, as a system of lenses has been introduced containing four surfaces exposed to the air, there is necessarily a loss of light to the amount of 20 per cent., but under ordinary favourable

conditions of lighting this difference cannot be considered of great importance.

A departure may be made from the plano-parallel formation above represented by giving the outer surfaces of the telephoto combination a shallow curvature, thereby allowing of small residues of aberration being avoided. The same thing may be done by using glasses differing slightly from each other in refractive and dispersive power, whilst a further modification which can be made is to have one or both of the lenses made from the yellow glass manufactured by Schott during the last few years; the attachment then serves the purpose also of a compensating or contrast filter. The whole attachment may be fitted in a mount of the focussing type, care being taken that the mount is of such dimensions that it does not act as a stop and lead to vignetting of the image. It is readily seen that cameras, such as those made for stereoscopic photography, for a plate of 107 x 45 mm., may be fitted with a pair of these focussing lenses, so that even when lenses of large aperture are employed focussing may be done for the foreground or distance. For fitting to reflex cameras also it may be preferable in the case of a large lens to mount the latter in a fixed position, with its weight balanced on the camera front, and to provide focussing by means of the above-described attachment. The advantage of the suggested device lies in the fact that the same combination of lenses may be used for any objective, of whatever focal length, so long as the respective diameters are suited to each other. Also, in the case of lenses which already are fitted in a focussing mount, the use of the attachment allows of objects still closer to the camera being brought into sharp focus.

DR. H. HARTING.

ON THE MEASUREMENTS OF THE SPEEDS OF INSTANTANEOUS SHUTTERS.

II.

[In the following translation from "Photographische Mitteilungen" of the second portion of the paper by Herr Paul Thieme, which we continue from our issue of May 21, p. 397, it will be seen that the author has made a series of calculations showing the different results obtainable with different shutters on different systems of measurement.—Eds. "B.J."]

THE methods of measuring the speed of photographic shutters may be divided into three classes.

I.—Methods in which a moving body is photographed.

II.—Methods in which sources of light are photographed at brief intervals.

III.—Methods in which successive exposures made with a shutter are compared with the effect of one single exposure of longer duration.

As the measurement of the time of exposure by the different methods depends to a notable extent on the type of shutter, it should be clearly recognised to start with that there is a vital difference between the lens or diaphragm shutter and the focal-plane or blind shutter working immediately in front of the plate. Whilst the lens shutter exposes the whole of the plate practically at the same moment to the action of the light, in the case of the focal-plane shutter the different parts of the plate are successively exposed. In the first case, therefore, the time during which the shutter is open may be taken as the time of exposure, whilst in the case of the focal-plane shutter the time of exposure is that during which only a certain small section of the plate is exposed. We are speaking now of exposure as a means of producing a developable and sharp image, and it is these times which in the case of the focal-plane shutter are those given usually in tables of its speed. The shutter, however, remains open for a much longer time, that is to say for a time necessary for the slit to traverse the whole width of the plate. It is therefore necessary in the case of focal-plane

shutters to keep clearly in mind the distinction between what may be called the "time of exposure" and the "total duration of exposure," since this in the case of small slits may be very considerable. For example, in the case of a shutter having width of slit of 2mm., the actual time of exposure may be 1-1,000 of a second, but the total duration of exposure in the case of a plate 7 by 5 inches placed vertically will be 1-10 of a second. The blind of the shutter will traverse a distance of 2 mm. (the width of the slit) in 1-1,000 of a second, but in order to traverse the seven inches of plate (180 mm.) ninety times this time is necessary, that is to say approximately 1-10 of a second. It is this property of the focal-plane shutter which, in the case of very rapidly moving objects the images of which are moving on the plate in the same direction as the slit of the shutter, leads to too long an exposure, and therefore to an unsharp image. An example of this is a ball thrown up into the air, when the image is moving on the plate in a direction opposed to that of the slit. In the case of a falling ball, the effect is in the direction of shortening of the exposure, so long as the width of slit is small in proportion to the size of the image. Lastly, when the movement of the slit crosses the line of movement of the image on the plate, as in the case of a motor car, the effect is to produce a distorted image.*

Reverting now to the methods employed for measuring shutter speed, already referred to under I., namely, that in which a moving object is photographed, there are several variations of

* In each instance the slit is assumed to move vertically.

this principle which require to be considered. In each case the basis of the method is, of course, to obtain a prolongation of the image of the object as a result of the time the shutter remains open, the elongated or otherwise enlarged image being measured, and the speed of the shutter calculated therefrom.

(a) The moving object is a body allowed to fall freely. The photographic apparatus may be directed towards the wall of a house, and, with the aid of an assistant stationed at an upper window, a white or polished metal ball is allowed to fall and the shutter released at the correct moment. The ball will then appear on the negative as a dark band, the length of which, after the breadth has been subtracted, is the measure for the time of exposure. It is necessary to know the scale on which the image is formed in relation to the original, which is easily calculated from the focal length of the lens and its distance from the line of fall. The velocity of the ball at the moment of the exposure has also to be calculated from the height through which it has fallen by the well-known formula

$$c = \sqrt{2gh}$$

where h is the height from which it has fallen and g the acceleration due to gravity. It is necessary to ascertain what influence the movement of the blind of a focal-plane shutter has on the length of the image of the falling ball, but still more important is it to know what are the shortest periods of exposure which may be accurately measured by this method. If we assume the somewhat favourable case in which the exposure has been made at the moment when the ball had fallen 5 metres, its speed will then be 10 metres per second—that is to say, in 1-100th of a second it will have moved 10 cm. If the ratio of image to object is 1:100 the image will be 1 mm. This value is so small that a measurement, to be anything like exact, will require a microscopic measuring eye-piece. It will thus be seen that the method is quite useless for very short exposures.

(b) The moving body is a pendulum. A white or metallic ball is allowed to swing by a thread in front of a dark background. From the length and amplitude of the pendulum its speed at any point of its course may be calculated, although the calculation is one involving a good deal of trouble, and the process is therefore not to be used by those without some mathematical knowledge and patience. Herr Hans Schmidt has recommended an extremely simple method of getting over this calculation by photographing at the same time a scale representing the sine of the angle of the pendulum. Examining this method for its usefulness for short exposures, it may be assumed that a pendulum beating seconds (that is, of one metre length, and occupying half a second for a single swing) will have at its lowest point a speed of about .8 metres a second, that is to say, in 1-100 of a second it will move 8 mm. If we are photographing on the scale of 1:100 we thus obtain in an exposure of 1-100 of a second a shift of the image only .8 mm., which is no better than that of the falling body method described under (a).

(c) The moving body is a rotating rod. In this method, due to Eder, a rod mounted on an axis is provided with a small reflecting ball, which, on the rod being rotated from one end, gives an image on the plate which is part of the circle described by the extremity of the rod, and therefore allows of the exposure being measured when the number of revolutions of the rod per second is known. By this method much shorter exposures may be measured than by the foregoing, provided that the rod can be rotated at a series of fairly high speeds. In the case of medium speeds an ordinary bicycle may be employed and the number of rotations counted with sufficient accuracy. This latter method so clearly brings out the difference between the lens shutter and the focal-plane that it may be well at this point to examine this difference more closely.

In cases where the light obtains access to the plate for a considerable time we obtain an image such as that shown in

Fig. 1. The arrow indicates the direction in which the image of the ball has moved. When a shorter exposure is given there are obtained images such as those in Figs. 2, 3, and 4.

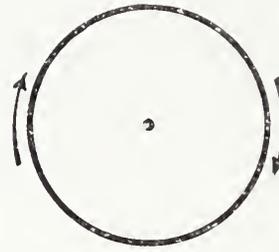

Fig. 1.

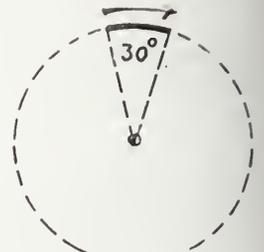

Fig. 2.

will be seen that these latter will indicate the same time of exposure in the case of a diaphragm shutter. This time will be ascertained as follows:—The rod making N revolutions

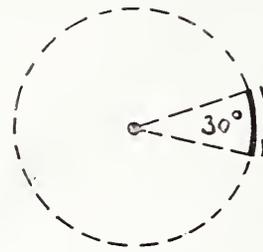

Fig. 3.

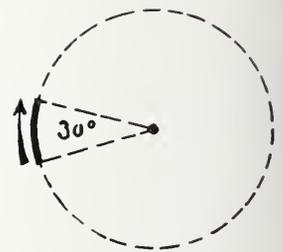

Fig. 4.

per second and B being the angle subtended by the portion of the image, the time, t , in seconds will be

$$(1) \quad t = \frac{1}{N} \cdot \frac{B}{360}$$

that is to say, when the rod makes 10 revolutions per second and the angular measurement of the arc of image formed is 30° , then

$$t = \frac{1}{10} \times \frac{30}{360} = \frac{1}{120} \text{ of a second.}$$

In the case of the focal-plane shutter, however, the slit of which may travel in relation to the revolving rod in the three different ways shown in Figs. 5, 6, and 7, it will be seen that the above formula only holds good in the case of Fig. 5, in

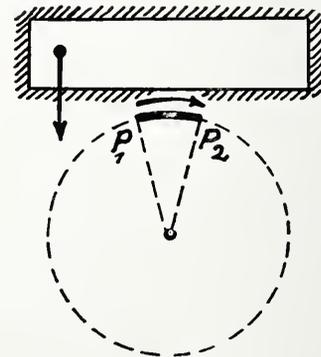

Fig. 5.

which points P_1 and P_2 of the arc B (representing the movement of the slit) can be regarded as one point. In Fig. 6 the slit has moved in the same direction as the point of light, and as a result there is a greater length of arc than that corresponding to the time of exposure calculated from the above formula; or, in other words, the time of exposure is less than would be given from the arc B according to formula 1. The exposure begins at the instant in which point P_1 is reached (compare Fig. 8); the slit then has the position shown. Exposure ends at

the moment when the point P is covered, at which stage the slit has the position shown in the dotted lines (Fig. 8). In order to expose a zone of the plate corresponding to the arc

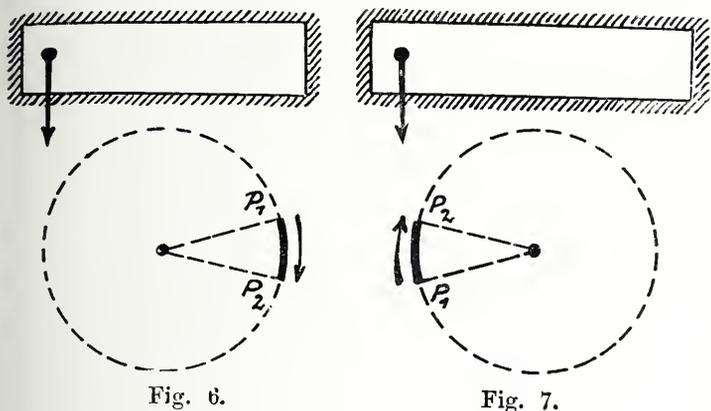

Fig. 6.

Fig. 7.

P_1, P_2 , the slit requires to move through the projection h of the arc $P_1 P_2$ in the direction of movement of the shutter and also the width of the slit b , for which purpose it requires the

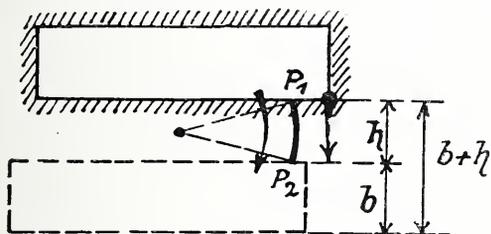

Fig. 8. (Corresponding with Fig. 6.)

time t . We thus obtain from the formula for the uniform movement only the speed c of the blind—namely,

$$(2) \quad c = \frac{h + b}{t}$$

of which h is measured on the plate, b on the slit of the shutter, and t obtained from formula 1. The speed of the shutter blind is, however, by no means identical with the time of exposure. The latter is the time T which the blind requires in order to run the width of the slit b —that is to say

$$T = \frac{b}{c}$$

or, taking the value of c from formula No. 2, we get

$$(3) \quad T = \frac{b \cdot t}{b + h}$$

Similarly, in the case shown in Fig. 9 we obtain

$$(4) \quad T = \frac{b \cdot t^*}{b - h}$$

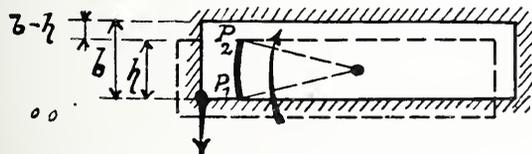

Fig. 9. (Corresponding with Fig. 7.)

The formula must, of course, apply also to Fig. 5 if it is of universal application. In this latter case h is equal to zero, therefore

$$T = \frac{b \cdot t}{b \pm h}; \text{ i.e., } T = t.$$

In this particular case formula 1 might be used, but as it is a matter of chance in which part and in what position the rotat-

* The width of the slit b is shown greater than the height h , as, in case of Fig. 7, h must be smaller than b , but these ratios cannot be ascertained to any closer degree of accuracy.

ing ball will be with regard to the moving slit of the shutter, it is best to adopt formulæ Nos. 3 and 4. The following numerical example will show the way in which the formulæ are used:—Suppose that the arc B subtends an angle of 30, then for a lens shutter which gives a result such as that shown in Fig. 5.

$$t = \frac{1}{10} \times \frac{30}{360} = \frac{1}{180} \text{ of a second.}$$

In the case of an image such as that in Fig. 6, the distance h must be measured (amounting, say, to 20 mm.) and also the width b of the slit, equal, say, to 40 mm. Taking now formula 3 we have

$$T = \frac{40 : \frac{1}{180}}{40 + 20} = \frac{\frac{1}{3}}{20} = \frac{1}{180} \text{ sec.}$$

In the case of Fig. 7 we obtain from formula 4

$$T = \frac{40 : \frac{1}{180}}{40 - 20} = \frac{\frac{1}{3}}{20} = \frac{1}{60} \text{ sec.}$$

To summarise these different results:—

Lens or focal-plane shutter, with the image in the position shown in Fig. 5, 1-120 sec.

Focal-plane shutter, with slit and image movements in the same direction (Fig. 6), 1-180 sec.

Focal-plane shutter, with slit and image movements in opposite directions (Fig. 7), 1-60 sec.

It is thus seen that Eder's method is much less suitable for focal-plane shutters than for lens shutters, although it is one of the best methods here mentioned.

(d) Dial methods of shutter measurement. These dials are nothing more than a variation of Eder's method. The moving pointer is photographed along with the scale over which it moves, so that there is no necessity for measurement on the plate. Everything said above in regard to the use of Eder's method applies also in this case in connection with focal-plane shutters, and the four methods which we have just described include the chief of those coming under section I.

Of the methods classed under II. must be mentioned that of the author already described ("B.J.," May 21, 1909) and that of B. Wiski, described in "Photographische Mitteilungen," 1908, page 335. This latter is of the greatest simplicity, but has the disadvantage of being unsuitable for very short exposures. It serves only up to about 1-25 of a second. An arc lamp on an alternating current is used as an intermittent light source, the arc being struck and extinguished about 100 times per second with great accuracy. The intermittency of the light is not seen by the eye, but if a highly reflecting object is moving in such a light the intermittent character of the latter is plainly shown by the fact that the object becomes at times invisible. On photographing such a light with a moving camera a series of points are obtained, each of which represents less than 1-100 of a second, the precise value corresponding to each point, however, whether 1-200 or 1-150 of a second unfortunately cannot be determined, and therefore the method is not accurate enough if only a few points are recorded.

A further method is as follows:—In front of a constant source of light a screen containing a number of holes is rotated exactly in the method already described by the author, so that an intermittent series of light impressions is obtained. These record themselves on a film stretched on a roller which rotates, and at the same time is given a certain shift along its axis, so that the images of the points of light are formed as a sinuous curve on the film. Exposures of any length may be measured in this way, but the method requires some complicated mechanism; at any rate more complicated than that of the apparatus devised by the author. An apparatus of this kind is used by the firm of Goerz.

Of the methods classed under III. in which the shutter is released a number of times so as to give an effect comparable with a single long and known exposure, that of Weber may be mentioned. The camera is directed towards a bright surface

illuminated by a constant light, and a plate exposed for a time which must be sufficiently long to be capable of accurate measurement—that is to say, must be at least 2 seconds when using a stop-watch working to 1-5 of a second. A second plate is then exposed, strip by strip, pulling out the shutter of the dark slide 1, 2, 3, cm., etc., and at every stage exposing by means of the shutter a certain number of times. For example, if the supposed speed of the shutter is 1-50 of a second, 100 operations with it should be required in order to ascertain to what extent the shutter departs from its marking. The dark-slide is withdrawn, say 1 cm. and 50 operations of the shutter given, at 2 cm. opening of the dark-slide 60 operations are given, and so on, so that the plate has the following series of shutter operations impressed upon it—50, 60, 70, 80, 90, 100, 110, 120, 130. The plate exposed in this way is developed with that which has received the 2 seconds' exposure and a comparison of the density obtained made, from which it may be determined which series of shutter operations corresponded most closely with that of the whole plate. Supposing that this was

the case with the strip which had received 80 shutter operations, the speed of the shutter is obviously 1-40 of a second.

This method of all those described is the one calling for the least apparatus, but there are drawbacks to it which must not be overlooked. It is only useful for shutters up to 1-50 of a second, and it occupies the more time the shorter the exposure required to be measured. Further, a comparison of the densities requires a practised eye. In putting the method into practice care must be taken that the light reaching the plate at each operation of the shutter shall be in excess of that just sufficient to give a developable image. The reason for this is that a series of the very minimum exposures, even to a considerable number, will not result in density comparable with that produced by the sum of these times acting continuously. On the other hand, if each single exposure is too great the bands will be in densities so great that proper comparison cannot be made between them. The brightness of the surface photographed and the stop in the lens must be used in adjusting these conditions.

PAUL THIEME.

THE DRESDEN EXHIBITION.

V.

A PALACE specially built for the purpose accommodates the 181 separate stalls or galleries taken by the houses in the photographic trade in Germany and other countries. The great number of the rooms, many of which are devoted to the exhibits of a single firm only, might have proved bewildering in making a tour of the building had not the organisers so arranged matters that the visitor is compelled to pass from one apartment to another in a certain order. Passing in at the main entrance, one may proceed straight forward up to the circular gallery or rotunda occupied by the Kodak Co., and thence to the right along the galleries occupying the inner portion of the palace to emerge again at the entrance. The remaining portions of the exhibits are reached by turning sharp to the right or left on entering, and thus traversing the galleries which lie on the outside of the building. The distances which thus separate the different rooms may be gathered from the fact that in one or two instances firms which have two separate rooms in different parts of the palace have found it necessary to have them connected by telephone. It will be impossible to refer individually to this very large number of exhibits. The majority of them represent German manufacture in the way of apparatus, plates, and papers. Excepting the eminent optical houses with reputations for photographic lenses which are world-wide, there is very little of interest in the shape of apparatus. In many instances the actual cameras, chiefly the less expensive metal instruments, are actually upon the English market. So far as concerns the more expensive patterns of hand and stand cameras and of studio apparatus, it cannot be said that any of the German makers have come up to the standard of work-

manship of those in this country, nor do they seem to have shown themselves equally active in improving the design and movements of this essential portion of the photographer's equipment. In the better class apparatus for the amateur photographer the most notable product of the German factories is the folding focal-plane camera, which, since its origination by the Goerz factory, has found many imitators, and may be said to be made in a greater number of varieties by the German houses than by those of other countries.

It is in the display that is made of the manufacture of photographic printing papers that the chief interest of the trade section at Dresden lies so far as the English visitor is concerned. Dresden itself contains a large number of factories of collodion and other papers, and the numerous galleries devoted to the showing of the very finest work, not by the makers themselves, but by well-known professional photographers, is a tribute to the high standard which has been reached in this branch of manufacture. Firms exhibiting their manufactures in the way of plates are comparatively few compared with those in the paper trade, but those which do exhibit—notably the firms of Schleussner and Richard Jahr—offer an impressive demonstration of the qualities of their products. This general summary of what is to be seen in the trade palace at Dresden should be sufficient to show that in undertaking a detailed review of every exhibitor's stall we should be rendering no actual service to our readers, and it will be sufficient if we select for mention those exhibits which do offer particular points of interest, or which show the part being taken by firms well known in this country.

THE TRADE SECTION.

No. 1 in the catalogue of the trade section is the reading and writing room most tastefully fitted up by our contemporary "Die Photographische Industrie," the leading organ of the trade in Germany, and ably conducted by Herr K. W. Wolf-Czapek. The room is most comfortably furnished, and conveniently provided with facilities for writing, and with a small library of photographic books. It also provides copies of most of the current photographic periodicals, and, by its very central position in the exhibition, provides a constant emphasis of the association of the press and the trade.

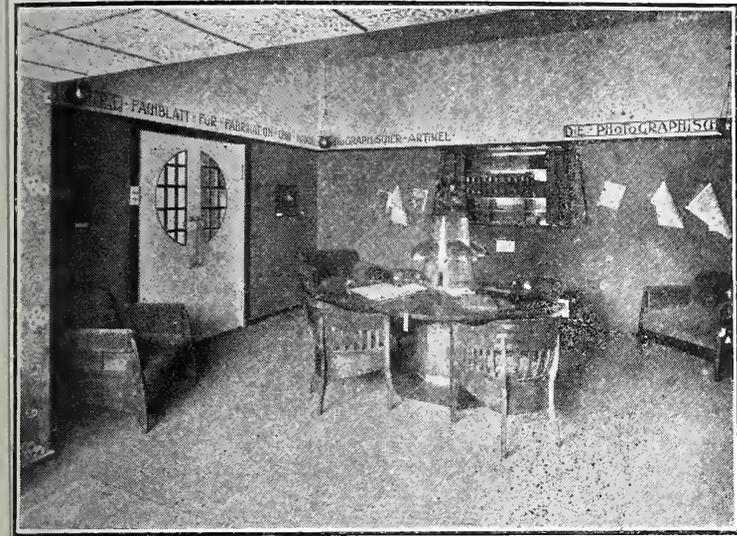

At stall No. 6 Meister Lucius and Brüning exhibit a series of the well-known Hoechst products, namely, dyes for sensitising dry plates and for the making of filters and safe-lights.

A number of pinatype prints and transparencies in colour are shown here, with about an equal proportion in monochrome, which are perhaps more interesting than the multi-colour ones, from the practical standpoint, as they show the very pleasing transparencies to be made by this process.

The exhibit of the Leonar Works of Arndt and Löwengard (No. 12) may be taken as typical of many another by German houses. Its chief products are gaslight, bromide, and collodion papers, in all which three media a number of excellent prints—brown, black, and red-chalk in colour—are exhibited. At the stall of Goltz and Breutmann (No. 16) makers of reflex and other cameras, we found an introduction of notable interest, namely, a folding reflex camera quite distinct in pattern from

ny other on the market. The principle adopted by the makers is to retain the box body of the camera, but to build it in two parts, one folding into the other, so that the bulk of the apparatus, when made ready for carrying, is nearly half that of the ordinary reflex. The adjustment is very nicely contrived so that the closing of the camera, including the placing of the mirror in the correct position, is all done by turning the head like that used for the focussing pinion.

The exhibit of the Kodak Co. is contained in the large circular hall or rotunda placed at the very centre of the trade building. The whole scheme of decoration is excellent in

The writing-room of "Photographische Industrie."

every way. A figured fabric is used as the wall-covering, and the different sections of the exhibit enclosed within beading of white picked out with gold. A floor-covering of Japanese matting harmonises well with this scheme of decoration, and the whole impression of the exhibit, despite the great amount of material collected in it, is light and refreshing. Around the top of the room, forming a sort of frieze, are a series of enlarged photographs, seen in the illustration, representing the headquarters of the Kodak Co. in the various capitals and countries of the world. As regards the exhibits themselves, it is not necessary to say more than that they include the

number of metal cameras made by Otto Spitzer (No. 21) there is also shown an ingenious stand for the camera which may be attached to a fence, a trunk of a tree, or other object, and thus made to take the place of the more bulky tripod.

No more impressive display of their manufactures is to be found in the exhibition than that of the Dresden firm of Ernemann, which occupies two large galleries, the first (No. 26) being decorated in a somewhat lurid scheme of ochre and blue, a large wall painting in which the latter colour predominates occupying the end of the room. The firm shows its many excellent manufactures in the way of folding cameras of various types, reflex cameras, and cinematograph instruments. It naturally gives a good deal of prominence to its latest production, a small cinematograph camera made entirely of metal, and serving not only as a camera, but also as the printing and projecting apparatus. The whole bulk of the instrument is scarcely more than that of a quarter-plate box hand-camera, and not much more in weight, and its working parts are evidently of a kind to withstand rough usage, even from those little accustomed to handling such apparatus. The instrument takes 100 pictures per metre—that is to say, twice the number of the standard cinematograph film, and gives an excellent 6ft. projection of the results. Apart from its use as a pastime, considerable advantage has been taken of it by teachers and educational bodies as a means of interesting and instructing children in many subjects. In their second gallery (No. 49) Messrs. Ernemann occupy the whole of one side of the room with a collection of the working parts and pieces of material—wood, metal, and leather—used in making one of their cameras. Here they show also cameras for process work, including one adapted for use both vertically and horizontally.

The old-established Brunswick firm of opticians, Voigtländer and Sohn, adopt at their stand (No. 34) a somewhat reserved and dignified tone, which accords well with their traditions in the optical trade. In addition to showing the many manufactures in the way of lenses and prisms, they carry the visitor back to the early history of their firm by showing catalogues of the year 1856 and later. A number of excellent prints and transparencies of portrait and landscape subjects are shown in demonstration of the capabilities of the modern Voigtländer lenses.

The Busch Optical Works of Rathenow show all the stages in the manufacture of a lens from the raw, rough-cut, and ground glass through the stages of polishing to the final cen-

The Kodak Rotunda.

numerous specialties of the company in apparatus and materials. At the demonstration table, also seen in the photograph, the manipulation of the company's papers and of its daylight system of developing plates and films are demonstrated.

The firm of Emil Wunsche exhibits the many substantial folding hand-cameras known to users in this country. Another notable piece of apparatus is an immense ladder tripod and camera specially designed for criminal photography: the camera may thus be used at an elevation of 12 or 14ft., being pointed vertically downwards upon the scene of any accident or murder. The legs of the tripod, including that built as a ladder, are made to fold into three for carrying. Among the

tred instrument, and they illustrate by some excellent diagrams the features of the "Bis-Telar" lens compared with one of ordinary type as regards its smaller size and shorter back focus. The exhibit itself includes the many well-known lenses and cameras of this firm. Messrs. C. P. Goerz present an exhibit which is very much on the lines of that usually arranged by them in this country, including a large number of enlargements showing the great resolving power of the Goerz anastigmats, and including a number of portrait subjects.

The Zeiss exhibit (No. 50) is representative of the many optical activities of the Jena factories. It includes a number of enlargements from quarter-plate negatives taken with the

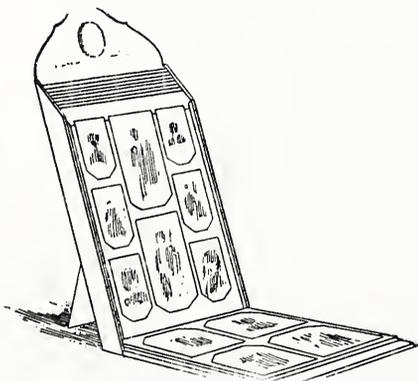

“Palmos” cameras from the Zeppelin airship, and Autochromes made with the “Ducar” filter, obviating any alteration from reversal of the ground glass when using the Autochrome plate. “Verant” viewing instruments are also shown, and one feature of the exhibit is the way in which the construction of the Zeiss lenses is shown by means of section models showing the curves and separation of the glasses. A smaller theatre in which demonstrations are given with the Zeiss “Epidiascope” projection lantern forms part of the exhibit.

Dallmeyer lenses occupy stand No. 39, and include the portrait, stigmatic, and telephoto objectives which are sold in

Germany by this leading firm's agents, Messrs. Carl Simonsen and Co.

At stall No. 83 the use of the dry adhesive binding-strips for lantern slides and passe-partout mounts is shown by the maker, Dr. Julius Neubronner. The binding strips are supplied in rolls of from 25 to 50 yards' length, or in lengths suitable for mounting the various standard sizes of transparencies and plates. A novel form of portfolio for holding and exhibiting photographs in the studio is shown by Oswald Weisser (No. 86a).

The portfolio is made with an open kinged front, and contains a series of mounts each taking seven or eight photographs, which mounts are similarly hinged to the bottom of the case. The latter stands of itself on a table, and the series of mounts can be turned down one after the other when showing prints to a visitor, both sides of each mount being available for the purpose.

Messrs. Raines and Co. have done their excellent work justice, and at the same time have given visitors to the Dresden Exhi-

bition some idea of the work of professional photographers by exhibiting a collection of prints and enlargements from negatives placed at their disposal by a number of leading professional photographers. Among these are H. Walter Barnett (London), Speaight, Ltd. (London), Drummond, Young, and Watson, and John Watson (Edinburgh), William Gill (Colchester), Harold Baker (Birmingham), F. A. Swaine (London), Brigham (Scarborough), Lena Connell (London), Oscar Hardee (Chislehurst), Elwin Neame (London), and Noreen Kirby (Liverpool). The portraiture is shown in the various media of bromide, platinotype, and carbon, and in execution of these processes, as well as in the style of mounting and framing, is quite representative of Messrs. Raines' standard of quality. Messrs. Speaight's work, portraits of H.R.H. Prince Wilhelm of Prussia from the sitting given to Mr. Richard Speaight at Potsdam, should be specially interesting to German visitors.

A new method of making enamel or ceramic photographs is shown at stall No. 97 by Mrs. R. Fuhrmann, by whom is supplied the dry plates which are the only material required in the process. Photographs transferred by this method to wood, stone, porcelain, and metal are exhibited. The many chemical specialties and dry plates of the firm of J. Hauff and Co. (No. 100) are shown in the exhibit of these well-known products. At stall No. 102 Ganzino, Ditta, Namias and Co., of Milan, show a screen for the projection of cinematograph and other pictures in daylight. It consists of two series of low, thin partitions running at right-angles to each other across the surface of the screen, which is thus divided up into a number of cells each about one inch square and about the same depth. The result of this screen was not shown in actual working, but it was easy to see that, although projections would be shaded from diffused light, the angle over which they would be visible would be very limited.

The dry plate works of Richard Jahr (No. 106) contains a large number of transparencies, many of them of considerable technical interest, apart from the testimonial they provide for the excellence of the manufacture. They include transparencies from exposures taken by ordinary lamp and gaslight, examples of night photography, comparative examples of ordinary and backed plates, reproductions of colour charts with different filters, and negatives and transparencies of a series of interior subjects, together with an excellent number of warm-toned lantern slides. In addition to these exhibits—representing the “Sigurd” and other Jahr plates—examples are shown of the interference colour results by Dr. Lehmann, of Jena, the plates for which are now made by Mr. Jahr. A fine collection of Autochromes occupies the stall of Messrs. Lumière, of Lyons, who also show a number of prints upon their various well-known papers. The Leto Photo Materials Co., of London, show examples of the excellent prints made on “Seltona” and other self-toning papers.

A companion pair of exhibits are those by the firm of raw paper-makers, Felix Schoeller, Jr., and Gevaert and Co., makers of printing papers, of Antwerp. Messrs. Schoeller, as sole suppliers of raw paper to Gevaert, exhibit a large number of prints made on papers of the latter manufacture, whilst Messrs. Gevaert exhibit a similar set, with intimation that the raw stock employed is that of Schoeller. The combined effect is to provide a very convincing display of the qualities of both manufacturers' products. The Gevaert Co. devotes a quite separate room to an exhibition of prints on their papers solely from the negatives of professional photographers, and a very fine collection of professional work is here brought together. The printing processes represented include the many grades of the Gevaert collodion papers, bromide and gaslight. Some interesting prints are shown by Emil Bühler (No. 116) in the way of prints of various colours made on a direct printing-pigment paper, which gives pictures of a very fine matt surface in which the half-tones have the rendering somewhat appropriately described

as "pearly." Another very fine collection of pigment prints is that made in the so-called "heliogravure" tissue of Alois Rieger (No. 120), which very closely imitate the appearance of a photogravure.

The exhibit of the Neue Photographische Gesellschaft, the parent firm of the Rotary Photographic Co. (which even Germans abbreviate to *En Pay Gay*), is big, and essentially commercial. The company have set themselves to demonstrate the large industrial use which they and others make of their products in the way of picture postcards, show cards, and many varieties of fancy goods (such as chocolate boxes, etc.) embellished with photographic prints. The rotary printing methods employed in this form of "photography by the mile" are emphasised by the exhibition of rolls of the raw and printed paper, and by a huge pyramid said to represent a record daily production of 21,942 metres of photographic paper. In addition there are examples shown of three-colour prints by the company's pigment films, which, however, do not show that any great advance has been made in this process. The company also demonstrate their new "Askau" or dusting-on process, in which prints of any colour are obtained by exposing under a positive transparency a paper coated with a sensitive mixture of rubber and asphaltum. This form of the dusting-on process has the advantage that the sensitive film may be applied from a non-aqueous solution, and in this way employed for the decoration of all kinds of surfaces—metal, leather, etc. The facilities provided by the "Askau" process for multi-colour prints are shown by a number of large examples, but the method would seem to have possibilities also for the making of prints in several colours of moderate size.

The well-known firm of Schering (No. 124) exhibits samples of its many chemical products, such as pyrogallie acid, hydroquinone, etc., and of the "Satrap," "Aristo," and other brands of printing papers. The General Paper Co. (No. 127), of Brussels, the combination of the factories of Blanchet Frères and Kleber, and of Steinbach, display their products on a most ornate setting of cream and gold, in which is included a list of the many Continental firms of which they are the sole suppliers of raw paper for photographic purposes. These include the Lumière Co., the Eastman Kodak Co., the Platinotype Co., and Kentmere, Ltd., in addition to about fifteen German factories. The well-known Dresden factory, the Vereinigte Fabriken, manufacturers of the "Crossed Swords" and other brands of printing papers, show the qualities of their products as expressed in the work of leading professional photographers, among whom are Dührkoop, Erfurth, Grainer, Pietzner and Raupp, all users of the "Albumat" paper. The only large exhibit of a British firm of manufacturers is that of the Ilford Co. (No. 130), which contents itself with three or four enlargements of considerable size on bromide paper, the quality and freshness of which, nevertheless, make an imposing display even after one has made the tour of many galleries of prints. The Auto-

type Co. (No. 131) show a selection of portraits and landscapes on their various tissues. In the exhibit of Trapp and Münch (No. 133) there are again represented photographers such as Dührkoop, Grainer, and Rauff, whose work on matt-albumen, and other papers is as fine as anything in the way of a photographic print in the exhibition.

Among the stalls of apparatus one of special interest is that of Gustav Geiger, of Munich (No. 140), who shows models of the "Ewon" automatic arc lamp and of folding finders and adjustable tripod heads. The firm of Siegel and Butziger (No. 144) show what may be termed a triple extension dark-room, designed for use in hotels or other places in which space may be thought to be a consideration. The table and shelving of the dark-room are built in a framework which forms the back of the room, fitting in which are two other supplementary frameworks, the smaller of which is closed and provided with a door. These two extending frames may be pulled out from the back frame in order to provide "at the full extension" about three times the space. The exhibit of Ed. Liesegang, of Düsseldorf (No. 149), includes a great variety of lantern, cinematograph, and projection apparatus, among which is an arrangement for the automatic delivery of slides into the stage of the lantern, the slides being fitted into a carrier which can be actuated so as to drop them one at a time behind the condenser, the previous slide at the same time dropping into a receptacle. Hugo A. Schneider (No. 153) shows some powerful incandescent gas lamps burning petroleum under pressure and mounted for use as studio lights. The intensity of the light apparently is quite sufficient for this purpose, although the system has the drawback of producing a hissing sound while the light is in action. The Aerograph Co. (No. 155) exhibit their methods of spray colouring and retouching, their stall being fitted up for the constant demonstration of the method of using the air-brush. The firm of Koebig (No. 178), makers of machinery for photographic plate and paper making, have put down quite an installation of these machines, whilst visitors to Dresden will have the opportunity of visiting their factory in the suburb of Radebeul. Lastly, mention should be made of the portable flash-lamp apparatus of Friedrich Schroeder (No. 179), which is now made in an improved form, allowing of the light being raised some 15ft. high, as is frequently necessary in taking flashlight groups of large size. The Schroeder lamp, of which good use has been made by many professionals in Germany, and by some in this country, has been used in making a number of excellent examples of portraiture, which are also shown.

This concludes the account we can give of the trade exhibits in the exhibition, except to mention the two shops which are arranged one on either side of the main entrance. These are the establishments of Oskar Bohr and Louis Lang, both photographic dealers of Dresden. Each includes a dark-room, where plates may be changed and developed, and where ordinary photographic requisites may be obtained.

DEVICES FOR THE AUTOMATIC DEMONSTRATION OF FACTS OF LIGHT, COLOUR, AND PHOTOGRAPHY.

II.

[The following notes complete the description of the experiments arranged by Dr. Goldberg at the Dresden Exhibition for the popular demonstration of the elementary facts of light and colour. As already stated, each experiment is arranged in a cabinet in such a way that the observer is able to perform it himself.—Eds., "B.J."]

28. *Mixtures of Coloured Grains.*—Instead of distributing the colours in lines they may also take the form of grains spread in a thin film (Lumière Autochrome process). In such methods the grains collect in islands which are, however, visible to the eye.

Experiment.—A wheel, composed of two plates of glass, fixed at a distance of about half an inch apart, and closed round the edge, is about half filled with coloured beads—red, green, and

blue. The wheel is caused to rotate by means of a handle projecting from the front of the wheel, when it is found that, however much the beads may be mixed in this way, there are always present numbers of "islands," formed by a number of beads of the same colour.

29. *Additive Mixture by Coloured Illumination.*—Certain processes of colour photography (Ives, Miethe) depend on the combination

of coloured rays, which are projected together upon the screen. In principle the colour mixtures are the same as those in the previous experiments: the mixtures thus produced suffer from dilution with white exactly in the same way.

Experiment.—Above the peep-hole of the cabinet (that is fixed inside to the top of the front wall) are three incandescent lamps with globes of red, green, and violet. A mirror fixed to the back wall of the cabinet and slightly inclined allows of these being seen from the peep-hole. Below it, opposite the hole, is a white screen. On pressing the switches (outside the cabinet) of all three lamps the screen is seen to be illuminated by white light; on using any two pairs of the lamps together the effect of the mixed colours can be seen on the screen, the lamps themselves being seen at the same time in the mirror. The whitish effect of the mixed colours is to be noticed in this case also.

30. *Subtractive Colour Mixture by Colour Illumination.*—Whilst in the case of additive mixture a very whitish-yellow is produced from green and red, in the case of subtractive mixture the result is black. In order to mix the colours in the subtractive way a con-

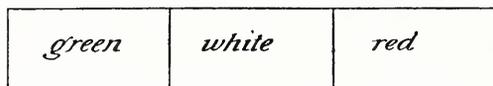

Fig. 12.

venient plan is to illuminate an inscription in colours with light of different colours. The same effect is produced by illuminating the inscription with white light and examining it through various coloured glasses.

Experiment.—To the back of the cabinet is affixed a printed inscription, in red on a green ground, to the effect:—

“THIS RED WRITING IS BLACK ON WHITE IN GREEN LIGHT; WHITE ON BLACK IN RED LIGHT.”

The three switches on the outside of the cabinet allow of a green, red, or white lamp being put in action. The effect of subtractive mixture can be observed by using either the red and green lamps or by illuminating the writing with white light and examining it through a red glass, the front aperture of the cabinet being made in the form of a slit, as in Fig. 12.

31. *Subtractive Mixture by Coloured Particles.*—Mixture by coloured grains in a film of sufficient thickness leads to subtractive mixtures, and therefore gives blackish instead of whitish tones. Mixtures of printing colours and pigments, as well as of solutions, belong to this class of mixture.

Experiment.—A glass tube, about one inch in diameter and about nine inches in length, is mounted on an axis so that the contents can be shaken up by the lever affixed to the outside of

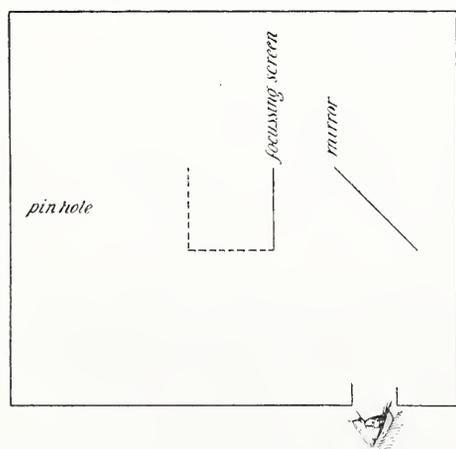

Fig. 13.

the cabinet. It contains a green solution, and above it an oily red solution, which, on being shaken up with the green, rapidly separates from it. On putting the lever into rapid action the mixture is seen, by a light placed behind it, to be a dark blackish-brown. It separates in a few seconds into its two constituent layers of red and green.

32. *Pinhole Camera.*—Light, so long as it is proceeding in one and the same substance, moves in straight lines. On this fact is based the simplest of all photographic apparatus—the pinhole camera.

It consists of a small opening in the side of a box, at some distance from which is placed the ground glass. Each point of an illuminated object—e.g., an incandescent lamp—sends a ray of light through the small opening, which ray passes to the ground-glass screen, and there illuminates a small corresponding point. In this way a complete but inverted image of the object is formed on the ground-glass screen. The pinhole camera has no focus, and therefore gives invariably sharp pictures, so long as the pinhole is small enough. If the hole is larger, the image on the ground glass becomes unsharp, since the light from a single point of the object obtains access to different parts of the ground glass.

Experiment.—The left-hand side of the cabinet is provided with a pinhole of adjustable size, a lever on the front allowing of the hole being enlarged or contracted by means of a sliding plate. A ground-glass screen is placed opposite the pinhole, and can travel to and from it within limits of about 4 inches. On the further side of the screen from the pinhole a mirror is placed at an angle of 45 degrees, the peep-hole in the front of the cabinet opposite this mirror allowing the image on the ground glass to be seen. The object is an incandescent lamp, placed outside the cabinet, or, in the case of a series, in the adjoining cabinet. (Fig. 13.) On moving the focussing screen the image is seen to alter in size only whilst retaining its definition. By moving the pinhole lever the unsharpness due to enlargement of the hole is seen, in both cases, by reflection in the mirror.

33. *Laws of Reflection from Mirrors.*—Light which meets with any object is divided into three parts—(1) that thrown back by the object (reflected), (2) that entering the object and absorbed by it, and (3) that passing through the object. As regards the direction of the light reflected, this follows the law that the ray of light is reflected at the same angle as that at which it met the surface.

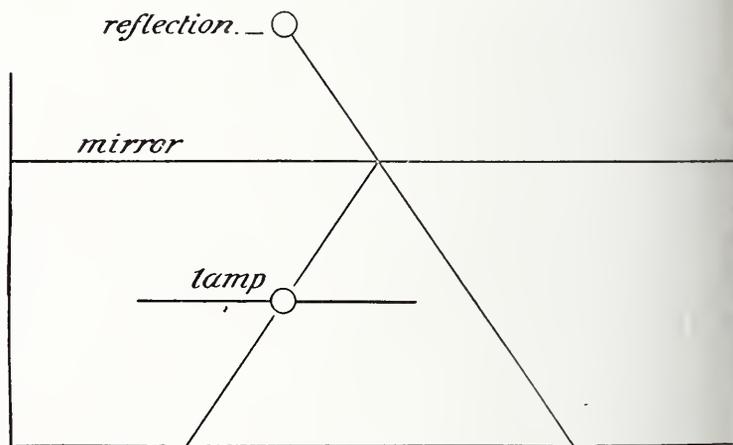

Fig. 14.

As a result of this it follows that an object reflected in a mirror appears to be behind the mirror, and at the distance equal to its actual distance from the mirror.

Experiment.—Two peep-holes are provided on the front of the cabinet. An incandescent lamp is placed a little to the right of the left-hand hole, being mounted in a screen, represented by the line in the figure. At the back is a mirror, and in looking through the right-hand peep-hole, the reflection of the lamp is seen at an apparent distance behind the mirror equal to the actual distance of the lamp from the mirror.

34. *Bending the Light in a Prism.*—When any transparent body is placed in the path of light rays, the light is bent by this object altering its direction.

Experiment.—The front of the cabinet is provided with two apertures, A and B, of a length about 5 inches apart. At the back of the cabinet, about midway between the two apertures, is a red incandescent lamp, the light from which can be seen from aperture A. On turning a lever and moving a prism into the path of the rays the light disappears, owing to refraction, and the eye must be applied to aperture B in order to see it.

35. *Bending of Light in Different Substances.*—The angle through which the light is bent on passing through a substance depends on the form of the vessel in which the substance is contained, and on the substance itself. Different substances have different powers of refraction.

Experiment.—The cabinet is made with two apertures on a level, A and B, between which (in the cabinet) is placed a three-cornered vessel, containing water and anisol (oil of aniseed), the latter floating on the water. An incandescent lamp is so placed behind this double prism that, through the portion filled with water, the light is bent to aperture A, whilst the stronger reflective power of the anisol brings it to aperture B.

36. *Diffraction of Light and the Spectrum.*—Light falling on a plate, which is provided with numerous fine lines like a grating, is partially altered in direction. Whilst in the case of the refraction of light the whole of the light transmitted changes its direction, light passing through a grating divides into three portions, one of which proceeds in the original direction, whilst the second is bent to the right, and the third to the left, through a certain angle. This angle of diffraction depends on the colour of the light.

Experiment.—The light of a red lamp is caused to pass through a fine grating of 800 lines per mm. The red lamp can then be seen simultaneously through apertures 1, 2, and 3 in the front of the cabinet. On turning a lever up to a stop a lamp is brought into position, giving both blue and red rays. In this case the image seen through opening No. 1 is violet (mixture of red and blue); in openings Nos. 2 and 3, on the other hand, the red and blue images of the carbon filament are seen separated from each other. On turning a second lever to a stop, a white lamp is brought opposite opening 1; the images in openings 2 and 3 are then seen spread out into a coloured spectrum band.

37. *Diffraction of Light in the Half-tone Screen.*—Diffraction, as seen in Experiment No. 36, takes place when light passes through any series of fine lines, as, for example, through the half-tone screen used in process work. If the light-source be observed through such a screen a system of small spectra result, which combine to form a cross, having the same direction as the lines of the screen, and therefore rotating with the rotation of the screen.

Experiment.—A half-tone screen is mounted in the cabinet, so that it can be rotated through an angle by a lever on the front. On observing the light from a distant lamp through the screen the former is seen to be diffracted from all sides, forming a cross, which can be turned to an angle by turning the screen.

38. *Interference.*—Allied with diffraction phenomena are those of interference. They occur in the case of an extremely thin transparent film—*e.g.*, beautiful interference colours are shown on soap-bubbles. Such colours frequently occur when two glass plates are pressed together, as in the printing frame. Pressure upon the two glasses causes the formation of coloured rings (Newton's rings).

Experiment.—A printing frame provided with two glasses is fixed rigidly at the back of the cabinet, a lever operated from the front allows of the glasses being pressed in contact, and showing the coloured Newton rings.

39. *Absorption of Light.*—All substances have the property of absorbing a portion of light passing through them, and in this way reducing the intensity of the light. Only a few substances are known which absorb all the colour elements of white light uniformly. Such substances have invariably a grey colour: among them is the finely powdered silver of the photographic plate.

Experiment.—In one of two apertures on the front of the cabinet a direct-vision spectroscopy allows of the spectrum of white light being seen. By turning a lever successively into positions 1, 2, 3, 4, 5, 6, 7, 8, the light is damped down with films of increasing opacity. The spectrum, as a whole, becomes feebler, but its character is not changed.

40. *Selective Absorption and Absorption Spectrum.*—Most substances absorb the different constituents of white light in very different degrees. Most of these substances are recognised from their more or less strong colour. By spreading out the light transmitted by the coloured substance, by means of a prism or grating, the absorption spectrum of the substance is seen. As an approximate rule it may be said that a colouring matter shows in its absorption spectrum a dark band—absorption band—which is the complementary of its own colour. Thus most blue bodies have an absorption band in the yellow part of the spectrum, all red bodies in the green, etc. The rule is not without exceptions—*e.g.*, most green dyes transmit a good deal of red light.

Experiment.—A series of eight different coloured dyes, mounted in gelatine films upon a disc, are examined by looking through

aperture A; aperture B is provided with a direct-vision spectroscopy, and allows of the absorption spectrum of each material being compared with its appearance in white light.

41. *Alteration of the Absorption with the Thickness of Film.*—When examining one and the same dye in different degrees of thickness it is found, as a rule, that the character of the absorption spectrum varies with the thickness of the film—that is to say, the absorption spectrum applies only to a certain thickness of film of the dye. Alteration in the concentration of the solution of a dye has the same effect as alteration in the thickness of the film.

Experiment.—Two apertures in front of the cabinet allow (1) the appearance of a dye solution, to be observed in several degrees of concentration, whilst through the other aperture the absorption spectrum of each can be observed.

42. *Dichroic Substances.*—In many cases the absorption spectrum undergoes such great alteration with different thicknesses of film that the colour tone of the film is entirely different in the two cases.

Experiment.—A wedge-shaped vessel is filled with a solution of dye, and may be moved across an aperture so as to show the different appearance at greater and greater depth of solution. In the case of a thin layer of liquid the colour is green; in a thicker layer, yellow; and in very thick, red (mixture of methyl-violet and tartrazine).

43. *Absorption Curves.*—In order to obtain a complete record of the character of the spectrum with different thicknesses of film, the various spectra may be thrown one on the other, and their features connected with a line. This line is the absorption curve of the dye.

Experiment.—The apparatus is arranged so as to show the spectrum of a dye formed so as to show the amount of absorption in different parts of the spectrum.

44. *Relation Between Absorption Spectrum and Colour of a Dye.*—Two dyes of similar absorption spectrum are necessarily of similar colour, but two dyes may have the same colour and appear absolutely alike yet have very different absorption spectra.

Experiment.—In one opening A of the cabinet are affixed two green glasses of identical appearance; the opening B contains a spectroscopy, in which it is seen that the spectra of the two glasses are altogether different.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications have been received for patents between June 7 and 12:—

FILMS.—No. 13,328. Improved manufacture of photographic films. Edwin Brandenberger, 111, Hatton Garden, London.

FLASH-LIGHT.—No. 13,331. Improvements relating to flash-light powders. August Lesmüller, 7, Southampton Buildings, London.

ILLUMINATION.—No. 13,458. Improved process for illuminating opaque images on a brilliant metallised ground for the purpose of projecting them. Charles Dupuis, 18, Southampton Buildings, London.

LAMPS.—No. 13,473. Improvements in mercury or metallic vapour lamps. Henry Andrew Kent, The Poplars, Maidstone Road, Bounds Green, London.

MOUNTING.—No. 13,504. Improved method of mounting photographs. Harry Robert Betts, 35, Cannon Street, London.

SCREENS.—No. 13,508. Improvements in light-controlling screens for photographic purposes. Joseph Walter Freckleton, 111, Hatton Garden, London.

CINEMATOGRAPHS.—No. 13,649. Improvements relating to cinematographs and like apparatus. Albert Harrison Moorhouse, 18, Southampton Buildings, London.

PHOTOGRAPHIC IMAGES.—No. 13,666. Improved method of making photographic images divided into separate elements. Rudolf Widmann, 6, Lord Street, Liverpool.

PNEUMATIC TUBES.—No. 15,686. Improved automatic device for actuating the pneumatic tube and shutter of photographic lenses.

Charles Dickens, 14, Washington Street, South Circular Road, Dublin.

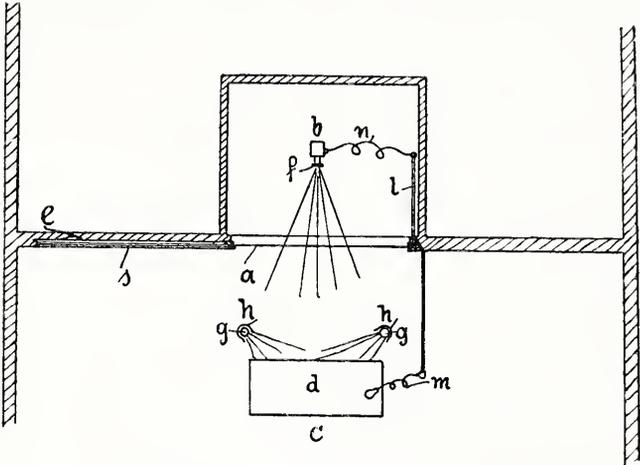

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STUDIO MIRROR ACCESSORY.—No. 3,763. 1909 (February 18, 1908)

This invention relates to means by which the sitter can observe himself as in a mirror at the moment of being photographed. A mirror does away with the diffidence or shyness of the sitter which occurs frequently, particularly in children, when looking at the camera. Further, the sitter can himself exactly adjust his position, as he can observe himself in full size in a mirror before

and during the exposure. An ordinary non-transparent mirror arranged beside the camera is not employed, but a so-called black mirror is formed. The studio is divided during the exposure by a glass wall into two chambers, of which that in which the camera and photographer are located is but little illuminated, whereas the chamber occupied by the sitter is illuminated brightly. In this arrangement the pane of glass acts as a mirror, by looking into which the sitter can place himself in any desired position.

The room is divided by the colourless plate-glass wall *a* into the camera-chamber *b* and the sitter's chamber *c*, the latter containing the place *d* for the person or group of persons to be photographed. The plate-glass wall is preferably movable on rails *s* along the wall *e*. When the glass wall is put in position between the camera and the sitter, the illumination in the camera-chamber *b* is diminished. When daylight is not being used, the artificial light required for the photographic exposure is adjusted, e.g., lamps *g* are lit, the lamps being provided with shades *h* which keep their rays of light from the camera-chamber.

The plate-glass wall thus acts as a black mirror and consequently allows the person being photographed to observe and correct his position and expression during the exposure without being influenced at all by the view of the camera and the movements of the photographer. In addition the embarrassment of the photographer in making the necessary manipulations is also done away with, as he receives sufficient reflected light for his work from the chamber *c*.

If a tube *l* connected with an instantaneous pneumatic shutter is placed in known manner within reach of the sitter, he can himself bring about the exposure at the correct moment by means of the tube *m*. A connecting tube *n* admits of the camera being moved in the camera-chamber. Adalbert Iser, 237, Friedrich Strasse, Berlin.

DARK-SLIDES.—No. 14,827. 1908 (July 13, 1908). The invention is a form of dark-slide or plate-holder which will not perceptibly add to the thickness of the camera. The plate is held in a chamber formed on a back plate adapted to fit into an opening which is in the removable back of the camera. The back plate is extended beyond the ends of the chamber and provided with a slot through which a removable slide or shutter composed of comparatively stiff but flexible material is inserted from the rear of the holder to close the exposed surface of the photographic plate. The

preferred form of plate-holder comprises a back plate having an intermediate frame on the front surface thereof, this frame forming the plate chamber, and a covering plate having flanges which extend round the frame and back plate to the rear side of which they are secured.

Near the slot in the back plate through which the shutter or slide is inserted a trap is provided which prevents light entering the plate chamber when the slide has been removed. Kodak, Ltd., for Robert Krödel, Rochester, U.S.A.

CINEMATOGRAPH-PHONOGRAPH.—No. 16,728. 1908 (August 8, 1908).

The record cylinder or disc of the talking machine is provided with holes or pins to allow of readily connecting to it the electric contact mechanism, which may consist of a plate having a contact strip on which alternately bears a spring upon an arm in perpetual contact with a strip, or a revolving tappet which comes into contact with a spring plate and is actuated by a mitre wheel gearing with a similar wheel on the gramophone disc. Oskar Messter, 18, Schiffbauerdamm, Berlin.

New Trade Names:

COTTAGE (DESIGN).—No. 312,145. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. W. V. Aldridge and Son, 7, Islington Green, London, N., merchants. April 8, 1909.

KINOGRAPHON.—No. 312,735. Apparatus consisting of a cinematograph in combination with a talking machine and synchronising contrivance. Nürnberger Metall- und Lackierwaarenfabrik vorm. Gebrüder Bing Actiengesellschaft, Blumenstrasse 16, Nürnberg, Germany, manufacturers. May 1, 1909.

Exhibitions.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

This year for its annual members' exhibition the North Middlesex Society has adopted the altruistic method of transferring its exhibition *en bloc* to the lecture hall of the Islington Public Library, a course which must have given a good deal more trouble than displaying the pictures nearer home, but has afforded the opportunity of bringing some pictorial fruits of photography before the public in this crowded district of London. The photographs are arranged in nine panels around the walls of the hall, to which admission is free until July 3, whilst lectures by members of the society and others are given on one or two nights in the week. The result should be to stimulate an interest in photography as a pastime, even if not as a medium of artistic expression. The staunch members of the North Middlesex Society, whose work is to be seen each year at this members' exhibition, as well as at that of the R.P.S., are well represented on this occasion. We very much like Mr. Fraser Black's two pictures, one entitled "A Sunny Sea" and the other "Evening Ebb," and both in a scale of light tones which well renders the delicacy of the subjects. Mr. Charles Beadle, in one or two of his subjects, has essayed to use an oil or bromoil process in place of the carbon or platinum, in which his work has usually been done, and the result is to give a poor version of what is doubtless in the negatives. In the oil prints there is a patchiness and artificiality which make a print such as that of the "Dee at Ballater," infinitely preferable. Another oil print of the "Precincts at Ely," by E. H. Piddington, has the appearance of having been made with a camera which was jarred at the moment of exposure. We doubt if this had been hung at all if it had been in any other process. We might almost exclaim, "Oh, oil, what crimes are committed in thy name"! Mr. H. W. Fincham, president of the society, shows a good deal of excellent work, of which we specially like "The Crypt of St. John's, Clerkenwell." Mr. J. C. S. Mummery is represented by some of his characteristic work in the gum process, among which "A Sunny Waterside, Chesham," is perhaps the most pleasing. One very clever rendering of the natural beauty of sunshine is a photograph by E. Burton. The subject is a white lodge or summer-house overhanging a canal. We are glad to see again the "Winter Showers," by Mr. S. E. Wall; its convincing tone of a winter landscape and the good placing of, and movement in, the figure of the peasant make it an excellent piece of work. Equal to it in its fidelity of a somewhat similar aspect of nature is "January,"

by Mr. H. Stuart. Mention should also be made of the quaint figure studies of children by Mr. Louis Dick, and of one print by Mr. E. C. Ridge, entitled "Dawn," and very closely representing an exposed clump of trees in an open country by early morning light. The hanging and arrangement of the pictures in a room which is not particularly fitted for the purpose says much for the pains taken by the committee and its secretary, Mr. Charles A. Morgan.

Analecta.

Extracts from our weekly and monthly contemporaries.

Peppertype.

Mr. W. W. Wall, writing on the above process in "The Amateur Photographer and Photographic News" for June 22, says: "The formula is as follows:—

- | | |
|---|----------------------|
| A. White pepper | 20 $\frac{1}{2}$ lb. |
| Benzole | 20 ozs. |
| B. Solution of 1 in 20, gum dammar and benzole. | |
| C. Solution of indiarubber in benzole, fairly thick (bicycle cement will do). | |

For use, take A, ten ounces; B, one ounce; C, one ounce. Filter, and you are ready to coat any hard glazed surface, as glass, opal, or hard-sized white paper such as the Autotype Company supply.

"The next procedure is to expose for a few minutes in the sun under a transparency, and then dust over with any litho dry colour or powdered metals, as gold, silver, bronze, etc., and, with a final brushing with a clean soft brush, the whole thing is complete."

New Materials, &c.

"EALING" P.O.P.—A sample of this printing-out paper, sent to us by Mr. T. R. Harris, 2, Clovelly Road, Ealing, London, W., has proved in our hands to give excellent results of rich deep tone when treated in the ordinary gold and sulphocyanide bath. The tone does not alter in the fixing bath, and the paper is evidently one of high quality. Free samples may be obtained by readers of the "B.J." on application, and a cash discount off the standard price of 15s. per quire is offered to bona-fide professional photographers.

CATALOGUES AND TRADE NOTICES.

"THE GOERZ LENS AND ITS USE."—The new list of the C. P. Goerz Optical Works, Ltd., just issued under this title, is a 24-page booklet, only three pages of which are given up to a price list; the other twenty-one contain advice on the choice of a lens for hand-camera, architectural, and other photography, and, though written in reference to the various Goerz objectives, is none the less a reliable guide in the matters pertaining to the selection of focal length, aperture, separability, etc., of a lens in view of particular requirements. If testimony were needed of the high optical and mechanical qualities of the Goerz lens it is provided by the many illustrations of all descriptions of subjects. The booklet is one which is deserving of a careful perusal. It is sent free on application to Messrs. Goerz, 6, Holborn Circus, London, E.C.

STREATHAM PHOTOGRAPHER'S DEATH.—At a Westminster inquest last week on Samuel Jutsum, 50, a photographer, of Knollys Road, Streatham, who died in Charing Cross Hospital, it was stated that he deceased went home in great pain, saying he had fallen off a bus at the foot of York Road, West Norwood. Death was due to peritonitis, which, in the opinion of the doctor, was set up by some form of violence. Neither the relatives nor the police had been able to discover anything about the accident.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 26.

Kinning Park Co-operative Camera Club (Govan). Outing to East Kilbride.
 South London Photographic Society. Excursion to St. Albans.
 Birmingham Photographic Society. United Excursion for Societies in District to Stratford.
 South Suburban Photographic Society. Outing to Monk's Wood, Epping Forest.
 Hackney Photographic Society. Outing to Claygate.
 Southend-on-Sea Photographic Society. A Trip in the Thames Estuary.
 Borough Polytechnic Photographic Society. Outing to Bookham.
 Handsworth Photographic Society. Excursion to Stratford-on-Avon (Midland Photographic Federation, Local Societies).

TUESDAY, JUNE 29.

Hackney Photographic Society. Negative and Print Display.

THURSDAY, JULY 1.

United Stereoscopic Society. Paper: "Natural History Photography."

SOUTHAMPTON CAMERA CLUB.—Dr. W. P. Purvis gave a very interesting lecture last Monday on Radiography before a large audience. The lecturer stated that Professor Röntgen discovered, by accident, during some experiments with a Crooke's vacuum tube that a photographic plate enclosed in a dark box exposed to its rays received an image of metal objects, the box itself appearing transparent. A novel field of photography was thus opened up and photographs were now obtained which show plainly the bones in the body, even to details of their texture, while bullets, needles, or other foreign bodies of metal, are instantly located. By the aid of a screen coated with platino-cyanide salts or other fluorescent substances, it was possible to see the bones or other interior parts of the body. By the courtesy of Dr. Norman Aldridge, who had kindly lent a portion of the apparatus, the lecturer ably demonstrated the use of the Crookes tube, and also a fluorescent screen. Numerous radiographic negatives were shown which illustrated the practical utility of the Röntgen rays in use. Various questions were answered by the lecturer, and a hearty vote of thanks, proposed by Mr. F. G. Ryder and seconded by Mr. S. G. Kimber, was accorded the lecturer, and also the society extended their appreciation to Dr. Aldridge for his kindness which greatly contributed to the interest of the lecture.

Commercial & Legal Intelligence.

CANVASSER SENTENCED.—At Somerset Assize at Wells, last week, George Benjamin Bates, canvasser, was indicted for converting to his own use certain sums of money, amounting to £2 5s., received by him on account of his employer, Ernest English Cox, at Taunton, between May 1 and 25. Mr. Goodman prosecuted, and Mr. Mathias (for Mr. Inskip) defended. It was alleged that the prisoner retained moneys received by him for photographs on behalf of his employer. The jury found prisoner guilty, and sentence of six calendar months' imprisonment, with hard labour, was passed.

A CITY BANKRUPTCY.—The first meeting of creditors in the case of Alfred James Lewis, photographer, trading as W. Wright, at 85, Bishopsgate Street, E.C., was held at the London Bankruptcy Court on June 17. Debtor's statement of affairs showed unsecured liabilities amounting to £1,140, and the fully secured creditors claimed £1,622, holding securities worth £2,070, leaving a balance of £447 for the estate. Beyond this the only assets disclosed were the trade furniture, which was valued at about £20. The bankrupt, who is twenty-five years of age, states that he commenced business as a photographer at 85, Bishopsgate Street, about 1900. He bought the business from Mr. Wright for £800, and took over certain liabilities. The purchase price was to be paid by instalments over a period of two years. Debtor had no capital when he commenced, but he carried on the business successfully. About three years ago he took a large house with the idea of letting lodgings. This business proved a failure. Debtor executed mortgages on his business premises, which he held on an eighty-seven years' lease at a rent of £90 per annum. The first mortgage was for £1,500, the second for £50, and the third for £1,000. Debtor said he thought the busi-

ness might with advantage be carried on for the benefit of the creditors. The O. R.: "Not unless you pay the rates, and the interest on the mortgages." In further examination the debtor said he estimated his gross profits to be about £350 a year, and his personal expenses had been £200 per annum, which he estimated to be his net profit. He considered that the business had been profitable up to the last twelve months, since when trade had been very bad, and to this and to the interest on the mortgages he attributed his present position. The Official Receiver said he thought that taking into consideration rates and taxes and the charges on the mortgages, debtor had over-estimated his net profits. There were only three creditors present, and the matter was left in the hands of the Official Receiver.

HASTINGS PHOTOGRAPHER'S AFFAIRS.—At Hastings, on June 15, the public examination took place of Alfred Chapman Blades, photographer, 50, Queen's Road, Hastings. The liabilities were put down at £149 12s. 9d., and the assets at £24 14s. 8d. Debtor said he commenced business in December, 1908, with a capital of £20, he being twenty-one years of age at the time. He agreed to buy the business in Queen's Road for £80, and paid half of this down with money borrowed from his father, the arrangement being that the balance should be cleared in quarterly instalments. It was represented that the takings were £7 per week, but he found the takings were only about £3 a week, out of which he had to pay expenses. An action had been commenced against the vendor for misrepresentation. The unsecured liabilities included a claim by the father for £92 for money lent and £28 odd balance owing to the vendor of the business. The examination was concluded.

LEGAL NOTICES.—Charles Hamilton Walker, carrying on business under the style of the High Street Photographic Company, with a partner, at 120A, High Street, Margate, has been adjudicated bankrupt. The Receiving Order was made on June 10 on debtor's own petition.

A meeting of creditors and shareholders in the British Cinema Company, Ltd., registered office, 47, Old Kent Road, S.E., is to be held at the Companies Winding-up Department, 33, Carey Street, on July 1 at 11.30 and 12 a.m.

Notice is gazetted of the voluntary winding up of the Improved Bioscope Co, Ltd. Mr. Harry Wilson, 23, Devereux Court, Strand, has been appointed liquidator.

NEW COMPANIES.

COTSWOLD PUBLISHING COMPANY, LTD.—Capital, £1,000, in £1 shares. Objects: To acquire the business of the Cotswold Publishing Company at Britannia Mills, Wotton-under-Edge, Glos.; to adopt an agreement between C. R. W. Bagwell and T. W. Barry, and to carry on the business of photographers, photo-mechanical printers, gold blockers, etc. Private company. Table "A" mainly applies. Registered office, Britannia Mills, Wotton-under-Edge, Gloucester.

SARONY AND COMPANY, LTD., have been registered as a private company with a capital of £2,000, in £1 shares, to take over the business carried on at Scarborough and Harrogate by a company of the same name, and to act as photographers, painters, artists, designers, picture dealers, etc. The first directors are Mr. A. O. Fisher, Mr. G. G. Perfect, Mr. S. W. Fisher, and Mr. S. P. Turnbull.

PESTALOZZI STEREOGRAPH AND DIAPOSITIVE COMPANY, LTD.—Registered June 7. Capital, £100, in £1 shares. Objects: To carry on the business of dealers in stereoscopic views, stereoscopes and lantern slides, photographers, makers of and dealers in photographic and optical apparatus and instruments, etc. Registered without articles of association. The first directors are: D. Paisley and A. S. Forsythe.

THE HEALTH RESORTS DEVELOPMENT ASSOCIATION has published booklets for the Town Councils of Chepstow, Deal, Llandrindod Wells, Malvern, Sidmouth, which, in view of the approaching holiday season, should interest our readers and will be sent free if a post-card request is sent to the respective Town Clerks. The guide to Sidmouth is particularly well illustrated, chiefly from photographs by Mr. G. T. Harris, of the Western Studio, Sidmouth, by whom also the text of this guide has been written.

News and Notes.

AN INVITATION TO PHOTOGRAPHERS.—As we go to press we are enabled to make the announcement that Messrs. Speaight, who for the past few weeks have been holding at their galleries in New Bond Street an exhibition of portraits of "Fair Children," have fixed the evening of July 21 on which to invite members of the photographic craft to pay them a visit. The gallery will be specially set apart on that evening from 6 to 8 p.m. for the purpose, and any photographer or photographer's assistant will be made welcome on presentation of his own card or that of his firm, it being Messrs. Speaight's hope that the exhibition of Royal Children, which has attracted a great deal of notice in the press, may interest their fellow photographers. A further announcement in reference to this visit must be postponed until next week.

THE DEATH is announced of Mr. Francis Kotch, who has carried on business as a photographic dealer under the name of Kotch and Friedlander, 10, Coleman Street, London, E.C., since 1888. The business will be wound up.

THE NORTHERN PHOTOGRAPHIC EXHIBITION, held in the Mosley Street Art Gallery, resulted in a profit of £100, and as a mark of their appreciation of his services as exhibition secretary the members of the Manchester Amateur Photographic Society have presented a grandfather's clock to Mr. S. L. Coulthurst. In acknowledging the gift at the society's meeting, Mr. Coulthurst expressed the opinion that the exhibition raised photography higher in the estimation of many who had been inclined to scoff at camera work as an art.

B. J. EDWARDS AND Co., Castlebar Works, Ealing.—This business has been purchased by the Leto Photo Materials Co. (1905), Ltd., by whom the manufacture of the Edwards' plates, films, and other specialties will be continued. All communications should, however, be addressed to the head office of the Leto Co., Roman Wall House, 1 Crutched Friars, E.C.

MR. G. ALBERT SMITH has been awarded the silver medal of the Royal Society of Arts for his paper on "Cinematography in Natural Colours" read at an ordinary meeting of the society last year.

ENSIGN FILM COMPETITION.—Captain M. McNeill, D.S.O., of Dungrinach, Oban, is the winner of the "Ensign" Roll Film Competition for June. Houghtons Ltd. offer a three-guinea camera every month for the best negative on "Ensign" film. The entries close on the 3rd of the month. Entrance is free, and a competition form is enclosed with every spool of "Ensign" film.

INTERNATIONAL CONGRESS OF APPLIED PHOTOGRAPHY.—The following is the complete prospectus of the Congress to be held at Dresden from July 11 to 15, 1909. The apparent scientific character of the Congress, as evidenced by the subjects on which papers have already been promised, will not prevent the proceedings being of a popular nature, and attractive as also instructive to a wide circle of amateurs and others engaged in industrial undertakings. The list of papers includes the following:—Professor Dr. E. Doležal (Vienna), "Photogrammetry"; P. H. Eijkman (Scheveningen), "Recent Applications of the Röntgen-stereoscopy"; Dr. K. Kieser (Düsseldorf), "Sensitometry of Photographic Printing Papers"; Professor Dr. Konen (Münster), "Spectrography"; Dr. A. Kopf (of the Königsstuhl-Observatory, Heidelberg), "Photography in Astronomy"; A. and L. Lumière (Dr. Seyewetz), "Autochrome Plates" (lantern lecture); Dr. C. E. K. Mees (London), "Report on the Present Condition of Sensitometry"; Professor Dr. A. Miethe (Charlottenburg), "The Preparation of Schumann Plates"; Dr. Panconcelli Calzia (Marburg), "Application of Photography to Experimental Phonetics (Physiology of the Voice and Speech)"; Professor R. A. Reiss (Lausanne), "Photography in the Administration of Justice"; Dr. W. Scheffer (Berlin), "Mosaic-screen Plates in Colour Photography" (lantern lecture); Professor C. G. Schillings (Weiherhof), "Contributions to Photography of Animals Living in a State of Nature." Among those attending the Congress will be representatives of the Royal Saxon Government, of the City of Dresden, of the three High Schools at Dresden and other State institutions. The hon. presidents are Messrs. W. de W. Abney, Alfonse Bertillon, L. A.

Ducos du Hauron, A. Freiherr v. Hübl, F. E. Ives, Robert Koch, Hermann Krone, G. Lippmann, A. and L. Lumière, G. N. Lockyer, Ernst Mach, A. Michelson, R. Namias, G. Pizzighelli, P. Rudolph, H. Roscoë, C. Röntgen, M. Wolf, R. W. Wood, J. Waterhouse, and others. Intimations of intention to attend should be addressed to the Hon. Secretary of the Congress, Herr Dr. H. Weisz, 27, Winkelmannstrasse, Dresden-A., of whom all information on the Congress may be obtained.

Correspondence.

- We do not undertake responsibility for the opinions expressed by our correspondents.
- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

BRUSSELS INTERNATIONAL EXHIBITION, 1910.

To the Editors.

Gentlemen,—I venture to request that you will be good enough to permit me to draw the attention of your readers, through your columns, to the importance of the International Exhibition to be held at Brussels in 1910. As you are no doubt aware, a new departure has been made by his Majesty's Government in inaugurating a permanent Department—the Exhibitions Department of the Board of Trade—to promote British interests in connection with foreign exhibitions, which Department is, for the first time, organising a representative British Section at Brussels. In addition, his Majesty has appointed a Royal Commission to assist the Exhibitions Branch in its efforts to further British trade interests at the Brussels and certain other forthcoming exhibitions.

It may interest you to know that his Majesty's Government have acquired a suitable site for the British Section, and are offering special facilities to exhibitors of British manufactures, such as the general management of the section, the provision of show-cases free of charge, the taking of delivery of goods, the storing of packing cases, the provision of unskilled labour to assist exhibitors in packing and unpacking, and many other important advantages, particulars of which can be obtained on application to The Director, Exhibitions Branch, Board of Trade, Queen Anne's Chambers, London, S.W.

It is particularly desired that the exhibit of photographic appliances and accessories should in no way fall below the level of the corresponding exhibits of other countries, and with that end in view I call the attention of your readers to the advantages offered to firms and individuals exhibiting at the Brussels Exhibition.—I am, Sir, yours faithfully,

CECIL HERTSLET,
H.B.M. Consul-General for Belgium.
Member of the Royal Commission for
the Brussels Exhibition.

IMPRESSIONISM AGAIN.

To the Editors.

Gentlemen,—In reading the current "Journal of the R.P.S." I have been struck by the persistence with which references to impressionism crop up in matters both scientific and artistic. Everyone ventures his own definition, and whilst none can be called wrong, none, on the other hand, seems to me to give the very simple and obvious meaning of the term. Moreover, everybody seems to want to go one better than the last explainer, even as I myself am imagining that I can go one better than all they. A lecturer states his definition, and one of his audience rises to acquiesce and define all over again in his own particular way. Many of the definitions advanced show a mixing up of symptoms with diagnosis. Impressionism may be the antithesis of Preraphaelitism; it may be devoid of detail; it may deal in indeterminateness of form; it may be "fuzzy"; but these things do not constitute its impressionism, though many definers would appear to think that they do. They are but indirect results, arbitrary and accidental, of methods in which impressionism may (or may not) find expression. They are symptoms

merely, and symptoms, moreover, common to many other isms, and also very readily manifested by incapacity, ignorance, hurry, laziness, feeble-mindedness, "bounce," "side," and "swank." There is nothing diseased about honest impressionism, however, and it is not fair to state these symptoms and to describe them in the idea that one is describing impressionism. If one merely states that impressionism is the expression in art of the impression of a scene upon the mind, what is the need to say more? And is it safe to say more? The process may be thus tested: Take an impressionable artist—not a mechanical one—and, having first confined him until former impressions have become smoothed out in a chamber from which no outside prospect is visible, let him be blindfolded and then led out to a natural scene. Uncover his eyes and give him two minutes to gaze at the landscape, rebandage him and lead him back to his studio, where he may reproduce the impressions the scene has made upon him. The result will be pure impressionism. He may take five minutes or he may take the rest of a long life over it. That matters not the least, and disposes of the idea that rapidity is a *sine qua non*. There will be little detail in it, but that will be because there was no time in two minutes to come from the general to the particular. Yet if there was in the view a point of detail important enough to enter into a generalisation, it would assuredly be given—such, for instance, as an incident asserting itself upon the skyline of a near field, or something in the air strongly relieved against its surroundings. Further, there may be much indeterminateness of form, or there may be hard outlines; that will be merely according to whether the artist stops short where his memory stoops short of forms in the actual scene, or whether he completes them from his knowledge of the nature of such forms, which he may do by hard outlines. That does not affect the point, and disposes of "fuzziness" as a description or as a symptom of impressionism. The great thing is that if our artist-martyr were worth his salt as an impressionist, we should see in his work the things which made the most rapid and most forcible appeal to his senses. According to his predilections his work would chiefly record the glow, the harmony, or the transition of colour; the effect of the chiaroscuro or the disposition of the light and dark parts, their contrasts and gradation; or, again, the "patterning" of the parts of the scene under the influence of the other conditions. If he were given a full range of materials his result would probably include his impressions of all these conditions, because it is impossible to divorce them entirely without a special effort of the mind. Impressionism is the kind of painting that answers in the main to these conditions; it is not necessarily want of detail, nor loss of form, nor can it be correctly described an anti-Preraphaelitism.

It is highly irritating to hear people talk before a picture that is slovenly, or washed-out or fuzzy, or chaotic, and describe it as impressionistic. Whether the term be used in derision or in extenuation, it is equally abused as a rule, particularly where photographs are concerned. It must be infinitely more difficult to be really true to one's impressions in making a photographic picture than it is when using artists' materials. That breaking off and the intervening time occupied whilst photography steps in *must* permit the spirit of the thing to evaporate, and the impression to become dulled. One is tempted to suspect, therefore, that the so-called impressions of photographic art are in reality nothing of the kind, unless they be impressions of other "impressions" and the employment of a trick or knack in picture-making that is born in the picture-gallery and is no child of Mother Nature.—Yours truly,

June 18, 1909.

F. C. TILNEY.

TRADE, PROFESSION, AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen.—The letters between your two correspondents, Mr. Redmond and "Playfair," have unfortunately developed into a personal combat, instead of promoting the cause of the photographer's assistant, which was undoubtedly the aim of the original writer. The perusal of these letters and the title under which they have appeared has suggested to me an opportune time for sounding a note of warning to those photographers who regard themselves as professional men and who are desirous of upholding the dignity of their profession. It is the alarming increase of the complimentary sitting

to which I refer, and is a matter which equally concerns the assistant of to-day, as this is a problem which may have to be faced by the master of to-morrow.

By the unprofessional methods of some of our leading establishments, who produce the best of work, and who number among their clients some of the most distinguished members of our English society, photography is rapidly losing that dignity as a profession which it once possessed. And if these methods are allowed to spread it does not seem difficult to forecast the ultimate end of portrait photography as a profession.

To obtain something for nothing is a weakness of humanity, which equally pervades the highest class of society as the lowest. And in this way, by invitations sent broadcast all over the country, many are tempted away from those houses which had hitherto their entire patronage for years.

Those men who are producing work of the highest artistic excellence cannot but have felt how much more difficult it becomes year by year to satisfy the demands of their clients, whose knowledge of the possibilities of photography is greater, whose artistic perception is keener, and who become more and more exacting as time goes on, and who in themselves are more difficult to photograph. This fact alone should show how utterly impossible it would be at a future time to carry on a business by invitation only.

Unfortunately, I can see no remedy against those who have already embarked upon this contemptible system of trading. To bind themselves together to oppose this kind of thing to the utmost is what photographers must do, and that done soon, or the evil will be past repair.—I am, gentlemen, yours faithfully,

June 21, 1909.

Roco.

THE SPEED NUMBERS OF PLATES.

To the Editors.

Gentlemen,—No one will disagree with Mr. Biermann in his desire to get more uniformity between different makers' H. and D. numbers. The want of uniformity is a well-known fact, and has been pointed out repeatedly. It will perhaps continue as long as it is considered a merit to advertise speed numbers higher than any one else, and is partly due to want of uniformity in standard light, and partly, I think, to a great difference in the reading of different type photometers. It is not, I think, due to any defect in the H. and D. system.

But surely Mr. Biermann does not put forward the trials of which he gives details, as being conclusive evidence regarding the relative speeds of the three brands? Even granted that an observation of the lowest developable tone will indicate the speed of a plate (and this is not yet conceded by all experts), he selects the one developer—hydroquinone—which is most likely to lead to error. In fact, there is quite a probability that his tests may be tests of the development speed of the plate, and not of its exposure speed at all. As a slow (exposure) plate is usually very rapid in development, the two speeds are absolutely different. The H. and D. method is quite independent of the rapidity with which a plate develops. Again, he uses an abnormal light for testing, one which differs enormously as regards spectrum quality both from daylight and from the standard lights used in H. and D. testing.

ALFRED WATKINS.

Hereford, June 19, 1909.

To the Editors.

Gentlemen,—The letter of Mr. E. A. Biermann in your last issue is opportune, and plate-users, both amateur and professional, must wish him success in his endeavours to bring about more reliable speed statements than manufacturers at present indulge in. For some time past my attention has been given to the same matter, and I have on more than one occasion contemplated protesting in your pages against the absurdities of plate-speeds as given by some of the plate makers; but I am myself a very limited user of commercial plates, so the matter does not seriously affect me. This, however, has not prevented my acquiring, in a spirit of curiosity, some knowledge of the vagaries at present existing in the speed statements of plates now in the market. My attention was first directed to the subject when using two kinds of plates from the same source, ordinary and orthochromatic, both speeded 250 H. and D. In the innocence of my heart I rather expected that these would require about the

same exposure (the conditions, of course, being identical), but I was forced to realise that the orthochromatic required at least 50 per cent. additional exposure. I then obtained two additional brands of plates, both speeded 250 H. and D. One required much more exposure than the first maker's 250, and the other much less than either. What, then, does 250 H. and D. mean in these manufacturers' hands beyond being a loose statement that has no true reference to the actual speed, which could be equally well as described as "extra-rapid"? Take the case of a tourist who has become accustomed to the exposures required by some plate speeded at 250 H. and D. He comes to the end of his supply of plates when away from home, and the local dealer can only offer him one brand of plate, and that different from his customary plate. If 250 H. and D. was the same with both manufacturers his exposures would not be seriously affected by the change, but if the one plate is fifty per cent. lower than he has been accustomed to, although marked 250 H. and D., he is all at sea, and, unfortunately, without knowing it.

Another instance showing the absurdity of the matter may be given. Wishing to test a batch of plates prepared by myself against a good commercial plate, I procured a brand speeded at 250 H. and D. The exposure for this speed, worked out for subject and light by a certain exposure calculator, was, with $f/22.6$, one-third of a second; in actual practice one and a half second proved correct. If manufacturers intend "to stand by their own rendering (*sic*) of the system," as Mr. Biermann's reply received from the R.P.S. states, at least they should have the fairness to state on the labels that the speed number is meant more as an embellishment than as an actual statement, and need not be taken seriously.

It would seem that an opportunity for doing photographers a signal service is open to the R.P.S. if they would take the matter in hand and formulate some speed standard that would make impossible the present state of chaos. Probably rescue will come from German shores!—I am, gentlemen, yours faithfully,

Sidmouth, S. Devon.

G. T. HARRIS.

INTENSIFICATION MARKINGS.

To the Editors.

Gentlemen,—I am obliged by your correspondents' replies on this head, though they do not quite clear up my difficulty. My marks are not all visible until after the ammonia, and then, as I said, are irremovable. I find that by much rubbing with methylated spirit they can be much reduced. Perhaps Mr. Barnett's method may answer better, but without some definite formula should be afraid to try it, as iodide of potassium will easily stain a negative. I do not like the idea of rubbing at all; however careful you may be, when you least expect it, a little grit may ruin a negative, and prevention would be better than cure. Perhaps my mercury bath is too strong or the ammonia too weak, so shall be thankful for details that will produce no streaks if possible.

PROF.

FREE SITTINGS.

To the Editors.

Gentlemen,—Scanning the advertisements of the present day, the observant mind can recognise the pulse of the world, or, in other words, read the "Signs of the Times." For instance, in "Houses to let or for sale," one of the advantages advertised is: "Well away from motor dust"; and in another advertisement (in which we are most concerned), that of a photographic business for sale, the following advantage is made much of: "No free sittings or coupon trade." Comment is needless.—Yours faithfully,

W. BARRY.

7 and 8, Park Street, Anlaby Road, Hull.

June 22, 1909.

REMOVING HARDENED PUTTY:—An American contemporary, in reply to a correspondent asking how to get rid of putty which has set hard on glass, advises as follows: Slake 3lb. of quicklime with water and add 1lb. of American pearlash, making the mixture about consistency of thick paint. Apply this to the putty and let remain twenty-four hours, when the putty should be sufficiently softened to be easily removed. This mixture will soften old and hard paint in the same way. Use an old brush, as it will spoil a new one.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

ould, 19, Station Road, Aldershot. Photograph of F. Lansdowne, Baden Powell Scout.

M. E. McArthur, Hawke's Studio, 8, George Street, Plymouth. Two Photographs of H.R.H. Prince of Wales. Photograph of T.R.H. Prince and Princess of Wales, taken June 11, 1909, at Princetown, Devon.

HALF-TONES DIRECT.—In the "British Journal Almanac" for 1897 I read an article by Mr. A. Mann on "Half-tone Direct from Life and Nature" by a simplified process. Can you please tell me whether such screen as he described can be obtained, and, if so, from whom? We are anxious to produce some half-tone pictures on our missionary paper, hence the inquiry.—PHOTO-ENGRAVER (Cape Town).

Half-tone negatives can be made direct through the ruled screens, but the method is never used on account of the length of exposure and the difficulty of taking about a process camera. If you want half-tone blocks, why cannot you make them in the ordinary way, have them made by one or other of the firms mentioned on p. 1,331 of the "Almanac," 1909? So far as we know, the special screen you refer to is not on the market—at any rate, the method is not used at all in photo-engraving.

FERO-TYPE DRY PLATES.—Would you tell me how to make ferrotype plates and of any book that gives such directions? Could collodion wet-plate process be modified in some way to answer?—FERO-TYPE.

The wet-collodion process is the most suitable. The "Mawson" collodion is used for the purpose, and directions given in Mr. Arthur Payne's manual "The Wet Collodion Process."

EMPLE (Nowshera Cavalry Cantonment, N.W.F.P.)—The process as not described as one fully worked out for practice, and, so far as we know, is not in regular use. The manipulations involved in making the print-plates are those of the ozobrome process, but from our own experience is that it is well first to make one or two print-plates in the usual way from transparencies before trying the other method. We should think that, situated as you are, you could find the three-colour carbon method the easiest to work—7s., with the pigment films of the Rotary Company.

MUSICAL-BOX.—About twelve months ago I saw an advertisement of a musical-box for attracting the attention of juvenile sitters. It was a small musical-box with a revolving wheel (to which bells were attached) on top. As I have lost the address I shall consider it a favour if you will kindly let me know where I can procure one.—EMPLE.

We cannot trace the particular advertisement. Many studio cameras are fitted with a somewhat similar device, and Fallowolds, we see, list a musical doll, and could no doubt obtain the necessary you require.

ON.—We should say there is no such place to be found.

COLOURED GELATINES.—We would esteem it a personal favour if you will kindly inform us as to the name and address of any firm that manufactures gelatine assorted colours, as used in stage lamps.—BAXENDALE BROS.

These coloured gelatines are obtainable from Gilbert Dyas, The

Mimascope Company, 9, Mary Street, Dublin, but they cannot be exposed to great heat without danger of shrivelling up. If there is much heat coloured glasses as supplied by Hetley, Soho Square, would be better.

ELECTRIC LIGHT.—So far as our recollection goes, the No. 1 lamp is a little shorter (can do with less height in the studio), but otherwise there is nothing to choose between the two. You will certainly require two, and we should advise you to get both of the same make.

Loco.—It is out of our province to make tests of mounting materials. The boards should be sent to an analytical chemist to be examined for impurities (hypo, etc.) capable of injuring the prints, or a practical test made as follows:—Lay a piece of paraffin paper or thin celluloid over half the mount, and on this again an albumen print (finished and perfectly washed, but unmounted). Back up with a piece of pure filter-paper, and several thicknesses of blotting paper, put the whole in a printing frame between glasses (to keep in the moisture) and place in a warm place for two or three weeks. If the half of the print in contact with the mount deteriorates before the other, the mount may fairly be taken as defective.

JOHN H. BARRAS.—1. There is no special book on this subject; the chief contributions have appeared in articles of late years in our own and other pages. We may refer you to those on three-colour carbon in the "B.J." for Sept. 29, 1905, Feb. 9, June 15, July 20, 1906, and June 21, 1907, as well as in the issues of the "Colour Photography" supplement published each month. 2. It is the most direct method, and has produced the finest results of any. 3. Such are supplied by Sanger-Shepherd and Co.; see their list in the "Almanac," page 1079.

SPOTTY PRINT.—Will you say what is the cause of yellow spots on enclosed print? It had the usual manipulations and the paper is of largely used manufacture, and free from any markings before soaking or toning.—P.O.P.

The spots are due to careless manipulation. Small air bells have probably been allowed to adhere to the surface of the paper when the prints were first put into the fixing bath, and have caused the small yellow spots.

D. J. DAVIS.—1. No. 1 we think is the best pictorially. It gets rid of the incongruous iron railings and introduces a good foreground, which sets the abbey better in its surroundings. 2. Five inches is not much of a wide angle on postcard size. You would do better with the f/16 wide-angle series of the same maker. No. 2. of four inches focus.

BIRDS, BEASTS, AND EMINENT PERSONS.—My aim is to make a photographic album of Egyptian views, plants, birds, beasts, animals, costumes, fishes, eminent persons, etc., etc., and I would like to add to it some European and American pictures of the above-mentioned. Please to inform me where can I buy photographs of European and American views, eminent persons, etc., etc.—TADROUS HANNA (Assiout, Egypt).

For trees and plants try Henry Irving, The Rowans, Herley Surrey. For animals, F. Martin Duncan, 59, Bradley Gardens, Ealing, London; R. B. Lodge, Enfield, Middlesex; W. L. F. Wastell, South Woodford, Essex. For portraits, Elliott and Fry, 55, Baker Street, London, W.

CONTRAST IN NEGATIVES.—1. Will an ordinary slow plate give more contrast than a rapid one, providing the exposure is the same (in proportion to the speed of plate) and the development carried out with a similar solution? I have always thought you would get greater contrast on a slow plate until the other day, when, speaking to a friend who is very well up in photography, he said there was not much difference; if anything, it was the other way about.—DOUBTFUL (Surrey).

With many very fast plates just as great contrasts will be obtained as in slow emulsions under the conditions you instance. But if the greatest degree of contrast is wanted with, at the same time, great clearness in the shadows (e.g., bare lines in the negative of a line drawing), slow plates will give a result which cannot be obtained with the very rapid emulsions.

PROFESSIONAL.—With regard to Nos. 1 to 3, it is difficult for us to express any opinion. The results seem to represent the subjects very effectively, but in the absence of other specimens made on

ordinary plates we cannot say whether the advantages of "ortho" methods are proved or not. No. 1 would, however, certainly have been a difficult subject to secure on ordinary plates. Nos. 2 and 3 seem to us to show rather well the effectiveness of intensification upon over exposed plates, but we do not see how they suggest the ideas put forward. In Nos. 4 and 5 the last seems to be rather better exposed than the other, while in No. 4, detail in the grass is lost by movement; otherwise there is not much difference between the two. Comparisons between plates called "ortho" and "ordinary" convey little information unless we know the actual degree of colour-sensitiveness of each plate. Some "ordinary" plates have a certain amount of sensitiveness to colour, which makes them approach real orthochromatic plates in effectiveness. Beyond this a number of varying exposures are required to determine what is the actually best result obtainable with each plate.

"PHOTO-MINIATURE," AND OTHERS.—In our next.

DOUBTFUL.—So far as we know, damages for infringements of copyright have not hitherto been recoverable in the County Court. We think that if you took the matter up through a solicitor the "receipt" of the copyright registration which you should already have will be sufficient. It is the "certificate" for which a charge of 5s. is made by Stationers' Hall. Possibly you are confusing the two.

H. C. CLARKSON.—If the usual press agencies, for illustrated matter cannot place the photographs, we should advise you to try Sanders and Co., 71, Shaftesbury Avenue, W.

SILVERTYPE.—Messrs. Butcher and Sons, Farringdom Avenue, are the makers.

M. LYNCH.—We believe one is made by Bilcliff's Camera Works, Manchester, S.W.

COPYRIGHT.—1. From two negatives which I recently took, Messrs. So and So have made a combination enlargement for me; they have been paid for their work. The copyright of this enlargement I now wish to register. Can you tell me whether or not it is necessary to mention on the Stationers' Hall form the name of the enlargers, as part "authors of the work?" Or would it be better to register the more important of the two original negatives? 2. I have learnt that a French journal on February 25 last published a photograph of mine without my permission. The copyright of it is not registered. The size of the reproduction is about 5 x 3 inches. Would you advise me to write to them demanding a remuneration? How much? 12.50 francs? 3. A friend has asked me to develop for him a few plates, which he prizes, but has unfortunately exposed for minutes instead of seconds, i.e., they are sixty times over-exposed. The plates are Royal Standard S.E.R. brand. Can you tell me whether there is any chance of saving them, and if so, how to proceed?—H. H. B.

1. It will be sufficient to register the more important of the two photographs. Any infringement will be bound to include this portion, and that will be sufficient for your purpose. There is no need to register the makers of the combination group as the author. 2. We should certainly write, although copyright law is rather loosely administered in France, and we should advise you not to spend money on the chance of getting payment; 10s. 6d. would be reasonable. 3. You could do best with highly restrained pyro-ammonia, say, pyro, 4 grs.; bromide, 8 grs.; ammonia, 2 to 3 minims per ounce.

STOPPING-OUT SUN.—Since the fine weather has set in, I am much troubled with the sun shining on the roof of the studio. Can you tell me of any way of dulling the glass so as to give it the appearance of ground glass. I know that painting it over will answer the purpose; I did it that way once, but the paint turned yellow, and it was such a job to clean it off. Can you suggest anything better?—R. C. W.

Yes. Mix common whiting with thin starch paste and stipple the glass over with that. It can easily be cleaned off with a sponge and water when the sun ceases to cause trouble.

FACTORY ACT.—Will you be good enough to enlighten us on the following? Our business is a very cheap one, and we have to get our work done as cheaply as possible to make it pay at all. We employ, all told, seven girls, but they are all over sixteen. We did not know that photography came under the factory law, and doubt

if it does. A few days back an inspector called and demanded go over the whole place, which we allowed him to do to save our bother. He then told us that the girls must not be worked such long hours, that they must have a half-day holiday each week, and longer time for meals. He also said that the workrooms must be cleaned and the walls whitewashed, and a lot of other "twaddle." If we have to do all he says it will mean some outlay, and we shall have to take on two more girls to get through the work, which will reduce our profits. Does photography come within the Factory Act?—COMPO.

Yes, certainly it does, and you will have to conform with it. It is to meet such cases as yours that the Act was passed, in order to prevent young persons being "sweated," as apparently they have been in your place. You will have to do what the inspector has told you, or you will find yourselves in trouble.

PATENT QUERY.—In your notices of Applications for Patent recently, I see one mentioned for a purpose that I have made an invention for and think of patenting. Can you tell me when it is likely that you will publish the complete specification, so that I can learn wherein the two differ before I take out my patent?—INVENTOR.

We cannot say, as possibly the specification may not be published at all. If a patent is not completed, the provisional specification is not published, and there is no means of learning anything about the invention unless the inventor likes to tell you.

STUDIO BLINDS.—I have had my studio blinds—the white ones from the roof—washed, but they will not run well on the rollers as they did before. They pucker up and crease as they are rolled up, and hang baggy when they are drawn down. I have had them well mangled and also ironed. Can you suggest any way of improving them?—J. FORD.

We are sorry we cannot. This is a very general experience when blinds are washed. It is, as a rule, more economical to place dirty blinds with new ones, and utilise the old ones for dusters and such-like purposes.

BUILDING LAWS.—I propose putting up a studio in the garden and am told I must submit plans to the Urban Council. I have done that, but its surveyor has condemned them as not conforming to the Council's laws. He wants such alterations that it will quite double the cost of the building, and that I cannot afford. What I should like to ask you: is there any way of appealing against the Council's dictum?—ANNOYED.

District Councils are empowered to make their own by-laws, and you may depend upon it that they are well within their rights when they refused to pass the plans. The only suggestion we can make is to alter them so that they conform with them.

FADING PICTURE.—I have a photograph of a deceased friend, that is rapidly fading and the negative is destroyed. If I were to stop it off the mount and well wash it would that prevent it fading further?—T. DAVIDS.

No, it would not. In such cases the treatment you propose is of no avail; indeed, it has sometimes been found that it hastens fading rather than otherwise. Your best way, as the negative is not available, will be to copy the print before the fading goes further.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Convention. Next Monday, it is hoped and believed, will discover photographers gathering at Canterbury in record numbers for a full week of excursions and papers. (P. 516.)

We regret to record the sudden death last week of Mr. G. W. Morgan of Aberdeen. (P. 521.)

The profitable use to be made by the professional photographer of a reflex camera is emphasised by one or two examples mentioned in an article on page 511.

Mr. Foster Brigham contributes a description of the usefulness of the card-filing system in obtaining business. (P. 513.)

Albumen paper being still the stand-by of photographers where the climatic conditions are severe and sources of supply distant, some notes are given on page 512 on the working of this process.

The awakening of the Board of Trade to a recognition of the valuable aid it can render to British firms is taking practical shape in the way of an "exhibitions department," the work of which is commencing chiefly in reference to next year's international exhibition at Brussels. (P. 515.)

We call attention to the use which can be made (with precautions) of heat in drying negatives. (P. 510.)

Mr. Speaight's invitation to photographers is referred to on page 509.

An anti-halation substratum consisting of a substance which is removed by the developer has recently been patented. (P. 509.)

Adjustments of enlarging cameras, exposure indicators, and other apparatus figure under "Patent News." (P. 518.)

"Photo-mechanical Notes" is this week occupied by the questions set at the last "City and Guilds" examination. (P. 517.)

Home-made contrivances for holding orthochromatic screens are the subject of some brief notes on page 510.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

A German contributor, Dr. F. Limmer, describes the difficulties encountered in working out a process for making a screen-plate by transference of dye contained in coloured particles of gelatine. (P. 49.)

M. F. Monpillard describes the modified working found advisable when using flashlight for the making of Autochrome pictures. (P. 51.)

A French worker, M. J. Thovet, has recommended an extra sensitising of the Autochrome plate for the purpose of giving shorter shutter exposures than can be done in the ordinary way. (P. 52.)

The newly issued instructions for the use of the "Thames" screen-plate are given on page 55.

A patent has recently been taken out in Germany for dyes which are said to bleach-out with great rapidity in light. (P. 56.)

Dr. Miethe has published a book on Egypt, very fully illustrated in colour from exposures made by the author. (P. 56.)

A recent lengthy paper on the aberrations caused by colour-filters has led the author, M. Sacco, to the conclusion that in the conditions of ordinary work the permissible angle between the two sides of a presumed plane-parallel filter should not exceed one minute. (P. 53.)

EX CATHEDRA.

The Brussels Exhibition. The letter from Sir Cecil Hertslet, which appeared in our last issue, receives further emphasis from a communication from the new Exhibitions Department of the Board of Trade, some extracts from which we print on another page. Photographic firms will be glad to be reminded that the Government are at length stirring themselves in the way of affording assistance in the representation of British firms at various large exhibitions abroad, a valuable means of furthering trade in our home products which has been to a great extent neglected. In the case of Brussels in particular the presence of Sir Cecil Hertslet on the Commission which will have under its care the interests of English firms should be a further inducement to those in the photographic business to consider the advisability of being represented next year at Brussels in a prominent way.

Mr. Speaight's Invitation. The brief mention made last week of the special invitation of Mr. F. W. Speaight will, we hope, not escape the attention of our readers. Mr. Speaight, with his brother, Mr. Richard Speaight, has in the course of a very few years built up a business which is now established in a place without an equal in London, and probably in the world. It is an open secret that the brothers Speaight divide their activities in their occupation very sharply, the younger being responsible for the photographic work and the elder bringing to the duties of management great originality and the determination to take a firm stand for photography as a profession. The persistence and resourcefulness of Mr. F. W. Speaight are already as familiar to his brother photographers as to the general public, in the matter of certain London improvements, and just now the managerial head of Speaight, Ltd., like the dual monarchs of Barataria, has the satisfying feeling that his duty has been done in causing the public to visit a collection of his brother's photographs on the same terms as those on which that same public visits exhibitions by Royal Academicians in Bond Street, namely, by payment of one shilling. Probably if you pressed the question Mr. Speaight would admit that the public ought to feel they were being admitted cheaply to a photographic exhibition at two shillings, and perhaps that explains why this enterprising action succeeded. On the score merely of the clever stage-management which the exhibition represents, it is to be hoped that Messrs. Speaight's invitation to photographers, of whatever degree, to visit them on July 21, from six to eight p.m., will be largely responded to.

Anti-halo Plates. The employment of a non-actinic film between the sensitive emulsion and its glass support has been many times recommended as a means of producing a plate free from halation caused by

reflection from the back of the glass, the chief difficulty having been to find a body which was both without action on the sensitive emulsion and obstructive of actinic rays—in fact, of non-actinic rays also, if the “backing” is to be used for orthochromatic emulsions. According to a recent German patent, a compound which has been found suitable in this double respect is ferrocyanide of molybdenum. It is formed by coating the glass plates with a solution containing in 100 ccs. of water 3 gms. of gelatine, 1.5 gms. of potass ferrocyanide, and 1 gm. of ammonium molybdate. When this coating has set, it is treated for five minutes in 2 per cent. hydrochloric acid, and placed to dry. The patentees, Messrs. J. Hauff and Co., of Feuerbach, evidently intend the backing to be removed by the alkali of the developer, so that if it is found that the process can be carried out satisfactorily in the factory, the user of these anti-halation plates will not be called upon to perform an additional operation.

* * *

The Quick Drying of Plates.

Though many devices to assist in quick drying are proposed at various times, the one in most use seldom finds mention in print, and that is, simple drying by heat. Of course, this is the method that first appeals to the beginner, but it is also the first rejected by him, because he overdoes the process and spoils his negatives. Nevertheless, it is a remarkably effective method, and one that many experienced photographers resort to constantly with never a failure. One worker that we are acquainted with dries all his plates, whether negatives or lantern-slides, by placing them on edge, leaning against a board, four feet in front of a gas fire. They will dry in this position in something like an hour, but the method we have adopted for some time is quicker. Our room is heated by a gas stove that has a flat iron top. On this top a sheet of asbestos is laid, and on the asbestos some ordinary wire plate-racks are always kept. Each plate as it comes from the washing-tank is wiped dry on the glass side with a cloth, while the surface water is removed from the film side with a wad of damp cotton wool. The plate is then dropped into one of the racks, and in about half an hour it is bone dry and ready for finishing or for printing. The racks never get hot, but are always warm to the touch. Without the asbestos they get too hot, and there is then danger of the gelatine melting along the bottom edge of the plate. A similar method can be adopted if hot-water pipes or radiators are available.

* * *

Drying by Cold Air.

In the absence of heat a strong draught of air can be utilised. This is a slower method, but still very effectual. A ventilating-shaft is an excellent place to put a rack of plates that are wanted in a short time, while the whirler is a well-known expedient for drying single plates. A whirler, however, requires driving, and an excellent substitute for this apparatus can be found in one of the old-fashioned clockwork kitchen jacks, with which a number of plates can be kept moving for a considerable time, and without any attention whatever. The plates can be laid flat on a horizontal table suspended from the jack, or one of the circular racks on the market can very well be utilised to hold them. If the jack is weighted with a good heavy horizontal fly-wheel the motion is fairly rapid, and drying should be rapid also.

* * *

Mounting Orthochromatic Screens.

Many people are deterred from the use of orthochromatic screens by reason of the expense they involve, for when the screens are obtained they have to be fitted to the lens, and the total cost of, say, three screens properly mounted and fitted so that they can be screwed into the lens-hood, is

somewhat heavy. The cheapest way of obtaining the screens is to buy them in the simple form of stained gelatine, and do the rest of the work oneself. The gelatine has to be mounted between two pieces of thin glass—patent plate for preference—though suitable glass can often be selected from lantern-slide cover-glasses of good quality—and the refinement of cementing can be dispensed with. There is no difficulty in the mounting, for the glasses can be cut to shape with a sixpenny wheel cutter, and then be bound with thin lantern-slide binding strip. The real trouble begins when the problem of fitting the screen to the lens has to be tackled, for this must be done so effectually that no light can reach the lens excepting through the screen. Anyone possessing a lathe can adopt the following method, which we have now used for a long time: From a piece of mahogany board a ring is turned that will just fit the lens hood when velvet lined. To the face of this ring a small wooden frame that will hold the screen is then attached, and upon fixing the screen in position the work is done. The screen can be held in by turn buttons, or fixed more permanently with binding-strips. The whole thing can easily be completed in half an hour, and it is as effective as can be desired, for a very little practice at the lathe enables one to produce a ring that will fit “like a glove” when lined with velvet.

* * *

Still Simpler Mountings.

Those who do not possess a lathe must vary the method slightly. In any case, the screen must be mounted in a small frame of wood or millboard; this is quite easily done. A ring can then be cut from a large cork or bung to fit the lens hood, and when this is glued to the back of the frame a quite effective mount is obtained. Another method is to make a paper ring. The hood is first covered with a strip of clean paper, secured by joining the ends with gum or paste. A long strip of brown paper is then cut, soaked thoroughly with paste, and wound round and round the hood until a sufficiently thick ring is built up. It is allowed to dry on the hood, removed, and glued to the frame as before. The appearance may not be so neat as the compact metal frames that can be bought, but the result will be quite as effective; more so than in the case of some metal fittings, which are not light-tight. We use none but wood fittings made entirely in the lathe, and with circular fronts over which a large lens-cap can be fitted. This has proved an admirable arrangement in practice, and it is quite a small matter to make a new fitting for any odd size screen that may have to be tested, a metal fitting for which is often not obtainable without trouble and delay.

* * *

The Spirit Photography Commission.

The result of the Spirit Photography Commission organised by the “Daily Mail” is just what might have been expected. Nothing but a series of obviously faked photographs was submitted to the photographic experts, while the spiritualistic experts evaded the difficulty of explaining the absence of any experimental proof by contending that the other members should first go through a preliminary training in spiritualism or theosophy. The spiritualists have thus once more failed to prove a single one of their claims, and have resorted to a very transparent excuse for explaining their failure. The final reports drawn up by the two sections of the Commission read more like ancient history than actual reports of a modern investigation, and it is surely time that such futile inquiries ceased to be held. There will always be people capable of believing the wildest tales with regard to spiritualism, and no commission of any kind will ever convert them to the legitimacy of experimental investigation.

**Outfits
or
beginners.**

Recently we have come across several young amateurs who have either given up, or proclaim their intention of giving up, photography. On asking the reason of this momentous decision we found that in each case it was the same. The boy had never had anything but a very small camera of cheap and toylike character, and was simply disgusted with the poor results obtained. We are much disposed to think that there are too many cameras of this type available, and that their introduction was never very wise from the business point of view. A result that is both small and poor will satisfy no one, and the beginner soon loses interest if his results are too small to show and too poor to bear enlargement. For the very small camera fitted with good lenses there is a distinct use and demand, but when cheapness is the all essential point poor quality of definition is not easily tolerated in a picture that is much under quarter-plate size. Direct prints from quarter-plates will easily satisfy the young amateur, but direct prints from negatives of about the size of postage stamps do not please him for more than a very short time, and when he finds they will not bear enlargement he is very quickly discouraged. If the young amateur is to be encouraged—and he is a very important person in the photographic world—he should be provided at the start with apparatus capable of doing work that is sufficiently good to lead him on further. If his progress is checked by the inefficient nature of his apparatus, the blame does not lie so much with those who bought it for him as with those who provided it and permitted it to be sold. It is a matter of common knowledge that some very efficient little cameras are obtainable for a matter of only a few shillings, while other much less efficient ones are sometimes also obtainable for higher prices. When a dealer is asked to recommend a cheap outfit for a small beginner he will show his wisdom most fully if he makes efficiency his first consideration and disregards other matters.

THE REFLEX CAMERA IN PROFESSIONAL PHOTOGRAPHY.

WE do not hear the loud and bitter controversy about the respective merits of hand and stand cameras that at one time annually made its appearance in the photographic press. The reflector type of camera is in a great measure responsible for this, since it combines the certainty of focussing and included view of the stand camera with all the best features of the hand instrument. Moreover, the ease of focussing makes a half-plate hand camera an instrument of precision, whereas optical considerations make the ordinary box-form view-finder type very uncertain. This uncertainty, combined with size, has made the reflector camera practically a necessary addition to a professional outfit. Many who argue that such a camera can be only of occasional use will doubtless manage without incurring the great expense, but doubtless at the loss of some business and advertisement. Others, more conservative, will swear by the whole-plate camera and tripod, as being more certain. We know, however, that a great many professionals have been wideawake enough to expend the necessary capital on one of the beautiful reflector cameras. In a town of a population varying from 30,000 in the winter to 50,000 in summer, there are at least four professionals who use them, one, too, whose work is of the twelve for sixpence order.

To those who hesitate to incur the expense, the account of one or two actual incidents may turn the scale. There was, as a big local event, with Royalty present, to lay a foundation stone or something of the sort. The Press stand—and, by the way, photographers can always get Press tickets by applying a few days in advance to the town hall—was a

small space on top of a rockery, with no flat surface. Before arrival, at least an hour before the ceremony, this space was already occupied by the conservative contingent with one half-plate, one whole-plate, one 12 x 10, and one 15 x 12 camera—quite an up-to-date show-room. Our reflex photographer mentioned casually that the reflex was the only possible instrument for these jobs, but the stand camera men all claimed their own instruments were more certain. They were not so sure about it afterwards, when it was found that the Royal party were not passing the coign of vantage, as expected, but taking another path. This did not trouble the reflex and other hand-camera men, as they rushed round to the other position, but the gentlemen who had been carefully focussing, adjusting, and un-adjusting stops for an hour previously were somewhat upset. Even the luckiest, who had a good position, only made one exposure, whilst our reflex worker made eight of different subjects.

With regard to profit, one professional of our acquaintance, with a new reflex, almost paid for it in rights to reproduce in the London papers and on postcards, and has also made much money and advertisement by photographing local golfers on the links.

One local man makes a feature of exhibits at cattle shows, and nothing can beat a reflex camera for making a number of exposures quickly, and without the rest of the subject moving. With a long bag three or four dozen exposures can easily be made without fatigue in the afternoon. Another line of work that even the highest class studio will find remunerative—in fact, only such studios will get such business—is the photographing of equestrians, either stationary or moving. A correspondent writes us that he formerly used a whole-plate stand camera, with focal-plane shutter, for this work; but found that the necessity of focussing before inserting plate made it practically useless. The same may be said of the use of such a camera at school sports, another profitable line. Perhaps no better argument for the reflex camera can be adduced than the recital of the troubles of the same correspondent at a time when he had not one:—

The incident was a commission to photograph the meeting of the Admiral of the Channel Fleet and the Mayor of —, with the usual presentation on the flagship of the address of welcome. Knowing the steadiness of a man-of-war, it was decided to take something important—to wit, an assistant, one whole-plate camera, one large case with two lenses, focal-plane shutter, four double backs, focussing cloth, and, lastly, the tripod. The two photographers embarked with the help of a Press ticket on the official tug, and proceeded to the fleet, lying two miles off-shore. The weather was rough, and the boat pitched and tossed like an empty bottle. At first it appeared too rough to bring the tug alongside the leviathan, but after a somewhat stormy consultation with someone, who was presumably the navigating lieutenant, and after a great deal of navy talk, a narrow plank gangway was got across. Since it sloped at an angle of 60 degrees, and the mayor was somewhat inclined to stoutness, he rather wisely decided not to risk his life in the municipal service. The whole-plate camera and etceteras appeared as if they were to be rather useless. Luckily, however, the mountain decided to come to Mahomet, and presently descended from the heights above to the dirty and insignificant tug in the shape of a large individual, resplendent in much gold lace and other trimmings. The poor photographers had not bargained for this, and had kept the traps in the case out of the wet. They were got out in good time, and after fixing lens, shutter, and opening camera, an attempt was made to place the camera on its tripod, but the wet, pitching deck made it impossible to get to work, and the day's opportunities were gone. In such an instance as this, which might be multi-

plied indefinitely, the ever-ready reflector camera would have meant the whole of the difference between success and failure.

PRACTICAL NOTES ON ALBUMEN PAPER PRINTING.—I.

It may seem to some a waste of time to write anything on the subject of printing on albumen paper, seeing that so little of it is now used by photographers—at least in this country. Gelatine and collodion P.O.P. have largely supplanted it—almost entirely amongst amateurs—but many professionals adhere to it, and possibly more would use it if they, or their assistants, were really more familiar with its working. In the opinion of most persons there is a certain charm about a good albumen print that one does not see in gelatine, whilst the results are at least as permanent as those on the emulsion papers. Albumen paper in the sensitive state is a material which will not keep for a great length of time, particularly in hot, moist climates. As it is largely for the benefit of our readers thus situated that these notes are penned, it is first necessary to point out that the most advisable procedure is to obtain the albumen paper in the unsensitised condition, that is, albumenised only, and to sensitise this as required. At the present time little, if any, paper is albumenised in this country. The albumenising trade has passed on to the Continent, mostly to Dresden, but the paper can be had from the larger photographers here. Some samples are quite inodorous, while others have a very fetid smell, which becomes very offensive while the paper is being sensitised. That is due to the use of the albumen in a decomposed state. When employed in that condition it is easier to apply, while it gives a more glossy coating than if it were used fresh. It might be surmised that such paper would not yield such permanent prints as would those made with the inodorous coating; but it has been found by the test of time that, in this respect, one is as good as the other.

Coming now to the silver or sensitising bath, its strength, theoretically, should depend upon the amount of chloride with which the albumen is salted. As this latter is not stated, one will do well to use the strength recommended by the makers of the paper. As a rule, the stronger the silver bath is the greater the vigour in the prints. But this holds good only up to a certain point, for it has been found in practice that no advantage is gained in this direction by increasing the silver beyond seven to eight times the weight of the chloride in the albumen, supposing that to be of ammonium, or its equivalent in other chlorides. From fifty to sixty grains to the ounce is a good average with most papers if deep rich purples are desired. Here is a suitable formula for general work, and it is well to make up a good quantity at a time:—

Nitrate of silver.....	10 oz.
Distilled water	80 oz.
Nitric acid	10 minims.

This quantity will about fill a Winchester quart bottle. After filtration, some is poured into a dish to a depth of half an inch or more, and the paper floated on it. There are different ways of doing this. A good method is to take the paper by two opposite (diagonal) corners, i.e., form it into a bow, then lay one of the other corners on the surface of the solution and gently lower the rest of the sheet, taking care that no solution gets on the back. As soon as the whole sheet is on the liquid it is a good plan to raise the corner first applied to see if any air bubbles have become imprisoned, and, if so, to remove them with a small piece of blotting paper. If, when the paper is floated, it is seen that it has a tendency to curl away from the solution, gently breathing on the back for a few seconds will cause it to become flat again. When the paper is exceptionally

dry, it is a good plan to place it, exposed, in a damp place for an hour or so before floating. This will reduce both its tendency to curl and that of the prints to blister in the fixing bath. With regard to the time of floating, that, to an extent, must be governed by the temperature. In hot weather, with most papers, a minute and a half will suffice with a bath of the above strength; in very cold weather, from two and a half to three minutes will be none too much.

After the paper has floated the necessary time, it is taken by the fingers by two corners, gently and slowly taken off with a somewhat dragging motion, and pinned up on a line to dry. The best pins for the purpose are black or mourning ones: if the ordinary ones are used, the bare metal causes a reduction of the silver, which runs down the paper, and renders those portions useless. American wooden clips are often used for suspending paper, and are very good for the purpose. When the paper is suspended, a scrap of blotting paper should be put on the lowest corner to absorb the drips. The reason for removing the paper in the way just described is that very little solution is taken away with it—only a few drops; whereas when taken off quickly, there is a lot to drain off and much waste of bath results. After the paper ceases to drip, it may be quickly dried before a fire.

Paper sensitised as above should be used the day of preparation or that following, as it will not keep more than a day or two. If, however, the paper be kept between pure blotting paper that has been moistened with solution of carbonate of soda, and then dried, it will keep for many days. If, in place of the nitric acid, citric acid be used in the proportion of about a fourth of the weight of the nitrate of silver, the paper will keep white for many weeks, but it will print very red, and it will be difficult to tone beyond a red-brown colour without meanness. If the paper is required for keeping, the best way is employing the citric acid as a preservative is to float the paper first on the silver bath as above, and when the superfluous solution has thoroughly drained off to float the bath of the moist paper on a solution of citric, about thirty grains to the ounce, for a minute or so; finally suspending to dry. Some samples of albumen when taken from the solution will appear to have a greasy and repellent surface, and the superfluous solution collects in drops or tears, which would show as spots in the prints. In such cases the paper must be blotted off between sheets of pure blotting paper, when it is removed from the bath. The blotting paper may be used over and over again, or until it ceases to be absorbent, and can then be added to the residues.

After six or eight sheets have been floated, the bath should be stirred up with a glass plate in order to keep its strength uniform. The paper, it may be explained, is floated in the bath proportionately of more silver than it does want, consequently the bath gets weaker by use, and on the face first, hence the stirring up is necessary to obtain formally sensitised sheets. And since the bath by use becomes weaker in silver, it becomes necessary to test it from time to time. Small hydrometers, called "argentometers," are sold for the purpose by the dealers. In the use of a bath they indicate its strength in silver accurately. After the solution has been in use for a time they do not act, as the bath then contains a considerable quantity of nitrate salts introduced by the decomposition of the silver in the albumen, which adds to its specific gravity. These little instruments are convenient in use, and serve all practical purposes if an allowance be made (in the case of an old bath) that it is weaker in silver than the argentometer indicates. After a little time the sensitising solution will become discoloured. Methods of de-colouring and further details in working the albumen process, will be dealt with in a future article.

THE CARD-FILING SYSTEM IN OBTAINING BUSINESS.

The paper on the card filing system for photographers in "B.J." of November 27, 1908, the utility of the card list of clients' names for advertising purposes was mentioned. It is advisable to keep in touch with sitters by the use of letters, booklets, or other appropriate matter with the suitability of portraits for miniatures, enlargements, reproduction in a new style, or embodying a suggestion for a fresh sitting, their names should form only the beginning of a far larger and more inclusive list of the names and addresses of those residents who, from their public position, it is desirable to secure as customers. A selected mailing list will not only simplify the despatch of circulars and give much better returns than a list selected haphazard from the directory, but one is prevented from using stamps and stationery by duplication of addresses or the inclusion of known undesirables. The card system of entering one name only on each card, and indexing, and perhaps crossing the whole, is far superior to any other method. Only names actually circularised are retained, it is simple to remove names from cards, and the list can be divided amongst a number of workers without fear of duplication or error, additions can constantly be made without disarranging alphabetical or other order. The ease of classification is the chief case, as in all other uses of the card index, the greatest advantage is in favour, and the chief reason for its superiority over other systems. This classification enables one to easily remove cards or names of people as they become clients, to enter details under the name to which they refer, and, above all, it is the only way to keep an efficient check on one's advertising.

Cards may be ruled in various fashions, or may, for convenience, be left blank. The surname should occupy the most conspicuous position at the top of the card, the address should come next, and ample space be provided for entering the name of the person of posting distinguishing mark of advertisement, and room for any necessary remarks at the foot. Illustration No. 1 shows a useful type of card of the standard size 5 in. by 3 in. The name "Vertigan" is prefixed by "Mrs." in the envelope. In the rare* cases when Miss or Mr. are used these are denoted on the card. The address may be written in any way, so long as it is easily understood by the addresser. The identifying marks shown as entered on the card need only be entered on the enclosing case, if the contents receive the same advertisement. It sometimes happens that only part of the list receives matter, and that matter is sent at different times. In this case the cards should be marked. A copy of each of the advertisements is filed, and legibly marked with its number as entered on the card.

The identifying marks should be kept as simple as possible. In the case of a return, as shown in the illustration, the card is removed from case and a record of all the matter sent carefully kept upon it. "X 1. 11-9," for instance, means that the card was Christmas leaflet No. 1, forwarded on November 9. "B. 2" signifies booklet No. 2, March 18; whilst "L. 6" is personal letter No. 6, that brought an inquiry on the mailing list.

Whenever one receives a return from any name, whether by mail, personal visit of inspection, or inquiry, the card is removed from the general case and placed by itself for further

attention in case of inquiries, or kept apart if a sitting results, for then the name will be on one's more valuable clients' lists. In the former case, should the inquiry not crystallise in a day or two, a letter, written to meet each special case, is forwarded, and certainly ought to secure the appointment if there is any truth in the statement that "it's dogged as does it."

<i>Vertigan</i>	<i>18. Princess. Rypl.</i>
	<i>PK</i>
<i>21</i>	<i>11-9</i>
<i>B 2</i>	<i>3-18</i>
<i>L 6</i>	<i>14-16</i>
	<i>Requested Price List</i>
	<i>14-21</i>
	<i>Appointment 14-23</i>

The cards from which one has a return in some form or another should prove of great value in improving one's advertising education. One can tell from them the type of circular that pays best, and frequently prove that expense is no criterion of the pulling power of an advertisement. The respective returns from the first, second, third, or more distributions to the same house can also be seen. This may appear costly, but all advertising experts are agreed that three different circulars to a thousand people will do far more than one circular to three thousand.

At the same time, we must warn the reader not to expect too much direct return; in very many instances one cannot trace the influence of one's advertising at all except at the end of the year, when an increase in receipts, probably attributed to something else, will be noticed. In any case, there will be little response to the first effort, slightly more to the second (if forwarded within a reasonable time of the first), whilst the third should begin to send one's money back.

The actual collecting of the names upon which to expend one's stationery and printing will be a comparatively simple matter if you have resided for some time in a small town. The best residential parts and, to a certain extent, the most desirable names will be familiar to you. A newcomer would be well advised to seek the advice of some friendly resident. A city list is a far more difficult matter, more especially if financial reasons make a small list a necessity. Selection of the most likely names then becomes a matter of difficulty. A few of the very best names should be taken from the directory. In giving this advice we presume that your work is good enough to please such people, and your premises are smart enough not to repel them. If your work is not of this class it is essential that only those names to whom your work is likely to appeal should be chosen, for it is equally a waste of money attempting to get the patronage of a better class than one's work merits as it is to advertise expensive work to a poor class.

Names may be selected from subscribers to concerts, guests at balls, hospital patrons, bazaar-stall holders, and church helpers generally, and, in fact, from any and every published list of names that agrees with one's clientèle. The keen man will carry a few loose cards in his pocket-book, and jot down on the spot any name that appeals to him in the local Press or gathered in conversation. If the cards are properly indexed a very few moments enable one to discover duplicates, if such

*It is generally conceded to be the best policy to direct one's pressing attention to the male sex. To advertise such articles as photographs to the male sex is certainly a more difficult effort, the persuasions of the ladies of the household being more effective than those of your matter. One rarely finds a "Miss" entered in the directory as a householder, and hence they may profitably be omitted, excepting the most comprehensive lists.—W. F. B.

exist. In this way the list will steadily grow, and, if care is taken to remove any undesirable as soon as known, the trouble involved will be rewarded by the possession of a valuable business asset, which must, however, be kept thoroughly up to date if its full value is to be retained. For one thing, the list must be carefully checked for removals each time a new directory appears, and any returned advertisement must be kept and the erroneous address removed from the filing case.

Some photographers possess not one but as many as four lists. One a list of the best local families not being clients, to whom matter dealing with the best work and highest prices is forwarded; the second a list of middle-class people, who receive matter dealing with quality and moderate price; thirdly, at a pleasure resort, a list of apartments may be kept; and, fourthly, county families. The matter forwarded to No. 3 is very carefully selected, and special offers are made to introduce one's work to this class. It being frequently impossible to reach the visitor direct, those residents who come in closest

contact with them should be carefully nursed in the belief of the superiority of one's work so that your name naturally comes to their minds when asked for advice on the merits of respective establishments.

It would obviously be foolish to forward non-residents the same class of matter as residents, so that if efforts are made to increase the circle of one's influence such names should be kept apart. At-home portraiture, domestic architecture, animal photography, the copying of pictures or antiques of any description, or any work that does not come under the heading of studio work, may be profitably dealt with.

If one keeps separate lists in this fashion, although not necessary, it is advisable to use cards of different colours for the different lists—say, white for town, blue, county, and perhaps pink for other divisions. It will be noticed that the size advised is smaller than that for the cards used in the reception-room, so that there is no fear of mistaking the one for the other.

W. FOSTER BRIGHAM

THE DRESDEN EXHIBITION.

VI.

A LARGE section of the Dresden Exhibition, upon which we have hitherto touched very briefly, is that which corresponds with the record and survey work carried on in this country. An immense amount of space, more than the character of the exhibit warrants, is given up to these photographs. The subdivision again is into towns and provinces, but in few cases are there signs to be seen that the photographs have been made with anything like a definite purpose. In most cases they appear to be simply photographic views brought together for the purpose of representing the features of a city or district, and in many instances the photography might have been considerably better in a technical way. About the best section is that representing the Free Town of Hamburg, but in none of the twenty-one rooms which contain these survey photographs could we see quite the same distinct aim to record departing features, vanishing landmarks, or customs falling into desuetude, which is evident in most of the record work done in this country.

A number of countries foreign to Germany are likewise included in this section, about the most interesting photographs being those from Russia, where again M.S.A. Lobowikoff exhibits a number of his clever photographs of peasant types. England is represented by a large collection of photographs by Sir Benjamin Stone of customs and ceremonies surviving from former days. A separate catalogue explaining these photographs is obtainable in the exhibition. In the section relating to the Far East a good deal of the well-known work by Mr. H. G. Ponting is shown, but the only other English work in this section is that sent by the High Commissioner for Australia. These photographs, though not of particular photographic interest, are of value in showing the still unexplored districts in our Australian colonies. The exhibit by the United States may be instanced as an example of the kind of photograph which most properly belongs to a section of this kind, since it includes a large number of very excellent portraits of Indian and other types, lent by the Smithsonian Institution, Washington. These photographs, as well as those of Indian dwellings, possess great ethnological value, a quality which is missing from a great deal of the photographic work shown by other countries.

Schools of Photography.

Placed between the amateur and professional sections are the exhibits of a number of institutions in Germany where photo-

graphy and its allied branches are taught. The place of honour among these is given to the Munich School of Photography and Photo-mechanical Processes, directed by Professor Dr. Emmerich. A great deal of portraiture by students is shown, all of which, it must be said, has a certain amount of sameness, and is mostly done in a low tone. Apparently more regard might be paid to the very various requirements of commercial portraiture. The "process" work makes a much more interesting collection, and includes reproductions of works of art in monochrome, and colour by the intaglio, relief, and lithographic methods both in monochrome and colours.

Still finer examples of students' work is shown by the very large exhibit from the Imperial Academy of Graphic Arts, Leipzig, whilst there are other similar exhibits by some half-dozen other schools where photography is taught.

The Austrian Exhibit.

An annexe to the main buildings of the exhibition has been built by the Austrian Government, and the whole of the exhibits, both in amateur and professional photography, as well as in reproduction processes, has been brought together in a series of seven beautifully appointed galleries, which in the way of furnishing and decoration represent the high-water mark in the exhibition. A committee of artists and architects have been responsible for the arrangements, which have been carried out with the most minute care in every detail. One example of the pains taken to preserve a harmonious but nevertheless varied scheme of decoration may be mentioned. In one gallery a floor covering of a dove-grey colour was used, whilst the adjoining room had been covered in the same material. When both were down it was thought that the larger apartment would have done with a floor-covering with some design on it, in order to differentiate it from that which joined it through the entrance into the next room, and therefore a stencil pattern was done in black over the whole floor, forming a carpet which gave the apartment a sufficiently distinctive appearance. Formal and symmetrical, like most of the Austrian schemes of decoration the arrangement of the galleries into alcoves and the furnishing with cabinets and small articles of china and pottery are very gracefully done, but the whole result is that the Austrian exhibit possesses more interest from a national point of view than from the photographic standpoint. One of the mo

striking exhibits is that of the Society (existing under Government support) for the Encouragement of Travel in Austria, and particularly on the eastern coast of the Adriatic. A special photographic department also has been established in the Austrian State railways under the direction of Dr. F. Benesch, a photographer whose work may be described as topography very artistically done. The exhibition contains a whole series of photographs made by Dr. Benesch, of the Austrian Tyrol, and in many other parts of the Austrian Empire which are as yet almost unknown to the English tourist. These exhibits, which deal also with the opportunities for winter sport in Austria, form a notable proportion of the contents of the Austrian house, and also of the specially illustrated catalogue issued by the Austrian section.

In the domain of amateur photography a large exhibit is sent by the Vienna Photo-Klub, chief among the exhibitors in which are Karl Prokop, Franz Holluber, and C. Hermann Kosel. The exhibit also includes a great selection of the remarkable work of Paul Pichier. In addition, a collection of the works of amateur photographers in Austria is brought together, and includes a great deal of the clever, but not very convincing, multi-colour gum work of Dr. Bachmann. The general aim of the Austrian pictorial photographer seems to be at big bold effects of lighting with heavy contrasts in tones, and it is rare to find the same delight shown in the more delicate nuances of nature such as English workers (perhaps not now so much, unfortunately) have successfully rendered. And apparently, too, the obsession of multi-coloured gum is present with a good many, such as J. E.

von Donhauser, Josef Mayer, and Dr. Ledenig, who, in our judgment, makes the best, because the least, use of this method. One very fine seascape should be mentioned, that (No. 1,232-82) by F. Larisch-Moenich. A very clever piece of work is that by Dr. E. Meyer (No. 1,241-115), representing a number of couples dancing on skates under electric arcs. Some most pleasing landscape work, big and broad, yet open and pleasant, is by Karl Melichar (No. 1,243-122). Similar work, which makes a special appeal on account of its delicacy and open air character, is that of Dr. R. Reininger (No. 1,251-137).

Naturally, in an Austrian exhibit, the work of the Imperial School of Graphic Arts, presided over by Dr. Eder, takes an important place, and the many examples of students' work in photo-mechanical and photographic processes are used to make an imposing exhibit. The professional photography is rather scattered, but among it must be mentioned the technically fine work of Ludwig Grillich, the work also of Pieztner, and the beautifully soft portraits of beautiful women by Hermann Kosel. The photographic trade in Austria is also represented by exhibits of apparatus and materials by firms such as Lechner, Reichert, and others. To the work in "process" we must refer in some later notes on the photo-mechanical exhibits, which will conclude these reviews of the Dresden Exhibition, but it may be said that the reproductions in monochrome and colour by half-tone, photo-lithography, and photogravure processes, shown by Angerer and Göschl, Husnik, and Häusler, as well as by a number of other Viennese firms, demonstrate the perfection to which these houses have brought the process craft.

GREAT BRITAIN AND INTERNATIONAL EXHIBITIONS.

UNUSUAL importance attaches to the British section of the International Exhibition to be held next year in Brussels, from May to October. Manufacturers have to consider, in regard to it, a totally new situation. Their very reasonable discontent with the character of international exhibitions in general, with the management of former British sections, and with the results of exhibiting, has brought this about. For the first time, what may properly be called a representative national exhibit is to be attempted, and this is being organised on novel lines.

Official Aid to British Exhibitors.

Exhibitors are no longer to be dependent on a voluntary committee; or left to install their goods as best they can; or exposed to the risk of being obscurely placed; or required to defray the cost of a general scheme of decoration; or engaged in a speculation, the cost of which they cannot ascertain beforehand. The section is in charge of a new department of the Board of Trade acting in personal touch with them, and taking responsibility for these matters.

French and German exhibitors have long been assisted in systematic ways. Our own were at a disadvantage everywhere, and the result has been harmful to British prestige. But the new organisation undertakes to do more than is done for the exhibitors of any other country. In these circumstances Mr. U. F. Wintour, the British Commissioner-General, is approaching all the staple trades of the country with a view to secure at once that arrangements shall be made for an exhibit showing the scope and real importance of British manufactures.

Position of the Section.

Perhaps the most prominent position in all the exhibition has been secured for the general section. Visitors must pass through the British galleries to reach those of Germany, the United States, France, Italy, and other nations. In the Machinery Hall the portion allotted to Great Britain occupies the centre, and the total space, 203,410 square feet, compares favourably with what has been granted by the Belgian Commissioners to our rivals.

How the New Order was Created.

The Royal Commission, which is presided over by the Prince of Wales, has its offices in Queen Anne's Chambers, Westminster. It is constituted wholly of well-known business men, and, the occasion being unique, His Royal Highness is giving active help to the Commissioners.

A departmental inquiry, concluded two years ago, was the means of opening this fresh chapter in the history of international exhibitions. It was presided over by Sir Alfred Bateman. Taking the opinion of a large number of important manufacturers, the committee found a strong and growing prejudice against exhibitions on the old lines, and came to the conclusion that it was largely justified. But as it would evidently be ruinous for Great Britain to abstain alone from a form of advertisement which is now established, they recommended effective means of meeting the grievances of British exhibitors.

The Exhibitions Department of the Board of Trade, which has been placed under the direction of Mr. Wintour, is the chief outcome. Instead of every exhibition being treated as a new problem of organisation—a problem more or less hastily and badly solved—this Department exists as a permanent machinery for the care of British interests in such matters.

Exhibiting Simplified.

To enumerate the facilities now first offered to exhibitors is to realise that a principal aim of the Exhibitions Department has been to simplify the business of exhibiting. These facilities are such that an exhibitor may know beforehand, to a penny, what his venture will cost him.

Except in the case of machinery, the only charge made within the exhibition itself is a low charge for space, and tenders will be obtained from Belgian contractors for the installation of machinery. This charge for space covers the provision of show-cases, the cost of the general decorative scheme, the handling of exhibitors' goods, the publication of a catalogue in French and English, and some other benefits to be noted presently. "Handling" means that officials of

the Commission will take delivery of packages at the exhibition entrance; unload and place them on the space allotted; take away, store, and return the packing cases; re-load at the close of the exhibition. Further, the Commissioners will provide, free of cost, as far as possible, an adequate supply of unskilled labour to assist exhibitors with the installation of their goods. Machinery will involve, of course, the additional cost of foundations and shafting—that of main switches, safety fuses, and motors for electricity, stop valves for steam, and valves and motors for water, and that of the power used for driving. Crane power is supplied free of charge.

A Uniform Scheme of Decoration.

There is a very striking novelty in the internal architectural design of this British section. The character of the design is not such as one associates with exhibitions in general. It has dignity and elegance. In harmony with the section's importance, it will give the British exhibit a conspicuous value for the most casual eye. The provision of show-cases in a uniform style is part of the conception. It will not deprive exhibits of individual character. Exhibitors are not even required to use these cases, or any cases. If they desire to provide their own, there will be every disposition to meet them in the matter, so long as their cases are not destructive to the national scheme. But the provided cases may be had in all sizes and for all positions, and they are dust-proof and extremely handsome, being made of seasoned mahogany, selected under careful inspection. Samples may be seen at the offices of the Royal Commission, 30, Broadway, Westminster.

Cost of Exhibiting.

The tariff of charges for space is as follows:—

	Per sq. foot.
	s. d.
Including the use of an isolated show-case, or part of a case, having more than one frontage	6 0
Including the use of a wall-case	4 0
Including the use of a platform and ornamental façade without glass	4 0
Including the use of a platform only	2 6
On wall or screen	2 6
In the Machinery Hall, including the use of platform and hand railing where required	2 6

For motive power the charges are unusually low. The Royal Commission will defray half the charges made for it by the Belgian Administration, on all machinery driven to illustrate processes of manufacture. Thus exhibitors will pay:—

For steam (133 lb. pressure)	$\frac{1}{2}$ centime per kilogramme
For gas	1s. 3d. per 1,000 feet.
Electricity (2 x 220 volts continuous)	1 $\frac{1}{2}$ d. per kilowatt hour.

Water will be supplied free for pumps or condensers. The charge for purer water in the Machinery Hall will be 1s. 10 $\frac{1}{2}$ d. per 1,000 gallons (50 lb. pressure), and in the Industrial Hall 1s. 8d. per 1,000 gallons for domestic, and 10d. for industrial purposes.

Not only will there be crane power, but the laying of foundations by Belgian contractors will be superintended by a competent engineer employed by the Royal Commission. With the above particulars the railway and shipping freights, and the contractors' tender, an exhibitor of machinery can make his calculations with a degree of confidence not hitherto possible.

Other Facilities

The special catalogue for the British section, published in English and French, will give a free insertion of twelve lines; the general catalogue a free insertion of four shorter lines.

All necessary steps will be taken by the Belgian Government for the protection in Belgium of inventions, industrial designs, and trade marks.

Another provision made by the Royal Commission is that of a suite of rooms for exhibitors' agents. This is a new thing in exhibition practice. There will be a reference library and a staff of high-class interpreters attached to the establishment, and it will be furnished with all the necessary equipment for transaction of business, correspondence, and so forth.

Reduced Transport.

The Belgian State Railways, charging full rates on the outward journey, will return exhibits to their termini free of charge. The

British railway companies will make a reduction of 50 per cent. on returned exhibits not sold, and travelling by the same route to the station from which they were sent out. Twelve shipping companies have also agreed to this 50 per cent. reduction. It will be understood that all preparations begun so far in advance by the Exhibitions Department are part of the reform which has been described, and that a prompt response to the campaign now being carried on throughout the country is advisable in the interests of exhibitors, as well as of the general scheme.

The Royal Commission is very influentially constituted of business men. Its chairman is the Earl of Lytton, and its vice-chairman Sir Swire Smith. Special committees have been formed for the various staple trades and for groups of allied trades.

THE EVE OF THE CONVENTION.

THE proverbial good luck of the Convention in the matter of weather may be relied upon for next week at Canterbury, quite apart from meteorological forecasts to the effect that the present cyclone is passing off to the Continent, and July is to usher in the summer in real earnest. But as those know who have been in the confidence of Mr. F. A. Bridge, rain or fine, the success of a

Photograph by

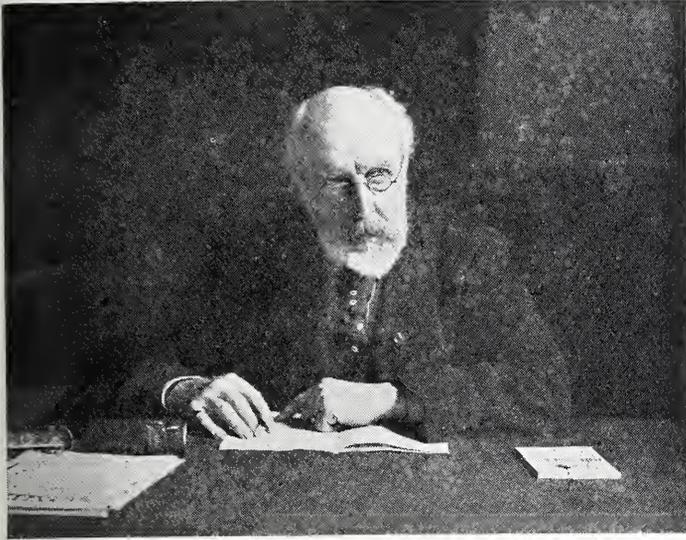

The President.

[Elliott and Fry.]

Convention is assured beforehand. Photographically the programme possesses great latitude, it provides opportunities for photography in circumstances when outdoor work would be uncomfortable, and at Canterbury and the surrounding Kentish towns conditions particularly favour such alternative arrangements. But away with forebodings. In the bright vocabulary of the Convention there is no such word as—wet. July 10 will probably see Conventioners disbanding from Kent after a week of summer spent in the garden-county.

The Convention handbook is so commendably informative—emphatic even—that it is impossible to add further details to

those mentioned. But as there may be those who—to their loss—have never yet joined a Convention party, we may point out that the proceedings open in an informal way on Monday next at St. George's Hall, Canterbury, and end on Saturday, in which six days the choicest parts of the Kentish coast, country-side, and his-

Photograph by]

torical places will be visited, and the visitor, moreover, provided for his evening recreation and instruction with a series of papers and lectures.

Photo-Mechanical Notes.

The City and Guilds Examinations in Photo-Mechanical Processes.

At the last examinations held by the City and Guilds of London Institute, the following papers were set in photo-mechanical processes. The number following each question is that of the number of marks given for it

ORDINARY GRADE.

WRITTEN EXAMINATION.

1. What do you understand by the term "half-tone"? In what respects does a print from an etched half-tone plate differ from (a) a print from an etched line plate, (b) an ordinary photographic silver print? (30)
2. Give an elementary explanation of the mode of formation of the "dot" in a cross-line screen negative. (50)
3. You are required to ascertain by direct experiment and in a simple manner whether a photographic objective produces an image free from distortion. State how you would carry out such an experiment. (30)
4. For what purpose is a reversing mirror used? Describe a simple process for the silvering of the surface of a sheet of glass intended for use as a mirror. What conditions must the mirror fulfil in order to be effective? (30)
5. Describe any recent modification in the construction of ruled cross-line screens. (15)
6. What is a yellow "screen"? How is such a screen made, and what is its use in photograph negative making? (30)
7. How would you make a solution of silver nitrate suitable for the preparation of wet collodion films? What difficulties are you liable to meet with in the use of the "bath," and how can they be avoided? How would you ascertain the total amount of silver nitrate present in the bath at any interval after use? (50)
8. What is collodion emulsion and how is it used in negative making? Under what circumstances can this substance be employed with advantage? (30)
9. What defects are liable to be produced in negatives made from drawings by the chemical processes of reduction and intensification? (30)
10. How would you prepare a film negative from a wet collodion

plate suitable for direct photo-lithography? If the stone to be used be of considerable size and it is not practicable to use a printing frame, how would you proceed? (50)

11. What are the principal physical differences between gelatine and gelatose? What form of gelatose is generally employed in the making of resists? By what means may these two substances be rendered sensitive to light? (50)

12. Describe the operations in the mounting of a line zinc plate having large open spaces. (25)

13. Give a brief account of any process with which you may be acquainted for direct photo-zincography of subjects in graduated tones. (30)

HONOURS GRADE.

WRITTEN EXAMINATION.

1. What are the most serious drawbacks to be found in cameras and their accessories (excluding the optical equipment) as ordinarily constructed, for the making of negatives for photo-mechanical processes? Describe any recent improvements in design with which you may be acquainted. (50)

2. Explain the simple principles which underlie the effective illumination of a room which is to be used for the manipulation of sensitive surfaces for negative making. Apply these principles to the design of a lamp suitable for lighting a room in which wet collodion plates are to be prepared. Your answer must be illustrated by a sketch. (50)

3. What is meant by a "physical" and a "chemical" restrainer respectively in a developing solution for wet collodion plates? Give examples. (30)

4. What do you understand by the term "fixation," and why is the operation necessary? The so-termed "fixing" bath for wet collodion plates is usually a solution of potassium cyanide in water. Explain the changes which take place during the fixing process. Why is this solution not used for the fixation of gelatine plates? (30)

5. Describe how you would use the metzograph screen in negative making. For what particular purposes is this method of translation useful? (50)

6. Explain how you would produce *direct* from a drawing in colour a cross-line screen negative suitable for making a type-high printing block. (30)

7. Give a brief account of your experiences in the use of different classes of "original" for the making of screen half-tone negatives. State any conclusions you may have formed as to the suitability of the various kinds. (25)

8. In the process of producing a half-tone relief block a copper plate bearing a resist is submitted to the action of a solution of ferric chloride. What differences may be produced in a series of similar plates in the etching process by varying the concentration of the iron chloride solution, its temperature, and the mode of its use? (50)

9. What are the drawbacks to the use of zinc in the ordinary enamel-line process for the production of type-high blocks? What processes are available for the making of resists which avoid these disadvantages? (25)

10. Explain the construction of the Albert etching machine, and describe how it is used. (25)

11. Give an outline account of any photographic intaglio process which may be used for the production of copies of maps. (25)

12. Discuss the principles underlying the use of "overlays" in the printing of illustrations. Describe some of the more important photographic methods of making overlays suitable for use in the printing of type-high half-tone plates, and mention some of the difficulties which are met with. (50)

13. Can you foresee any extension which may possibly take place in the use of the three-colour process owing to different modes of printing from that usually adopted? Support your views by any facts which are matters of public knowledge. (50)

In the practical examination in honours, the subjects selected can include three-colour process, photogravure, colotype, or negative-making.

CHANGE OF ADDRESS.—J. F. Upjohn, photographer, Acton, W., has moved from 201, High Street, to temporary premises at 128, Churchfield Road, Acton, W.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between June 14 and June 19:—

PRINTING.—No. 13,972. Improved rapid printing and enlarging machine for printing photographs by artificial light. Hubert Frank Byerley, 4, Havelock Road, Southsea, Hants.

FILM.—No. 14,039. Improved cinematograph film and its process of manufacture. Reginald William James, 1, Queen Victoria Street, London, for the Compagnie Générale de Phonographes, Cinematographes, et Appareils de Précision, France.

DAYLIGHT-LOADING.—No. 14,081. Improvements in day-light loading roll films. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.

GLAZING PHOTOGRAPHS.—No. 14,095. Improvements in or connected with apparatus for burnishing or glazing unmounted photographs and burnishing mounted photographs. Gordon MacDonald, Lloyds Bank Buildings, Canute Road, Southampton.

FILM PACKS.—No. 14,243. Improvements in film packs for use in three colour photography. Frederick Eugene Ives, 31, Bedford Street, Strand, London.

GLASS MEASURES.—No. 14,331. Improvements in measuring glass for dark-room purposes. Isidor Joseph, 322, High Holborn, London.

FILMS.—No. 14,343. Improvements in the manufacture of cinematograph films. Charles Dupuis, 18, Southampton Buildings, London.

COLOUR PHOTOGRAPHY.—No. 14,406. Process for obtaining photographs in colours. Reginald William James, 1, Queen Victoria Street, London, for Compagnie Générale de Phonographes, Cinematographes, et Appareils de Précision, France.

CINEMATOGRAPHS.—No. 14,407. Process for recuperating the material for the support of cinematograph films and waste portions of the same. Henry Danzer, 1, Queen Victoria Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ENVELOPE PLATE-HOLDERS.—No. 11,779, 1908 (May 30, 1908). The invention relates to improvements in envelopes used to carry sensitive plates or films, before and after their exposure in a photographic camera, such as are described in Wishart's Patents, Nos. 10,097 of 1904, 15,958 of 1905, and 4,992 of 1906, to which envelopes the improvements are particularly applicable. The inner sheath of the envelope is provided at its open end with a strip or band, which extends entirely across the space between the side flanges, and forms a mouth for the plate to enter. This band is preferably formed in a piece with the side flanges in the process of stamping the part forming the inner sheath, and when the plate is in position it is deep enough to form a narrow flange along its top edge in the same manner as the side flanges act in respect to the sides of the plate, or the strip may be a separate part fixed to the side flanges.

In place of the paper tongue, hitherto used to form a stop to prevent the plate from shaking upwards out of position, is fixed a solid stop of cardboard, either on the inner surface of the back of sheath or on the inner surface of the band, as in patent No. 4,992 of 1906. In the latter case the band is cut at each side where it joins the side flanges, to form a flap, to allow of that part on which the stop is fixed to be turned outwards when inserting a plate, otherwise there would be a danger of the stop scratching the sensitive surface as the plate entered. After the plate is in position the flap is returned to its original position and the stop will just clear the top edge of plate and prevent its upward movement; the outer cover, being placed on, keeps the flap and its stop securely in place. In removing the plate after exposure the

reverse of the above process allows the plate to slide out of the sheath when the latter is inverted.

A further improvement is in respect to the inner blind which has hitherto been a loose part and has required a separate operation to place in position. This blind is permanently fixed to the outer cover so that, when adjusting the latter over the inner sheath, the blind slides on the outer surface of side flanges, instead of underneath as was formerly the case. The safety extension of blind projects below the opening of the outer cover and engages under the lower flange of inner sheath to ensure against light leakage at the joint.

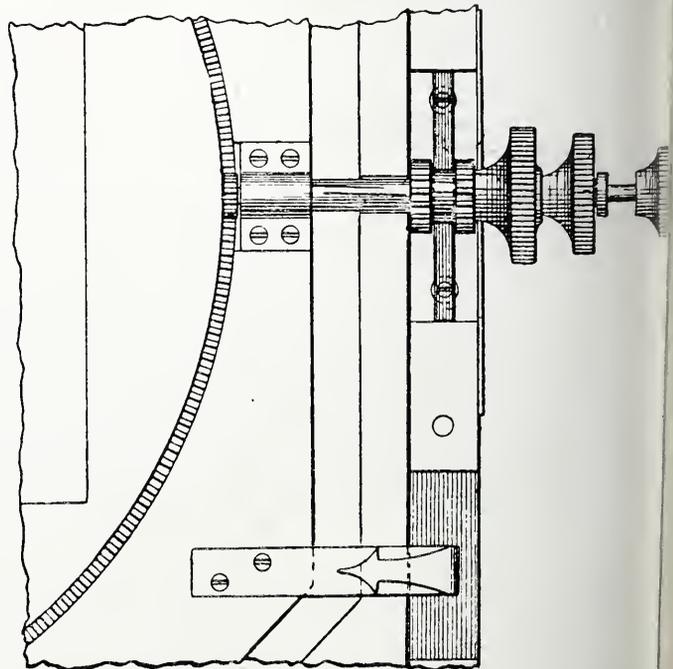

The inner blind acts as an intermediate protecting cover to the sensitive plate, and when represented by a loose or independent leaf it has proved somewhat troublesome to place in position, whereas by the plan of fixing this part to the inner surface of the outer cover it is always in position and at the same time renders the process of loading envelopes more simple. Edgar William Houghton, 88-9, High Holborn, W.C., and Houghtons, Limited, 88 and 89, High Holborn, London, W.C.

NEGATIVE CARRIERS OF ENLARGERS.—No. 18,640, 1908. (September 5, 1908.) The invention relates to the negative which is used in the stage of an enlarger or reducing camera for the purpose of giving the negative an up or down, sideway or circular motion by rack and pinion adjustment. It is now arranged to have the pinions operating these different racks all on the one axis, as shown in the figure.

For this purpose on one side of the inner or secondary slide a bearing for the spindle of the pinion is arranged which gears with the circular rack of the circular negative holder. The spindle terminates at its outer end in a disc-like head, by turning which the spindle is rotated.

On and near the outer end of the spindle a second pinion is mounted so as to be capable of a free or rotary motion thereon, the second pinion having a large flange or milled head by which it may be rotated in one or other direction on the spindle. The last-named or free pinion gears with a fixed vertical rack on the negative carrier proper.

A limited horizontal sliding adjustment of the inner or secondary slide is also provided by forming a screw thread on the outer end of the spindle and arranging a milled nut thereon, the nut bearing at its inner side against the head of the travelling pinion. By rotating the nut in one direction the spindle is drawn outwards

thereby giving motion in an outward direction to the inner slide. The reverse movement may be effected, when the nut is rotated in the other direction, by a spring or springs, but the spring springs may be dispensed with. George Lloyd Moore, Managing Director of The Midland Camera Company, Limited, Slater Street, Birmingham.

PRINT TRIMMERS.—No. 21,266, 1908. (October 8, 1908.) The invention relates to the trimming apparatus of Patent No. 2,922, 1899. It is now arranged to mount the oblique blade on the base board in such manner that it can be folded down when not required for cutting, thereby economising space in packing and making the apparatus more portable. The oblique blade is also provided with a spring which can be adjusted in tension, one end being secured to the blade and the other to the cutting board or base frame of the apparatus. The cutting board is also mounted by means of gudgeons or pivot pins in a slotted bearing or bearings in the base frame of the apparatus so as to provide for the ready removal thereof when desired. John Merrett, Trowbridge, Wilts.

FOLDING DEVELOPMENT BOX.—No. 21,684, 1908. (October 14, 1908.) The apparatus consists of a series of hinged walls which can be fastened together to form the box, which is provided with ruby window, sleeves for the insertion of the hands, etc. Nicolas Wladimiroff, 20, Boulevard Emile Augier, Paris.

EXPOSURE INDICATORS FOR DARK-SLIDES.—No. 4,243, 1909. (February 20, 1909.) When the photographic plate *m* is inserted in the chamber of the plate-holder, one edge bears against the strip spring *g*, which is compressed under the pressure of the plate and pushes the bolt *f* outwards. The hooked end is thereby

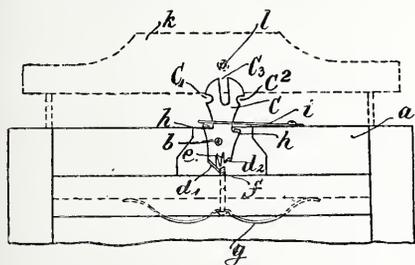

Fig. 1.

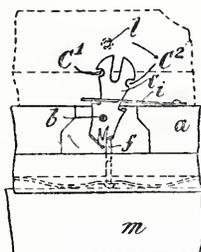

Fig. 2.

moved into contact first with the end of the tongue *e* and later with the edge *d*². The locking plate is thereby turned (Fig. 2) into such a position that when the shutter *k* of the plate-holder is closed, the pin *l* encounters the curved edge above the recess *c*¹, whereby the locking member is deflected in the direction indicated by the arrow out of the path of the bolt *f*, and the pin *l* snaps into a recess *c*¹. This condition of the locking member *c* indicates that the plate-holder is charged with an unexposed plate.

When the plate *m* is to be exposed, the locking plate is released from the pin *l*, and the shutter is drawn out, the locking member automatically adjusting itself under the action of the spring *i* into

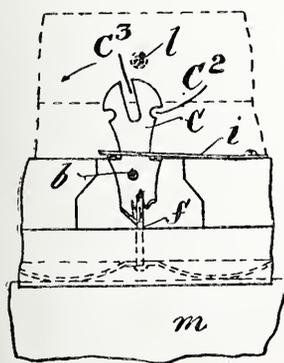

Fig. 3.

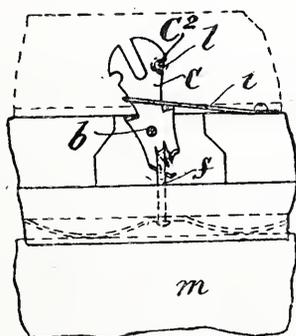

Fig. 4.

the position shown in Fig. 3, in which the slot *c*³ assumes an inclined position and the edge of the locking member located above the recess *c*² comes into the path of the pin *l* in such a way that on the shutter being pushed in after the exposure of the plate, the locking pin *l* snaps automatically into the recess *c*² (Fig. 4). When the plate-holder is emptied, the spring *g* is released, which draws back the bolt *f* and allows it to slide along the curve of the edge *d*¹, whereby the locking member *c* is erected and brought into the position shown in Fig. 1, in which the slot *c*³ lies opposite the pin *l*, so that the pin must pass into the slot *c*³ when the empty plate-holder is closed. W. P. Thompson, for Ernst Jähde, Schönborn, Nieder-Lausnitz, Germany.

DARK-SLIDES FOR TWO PLATES FACE TO FACE.—No. 11,816. 1908 (June 1, 1908). According to the invention the plates are ready packed face to face in a sheath, which sheath is carried in a special dark-slide serving to expose the plate in the camera. The sheath is formed as a shallow box, with one cover which fits round the sides into another cover, in a light-tight manner. A sensitive plate is fixed in each part with its surface outside so that when the parts are closed together the sensitive surfaces come close together and are preferably in contact. Means are provided so that the two parts can be easily separated for exposure of the plates, and afterwards closed together again.

A dark-slide for holding the sheath is also made in two parts in the plane of the plates, each part being provided with a sliding shutter over the face which joins that of the other, the back of each part preferably having an opening therein. One part is adapted to hold the complete sheath between its shutter and its back and to grip the outer part of the sheath. The other part is adapted to hold firmly the inner part of the sheath. The openings in the backs of the dark-slide enable the two parts of the sheath to be separated when the shutters are withdrawn, and to be closed again. After the parts of the sheath are separated, the shutters are closed and the backs of the two parts of the dark slide may be placed together.

With the parts reversed, the dark-slide can be used in a camera as an ordinary double dark-slide, or each part may be used separately as a dark-slide. Arthur Augustus Brooks, "Cranleigh," Park Avenue, Ashton, Cheshire.

DIAPHRAGM SHUTTERS.—No. 11,687. 1908 (May 29, 1908). The shutter comprises a casing having a ring journalled therein on ball bearings and carrying the exposure blades. A removable assembling plate is disposed between the shutter blades and the front wall of the casing (as has previously been proposed) carrying the mechanism for controlling the movement of these blades. A ring rotatable within the assembling plate carries the iris diaphragm blades whereby the size of the exposure aperture is varied, and detailed improvements are provided in the shutter-actuating mechanism enabling time, bulb, and instantaneous exposures to be made with greater accuracy and certainty than hitherto.

The shutter operating controlling mechanism which is mounted on the removable assembling plate comprises a master member, an operating trigger and bulb and time levers, each of these elements being broadly old but possessing detailed improvements, in particular a stop or projection being formed on the time lever adapted to engage the master member and prevent accidental operation of the exposure blades when the operating trigger is insufficiently compressed.

Moreover projections or stops are formed on the bulb lever also whereby the master member is locked and prevented from making comparatively instantaneous exposures when a bulb exposure only is required.

The springs controlling the movements of the master member and shutter blades are connected to the speed regulating device in such a way that when a shorter exposure is required their tension is simultaneously adjusted. The pivot points of the master member, operating trigger, and similar parts exposed to much wear are preferably formed with a bearing member at either end, in some cases operating springs being wound round such pivots and rotatable in position to the bearing members.

An indicator is conveniently provided which registers the number of exposures made. This indicator is either separately operated by hand or, as has previously been suggested, connected to the opening trigger, thus recording the number of times the latter has been depressed. Kodak, Ltd., for Paul J. Marks, Rochester, U.S.A.

CINEMATOGRAPH-PHONOGRAPH.—No. 9,419, 1909 (April 21, 1909).

The claim is for apparatus for indicating deviations from synchronism between two machines in action by means of two discs placed side by side and rotated independently on the same axis, in the same direction, each in connection with one machine, so that any difference of speed is at once indicated. It includes the arrangement of a pair of discs, the outside one of which is provided with an aperture through which different coloured signals or the equivalent upon the other can be viewed for the purpose of

obtaining synchronous action. Frederick Mayer and Arthur Edward Jones (trading as J. Bonn and Co.), 97, New Oxford Street, London.

New Crade Dames.

FAPOLA.—No. 312,575. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. R. T. Bruce and Co., Sitwell Street, Groves, Hull, manufacturers. April 27, 1909.

New Materials, &c.

“Invincible” Bromide Papers. Sold by F. E. Jones and Co., 22, Gray’s Inn Road, London, E.C.

A series of three varieties of bromide paper has just been issued by Messrs. Jones under the above name, the papers being glossy, velvet, and “cream semi-rough.” This gives a selection answering the majority of both professional and amateur purposes. The velvet paper possesses a most pleasing semi-glossy surface, very suitable for portraits and serving excellently for prints from which half-tone blocks are to be made. The “cream” paper has also an exquisite surface, not exactly rough, but of a faint texture which is very pleasing, the tint being a full cream which suits a warm black or brown (sulphide-toned) image. In the case of the glossy paper, a high glaze is obtained by stripping, and the paper develops without markings or lines. In all three varieties, the cleanness of working and sensitiveness are excellent, and fit the paper for both contact and enlargement work. Messrs. Jones will be pleased to send samples and particulars of prices on application.

Criterion Nonstress Bromide Paper. Made by the Birmingham Photographic Co., Ltd., Criterion Works, Stechford, Birmingham.

At the request of the Birmingham Photographic Company we have recently put to the test the new variety of their bromide paper just introduced. “Criterion” bromide we have known for long, and have been able to write in favourable terms of its general qualities. The makers, however, have doubtless done no more than re-echo the feeling of many customers in expressing their dissatisfaction with the paper as regards its toning by the sulphide method. Sepia and brown tones being now so largely produced on bromide papers and postcards, it has become as necessary for a paper to meet photographers’ requirements in this way as to develop with satisfactory cleanness and vigour. The modifications now made in the Criterion paper have led to an emulsion which is as rapid and as clear as its predecessor, and further gives as good a sepia tone as can be desired. We used the customary ferricyanide-bromide bleaching-bath and the sulphide solution, and were very pleased with the fine vigorous tones obtained on the paper. Thus modified, the Criterion paper may justly claim to possess all the properties which are regarded as desirable in a paper of this class, for, in addition to other notable features, it has the excellent property of giving no stress marks, a fact which we have recorded on a previous occasion, and is reconfirmed by our present tests of the “glossy” variety of the paper. In this toned bromide the photographer has an excellent substitute for P.O.P., whilst the matt and semi-matt papers, toned or untuned, serve admirably for the many varieties of portrait and other prints.

DEATH OF A SUCCESSFUL PHOTOGRAPHIC ARTIST.—On Sunday passed away, at Barnsley, Mr. Warner Gothard, photographic artist, founder of the firm in Eldon Street, and one of the largest businesses in the photo line in Yorkshire, aged 73. After studying as an amateur at his home in Littleport, Ely, he commenced business in Grimsby, with the glass positives, and in 1865 removed to Wakefield, where he was always to the front in every new process and improvement. He led the way in cartes de visite, the dry gelatine plate with imitation crayon drawings, the collodion dry plates (dispensing with the nitrate silver bath and iodised collodion, so injurious to the health of the operator). The deceased retired sixteen years ago to an estate he had purchased in Kent. Ten months ago he and his wife went to Barnsley, whither his family had removed. He leaves a widow, four sons (in the profession), and six daughters.

CATALOGUES AND TRADE NOTICES.

FALLOWFIELD’S PHOTOGRAPHIC ANNUAL.—We feel each year at a loss for new adjectives to apply to this annual landmark of photography. For the past twenty-five years we have personally had always at hand the yearly Fallowfield’s Annual, and we still find it an indispensable reference book and price list of all things photographic, and, as we have said of past issues, the most comprehensive encyclopædia of photographic apparatus and material a photographer can have. Like its forty-six predecessors—the Fallowfield firm points back to fifty-three years of honourable trading—the present Annual is very fully illustrated, is equally explicit in detailing the goods described in its pages, and apparently the compilers have succeeded in compressing the contents into a somewhat smaller number of pages, for which relief the present reviewer will be as grateful as anybody to them, for the physical exercise of consulting “Fallowfield’s list” in the whole course of a year must total to a considerable number of foot-pounds or other unit of force. The Annual is sent post free for 1s. 6d. (foreign stamps accepted from abroad), and those who are not able to visit large photographic establishments can take no better look over the goods of the time than in its pages.

PORTRAITS IN OIL COLOURS.—Art Photography, Ltd., Essex House, Leyton, London, E., have just issued a new list of portraits in oils from photographers’ negatives or prints at very moderate prices.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 3.

United Stereoscopic Society. Outing to Hayes and District.
Hackney Photographic Society. Annual Sports.
Manchester Amateur Photographic Society. Ramble to Grindleford.

MONDAY, JULY 5.

Southampton Camera Club. Demonstration of the Arrangement and Copying of Still Life Objects. A. E. Henley.
South London Photographic Society. “Trimming and Multiple Mounting.” J. A. Lovegrove.

TUESDAY, JULY 6.

Kinning Park Co-operative Camera Club (Govan). Club Meeting.
Hackney Photographic Society. “Exposure in Landscape Work.” J. Linley.
Handsworth Photographic Society. Council Meeting.

THURSDAY, JULY 8.

Handsworth Photographic Society. Open Air Meeting at “Moorfields,” Church Lane.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the annual general meeting, held on Thursday, June 24, the hon. sec. (Mr. Ernest Human) reported that the average attendance had largely increased during the year, and stated that he hoped that the increase would continue. The following gentlemen were elected to take office for the year 1909-10—viz.: Messrs. T. E. Freshwater and A. Haddon, trustees. Committee: Messrs. R. Beckett, C. L. Finlay, Chas. Greenwood, J. I. Pigg, H. C. Rapson, A. E. Smith, J. S. Teape, and the Rev. F. C. Lambert. Librarian: Mr. W. J. Ferry. Lanternist: Mr. E. T. Wright, Hon. Sec., Treasurer, and Recorder; Mr. Ernest Human, 43, Whitta Road, Manor Park, Essex. The hon. sec. will forward particulars of the association on application. Meantime, a hearty invitation is extended to anyone who would like to pay the association a visit at any of their meetings, which are held every Thursday, at 7.30, at “The Apple Tree and Mitre,” 30, Cursitor Street, Chancery Lane, E.C.

HACKNEY PHOTOGRAPHIC SOCIETY.—On June 22, Mr. Stuart Woodhouse gave a lecture and demonstration on negative retouching, and the use of megilp for improving bromide prints. In dealing with retouching in portrait work the lecturer said that the need for it should as far as possible be avoided. Suitable lighting, full exposure, and the use of orthochromatic plates with colour-screens would do much to render retouching unnecessary; but one did at times get negatives which were not perfect, and in such cases retouching could do much to improve them. He thought that a pyro-developed negative was better for retouching on than one produced by any of the developers which gave a black or blue-black image, as the pencil marks blended better with the brownish-black deposit. No more retouching should be applied than necessary, and portraits

of children should not be retouched at all. In using megilp to improve the surface of bromide prints Mr. Woodhouse said it was the outcome of many experiments with different substances. It has been suggested that megilp contained material that would be deleterious to the silver image, but so far he had found no ill-effects from using it. To brighten up the shadows of a print megilp is applied to the surface with the finger and rubbed in as evenly as possible, any uneven marking being subsequently removed by wiping with a piece of clean linen. Any amount of working-up may be done by applying pigment mixed with megilp, and it can be so spread and blended by means of the finger tip that in the finished result it will be difficult or impossible to see where pigment has been applied. The megilp treated surface will take blacklead pencil without the marks showing afterwards. Prints treated by the lecturer at the meeting proved fully all that was claimed for the method dealt with.

News and Notes.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—The last of the series of summer exhibitions organised by the above society and held at their headquarters, 9, Eberle Street, opened on Monday last, and consists of a selection of pictorial work by members of the Linked Ring. The exhibition will be open daily from 10 to 7 (Saturdays 10 to 4) till July 17. Admission is free.

L.C.C. CONTRACT.—The Stores Committee of the L.C.C. has accepted the following tenders for the annual supply of lanterns and lantern accessories:—R. R. Beard, 10, Trafalgar Road, Old Kent Road, S.E., estimated value of goods to be supplied, £26; British Oxygen Co., Ltd., Elverton Street, Westminster, S.W., £117; W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, E.C., £66; A. Clarkson and Co., 63, Farringdon Road, E.C., £17; W. C. Hughes, Brewster House, Mortimer Road, N., £7; Reynolds and Branson Ltd., 14, Commercial Street, Leeds, £9.

PHOTOGRAPHS OF OMNIBUS DRIVERS.—In the House of Commons on June 24, Mr. C. Hay asked if, in the interests of the men, some other arrangement could be made instead of bringing omnibus, etc., drivers and conductors to Scotland Yard to be photographed. Mr. Gladstone replied: Only a triennial attendance at New Scotland Yard is required, and men may attend at their convenience on any day during the month preceding the expiration of their licence. This requirement does not appear to be too exacting, and it is not practicable to arrange for the men to be photographed elsewhere.

A NOTE TO SECRETARIES.—The Kodak Co. announce that they are now open to receive applications for the delivery of a new lecture, entitled "Large Prints from Small Negatives," by their Mr. W. F. Slater, before photographic societies during the coming season. The lecture will deal with the advantages of using a small camera for taking the original negative, and the ease and simplicity with which large prints may be produced from such. A practical demonstration of enlarging on Kodak bromide papers will accompany the lecture, and secretaries who wish to include this fixture on their winter programme should make early application for a suitable date to the Kodak Co., 57-61, Clerkenwell Road, London, E.C.

SEEING BY WIRE.—The "Politiken," of Copenhagen, announces that two Danes, the brothers Andersen, already known as inventors, have invented an apparatus by the use of which it is possible to see what is going on at the other end of a telephone wire. The technical details of this invention are so far kept secret, but the "Politiken" recently employed an engineer of repute to test the brothers' claim, and this expert declared the claim to be justified, and described the process as entirely new and very simple. The process differs from the Korn and other systems of phototelegraphy in that it makes no use of photography, but transmits light and colours directly. A speaker at a telephone fitted with the apparatus can be seen, and he can show anything he likes across the wires. The inventors are described as sons of a saddler of Odense, and are aged twenty-eight and thirty. They have been eight years at work on the invention.

"TRAVEL AND EXPLORATION" in its July issue maintains the high standard of interest of its preceding six issues. Perhaps the contribution of greatest photographic value is that by Clive

Holland, entitled "Through Wessex by Caravan," detailing the pleasures and vicissitudes of a ramble through Dorset, gipsy fashion. The figures of the cost for a holiday taken in this way may be particularly noted. Mr. E. H. Shackleton is the subject of a lengthy character study by Dr. Hugh Robert Mill, and other articles in the number are "Life on an East African Farm," by Lord Hindlip; "Life in a Mexican Mining Camp," by Mr. F. L. Bensusan; and the first part of an account of a journey to the Arctic shores of Canada by Miss Agnes Deans Cameron. There are sections devoted to Travel Literature, the Exploring World, Tourist Travel, Motoring in Many Lands, and Aerial Flight, while the illustrations include 16 pages of reproductions of photographs on art paper.

DEATH OF MR. G. W. MORGAN.—It is with great regret that we record the sudden death of Mr. George Wilson Morgan, Aberdeen, the well-known photographer, as the result of a fall from a corridor railway carriage south of Carstairs, last week. About one o'clock the driver of a goods train observed the body of a man lying in the six-foot way, about 400 yards south of Pettinain signal cabin. The body was immediately removed to Carstairs, where later in the day it was identified as that of Mr. Morgan.

It appears that Mr. Morgan had been travelling with another gentleman by the 7.50 p.m. express Aberdeen, which passes Carstairs about 12.27 a.m., and both of the men having fallen asleep, it is supposed that, on waking, the deceased had mistaken the carriage door for that leading to the corridor, and stepping out, had fallen from the train.

His companion on waking at Beattock, missed him, and, becoming alarmed, pulled the communication cord, and the train was brought to a standstill. A thorough search was made, but no trace of the missing man could be discovered, and the journey to Carlisle was resumed.

Upon the arrival of the train at Carlisle the companion was notified of the discovery at Carstairs, and journeying back by the next train, he duly identified the body.

Mr. Morgan was widely known for his group photographs of Royalty on Deeside and pictures of rural scenery.

CANVASSING AMENITIES.—Leonard Palmer, a canvasser, of Balham, was summoned last week for assaulting Mary Ann Desmond, of 38, Kender Street, Deptford, who in turn was summoned for assaulting Palmer. Frederick Desmond was also summoned for assaulting Palmer. Mr. J. C. Scard appeared for Mr. and Mrs. Desmond. Mrs. Desmond stated that about six weeks ago a woman called at her house and asked if she had any photographs which she would like copied, and that if so she would have them done free of charge. She gave the woman a photograph of herself, and later another woman called and brought a copy of this, but not the original. On the 10th inst. defendant came to her house and asked if she wanted the copy of the photograph framed. She replied in the negative, and asked him for the original. He told her that his people could not work for nothing, and struck her a severe blow on the eye, causing it to blacken. Mr. Jameson, a neighbour, deposed to stopping Palmer as he was riding away on his bicycle. Palmer denied that he struck Mrs. Desmond, and said she hit him, and that later the same evening Mr. Desmond came to his house and asked him why he had struck his wife. On his denying that he had done so Mr. Desmond struck him on the chest. Palmer was fined 30s. with 20s. costs or twenty-one days, and Mr. Desmond was bound over to keep the peace, the summons against his wife being dismissed.

THE LETO OUTING.—The staff of the Leto works held their third annual outing on Saturday, June 26th. The weather all through the week had been so unsettled that there was some doubt whether it would be possible for the outing to take place on the date fixed, but all doubts were dispelled when the clouds cleared away on Saturday morning, and sun and sky once more appeared. The main party started from the Works, Edgware, at 10 a.m. in brakes for Windsor, and were joined on the way at Uxbridge by the staff from the Castle Bar Works, Ealing, which have just been taken over by the Leto Co. The number was further augmented by some of the Head Office staff and friends, who proceeded to Windsor by train. All joined at Windsor a little before 2 o'clock, and after partaking of lunch the party broke up into groups, some proceeding to inspect the Castle, Eton College, and other places of interest in the famous Royal Borough, others going in for boating, while

others again found the cricket match between Winchester and Eton a great attraction. Tea was provided at 5.30, after which it was time for the return journey. Altogether a most enjoyable time was spent by all concerned.

Correspondence.

•• We do not undertake responsibility for the opinions expressed by our correspondents.

•• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

THE SPEED NUMBERS OF PLATES.

To the Editors.

Gentlemen,—A Hurter and Driffield speed number should be one obtained by using their method in conjunction with their standards. The standard light being that of the standard candle burning under the conditions set out in their original paper, and the standard developer being one containing 8 parts of pyrogallol, 40 parts of sodium carbonate, and 40 parts of sodium sulphite in 1,000 parts of solution.

Speed numbers so obtained are strictly comparable.

But when different makers use different standards of light and different developers, the numbers so obtained are not H. and D. speed numbers, and are not comparable among themselves, as Mr. Biermann and many others have found out.

However, though the makers will not adopt a uniform system as to method, light, and developer, yet, fortunately for photographers, Mr. Watkins has done the thing for them by testing all their various plates on his system, and his numbers, as published in the successive Watkins speed lists, I find comparable among themselves, and reliable within the limits he mentions.—Yours faithfully,

48, Compayne Gardens, N.W.

W. B. FERGUSON.

To the Editors.

Gentlemen,—In reply to Mr. Watkins' criticism of my speed tests, I should like to point out that the plates under consideration were all "process" plates, and that the developer used is the one recommended by the makers, and is, in fact, the best one that can be used for the purpose for which the plates were made. So what is the use of testing with a developer that cannot be used for practical work?

With regard to the suggestion that the tests are only development speeds this was carefully guarded against by the fact that each plate was developed completely out, and then examined for half-tone dots only, not for density, and this I claim is the only true test of a "process" plate.

Now, I find on the latest Watkins speed card that these identical plates are marked as follows in the order of my tests: 16, 32, 24. The H. and D. numbers, it will be remembered, were: 15, 80, 95, so it will be seen that Mr. Watkins is totally at variance with the makers, and is much nearer to my results than the makers' figures, the exception being the H. and D. 80 plate, which is orthochromatic. This probably accounts for the high reading with the candle test, which is totally misleading when it comes to the rendering of printable half-tone dots.

With regard to the abnormal light, I take it that any light that can be used for the making of half-tone negatives would be abnormal by comparison with a candle; but why quibble at the means when we are both working for the same end?

Now, if you will allow me, I should like to make a few comparisons between the latest speed cards issued by the respective meter makers. I find eleven different makes of plates on the Wynne card, all marked $f/90$, which on the Watkins card are as follows: 4 are given as 250, 4 as 180, 1 as 130, 1 as 90, and 1 as 65. Then on the Watkins card I find 15 different plates marked 180, which on the Wynne card are marked: 4 as $f/90$, 8 as $f/78$, 1 as $f/64$, and 2 as $f/56$, and there are similar variations in all the other speeds.

I think, Gentlemen, that these figures speak for themselves, and show conclusively that there is just as much need for the standardising of the meter makers' speeds as the plate makers'. I have every faith in the H. and D. system as such, but it is the great variation in the rendering of the system that is at fault, and this is what we wish to get standardised.—Yours faithfully,

63 and 64, Ludgate Hill, Birmingham.

E. A. BIERMANN.

TRADE, PROFESSION, AND PHOTOGRAPHERS' COMPETITIVE METHODS.

To the Editors.

Gentlemen,—Your correspondent "Roco," in his denunciation of complimentary sittings, may or may not be right in designating the system as evil. Certain it is that such a diagnosis of the disease ruining the photographic profession of to-day is wide of the mark. One only needs to glance down the "Situations Wanted" and "Vacant" columns to see where the root evil lies. Clearly the cutting of prices is carried on at the cost of the underpaid and over-worked assistant.

The questions asked by "Compo" in your "Answers to Correspondents" column reveal a condition of affairs disgraceful to the profession.

Cannot an assistants' union be formed? The profession would have everything to gain by the formation of such a union. The P.P.A. in their own interests would do well to take the matter up, and you, Sirs, have unrivalled opportunities to lead in such a movement.

W. RIDDICK.

The Ark Studio, Bath Road, Melksham.

INTENSIFICATION MARKINGS.

To the Editors.

Gentlemen,—I have repeatedly got the markings mentioned by "Prof." in your last issue, when I have been interrupted during intensifying negatives. The easiest way to get them is to bleach the negative as far as it will go, and then slip it into a rather strong ammonia bath and let the negative stand while you attend to something else. Come back in a few minutes and you will probably find a very spirited plan of an imaginary estuary at low tide, with the chief channels and sandbanks crowded about that part of the negative you value most. However, if the patchy negative is now returned to the hypo bath, all the intensification will be taken out, stain marks too, and so, when the refixed negative has been duly washed the regulation time, it may again be intensified to any degree desired.

The danger seems to be in too steep a gradient in the ammonia blackening process, so it is safest to start with a very weak solution of ammonia, and keep the dish rocking until the bleached negative changes to a faint sepia all over, then it can be hurried up in a stronger solution if time is pressing.

Should "Prof." have a negative stained with fine lines that will not yield to the hypo bath, it is best to make a transparency and retouch them out, before making the second negative from it.

Lincoln.

A. F.

To the Editors.

Gentlemen,—I am greatly interested in the correspondence in the "Journal" with regard to "Intensification." I have had many years' experience in all the various branches of photography and have intensified some hundreds of negatives, but I have never come across the "markings" referred to by "Prof." My modus operandi may be helpful, and is as follows:—I am old-fashioned enough to use the good old pyro-ammonia developer in preference to the many newfangled developers, which may be all right in their way, and if I desire to increase the density of a negative I entirely free it from hypo by washing thoroughly. I then bleach the negative in a saturated solution of mercuric chloride to the required density, and then—and I think this is the great secret of successful intensification—well wash the negative in running water for quite twenty minutes, and then darken up with ammonia and water just strong enough to darken the plate in about a minute.

I think the cause of many failures is owing to insufficient washing and possibly to the use of too strong ammonia.

Trusting this may interest your readers,—Yours faithfully,

AN OLD PRO.

To the Editors.

Gentlemen,—I have been following the discussion on "Intensification Markings." May I be permitted to give my experience with regard to the above subject? Up to the present I have been unable to produce any of the markings referred to except by doing what no self-respecting photographer would do—namely, using dirty used up fixing and improper washing. My mode of operation is: After developing rinse well, fix in a clean fixing bath made of hypo 4oz. in water 20 oz., with a little metabisulphite, for not less than twenty minutes, then wash for twenty minutes to half an hour. I use a

ordinary "Rational" plate-washer. After washing I bleach in the mercury till the plate is clean white right through, then rinse for a minute or two under a tap, then blacken in the ammonia till lakened right through. After being thoroughly blacked, wash as usual. I intensify between two and three dozen negatives daily, and they all get the above treatment. I have negatives about two years old, which are as clean as the day they were made. I enclose specimen of the results obtained. This was done in July last year. I am, Gentlemen, your faithfully,
KENT.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Watson, 34, Crown Street, Bury St, Edmunds. Photograph of the Colours of 5th Batt. Suffolk Regt. (Territorials).
Deacon, Dovecourt House, Main Road, Harwich. Photograph of Cat and Mouse taken from Life, entitled "Captured."
Turnbull, 30, Seymour Street, Crossmyloof, Glasgow. Two Photographs of Kilmanning Rangers Football Club; Groups of 12 and 27 respectively.
W. Collier, 339, Bolton Road, Pendlebury, near Manchester. Photograph of Dr. A. Dewes and Mr. E. Heywood in an Open Carriage.

PRIMUS LENSES.—I have just bought a "Primus" casket of lenses but cannot find any name on them. Could you inform me who the makers are as I wish to get proper combination for using them?—OAKSIDE.

Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, E.C.

PHOTOGRAPHING COLOURED OBJECTS.—It is desired in photographing some coloured objects to make some of the non-actinic colours give opacity in the negative. I find that in the usual way blue reproduces yellow on bare glass, now I desire opacity, or to print white; also green reproduces red on bare glass, now I desire opacity, or to print white. Can you inform me the special light filter and the special plate that will do this?—S. V. P.

If you want a yellow to be fully recorded on the negative, you must use a plate which is sensitive to red and to green, as yellow is made up of these two lights. Therefore, you will need a panchromatic plate, and if blue is being photographed at the same time, you will need to use a yellow filter, to absorb some of the blue light, to which the plate is specially sensitive. Otherwise you would get a complete exposure before the yellows had time to record themselves. If you want to record red, you must gain used a red-sensitive plate (Pinacyanol bathed) or a panchromatic and a red filter. If you have greens and blues to photograph at the same time as the red, then you can only use a yellow filter, which will permit the red to go through and also the greens, and if it is properly chosen it will admit sufficient of the blue to affect the plate, which has so much sensiveness to blue. That is to say, a yellow filter must be used that absorbs some of the blue but not all of it. Such a filter could be Rapid Filter K in weak strengths, or Brilliant Yellow.

EX MINIATURES.—Could you kindly tell me if in colouring small photographs as miniatures on ivory, further preparation is required after the photographic film is fixed on the ivory? I have tried miniatures of this kind, and my difficulty is that the water-colour paint does not stay properly on the film, but flakes off in places with the slightest touch. I think it possible something

may require to be done to the film, after it is on the ivory, before beginning to paint, and shall be glad if you will kindly tell me how to proceed.—PHOTO-MINIATURE.

We have not heard of this trouble before. All carbon pictures on ivory—and we presume these are what you refer to—are done by the double transfer method. The only way we can account for your difficulty is that there is a trace of the waxing compound, of the flexible support, on the surface of the carbon film. This can be easily removed by rubbing the picture over with a pledget of cotton-wool moistened with benzole before beginning the colour.

NEMO.—We are sorry that we are unable to say. Our own preference and practice is to avoid the use of such reagents.

BROMIDE PRINTS.—I should like to print some twenty or thirty heads, from separate negatives, on one sheet of bromide paper 4ft. by 25in. How could I do this without fogging any part of the paper, or getting unequal development from varied exposures?—MULTI.

You will need a special frame for the job, the full size of the bromide paper, and provided with a series of black paper masks with which you can cover all the space except that of one print. If you adjust exposures to be, say, 30 seconds at least you should have no difficulty in getting even prints. The work would be simplified by making a set of duplicate negatives sufficient for one complete row of prints across the paper.

RETOUCHING (Reply to "Kitty").—1. There is no need to criticise your prints separately. From the commercial standpoint they are excellently retouched, and with your other accomplishments we consider you fully worth the salary you mention—and more—if you can get it in these strenuous days of competition and cutting prices. Your time is good for the quality of the work, but we advise you to vary your touch more, and according to the nature of the study, and to avoid a tendency you have for a rather hard effect—make for softer blending and lighter work generally. You are also inclined to thin the nose; guard against this, and so retain the likeness more fully. 2. As you are paid a weekly salary you do not require to give more than a week's notice.

LUMBERMAN (Annprior, Canada).—1. Unfortunately, makers are all alike in persisting in giving the highest speeds. Your question, therefore, resolves itself upon other points—those of reliability and convenience in use, and we would name Nos. E and D. H is the same instrument as D. In our opinion E is worth its extra cost. 2. The multiple slit you allude to is very convenient in practical use, much more so than the doubly adjusted shutters (slit and tension), of which there are a good many examples here. The best system in our experience for a moderate range of speed is that in which the width of slit only is altered. In any case, it is important that the adjustment should be "makeable" while the shutter is set in readiness for exposure. In A, F, G, and J this cannot be done.

SKETCH.—If, as we take it, the lens is to be used on a stand-camera, we should advise one of 8 or 9 inches focal length, and at least $f/6$ aperture. Unless your work will lead you to very rapid exposures we should not advise a larger aperture than this. As regards the make, there are a great number of good lenses to be had, and we advise you to look up the price lists in the "Almanac." A list of the makers themselves will be found on page 1552 of the "Almanac."

COPYRIGHT.—I should be glad if you would let me have a reply to my question in your next issue, as the matter is urgent. Some time ago I invited, through the committee, some amateur performers to sit for photographs for a widow display advertisement. Since then a newspaper has reproduced one, and I wish to know if I can claim from them. I did not copyright the picture, as I understood it was not necessary, but it would need to be copyrighted before action could be taken. Is this so? I did not give photographs or anything to the party for sitting, but I sold copies at a reduced rate—viz., 12s. per dozen cabinets. My usual price is 18s. 6d. dozen. I did not make any stipulation at the time I did these that the reduced price was made, because I wanted to hold the copyright. Was it necessary to do so?—PYRO.

You are under a wrong impression. You cannot take action for

any infringement done before registration. All you can do is to prevent further sales; little use, we should say, if the paper is a daily or weekly one. Moreover, you should have obtained the agreement of the parties, in writing, to your retention of the copyright. In the circumstances, the best thing you can do is to lie low and say nothing. We advise you to study the Copyright Act, or the article upon it in the 1906 "Almanac."

COPYRIGHT.—I took some photos of a public procession and handed a number of copies, both postcards and half-plate, to a stationer for sale or return. A few days later a photographer called and asked my permission to make a copy of one, and as I was pressed for time, and, as a matter of courtesy I lent him the negative to do so. When he returned it he said he had taken only two copies and thanked me for the concession. Later, to my great surprise, I saw a copy of the best portion of that subject enlarged and evidently produced from an enlarged negative, the finish making it plain that the photographer had gone further than merely making the copies I allowed him to make. Further, the stationer has on his counter for sale copies evidently from the same source, without my usual mark, and which will probably be sold as my work. I have not registered the copyright, but what I desire to know is if I can, in spite of that enlargement claim the copyright for registration, or if I can at once stop the sale of copies not produced by myself, as I gave him no permission to make other than the two copies from the actual negative.—**DELUVIUS.**

As the photographer has no written permission from you to make the copies you can do as you suggest, but you cannot take any action in respect of infringement committed before registration, that is to say, in the case of copies made before registration it will be necessary to take action against the people who are now selling them.

A. W. TEAR.—Thanks for the article, on which we will comment later. The remedy you suggest offers, we are afraid, too much difficulty in the way of collection by the Government to be taken up.

DRY MOUNTING, ETC.—I have had a considerable amount of trouble in dry-mounting "carbon-surface" bromide prints. The trouble is they will not stick to the mount, which is usually art paper. I press them five or six times, but you only have to bend the mount back and off they come. I generally mount C.C., P.O.P., etc., at the same time, and find they go down splendid. The art paper, prints, and plates are thoroughly dried before starting, so dampness is not the cause of trouble, and the bromides are usually left till last. The heat of dry mounter is kept between 122-167 deg. Fahr., as directed in Dry Mounting Company's booklet. Any help you can give me on this point will be very acceptable. 2. Is sodium sulphite an acid, neutral, or alkali compound?—**A. R. B. KINGSFORD.**

1. It is usual to use a little higher temperature for a heavier coated paper, such as bromide, but your figure is about right. Try a longer dwell. 2. Sodium sulphite, though in a chemical sense a "neutral" salt, is actually alkaline (to litmus paper), and requires a certain amount of acid to neutralise it.

GLASS.—We can make no other suggestion except the use of the old glasses as opalines, now gone out of fashion, but perhaps capable of being revived in some quarters for sale. Fallowfield's supply suitable mounts.

H. C.—The address is: F. J. Fletcher and Son, 69, Durham Road, Sparkhill, Birmingham.

DIFFUSER.—1. Thin muslin. The joins will not show. 2. The diffuser usually needs to be about 4ft. square, but naturally its size depends on the distance it is found necessary to place it from the lamp.

DUSTING-ON PROCESS.—I have tried the dusting-on method for the local intensification of negatives as recommended by you in your issue of the 19th with some success. I am somewhat troubled, however, with the shadows coming up blotchy. They do not take the powder quite evenly. The only thing I can think of to account for this is that the graphite is not perhaps of sufficiently good quality. I have only been able to obtain what is supplied for lubrication purposes, and cannot obtain the electrotype graphite anywhere. I have used the dextrine-candy formula. Is this as

good as the other? Any further hints you may be able to give in connection with this most useful and interesting process will be much appreciated. I may say I take great care not to breathe on the negative while working.—**JOHN.**

Your trouble, no doubt, is due to the plumbago you are using. It should be in the finest possible state of division. A suitable kind may be had from Messrs. Penrose and Co., Farringdon Road or from Messrs. Hopkin and Williams, Cross Street, Hatto Garden. The formula you are using is a very good one, though the other is equally good. It is possible that the film was a little too moist when the plumbago was applied. You can scarcely expect to succeed with a new process with the first essay.

A. THORBURN AND OTHERS.—In our next.

VARNISHES, ETC.—1. I have been using for some time a negative varnish of celluloid and amyl acetate, as given in "B.J. Almanac" (but with more celluloid), and find that in machine-printing the negatives are easily marked with lines caused by the paper passing over them. These lines are not removed by cleaning off the varnish, as corresponding black lines remain on the film. Should be very glad to know of anything that can be added to the varnish, or of another cold varnish (not shellac) that will obviate this trouble. This varnish is very suitable otherwise. 2. Should be glad to know of a bath for removing abrasion marks on bromide paper. Cannot use one containing ferricyanide because of alum toning and hardening baths, and at present have to resort to rubbing.—**J. H.**

(1) We think you will have to resort to a shellac varnish if, as appears to be the case, the conditions call for a very hard film. You might try the varnish (cold) made up by the Vanguard Co. as "Vitrivine," which may be used in the same way as that you are now employing, and may possibly give a harder surface. If methylated spirit applied with cotton-wool will not read remove the marks, try the iodine cyanide reducer given on p. 10 of the "Almanac," diluting it with a goodly proportion of water.

MINIATURE PAINTING.—What is the best method of producing good permanent coloured miniatures, also a good process of colouring portraits, and where could I get good permanent colours for the (water-colours)? I have been using —'s colours for miniatures, and these look very nice when done, but colour soon fades when put in show-case. I have been using aristo-plat as a basis (well finished, fixed, and washed). I would therefore like to know of more permanent colours or processes both for first-class work, also suitable for colouring enlargements. Kindly state in answer where I can obtain good permanent colours.—**J. F. M.**

Undoubtedly the most permanent processes of photography are the platinotype and the carbon, and both are very suitable for colouring. The colours you have been using are coal-tar colours, many of which are more or less fugitive if exposed for long to a strong light. The most permanent water-colours are those used by artists' colourmen, and you would not find them fade in show-case if they are obtained from a good source, such as Winsor and Newton, Rowney, and similar high-class makers. The colours are used as in ordinary water-colour painting, and are the best for colouring enlargements.

METOL.—Taylor and Co., No. 1 Wharf, New Wharf Road, King's Cross, N.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

SUMMARY.

The Photographic Convention. The first part of the proceedings of the Convention, now being held at Canterbury under the presidency of Mr. H. Snowden Ward, F.R.P.S., are reported on pages 530 to 533. The president's address dealt with the oft-discussed subject of the relation of photography to art. Its dominant note was the need of a higher culture among those who claimed to employ photography as a means of artistic expression.

The group of members of the Convention taken on Wednesday afternoon last by Mr. H. B. Collis is presented as a supplement to this issue, the block (by the London Studio) having been placed in the printer's hands within a few hours of the exposure having been made.

Mr. Douglas Carnegie, in an article on page 528, describes one or two modifications of the method of making lantern slides direct in the camera by a reversal method. He employs the ordinary gelatine lantern plate and ammonium bichromate as the reversing agent. He adds some further notes on a convenient form of easel for use when copying from book illustrations.

Some notes on the manipulation of the "Ensyna" paper and of the use of the "Ensynoid" developer by Mr. J. Peat Millar appear on page 537.

Dr. R. A. Reiss has recently contributed a useful resume of the methods used by him in copying faded or partially burnt documents. (P. 533.)

A note on a principle which may be usefully borne in mind in making dust-proof receptacles for drying negatives or prints is mentioned on page 526.

Still another apparatus for the measurement of the speeds of shutters has been devised by Dr. R. Birkhäuser. The principle of the apparatus and a sketch of its construction are given on page 535.

Film cameras, tripods, and rotary printing machines appear among patents of the week. (P. 539.)

The thiocarbamide toning bath has been recommended by a German worker. (P. 525.)

Some further notes on the working of the albumen process, particularly in severe climatic circumstances, are given on page 527.

EX CATHEDRA.

Feats of Night Photography.

If we may judge from one incident which came before us on a recent evening it would appear that the enthusiasm of the night photographer may at times exceed his discretion. Passers down Piccadilly, London, will perhaps have noticed a window advertising some baths in the south of France. The chief object in the window is a piece of statuary which at night is illuminated, and then attracts a constant crowd on the pavement. Our night photographer, we observed the other evening, had taken his stand on the other side of the roadway, and was pointing the lens of a very businesslike Sanderson camera towards the statuary, intermittent glimpses of which he must have secured through the stream of vehicular traffic. We can only surmise that the fortunate man (was he a member of the S.N.P.?) had got Dr. Mees to provide him with a filter with an absorption band for motor 'buses and taxi-cabs.

* * *

The Simplest Combined Bath.

A recent short note in a German contemporary records the writer's satisfaction throughout a long period of time with a combined toning and fixing bath composed simply of hypo, water, gold chloride, and a certain proportion of thio-carbamide, or thio-urea as it is more usually named. The proportions recommended are 200 gms. of hypo, 10 gms. of thio-urea in 1,000 ccs. of water, to which the usual quantity of gold is added last of all. This permits of the prints being left in the bath for any reasonable time without detail suffering. Moreover, the bath may be used to exhaustion, and gives reddish to black tones, according to time of immersion. The writer, Dr. Carl Arnold, does not refer, however, to the necessity of retaining the prints in a faintly acid condition while the thio-urea is removed, otherwise decomposition may be caused by alkali in the water, just as in the case of hypo minute quantities of acid lead to the formation of sulphide compounds in the print. While we have not yet tried the process, it is necessary to say that from the chemical standpoint the correct use of both hypo and thio-urea in the same solution would appear to be an a priori impossibility except with the aid of some acid such as sulphurous acid, which does not decompose hypo.

* * *

The Speaight Exhibition.

Since previously announcing the invitation which Messrs. Speaight are making to photographers of every degree to visit their exhibition of "Fair Children" on July 21, we learn that some new portraits have been added, and the exhibition thus represents the most recent opportunities which Messrs. Speaight have had, or perhaps we should say have created, for making portraits of the little ones of European Royal families. However, as we have already announced,

the manner of the exhibition, quite as much as or even more than its matter, should be of interest to our professional readers, and in thus reminding them of the invitation we may perhaps correct a misapprehension which may exist in the minds of more than the one or two that have written us, namely, that admission to the exhibition on this occasion is, of course, without charge.

* * *

Measuring the Speed of Shutters.

A writer in a contemporary suggests that the speed of a shutter can very easily be ascertained by simply photographing a moving object, such as a train or cycle, as it passes the camera in a direction parallel to the plate, and he supplements the suggestion by instructions for calculating the distance through which the train has moved during the exposure, remarking that it is quite easy to ascertain the speed of the shutter if we know the speed of the train. This is, however, the crux of the problem as it appears to us, and the only suggestion that he gives with regard to ascertaining the speed of the train is that it should be timed during its passage between two points a measured distance apart. Presumably, this involves the use of a stop-watch. We can see no other way of doing it, while experience teaches that nothing but long continued practice enables one to use a stop-watch with any approach to accuracy. The method is described as requiring no special apparatus and no elaborate calculations, but this description hardly seems to fit the case. A good stop-watch is expensive, while a cheap one is quite useless for the purpose; and to ensure reasonable accuracy two watches would really be required, each being held by a person situated opposite the datum marks. Further than this, the subsequent calculations would not be particularly easy unless the rate of the train happened to be a convenient one for the speed of the shutter. All things considered, the old methods of the revolving bicycle wheel or the pendulum consisting of a bullet and a piece of string seem much less elaborate and far more likely to give satisfactory results.

* * *

Dr. Birkhauser on Shutter Speeds.

In the article which we translate on another page it will be seen that this method does not differ very greatly from that of Herr Paul Thieme, described in our issue of May 21. The apparatus is, however, rather less complex, while the method by which the speed of the revolving disc is controlled is noteworthy for its simplicity. It must be observed that this method could hardly be expected to be quite satisfactory excepting with very nicely constructed ball bearings to the disc axle. There is, it appears to us, one feature of these methods of measuring shutter speeds that is open to objection. It is essential to have a variety of speeds of revolution available, else too long an exposure produces a result in which the various dots of the record merge together and become indistinguishable. In this respect the "sine curve" methods all have a great advantage, for each unit of light effect falls on a different part of the plate, so that a large number can be recorded in one test. This is certainly an advantage when a variety of speeds have to be tested. Another point is also obvious. None of these recently advocated methods give even an indication of efficiency, and we really know very little about a shutter if efficiency is quite ignored. Sometimes a knowledge of this duration is of much greater practical importance, as we have pointed out before, but still it often happens that high efficiency is the essential thing. This is a trouble-

some factor to measure exactly, but the somewhat rough indications of it given by methods such as the one devised by Mr. Salt afford about as much information as is really necessary.

* * *

Dustproof Drying-Boxes.

Last week we referred to methods of drying negatives in a draught of cold air. One objection to any such method is, of course, the probability of the draught carrying dust on to the films, and in connection with this it is interesting to refer to a paper by Mr. T. Pridgin Teale read before the Society of Arts about seventeen years ago. In this paper he pointed out the impossibility of keeping dust out of closed boxes, when reliance was placed on well fitting joints alone. Indeed, the finer the fitting the stronger is the draught of air through the crevices, and the further is the dust carried. As every change of temperature creates a draught through all the cracks, the remedy was to provide large apertures through which the air could pass at low velocity, and to filter it through flannel during its passage. Here, it appears to us, we have a hint that may be turned to account for plate drying. The plates can be enclosed in a tin box formed of open frames filled in with flannel, while a current of air through the box can be ensured in several ways. Possibly the kitchen jack, to which we referred before, could be utilised with advantage. The box could be suspended from it and kept rotating, but a most efficient method would be the following: Make a long box with flannel sides and shape it so as to fit an ordinary window between the lower sash and the sill. The side of the box towards the room can be made to open and the plates can be carried in wood grooving fixed to top and bottom of box. Two or three hundred plates can be inserted in such a box made to fit a three-foot window, and the simple expedient of leaving the room door open will create sufficient draught to dry the plates in a very short time.

Cinematograph and Talking Machines.

Readers who study our Patents Column cannot have failed to notice the large number of patents that have recently been published relating to the synchronisation of cinematograph and phonograph, or gramophone. The difficulties have been very successfully surmounted in many cases, for we have seen a number of films with which the synchronisation leaves nothing to be desired, but we are distinctly of opinion that it would be very desirable as soon as possible to supersede the devices in which an indicator in full view of the spectators is employed. To the uninitiated the sight of a revolving indicator in the corner of the picture is puzzling, while it is irritating and disturbing to all, including those who know its object. In this respect improvement is very desirable and we may suggest also it is equally desirable to use coloured films in preference to monochrome ones. We all know the perfection to which coloured films have not been brought, while the appearance of monochrome figures that talk or sing is very incongruous and unconvincing. The results seen up to the present are, however, very encouraging, and we feel convinced that in a short time this style of entertainment will become very popular. The talking machine has already reached a high state of perfection, and so also has the cinematograph, if we judge it by the best films on view. A combination of the best results obtainable with the two machines should therefore give very satisfactory results, though the premature attempt to combine indifferent films with the talking machine is not likely to be advantageous in any respect.

PRACTICAL NOTES ON ALBUMEN PAPER PRINTING.—II.

It was mentioned at the conclusion of the previous article that after the sensitising bath has been in use for some time it becomes discoloured. With some papers it will become discoloured after a day's use; with others, more slowly. In any case if the bath has anything beyond a pale tint the paper sensitised on it will be more or less tinted, in which case great purity of the white in the prints must not be expected. Various methods of decolourising the solution have from time to time been suggested, but the simplest, and at the same time the best in practice, is to add to the discoloured solution—for the quantity given in this former article—three or four teaspoonfuls of kaolin and well shake for a minute or two. By the next morning the kaolin will have settled compactly to the bottom of the bottle and the solution will be as clear as when first made. The clear solution, or part of it, is then passed through a filter placed in another bottle. The same filter may be used over and over again if the first few ounces that pass through are given a second filtration. It is a good plan to return the bath to the stock bottle after the day's sensitising is finished and well shake it up, as it will then be found clear and bright for immediate use. The one supply of kaolin, if left in the bottle, will serve for a very long time.

If after use for sensitising the solution is left in the dish for an hour or two, and it is then required to sensitise more paper, it will be found that there is a scum on the surface, which scum will be taken up by the sheet of paper. Therefore, before being again used, the bath should be skimmed by passing the edge of a strip of blotting-paper over it, taking care that the paper is long enough to completely cover all parts as it is passed over.

It is desirable to keep a stock solution of nitrate of silver of a hundred grains to the ounce of water to replenish the bath with. This will generally be found to keep the solution up to its original strength. If it makes it stronger by the "Argentometer," as may happen by evaporation if the bath is left standing in the dish for long periods in hot weather, a little water must be added. If on the other hand the bath is found below its original strength, some crystals of nitrate of silver must be added.

Little need be said with regard to the printing, but it should be mentioned that if dark purple brown be required the printing should be carried further than if only light browns are desired. There is one other point that may be mentioned in connection with home-sensitised papers, more particularly for the benefit of those working in hot and dry climates. It is that the paper should not be printed in an abnormally dry condition; otherwise there is a difficulty in obtaining good tones, and the prints when toned are liable to become mealy in the toning operation. This state of things is likely to occur in this country in very hot weather, particularly when the printing frames and pads, as is very usually the case, are kept in the printing room where they become abnormally dry. In this case the paper will take quite a different tint in printing from that which it assumes under normal conditions, and it will also refuse to tone beyond a very light stage before it becomes grey and mealy. When this state of things is experienced the best remedy is to put the frames and the pads, exposed, in a damp place for the night, when they will generally absorb sufficient moisture to restore them to their normal state. This trouble is more likely to arise with paper of home sensitising than with the ready sensitised. The tint taken by the paper in the printing is somewhat dependent upon the particular chloride used in salting the albumen as well as on the degree of moisture the paper contains at the time of printing. For example, if two pieces of the same paper be

printed, one after complete desiccation (and of the frames and pads also), the other normal, and with frames and pads in their normal state as regards moisture, it will be found that there is a very material difference in the colour. It will also be found on toning that the former will not tone except to an unpleasant tint and will be mealy, while the latter will readily tone to almost any colour.

After printing, the free nitrate of silver must be washed out before the pictures are toned. Common water suffices for this. Two or three changes will be enough, that is if the third one has only a slight milkiness. If the paper is sensitised in the bath the formula for which was given in the previous article, and very warm red tones are desired, it is a good plan to pass the prints through a very weak solution of salt in water. This will change the colour of the prints to a yellow tint, and they will tone to a pleasing warm red brown. If the paper is sensitised on the bath with citric acid it is a good plan, after washing out the silver, to pass the prints through a solution of common washing soda, say a crystal about the size of a walnut in a quart or three pints of water, and then rinse in plain water. This neutralises any acid that may remain and greatly facilitates toning, especially to the purple stage. The treatment is also useful when using some brands of ready sensitised paper. The free silver having been got rid of, the next thing is the toning of the prints. There is a great variety of toning baths, though most operators have their pet formula to which they rightly confine themselves. We shall here give formulæ for one or two of the baths most generally used. One of the most favoured ones for general use is the acetate bath. It is well suited for warm red browns, and with rather deep printing, from vigorous negatives, rich purple browns may be obtained. The toning agent in all cases is gold, and it is convenient to keep the chloride in solution. A convenient strength is a fifteen grain tube dissolved in fifteen drachms of distilled water, one drachm then containing one grain of the chloride, at which strength it keeps better than when more diluted. The formula for the acetate bath stands thus:—

Acetate of soda	30 grs.
Water	8 to 10 ozs.
Chloride of gold	1 gr.

This bath must be made up at least twenty-four hours before it is used, otherwise it is apt to yield mealy prints. The bath may be used over and over again, if more gold be added from time to time, but the addition should always be made the day before the bath is next to be used. The bath should be kept in a dark place, as light would cause some of the gold to be deposited on the sides of the bottle. With this bath one grain of gold will tone a full sheet (22 in. x 17 in.) to a deep purple brown. Another bath which is a favourite with many is the phosphate bath:—

Phosphate of soda	20 grs.
Water	10 ozs.
Chloride of gold	1 gr.

This bath, unlike the acetate, may be used as soon as it is made, but it will not keep. It gives dark purple brown tones. A bath well suited for colder tones than either of the above is:—

Bicarbonate of soda	4 grs.
Water	8 ozs.
Chloride of gold	1 gr.

This bath like the phosphate is ready for use directly it is made, but it will not keep for many hours.

Albumen prints can be toned in a combined toning and fixing bath, indeed in the earliest days prints were universally toned by this method—though for theoretical reasons it is not to be recommended. Yet it must be

admitted that many of the pictures toned in it forty or fifty years ago, as regards tones and permanency, leave little to be desired. A very general formula for the bath was:—

Hyposulphite of soda	12 ozs.
Water	15 ozs.
Chloride of gold (in 2 ozs. water)	15 grs.
Nitrate of silver (in 2 ozs. water)	30 grs.

When the hypo is thoroughly dissolved the solution of chloride of gold is added by degrees with constant stirring and then the nitrate of silver in a similar way. The bath

should stand a day and then be filtered. In some cases, the prints, without washing, were put straight from the frame into the bath; in others the free silver was washed out. In either case the toning was a slow operation; in cold weather it would sometimes take several hours. With this combined bath there is no question that the prints are thoroughly fixed before they have acquired the necessary tone. It will be noticed that the bath is quite different from those now used for P.O.P. It contains no lead, alum, etc. It is simply water, hyposulphite of soda, gold, and silver, and the latter was often omitted.

THE PREPARATION OF LANTERN-SLIDES DIRECT IN THE CAMERA.

EXPERIENCE gained since the publication of my process for obtaining lantern-slides direct from the camera ("B.J.," October 23, 1908) has suggested several modifications in the direction of betterment which seem worthy of record.

The process as originally described (*loc. cit.*) gave reversed positives; furthermore, any fog or veiling that happened to be formed was deeper down in the gelatine film than the image, thus rendering its removal without degradation of the strength of the image difficult and precarious.

In accordance with a suggestion (made privately by Mr. Arthur Payne, and through the correspondence columns of the "B.J." by Mr. Fenske), the method of procedure has been modified so as to give non-reversed positives, which, as regards strength and pluck, compare favourably with the best that contact printing from intensified negatives can give; and furthermore, in the process as here set forth, any fog that may be formed (in cases of unsuitable primary exposure) is superficial, and so can be cleared away without difficulty or risk. The working conditions have been so definitely established and standardised that the process is now, I consider, "fool-proof."

Primary Exposure.

For the sake of constancy of illumination, and failing to command electric light, I always use an injector lime jet as the source of light. The exposure given for diagram work is ten seconds from each side of the camera body, the lens being stopped down to $f/11$. During exposure the jet is waved about just far enough behind the lens to prevent any direct light from entering it. I never vary the exposure. Whatever the scale of reproduction may chance to be (*i.e.*, whatever the camera extension employed), the same stated exposure is given. Though I presume it must be generally known, I have nevertheless never seen any specific allusion to the following simple deduction from the law of conjugate planes, taken in conjunction with the law of inverse squares, *viz.*, that if the source of illumination is at the anterior focal point of the lens and the time of exposure kept constant, the plate must always receive the same effective exposure per unit area, whatever the scale of reproduction may be. Of course, in actual working the locating of the light at the front focal point of the lens is impracticable, but in the case of a lens of short focus (5 in., say) there is no difference of practical significance in the densities of the negatives obtained, if, complying with the exigencies of the case, the source of light is moved back a short distance behind the lens and the precept of constant time for all scales of reproduction adhered to.

As in the Autochrome process, the plate ("photo-mechanical" or "process") is placed in the dark-slide so that the glass is in contact with the rebate, the diagram having previously been focussed on a reversed focussing-screen. Before placing the plate in the dark-slide the glass face of the plate should be examined for splashes of emulsion, and these, if present, must be wiped off. The object in stopping the lens down to $f/11$ is to minimise the effects of any small differences that may exist between the thickness of the plates and the focussing-screen.

Development.

The developer is compounded in accordance with the recipe:—

A.—Metol	24 grs.
Hydroquinone	90 grs.
Sodium sulphite	2 oz.
Potassium bromide	40 grs.
Water	30 oz.
B.—Sodium carbonate (crystals)	2 oz.
Water	30 oz.

For use, equal parts are taken of A and B. In very warm weather it is advisable to increase the amount of bromide. This developer is very well suited to intermittent work, as it has excellent keeping qualities.

Some surprise may be occasioned by the recommendation to include metol in the composition of a developer for a process in which extreme hardness in the negatives is the desideratum. The general practice in line-work is to use a simple hydroquinone developer; but such a developer necessitates the use of caustic soda as an accelerator, and caustic alkali is not at all suited to the process here described. The addition of a little metol permits of the use of hydroquinone with sodium carbonate as accelerator, and there is no objection to the carbonated alkali.

The exposed plate is placed, film up, in the developer, covered, and left for five minutes. At the end of development the image should be clearly visible on the film surface. The plate is now well rinsed in the dish for one minute, and then flooded with the reversing solution, in which the silver image is dissolved. When rinsing, the plate should always be temporarily removed from the dish, and the dish itself rinsed out. Otherwise solution is persistently retained by the capillary space between the plate and the dish bottom. This effect of capillary attraction is very manifest when washing (without removal from the dish) after using the permanganate reverser in Autochrome work.

The Silver Solvent Solution.

In my previous paper acidified potassium bichromate was recommended as silver solvent, but increased experience has shown the advisability of substituting ammonium bichromate for the potassium salt. Reference was made in the paper (*loc. cit.*) to a kind of opalescence, discernible by obliquely reflected light, produced in the film by the potassium bichromate bath. Such opalescence is obviated by the use of ammonium bichromate. The solution has the following composition:—

Ammonium bichromate	300 grs.
Nitric acid (concentrated)	3 drachms, fluid.
Water	40 oz.

Two or three minutes' immersion of the plate in this solution will wipe out the densest silver image. The plate, having been well swilled again for one minute after removal from the bichromate bath, is ready for

Re-Exposure and Re-Development.

Since during the re-exposure the plate must be exposed in the developer *glass side up*, provision must be made that the film itself does not come into contact with the bottom of the

developing dish. This is secured by sticking (by means of coaguline) narrow strips of glass on the bottom of the tray (preferably a black one) at either end, so as to act as small shelves for the plate. The previously used developer is poured into the dish; one end of the plate, itself held in a slanting position, is immersed, and then the other end of the plate gradually lowered, till it is completely immersed. This method of inserting the plate must be followed, for air-bubbles in contact with the film would be fatal. If the plate is first placed in position on the shelves in the dish and the developer then poured in, bubbles are a moral certainty. The plate is rocked in the developer for half a minute, the dish placed on the floor, and three-quarters of an inch of magnesium ribbon is burned at a vertical distance of 3 ft. above it. The plate is then left covered for five minutes, when secondary development will be complete. Fix in an acid fixing-bath, and wash.

When soft results are required (as, for instance, in making a slide from a photograph with a delicate range of tone gradation), magnesium light should not be used for the reversal exposure. In such cases the weaker light of a number 4 flat-flame gas burner is to be preferred. In my own practice the light from a gas pedestal, about a foot high, and standing on the table, is reflected by means of a mirror on to the plate as it lies glass side up in the developing dish. The mirror is clamped at an angle of 45 deg. to the vertical a foot above the dish, and the gas flame is placed some eighteen inches from the mirror. The light is kept on during the whole time of development, the duration of development being now regulated by inspection of the plate and the character of the slide required.

Reduction and Clearing.

Even if there be no appreciable fog, short immersion in a reducing bath always enlivens and brightens up a diagram slide. The best method of procedure is as follows: Place the plate for a minute or so in water to which enough potassium ferricyanide has been added to colour it distinctly yellow. Wash, and then immerse in a very weak hypo bath. If there has been fog or veiling of the background, and it is not yet removed, repeat the process. Do not expect the veiling to disappear in the ferricyanide solution. I find that this plan of applying the Howard-Farmer reducer in stages removes fog or veiling without detracting from the pluckiness of the image, as the employment of the mixed reducer is very apt to do.

Masking and Binding.

The paper mask is an abomination. Unless specially dried before binding up in the slide, it carries a lot of moisture, and is partly responsible for the dewing of slides when in the lantern. I mask my slides photographically, and thus ensure not only economy in time, but also an increased life for the slide.

The diagram to be copied is trimmed up square, and the copying-board on which it is supported during exposure is covered with the best black velvet. For the purpose of fixing the drawing to the board I at first used home-made drawing-pins (needle-points soldered into brass plates). These "pins" were made with large square heads painted dead black. They were fixed in the board so as to just cover and secure the four corners of the diagram. This procedure, of course, gave a masking of this shape:—

Lately I have adopted a far simpler plan of affixing the diagram to the copying-board—a plan which gives truly rectangular masking. Two thin slips of wood of the same

length as the board, and about 2 in. wide (I utilise that most invaluable commodity to the amateur craftsman, Venetian-blind slats) are bevelled off sharply along one edge. The slips are then covered both sides with black velvet, using Higgins' vegetable glue as adhesive. If the diagram is placed in position on the board and the covered laths be pressed on the board so that their bevelled edges slightly overlap the right and left-hand

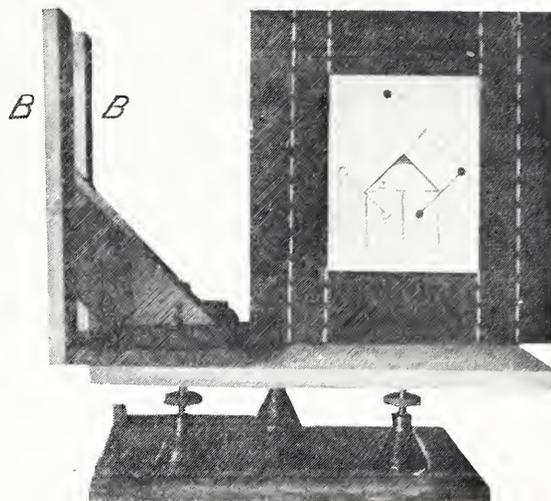

Fig. 1.

edges of the diagram, they will adhere to the board and firmly support the diagram, in virtue of the interlocking of the piles of the opposed velvet surfaces. Fig. 1 represents the copying-board with a diagram fixed thereto as described; the dotted lines touched into the print indicating the positions of the photographically invisible supporting laths.* Fig. 2 represents the arrangement of the board when copying from books. The method of supporting the book by the adjustable brackets B B is, I think, clearly enough indicated. The dotted lines again

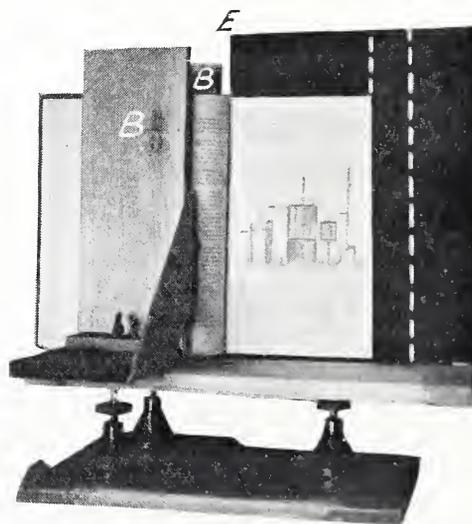

Fig. 2

show the position of the lath which is keeping the page taut and flat against the surface of the board. The hinder edge E of the board is bevelled off, so as to fit snugly into the angle that a reflexed book presents. By this device a perfectly flat page is expeditiously secured, and this without any detriment to the book. Unfortunately, there is no avoiding the ordinary paper masking in the case of copying diagrams which only form portions of a book page.

The conventional gummed binding-strip is a deeper abyss of abomination still than the paper mask. It is of little avail to dry your slide and its mask if the finishing touch on the

* The copying board as described is supplied to order by Messrs. Butcher and Curnow, Blackheath.

confection is the clotting it round with a substance of so hygroscopic a nature as gum. The adhesive tape sold for surgical purposes is a very efficient binder, but it is rather coarse and unsightly. The same objection of unsightliness and lack of finish unfortunately applies to the method of fixing the cover-glass by an edging of "Cementium" or Stickphast cement. There would seem to be a good opening here for the trade to supply an easily applied dry adhesive binding.†

In the method of lantern-slide making just described, both lantern plate and paper mask have been dispensed with; a future article which I hope to communicate shortly will describe how the mediacy of the camera itself may be eliminated in the preparation of full-scale positives direct from the print.

DOUGLAS CARNEGIE.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

TWENTY-FOURTH ANNUAL MEETING—AT CANTERBURY.

THE Canterbury meeting of the Photographic Convention opened on Monday last under pleasant weather conditions, which, unfortunately, were not maintained on the following day, and at the time of writing it is difficult to summon up enough confidence, even in the vagaries of the English climate, to convince one that uninterrupted opportunities for photography are to be the privilege of conventioners during the remainder of the week. And that is to be the more regretted inasmuch as the practical side of photography figures more largely each year at meetings of the Convention. It would seem that the unpropitious weather of the past few weeks has had a discouraging effect upon those who usually make the Convention the occasion of a week's holiday, for the numbers which turned up at Canterbury on Monday were noticeably smaller than in previous years, a fact which is perhaps in some degree attributable also to the geographical position of this year's venue. However, under the inspiring presidency of Mr. Snowden Ward, the early part of the week's programme passed off with much success. Monday was devoted to visiting the many architectural and historical features of Canterbury. The evening took the form this year of a re-union, at which the presidential address was delivered, after which the annual general meeting of the Convention was held, this plan having the advantage that all the business part of the week's programme was disposed of at the start. Among those who assembled at St. George's Hall on Monday were:—Sir Cecil

Hertslet (Retiring President), Mr. and Mrs. Snowden Ward, Mr. and Mrs. E. J. Humphery, Mr. and Mrs. F. A. Bridge, Mr. and Mrs. A. W. Atkinson, Mr. and Mrs. T. K. Grant, Mr. and Mrs. S. G. Kimber, Mr. and Mrs. Walter Potter, Mr. and Mrs. Ward Thompson, Mr. and Mrs. J. B. B. Wellington, Miss Rosalind Goodey, Messrs. J. H. Baldock, R. R. Beard, G. Bingley, C. H. Bothamley, George E. Brown, F. B. Catley, E. F. Crouch, W. E. Dunmore, S. H. Fry, A. W. Green, F. W. Hindley, W. S. Hobson, C. Phipps Lucas, Thomas Manly, Sydney A. Pitcher, P. R. Salmon, T. A. Scotton, W. H. Smith, A. J. Snow, F. C. Starnes, T. B. Tompkins, Courteney Wells, Charles Winter.

At the opening of the proceedings, with Sir Cecil Hertslet, retiring President, in the chair, the Mayor of Canterbury, Mr. F. Bennett-Goldney, addressed a speech of welcome to the Convention, in which he referred to the useful part played by photography in making known such places of interest as Canterbury to those who might be led to visit them. He added that, as representing the citizens of Canterbury, it was a gratification to learn that on the first occasion on which the Convention had selected its own place of meeting it should have chosen the city of Canterbury.

Sir Cecil Hertslet, in then withdrawing from the presidential chair, conferred the badge of office upon Mr. Snowden Ward, who then delivered his presidential address. Votes of thanks to the Mayor and to others who had taken part concluded this part of the proceedings.

THE PRESIDENT'S ADDRESS.

(The following was the address given by the President of the Convention, Mr. H. Snowden Ward, F.R.P.S.)

My first words must be thanks, sincere and heartfelt, for the great honour you have done, and the great gratification you have given, to Mrs. Ward and myself. To some people, even in the photographic world, the presidency of The Photographic Convention of the United Kingdom may mean little: to us, and to all who really know the Convention and its members, the position means very, very much. The honour that one receives amongst one's own people is the great and the real and the appreciated honour, and we have learned to know the Conventioners so well that they all seem to be very specially and intimately our own folk.

With the honour came opportunity, with the opportunity a great responsibility, of addressing you, and through you the great world of photography which you represent. And with a full sense of that responsibility, the subject chosen has been Photography and Art.

To the old trite question,

"Is Photography Art?"

one must answer unhesitatingly, No! Photography is no more art than is painting, sculpture, the writing of verse, or that combining of noises into tunes which is often called music. In asking "Is photography art?" we begin with a question wrongly stated. I prefer to re-state it—"Can photography be used as

a means of artistic expression?" and to this the answer is unhesitatingly "Yes!" The man who hath real music in his soul is an artist, whether his means of expression be brush and paint, stone and chisel, or sun and sensitive salts; and I regard this as a fact to be stated rather than a subject to be argued about. Its demonstration to the world lies with those photographers who have pictorial aims. To-night let us consider briefly what those aims are, what are the means toward their attainment, and lastly—or perhaps firstly in this utilitarian age—"Is picture-making worth while?"

Many definitions of art have been given. For our present purpose let us hypothecate that art consists of

Seeing, Recording, and Suggesting.

All photographers are recorders. When they see, and suggest in any high, broad, noble sense, they are artists. The record, even the perfect record, is not necessarily artistic. Some of the earliest draughtsmen, working on lines which still appeal to the child, devoted themselves to portraiture. They showed the human head in profile, but realising that the normal face had two eyes, placed both of them, and a full front mouth, in the side of the head toward the spectator. Then realising that a full face without a nose looked odd, they drew a line between the eyes and mouth; and sometimes they inserted an ear

MEMBERS OF THE TWENTY-FOURTH ANNUAL PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

HELD AT CANTERBURY, JULY 5 TO 10, 1909.

LIBRARY.

but not always. In some ways this kind of portraiture is a better record than the more normal form; for both the profile and the full face are interesting; yet it has been abandoned by general consent.

Another phase in the presentment of the human form was reached by certain Egyptian artists, who displayed the head in profile, the body and arms full front, the legs and feet in profile, walking the same way as the head. Another step in artistic evolution is represented by those Japanese works in which the head and body are shown as actually seen, but drawn as if they were flat, without any attempt at relief or roundness, without any real suggestion that the nose on a full face is nearer to the spectator than is the ear. We progress by stages to methods which suggest roundness, relief light-and-shade, and space between the sitter and his surroundings. This means a considerable advance towards art, but it is art of a mechanical, conventional class; and this is the highest that has been attained by most photographers.

The Beginning of Real Art.

is reached when one begins to see, and to record so that others can see, something beyond the mere physical facts, some hints of the inner, mental, or spiritual quality. At this stage we begin to realise that the subject is merely a means to an end, and that what we call a beautiful baby is no more pictorial than a wrecked old man. A picture does not mean a beautiful thing photographed, but a thing beautifully photographed. And pictorial ability depends upon insight, natural or cultivated, rather than upon technical ability. It depends upon the power to see beyond the obvious; upon the God-like power of sympathy which is not pity, but is understanding. Art sees beauty in the noble head of a fine old man who has done and triumphed greatly, or of a gentle lady who has suffered and been strong; but a greater art is that which sees the marks of struggle and of high aspiration in the degraded face of the man or the woman who has failed in life's fight.

Let us turn for a moment to the study of nature and of man's work as apart from man himself. Let us consider some of the differences between

A Picture and the "Usual Thing."

Photography, generally, is in the stage of the Japanese artist, who considers only the flat shapes of things. It depicts in landscape a certain amount of light and shade, but no roundness, and it ignores all effort at decorative placing and at beautiful or natural relations of its masses of light and dark. Beyond this point photographers are moving slowly. Many have already gone far beyond it. Let us take a concrete instance: the beautiful Bell Harry tower of the cathedral that stands near us. We know how it is ordinarily photographed. The picture postcards show it. We may see it bare and bald, rising above, but dwarfed by the lower buildings and the trees, often rising into a blank sky, sometimes almost lost in untrue printed-in clouds. And this sort of thing satisfied photographers for many years, while artists, who were not satisfied, blamed photography instead of blaming the men who misused our beautiful process.

When one realises that the tower has attributes of height, majesty, grace, and delicacy, one attempts to show these by selecting position, lighting, and treatment. To emphasise the tower and to subdue all competing detail becomes the object. The Prior's Green makes a good view-point: with the Dark Entry giving a rich gloomy base, from which the light, graceful tower appears to spring. When the subject is photographed in the ordinary way, whatever care we may give to exposure, development and printing, the result is untrue; even though many people may admire it and few may detect the untruth. The beauty of the Bell Harry tower in sunshine is when it shows white and filmy and lace-like against a deep blue sky of distinctly darker tone. In the print the tower is a light grey, against a sky of lighter grey

or white. It is not difficult to record the subject in its true values; the colour-sensitive plate and light-filter enable us to do that: but the study of nature that makes us realise the necessity for doing it is the artist's part.

If portraits may be treated to show character, landscapes may be made to typify peace, sunshine, prosperity, grandeur, or havoc; and architecture to show the ideas of worship and sublimity that inspired the cathedral builders, or the heroism and defiance of fate that are part of the very fabric of our historic castles. The maker of local views goes to Harlech Castle and gives us a print in which every stone is distinct, and the towers and bastions are smoothly lit and gently rounded. It can be properly described by the feeble adjective, "pretty," and it pleases the ordinary buyer of local views. But speak of Harlech Castle to the imaginative Welshman, who knows something of its long sieges, its stern defiance of the foe, its endurance of hardship and its times of triumph. Mention it to the man who knows that "Men of Harlech" was written during one siege, and set to the stirring, defiant strains of a tune composed during another siege by men who were in the front of the fighting; and while the thought of the great march quickens his every pulse, the vision of Harlech Castle called up in his mind is very different from that of the "local view" man. [I will show it to you, as imagined and recorded by Mr. George Davison.]

These thoughts raise the consideration of

The Equipment of the Picture-maker.

He should not only know something of history and of music, but also even of the history of music. In fact, he should know everything, and enjoy everything great and beautiful and noble—yea, he should even know the depths of sorrow and of disaster. A wide culture is demanded. No knowledge is useless. Every form of art, literature, poetry, music, history, architecture, anatomy, religion, politics, even engineering and manufacture, may be studied with advantage. But first and last and best and greatest of all is the reverent study of nature and of man. The question

Is Picture-making Worth While?

or should we not be content with excellent record work? is answered in the last few words. If it is worth while to associate with the best people, the best thoughts and the best aspirations of the world, then it is worth while to study and interpret, to see and to suggest, not merely to record in a mechanical way.

Photography may be a matter of teaching: art is a matter of education, which I prefer to call e-ducation, to remind us of the real meaning of the word. The drawing out, the cultivation, the unfolding of the best that is within a man is the making of an artist, and as he gives of his best to others he grows and gains for himself.

The Position of Photography amongst the Arts.

is destined to be a most important one, and it can never be too strongly impressed upon outsiders that what have been spoken of as the limitations of photography are really only the limitations of photographers. We have hardly begun to exploit the possibilities of our great versatile process. Even so, we have some achievements to our credit, and while there are many things in which we must long be content to learn from the great masters in other modes of expression, there are a few points in which I claim that the best photographers stand ahead of the popular successful painters of the day. In painted portraits that secure the highest prices and the chief places in exhibitions, one sees certain weaknesses that would be condemned if found in the work of the photographer, and I venture to claim, quite seriously, that to-day some leading portraitists might learn good lessons in (a) the placing of the figure within the canvas; (b) the proportion of the figure to its surroundings; and (c) the tone-harmonies of figure and surroundings, from the leading photographers. In these directions, at

least, our exhibitions of paintings show mastery quite inferior to that of Annan, Crooke, Hollyer, Furley Lewis, Hoppé, and several other British workers—not to mention many in other countries.

The Photographic Art Critic

demands a few words, and I hope for your pardon if, in talking of him I am talking "shop." He is badly needed in photography; and he needs to be more confident as well as more competent. His function is to interpret, to encourage. If he has to check the evil, it is only that the good may grow. He need not be an executant, and in my opinion he *ought not* to be an exhibitor or competitor, for he needs breadth of view and catholicity in the extreme, and it seems to me that the successful executant needs specialisation, which must give him bias in favour of the field of his own study. He needs insight, sympathy, and sterling honesty. Above all, he must be a seer. He should have facility of expression, for a single apt phrase may work an artistic revolution, as did the coining of the term "bald-headed landscape" to scarify the blank-sky abortions that too long satisfied the unseeing landscape worker.

Ultimately, the critic of photography will rank with the critics in other fields of artistic endeavour, and will use the same standards. He will compare the work before him with the best of which the process is capable, and will condemn what falls short. At present, however, he is beset by certain difficulties that are not fully realised by those who criticise the critic adversely. If he is not to quench the smoking flax of aspiration, he must judge leniently, and compare individual works with the achievement of to-day, rather than with the ultimate possibilities. And, while individuality and originality of thought are so rare amongst photographers, he must praise these qualities beyond their real worth, must exaggerate their value to encourage their growth. Thus he praises as exhibition prints many things which he could not recommend anyone to hang as home decoration or as "pictures to live with."

THE ANNUAL GENERAL MEETING.

The chief business of the meeting was the selection of the place of meeting for 1910. It was announced that the Council, as the result of several discussions of the question, had named Scarborough as a suitable meeting place for next year, and had added Nottingham as an alternative. Some short discussion on the merits of these two meeting places ensued, but, as pointed out by Mr. Godfrey Bingley, Scarborough provided very excellent facilities for a series of varied excursions, both to coast scenery, such as Whitby and Robin Hood's Bay, and to inland and architectural centres in Yorkshire. In the case of Nottingham it was further pointed out by Mr. W. E. Dunmore that most of the places which could be visited from that centre had already figured in the programmes of the Convention on the two occasions that it had held its meetings at Derby. An amendment that Nottingham should be the place of meeting was lost, and the original proposition that the 1910 meeting should be held at Scarborough was carried *nem. con.* Further

THE TRADE EXHIBITS.

Several of the leading houses in the photographic trade are represented at this year's Convention. The Platinotype Co. make their accustomed most effective exhibit of the results produced by this most beautiful of processes in the ordinary and "Japine" varieties. The photographs exhibited are of all descriptions of subjects, both portraiture and landscape, and the mounting and framing showed the great variety of ways in which the platinum print lends itself to effective presentation. More than this, the Company had prepared a little surprise. In outward appearance the frames, which hung upon a background of cloth, presented no unusual feature, but the mounting

He places more value upon an original effort that may be faulty in many particulars, than upon commonplace, tame work that is free from faults.

Of Photo-Pictorial Politics

a few words must be said, though to touch them at all is to invite misunderstanding and opposition. The one thing needful, as it seems to me, is the broadest possible catholicity, and the breaking down of all artificial barriers. The aim of an exhibition's management should be to obtain a strong, broad-minded board of judges, and to obtain entries representing every school and phase of pictorial effort. The aim of the exhibitors should be to support every exhibition that is on honest, catholic lines, regardless of whether any other exhibitor or school or society does or does not give it support. I know that great success has been achieved, and notable work done for photographic art on other lines, but the conviction remains that the broadest possible freedom must be the ultimate aim, that the best presentment of photography can only be gained by the selection of work from the whole field. We shall never place ourselves truly before the artistic world until faction is obliterated, and until exhibitions realise that they cannot afford to omit a work good enough for their selection committee merely because it may happen to be shown at another place at the same time.

In conclusion, may I repeat what I have often said to other meetings? I believe that there are in this room half a dozen people who have not yet taken up pictorial work, but who, if they would give as much time to it in the next five years as many a man gives to golf and many a woman to needlework, might take a position in pictorial photography higher than that of anyone save six or eight leaders in the present day. This I do believe most sincerely. And I believe photography to have such enormous possibilities in the pictorial direction as even painters and sculptors may envy. May it be part of the lot of many here to help in the realisation of these possibilities.

brief business included the re-election of the auditors, Messrs. C. L. Burdick and Alexander Corbett, and the election of a new member of council to fill the vacancy caused by the resignation of Mr. Bainbridge, who is succeeded by Mr. F. B. Catley, of Harrogate.

On the proposition of Mr. Godfrey Bingley, seconded by Mr. J. H. Baldock, the thanks of the Convention were given to Sir Cecil Hertslet for the great services rendered by him on the occasion of the Brussels meeting. Sir Cecil Hertslet, in acknowledging the vote of thanks, expressed the pleasure it had been to him to have been of any service to his countrymen and countrywomen on the occasion of their visit to Belgium.

The only other vote of thanks which figured in Monday's programme was that to the Secretary, proposed by Mr. C. H. Bothamley, seconded by Mr. E. J. Humphery, and received with every acclamation.

and framing had been so arranged that each print was illuminated from the back as well as from the front, the prints, without any special treatment, being mounted by the edges in cut-out mounts, or simply placed against these latter and appropriate apertures being cut in the supporting wall on which the frames were hung. With the ordinary front illumination the result of this extra light behind the pictures imparted a certain added richness, the difference being quite perceptible on the light behind being switched on, whilst if the front light was cut off the prints appeared to excellent effect as transparencies. The ready way in which a small exhibition, or series of panels of

prints, is arranged in this way suggests that photographers might frequently make use of a similar device as a window display, which would attract a good deal of notice.

Messrs. Wellington and Ward showed a series of prints and enlargements on the many Wellington bromide, gaslight, and print-out papers, which, like every previous exhibit by the renowned Elstree firm, served to emphasise the high qualities of these standard products.

Messrs. John J. Griffin and Sons exhibited prints on bromide and self-toning papers of their manufacture, together with apparatus of which they make a specialty, such as automatic enlarging lanterns, etc. One novelty just appearing on the market and not previously exhibited is a developing tank for plates which possesses one or two advantageous features. The grooves of the tank are made of double width, so that the plates are readily inserted at either end, a transverse guide passing down between the two sides of the groove serving to keep the plates apart. This little device thus allows of the

more ready insertion of the plates in the dark. The tank is also made so that it can be hung on a tap and used as a washer for the plates, and it has the further good point of being provided with means for delivering the developer down the sides of the tank instead of centrally, thus leading to more uniform action upon the plates. The tank is just being issued by Messrs. Griffin at the price of 7s. 6d. in quarter-plate size.

The Lumière Co. exhibit a large collection of Autochromes, most of which are transparencies made in France and showing the marvellously beautiful results to be obtained on the Autochrome plates. The transparency and brilliance of a number of these pictures show the qualities which can be obtained when the manipulation is in the most skilled hands. In the rendering of some of the quieter tones of landscapes some of these Autochromes are among the finest examples of the process. There are also one or two more striking effects, particularly one of a portrait by lamplight.

PHOTOGRAPHIC METHODS FOR DECIPHERING FADED OR BURNT DOCUMENTS.

[Among those who have specialised in the use of photography in reproducing writings, etc., on documents which have faded in the course of time, or have been damaged by fire, Dr. R. A. Reiss, of Lausanne, has taken a prominent place, and some of the remarkable results obtained by him have been seen in recent exhibitions. A recent issue of the "Bulletin Belge" gives a résumé of his methods prepared from papers contributed by Dr. Reiss to recent congresses of "documentation photographique" held on the Continent.—Eds. "B.J."]

AMONG the many great services which photography now renders in modern life, its use for the reproduction, or, rather, the reconstitution, of documents has become indispensable. The characteristic sensitiveness of the photographic plate allows of impressions being recorded which are invisible to the eye, and as a result traces of writing left in a document which has faded in the natural way, or has been tampered with, may be brought to light again by suitable photographic methods. Suggestions have been made, and have been put into practice, to treat such documents by chemical means, as, for example, with solutions of gallic acid, sulphide of ammonia, etc. Although these methods may at times afford good results, they suffer from the obvious drawback of injuring the original document, and in every case there is no necessity to make use of them in preference to a photographic process. The latter is sufficient to give the most conclusive results even without any chemical treatment of the document. Further than this, photography provides the only means of reconstituting written documents which have suffered damage by fire, a branch of work which is of great importance, particularly in criminal investigation. It may, therefore, be of service if a brief account of the most suitable photographic methods, many of which have been worked out by myself, should be given. We will deal both with the recovery of faded writing and of that in which a document has been more or less carbonised by fire.

Take first the case in which inscriptions have been removed by mechanical or chemical means, or have disappeared in a natural way as a result of storage in a damp atmosphere, etc. In either case the method is the same, but it may perhaps simplify the description to refer only to those of the first order.

Chemical Methods of Tempering with Documents.

When removing writing from a written document other means are employed than that of mechanical erosion. Among the chemical methods which are practised are such agents as oxalic and hydrochloric acids, applied by means of a brush, and subsequently removed with water applied in the same manner. A finely powdered mixture of sulphur and ammonium carbonate wrapped in a small muslin bag is also employed, the writing

to be removed being rubbed with it. Another reagent is chloride of tin applied with a brush, and solutions of sodium hypochlorite and of chlorine water are also used.

Copying Faded Inscriptions.

By the employment of these chemical means it is not difficult to remove every apparent sign of inscription, but in the majority of cases there results at the same time a change in the colour of the paper in the parts treated. The same thing happens in almost every case where writing has disappeared by natural process of time aided by keeping in improper conditions. This change of colour is frequently very small and imperceptible to the eye, but in the majority of cases it can be brought to light by the photographic plate. For example, the portions which have been treated, or where the writing has disappeared, will have become yellowish and a negative made on an ordinary plate will show this portion as of lesser density than the rest. Conversely, paper which had in the first place a faint yellowish tint and had been treated with a bleaching liquid will reveal the fact by the removal of the colour, a change which is shown in the plate by the greater density of the treated portion. As will be supposed, these operations are not as easy in practice as they look in theory, and a good deal of patience and many attempts are necessary before conclusive results are reached. The following is the method of working:—The document to be examined is placed in a printing frame behind a plain piece of glass. It is exposed to as uniform and intense a light as possible, preferably direct sunlight or the light of an arc lamp. A series of exposures on ordinary plates and with different times of exposure will show the operator the nature of the treatment which the original has had, or of the vanished writing. As already said, the part of the negative in question will be lighter than the remainder if a solution has been used giving a yellowish tint to the paper, whilst on the other hand the density will be greater where a yellowish paper has been bleached. The amount of the contrast in such cases may be intensified by using a blue filter, preferably a glass cell containing a solution of copper sulphate to which ammonia is added, giving a clear blue solution.

The negatives obtained in this way are printed on paper giving plenty of contrast. A very suitable print is the "Carbon Velox," or the special Rembrandt papers made for getting strong prints from weak negatives. Some further methods of increasing the contrasts are given below.

The Use of Enlargements.

All these operations serve not only to show markings produced by a chemical treatment of the document, but they disclose writing which has been removed by an eraser or by the destructive action of time. If all trace has disappeared so far as the eye can see, it is more than probable that minute traces of black ink or of particles of yellowish oxide of iron or other colouring matter remain in the body of the paper, and their existence may be brought to light by taking steps to record such minute differences of tint. In many cases it is advisable to make use of enlargement upon a considerable scale in accordance with the following method:—The original is placed in a printing frame along with some finely printed matter by which an exact focus can be obtained. It is strongly lighted by sunlight or arc light, and enlarged direct in the camera up to at least two diameters: all the better if the degree of enlargement is four to five diameters. The blue filter already recommended is used, and a normal exposure given. The most suitable developer is one acting slowly, such as ferrous oxalate. A negative having been obtained showing traces of the writing, a print is taken on paper. Frequently at this stage the writing is very feebly reproduced, and special means require to be taken in order to obtain a sufficient exaggeration of the contrast. This may be done, as has already been said, to some extent by a suitable choice of printing paper. Another means is to print through a yellowish or green glass, a method which can be used with print-out papers and with those which are developed. In the case of the former, exposure is commenced without the coloured screen, and as soon as a sign is seen of the inscription, the remainder of the printing is done with the coloured filter.

Increase of Faint Contrasts by Repeated Reduction and Intensification.

Intensification with mercury, as also reduction, may be used to intensify the contrasts, but about the best plan is to combine the two operations. The negative having been thoroughly cleared of all trace of hypo by means of a weak (1 per cent.) solution of ammonium persulphate made slightly acid with sulphuric acid, it is again washed, and, after drying, treated with the bichloride bath. The bleached image is then darkened with an ordinary developer, and, by properly adjusting the degree of reduction and of after intensification, this method will considerably increase the contrast.

Greater Contrasts by Copying.

But the best means for securing an increased degree of contrast is to make a second negative *viâ* a positive transparency. This allows of the first negative being retained intact as made in the enlarging camera. A positive transparency is prepared by contact on an ordinary plate, the weak light of a match burnt about twenty inches from the printing frame is used for the exposure, and a strong developer well restrained with bromide employed to get a vigorous positive, which, if necessary, may be intensified with mercury and a developer, reduced, and again intensified, as directed above. This positive will show a much greater contrast than the negative from which it was made, especially if a slow plate and ferrous oxalate developer be used. A precisely similar procedure is employed for printing a second negative from it.

One last method, very difficult in manipulation, but capable of greatly enhancing the contrasts, is to make a series of negatives from the same original and, stripping the films from the glass supports, to lay them one on the other. This is by no means an easy business, but results which I have obtained

in this way have been most satisfactory. Still one further method should be mentioned—namely, the so-called chromolytic process of Burinsky, in which the work is done by the wet collodion method. The manipulation is long and complicated, and can only be recommended to those making a specialty of this class of work: used with skill, however, it gives very striking results.

Preparing Partly Burnt Documents for Photographing.

There are many occasions on which it is very important to decipher writing from printed documents which have been accidentally or intentionally destroyed by fire. Obviously, this can only be done if the carbonised document has not fallen into pieces. Frequently the text can be read, but the document cannot be preserved on account of its fragility. In treating such cases the following process is employed:—The burnt paper is laid on a sheet of glass and carefully unfolded. As most papers cockle up whilst burning, the task of evening them out is surrounded with the greatest difficulties, but these may to a large extent be overcome by spraying the burnt paper (by means of an atomiser) with a fixative such as is employed for fixing crayon or pastel drawings. The particular fixative which I use is that of Dr. Schoenfeld and Co., of Düsseldorf. After this treatment the paper is much less fragile, and may be spread out on the glass by the aid of a couple of small soft brushes. When this has been done, the glass plate bearing the paper is placed in a printing frame and finally gently but strongly pressed between two glass plates. It is then in a state for copying by direct sunlight or strong arc light. In the case of writing inks composed of iron it will be found that the writing can be seen as dark grey on the black ground of the carbonised paper. On then exposing an ordinary plate, slow and restrained development with ferrous oxalate will give a satisfactory result. In the case of printed originals, or documents made in Indian ink, the writing will be as black as the ground. In this case the plate and its treatment are selected as already described. In cases where the writing has been produced by aniline inks, or by vegetable solutions, it will be found that at this stage there is nothing visible to the eye, but an orthochromatic plate and a coloured screen will give a negative showing traces of the inscription, the contrast being worked up by the means already mentioned.

Paper bearing writing done with an iron ink presents no difficulties in photography when the paper has been entirely calcined, not merely carbonised; the writing appears brownish on a white ground. However, an original of this sort is so extremely fragile that the mechanical difficulties of obtaining a photograph are very great indeed.

Copying Burnt Pencil Notes.

In cases where it is desired to obtain copies of a burnt paper on which writing has been done in pencil the photographer's task is by no means easy. The following method communicated to the International Congress of Photography at Liège some years ago has given very good results, and by means of it a number of pencil notes made on paper which had been burnt were successfully deciphered. The original is laid on a horizontal copying board, or, if it has become crinkled, is pressed in a printing frame; in either case the surface is placed at an angle of about 60 to 65 deg. to the axis of the lens. The lighting is provided solely and only by an incandescent gas burner provided with a reflector. This burner is placed to the side of the original remote from the lens, so that the rays fall upon the surface at an angle of about 30 deg. A yellow-sensitive plate is used. The rays are reflected by the inscription, and the latter can sometimes be faintly seen on the focussing screen. In the negative the inscription is thus obtained in black on a more or less transparent ground. A very protracted exposure requires to be given.

DR. R. A. REISS.

THE BIRKHÄUSER APPARATUS FOR THE MEASUREMENT OF SHUTTER SPEEDS.

[Since, in the review of the Dresden Exhibition, we made brief mention of the apparatus exhibited by Dr. Rudolf Birkhäuser, of Berne, we have received from him a description and seen from the translation which follows, is a modification of the method in which a rotating body or point of light is photographed on the stationary plate. Dr. Birkhäuser dispenses with the use of a scale photograph along with the rotating object, and obtains results to a very considerable degree of accuracy in the shape of points or dots on the plate, the number of which, in conjunction with the setting and speed of the apparatus,

allow of the time of the shutter being calculated.—Eds. "B.J."]

METHODS for the measurement of shutter speeds are divisible into four groups:—(1) By means of the kymographon, (2) photographing a falling body, (3) photographing a pendulum, and (4) photographing a rotating point or object. The first method gives the most exact results, but, on account of the complex nature of the apparatus, is only suitable for use in a physical laboratory. Methods 2 and 3 are the most simple in principle, but have found no extended use, since the final result requires to be calculated from a number of involved data. The use of a body rotating as uniformly as possible in a circle has been most largely adopted in practice, since it is readily carried out. A luminous point moving in a circle at a known uniform speed is photographed by means of the shutter to be measured, and in the resulting negative the length of the arc serves as a ready means of measuring the time that the shutter was open. This system, however, is not suitable for all descriptions of shutters, and is particularly unsuitable for the focal-plane shutter. With these considerations in view, I have endeavoured to design an apparatus which is fitted to give the uniform movement of a point in a straight line, this apparatus to have as simple mechanism as possible, to be readily manipulated, and to give uniform results.

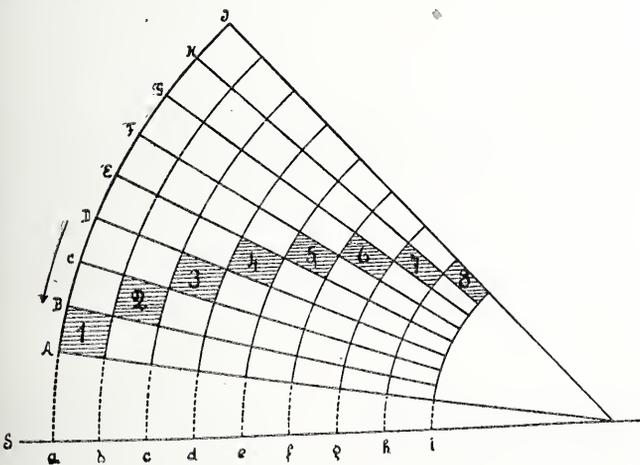

Fig. 1.

If a luminous point moves in a straight line at a uniform and known speed, it may be used as a test object for shutters of all kinds. If such a point is photographed during its motion, its image is a straight line, the length of which is a measurement of the time during which the shutter has remained open, the focal length of the lens and the distance of the latter from the object being known. In order to avoid unnecessary calculation, the point may be photographed along with a scale, but a still simpler method of arriving at the final result is to so arrange the straight line movement that the path of the point is broken up into a series of dots separated from one another by equal intervals of time. If such a system as this is photographed there is obtained on the plate a series of dots, each of which represents a certain unit of time. Taking as unit the time of 1-100th of a second, the exposure given by a shutter in the case of five dots recorded on a plate will be 5-100ths of 1-20th of a second. The apparatus now to be described is built on this plan, and thus supplies in a very simple way—simply the

counting of a series of dots—the means of determining the speed of shutters within a very considerable range. As shown in Fig. 1, the sector of a circle is divided by radii A to J into eight equal sectors. Concentric with the circumference of the circle are eight arcs of the circle a to i. If the circle is rotated at a uniform speed in the direction of the arrow, the radius A is the first to reach the line S, and the shaded area 1 passes S between a and b. As soon as 1 has disappeared the radius B arrives on the line S, and the area 2 passes between b and c, the process continuing in this way. As the divisions of the sector are equal, the same time is required by each in passing the line S—that is to say, each of the areas 1 to 8 require the same interval of time in passing the line S. Imagine now these areas 1 to 8 being cut out of a metal disc, and imagine also in place of the line S a narrow slit. If now these arrangements be placed in front of a light and put in rotation there will first be seen the area a to b, then b to c, and so on, each for the same period of time. If one second is required for all these sectors to pass by, the total distance a to i will be divided into

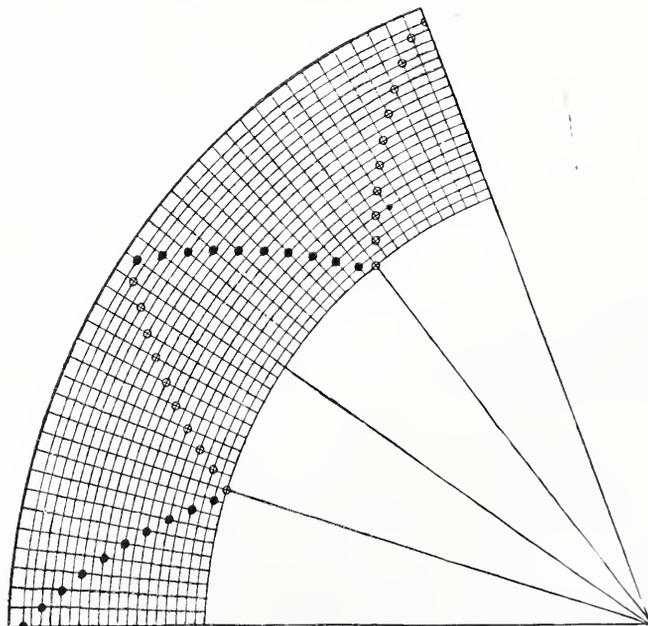

Fig. 2.

eight luminous impressions, each of which lasts $\frac{1}{8}$ of a second; in other words, each area of the series 1 to 8 represents the time of $\frac{1}{8}$ of a second.

It should here be mentioned that in practice a metallic sector of this kind is by no means an easy matter, and therefore the square apertures are replaced by circular holes of equal diameter. Since the separate sectors are only a small distance from each other, and since also the concentric circles take in only about 1-5th of the radius, it follows that the various apertures are necessarily very small, so that no error is involved in making them of circular instead of square aperture. In doing this the centre of each aperture is placed at the intersection of the radius and the arc of the concentric circle in question.

The division of the screen thus becomes that of Fig. 2. A circular surface is divided into 10 equal sectors (only 4 of which

are shown in the drawing), and these again subdivided, sector fashion, into 10 parts, so that the whole screen carries altogether 100 sector divisions of equal size. Starting from the circumference, there are 20 concentric circles placed at the same distance from each other. For the first sector (the lowest in the diagram, Fig. 2) the concentric circles 1, 3, 5, and 7, and the radii 1, 2, 3, 4, 5, etc., are chosen to form the centres of the circular apertures. We thus obtain in the first sector the 10 holes shown in black in Fig 2. In the next sector we take the concentric circles 20, 18, 16, 14, etc., in conjunc-

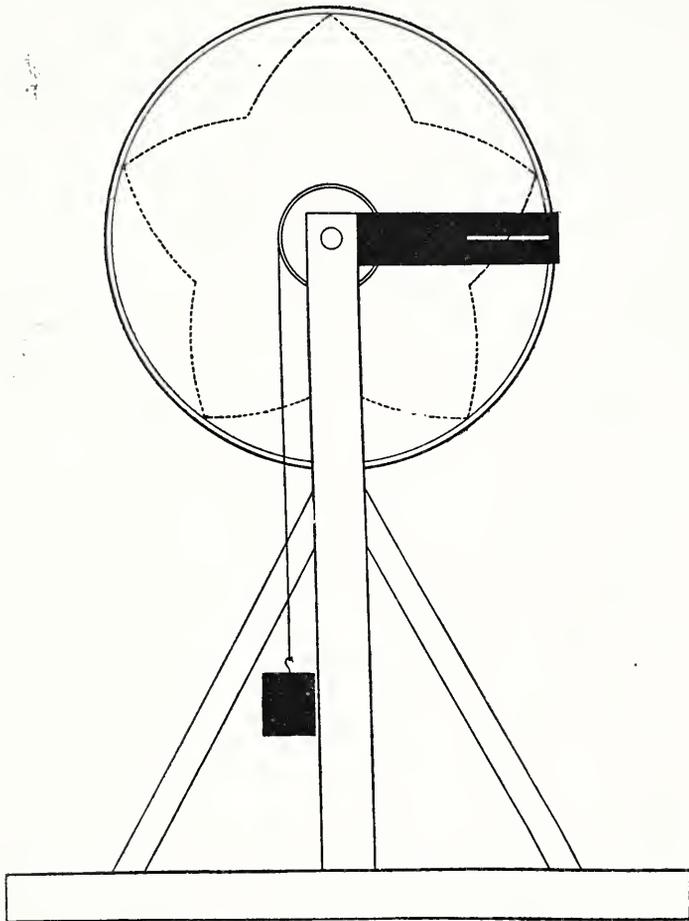

Fig. 3.

tion with the radii 11 to 20 to form the centres of the 10 apertures shown as white in Fig. 2. Sector 3 is constructed as sector 1, and sector 4 as sector 2, this alternation being repeated throughout the 10 sectors. If now this screen be rotated behind the narrow horizontal slit there first pass the holes of sector No. 1 in the order from left to right. The distance between each hole is a little less than the diameter of the hole. As soon as sector 2 arrives behind the slit its series of holes become visible through the slit from right to left, their images being formed on the photograph intermediate between those of sector No. 1. This arrangement makes it possible to employ as many as 20 holes for measurement, a point of considerable advantage. The process takes place in the way just described in the case of the other sectors.

The screen is perforated in this way, except that the 10 sectors are divided each into 25 sector portions, so that 25 holes come to each sector, or a total number for the whole screen of 250. That is to say, as many as 50 holes may be employed for measurement.

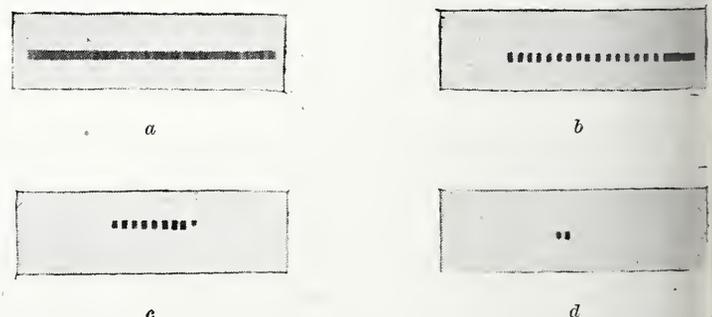

The screen is rotated uniformly in a simple manner. It is made about 43 cm. in diameter of stout metal, and mounted on a horizontal axis. To this a pulley with loose cord is firmly attached, and provided with a simple form of strong stop, so

that the disc can be held in any position. As motive power a weight is used, the cord by which it is suspended being wound on the journal of the disc. The weight being at its highest point is held by the stop, but when this latter is released, by pressure on a small lever, the cord unwinds from the axis, and the weight descends with increasing velocity. When the weight has almost reached the base of the apparatus, the string detaches itself from the axis, and the screen, which runs very lightly on its ball bearings, maintains for some seconds a perfectly uniform speed. The narrow horizontal slit is cut from a metal plate, and mounted as close as possible to the disc. On the other side of the disc from that on which the slit is placed a long mirror is mounted lengthwise on an axis, and the light from a clear sky thereby reflected through the holes of the disc, which, it will be understood, rotates between the mirror and the slit. Three different weights are used. The first gives to the disc at the moment that it detaches itself a speed of one revolution per second, the second one of two, and the third one of four revolutions per second. As the disc carries 250 holes, each hole thus represents the following spaces of time according to the speed of the disc:—

- 1-250th of a second at 1 revolution.
- 1-500th of a second at 2 revolutions.
- 1-1,000th of a second at 4 revolutions.

It will thus be seen that the smallest speed which can be measured with the apparatus as thus adjusted is 1-1,000th of a second, whilst the longest time is 1-5th of a second. If a still greater weight be employed, say one to give 8 revolutions per second, a speed as high as 1-2,000th of a second can be measured.

In making use of the method for measuring the speed of a shutter the apparatus is placed at a window or out of doors, and the mirror adjusted to reflect the maximum of light through the slit. For small speeds up to 1-100th of a second weight No. 1 is attached to the axis and wound up to the top position. A camera provided with the shutter to be tested is then brought as near as possible to the slit, which is focussed on the ground glass. The shutter having been set and a plate or film placed ready for exposure in the dark-slide, the weight is released and the disc set in rotation. As soon as the weight has descended on to the base of the apparatus the shutter is released, and on subsequent development the plate is seen to have been impressed by one or more dark dots corresponding to the holes in the disc. As already mentioned, each dot represents either 1-250th, 1-500th, or 1-1,000th of a second, according to the

- a. One revolution per second : 50 dots = $\frac{1}{10}$ sec., i.e., shutter speed $\frac{1}{10}$ second.
- b. One revolution per second : 24 dots = $\frac{1}{10}$ sec., i.e., shutter speed $\frac{1}{10}$ second.
- c. One revolution per second : 8 dots = $\frac{1}{10}$ sec., i.e., speed = say, $\frac{1}{20}$ second.
- d. Two revolutions per second : 2 dots = $\frac{1}{250}$ sec., i.e., shutter speed $\frac{1}{250}$ second.

Fig. 4.

speed of the disc. Examples of a number of records made in this way are shown in Fig. 4. The apparatus also serves for measuring the times of combustion of flashlight powders, which are fired behind the apparatus, the mirror being removed.

RUDOLF BIRKHAUSER, M.D.

THE USE OF A COPYING CAMERA IN LIBRARIES.

THERE is a short article in the current issue of "Photographische Mitteilungen" which emphasises a wish that has often been expressed by scholars and students who have occasion to make use of public libraries containing manuscripts and other documents. This is that in many cases time will not allow of an ancient parchment or other document being copied by hand or studied in the library, whereas if facilities were available for making photographic copies the labours of those engaged in research of this kind would be very greatly assisted. Our author, Herr Joseph Fassbinder, instances a case in which it was necessary for him to make copies of a large number of pages, for which purpose he provided himself with a

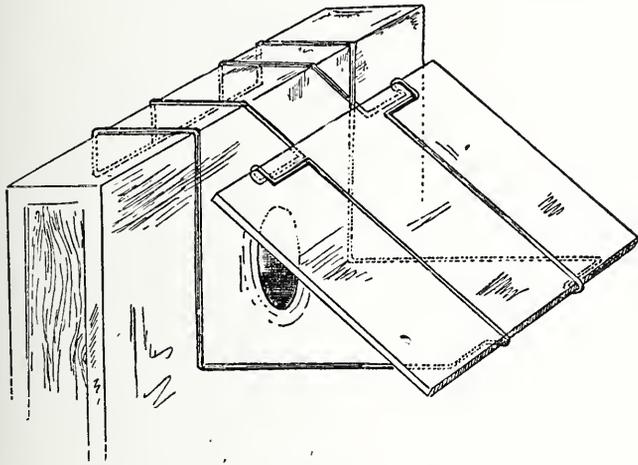

Fig. 1.

camera, to which had been fitted a reversing mirror by a simple attachment such as that shown in Fig. 1. This allows of the camera being placed on the edge of a table and the pages of the book to be copied laid on a shelf below it so that the photographic operations entailed no chance of damage to the document, whilst the pages could be more easily laid out flat and brought in position one after another for focussing. In undertaking work of this kind a changing bag is a necessity in places where no dark-room is at disposal close at hand. The exposures were made on a glossy bromide paper, each copy being thus obtained in white lines on a dark ground, a form of record which is even more suitable for the purpose of after study than that made in positive form by taking a negative and printing from it. If there is any difficulty in getting the printed page to lie flat a piece of plate-glass may be laid over it; but if this is not

necessary it is better to keep the page in position simply by means of short lengths of silk to each end of which is attached a weight, as shown in Fig. 2. With bromide paper of the rapidity obtainable commercially, exposures are possible of 20 to 30 seconds at an aperture of $f/18$, and the author states that with some practice he can make six separate exposures in ten minutes, including the reloading of his six dark slides. In doing a large number of pages from a single work it is naturally found most convenient to take first six right hand pages and then six left-hand, in order to avoid the trouble of re-focussing and re-adjustment on the ground glass. It was found that when reducing to about one-quarter the natural size the chief

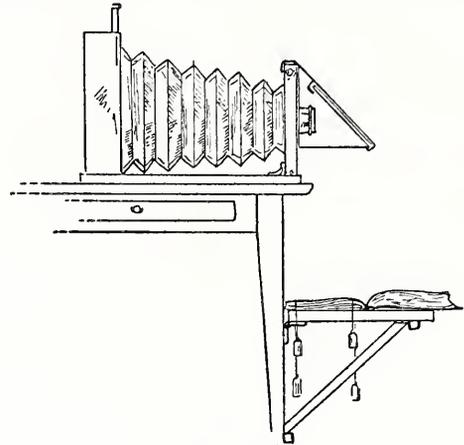

Fig. 2.

portions of the manuscript were decipherable with the naked eye, whilst some finer writing could be easily read by aid of a lens.

If it is wished, for purposes of reproduction, to obtain the copies in the positive form, the author transfers from the developer into a 3 per cent. solution of acetic acid, and after washing in running water dissolves away the silver image in copper-chloride solution. The bleached print is then given a short exposure to daylight, and placed back in the developer, a positive copy being then obtained in black lines on a white ground. After this the prints are washed and fixed in the ordinary way. It would seem that in many instances great use could be made of photography by many libraries if the very simple facilities which are necessary for work of this kind were provided and the opportunity given for students to make use of an apparatus kept at the library and placed at their disposal under any supervision which may be thought necessary.

"ENSYNA" AND "ENSYNIDS."

Of all that has been written with regard to "Ensyna" the greater portion has been with reference to its admirable qualities as a gas-light development paper, but it seems to have escaped notice that it can also be used for enlarging, and that if sufficient exposure is given first-class results may be obtained. When using daylight I have found that the exposure required for "Ensyna" is about as many minutes as one would give seconds to the average bromide paper. Development appears to take a little longer than usual, the chief difficulty being to prevent the paper becoming stained. If the dishes are clean these stains can always be traced to finger-marks. This difficulty, however, may be considerably lessened by adopting the following plan:—Instead of fastening the paper to the easel with pins fill a printing frame with a piece of white cardboard and focus on that, then remove the cardboard and replace with the paper, being careful to handle the latter as little as possible, then place the frame in the same position as when focussing and make the exposure.

"Ensyna" can also be used as a printing-out self-toning paper, and prints out in about the same time as ordinary P.O.P. With a thin negative the final result is rather flat, but a good strong negative gives a very satisfactory print, and from a negative inclined to print hard a better result may be obtained with this paper than with any other. Printing requires to be carried rather far, as there is a decided loss in the fixing bath. On being taken from the frame the print should be immediately plunged in the usual fixing bath, where

it at once assumes a decided good brown colour. After fixing and washing the tone of "Ensyna" prints may be altered to a considerable extent by placing them in an ordinary gold toning bath, where they take some time to tone and get, if anything, a little stronger in contrast. Although the fact that "Ensyna" paper can be used for printing-out is perhaps of no great advantage, still it is at times convenient to know that one has a paper at hand on which a good print may be obtained from a negative that by some mischance has been considerably over-developed.

"Ensyna" has been referred to as "a magic paper," but as no developer other than that supplied with the paper can be used in its manipulation it occurred to me that some of the "magic" might be in the developer. I therefore exposed a piece of Imperial glossy P.O.P. under a negative for about one-fourth of the time necessary to print fully, then placed it in water for a short time, and finally poured over it some very dilute "Ensynoids" developer. To my surprise I saw the print begin to develop and gain strength, just as if it had been a piece of "Ensyna" paper, and when finished it looked a good strong print, almost like a piece of toned P.O.P., but when placed in the hypo bath turned an odd greenish colour in no way suitable for a finished photograph. Several other pieces of P.O.P. were then printed to various depths, some being exposed for only one minute and showing a very faint image, both Imperial glossy and Ilford carbon-surface being used. All the prints developed up well without stain of any kind on the surface, though in some cases

odd dark markings were observed on the backs. After being developed, the prints were well washed and placed in a gold toning bath (Rae's "Okra" bath, which is rather energetic) for five minutes, washed, and fixed in hypo. When finished and dried the prints are of a brownish-grey tone, not unlike P.O.P. prints a little over-toned. The dilute developer used was: Water 1 oz., "Ensynoid" liquid developer 4 drops, or dissolve one A and one B "Ensynoid" tablet in 8 ozs. of water. A quarter of an ounce of this was taken and made up to one ounce with water. The final tone is not perhaps what every one would like, but I only give the results of my haphazard experiments and leave it to some one else better able to work out proper formulæ to give different and more agreeable tones. One thing at least is certain, that in "Ensynoids" we have a developer that will, without any additions except water, develop a piece of partly printed P.O.P. without stain. Some experiments with P.O.P. postcards showed that they were not so well suited for the purpose as paper, as a granular effect was produced on the surface, and a self-toning paper also tested did not develop up at all. J. PEAT MILLAR.

New Apparatus, &c.

The Watkins Daylight Time Tank. Made by the Watkins Meter Company, Hereford.

Several new and commendable features are embodied in this piece of apparatus. These apply quite as forcibly when the tank is employed for development by inspection of the negatives instead of when the instrument is used for the specific purpose for which it is made, namely, development by time only. In the first place, the rack, which holds a dozen plates, is made one with the cover of the tank, the racking being mounted in it so that the plates are held horizontally, not vertically, in the solution. The advantage of this arrangement is that when only one or two plates are to be developed they may be placed in the lower grooves, and thus a small quantity of developer only is needed; that is to say, while the full dozen of plates requires 18 ozs. of developer, two plates can be developed with 4 ozs., and further plates with an additional 3 ozs. for each two. The delivery piece of the tank which projects from one end serves, not only for admission and discharge of the developer,

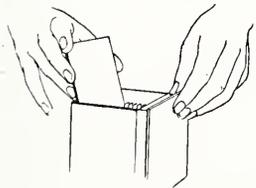

Fig. 1.

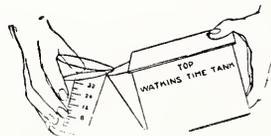

Fig. 2.

but also accommodates a thermometer, which serves to check the temperature of the solution. The tank is very substantially made, and, if care is taken to rinse it out and set it to drain after each time of use, will last for a long time, but it should not be forgotten that, like any other metal dish, if allowed to stand in a damp place, where any last traces of water will not dry up in it, its life will be considerably shortened. The arrangements of the rack make it very easy, we find, to load plates into it even in the dark, the edge of the empty rack, and afterwards the edge of each plate, serving as a guide for the insertion of the next. As we have said, this piece of apparatus is one of great usefulness in the dark-room as an economiser of time and space, and this, equally when working by time or by the method of inspection, which perhaps the more old-fashioned workers will still prefer to adopt. The price of the tank in the quarter-plate size is 5s.; it is also made in the half-plate size, holding 36 ozs. of developer.

The Watkins Time Thermometer. Sold by the Watkins Meter Company, Hereford.

Still another of the many pieces of equipment with which Mr. Watkins has provided the photographer is now introduced in the shape of this thermometer, which is unlike any instrument of the kind, inasmuch as the scales with which it is provided are not marked with temperatures but with times of development for certain developers and certain species of plate. Development being

more rapid the warmer the developer, it therefore follows that the scale is a descending one, and this fact should not be disregarded, otherwise a mistake may easily be made in reading the thermometer. For example, if the mercury stands half a division above 15, the reading is not 15½ but 14½. It will thus be understood that the thermometer represents a variation of the system of providing for differences in temperature in time development, the modified method being to develop for the time corresponding to a certain temperature and to make allowance for the differences among plates as regards speed of development by modifying the composition of the developer, that is, by using it at greater or less dilution. The thermometer itself contains a table giving the dilutions which must be taken for plates of the seven different classes and for four separate developers. These are the Watkins one-solution (time) developer, a pyro-soda and metol-hydroquinone developer (of which the formulæ are given), and, lastly, the one-solution commercial developer, such as Rodinol,

Azol, Certinal, and Victol. Also a separate scale on the thermometer gives the correct time for the various Kodak and Premo film tanks, with their appropriate Kodak tank powders. It will thus be seen that in this instrument the Watkins Meter Company have endeavoured to provide the amateur worker with a method of controlling his results, which involves nothing more than the reading of the simple leaflet of instructions, and relieves him of the necessity of keeping his dark-room or his developer at a normal temperature. At the same time it must not be overlooked that the times given on the thermometer and in the leaflet are for a certain degree of contrast, and workers who may wish to produce negatives which depart more or less from this standard must make one or two experiments for themselves in order to know what allowance must be made in reading the thermometer or in diluting the developer. While the modified system, therefore, is a distinct gain to the careful worker, it does not thereby prevent him from adjusting the conditions of his work in accordance with the type of negative which he wishes to produce. In all cases, too, an exposure which is practically correct must be assumed in using these methods, and on that account beginners who would make the most of the later forms of assistance which the Watkins Meter Company offer them must not neglect the use of an exposure meter nor the study of the Watkins Manual. The price of the thermometer in a wooden case is 2s. 6d.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications have been received for patents between June 21 and 26:—

CINEMATOGRAPHS.—No. 14,472. Improvements relating to cinematographic lantern accessories. John Weightman, 75, Warwick Street, Middlesbrough.

OPTICAL LANTERN.—No. 14,482. Improved optical lantern for projecting opaque objects. Frederick Charles Meyer and Herbert Dickinson, 112, Stamford Hill, London.

PHOTOGRAPHS.—No. 14,484. Improved surface for photographs. Alfred Herbert Pearce, 14, Baches Street, London.

PRINTS.—No. 14,502. Improved method of preparing photographic prints. Gustav Kogel, 18, Southampton Buildings, London.

SHUTTERS.—No. 14,509. Improvements in or relating to photographic shutters. Henry Frank Purser, 8, Quality Court, Chancery Lane London.
