Since then therapeutics and medicine had progressed, but essentially such works as those closely resembled the great treatises on therapeutics of the present day in the curious mixture of truth, error, and superstition which they contained. There were four outstanding authors, however, whose works dealt specially with matters of interest to pharmacists and who for long were held as authoritative among apothecaries. There were Mesne (died 1015), Nicolas of Salerno (twelfth century), Matthæus Platearius (twelfth century), and Myrepsus (thirteenth century). In the fifteenth and early sixteenth centuries a number of manuals were written specially for apothecaries by different authors, none of whom was of any great note. The first book of the kind to receive the impress of any authority beyond that carried by the author's name was the '*Antidotarium Florentinum*,' published in Florence in 1498, a collection of medical recipes sanctioned by the university or medical college of the city. But the first

pharmacopœia sanctioned by the civil authority, and enjoined to be used under penalties by dispensers and compounders of medicines, was that of the town of Nuremberg published in 1545, and compiled by Valerius Cordus from various sources, but chiefly founded on the practice of Galen. The style and methods of this book had been closely followed down to the present day, and in it were found much the same preparations as in the British Pharmacopœia of to-day and under the same names. As a fair example they might take the *Electuarium Commune*, which was directed to be made as follows:—*R Pulpæ cassiæ, pulpæ tamarindorum, senæ mundatæ, aa ʒii.; rhabarbaru, violarum, anisi, polypodii, aa ʒi.; sacchari albi, ʒii.; liquiritiæ, ʒii.; fritis conterendis et incisicis reliquis, admisceatur syrupus; polypodii, ʒiii.; sem. fœniculi, ʒvi., cum aquæ pluvie, quantitate sufficiente, et sacchari optimi, lb. ii., paratus.* This would make a very agreeable laxative, but it was difficult to understand the value therapeutically of the *species de Gemmis*, made up of pearls, coral, sapphire, granite, and other stones, with sugar, roses, borage, etc.; or the *pulvis contra casum*, consisting of crabs' eyes, mummy, dragon's blood, dried goat's blood, clay and rhubarb. But the whole book is a mixture of good and bad recipes, the former perhaps predominating. The '*Pharmacopœia Augustana*,' published in Augsburg in 1646, a copy of which he showed, was a handsome volume, and was, he said, in some ways one of the most interesting of its time, owing to the minute and paternal directions given to the apothecaries by the editor and by the Town Council, under whose authority it was published. This book contained many good recipes, by means of which an experienced and acute physician could treat well many conditions, but he would have to pick and choose carefully. The Pharmacopœia of Brussels, published in 1671, was another large and handsome volume.

Until 1617, apothecaries and grocers sold medicines, but in that year the former obtained a charter of their own and became a separate guild or corporation. In 1621 the College of Physicians published the first edition of the '*Pharmacopœia Londinensis*,' which was made authoritative in England and Berwick-on-Tweed by an order of the King in Council. For the next hundred years it did not differ much from the very worst Continental ones. In 1668 over 1200 simple medicines were enumerated, and these included the fat of man, lion, and vulture, hair, urine, blood, etc. In 1721 it was greatly simplified, and there was a steady improvement till the last edition was published in 1851. That was still in Latin, but contained only 273 separate drugs, apart from their preparations. Previous to the publication of a pharmacopœia some of the books he had mentioned earlier and Gerard's well-known herbal were in use in England by apothecaries. The first edition of the Dublin Pharmacopœia was published in 1807, the last in 1850. The first authoritative pharmacopœia in Scotland was published by the Royal College of Physicians of Edinburgh in 1699. The first edition, a book about the size of a pocket testament and looking insignificant beside the bulky Continental tomes, was, as he expressed it, a very humble production, badly printed and poorly got up, but dedicated to King William. It enumerated nearly 900 simples, these being the usual mixture of what were now considered to be efficacious or the reverse. The last edition of the Edinburgh Pharmacopœia appeared in English in 1841, and was also a modest volume. Since the first edition the number of efficacious drugs had been reduced from nearly nine hundred to a little over three hundred. This brought them down to the British Pharmacopœia, the first edition of which was published in 1864 by collating those of London, Edinburgh, and Dublin, and the whole history of which and its successors was accurately set forth in the preface to the present edition. Speaking, in conclusion, as to whether the earliest pharmacopœias of this country accurately reflected the state of therapeutics at the time of their publication—the seventeenth and eighteenth centuries—he said at that time the practice of medicine was in a very backward state, and medical teaching still more so. In the '*Arcana Fairfaxiana*,' a manuscript book of domestic medicine and undoubtedly used by members of the well-known Fairfax family in England, they found prescriptions of frogs, goats' dung, and many other disgusting things.

But a still more unpleasant picture of the medical practice of the time was furnished by the '*Pharmacopœia Bateana*,' a collection of the recipes of Dr. Bate, who was physician to two kings of England and the Protector. These were thought to be of such value that the volume was edited with notes by William Salmond, Professor of Physic, dedicated to King William III., and published in London in 1694. Here were

gravely prescribed and commented on such applications as a plaster for internal worms, a poultice of pigeons' dung for the plague, an amulet against the pestilence, alongside more sensible remedies. This was the work of a doctor of medicine, and was described as "exceeding in its benefit and usefulness to mankind all the dispensatories this day extant in what language soever." He was inclined to think, however, that the actual practice of medicine was not in such a backward state as these books would lead one to expect. No doubt such cures were used popularly just as some of them are to the present day, but he doubted if their use was very widespread or encouraged by the bulk of physicians. He had come to that opinion by the perusal of a price list of medicines published in Aberdeen in 1625, and which professed to contain all those in common use. It had a remarkable resemblance to price lists of the present day, though human fat was priced at 12 shillings, Scots, per ounce, mummia of Egypt at 2 shillings, Scots, per drachm, and powder of earthworms. These, however, almost exhausted the list of such substances. He was clearly of opinion that such a trade price list, compiled by a man for the use of his customers, and whose worldly prosperity depended on his supplying them to their satisfaction, more accurately represented the drugs in actual every-day use than any medical compilation made at an age when ancient authors were slavishly followed and tradition held all powerful sway.

Mr. FOSTER in proposing a vote of thanks to Professor Stockman for his most interesting lecture, said it would be impertinent for him to attempt to criticise the lecture, which was the result of deep research and intense enthusiasm and interest in the subject. He expressed the hope that they would soon have him lecturing to them again.—Mr. SUTHERLAND seconded, and the CHAIRMAN also expressed the pleasure he had experienced in listening to the lecture. In Professor Stockman, he said, they had a gentleman who would inculcate into the rising generation of medical men the true method of treating disease, who would teach them how to prescribe drugs, pure and simple, and who would not recognise in any way the medicaments and compounds at present thrust before them, and of which they knew little or nothing.—Professor STOCKMAN said it would ill become him if he did not do what he could to oblige pharmacists anywhere. For many years past he had received great kindnesses at their hands, and curators of their museums, librarians, and so on, had taken great trouble to get him reliable information.

LEEDS CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held on Wednesday, October 26, in the Committee room of the Leeds Institute, Mr. G. WARD, F.I.C., F.S.C. (Vice-President) in the chair.—Mr. W. D. POLLITT (Hon. Secretary) read the following report:—In presenting the thirtieth

Annual Report

the Council is able to state that the Society has maintained its numerical strength, whilst its usefulness as an educational aid for associates preparing for the Minor examination has not decreased. The Library possesses a good number of up-to-date books and has been regularly supplied with trade journals. At present the building is undergoing structural alterations, which it is hoped will make our room still more comfortable for our purpose. Under the auspices of the Society two social meetings of registered chemists were held during the past session, at which subjects of importance to the trade were discussed. There was a fair attendance, and a very friendly feeling existed, which it is to be hoped will result in creating more interest in our work. In response to the wishes of some of the speakers, an effort was made, in conjunction with the Leeds Technical School, to establish day classes for the study of Pharmaceutical chemistry, but only five students (four elementary and one advanced), indicated their willingness to attend, and therefore the classes were not formed. Perhaps another attempt may be more successful next year. The Council gave its support to the Pharmaceutical Society in the effort to get the Pharmacy Acts Amendment Bill passed, and records with pleasure that the members of Parliament for this city promised their assistance. It is satisfactory to know that the object has been achieved. The Council watched the progress of the Poisonous Substances Bill, and took steps to oppose that measure, which was eventually withdrawn. The Council is in sympathy with the objects of the Proprietary Articles Trade Association, and has signified its willingness to work in conjunction with that Association. The

receipts for the past year were £9 7s. 6d., and the expenditure £10 2s. 9d.—The report and financial statement were adopted on the motion of Mr. R. REYNOLDS, seconded by Mr. G. WARD.—On the motion of Mr. E. YEWDALE, seconded by Mr. WOLFOLK votes of thanks were accorded to the Pharmaceutical Society for the gift of the *Pharmaceutical Journal*, and to the Executive Committee of the British Pharmaceutical Conference for the gift of the 'Year-Book of Pharmacy.'—The officers of the Association were thanked for their services during the past year.—The following were unanimously elected officers and Council for the ensuing year:—President, Mr. E. Yewdall. Vice-President, Mr. G. W. WOLFOLK. Hon. Treasurer, Mr. J. J. ANNING. Hon. Secretary, Mr. W. D. POLLITT. Council, Messrs. J. H. BEACOCK, F. W. BRANSON, F.I.C., W. JOHNSON, R. REYNOLDS, F.I.C., S. TAYLOR, and G. WARD, F.I.C. Auditor, Mr. E. BROWN.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

The second meeting of this Association for the present winter session was held on October 25 at the Exchange Rooms, Birmingham.—Mr. J. SELBY, Vice-President, in the chair.—Mr. F. H. ALCOCK read a paper on

Bacteria,

which was illustrated in a most interesting way by lantern slides thrown upon the screen by Mr. J. DAVIS. Mr. Alcock dealt with his subject, wide though he admitted it to be, in a very exhaustive manner. He first classified the different bacteria, explained their functions as illustrated by the changes they set up in urine, milk, and saccharine fluids, and showed the part they played in putrefaction. He went on to deal with the formation of nitrites and nitrates in soil, showed the value of these in the economy of nature, spoke of the position of the bacteria in their relation to other plant life, and described their composition and mode of production. Mr. Alcock went on to explain at what temperature these lowly forms of plant life were favourably propagated, showed the temperature at which their power of reproduction was destroyed, and described the action which the atmosphere, currents of electricity, chemical agents, and other forces had upon them. The following types of the different classes were thrown upon the screen:—*Micrococci* (single variety); *Diplococci* (double variety); *Streptococci* (chain or rosary variety); *Micrococci tetragoni*, illustrating a group of Tetrads; *Sarcina lutea*, illustrative of the packet cocci. These were referred to as the chromogenic bacteria. Then followed the dumb-bell shaped cells of the *Bacterium termo*, illustrating the actively motile bacterium with flagella. The various stages of the bacterium which produces wool-sorters' disease, the *Bacillus tuberculosis*, associated with consumption, and the leprosy bacillus were all illustrated and ably described. Several specimens of the spiral variety were exhibited, including that associated with Asiatic cholera, commonly known as the "Comma Bacillus" on account of its microscopic appearance. Several specimens of the common marsh *Spirochaeta* were next thrown upon the screen and described, and the remarkable movements of the Monad with its short cylindrical cells and furnished with its flagellum, were followed with much interest. Vibrios were represented by *Vibrio rugula*, which is said to possess the power of causing fermentation of cellulose. An enormously magnified specimen of *Saccharomyces cerevisiae* was shown, and its life history described, together with the part it plays in the art of brewing. Pictures were also shown of the hyphomycetous fungi and the *Penicillium glaucum*, one of the commonest fungi, and well known to pharmacists as being concerned in the production of lactic acid from saccharine fluids. When Mr. Alcock's paper came to an end there was still a little time to elapse before it was necessary to break up, and the lantern exhibition was proceeded with, a series of views illustrating beautiful microscopic objects, taken from the three kingdoms of nature, being shown. There was the proboscis of the blow-fly, the tongue of the hive bee, the spiracles of the water beetle, the eyes of the ephemeron fly, specimens of the ant and of the male and female flea. Then followed a collection of shells, obtained by H.M.S. "Challenger," some at a depth of 3000 fathoms, a number of sea urchins, and specimens from the vegetable and mineral kingdoms. The animal kingdom, dealt with last, included scales of the gold fish, blood discs of man, the frog, and other animals, and a photograph of the lung of a frog after injection of the blood vessels, the operation showing in a remarkable manner the structure of the organ. After a short discussion Mr. Alcock and Mr. DAVIS were both heartily thanked.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The opening meeting of the twenty-first session was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Wednesday, October 26, at 9.15 p.m. Mr. G. H. C. ROWLAND, President, in the chair. There was a large attendance. The minutes of last meeting were read and approved. The SECRETARY read the report of the Prize Committee, from which it appeared that the McLaren prize for excellence in prescriptions, botany, chemistry, and materia medica had been gained by Mr. George Mack, 119, George Street. The prize, value £2 2s. may be invested in any course of instruction for the Minor examination approved of by the Committee. The Bowman botanical prize, value £1 1s., for best knowledge of the practical botany embraced in the excursions and summer meetings of the previous session, had been gained by Mr. J. G. Murdoch, 89, Gilmore Place.—Mr. DAVID McLAREN, the donor, then presented his prize to Mr. Mack in the form of a ticket admitting him to a course of instruction in the Royal Dispensary School of Pharmacy. In the unavoidable absence of Mr. John Bowman, Mr. McLaren also presented the Bowman prize—copies of Green's 'Botany' and Perkin and Kipping's 'Organic Chemistry'—to Mr. Murdoch. Mr. McLaren complimented both prizemen, and expressed a hope that they would be encouraged to apply themselves diligently and reach yet higher attainments.—The CHAIRMAN, in moving a vote of thanks to Mr. McLaren, which was cordially awarded, expressed the Association's deep sense of indebtedness to Messrs. Bowman and McLaren for their generous donations. Before proceeding to address them he mentioned that he had received apologies from Messrs. Bowman, Currie, Forret, Lunan, and Nesbit. He thanked them for the honour of his election. Memories of Flodden must have passed away when he—a foreigner from the southern kingdom—had been elected President of their Association in its twenty-first session. He then proceeded to give a *résumé* of

The Work and Workers of the Association

during the twenty years of its existence. He noted the fact that in 1853 a Pharmaceutical Improvement Association was founded in Edinburgh, and flourished for about eight years. In 1861 another abortive attempt was made to found an association. In 1862 an assistants' association was formed, called the Wilsonian Association, in honour of Professor George Wilson, who occupied the Chair of Chemistry in the Edinburgh University. This Association met weekly until 1871. In 1872 a Young Men's Chemists' and Druggists' Association was formed, but it had a very short existence. The present Association originated in a suggestion at an assistants' dinner in the Windsor Hotel in 1877. This was followed by a letter in the *Pharmaceutical Journal* in the same year, and at a meeting held in the Pharmaceutical Society's Rooms in George Street, early in 1878, the present Association was duly formed and office bearers elected.—Mr. ROWLAND then gave a very interesting account of the work of the Association during the successive years up to the present date. It was shown how great good had resulted from the Association's prize schemes, many of the winners having now attained to high distinction in medicine and in pharmacy. It was also shown that on questions such as the admission of women to the Pharmaceutical Society, a compulsory curriculum for pharmaceutical students, the metric system of weights and measures, the extension of the Preliminary examination, the Association had been not only abreast but often considerably in advance of the general body of pharmacists. It had also been distinguished by the fact that almost all the papers read to the Association had been contributed by members and had dealt largely with original and practical work relating to subjects of pharmaceutical interest. In conclusion he said:—Such is a brief and fragmentary history of the work of this Association. The position it has attained is an ample justification of the efforts made by its founders. I am told it has far exceeded their most sanguine expectations. I again remind you that this Association has now attained its majority and must resolutely address itself to the higher responsibilities belonging to this honourable position. The good work of the past furnishes a platform of advantage from which the work of the coming years ought to be carried on with greater energy and even more conspicuous success than has characterised the splendid record of the days that are

gone. I have been dealing in retrospect; it had been my intention also to say a word about the prospect. But the former has grown to such dimensions in my hands that I dare not presume to detain you any longer. I content myself with saying that the future is in your hands. I am neither a prophet nor the son of a prophet, but nevertheless I venture to anticipate that you will make the future worthy of yourselves and worthy of the heritage that has come down to you, and that the future history of the Association will be one of continued and increasing usefulness and prosperity.—Mr. J. D. SINCLAIR, Vice-President, moved a vote of thanks to the President for his most interesting address.—Mr. J. LAIDLAW EWING, in seconding the vote, heartily congratulated the Association on the successful attainment of its majority. Some of them on the previous evening had the pleasure of hearing a distinguished statesman discoursing on the value of such associations in bringing young men together and producing that sharpening of wit which always results from the contact of mind with mind. There was one point which he (Mr. Ewing) thought that distinguished statesman omitted. He referred to the value of an association like this for chastening self-conceit and engendering that modesty and mutual respect which was so becoming. He had gathered two things from the President's interesting address. One was that those who had filled offices in the Association now occupied high positions in the profession of pharmacy. The other was that during the entire period of their existence they had contributed to the Benevolent Fund of the Pharmaceutical Society. Many hard things were said of the Pharmaceutical Society, and also of the Boards of Examiners, with whose operations the Society was constantly identified. But, after all, he thought there were many good reasons why the Society should be regarded by them with gratitude and goodwill. For one thing they were indebted to the Pharmaceutical Society for a beautiful and comfortable hall in which to hold their meetings. They had also to remember that they were indebted to the Society for the help of the Society's Assistant-Secretary, who had always been distinguished for his sympathy with the hopes and aspirations of young men. He hoped they would have a very successful session, and it would always be a great pleasure to him to do anything in his power to forward the good work of the Association.—Mr. DAVID McLAREN, President of the Trade Association, and the first Vice-President and oldest surviving President of the Association, said he had listened with peculiar interest to the Chairman's description of the many incidents in the history of the Association of which he had a lively recollection. He joined the old Wilsonian Association in 1863, and from that time onwards he had borne a share and taken an interest in all the work among assistants till the present day. He trusted that in the future, as in the past, the Association would flourish and do good work.—The vote of thanks was put to the meeting by the Vice-President, and carried with acclamation, and the President returned thanks.—Mr. D. B. Kidd was elected Assistant-Secretary. The meeting then closed.

NEW REMEDIES.

TERPINOL IN BRONCHIAL DILATATION.—Rabow prescribes terpinol in pills or capsules thus: Terpinol, sodium benzoate, of each 1 gramme; sugar, *q.s.* Divide into 10 pills or capsules, and take one every hour or every second hour. Or, terpinol, 10 centigrammes; olive oil, 30 centigrammes, in a gelatin capsule, to be taken every two hours.—*Bull. Gen. de Therap.*, cxxxvi, after *Centralblatt für Therap.*

OXIDISED CHRYSAROBIN IN SKIN DISEASES.—Unna employs oxidised chrysarobin, obtained by the action of sodium peroxide on chrysarobin suspended in water, in eczema and other cases where the action of ordinary chrysarobin is too irritant. It is applied in the following ointment: oxidised chrysarobin, 2 to 5; vaseline and lanolin, of each 25.—*Bull. Gen. de Therap.*, cxxvi, July 8, 1898.

TRIBENZOYL-GALLIC ACID.—This is a new astringent obtained by shaking an alkaline solution of gallic acid with benzoyl chloride and purifying the resulting product by crystallisation, after boiling with water. The compound is odourless, tasteless, and colourless, it is not decomposed by substances with which it may come into contact in the mouth or stomach. An easy but complete separation of the gallic acid only takes place in the rectum, where all the specific properties of the astringent come effectively into play. The acid melts at 176° C.—*Zeit. d. allg. oest. Apoth. Ver.* li., 859.

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE PHARMACY ACTS.

PHARMACEUTICAL SOCIETY v. THOMAS HIBBERT.

At the Manchester County Court on Tuesday, November 1, before the Deputy Judge, Mr. W. Goldthorpe, the case of the Council of the Pharmaceutical Society against Thomas Hibbert, of 583, Ashton Old Road, Manchester, came on for hearing.

Mr. R. E. L. Vaughan Williams, instructed by Messrs. Flux, Thompson and Flux, appeared for the Society, and defendant appeared in person.

The proceedings were taken to recover two penalties of £5 each, the defendant having on July 8 sold or kept open shop for the retailing or dispensing of poisons and then sold paregoric, also for having on July 15 sold ammoniated mercury or white precipitate, contrary to the Pharmacy Acts.

At the request of His Honour Mr. Vaughan Williams handed up copies of the Acts, and explained that it was very important the public should be protected against the sale of poisons by unqualified persons. He stated that the defendant kept a shop, over which was the name "T. Hibbert, Herbalist," but that it was mainly devoted to the sale of newspapers. He called

Arthur Foulds, who stated that he resided in Manchester, and acting on instructions, he visited the shop of the defendant, over the door of which was the sign, "T. Hibbert, Bookseller and Stationer; Herbalist." This was on July 8, and he asked for some castor oil, and afterwards for sixpennyworth of paregoric. These substances were poured into bottles that he took, and he put on the usual labels for identification. The defendant's wife, who sold it to him, put on one of the bottles a label, on which was the word "paregoric." He handed the bottles over to Mr. Harry Moon. He called at the shop on July 15 and bought an ounce of glycerin, sixpennyworth of paregoric, and a pennyworth of white precipitate powder. He dealt with these as in the previous instance.

The defendant remarked that it was strange to him that his wife sold anything of the sort, because they had not got it in the shop to sell.

In reply to the defendant, witness said he purchased the articles at the shop, 583, Ashton Old Road, himself.

Mr. Harry Moon, clerk to the Registrar of the Pharmaceutical Society, deposed to receiving the various articles above-named and handing them to Mr. Eastes for analysis.

Mr. Ernest J. Eastes, F.I.C., who has had many years' experience as an analyst, deposed to receiving from the last witness the exhibits produced. One bottle contained an ounce and a quarter of fluid, which proved to be paregoric, and contained 2½ grains of opium, a dangerous poison. The white powder he found to be ammoniated mercury, commonly called white precipitate. It was a dangerous poison, and there was also a dangerous quantity, 95 grains.

In reply to the defendant, witness said there was nothing mixed with the paregoric, such as castor oil, glycerin, or anything of that description.

Defendant said he had not sold it, and his wife had not sold it. He had no white precipitate. He had been through his accounts for years and could find no record of it, and had not a bit in his place. He called his wife, who said she never sold the man (meaning Foulds) "a penn'orth of stuff in her life, only the *Evening News* and *Chronicle*. He's the biggest liar in England."

His Honour: Did you know him?

Witness: I know him by sight. He was never in the shop to purchase it.

His Honour recalled Foulds: Do you reside in this part?—No, your Honour, it is very rarely I go in that part.

She says she knows you by sight?—I have only been three times in my life—twice to make a purchase and once to have a look round the place.

Why did you go?—To look round.

At whose instigation did you go the first time?—The Pharmaceutical Society's.

Then you know her?—I know her perfectly well. There are two counters in the shop. The white precipitate she got from a brown bag on a shelf over the kitchen door.

Defendant's Wife: The little bit I had was for my own use.

His Honour: That finishes the case. The Pharmacy Act is one of the most excellent Acts ever passed, and what has been done in this case is necessary to be done. There is only one result; the Act must be enforced.—His Honour then gave judgment for the plaintiff Society for £10, with costs.

DISPENSING PROBLEMS AND NOTES.

EFFERVESCENCE WITH ALUM.

Sir,—I have had occasion to dispense the following prescription and the result was a violent effervescence:—

℞ Sodii Bicarb. ʒii.
Sodii Bibor.
Alum Sulph. aa ʒi.
Liq. Bismuthi ʒii.
Aq. ad ʒviii.
Ft. lotio. Sig.: "ʒss. ad Oi. Aquæ."

I found, after trying each of the ingredients separately with the sodii bicarb., that it was the alum which caused the effervescence. Is this due to free acid in the alum? The formula $Al_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$ or $Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$, as given by the B.P. for alum, is that of a neutral salt. I cannot see why neutral salts should give an acid reaction with vegetable colours, except that this property bears no definite relation to their constitution.

QUÆRO (18/6).

NOTE.—There is no need to assume the presence of free acid in the alum in order to explain the effervescence referred to. In this case it is due to the fact that aluminium being a weak base does not form stable salts with weak acids like carbonic acid. The alkali carbonates and bi-carbonates precipitate aluminium hydroxide from solution of alum because the aluminium carbonate which we might expect to obtain decomposes immediately into the oxide (which is precipitated in the form of hydroxide) and carbon dioxide. This is the cause of the effervescence observed. Taking the formula for aluminium sulphate in place of the formula for alum, in order to render the equation simpler, we may represent the equation thus:—

Aluminium bicarbonate is unknown; we get instead aluminium hydroxide and carbon dioxide—

The reaction with normal sodium carbonate is rather simpler to represent—

The aluminium oxide is not precipitated as such, since it immediately combines with water to form a hydroxide. [ED., P. J.]

A BISMUTH MIXTURE.

Sir,—Kindly say through your columns how the following prescription should be dispensed:—

℞ P. Bismuth. Subnit. ʒij.
P. Tragac. Co. ʒij.
Aq. Cinnamom. ad ʒvi.
M. Ft. mist. Sig.: ʒss. ter die.

I find that on standing a few hours the mixture becomes almost solid in the bottle and cannot be again shaken up into a presentable condition. Squire recommends that ʒiiss. of pulv. tragac. co. should be used for a six-ounce mixture, but I find even that is too much.

STUDENT (18/18).

NOTE.—The bismuth mixture described above is very commonly used, and the proclivities of bismuth salts to form hard deposits, difficult to diffuse by agitation, are well known. Authorities differ as to the relative merits of acacia and tragacanth for suspending the insoluble salt, and some prefer to use no gum at all. Even, however, in the latter case a hard deposit is sometimes formed, so that the difficulty cannot be referred entirely to the gum. A point which must not be overlooked is the slow decomposition which bismuth subnitrate undergoes in contact with water. This results in the formation of a more basic oxy-salt, with liberation of some nitric acid. If the mixture above, after standing some time, be filtered, the filtrate will be found distinctly acid. Our experience rather suggests that if a mixture like the above

be agitated at frequent intervals for some time after making (*i.e.*, until the formation of the more basic salt is nearly completed), the deposit which afterwards forms is not so prone to form a hard, indiffusible mass. In other words, the formation of the hard deposit may be due to the production of a compact mass of the more basic oxynitrate, if the oxynitrate be allowed to remain undisturbed at the bottom of the bottle while the decomposition proceeds. With regard to "Student's" query as to how the above mixture should be dispensed, the bismuth subnitrate and compound tragacanth powder should be well mixed in a mortar, and sufficient water added to form a thin paste. After trituration to a smooth product the paste is washed into the bottle. The quantity of compound tragacanth powder is larger than absolutely necessary—one drachm would be sufficient. [ED., P. J.]

COLORATION WITH TINCTURE OF SENEGA.

Sir,—If tinct. senegæ is treated with nitrous acid and then ammonia added a deep reddish-brown colour is produced. Is there any record of this reaction, and if so, what is the explanation? I first noticed it when dispensing a mixture containing sp. æth. nit., tinct. senegæ, and ammon. carb. If the two first are mixed together and then ammon. carb. added this colour reaction is produced, but if the sp. æth. nit. and ammon. carb. are first mixed and then tinct. senegæ added the colour does not develop. This led me to suppose that the colour was produced by the interaction of free nitrous acid, tinct. senegæ, and ammonia, which was verified by experimenting with the tincture of senega, sodium nitrite, acid. sulph., and ammonia. BARIUM (16/27).

NOTE.—The observations of "Barium" have been verified, but the cause of the coloration is not clear. A possible explanation is that the colour may be due to some reaction in which the methyl salicylate contained in senega is involved, and experiments are being conducted in the hope of elucidating the question. Meanwhile, some of our readers may be able to throw some light upon the subject. [ED., P. J.]

MERCURIC CHLORIDE IN A GARGLE.

Sir,—Would it be advisable to dispense the following prescription as written?—

R. Glycerini Hydrarg. Perchlorid	ʒi.
Glycerini Aluminis et Acid Tannici	ʒi.
Glycerin et Aq. Rosæ	ʒi.

M. Sig: The lotion for gargle; ʒi. to a breakfast-cup of water to be used as a gargle.

The preparation would contain about 13 grains of mercuric chloride in ʒi., and as formulæ for the two articles are in the 'Extra Pharmacopœia' I presumed the first was also meant to be compounded from the formula in the same book. E. G. H. (146/26).

NOTE.—The gargle dispensed according to the prescription from the unofficial formulæ mentioned would be unsafe for use unless unusual precautions were taken. The patient might easily swallow inadvertently a quantity of the gargle containing more than the maximum dose of mercuric chloride. In any case unless the mouth and throat were well rinsed with water immediately after using the gargle a sufficient quantity would be retained to have a very decided general physiological effect, in addition to the local action intended. Assuming the breakfast-cup to hold between 8 and 10 fluid ounces, the diluted gargle would contain somewhere about 1 in 300 of mercuric chloride. This is a much stronger solution than is usually employed as an antiseptic lotion. This case illustrates very clearly the necessity for the exercise of great care in dispensing unofficial formulæ. The prescriber ought in such cases to indicate in the prescription the exact nature of the preparation he desires by a reference to the book or formulary in which its formula is set forth. [ED. P. J.]

SALOL IN PLEURISY.—Jegorof finds that salol in doses of 12 to 42 Gm. is of great service in cases of pleurisy, increasing the diuresis and promoting the absorption of the effusion, without producing any of the ill effects previously observed from alkaline salicylates, such as digestive derangements, palpitation, and dyspnoea, which have been so generally followed in these cases as to lead many authorities to interdict the use of these salts.—*Nouv. Rem.*, xiv., 238, after *Vratch*.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

THE NEW TEXT-BOOK ON PRACTICAL PHARMACY.

Sir,—Lucas's 'Pharmacy' undoubtedly contains a good deal of useful information for students of pharmacy, but, as "Pharmacist" pointed out in last week's Journal, it needs carefully revising. In his table of solubilities the solubility of acidum boricum in water at 60° F. should read 30 instead of 25, that of apomorphinæ hydrochloridum as 50 instead of 70, that of atropinæ sulphas as 1 instead of 0.5, and that of codeinæ phosphas as 4 instead of 2. Atropinæ sulphas is soluble in 10 parts of 90 per cent. alcohol at 60° F., not 3 parts. The solubility data I give are, of course, those in the new Pharmacopœia which, I understand, we must accept as the standard work.

STUDENT (150/25).

NOTES ON ESSENTIAL OILS.

Sir,—I should be obliged if you would find space in your next issue for the following comments which I desire to add to your excellent notes on essential oils (see *ante*, pp. 458, 459) based upon the recently published 'Semi-Annual Report' of Messrs. Schimmel and Co:—

CITRONELLA OIL.—You state that "while adhering to the opinion that the relative value of citronella oil can be determined by acetylation, Messrs. Schimmel and Co. doubt whether 60 per cent. suggested by Umney as a minimum is not too low a standard for oil of good quality." You also state "that from the examination of several samples of Ceylon oil, Messrs. Schimmel conclude that there are two kinds differing in physical characters and in the percentage of geraniol." The method of determining the value of citronella oil by acetylation was suggested by me more than two years ago and the minimum of 60 per cent. given. Subsequently (see *P. J.*, August 14, 1897) in a paper by Swinton and myself the characters of two distinct classes of citronella oil were detailed, and the percentages of acetylisable bodies of the two classes stated to be as high as 90 to 92 per cent. in one case, and very much lower (only about 60 per cent.) in the other case. The oils of high acetylisable value were distilled by Fisher, of Singapore, and Winter, of Galle, Ceylon, the actual names being stated in our communication. The marks of seven out of nine of Schimmel's samples giving the high acetylisable value of 80.9 to 90.6 per cent., although not mentioned in the *Pharmaceutical Journal*, are mentioned in their report, and the marks J. F. and W. respectively appear to indicate that the oils were distilled by the two English firms whose products we examined. Pressure of work occasioned by the issue of the new British Pharmacopœia has prevented us from further work on the body of high boiling point which was separated from the oils having the low acety-

lisable percentage, which was described as a sesquiterpene, but which Messrs. Schimmel suggest may be methyl eugenol.

DILL OIL.—You state that Messrs. Schimmel give determinations to show that English oil has not always the high specific gravity required by the British Pharmacopœia (0.905 to 0.920). The only English sample (No. 10) however they quote has a specific gravity of 0.906. I stated in 1895 (see *P. J.* [3], xxv., 948 and 977) that German dill and caraway oils were frequently partially decarvolised. I adhere to that statement, which has been as true up to practically the present time as nearly three and a half years ago, as the following results of the examination during the last three months of German dill oils show:—

	Sp. gr. at 15° C.	Opt. rotation in a tube of 100 Mm.
1	0.8979	+51°.
2	0.8996	+45°.
3	0.8984	+46°.

Messrs. Schimmel add in their report that Mr. Umney says verbally (*sic*), "the oil distilled from the German fruits has practically the same characters as that distilled from the English fruits provided that no separation of carvol has taken place as in sample No. 3, a practice adopted to some extent on the Continent. We cannot but earnestly request Mr. Umney henceforth to omit such wanton insinuations alleged with a view to discrediting German competition evidently inconvenient to Mr. Umney." Messrs. Schimmel and Co.'s patriotism is praiseworthy, but they may not have as much knowledge of the German caraway and dill oils (other than their own) sent to this country as I have. I would remind Messrs. Schimmel also that in their 'Semi-Annual Report' of October, 1895, subsequent to my paper on the subject to which I have referred, they themselves referred (see page 9) to the decarvolisation of caraway oils, and stated that oils of caraway of lower specific gravity (*viz.*, than 0.908 to 0.910) were inferior because they have been deprived of a portion of the valuable carvol. My sole object in stating at Belfast that the characters of German and English dill fruits were the same was to make it clear that German oil could be employed. Up to the publication of the new British Pharmacopœia, or even till August, 1898, four-fifths of the oil used in this country was distilled from Indian fruits, which the characters of the new British Pharmacopœia excluded. The competition, or rather, I would say, the partial dependence on Germany for supplies is convenient rather than inconvenient, not only to me, but to the pharmacists of this country, as the quantity of dill hitherto cultivated in the British Isles has not been considerable, but I hope that by next season growers will have made us independent altogether of Continental supplies. In any case the trouble should be one of the past, as oil of dill (British Pharmacopœia, 1898) is well defined, and must of necessity be of good quality to comply with the characters and tests of the new work.

LEMON OIL.—You state that Messrs. Schimmel and Co. remark that the data on which Umney and Swinton infer the presence in lemon oil of a hitherto unobserved constituent are inconclusive (see *ante*, pp. 196-370). The extended results on page 370 (*P. J.*, October 1) were not published until Messrs. Schimmel and Co.'s Report doubtless was written, and contained practically all the additional proofs that they seek, both as to the source of geraniol and acetic acid, and fully meet their objections. It would, in my opinion, have been preferable if they had sought to disprove the results contained in our first paper by actual experiment rather than by a somewhat doubtful analogy.

Southwark, London, October 31, 1898.

JOHN C. UMNEY.

LOYALTY TO THE CRAFT.

Sir,—A very old member of the trade, and one whose experience of it cannot be much further prolonged, I would give my opinion of a letter signed by J. Rymer Young, which appears in the *Pharmaceutical Journal* of October 29. The tone adopted by him towards his despised brother is altogether harsh, cruel, and unjustified. What right has he to assume or suggest all those uncharities and probably falsities? What reason has he to doubt the statements of salaries and accommodations? Was there a greater demand on credulity in them than in the £200 which Mr. Rymer Young speaks of? For anything I can see on the surface "C. P." may be at least as worthy a citizen as Mr. Rymer Young, strange as that may sound. I am not in favour of company trading. If it can be met and vanquished in fair and honest open fight, good—go on and prosper. If only by taking away the subsistence of those who give service to it (company trading) I would

say the wish to do so is unblessed and even atrocious. To remove from the list of Members of the Society may be allowable; to delete from the Register of Chemists and Druggists or Pharmaceutical Chemists for such offence is a power our Legislature is not likely to give. I have always advised my sons, apprentices, and assistants to have nothing to do with company trading. That advisory treatment I would join in; the compulsory "per fas aut nefas," never.

Trurc, October 31, 1898.

SAMUEL FEAVER.

Sir,—In Mr. Young's reply to my letter he carefully avoids the point at issue, and as autobiography rather than argument seems to be his *forte*, I will give him a little more detail about myself. First, protesting against his accusation that I am stonethrowing from behind a wall, I have a fairly large acquaintance in the drug trade all over England, and I venture to suppose that my initials may disguise but do not hide my identity. Now, in answer to his three-quarters of a column of innuendo, let me tell him that I was seven and a half years in the historic house referred to (and my experience there is one of the happiest recollections of my life), so that presumably I was not an idle good-for-nothing, and while there successfully filled the offices of Secretary, Vice-President, and President of the C.A.A., so that presumably I was not an absolute fool. I passed my Minor at twenty-three, married at thirty-three. So I think his fancy portrait of me fails considerably. I now turn to the only statement of fact which Mr. Young's letter contains, *viz.*, that he knows several assistants in the neighbourhood of Warrington in the receipt of £200 per annum. If salaries of £200 are at all common, the drug trade is not in the "hopeless, helpless" condition it is the fashion to picture it, and these hysterical appeals for martyrs are only laughable.

November 1, 1898.

C. P. (150/41).

INCONSISTENT CHEMISTS AND DRUGGISTS.

Sir,—In various interviews with members of the craft I find considerable diversity of opinion respecting our Society. Some are merely faultfinders who can only complain of what has not been done rather than what has been effected, yet still hold aloof from joining the only legalised body that possesses any educational or social influence in the calling. Consequently their grumbling is merely a confession of weakness, and after forty years' wandering they are likely to die in the wilderness of oblivion. Whereas, if only from an instinct of self-preservation, to say nothing of loyalty as a united brotherhood, they would merge their differences they would acquire a representative faculty by which means reform might be effected and errors removed, besides securing for themselves and their successors a vastly improved social position. There is another class of discontents who actually ignore any benefit they have derived from the Pharmaceutical Society, which they accuse of self-seeking, and of no benefit to trade interests, exemption from jury service, etc., forgetting that the fact of their being registered as a distinct body will secure this advantage and place them in a better position than the mere seller of drugs, with whom he can always compete as regards quality and value compared with low prices. Before the foundation of the Pharmaceutical Society there was not in the market a single powder or extract but was shamefully sophisticated or substituted. This, on the authority of one of the fathers of English pharmacy, the late Mr. Thomas Herring; now we have not only protection from wholesale fraud, but penalties can be enforced for infraction of the law. Then, again, the standardisation of weights and measures. Formerly these were in reality unknown quantities. I remember that during my apprenticeship we used a 16-oz. cylindrical pint measure for several years. One day, however, it was discovered by accident that the said measure registered less than 15 ozs. A minim measure was examined, it was 20 minims in excess; such important details need no remark. There is, however, one feature that cannot be ignored by the most obdurate, namely, the existence of a Benevolent Fund, to the benefits of which every individual, whether a member of the Pharmaceutical Society or not, is open to participate. Half-a-crown per annum (about a halfpenny a week) entitles the subscriber to a vote, besides adding to the ability of the Committee to meet the heavy demands on their resources. Surely no one would wish for an absolutely gratuitous advantage, and, however, depressed in circumstances, would find so small a sum, or even obtain it from a relative or friend somewhat better off in the world.

October 27, 1898.

SIRIUS (150/3).

VISUAL OPTICS IN THEORY AND PRACTICE.

Sir,—The letter on the above subject in your last issue does, I suppose, call for some reply from me, as my article, which this letter presumes to criticise, appeared in your columns. I will at once state that there is one point, and one only, upon which I am in entire accord with the writer, and that is that it does not seem necessary to waste your valuable space with his discussions of my remarks. The letter, I might mention, bears a most remarkable resemblance to similar ones I have seen in another (not drug) trade journal. Mr. D. Jones is not a clever man, for he shows too plainly that the critic's cloak conceals the brief which he holds on behalf of those who find it inconvenient that retail opticians should be optically educated. In every sentence he has written he pleads the cause of these interested ones. Mr. Jones in so many words writes that retail dealers in optics do not need greater facilities for education than the past has afforded, and I will make bold to put into plain English that which he had only courage enough to hint at, namely, to advise chemists not to study optics under Mr. Lionel Laurance, because if they do the effect of their knowledge of the subject will run counter to the interests of a certain class of people connected with the trade. Shallow as it is, I will use Mr. Jones's letter to add a grain of weight to my observations on the present condition of the optical industry. Let it be for a moment conceded that what Mr. D. Jones says be true. How bad must be this condition if "60 per cent. of the glasses in use are supplied to ophthalmic surgeons and hospital directors, who take care their orders are faithfully carried through, and at very moderate prices." Or, if there be wholesale houses of the kind mentioned in the letter, it is only because there is an optically uneducated retail trade, for an optically educated retail trade would be the death-blow to such houses and their methods. My idea of what the trade should be is then very different from that of Mr. D. Jones. The retail optician should have a knowledge of visual optics, such that he need not be looked after by anyone, and such that he admittedly be capable of dispensing visual aids on his own responsibility. Mr. Jones seems to charge me with ingratitude to certain ophthalmic professors and qualified science teachers who have for years, according to Mr. Jones, taught the subject of visual optics to, and done so much for the British pharmacists who deal in optical goods, and he appears to be grieved because I am ungrateful to these creations of his vivid imagination. Even if they existed, except in the brain of this one illusionist, they do not appear to have taught much to him or to anyone else in the trade. I need hardly comment on the last sentence of Mr. D. Jones's letter, as no intelligent or honest member of the pharmaceutical trade can possibly have taken umbrage at my remarks.

London, October 31, 1898.

LIONEL LAURANCE.

A PLEA FOR PHARMACEUTICAL CHEMISTS.

Sir,—It has struck me for years as an anomaly that while the chemist and druggist who had passed the Minor could only be elected an Associate of the Pharmaceutical Society, the old-fashioned grocer and sundryman who made up, with infinite pains and difficulty, a simple prescription perhaps once or twice a year, and called himself a chemist and druggist, and as such got his name inserted in the Register as having been in business before 1868, could be elected a Member. It simply came to this. If a man advertised himself as A.P.S. you knew that he had passed the Minor, but if a man advertised himself as M.P.S. you did not know, without further information, whether he was a pharmaceutical chemist by examination or some old grocer, seedsman, and general dealer, who had made up a prescription or two and described himself as a chemist and druggist before 1868. Consequently (without further information) the A.P.S. was the better credential of the two. I always thought it an injustice that some men I know who have never been examined should be eligible to be elected Members, while I, having passed the Minor, could only be an Associate. Happily this state of affairs has now come to an end, and all of us who pay the subscription can now become Members, but still, I think the Major men have a right to demand the title of Fellow, or something to distinguish them as superior to us "Minor stars," for the public do not, will not, and are never likely to distinguish between a pharmaceutical chemist and a Member of the Pharmaceutical Society.

113, Stirling Street, Grimsby.
November 2, 1898.

W. D. MASON, A.P.S.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

URINE ANALYSIS.—Allen's 'Chemistry of Urine' (Churchill, 7s. 6d.), is the best work on the subject. [Reply to W. C. B.—18/3.]

BOTANICAL.—The name of the plant is *Chloris perfoliata*. [Reply to L. R.—18/20.]

LIBRARY AND MUSEUM.—The hours are 9 a.m. to 9 p.m., except on Saturdays, when they close at 2 p.m. [Reply to PHUSIS.—18/16.]

OIL OF STAVESACRE.—It would be advisable not to apply it to broken surfaces. [Reply to W. J. S.—18/25.]

PRESCRIPTION.—There is nothing sufficiently unusual in the prescription of which you send a copy to justify the printing of your letter. [Reply to M. G.—151/5.]

THE 1898 PHARMACOPŒIA.—Yes, the candidate's knowledge of what is special in the work will be tested by the Board of Examiners in January next. [Reply to A. R. J.—18/17.]

SPECIMEN OF DRUG.—It is the rhizome of *Dioscorea villosa*, known as wild yam, colic root, or rheumatism root. The habitat of the plant is the United States. [Reply to R. B.—18/22.]

RESTORING COLOUR OF WINE.—You cannot restore the colour by any justifiable method. The best plan will be to make another batch with a very dark coloured wine, and mix that with the deodorised preparation. [Reply to A. J. R. S.—150/44.]

APPLICATION FOR INNER SURFACE OF BICYCLE TYRE.—Probably a solution of gutta-percha in chloroform and benzene, made rather thin, would be the best thing to try. Let it dry thoroughly, and then rub well over with French chalk before putting in the other case. [Reply to H. B.—17/34.]

WHITENING LARD.—Good lard should need no whitening. If properly prepared and rendered it is quite white, the presence of any colour indicating either imperfect washing or overheating. Possibly digestion with granular animal charcoal and filtration, while warm, through a column of the same substance would remove the colour. [Reply to D. J.—18/24.]

GERMAN PRESCRIPTION.—The second item is Spiritus Serpylli, a German preparation made by macerating for 24 hours 1 part of the coarsely cut root of *Thymus serpyllum* with 3 parts by weight each of 90 per cent. alcohol and water, then distilling off 4 parts by weight. The product should be of s.g. 0.895 to 0.905. [Reply to QUID EST.—18/26.]

ACTION OF SALTS ON VEGETABLE COLOURS.—The question you raise is rather complicated, and can only be fully discussed in connection with the subject of the state of bodies in solution generally. It is well known that aqueous solutions of salts derived from strong bases and weak acids, and *vice versa*, do not exhibit a neutral reaction towards certain indicators. This may be easily verified by experiment with litmus paper upon solutions of potassium carbonate and acetate on the one hand, which have an alkaline reaction, and the sulphates of aluminium and copper, which, although neutral in composition, redden litmus paper. Those desirous of pursuing the subjects should consult Ostwald's book on 'Solutions.' You are therefore right in your assumption that the reaction of salts towards indicators is not entirely dependent upon equivalency in the acid and basic radicles. [Reply to QUERO.—18/6.]

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Creosote Pills. M. Agosti, an Italian pharmacist, has recommended for the preparation of creosote pills the addition of an equal weight of water and enough liquorice to form a pill mass. M. Delhaxhe has tried the formula and obtained pills which do not ooze with creosote, and at the same time readily disintegrate in water slightly acidulated with hydrochloric acid. He finds, however, that the reduction of the water to one-half improves the formula, which is here appended :—

Creosote.....	0.10	gramme.
Water	0.05	”
Powdered Liquorice Root	0.20	”

—*Répertoire*, x., 438.

Australian Poisonous Plants. Mr. J. H. Maiden directs attention to the poisonous properties of *Eremophila maculata*, F. v. M., when eaten by stock. Under the name of “Wedgera” the blacks are said to use the leaves as a blister when suffering from a cold.

He also publishes two cases of poisoning of pigs through eating the berries of white cedar fruits.—*Agricult. Gaz. of New South Wales*.

Composition of Human Milk. Ch. Michel publishes the results of recent analyses of woman’s milk. Samples were taken morning, noon, and night, mixed and then examined. From the study of the data derived from seventy-two analyses, he found that it was possible to draw a wide distinction between the milk of women recently *accouchées* and those who had passed that stage, a period varying between two and twelve months. Thus the milk of the former was notably richer in nitrogen compounds, extractive matter and mineral salts, whilst it was poorer in fat (*beurre*) and in lactose.—*Répertoire*, x., 452.

Insect Powders. *Chrysanthemum roseum*, Adam (*Pyrethrum roseum*, Bieb.), with rosy flowers, a native of the Caucasus, and *Chrysanthemum cinerariaefolium*, Visiani (*Pyrethrum cinerariaefolium*, Trev.), with white flowers, a native of Dalmatia. The inhabitants of Asiatic countries south of the Caucasus kept secret all details connected with the production and source of this drug until early in this century an Armenian merchant learned that the powder was obtained from the dried and pulverised flower-heads of certain species of *Pyrethrum* growing in the mountain region of what is now known as the Russian province of Transcaucasia. The history of the Dalmatian species of *Pyrethrum* still remains a mystery. There is reason to believe that the Caucasian species is not cultivated, whilst the Dalmatian plant is generally considered to be cultivated, though no definite information can be obtained on this point, owing to the jealous watch which the inhabitants keep in order to guard their valuable monopoly. The fourth report of the U. S. Entomological Commission, 1885, pp. 164-180, gives some particulars of the manufacture of the powder. The flower-heads should be gathered during fine weather, when they are about to open, or when fertilisation takes place, as the essential oil that gives the insecticide properties reaches at this time its greatest development. When the blossoming has ceased the stalks may be cut within four inches of the ground and utilised, being ground and mixed with the

flowers in the proportion of one-third of their weight. Care must be taken not to expose the flowers to the moisture or the sun’s rays, or still less to artificial heat. They should be dried under cover and pulverised. The efficacy of the product is proportional to the degree of comminution to which it has been brought. The powder should be kept in perfectly tight glass vessels or tin boxes. It is a specific, according to the *Botanical Magazine*, p. 6781, in the case of aphides, house flies, and mosquitoes (or gnats), and if used with bellows is effectual in killing the common insects that infest plants in houses. The powder may be burnt in the treatment of rooms, wardrobes, and greenhouses. The alcoholic extract diluted with water, the simple aqueous solution or decoction are other forms in which it may be used. The disadvantages of insect powder are chiefly its transient effect, and the necessity for actual contact with insects when used in the open air. Further, it has no effect on insects’ eggs or hard chrysalises, on beetles with hard elytra, and on the vast class of hemiptera (true bugs), whilst hairy caterpillars and spiders of all kinds are proof against it.—*Kew Bulletin*, cxliii., 297, et seq.

Glycerin Suppositories and Pessaries. M. Crinon has endeavoured to devise a perfect formula for the preparation of glycerin suppositories and pessaries (*ovules*). He finds that *grénétine*, the form of gelatin most highly esteemed for the purpose, is in reality not so good as that which is known in commerce as “*colle gélatine cagnet extra*.” The latter gives with glycerin a product which is absolutely colourless, and more transparent and more soluble than that derived from the former. The method adopted differs from that of the British Pharmacopœia in one or two particulars. The gelatin is first deprived of adherent powder by rubbing it under water with the fingers. It is then dried and weighed. To prepare suppositories the proportions are as follow :—

Gelatin, washed and dried	10	grammes
Water	20	”
Glycerin, at 30° C.	50	”

For pessaries the proportion of water is 50 per cent. higher, 30 grammes being used instead of 20, as a less rigid body is desired. In both cases, when the gelatin has taken up the required amount of water, it is transferred to the glycerin, in which it rapidly dissolves. The moulds are oiled with liquid paraffin, and the mixture sets perfectly in an hour. It is claimed for this method that, by the avoidance of directly heating the gelatin, the latter does not lose its cohesiveness. When a soluble substance has to be incorporated distilled water is used, one-third being reserved to dissolve it, and the solution is added to the moistened gelatin just before pouring into moulds. The preparation of gelatin-glycerin pessaries and suppositories containing tannin cannot be effected in the usual ways. If the tannin be dissolved in the water and added to the liquid basis a magma immediately forms, which cannot be poured into moulds, except by raising the temperature; when all the water is evaporated the mixture becomes limped, especially on the addition of a trace of nitric acid, but at the expense of a part of the tannin, which is converted into gallic and pyrogallic acids. Moreover, the product acquires a deep coloration. If, on the other hand, the tannin be dissolved in the glycerin, a product containing 1.3 to 1.6 per cent. of tannin may be obtained, but it quickly becomes less soluble. Satisfactory results are achieved by soaking the gelatin in a solution of tannin in such proportions that each 15-gramme pessary shall contain 50 centigrammes of tannin, and melt in water at 35° C., giving with ferric salts the usual tannin reaction. It is thought that the tannin, absorbed slowly and in small quantities by the gelatin, the latter being in large excess, yields with it a soluble combination.—*Répertoire*, x., 433.

DIGITOXIN AND DIGITALIN.

Kiliani publishes some further results of his investigation of these glucosides (*Berichte*, xxxi., 2454), from which he concludes that the formula $C_{22}H_{32}O_4$, already assigned to digitoxigenin as the most probable, certainly represents its composition, and that the previous uncertainty as to whether the formula of digitoxose should be $C_9H_{18}O_6$ or $C_6H_{12}O_4$ is now quite removed in favour of the latter formula.

Carefully conducted experiments showed that no other sugar but digitoxose is produced in the splitting up of digitoxin, and consequently the composition of that glucoside may with certainty be represented by the formula $C_{34}H_{54}O_{11}$, instead of $C_{31}H_{50}O_{10}$. The very characteristic blue coloration produced on mixing digitoxose with ferruginous acetic acid and concentrated sulphuric acid, distinguishes that sugar from arabinose, rhamnose, dextrose, galactose, lævulose, and sorbose, none of which give the least indication of a similar coloration. Kiliani considers that this peculiarity of digitoxose may be due to its having a cyclic constitution. He also considers that in the splitting up of digitoxin two molecules of digitoxose are produced according to the equation—

Anhydro-digitoxigenin, produced by the action of concentrated hydrochloric acid upon digitoxigenin, even at the ordinary temperature, is a crystallisable substance having a composition represented by the formula $C_{22}H_{30}O_3$ and it is probably produced from digitoxigenin by the abstraction of a molecule of water, as no simultaneous formation of sugar aldehyde or ketone could be detected. When oxidised with chromic acid, it yields a crystallisable product which has the characters of a ketone—toxigenone—which is sparingly soluble in alcohol or acetic acid, and its composition may be represented by the formulæ $C_{20}H_{26}O_3$ or $C_{19}H_{24}O_3$.

Molecular weight determinations lead to the conclusion that the formula $C_{16}H_{22}O_2$ for digitaligenin must be changed to $C_{22}H_{30}O_3$, or $C_{23}H_{32}O_3$, but in that respect analytical data require to be used with great caution, and to be controlled by other results.

Digitalose, $C_7H_{14}O_5$, the sugar produced together with digitaligenin by the splitting up of digitalin, has not been obtained in the crystalline form, but by treatment with bromine, *d*-gluconic acid and a crystallisable lactone, $C_7H_{12}O_5$, of digitalonic acid, $C_7H_{14}O_6$, were obtained, and thence the inference was drawn that digitalin yields *d*-glucose together with digitalose, a peculiar sugar having the composition $C_7H_{14}O_5$.

This altered view of the composition of digitaligenin necessitates alteration of the formula for digitalin. The analytical data obtained by Kiliani and Schmiedeberg agree well with $(C_5H_8O_2)_x$, and taking $x = 7$, the formula would be $C_{35}H_{56}O_{14}$, so that the splitting up of digitalin might be represented by the equation—

By oxidation of digitaligenin with chromic acid a crystalline product was obtained, together with resinous substances, and it appeared to be the toxigenone above described, though the quantity was too small for identification. If its identity with that substance can be established by further investigation an important step would be made in the knowledge of digitalis glucosides.

Last year Adrian put forward the statement that German digitoxin is identical with the "digitaline cristallisée" of Nativelle, but he did not give any experimental evidence in support of his opinion (*Nouv. Rem.*, 13, 78). Kiliani disputed

that view, pointing out that the analytical data published by Nativelle were not even remotely applicable to digitoxin, and at the same time he expressed some doubt as to the individuality of the French preparation. That circumstance has probably been the chief reason for the appointment of a commission by the Société de Thérapeutique to investigate the question. Kiliani had long before been engaged in the same inquiry, and though still unable to decide positively, he has now published some data which may be of assistance. In the first place examination of "digitaline cristallisée," prepared by Adrian and Co., has convinced him of its chemical individuality. By the splitting up of that preparation he has obtained products which are apparently the same as those yielded, in the same way, by digitoxin. The identity of the sugar product with digitoxose has been ascertained with certainty, and though some uncertainty remains as to the digitoxigenin and the anhydro-digitoxigenin, the very close relationship of the French preparation to the digitoxin of Schmiedeberg (Merck) cannot longer be doubted. The principal points of difference were as follow:—

1. French digitalin, as well as anhydro-digitoxigenin prepared from it, showed a somewhat higher amount of carbon than the corresponding German products.

2. A chloroform solution of French digitalin leaves, on evaporation, a transparent amorphous residue like varnish, which does not become crystalline until methyl alcohol is added to it, while a similar solution of digitoxin yields at once a distinctly crystalline residue.

3. Digitoxin can be split up at the ordinary temperature by a mixture of concentrated hydrochloric acid (2 parts) with 50 per cent. alcohol (8 parts), while the French product requires the temperature to be raised to 40° C.

4. So far as the crystalline form admits of measurement, there seems to be a difference.

For the final settlement of the point the preparation of definitely measurable crystals would be requisite, and in undertaking to carry that out in regard to digitoxin, Kiliani expresses a hope that the corresponding work may be carried out in regard to "digitaline cristallisée" by the French commission.

SELECTED PRACTICAL FORMULÆ.

HECTOGRAPH BASIS.

Shredded gelatin, 170, is mixed with water, 400, and allowed to stand until soft and swollen; glycerin, 1410, is now added, and the mixture heated on the water bath with continual stirring until it ceases to lose weight. While still warm it is poured into the frames.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 360.

HONEY CREAM.

Spermaceti, 60 grammes, is digested with nut oil, 480 grammes, and gamboge, 3.75 grammes, for 20 minutes on the water bath. Verbena oil, 10 drops, cassia oil, 20 drops, bergamot oil, 3 drops, rose oil, 3 drops, are then added. The mixture is filled into warm pots.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 360, after *Apoth. Ztg.*

FLUID DEPILATORY.

Tincture of iodine, 3; oil of turpentine, 6; castor oil, 8; alcohol (90 per cent.), 48; collodion, 100. Paint once per diem for three or four days.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 360.

PILOCARPINE HAIRWASH.

Tincture of jaborandi and of cantharides, of each 28 fl. pts.; eau de Cologne, 28 fl. pts.; ess. bouquet, 12 fl. pts.; distilled water to produce 480 fl. pts.

THE PHARMACEUTICAL SOCIETY AND ITS PRESIDENTS.

JOHN WILLIAMS.—1876-79.

MR. THOMAS HYDE HILLS was succeeded in the presidential chair in 1876 by John Williams, a worthy representative of the scientific side of pharmacy, in whom were also combined business capacity and perseverance. His published papers are marked by the practical application of chemical knowledge in the art of preparing medicines; as an instance may be mentioned those relating to salicylic acid and allied bodies. In another series he proposed to utilise the viscosity of glycerin to retain volatile substances, such as hydrocyanic acid and ethyl nitrite in solution. He was one of the first students in the Society's School, and as an indication of his future career, he gained the first prize in practical pharmacy in 1844. We are told that his knowledge of various branches of science in geology, entomology, numismatics, and physical science was astonishingly complete. He would rather amuse a visitor to his laboratory by the simplicity of his manner, and above all, he had the heartiest spirit of good-fellowship with everyone with whom he came in contact.

John Williams was born on March 9, 1824, and as a youth he entered the service of Mr. Morson, with whom he remained until he joined Mr. Hopkin to establish a firm long known in pharmacy. He was elected to the Council in 1870, to fill the vacancy caused by the retirement of Henry Bowman Brady; subsequently he became Treasurer and, later, President. In 1883, he was elected President of the British Pharmaceutical Conference. His firm became especially noted for the supply of fine chemicals, and he published many papers on chemical and pharmaceutical subjects.

The building which served as the business premises of Messrs. Hopkin and Williams was once the chapel in Hatton Garden rendered celebrated by the eloquence of Edward Irving. That was not the only time chemistry has invaded the precincts of theology; Professor Redwood did the same close by Red Lion Square. During the ministry of the great Scottish divine, the chapel was frequented by the Court and the aristocracy, and the Sunday services were regularly chronicled in the *Times* paper among the fashionable announcements. Mr. Williams died, March 3, 1889, having nearly completed his 65th year.

During his term of office, the Council of the Society was able to protect the interests of the trade in many ways. A Medical Act Amendment Bill, introduced by Dr. Lush and Sir Trevor Lawrence in 1877, contained provisions which would have affected chemists and druggists injuriously, but representations from the Council resulted in their removal from the Bill. Steps were also taken, in connection with the Dental Practitioners Bill, to secure registration for chemists who practised dentistry, and when

registered chemists were being threatened by the Medical Defence Association, the Society's solicitor was instructed to put himself in communication with the solicitor of the Society of Apothecaries, and a satisfactory result was arrived at.

Of still greater importance, however, was the attempt made by the Council of the Society to define the position of joint-stock companies in relation to the Pharmacy Acts. In February, 1878, it was reported to the Council that a grocer named Mackness, of Tottenham Court Road, who had been illegally carrying on the business of a chemist and druggist, under the style of the London and Provincial Supply Association, had paid a penalty for a breach of Section 15 of the Pharmacy Act, and subsequently sold his business to the London and Provincial Supply Association,

Limited. A month later proceedings were taken both against Mackness and against the Association for alleged breaches of Section 17 of the Pharmacy Act, 1868. With regard to the case against Mackness, it was held by the magistrate that the penalty he had previously paid under Section 15 covered the offence now charged under Section 17. One case against the Association for alleged insufficient labelling was dismissed, but the defendant company was convicted in a second case, notwithstanding that it was contended for the defence that a corporate body was not a "person" within the meaning of the Act.

In May following the hearing of these cases an action was brought against the London and Provincial Supply Association under Section 15, but though the sale of poisons by the defendant company was proved and admitted, judgment was given in its favour by the County Court Judge, on the ground that what had been done on behalf of the company was not unlawful so long

as the business was conducted by a duly qualified chemist and druggist. Reference was made to the fact that it was lawful for the executors of a registered chemist to continue the business if conducted by a duly qualified assistant, and the Judge expressed the opinion that this was a similar case, inasmuch as no offence would have been committed by the chemist in charge had he sold the articles for himself. It could not be contended, he said, that an offence had been committed simply because the profit made went into the pockets of unqualified persons, as that obviously was not within the mischief intended to be remedied by the Act. This decision was appealed against, the case being carried to the Court of Queen's Bench, which decided that the County Court Judge was wrong; the Appeal Court, on the other hand, reversed the Queen's Bench judgment, holding that the word "person" in Section 15 does not include a corporation, and as the House of Lords subsequently dismissed the further appeal by the Society, joint-stock companies have since been regarded as definitely exempted from the penalties imposed by Section 15 of the Pharmacy Act of 1868.

JOHN WILLIAMS.

THOMAS GREENISH.—1880-82.

Meanwhile, however, Mr. Williams had been succeeded as President by Mr. G. W. Sandford, who once more assumed the reins for a brief space, and he in turn had given place to Mr. Thomas Greenish, who yet, happily, survives. He is one who has seen many lands and peoples, and has not been content to study pharmacy at home. In 1841, he was assistant at Godfrey and Cooke's in Conduit street, of which establishment he is at this moment sole representative and proprietor. He has communicated various papers to pharmaceutical literature, the first being one on "Infusion of Horseradish"; and he is known in connection with the pharmacy of the phosphates. Mr. Greenish has also devoted himself to microscopic observation, and has made himself an authority in a special department of that science; indeed, he was one of the first to advocate the study of the microscope as bearing on pharmaceutical research. In 1871, Mr. Greenish was elected a member of Council, and he succeeded Sandford as President in 1880. He is probably better known to Continental pharmacists than any other English member of the craft, and his appearance at a foreign conference meets with instant recognition. It was during his presidency that the International Congress was held in London. His vacations have been spent in Hamburg, Rome, Paris, St. Petersburg, and Vienna; he has also visited New York, Philadelphia, and continued his journeyings as far west as Chicago, and thus he has become personally acquainted with many distinguished *confrères*, and accepted as a representative of British pharmacy.

One of the first steps taken after Mr. Sandford's re-election in those troublous times was to appoint a Pharmacy Act Amendment Committee. Another was the admittance of women as members of the Society. Useful work was also done in watching Bills in their progress through Parliament, the result showing, as Sandford expressed it, in his last address as President, the necessity of maintaining for the Society such a character as will enable it to assert itself before the Legislature when occasion may require. An occasion for such self-assertion on the part of the Society presented itself only too soon, for little more than two months later the House of Lords decided that corporations are not affected by Section 15 of the Pharmacy Act of 1868. Towards the end of the year 1880 the labours of the Pharmacy Act Amendment Committee resulted in the production of a draft Bill, one clause of which provided that the word "person" in Section 12 of the Pharmacy Act, 1852, and in Section 15 of the Pharmacy Act, 1868, should include corporate bodies. The idea of the draft Bill, which was submitted to the Lord President of the Council, was to render the restrictions on the practice of pharmacy and on the sale of poisons more definite.

Communications had been addressed to the Society by the Privy Council, directing attention to the public danger arising from the indiscriminate distribution of poisons and other poisonous drugs in the shape of so-called "patent" medicines, and asking whether the Society had arrived at any conclusion as to the desirability of legislation on the subject. The draft Bill was the reply to that

question, as it included a clause with regard to the labelling of stamped medicines containing poisons.

As a matter of fact the Bill, unfortunately, never progressed beyond the draft stage. The Lord President of the Council declined to take charge of it, and though he agreed to receive a deputation from the Council on the subject, valuable time was lost in waiting for further communications from the Privy Council that never came, and it was at last decided not to press the matter further. Meanwhile another Government department had approached the Society with regard to the sale of poisons, the Home Secretary having requested the President to bring the subject before the Council, and report whether it had any suggestions to make for the amendment of the law relating thereto. Suggestions were accordingly made in a letter forwarded by Mr. Greenish and, after the Home Secretary had received a deputation from the Council on the subject, another written statement of suggestions was sent for his further consideration.

Perhaps the most notable event of Mr. Greenish's term of office was the meeting in the Society's house of the fifth International Pharmaceutical Congress, the attendance at which was both large and representative. A commission of pharmacists was appointed by the Congress to prepare an International Pharmacopœia, but so far that commission has hardly justified its existence, and the International Pharmacopœia is yet in the womb of the future. A more practical step was taken in placing on record the opinion of the Congress that "it is the duty of all pharmacists to urge that, in the future revision of any national pharmacopœia, it is necessary that there should be a permanent committee or commission comprising among its members the largest possible number of pharmacists." But even that resolution has not yet borne fruit in this country, and altogether the Congress would appear to have been useful only in so far as it afforded an opportunity for the representative pharmacists of the world to become personally acquainted with each other.

It is worthy of note that, in his address to the members at the last Annual Meeting of the Society over which he presided, Mr. Greenish referred to the deep and general discontent which appeared at that time to prevail throughout the country with regard to the condition of the trade of chemist and druggist. He attributed the trouble that existed, in great measure, to excessive competition resulting from the fact that young men of deficient education were continually being hired into an overcrowded trade. Instead of being educated pupils, articled to a principal to learn a trade, they were admitted from a low social scale, with deficient early education and at small premiums, mainly for the sake of their manual labour. "The desire to obtain cheap labour," he said, "is greater than is consistent with a due regard to the advancement of pharmacy. The majority are utterly ignorant of the character of the examinations they must become qualified to pass, and also the expense that must necessarily be incurred in acquiring the requisite education." Subsequent experience has only tended to prove the truth of those words.

THOMAS GREENISH.

PHARMACOPŒIAL ANOMALIES.

BY EDWIN DOWZARD, F.C.S.

No doubt the revisers of the Pharmacopœia have made many valuable and useful additions to the methods for the examination of crude drugs, pharmaceutical preparations and chemicals, the aim seems to have been to abolish rule of thumb and to eradicate that phrase "about." There are, however, several inconsistencies which it would be well to point out.

In the preface to the 1898 B.P. the following words occur: "The amount (? quantity) in cubic centimetres of a volumetric solution which will react with a stated amount (? quantity) of a solid or liquid substance, instead of being extended to the two or three places of decimals which theory (? accuracy) would require, is given only to the degree of accuracy which may easily be observed on an ordinary burette. In short, the procedure in these and other chemical operations is now left to the skill and judgment of workers who are assumed to be duly trained."

This paragraph seems to indicate that the pharmacopœial testing should be performed by experienced analysts, and yet an ordinary burette is considered to be the instrument analysts are in the habit of using. So far as I am aware this is not the case. Standardised burettes, divided into tenths, which can easily be read to 0.025 C.c., are extensively used by first-class analysts. And again, the above paragraph would indicate that the figures given are to the nearest decimal place. It will be seen further on that in several instances this is not the case.

HYDROCHLORIC ACID.—The B.P. describes this acid as containing 31.79 per cent. by weight of hydrogen chloride, and it says that "Each gramme should require 8.7 cubic centimetres of the volumetric solution of sodium hydroxide."

$$0.03619 \times 8.7 = 0.31485 \text{ or } 31.485 \text{ per cent. HCl.}$$

There is a difference of 0.305 per cent. between this result and the percentage specified by the B.P. It would be more correct to substitute 8.8 for 8.7 C.c.

B.P. figure	31.790 per cent.
8.8 C.c.	31.847 "
8.7 C.c.	31.485 "

the error would then only be 0.057 per cent. in excess of the specified percentage.

HYDROCYANIC ACID (dilute).—The B.P. describes this acid as containing 2 per cent. by weight of hydrogen cyanide:—

"Each gramme should require 3.7 cubic centimetres of the volumetric solution of silver nitrate."

$$\begin{aligned} \text{But if 1 C.c. N/10 AgNO}_3 &= 0.00537 \text{ gram. HCN} \\ 3.7 + 0.00537 &= 0.0198 \text{ or } 1.9869 \text{ per cent.} \end{aligned}$$

LACTIC ACID.—The B.P. describes this acid as containing 75 per cent. of hydrogen lactate:—

"Each gramme should require 8.3 cubic centimetres of the volumetric solution of sodium hydroxide."

$$\begin{aligned} 0.08937 + 8.3 &= 0.74177 \text{ or } 74.177 \text{ per cent.} \\ 0.08937 + 8.4 &= 0.7507 \text{ or } 75.070 \text{ per cent.} \end{aligned}$$

In the case of nitric acid, the B.P. specifies that it shall contain 70 per cent. by weight of hydrogen nitrate, and adds that "each gramme should require 11.1 cubic-centimetres of the volumetric solution of sodium hydroxide."

$$\begin{aligned} 0.06258 \times 11.1 &= 0.6946 \text{ or } 69.46 \text{ per cent. HNO}_3. \\ 0.06258 \times 11.2 &= 0.7008 \text{ or } 70.08 \text{ per cent. HNO}_3. \end{aligned}$$

It will be seen from the above that the more correct figure is 11.2.

The above are not the only inconsistencies of the 1898 B.P., but just a sample. The discrepancies involved are certainly not great, but they would not be tolerated in a modern text-book on volumetric analysis.

No analyst would think of using exactly one gramme of bitartrate of potash.

If a sub-multiple of the molecular weight of the substance to be tested is taken, the actual percentage of bitartrate may be arrived at by simply multiplying the number of cubic centimetres used by 2, 4, 6, as the case may be, for instance. If 9.3375 grammes of bitartrate of potash (corresponding to half the molecular weight of bitartrate of potassium) required 48.75 cubic centimetres of the volumetric solution of sodium hydroxide, the sample would contain—

$$48.75 \times 2 = 97.5 \text{ per cent. bitartrate.}$$

The most convenient instructions would have been those which allowed the percentage to be read from the burette directly or by a simple multiplication.

A few cases are given below showing the means by which the revisers of the 1898 B.P. might have avoided erroneous statements:—

HYDROCHLORIC ACID, mol. wt. 36.19.—3.619 grammes should require nearly 31.8 cubic centimetres of the volumetric solution of sodium hydroxide.

B.P. description	31.790 per cent. HCl.
B.P. method	31.485 " "
Correct method	31.800 " "

LACTIC ACID, mol. wt. 89.37.—4.4685 grammes should require 37.5 cubic centimetres of the volumetric solution of sodium hydroxide.

$$37.5 \times 2 = 75.0 \text{ per cent. lactic acid.}$$

B.P. description	75.000 per cent. lactic acid.
B.P. method	74.177 " "
Correct method	75.000 " "

RECENT WORK IN BOTANY.

ARSENIC IN PLANTS.—Herr J. Stoklasa has investigated the occurrence of arsenic in the vegetable kingdom, and its poisonous effect on plants. He states that arsenious and arsenic acids are both highly poisonous, even in excessively minute quantities, and that the statement that arsenic acid may replace phosphoric is incorrect. Arsenic is, however, a very widely-diffused element, especially in association with sulphuric acid. In superphosphates it may even be present to the extent of 0.3 per cent., but its presence in the form of $\text{As}(\text{OH})_3$ or of $\text{AsO}(\text{OH})_3$ is not injurious to vegetation unless it exceeds 0.4 per cent.—*Zeitschr. f. landwirthsch. Vers. in Oesterreich*, 1898, p. 154.

FUNCTION OF IRON IN PLANTS.—Herr J. Stoklasa confirms the statement of Molisch, that iron is not, as has been stated, a necessary constituent of chlorophyll. He finds, however, in bulbs of *Allium cepa* and seeds of *Pisum sativum* a substance containing iron, and identical in composition with animal hæmatogen. The same substance was found also in *Mucor mucedo*, *Boletus edulis*, and *Bacterium megaterium*. Its function appears to be to take part in the formation of the cell-nucleus in young organs; and the author believes iron to be, like phosphorus, an essential constituent of the nucleus.—*Comptes rendus Acad. Sci. Paris*, cxxviii., 1898, p. 282.

FORMATION OF DIASTASE BY FUNGI.—Herr J. Katz has carried out a series of experiments on *Penicillium glaucum* and *Aspergillus niger*, from which he concludes that these fungi have the power of forming diastase, the presence of starch not being absolutely necessary for this process. The presence of grape or cane sugar checks the formation of diastase, but the sugar is inverted. In the case of cane sugar 1.5 per cent. prevents its formation, while of milk sugar as much as 10 per cent. is required. *Bacillus megaterium* exhibits very similar phenomena. The continual removal of the diastase as formed promotes the production of fresh quantities.—*Pringsheim's Jahrb. f. wiss. Bot.*, vol. xxxi., 1898, p. 599.

PHARMACEUTICAL SOCIETY.

—◆— EVENING MEETING IN LONDON.

The first evening meeting of the session was held on Tuesday, the 8th inst., when the chair was taken at eight o'clock by Mr. WALTER HILLS, President of the Society. The lecture hall was unusually crowded. He at once called on Professor Ramsay, F.R.S., whom he was proud to say was an honorary member of the Society, to give his promised lecture

On the Gases Present in the Atmosphere.

Professor RAMSAY, referring to the statement often made that science was international, and that there was no patriotism about it, said nevertheless it was a curious fact that all the discoveries in connection with the atmospheric air had been made by Britons. He then gave a brief *résumé* of the work done by early investigators, Boyle, John Mayo, Hales, Black, Rutherford, Scheele (to whom the credit of discovering oxygen was due, though he was anticipated in publication by Priestley), and Cavendish, pointing out that the latter in his investigations on nitrogen found a small residue, which seemed incapable of combining with oxygen even in the presence of caustic soda and when electric sparks were passed through it; the proportion he put at not more than 1/120th. After briefly referring to the researches of Boussingault and Schonbein on the air, principally in connection with the small dusty particles found in it, he came to the experiments of Lord Rayleigh, beginning in 1893, the object being to ascertain exactly the densities of the various gases as compared with hydrogen. Early in 1894 Lord Rayleigh wrote to *Nature*, announcing what appeared to him to be an anomaly, namely, that whilst atmospheric nitrogen was a little over fourteen times as heavy as hydrogen, nitrogen prepared from ammonia or from other chemical compounds was slightly lighter, the difference being about 1 in 230. No explanation was forthcoming at the time, but Lord Rayleigh talked the matter over with several of his friends, including the lecturer, who had some time before suggested to him, at his request, a method of preparing nitrogen by passing a mixture of air and ammonia over red-hot copper, when the oxygen united with the hydrogen of the ammonia, and the nitrogen from both the air and the ammonia passed on. He suggested to Lord Rayleigh that probably atmospheric nitrogen was not as pure as it was supposed to be, and directed his attention to Cavendish's experiments and the residue he had found when combining nitrogen with oxygen. Lord Rayleigh did not at first attach much weight to the suggestion, and thought it more likely that different compounds contained different kinds of nitrogen. These conversations led to their both making further investigations, Mr. Percy Williams, who was then a student in the University College laboratory, making some of the first experiments on the absorption of nitrogen by metallic magnesium, when it was soon found that the nitrogen thus obtained, or rather the last residue unabsorbed, was a little over sixteen times the weight of hydrogen, and before long, working on larger quantities, they obtained nitrogen nearly nineteen times as heavy as hydrogen. Mr. Williams then had to give up the work in order to prepare for and pass his examination, and he (Professor Ramsay) had to continue the investigation by himself. On August 18 in that year an announcement was made at Oxford of the discovery of this gas. Meantime Lord Rayleigh had not been idle, and repeating Cavendish's experiments with more perfect apparatus, he obtained a residue which could not be made to combine with oxygen by any means whatever. They then came to the conclusion that it must be a new gas, and the name argon was chosen for it, because it was not found possible to make it combine with any other element. It existed in the atmosphere to the extent of 0.8 per cent., a very considerable proportion being about twenty-five times as much as the quantity of carbonic acid usually present, and it was only reasonable to suppose that if it would combine at all, some of its compounds would have been discovered long ago. It had been tried with every conceivable substance, but no combination could be effected. The name argon was therefore chosen, signifying indifference, or incapacity for combination. On January 31, 1895, an account of these experiments was given to the Royal Society, and next morning he had a letter from Prof. Meyers referring to some experiments by Dr. Hildebrand of the United States Geological Survey, in which he got a considerable quantity of nitrogen from a rare

mineral called cleveite. He had heard of those experiments, but had forgotten them, but thereupon he obtained some of this mineral—all there was in London—and got nitrogen from it, though some air got mixed with it, and it was set aside for a time. In March some of it was put into a tube and its spectrum examined, when they were struck with the appearance of a bright yellow single line, which further examination showed not to correspond with the double yellow line of sodium. Having heard that a bright yellow line had been observed in the spectrum of the chromosphere by a French astronomer, which had been further investigated by Lockyer and Frankland, who had given the gas which produced it the name of helium, they calculated the wave length of this bright yellow line, and found it exactly corresponded, and therefore concluded that they had actually obtained from argon terrestrial helium. After purifying helium and argon it was found that argon weighed nearly twenty times as much as hydrogen (19.94), and helium practically twice as much. In the case of most gases, such as oxygen, nitrogen, or chlorine, their weights compared with hydrogen represented their atomic weights; but in the case of mercury, though its atomic weight was 200, the density of its vapour was not 200, but only 100 times that of hydrogen, and the conclusion drawn was that the molecule of mercury was mon-atomic, whilst each molecule of oxygen, hydrogen, nitrogen, and so on, contained two atoms. When the temperature of a gas was raised it expanded, and if it could not expand the pressure rose, but in the case of mercury vapour the pressure rose much more rapidly than in the case of oxygen or nitrogen, the explanation being that the heat communicated to these latter gases not only caused the molecules to move more rapidly in the chamber in which they were confined, but also created an inter-molecular movement of oscillation or vibration, but in the case of mon-atomic gases this could not take place, and therefore the pressure was increased. This was found to be the case with argon and helium, and the conclusion, therefore, was that the molecule of each contained only one atom, not two, as in the case of oxygen and hydrogen. The density of argon being 20, therefore its atomic weight would be not 20, but 40, as compared with hydrogen, following the analogy of mercury, and the atomic weight of helium on the same principle must be about 4. Reference was then made to the arrangement of the elements according to their atomic weights by the late Mr. John Newlands, who found that they fell into certain groups which he termed octaves, as after each set of seven a similar series seemed to recur, but with certain lacunæ here and there in the regular order of the series, and, curiously enough, helium and argon seemed to fit into this arrangement and fill two of the gaps. Following up this idea, there ought to be another element between helium and argon. If the atomic weight of helium were taken as 2 and argon as 20, the intermediate place—11—was already occupied by boron; but if they were taken as 4 and 40, as he had suggested, there was room for an element with an atomic weight of 20, and probably another further up the scale. They thereupon set about searching for an element with an atomic weight of 20, and first of all it was thought advisable to search further in the source of helium, because its spectrum rather indicated that it was not a simple gas but a mixture. Professor Norman Collie and himself spent the best part of one summer in fractionally diffusing argon through a clay tobacco pipe, but the passage of the gas was so slow that the experiments became very tedious, and only four diffusions were accomplished, the result being that the gas which passed first had a density of 19.8, and the last portion of 20.2, but they did not regard these experiments as conclusive. They then went on to helium, which they divided into two portions, one heavier than the other, but the spectrum of each was the same, and they could not regard either as absolutely pure. Later on Dr. Travers and himself resumed the investigation, and stuck to it for four months, the upshot being to prove that the heavier portion of the helium had a little argon mixed with it. Then the idea suggested itself that possibly the nitrogen of the air had still another gas mixed with it, and he and Dr. Travers started on another experiment, making large quantities of argon, which was carefully collected, as was also the residue (Professor Ramsay here described the method of preparation by means of nitrite of magnesium). By this time Dr. Hampson, who was working for Brin's Oxygen Company, had devised an ingenious apparatus by which large quantities of liquid air and liquid oxygen could be readily obtained; and getting a considerable supply of these liquefied gases they began to play with it in various ways. Their intention was to liquefy argon and then fractionally distil it, and eventually by this means they suc-

ceeded in obtaining a very small quantity of residue which, when all the oxygen mixed with it had been removed, showed a distinct spectrum, and to this they gave the name of krypton.

The lecturer here showed the method which had been found most convenient for preparing small quantities of argon, passing the nitrogen of the air through a tube containing a mixture of powdered magnesium and lime, which was heated by a gas flame, thus producing metallic calcium, which rapidly absorbed the nitrogen, leaving the argon as a residue. The argon thus produced was afterwards passed into a vacuum tube, and its characteristic spectrum shown. He also exhibited the original argon tube, which still contained the gas, its spectrum shown by means of direct vision spectroscopes, which were handed round. The spectrum of helium was shown in the same way. The temperature at which argon liquefied was found to be -184°C ., somewhat below that at which oxygen boiled, so that there was no difficulty in working with it. Argon formed a colourless liquid in which white specks floated. The first portion which boiled off had a new spectrum, and a density of 17; the last portion a density of 22.5, which they supposed to be due to krypton, so that, obviously, argon was a mixture, though its purity was equal to 99 per cent. The later portion had been subjected to the same method of purification—cold compression and subsequent evaporation—but there was still a residue which could not be made to liquefy. This was found to have a density of 9.76, and it looked as if it were the missing link of which they were in search. After much trouble in finding a name for it as they had had in conducting the experiments, they called it neon, or the new one. It had been further investigated and its spectrum photographed, when it was found that one of its lines coincided with the yellow line of helium, which proved that it contained that gas. The problem then was how to separate two uncondensable gases from each other. It could be done by diffusion, but the process would be so tedious as to be really impracticable. Dr. Travers then suggested liquefying some oxygen and neon together, and then boiling off the oxygen, which would probably take with it more helium than neon. This was tried very satisfactorily, and the neon which remained had practically the density they were looking for, viz., 10.1. That was again fractionated with oxygen and the heavier portion rejected, and the density was then found to be a little on the wrong side of 10. So it varied, a little heavier, or a little lighter, according to the proportion of helium or argon associated with it, and there could be little doubt that, if it could be obtained perfectly pure, it would occupy just the right position between helium and argon.

Krypton had not been much worked with as yet, but its spectrum, and also that of neon, contained a large number of red, orange, and yellow lines, which rendered it very beautiful, and also some in the green. The heaviest component of the air had a density of about 32.5, and there was a gap for an element between bromine and rubidium, having a density of about 41, and an atomic weight of from 80 to 82.5. This it was proposed to term xenon. There still remained another element to be discovered to make the series complete, coming between iodine and caesium, which would probably be a liquid, but up to the present there was no indication where it should be looked for. In conclusion Professor Ramsay said that though these gases had apparently no commercial importance, and probably no pharmaceutical interest, their discovery was of the highest scientific value from the confirmation they afforded to the atomic theory. 1/100th part of the atmosphere was argon, and if its combination with other elements were possible, some compound would almost certainly have been found. The demonstration of its existence, therefore, if not of any practical use, fulfilled a very important purpose in putting in order the ideas of the chemist.

The PRESIDENT proposed a hearty vote of thanks to Professor Ramsay for his brilliant and interesting lecture, which was carried by acclamation.

CITRIC ACID IN WHOOPING COUGH.—A 10 per cent. solution of citric acid in simple syrup is stated by M. Tilho to be a useful remedy in the treatment of pertussis. It is employed locally by swabbing the periglottic region of the larynx. It also proves to be an efficient prophylaxis against infection. He has succeeded in preventing the disease in many children living with others infected by this means, or merely by the administration of small quantities of citric acid lemonade.—*Boston Med. Journ. Surg.*, cxxxviii., June 30, 1898, 626.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School and House Committee, on Wednesday, November 9, the Librarian and Curator presented the following reports of donations:—

To the Library (London).

University of Durham:—Calendar, 1898-99.
 Royal College of Surgeons of England:—Calendar, 1898.
 City of London College:—Calendar, 1898-99.
 University College, Nottingham:—Calendar, 1898-99.
 Mason College, Birmingham:—Calendar, 1898-99.
 Pennsylvania Pharmaceutical Association:—Proceedings, 1898.
 Mr. W. W. Will, London:—Prescription Reading, 1898.
 Mr. W. D. Mason, Grimsby:—Defective Eyesight, 2nd edition, 1898. Two copies.
 Professor G. Lagerheim, Stockholm:—Sagina Normaniana, 1898; Mycologische Studien, 1898; Botaniken och det botaniska Institut, 1898; Rosenberg, Ueber die Verwendung von Prodigiosin, 1898.

To the Library (Edinburgh).

Mr. E. W. Lucas, London:—Practical Pharmacy, 1898.
 Mr. W. D. Mason, Grimsby:—Defective Eyesight, 1898.

To the Museum (London).

Sir E. Frankland, K.C.B., F.R.S., Reigate:—Specimens of the four poisonous active principles of *Urechites suberecta*.
 The Director, Royal Gardens, Kew:—Specimen of Longan fruits (*Nephelium longana*), as used in Shanghai for making a febrifuge drink.
 Messrs. Hodgkinson, Clarke, and Ward:—Specimen of opaque bdellium.
 Messrs. Burroughs and Wellcome:—A strophanthus pod and six specimens of strophanthus seeds.

To the Herbarium.

Dr. E. B. Ormerod, Queensland:—Specimens of *Solanum chenopodium*.
 Dr. C. Symes, Liverpool:—Living plant of the Japanese chilli.

CHEMICAL SOCIETY.

A meeting was held on Thursday, November 3, at 8 p.m., at which Professor DEWAR, F.R.S., presided. There was a fair attendance at this, the first meeting after the summer vacation. The minutes of the last meeting were read and confirmed, and after some of the newly-elected Fellows had signed the Register and formally shaken hands with the President, Professor DUNSTAN read out the certificates of the candidates for election. This paved the way for the business of the evening.—The PRESIDENT announced that he considered it his duty to express the regret and sorrow which all present in some degree must feel at the loss by death of John Alexander Newlands, one of the most distinguished Fellows of the Chemical Society. He wished to convey to the family of their late friend the sincere condolence of the members. It had been very generally held that the countrymen of Newlands had been tardy in recognising his great genius and his services to science in being one of the first to have an idea of a natural classification of the elementary bodies. Indeed, for many years the Chemical Society had failed to pay honour to so great a discoverer. These circumstances were due not so much to lack of appreciation as to a desire to foster practical research and give it precedence before mere theories. Far greater satisfaction, however, must have been Newlands' when he saw the elaboration and expansion of the theories which he at first tentatively propounded. In concluding his brief but eloquent and fitting tribute, the President threw out the suggestion that a large portrait of Mr. Newlands should be placed in the room to serve as a lasting memorial.—Referring to the large number of papers before the meeting (22), Professor DEWAR remarked that it would be impossible, in view of a subsequent committee meeting, to get through even one-half of them. Many would, therefore, be taken as read.—Dr. Scott was then asked to read a paper by George Dean, B.A., on

A Determination of the Equivalent of Cyanogen.

The investigation was undertaken in order to indirectly arrive at the atomic weight of nitrogen. This was done volumetrically, using pure materials and finding the equivalent of potassium bromide to silver cyanide. As a result the figure 14.066 was obtained, as against Stas's determination of the atomic weight of nitrogen as 14.044. One peculiarity of the process was mentioned, in that on adding one drop of the silver solution during titration it took nearly a week for the cloudy precipitate to subside.—Professor DEWAR, who alone discussed the paper, spoke in terms of highest praise of the work which was embodied in it. Himself and Dr. Scott were the first to adopt that indirect method of atomic weight determination, and had determined the atomic weight of manganese. He showed how from work

done in this direction by Stas, the atomic weight of carbon appears to be 11.981. He then called for a vote of thanks to the author for his valuable communication, and requested Dr. Sydney Young, F.R.S., to read a series of papers on

The American Hydrocarbons,

by himself, and also in conjunction with F. E. Francis, B.Sc., Ph.D., and D. H. Jackson, M.A. These dealt with the composition of American petroleum; the separation from it of normal and iso-heptane; the boiling points and specific gravities of mixtures of benzene and normal hexane; and the action of fuming nitric acid on the paraffins and other hydrocarbons. The impurities mixed with the hydrocarbons were removed by treatment with a mixture of nitric and sulphuric acids, and subsequent fractional distillation. It was found that American petroleum differs from the Russian and Galician varieties. The same hydrocarbons are present, but the American brand contains a larger relative amount of paraffins, the Russian having a larger proportion of naphthenes and aromatic compounds, while the Galician stands nearly midway in this respect. The investigations brought to light the interesting fact that the isoparaffins are readily acted on by fuming nitric acid. A curious point was revealed in that, on collecting the petroleum in fractions, benzene came over at 65° instead of at its boiling point (about 80° C.). The explanation for this anomaly may be that, though benzene and hexane are miscible in all proportions, yet they may behave as partly immiscible liquids in these circumstances, and have abnormal vapour pressure. Toluene behaves in a similar manner, distilling at 95° instead of 111° C. The American and Russian petroleums have many points of resemblance, *e.g.*, the ratio of the quantities of distillate for equal increments of temperature is constant.—This was followed by a paper by W. J. POPE on

A Composite Sodium Chlorate Crystal in which the Twin Law is not followed.

—The meeting concluded with two papers by T. M. LOWRY, B.Sc., on

Stereo-Isomerism of Chloro- and Bromo-Nitro-Camphor, and Camphoryloxime.

The remainder of the papers were taken as read, including a note on "The Action of Light on Platinum, Gold, and Silver Chlorides," by E. SONSTADT, and a paper on "Methane-trisulphonic Acid," by E. H. BAGNALL, B.Sc.

POISON: ITS LEGAL DEFINITION AND SALE.*

BY F. H. FREERICKS.

Legislation for pharmacy is at this time receiving general attention from those interested in its advancement, the result of which is evident in several recently enacted or amended pharmacy laws. While these improvements have been limited, as a rule, to requiring better evidence of knowledge and a higher standard of education from applicants for registration, the work of the American Pharmaceutical Association during the last few years indicates how deeply concerned the active and progressive men in pharmacy are regarding its improvement along other lines.

In determining the fitness of applicants desiring to practise pharmacy, the authorities are restricted to examinations, either oral, written or practical, but after the fitness of the licentiate has been established, the next most important function of the law is the regulation of the dispensing and sale of poisons.

The great interest manifested throughout the country in the efforts of the Committee on Legislation has resulted in a general and widespread desire to improve upon the poison and label laws.

Clearly and definitely it was proven by the splendidly formulated report of this committee last year that nowhere can there be found a clear and concise definition of the word "poison," positive enough to base a law upon. If it were possible to concisely state what shall constitute a poison, it would be a comparatively easy matter to frame effective laws regulating the sale of such substances.

But since it is impossible, or at least impracticable, to place upon

the word "poison" a construction sufficiently broad to be used without hardship and sufficiently limited to be safe, it is evident that if the life and health of the public are not to be grossly endangered, a positive and unequivocal definition of what shall constitute a poison must be promulgated from some authoritative source. The question next arising is, who can best assume the authority to give this definition? In the writer's opinion the proper authority for this purpose is the Revision Committee of the United States Pharmacopœia. The definition of this committee would at least be national in character and its provisions would be binding the country over.

State legislation, however much to be lauded, is insufficient; efforts in that direction, while no doubt often inaugurated by able pharmacists, are subject to the desires and changes of uninformed members of legislative bodies.

If the United States Pharmacopœia classifies substances to be recognised as poisons, the proper legislation will be within reach in the next few years, as all legislative bodies recognise the Pharmacopœia as an authority safely to be followed. The foundation for a law, just and applicable to all, will be furnished and legislatures will be prompt to act in accordance therewith and to finish that for which the Pharmacopœia can offer a basis, by defining what should constitute a poison, with proper laws regulating its sale.

Much has been said for and little against the proposition of the adoption of maximum doses in the next issue of the Pharmacopœia. The opinion now prevails that this will be done and, no doubt, such addition will prove of great advantage to physicians and pharmacists alike. If this can be done, why cannot the Pharmacopœia also state what drugs shall be considered as of dangerous character, based upon the maximum doses in which they may be administered? It can be argued that in the past it has been the distinct desire of the Committee of Revision to recognise only such substances as are of sufficient remedial value to deserve space in the Pharmacopœia and that there are a great many substances of poisonous character which have not been found deserving of such distinction. While this is no doubt true, it must be acknowledged that the Committee have no need of precedents in order to add to or omit from its scope of usefulness and if they deem it proper or necessary to separately or collectively define what shall constitute a poison, it certainly lies within their province to do so, whether all substances coming within that ruling are, or have been, otherwise officially recognised or not.

In order to determine more clearly the sense of the preceding lines and to illustrate the idea set forth therein, a rough classification such as the Pharmacopœia might adopt is appended below.

Class A.

Hydrocyanic acid, compounds of antimony, arsenic, mercury (except calomel), silver cyanide and sulphocyanide, nitrobenzin, oils of tansy, croton, pennyroyal, and savin. Phosphides, phosphorus, wood alcohol, cocaine, chloral, apomorphia, aconite, belladonna, cotton root bark, conium, cantharides, cannabis indica, colchicum, digitalis, duboisia, ergot, fish berries, gelsemium, black and white hellebore, hyoscyamus, ignatia, nux vomica, opium, poison oak, pilocarpus, physostigma, strophanthus, stramonium, veratrum viride, elaterium and their active principles.

All other drugs and chemicals the maximum dose of which is one decigramme or less, as given in standard works on pharmacy.

Class B.

Acids: carbolic, hydrochloric, nitric, nitrohydrochloric (conc.), phosphoric, oxalic, picric, sulphuric. Aqua ammonia all strengths. Compounds of barium, copper, cobalt, and soluble compounds of lead and zinc. Potassium and sodium hydrates. Bromine, iodine, bitter almonds, creosote, chloroform, ether, essential oils of mustard and bitter almond. The term compound as applied in Classes A and B refers to chemical combinations.

While such an arrangement and definition of all that shall be considered as of poisonous character is not perfect, the writer contends that it is an improvement and leaves room for severe criticism only in making a dividing line for all such not specifically mentioned as those the maximum doses of which are 0.1 Gm. or less. It must be admitted, as a matter of course, that there are some active principles and synthetic compounds, the dose of which is more than 0.1 Gm, that would possibly be considered as dangerous, but, on the other hand, these are such that if the limit line would be put 0.2 or 0.5, some of most harmless nature would be included.

* Read before the American Pharmaceutical Association at Baltimore.

NOTICES OF BOOKS.

GILL'S 'CHEMISTRY FOR SCHOOLS' is a well-known elementary text-book, and the tenth edition, revised and enlarged by D. Hamilton Jackson, B.Sc., Ph.D. (London: Edward Stanford. Price 4s. 6d.) is certain to maintain the reputation of the work. The book has long been a favourite with students preparing for the London University Matriculation Examination, but it contains much more information than is strictly required for that purpose, and it serves as an excellent introduction to the practical study of chemistry. "Its object is to supply a direct means of training the mind in habits of correct observation of facts and of accurate reasoning from facts to generalisations; in other words, to cultivate scientific habits of thought." The authors could have set no better object before them, and it must be acknowledged that it is fully attained.

'FIRST STAGE INORGANIC CHEMISTRY (PRACTICAL),' by Frederick Beddow, D.Sc., Ph.D. (London: W. B. Clive. Price 1s.), as its name implies, is adapted to the requirements of the Science and Art Department. It deals exclusively with simple experimental work, including the preparation of some common elements and compounds, simple quantitative experiments, and elementary systematic analysis. The book should serve as an excellent guide for beginners.

MITCHELL'S 'QUANTITATIVE EXERCISES,' Parts I. and II. (Reading: National Publishing and Supply Association, Ltd. Price 1s. each net), have now reached their second edition, as they well deserved to do. Sundry corrections and additions have been made by the author to Part I., and improvements introduced in the method of carrying out several of the experiments. The second part has been revised and enlarged by the insertion of a course of qualitative analysis, additional exercises in volumetric analysis for pharmaceutical students, and some typical preparations. The section on qualitative analysis is interleaved with blank paper for notes. Both these books can be cordially recommended to beginners in the study of quantitative chemical work.

BRIGGS AND BRYAN'S 'MIDDLE ALGEBRA' (London: W. B. Clive. Price 3s. 6d.), based on Professor Radhakrishnan's book, is adapted to the standard of examinations of intermediate difficulty, such as the intermediate examinations in science and art of the London University, and it will therefore meet a definite want. A knowledge of the more elementary properties of quadratic equations and progressions is assumed on the part of students using the book, and the Indian work has been subjected to numerous alterations and modifications to meet the needs of English students.

'SECOND STAGE MATHEMATICS,' by William Briggs, M.A., LL.B. (London: W. B. Clive. Price 3s. 6d.), includes Euclid, Books 2, 3 and 4, with miscellaneous exercises and riders thereon; algebra as far as the theory of quadratic equations, and trigonometry to the logarithmic solution of oblique angled triangles. For its special purpose the work contains all that the student requires, put as clearly and concisely as possible, and this useful addition to the Organised Science Series will be found just the thing for pharmaceutical students who have an elementary knowledge of Euclid and algebra, and wish, as they ought, to proceed further in the study of mathematics.

'THE QUALITATIVE EXAMINATION OF POWDERED VEGETABLE DRUGS,' by Professor H. Kraemar, is a reprint from the *American Journal of Pharmacy*, of a lengthy paper given in abstract at the Baltimore meeting of the American Pharmaceutical Association. The author gives a scheme for the determination of unknown powdered drugs, confining himself, of course, to American drugs and their adulterations. So little has as yet been published in the form of definite tables or analytical charts on this subject that the details are well worthy of perusal by every pharmacist and analyst who wishes to keep up to date with recent histological investigations of drugs. Professor Kraemar gives a primary division of powders according to colour. Subsequent divisions depend on the presence or absence of fibro-vascular tissues, the presence of crystals, secretion hairs or reservoirs, reserve starch, inulin, pollen grains, and tannin masses. Animal and mineral powders are recognised by burning, and by solubility or insolubility in water, also by various chemical tests. The importance of testing powdered drugs is apparently to be recognised in the next United States Pharmacopœia, and it is evidently intended that the education of pharmaceutical chemists in the United States shall keep pace with the times.

COMPANY TRADING.

At the official reception of the new Lord Mayor of London, at the Law Courts, on Wednesday, the Lord Chief Justice spoke at length on company frauds and the necessity of further regulating company trading by special legislation. He said:—I take this opportunity—which I think is suitable for the purpose—to call your attention to another class of fraud which is rampant in this community, fraud of a most dangerous kind, widespread in its operation, touching all classes, involving great pecuniary loss to the community, loss largely borne by those who are least able to bear it. And, even much more important than this, fraud which is working insidiously to undermine and corrupt that high sense of public morality which it ought to be the common object of all interested in the good of the community to maintain, fraud blunting the sharp edge of honour and besmirching honourable names. I need not tell you I am alluding to the frauds practised in abuse of the law relating to the formation of companies with limited liability. That law has effected much good. Its object was to enable that to be done by honest co-operation of the many which could not be done by the unaided efforts and resources of one or a few. But it has been, I am sorry to say, in many cases—of course a minority, and I hope a small minority of cases, but still a minority deserving and demanding public attention—prostituted by the greed of unscrupulous persons in the hurry to obtain great wealth without being willing to put forth for its acquirement honest toil and honest endeavour. This fraud, like the mythological character, Proteus, has assumed many and various aspects and disguises; and the problem, which is not yet solved, as I conceive and as experience shows, by existing legislation, is to reconcile the useful operation of the Companies Acts with such machinery, as will minimise, if it cannot wholly prevent, the evils to the nature and extent of which I have referred. . . . I have heard it said that it is impossible to make the law more stringent, because it will frighten away from the direction of public boards honourable and honest men. I do not say that consideration is to be disregarded. Far from it; but I do not believe that any honourable and honest man who desires, according to his conscience, to discharge the trust which is imposed upon him would suffer by greater stringency of the law to give effect to the two objects to which I have referred.

THE STUDENTS' PAGE.

EXPLANATORY NOTES ON THE B.P.

Confectio Sulphuris.—The replacement of part of the syrup by glycerin will prevent this confection becoming dry. The 1885 confection when stored in an ordinary covered jar very soon formed a dry crust on the surface, due to the crystallisation of the sugar through loss of water.

Decocta.—Thirteen decoctions were official in the 1885 B.P., but only three have been retained in the present Pharmacopœia. Of the ten omitted three were made from drugs not now official, viz., Iceland moss, pearl barley, and oak bark. The decoctions of poppy, pareira, sarsaparilla (simple), and taraxacum have fallen into disuse, while the decoction of broom is omitted and an infusion of the same drug introduced. The compound decoction of sarsaparilla may also be regarded as replaced by the concentrated compound solution of sarsaparilla, which follows the old compound decoction very closely in composition, although the sarsaparilla is exhausted by infusion in place of decoction. The only decoction whose disappearance from the Pharmacopœia may be regretted is that of cinchona. Although this decoction was unsatisfactory from a pharmaceutical point of view, yet it was extensively used, for the reasons given in the Students' Page, April 24, 1897.

Emplastra.—The only important changes in this group of preparations are the omission of chalybeate, galbanum, and brown soap plasters—all three little used—and the substitution of the standardised liquid extract of belladonna for the old alcoholic extract in making belladonna plaster. This should be a great improvement, because the 1885 belladonna plaster was undoubtedly variable in its action. Other changes of lesser importance are the purification of ammoniacum for ammoniacum and mercury plaster, the omission of expressed oil of nutmeg in pitch plaster and warming plaster, reduction in the strength of menthol plaster, and the substitution of hard soap for curd soap in resin and soap plasters.

Extracta.—This group of galenical preparations has been subjected to very considerable alterations. No less than seventeen extracts, official in the B.P. 1885, have been omitted, while five new ones have been added. Of the "green" extracts only two are now retained, viz., belladonna and hyoscyamus, and the term "viride" is added to their Latin names. In the case of belladonna this addition serves the useful purpose of distinguishing more clearly the green extract from the alcoholic extract of the same drug. In dispensing prescriptions written before the issue of the present Pharmacopœia it must be carefully remembered that the term *Extractum Belladonnæ* refers only to the green extract. In the processes for preparing extracts re-percolation has been widely adopted. The principle of this is to divide the drug to be treated into several portions—usually three or four. One portion is percolated with the menstruum, and the percolate from this is passed through the second portion. The second percolate is passed through the third portion, and so on. By this means we can exhaust the drug with a smaller quantity of menstruum than is practically possible by a single percolation. This economises the menstruum—an important consideration in the case of alcohol—and less evaporation is required to reduce the percolated fluid to the required bulk or consistence.

Milk sugar is used as a diluent in several cases, the object of the dilution being to produce uniformity in the potency of the extract produced.

Belladonna Extracts.—The alteration in the name of the green extract has been already referred to. The green extract is not standardised, and will probably be less used than the other preparations of belladonna, which are all made from the new standardised liquid extract. The liquid extract is prepared by re-percolating belladonna root divided into four portions. The fourth percolate is collected until from 32 parts by weight of root $12\frac{1}{2}$ fluid parts of strong percolate are obtained. Note that the percolation is *not* continued until the belladonna is exhausted. The object of stopping the collection of the percolate at this point is to ensure that the liquor already obtained shall *exceed* in alkaloidal strength the requirements of the finished extract, viz., 0.75 part of alkaloid in 100 fluid parts. After the assay, this strong percolate is brought to the required strength by the addition of more alcohol. With regard to the alcoholic fluid remaining in the belladonna marc, the official directions say nothing. Obviously

the manufacturer may either recover the alcohol by distillation or express the liquid. In the latter case, since the expressed liquor will contain a considerable quantity of belladonna alkaloids, it may be used with advantage to commence the percolation when the next quantity of liquid extract is made. The reasons for stopping the percolation at the point indicated, instead of continuing until the belladonna is exhausted, are: First, the comparative cost of belladonna root and alcohol; secondly, the concentration of the weak percolate obtainable by complete exhaustion, beside necessitating loss of alcohol, would result in a product of varying alcoholic strength. This follows from the difference between the boiling points of alcohol and water; hence if much concentration were necessary, the residue would be comparatively weak in alcohol. This would lead to corresponding variations in the final product, since resin, colouring matter, etc., soluble only in strong alcohol, would be deposited as the alcoholic strength decreased.

To assay the strong percolate a small portion is well diluted with water and, after addition of ammonia to liberate the alkaloids, shaken with chloroform. The dilution is necessary because chloroform mixes in all proportions with strong alcohol; moreover, belladonna alkaloids are freely soluble in strong alcohol, so that they are only extracted with difficulty from even moderately strong alcohol by means of chloroform. The separated chloroform containing the alkaloids is next shaken with dilute sulphuric acid, by which they are converted into sulphates. These sulphates being only slightly soluble in chloroform, pass, therefore, almost entirely into the aqueous layer, in which they are freely soluble, and after a second agitation with acidulated water are practically all removed. The acid liquor is next agitated with chloroform to remove colouring matter, the alkaloidal sulphates remaining in the aqueous portion. This chloroform is rejected. When the acid liquor is, however, made alkaline with ammonia and shaken with more chloroform the conditions of solubility are reversed. The free alkaloid so produced is much more soluble in chloroform than water, and hence passes almost entirely into the chloroformic layer. By repeated agitation with fresh chloroform the extraction is rendered practically complete. The chloroform is then to be shaken with a small quantity of weak ammonia water, presumably with the intention of removing a small quantity of aqueous saline liquor adhering to the chloroform through incomplete separation after the preceding agitation. The chloroform solution thus purified is then evaporated in a water bath and the residue dried and weighed. If the assay process has been properly conducted this residue will consist of the mixed alkaloids of belladonna associated with a very small quantity of non-alkaloidal matter not separated by the repeated shaking out with the immiscible solvents. In order to check any possible gross error in this respect the alkaloidal residue is dissolved in excess of hydrochloric acid and titrated back with soda solution. As the quantity of material dealt with is very small, decinormal acid and centinormal soda are employed in order to get the results as accurate as possible. The calculations are based upon the fact that atropine and hyoscyamine, which should constitute almost the entire amount of the alkaloidal residue, are *monobasic* and isomeric. One molecular weight of these alkaloids ($C_{17}H_{23}NO_3 = 287.05$) will therefore combine with one M. Wt. of hydrochloric acid ($HCl = 36.19$.)

1 litre normal HCl solution contains 36.19 grammes HCl.

∴ 1 C.c. " " " " 0.03619 " "

∴ 1 C.c. N/100 " " " " 0.0003619 " "

Now 36.19 grammes HCl = 287.05 grammes $C_{17}H_{23}NO_3$.

∴ 0.0003619 " " = 0.0028705 " "

From this it is seen that 1 C.c. N/100 HCl will neutralise 0.00287 gramme of atropine or hyoscyamine. In the official process 10 C.c. N/10 HCl are used to dissolve the residue. A portion of the acid combines with the alkaloids to form neutral hydrochlorides, and the excess of acid is then determined by N/100 NaOH. If no alkaloids were present 100 C.c. N/100 NaOH would be required, since 10 C.c. N/10 HCl = 100 C.c. N/100 NaOH. The difference between 100 and the number of C.c. N/100 NaOH actually used represents, therefore, the number of C.c. N/100 HCl which have been required to combine with the alkaloids. Since each C.c. N/100 HCl is equivalent to 0.00287 gramme of atropine or hyoscyamine (*vide supra*) we can, therefore, calculate the weight of alkaloid in the chloroform residue. The weight of this residue should not differ by more than a few milligrammes from the weight calculated by the titration method.

PHARMACEUTICAL PROBLEMS OF TO-DAY.

THE time is rapidly approaching when the registered chemists of Great Britain must decide whether they desire that any steps should be taken in the public interest, during the coming session of Parliament, to secure further legislative action with regard to pharmaceutical matters. If so, it becomes essential that they should devote careful consideration to the question—What is at the same time desirable and feasible? During the past session powers have been obtained to place membership of the Pharmaceutical Society upon a more democratic basis than at any previous period in the history of the body, and as a result it is rendered possible for the trade to exert its influence more directly and with a greater prospect of success than ever before. The new Bye-laws drafted in accordance with the Pharmacy Acts Amendment Act have been confirmed and approved by the Privy Council, so that no obstacle remains in the way of any registered chemist becoming a member of the Society with the same privileges as any other member. A very large accession of new members is urgently called for, since prior to any further steps being taken in the direction of securing the reform of the practice of pharmacy, unanimous agreement, as to any line of action to be taken, is imperiously called for. Beyond that, in anticipation of the Legislature being asked to do anything more in the direction of regulating the practice of pharmacy, it is obviously above all else necessary that registered chemists should agree among themselves what they are going to ask for. The Council of the Pharmaceutical Society cannot be expected to draft any measure except as representative of the members of the Society, and it will be useless for the Council to proceed with such a measure unless it has the sympathy and active support of the great majority of the trade, for it would be hopeless to expect to achieve any satisfactory result if opposition were threatened from within the ranks.

Assuming then that it is quite out of the question to approach Parliament with proposals for any reform that

cannot be fairly justified in the interests of the public safety, and that unanimity of purpose is essential, the problem remains to single out from what seems desirable such things as are feasible. In the former category the first place must be reserved for that which the Pharmaceutical Society endeavoured unsuccessfully to secure more than thirty years ago—restriction of the sale of medicinal drugs or preparations and of the compounding of medicines to registered chemists, as well as the enforcement of statutory qualification in the case of all persons engaged in that business. Such conditions obtain in Ireland, where a distinction is very carefully drawn between persons who are legally entitled to compound prescriptions and those who are merely licensed to retail poisons, and it obtains in other countries where the practice of pharmacy occupies its proper position. By some, it is considered to be extremely doubtful whether any restriction of that kind could now be secured in Great Britain, however much it might be to the public advantage, but in any case those are the objects to aim at. Another desirable provision, which would be amply justified in the interests of the public safety, would be the general exemption of registered chemists from jury service. That again, however, might be much more difficult to secure than is apparent at first sight, for the number of educated men at present exempted from service on juries is so great that the Legislature is extremely chary of extending what it is inclined to regard as an important privilege.

Another point for consideration is the restriction to be imposed on the sale of poisonous substances. In connection with the dispensing or sale of such articles for medicinal purposes, there should be no question as to the desirability of restricting that business to persons who, by their training and special qualification, are alone competent to handle such substances with safety to the public, but how much further than that it is desirable to go, if at all, remains to be considered. Then the question of "covering" is of extreme importance. The medical and legal professions do not tolerate anything of the kind, they possess ample disciplinary powers to prevent unqualified persons profiting by the employment of the holder of a recognised medical or legal qualification as a "cover" of unqualified persons. Unfortunately, the only representative body in pharmacy possesses no such disciplinary powers, and the Privy Council, which alone can direct a person's name to be removed from the Register of Chemists and Druggists, has naturally shown little inclination to exercise authority in a matter lying so much beyond the scope of its capacity. Lastly, arising out of this question of "covering," comes the problem of trading by corporate bodies. Should Parliament be asked to make the word "person" in Section 15 of the Pharmacy Act, 1868, include a corporate body?—or must it, in the public interest, suffice to endeavour to obtain powers merely to regulate company trading and to secure special registration of all qualified managers and assistants employed by corporate bodies? Registered chemists should weigh all these problems carefully, local associations should discuss them, and no time ought to be lost in arriving at a consensus of opinion on the important matters involved. But to repeat what was said at the outset, if anything is to be done practical unanimity must be secured, all internal opposition should be neutralised, and due regard must be paid to what is practicable under existing circumstances.

ANNOTATIONS.

THE NEW BYE-LAWS.—We are authorised by the President to say that a communication has been received from the Privy Council office confirming and approving the new Bye-laws of the Pharmaceutical Society, which have been drafted in accordance with the Pharmacy Acts Amendment Act. A long-standing obstacle to membership of the Society is thus removed, as the new regulations admit of all registered chemists and druggists now becoming associated together on a footing of perfect equality within the Society. In view of that possibility and of the very general demand for further amendment of the Pharmacy Act, there should be an immediate accession of members, and before the opening of the Parliamentary session the Society should represent in that capacity not less than eight or ten thousand registered chemists. As bearing upon this matter, readers are referred to the letter by Mr. James Reid, of Dumfries, at page 522. As that writer observes, it is absurd that registered chemists should fear an appeal to Parliament because a few interested persons talk wildly about the evils of monopoly. No idea of monopoly is, or ought to be, involved in the question of further regulating the practice of pharmacy. Registered chemists, as represented by the Pharmaceutical Society, have made many sacrifices in the past to fit themselves for their peculiar duties and to elevate the status of their craft: all has been done in the public interest, for the public benefits with every advance in pharmacy, just as it benefits by every advance in medicine, in science, or in any other department of human activity.

SWEET SPIRIT OF NITRE, according to Dr. Bernard Dyer, was really official in the British Pharmacopœia of 1885, though, unfortunately, not mentioned in that publication, and wicked chemists and druggists have taken advantage of the latter fact to supply the public with an inferior article, sheltering themselves behind the plea that unless spirit of nitrous ether were asked for they were not obliged to sell a preparation of any recognised definite strength. This nefarious practice, we are told, has been fostered by certain manufacturers and wholesale druggists, who have specified in their trade lists articles of different strengths at different prices. But now virtue is triumphant, the difficulty of the (?analyst's) position having been recognised and the term "sweet spirit of nitre" given in the new British Pharmacopœia as a synonym for spirit of nitrous ether. Thus is history made by public analysts. Of course, Dr. Dyer could hardly be expected to know that sweet spirit of nitre and spirit of nitrous ether have always been understood to be two totally different things, and that the chemist's customer who required sweet spirit of nitre has been apt to protest when offered spirit of nitrous ether at a higher price. The fact that the Pharmacopœia confuses different preparations by its misapplication of synonyms proves little beyond the fact that the compilers of pharmacopœias are not always infallible.

IN THE REPORT BY DR. DYER, upon which the foregoing note is based, he informs the Leicester County Council that a collection of samples of sweet spirit of nitre had been made in order to ascertain how far the official article is now being supplied. The result of the investigation was, on the whole, satisfactory and, in the analyst's opinion, it speaks well for the honour and integrity of the chemists of Leicestershire as a body that, out of fifty-one samples purchased, only seven were of such a quality as to call for complaint. But in

this connection the report affords evidence of a practice that has been steadily condemned in these pages for many years past, for Dr. Dyer avows having been in consultation with the Chief Constable, Mr. Holmes, with regard to the further steps to be taken in the matter. Thus, he states that "it was decided by Mr. Holmes, after consultation with myself, that, under the circumstances, the most appropriate way of dealing with those who supplied the inferior articles was to caution them, and direct their attention to the fact that the law now imposed upon them a responsibility in the matter of this drug, which could not in future, as heretofore, be set aside on the ground of the omission from the Pharmacopœia of its popular name." The course decided upon was a very proper one under the circumstances, but the public analyst ought not to have had any voice in the matter. His duty is to report on the composition of samples submitted to him, and nothing more.

THE SUPPLY OF CALCIUM CARBIDE is already a matter of considerable importance, owing to the rapidly increasing use of acetylene, which has pushed the demand for the carbide so close to the present limit of available supply that the questions of increased productive capacity, the future output, and probable price of this new and important material assume a definite international interest. The *British Journal of Photography* understands that the use of acetylene, and consequently the consumption of carbide, has increased somewhat more rapidly in America than in Europe, and that, notwithstanding the large output at Niagara Falls, the home demand has rather more than kept pace with the supply. The latter may practically be also said of Europe, at least of Germany, which country obtains almost its entire supply of carbide from Switzerland, notably from the great works at Neuhausen. The whole carbide industry, so far as Central Europe is concerned, is now in a transition stage, and the conditions of supply and price are likely to be greatly modified by the increased production of next year. The most important accession will probably come through the operations of a great combination headed by the Schuckert Electrical Manufacturing Company at Nuremberg, which expects to have in operation during the course of next year four carbide factories, the aggregate annual product of which is estimated at 20,000 tons, capable of generating 211,896,000 cubic feet of acetylene. Besides these plants the Aluminium Industry Company, of Neuhausen-on-Rhine, has this year increased its capital to £640,000 for the purpose of constructing a 7500 horse-power plant at Land-Gastein, in Austria. All these establishments will employ the original process, by which the lime and carbon are smelted together by the heat of an electric current.

TO STUDY THE INDIAN PLAGUE it has been decided, on the recommendation of the Government, to send to India a commission, consisting mainly of scientific experts, to report upon the plague. Dr. Thomas R. Fraser, F.R.S., Professor of Materia Medica and Clinical Medicine at Edinburgh University, and an honorary member of the Pharmaceutical Society, has accepted the post of President, and with him will be associated two other scientific experts, Dr. Wright, Professor of Pathology at the Army Medical School, Netley, and Dr. Rüffer, who has been for some time head of the Egyptian Sanitary Department at Cairo. Two officers of the Indian Civil Service, Mr. J. P. Hewett, C.I.E., and Mr. A. Cumine, both of whom have had much to do with recent plague affairs in India, have also been appointed to the commission by the Government of India. The scope of the commissioners' inquiries will include (1) the origin of the different outbreaks of plague; (2) the manner in which the disease is communicated; (3)

the effects of certain prophylactic and curative serums that have been tried or recommended for the disease. The members of the commission are expected to reach Bombay towards the end of the present month.

THE ARMY MEDICAL SERVICE is apparently not yet all that the profession could desire, for the Royal College of Surgeons of Edinburgh has addressed a memorial to the Secretary of State for War, bringing under his notice its opinion in regard to certain changes which it deems necessary. The present regulations for the competitive entrance examination are thought to be not well adapted to secure the best men. Too much importance seems to be given to elementary subjects, and too little to the practical and clinical work which now occupy the latter years of professional study. It is urged, therefore, that the compulsory part of the competitive examination should be limited to those subjects with which the student is mainly concerned in his last two years of study—namely, surgery and medicine. Further, it is represented that the non-existence of a system of "study leave" in the Army Medical Service is a serious impediment to the efforts of the ordinary medical officer to keep abreast of the progress of medical science, and the memorial says it is essential that the Army medical officer should have a period of leave afforded him for practical study, and that some advantages should be accorded him in recognition of such further study. Finally, the view is expressed that, if improvements on the lines indicated were introduced, the Army Medical Service would be better fitted to attract young medical men of talent and to attain to that state of high efficiency which it is alike the duty and interest of the country to secure.

THE HAMPSTEAD GUARDIANS have been investigating the expenditure on drugs used in their sick wards. The bill for drugs purchased in 1897 for the infirmary, probably the smallest of the metropolitan Poor Law infirmaries, amounted to £462 14s. 2d. It is alleged that there is evidence of over-purchase of medicines and of excessive charges for drugs generally. For example, bottles in considerable number of proprietary emulsion, bought eighteen months ago, remain on the shelves untouched and unneeded, and it is suggested that they have probably become worthless through deterioration. Then, according to *London*, "Pills that could be made for 1d. or 2d. have been obtained from a local chemist at a cost of 1s. 6d. or 2s. Strong extracts of drugs have been used in cachets, expensive articles made under a French patent—so expensive that they are rarely used except by the rich. The difference in cost between using these cachets and administering medicine in the ordinary manner is represented by the figures 1s. 8d. and 12s." The Vice-Chairman of the Board is reported to have said that if the Board employed a dispenser at a salary of £120 a year, it would save money. Other guardians thought that the saving would be still larger. To begin the work of economy, the guardians have decided to appoint a dispenser, who will probably be a lady.

ETHERION, A SUPPOSED NEW GAS, was the subject of an abstract recently published in the *Chemical News*, of a paper by C. F. Brush, and in the same journal, for November 14, Sir William Crookes brings forward the results of some old researches, published and unpublished, which tend, in his opinion, to show that the supposed new gas may be nothing more than aqueous vapour. He abstains from making any positive statement until Mr. Brush's complete paper comes to hand. The supposition that etherion is

nothing more than aqueous vapour rather than a new elementary gas is corroborated by Mr. Brush's observations that etherion is absorbed by phosphoric acid and soda lime, as well as by the powdered glass from which it has previously been driven off by heat. The most remarkable property claimed for etherion is its heat conductivity, which is twenty-seven times that of hydrogen at a pressure of 0.38 of a millionth of an atmosphere. Though Sir William Crookes has not yet tried the experiment at a pressure below a millionth of an atmosphere, since at such high vacuum water-gas gains so rapidly on hydrogen, he is prepared to believe that the ratio may even be as great as that ascribed to etherion.

THE FIRST OPTICAL EXAMINATION conducted by the Worshipful Company of Spectacle Makers was held on Tuesday, Wednesday, and Thursday of last week at the Northampton Institute. The first and second days were devoted to the *viva voce* examination, and on the third day the written part of the examination was taken by all the candidates, of whom there were about a hundred. The examiners were Dr. Lindsay Johnson, Professor Silvanus Thompson, and Mr. George Paxton. It would have been difficult to find three men who could have performed the duties of examiner better or so entirely to the satisfaction of all concerned. The examination was a modified one, inasmuch as it was based on visual optics alone, and intended only for those who have been dealing in optical goods for seven years or more, but it was by no means modified as to its scope. Among the candidates were some of the oldest established retail opticians in the country. Each candidate was taken in hand by each examiner in turn, and the arrangements were carried out most successfully, thanks to the untiring efforts of the Master of the Company, Mr. W. H. E. Thornthwaite, and the clerk, Colonel T. Davies Sewell, both of whom personally looked after every detail beyond the actual examination of the candidates.

THE CHEMISTS' ASSISTANTS' ASSOCIATION will hold its annual reunion in the Grand Hall, Freemasons' Tavern, on Thursday, November 24, at 8 p.m., when the chair will be taken by Mr. R. A. Robinson, L.C.C., and the vice-chair by Mr. Frank A. Rogers. This meeting, which is to take the form of a smoking concert, is intended to replace the *conversazione* formerly held annually, that trinitarian function having gradually become somewhat obsolete. The exhibition that used to be held failed to attract attention, the concert room was usually in great measure unoccupied during the performances, and the dance has been supplanted by the Cinderellas held at intervals during the session. An excellent programme has been arranged for the smoking concert on Thursday week, the services of several prominent performers having been secured, and early application should be made for tickets (1s. 6d. each) to Mr. C. Morley, 3, Bucklersbury, E.C.

PNEUMATIC CHEMISTRY, which formerly led to important technical results, has in its latter-day development been less productive of utilitarian knowledge, but it has revealed the existence of material entities which appear, by their enigmatic nature, to raise a question whether they are to be regarded, as it were, as fossil remains of a former state, or as representing stages of incompleting evolution. By the discovery and study of these bodies, of which Professor Ramsay gave such an interesting account last Tuesday, his name has been added to the honourable list of British investigators who have been conspicuous for their work in the same direction during the last two hundred years.

CHEMISTS' ASSISTANTS' ASSOCIATION.

Thursday, November 3, was the date fixed for the reading of short papers by members of this Association, but, with the exception of several short communications by Mr. H. E. MATTHEWS, the Hon. Secretary, none of the papers reached 73, Newman Street, W., in time to be read that evening. However, five new members were proposed for election and it is hoped that these may, in future, succeed where the older members failed.—Mr. F. W. GAMBLE, the President, occupied the chair, and after expressing his regret at the smallness of the number of papers submitted, announced that under the circumstances he intended to inaugurate an old, yet as far as the C.A.A. was concerned, a new method of discussion. Each member present would have a blank piece of paper handed to him to write any question relating to pharmacy upon which he wished to hear the opinions of others. The papers would be collected and again distributed, each one being expected to speak upon the question on the paper. Should a member receive his own question to answer he would exchange it for another.

Mr. MATTHEWS then proceeded to read a note on

Pulv. Rhei Co.

It is well known that there is some difference of opinion as to the best method of preparing Gregory's powder, various authorities stating that its miscibility with water is affected by the degree of pressure to which it is subjected in mixing, but there being no agreement among these authorities as to what is the best method. Some assert that considerable trituration of the powders in mixing results in a preparation that readily mixes with water, while others maintain that such a preparation is only obtained by lightly stirring the ingredients together with a knife. To clear up the matter, experiments were made with three quantities of powder, prepared as follows:—No. 1, by considerable trituration of the ingredients in a mortar, with heavy pressure; No. 2, by moderate trituration, with light pressure; No. 3, by lightly mixing on paper with a knife. A portion of each of these differently prepared powders was then mixed with water, with the result that no difference at all in degree of miscibility could be detected between any of the three. It is possible that the contradictory statements which have been made about this matter have been caused by the varying amount of oil contained in powdered rhubarb, which would of course materially affect the miscibility with water. This seems to be supported by the fact that in the above experiments, where the same rhubarb was used in each case, there was no variation in the degree of miscibility.

Mr. MATTHEWS next read a note on

A Method of Separating Magnesium and Lithium.

In the analytical separation of the bases, the residual metals, after the removal of the fourth group by means of an alkaline carbonate are magnesium, lithium, potassium, and sodium. General text-books of chemistry classify lithium as a rare metal and often exclude it from analytical schemes; in pharmacy lithium falls into the category of bases of common occurrence. When a mixture of salts, which may contain either magnesium or lithium or both, is under examination, the following method is useful for their detection:—Test a portion of filtrate from group iv. for magnesium and lithium with di-sodic hydrogen phosphate. If a precipitate forms, evaporate another portion of the solution with a little sulphuric acid to remove HCl, dilute and add sodium hydroxide. Most of the Mg but no Li is precipitated as hydroxide. To the filtrate add di-sodic hydrogen phosphate, lithium, if present, is precipitated as basic phosphate together with the remaining traces of magnesium. The flame test is always sufficient to determine whether lithium is present in the precipitate. To confirm magnesium wash the precipitated hydroxide and apply the flame test to prove lithium absent. Dissolve the washed precipitate in HCl, add Na_2HPO_4 and ammonia, the magnesium is precipitated as phosphate in the cold.

A third note by Mr. MATTHEWS was on the

Identification of Soluble Ferricyanide, Ferrocyanide, and Cyanide when Mixed Together.

To an aqueous solution containing a cyanide, a ferrocyanide, and a ferricyanide add excess of lead acetate; lead cyanide and lead ferrocyanide are precipitated. Filter off the precipitate and detect ferricyanide in the filtrate by means of a ferrous salt. Wash the precipitate rapidly until free from ferricyanide, and finally wash it into a test-tube. Add a little acetic acid and cover the

mouth of the test-tube with a cap of filter paper moistened with yellow ammonium sulphide. On warming gently the lead cyanide is decomposed, evolving HCN, which forms ammonium thiocyanide with the ammonium sulphide on the cap. A drop of ferric solution serves to detect the formation of thiocyanide. When the whole of the lead cyanide has been decomposed by gently boiling the contents of the tube for several minutes in a fume chamber, wash the residual lead ferrocyanide, dissolve in KOH, add ferric chloride and then excess of HCl, and the solution gives the reaction of a ferrocyanide.

The PRESIDENT said their thanks were due to Mr. Matthews for preparing the papers, especially as he had been doing the work of two secretaries, owing to the ill health of the Financial Secretary, Mr. C. E. Pickering. With regard to the subject of Gregory's powder, it had been much to the front during the past few weeks, and there seemed to be an opinion amongst some chemists that the age of Gregory's powder has something to do with its miscibility. It was difficult to reconcile that opinion with the reason given by Mr. Matthews. Personally, he was inclined to agree with him, because age would increase its miscibility rather than not.—Mr. T. MORLEY TAYLOR thought that it did not much matter what process was employed in mixing pulv. rhei co, if the powder was to be sifted afterwards.—Mr. MATTHEWS agreed with the opinion that age would make the powder more easily miscible with water, also that the method of mixing the powder would not materially affect its miscibility if it was sifted.

Impromptu Discussion.

Pieces of paper were then distributed to those present, and after being collected and re-distributed, Mr. Charles Morley was asked by the President to reply to the question on his paper, viz, When magnesium carbonate is one of the ingredients of a prescription, should the heavy or light be used?—Mr. MORLEY said it was the common practice to use the heavy variety when mag. carb. was specified. There were certain questions which a candidate for examination at Galen Place might safely put to an examiner when dispensing, but if called upon to dispense magnesium carbonate he should advise any candidate not to put that question, or he might be "sat upon."—Mr. MATTHEWS was desirous of knowing why the heavy is used instead of light, seeing that the light shakes up better.—The PRESIDENT said that when he inaugurated the new method of discussion he did not anticipate being made the butt of all the questions.—Mr. MORLEY remarked that if it were left to his discretion he should prefer to use the heavy, as it seemed to be more easily manipulated.—Mr. GEORGE ROE was asked if it is advantageous for a chemist's assistant to have some knowledge of drug-store business methods. Personally Mr. Roe had very little knowledge of retail pharmacy, but he could not help admiring the way in which the drug stores display their goods in the windows. Of the modes of procedure inside he could not speak, but he should imagine that a man might become smarter in putting up goods in a store than in an ordinary retail pharmacy. From a pharmaceutical point of view, however, he thought an assistant would not gain much useful knowledge.—The PRESIDENT differed from the expression of opinion as to smartness in putting up goods, inasmuch as he believed that the majority of store goods were factory put up.—Mr. MATTHEWS thought there was not much real good to be obtained from stores, while Mr. George Pearson was inclined to think an assistant might become more proficient in "stock-keeping" by a store experience.—Mr. MORLEY had no experience of drug stores, but if he could do so without sacrificing his self-respect, he, personally, would like to serve in one for a short time, as he believed a good deal may be learnt there.—Mr. T. MORLEY TAYLOR was in possession of a paper which asked "How will the increased study of preventive medicine influence pharmacy, and what difference will it make to the pharmacist?" He thought that was rather a "tall order" to answer straight away, but it was a question which might very well form the subject of an interesting paper. However, all would probably agree that the practice of preventive medicine will affect pharmacy by the introduction of new medicines, while the pharmacist will be required to have a good knowledge of antitoxins and similar things that, as a rule, he now knows very little about. As events are moving at present, Mr. Taylor thought it possible that in one hundred years from now pharmacy might be "knocked out," but at the same time he did not think it at all probable.—Mr. G. PEARSON was asked to state where a pharmacist may obtain material for bacteriological research. It was

not quite clear what kind of material was required, but if the questioner had no knowledge of the subject Mr. Pearson suggested that he might apply to one of the institutions where bacteriology is taught, or he could recommend Cruickshank's work as a useful source of information.—The PRESIDENT thought that bacteriology was a question that would affect pharmacy in the future, so that chemists ought to have a knowledge of the subject.—Mr. J. FOTHERGILL, in reply to a question as to whether "pharmacy is worth going in for," said he was not inclined to express any opinion on the matter, except to say that it depends very much upon the man who is going in for it.—Mr. MATTHEWS seemed to think it depends to some extent upon the object a man has in view when entering pharmacy.—The PRESIDENT was of opinion that most men entered pharmacy through circumstances over which they had in a measure no control. It was about as good a business as one could go in for, and, personally, he had no higher ambition than to be a good chemist, and he thought that others too would find it to be a good thing.—Mr. SOWDEN was called upon to say if chemists ought to advertise. Certainly! was the answer briefly put. Chemists must advertise if they wished to reach "the top of the tree." Those who had already attained to that coveted position were there largely because of judicious advertising.—As the hour was rather late the PRESIDENT intimated that no more questions need be answered that night, unless someone had a burning desire to express his opinion on any subject not previously mentioned. No one being possessed of such a desire, he went on to observe that the new method of discussion seemed to be rather good, as it had turned what would otherwise have been a dull evening into a very pleasant one. It had, at any rate, imparted a certain amount of life into the meeting.—The proceedings then terminated.

PHARMACEUTICAL SOCIETY OF IRELAND.

The monthly meeting of the Council was held on Wednesday, the 2nd instant, at 67, Lower Mount Street, Dublin.—The PRESIDENT, Mr. R. J. Downes, was in the chair, and the other members of Council who attended were Messrs. Grindley, Kelly, Michie, Bernard, Britain (Drogheda), Connor (Newry), Wells, and Dr. Walsh.—A letter from the Under-Secretary, Dublin Castle, enclosed a copy of a memorial from James Hogg, who had been fined £5 at Belfast Petty Sessions for unlawfully keeping open shop for compounding medical prescriptions, asking the Privy Council to remit the fine.—The PRESIDENT read a copy of a letter which he had addressed to the Lord Lieutenant and Privy Council on the subject, pointing out why the fine should not be remitted or abated.—On the motion of Mr. BERNARD, seconded by Dr. WALSH, the President's letter was approved of.—A letter from Mr. William J. Wade, in reference to an application made by him to be admitted to the Licence examination, was considered, and the matter was deferred until the next meeting.—A letter from the Board of Inland Revenue stated that they saw no reason why there shall be any change in the law with regard to the sale of methylated spirits.—Mr. BERNARD: I do not think the grocers are allowed to have it.—The PRESIDENT: They are. They may keep it on sale, provided it is not consumed on their premises. I was written to by the Board for information on the subject, and informed them of a fact which I had ascertained, namely, that a woman walks along the banks of the canal at night laden with noggin bottles of methylated spirit, which she sells at 6d. apiece.—Several reports were disposed of. One from the School Committee stated that they could not accede to an application which had been made on the part of students in the Botany and Materia Medica School, asking that those who desired to supplement their courses should not be charged an additional fee.—Dr. H. C. Tweedy and Mr. S. Brown were elected to conduct the Preliminary examination; Mr. J. Smith was elected examiner in the botany and materia medica division of the Licence examination; Mr. J. Guiler and Dr. D. J. McKenny were elected to hold the Registered Druggists examinations in Dublin and Belfast; and Mr. W. V. Johnston was elected to hold the Pharmaceutical Assistants examination.—A motion, of which the Vice-President had given notice, relating to the Licence examination, was postponed.—The following gentlemen were elected members of the Society:—Mr. James Allen, Lisburn; Mr. David Smeaton Bennett, Cork; and Mr. Edward M. D'Arcy, Dublin. The Council then adjourned.

MIDLAND PHARMACEUTICAL ASSOCIATION.

The winter session of this Association was inaugurated on Thursday, November 3, when the members and their friends assembled at the Grand Hotel, Birmingham, in considerable numbers. The chair was taken by Mr. JEFFREY POOLE, President of the Association, and Mr. G. CLARIDGE DRUCE, M.A., F.L.S. (Oxford) gave the

Inaugural Address.

At the outset, Mr. Druce touched briefly on professional topics, admitting at the same time that so much had been said and written about the subjects pharmacists had at heart that he felt like a traveller over a country which had been despoiled by locusts, so few and far apart were the relics of vegetation which he could gather. They followed, he said, an anomalous business. Originally it was mingled with the practice of medicine when that was the only professional rival of the priest-craft, and probably these were formerly united so that the priest was also the physician, having literally the gates of life and death and the fears rather than the hopes of the future at his command. In the course of the ages segregation took place, not only as regarded the priest and the physician, to whom the whole question of medicine in its widest sense was for a long time entrusted, but also in the separation of the physicians from the crowd of surgeons, barbers, empirics, sorcerers, and magicians. In 1518 the physicians succeeded in obtaining a charter, and in 1748 the apothecaries were equally fortunate. Just as the physicians were jealous of the apothecaries and surgeons, so in turn the apothecaries attempted to obtain penal powers over the chemists and druggists. To aid in resisting these attempts there was formed in 1794 a Pharmaceutical Association, which met at the Buffalo Tavern, Bloomsbury Square, but it was short-lived, and failed to carry out the objects for which it was formed. In 1802 the chemists and druggists successfully resisted the apothecaries' Bill of that year, which seriously threatened their interests. In the year 1841 another attempt was made, by the Bill to amend the laws relating to the medical profession in Great Britain and Ireland, to circumscribe the privileges of their trade, but this also was defeated, and indirectly led to the foundation of the Pharmaceutical Society, which was established in that year for the purpose of protecting the permanent interests and increasing the respectability of chemists and druggists, on the proposal of Wm. Allen, seconded by John Bell, on April 15, 1841. The *Pharmaceutical Journal* was issued during the same year. The School of Pharmacy was founded in 1842, and a charter of incorporation was granted in 1843. There was no need to trace the subsequent history of legislation affecting the business, nor the adverse interpretation of it made in some instances by the judicial tribunals; and, indeed, he had only introduced this summary of their history in order to show what were the original objects of the founders of the Society. It was founded primarily as

A TRADE DEFENCE SOCIETY,

while the object of increasing the respectability of the trade and making it in some sense a profession was a secondary motive. It could not be denied that for many years the primary object, if not lost sight of, was at any rate relegated to an unobtrusive position, and education, which the passing of the Pharmacy Act rendered to some extent an obligation, became almost the one idea of the Council, who appeared to be under the impression that a bold defence of the business rights of pharmacists was derogatory to the respectability of its members. They were grateful for the change of policy which now appeared to animate the Council, but so long as the Pharmaceutical Society received no support from the great mass of the trade so long must its powers be limited when fighting vested interests. With the increase of members greater pressure would be brought to bear upon their representatives on the Council, and a more forward policy would doubtless ensue. On these matters he did not intend to dwell. He might, however, be permitted to say a few words about the system of examination. He recommended those who had not already made acquaintance with it to read the excellent and very comprehensive address of Sir James Crichton Browne, and to mark the wise words of caution against making the Minor examination too severe. He particularly welcomed the suggestion Sir James made, that the examination should be divided into two parts, and especially did he agree with the manner in which Sir James would have the subjects divided. Sir James suggested chemistry, physics and botany as the subjects

to be taken in the first examination, and that the second or qualifying examination should be devoted to *materia medica*, pharmacy, and dispensing. Why he so warmly agreed with this subdivision was because he held that the primary object which influenced the founders of their Society and the view taken by the Legislature and the public was that their examinations should be essentially for a pharmacist, and that no botanist, however well read, nor any chemist, however proficient, was qualified to be a chemist and druggist unless he shall be a competent pharmacist. He dissented from the idea that a mere laboratory course of botany or chemistry was sufficient, and he viewed with regret the comparative effacement, or, at any rate, the subordination which pharmacy was being made to undergo in the process of examination. He was not in any way wishing to minimise the importance of the two sciences which were the foundation of the pharmacist's knowledge, but he would most certainly make them subordinate to pharmacy. He saw that this might be better accomplished by accepting this

DIVISION OF THE MINOR EXAMINATION

into two parts. But he must hark back for a moment in order to allude to the obvious fact that the two sciences he had mentioned were in themselves so wide and vast that it was evident only a comparatively limited knowledge of them could be acquired. This was especially true of botany, which really consisted of several sciences. He was afraid he should be considered old-fashioned when he expressed the belief that they would do well to make the teaching of these sciences as technical as possible. There were some high in authority who held that there was no such thing as pharmaceutical chemistry or pharmaceutical botany. He was not going to meet this idea with a flat contradiction, but it did appear to him possible to utilise examples having direct interest to the pharmacist. A student of mineralogy, to whom chemistry was important, was taught a technical chemistry which differed widely from that needed by their own business, and as far as possible it should be chemistry as adapted to pharmacy which should prevail in their schools of pharmacy. In botany he deplored the undue growth of the physiological and histological branches of the subject, and the subordinate part morphology appeared to be doomed to play, while systematic botany was almost pushed out of their syllabus. Now physiological botany as a science was one of great importance, but so far as it bore upon their business it possessed no special value, so that anything more than an elementary knowledge was not needed. On the other hand, the advantages to be gained from a course of histology could scarcely be over-estimated, since the powers of observation, the dexterity of preparing sections for the microscope, the knowledge of the proper use of reagents, and the skill of the pencil to delineate the objects examined were all stimulated and heightened by such study, while the knowledge obtained might be of great assistance in the future calling of the student. He also looked upon morphological teaching as highly necessary, since it equally cultivated the powers of observation, while to the proper study of *materia medica* morphology was an essential adjunct. The outlines of systematic botany should also form a part of instruction. Not only was it necessary for obtaining an idea of the wonderful variety of plant structure on this planet, but it enabled them to see in what manner certain characters were found to be peculiar to certain groups, and it trained the mental faculty to appreciate and understand that order to which all creation moved. For other reasons, what was sometimes contemptuously called field botany was most highly to be recommended to the pharmacist as not only a study but a recreation, the more so now as it was alienated from the course of study of medical men. Of chemistry he need say nothing more, except again to express the hope that the teacher would bear in mind that it was for a pharmacist that the teaching was needed, and that, as in botany, one would like the *materia medica* to be the sources wherever possible for the objects taught and demonstrated. The first examination, therefore, would clear

THE SO-CALLED PROFESSIONAL SUBJECTS,

and with the knowledge thus obtained the student would with good auspices attack the remaining subjects, namely, *materia medica*, pharmacy, practical dispensing, and prescription reading. This second examination might conveniently occupy two days, as he considered three hours insufficient to comfortably examine a student in both practical pharmacy and dispensing, and he held that it should be conducted only by qualified pharmacists. He would relegate as far as possible the calculation of intricate percentages to the examina-

tion in prescription reading, as in that the candidate was not worried by his fellow students continually jostling him, nor by the nervous strain involved by attending to his other preparations. In adopting this course, one day would be devoted to the oral examination in pharmacy, prescription reading, and *materia medica*. In this way, he thought, the extremely high percentage of failures in the Minor examination might be reduced, as at present, although the subjects in themselves were not abnormally difficult, nor was there, he was convinced, too high a standard set for any undue severity in one subject, yet the large number and wide range which these subjects covered, compressed as they were into too small a space of time, assisted in making it a very difficult examination. He believed that not only would the percentages of passes improve, but what was even of more importance to the craft, the candidates would possess a greater practical knowledge of pharmacy; and the reproach which was not infrequently urged—and, he was afraid, not entirely without reason—that an examined man was not necessarily a better pharmacist than his unqualified neighbour, should not be heard. This reproach their system of education should do all in its power to avoid. The way to avoid it was not to hand over their qualifying examination to scientific men who had had no experience of the art of pharmacy. In the Major examination he would restore pharmacy as a subject, and in place of combining *materia medica* with botany he would give the former a distinct position. The knowledge of drugs, their adulterations and qualities, was of infinitely higher importance to a pharmacist than that of botany, which indeed might be deleted from the final examination, or at any rate be made to occupy a subservient position as formerly it did for many years. In fact, to summarise, let them endeavour to bring back to their examinations the appreciation of technical knowledge which was to be obtained in the pharmacy rather than in a cramming school, at the dispensing counter, not less than from text-books and manuals. Mr. Druce then proceeded to deal in a most interesting fashion with the history and peculiarities of the different monarch trees to be found in the British Isles, his remarks being well illustrated by an excellent series of views thrown upon the screen by Mr. C. F. Jarvis (Handsworth).—Mr. T. BARCLAY, proposed a vote of thanks to the lecturer, which was seconded by Mr. ELLIS, and carried amid applause—Mr. DRUCE having replied, a musical programme followed and light refreshments were served before the company separated.

IRISH PHARMACISTS' ASSISTANTS' ASSOCIATION.

At Dublin, on November 4, the third annual opening meeting of this Association was held at 67, Lower Mount Street, the newly-elected PRESIDENT, Mr. Henry Hunt, in the chair. There was a large attendance. The minutes of the last meeting were read and confirmed, and seven new members were elected.—The SECRETARY read extracts from the proceedings of the last committee meeting, referring to the establishment of an employment agency and to the holding of a concert early in December.—Mr. WILLIAMS objected to committee work being made public. His contention was upheld, and the matter was postponed until the Committee met at the close of the general meeting.—On the motion of Mr. WILLIAMS, seconded by Mr. JONES, it was resolved in future to keep the minutes of committee meetings separate from those of general meetings.

The President's Address.

Mr. HUNT then delivered the presidential address. He traced step by step the progress of the Association from its inception three years ago to the present time, and alluded to the many interesting functions held under its auspices. The financial position of the Association was sound. It was well supported by employers and assistants, and continued to successfully carry on the work for which it had been formed. The publication of the new British Pharmacopœia provided a wide field for work and discussion, and he hoped many members would contribute papers upon it. Pharmaceutical history during the year had been enriched not only by the publication of a new B.P., but by a considerable amount of legislation, successful and otherwise. During the last two sessions, ten per cent. of the members of the Association had become proprietors. Mr. Hunt then referred to the Poisons Bill introduced last session, and stated that it was not improbable that a second Bill, dealing with the distribution of poisons, might be introduced next year, and it would be advisable for all who were

qualified to obtain the benefit of the franchise and enlist the sympathies of any Members of Parliament they might be able to approach. He did not intend to allude to the rights or wrongs of company pharmacy, but would ask qualified assistants to remember the fact that they were essential to the company promoters, and should place a proper price upon their services. He was glad to find that the committee were making arrangements to establish an employment agency in connection with the Association. Owing to their limited resources, they could not attempt anything on an ambitious scale, but he thought a register of vacancies, kept by the Secretary, would be of much use to assistants and employers. Its utility could only be estimated by a practical trial, and, if successful, it would be an inducement to country assistants to become members. Mr. Hunt concluded by asking those present to make the success of the Association a personal matter. Some years ago there would have been no room for an assistants' association, as, with most of their predecessors, pharmacy was but the stepping-stone to medicine, the leisure time of the assistant being spent in the dissecting room or the lecture theatre. The old order had changed—most of the assistants had now to make pharmacy their life work. Let them endeavour to put their best energies into it and make pharmacy worthy of being called, not the handmaid, but the sister of medicine.—Mr. JONES said they all ought to be much obliged to the President for his very able address. It was gratifying to learn that their membership was on the increase, and it was only by keeping united that they would advance.—Mr. WILLIAMS spoke on the *personnel* of the Association. He thought it would be advisable if a request were made to the proprietors for a donation to put the new employment agency into operation at once. Seeing that 10 per cent. of the members had last year become employers and 10 per cent. the year before, it followed that there were now 20 per cent. of their friends in a position to help them. It was absolutely necessary to have an office for the carrying on of an employment agency, and where country members and others could meet one another. They would double their members when the new departure came to be known generally. He thought the balance in hand would be well invested in an office.—Mr. CONYNGHAM highly commended the Committee for starting an employment agency. There should be a list kept not only of members but a reference list of country members requiring employment. A small fee might be charged for the service, and that would add to the Association's income. He considered that having a register of vacancies would bring the young men of pharmacy together. It was a great hardship for assistants to be obliged to come up to Dublin for their examinations. That very fact kept down the market price of assistants. The youth coming up to Dublin from the provinces had to choose in most cases between idleness while reading for his examination or taking a situation at whatever salary offered. The result was that advantage was taken of his desire to work and study, and the general body of assistants suffered in consequence. He thought the Society ought to be compelled to widen its doors and to establish local examination centres in the principal towns of Ireland, such as Cork, Limerick, Galway, etc.—Mr. SAVAGE said the employment registry was now an accomplished fact. They proposed circularising all the employers in Dublin, and were open to receive lists of "wants" and "wanted."—Mr. CONYNGHAM: By paying a fee.—Mr. SAVAGE said that was an excellent suggestion, and the Committee would give it their best attention.—Mr. ASHE said the Committee's proposal was good in theory but they ought to move very carefully in a matter of that kind. Their funds were not large enough to carry out the scheme properly, and they might later on be sorry at having embarked in the matter.—Mr. JONES said they were not ungrateful to the Society, and their feelings towards that body were shown in a resolution passed at the last meeting, thanking the Council gratefully for past and present kindnesses. The assistants were a strong, loyal, and intelligent body, and could not be blamed for striking out a distinct line for themselves.—The PRESIDENT said they were in perfect accord with the Society. The suggestion to combine an office with a place where country members might meet their friends, where committee or special meetings could be held, and where the daily newspapers could be read nightly was a feasible one and not difficult to put into practice.—Councillor KELLY approved of the Association having a room where its members could meet and read the chemical and other journals, and Mr. CONYNGHAM offered to guarantee half the amount required for the rent of such a room.—On the motion of Mr. ASHE, seconded by Mr. SAVAGE, a vote of thanks was accorded to Mr. Conyngham for his liberality.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

THE NEW TEXT BOOK ON PRACTICAL PHARMACY.

Sir,—The writer of a book on such a subject as I have ventured to take up, necessarily lays himself open to a good deal of criticism. I freely admit the clerical and other errors—many of which I discovered too late for correction—and I am much obliged to all those who have taken the trouble to point them out. On the other hand, there are many points to which exception has been taken which are matters of opinion, and I shall be quite ready to defend my position when a proper occasion offers. While saying this I feel bound to add that those who undertake the criticism of a work should be careful not to misinterpret the statements of the author, and I hope that you will see the justice of publishing the following extracts from your criticism of October 22, with my remarks thereon.

'PHARM. JOURNAL' REVIEW.

Page 441, line 7.

"The author should not appear to imply that he would countenance an error of 5 grains in a weighing machine, the maximum load of which is 1 oz."

Page 441, line 39, *et seq.*

"There is a little confusion of ideas If pure water be supplied to a boiler, the use of a pump does not contaminate it so much as to spoil the condense, but if oily water be fed to the boiler by an injector, the use of the latter in place of the pump would not improve the quality of the condense."

Page 442, line 52.

"The statement at p. 194 that ordinary potash ley is now used in making hard soap is at least questionable."

Page 442, line 31.

"At p. 332, dried sulphate of iron of the Pharmacopœia is said to be of uncertain composition, a statement which is scarcely justified."

Page 443, line 17.

"No authority can be found for the statement that bleaching powder may be considered as consisting of Ca(OCl)Cl."

Page 443, line 21.

"No authority can be found for the statement that ethylic alcohol is always the product of vinous fermentation."

REMARKS.

Lucas' 'Pharmacy,' page 16.

This table of the limit of error in balances is accurately extracted from the Weights and Measures Act.

Lucas' 'Pharmacy,' page 58.

A pure water *may* be made oily by passing through the pump attached to a steam engine, but it cannot be contaminated in this way by passing through an injector, since the latter does not need lubricating.

Authorities.

Crookes' Wagner's 'Chem. Technology.'

Alder Wright's 'Manual.'

B.P., 1898, says:—

"Residue should weigh about 60 per cent. of the original salt. One gram should require at least 54.6 C.c., etc., corresponding to at least 92.5 per cent. of FeSO₄.H₂O."

Authorities.

Thorpe's 'Dictionary,' vol. i., p. 525, Ca $\begin{matrix} \text{OCl} \\ \text{Cl} \end{matrix}$ and later Ca(OCl)Cl. See also Lunge, Odling, Tilden, etc.

Lucas' 'Pharmacy,' page 129, line 6.

"Ethylic alcohol is always a product of vinous fermentation."

Page 443, line 22.

"No authority can be found for the statement . . . that in the preparation of ferrie chloride, nitric oxide, and oxygen are evolved together."

(The italics are mine.)

I will not take up more of your space, except to say, with regard to "Student's" letter of November 5, that the Pharmacopœia statements as to solubilities cannot always be depended upon.

London, November 7, 1898.

E. W. LUCAS.

* * In view of this departure from ordinary usage, Mr. Lucas' complaint of misinterpretation of the statements criticised may call for some remark from the reviewer of the book. Meanwhile, most readers will probably find in Mr. Lucas' own quotations sufficient justification for the criticism which has appeared in the Journal. [Ed. P. J.]

Sir,—The author of the above work will no doubt welcome the pointing out of solubility differences by "Pharmacist" and "Student"; but if any data can lay claim to variableness, surely it is solubility tables—only accentuated by practical manipulation. Blind uniformity is not accuracy! A year or two back, in looking up the solubility of picrotoxin, the departures struck me markedly: B. P. (Addendum), 1—330. Martindale, 1—240. Squire, 1—150. Dorvault, 1—150. U.S. Pharmacopœia, 1—150. Merck describes it in general terms as "soluble in water, alcohol, and alkalies." This is not *ex uno disce omnes*; it is "one, out of many more." I pursue the details no further, beyond one specific objection, *i.e.*, acid boracic. Lucas gives 1—25. "Student" refers to B.P., 1898, 1—30. This is a recent decision; and B.P., 1885, gives 1—25, in harmony with other authority. There is a danger of conveying an impression that a useful book is careless or inexact; such judgment should not be based on uncertain grounds, as viewed by shifting lights. No protest is made against the communications referred to; the endeavour is simply to modify what might otherwise be a hasty conclusion.

November 7, 1898.

DELTA (152/31).

THE CASE OF LOCAL SECRETARIES.

Sir,—Reading over the current issues of the journals, I am a little amused by the varying reports of Mr. Atkins' sentiments *re* local secretaries. In the *Pharmaceutical Journal* I read: "Mr. Atkins said he could state from personal knowledge that some of the local secretaries were hardly deserving of the thanks of the Council." Another report runs: "Mr. Atkins was glad to hear the President thank the local secretaries, as from his personal knowledge some of them deserved thanks." I have no doubt both reports are accurate, only the second report puts it a little more politely; however, we may connect and read them together. It is a coincidence that before opening my journals and reading the above I had sat down to write this letter, inspired by a recent paper on "The Duties of a Local Secretary." I wished to remind the Society of its duties to a local secretary, but in the report of the Council meeting I read so many kindly remarks in recognition of the service rendered by its representatives that I will content myself by contrasting these sentiments with a bit of ancient history. I know a provincial pharmacist who acted, to the best of his ability, as local secretary for some thirty years, during that period he never debited the Society with any costs, and ultimately retired voluntarily in favour of a younger and more active man, possibly he was considered as "hardly deserving," anyhow he never received a single word of acknowledgment, official or otherwise, simply dropping out of the ranks. I am glad to believe this will not be repeated.

Scarborough, November 7, 1898.

JOHN WHITFIELD.

* * The general tenor of Mr. Atkins' remarks and of the whole discussion was quite in accordance with the sentence quoted by Mr. Whitfield from the Journal, but on referring the matter to the reporter we find that he had apparently abbreviated the word "thoroughly" in such a way that it misled the compositor, who took it for "hardly." [Ed. P. J.]

Sir,—The word "hardly" in my report of Mr. Atkins' remarks at the last Council meeting (see p. 487) is a misprint for "thoroly," for which I suppose my bad writing is responsible, but I did not think it was quite so illegible.

London, November 9, 1898.

YOUR REPORTER.

THE POSITION OF PHARMACY.

Sir,—The more that I read, the more that I hear, the more that I see of pharmacy throughout the country, the more I become convinced that the necessity for large reforms is urgent. We have reached a stage at which every grain of energy to be found in the pharmaceutical world ought to be exercised in the direction of the suppression of unqualified competition. Anti-cutting associations, increased educational demands, even more energetic organisation, are all but trifles if they do not help in this direction. I do not think that it is too much to say that at the present time two-thirds of the profits derived from the drug business are finding their way into the pockets of those whose names do not appear upon the Register of Chemists and Druggists. This is a position I should think unique in the history of callings for which the State requires special educational qualification, and viewed from the standpoint of common sense and common justice, it is absolutely absurd. I will go further and say that when the position is quite understood by the general public we will receive overwhelming support from all classes. This country loves justice, and it never lends its support to injustice longer than its ignorance of the subject exists. The position of pharmacy is one which the people have little understood in the past. Men who never were chemists have arrogated to themselves the positions and privileges of chemists, and even their title, and I find that the people are astonished when they are informed that these men are not chemists. I have never yet met an intelligent man who failed to see the injustice of all this when he was led to understand it. Even in the House of Lords a sense of the position is beginning to dawn, and I reckon that when the light begins to break upon the House of Lords the nation is not in darkness. School teachers, civil servants, and even men who have no examinations to pass, such as Poor Law officers, are all agitating for better positions, and we alone are afraid to go to Parliament because, forsooth, a few unqualified men who are interested harangue a public which they have already misled about monopoly. The fact is, the trade done in drugs is too limited everywhere to support this hordo of unqualified bloodsuckers, and pharmacy is not fighting for a luxurious living, but for a bare existence throughout the country. Now I would suggest that as the present Parliament has yet about three years to run, the Pharmaceutical Society do now set about getting ready for the next general election. To this end we ought, if at all possible, to go hand in hand with the British Medical Association, the Dental Association, and the Veterinary Surgeons' Society. I consider that the President of the Pharmaceutical Society is the right man to negotiate this, and from the able manner in which he carried through the Pharmacy Acts Amendment Bill I believe that he has tact and skill enough to succeed. Meantime local associations should be encouraged, and these ought to be instructed to wait upon their Parliamentary Members in deputations, and see that in Parliament every man has a knowledge of the real position. Then a proper Bill dealing with this matter ought to be drafted and introduced boldly into the House of Commons, and I do not think that it would be difficult to get a Minister to introduce it. I am sure that the Ministry would support this measure if a similar one appeared from the other professions dealing with the same subject at the same time. I am no advocate of noisy agitation, but we ought never to forget that the House of Commons is ready to rectify grievances when it is fully cognisant of them, but it seldom goes out of its way to search for them. We must bring them under its notice.

Dumfries, November 8, 1898.

JAMES REID.

LOYALTY TO THE CRAFT.

Sir,—In your issue of this week you have made me say that I "successfully filled the offices, etc." I wrote, or intended to write, "successively." I have some modesty left. I never for a moment expected that you would have any sympathy for the views I have given utterance to, but I do think I have a right to fair comment from you, and how anybody can possibly twist the sentence, "If salaries of £200 are common," into a denial that "any assistant is earning a salary of £200," entirely passes my comprehension. Perhaps that is another symptom of "eccentricity."

London, November 5, 1898.

C. P. (152/12).

* * Our correspondent conveniently loses sight of the fact that in passages omitted—for his sake—from the letter published last week, he accused Mr. Rymor Young, by implication, of untruthfulness in stating that he knew of several assistants in the receipt of £200 per annum, and also suggested that when Mr. Young said £200 per annum he meant £2 per week. [Ed. P. J.]

WINDOW-DRESSING AS AN AID TO BUSINESS.

Sir,—As the Christmas season is approaching, I would venture to suggest your opening a discussion in your columns on window dressing, from which I feel sure we should all benefit individually, for the quantity of articles sold from an up-to-date window is enormous as compared to days gone by twenty years since. A colleague remarked he considered Messrs. Hooper's, of London Bridgo, one of the best dressed chemist's windows in London. I asked why? He said it was quite full, everything could be seen, and yet at the same time not crammed. To anyone at all observant, a marked improvement has taken place in connection with chemists within the past few years, more especially in connection with the windows. One thing appears fairly certain—that is, the days of the carboy and specie jar are numbered. In this practical age the mystic ornaments will have to give place to everyday useful articles. I consider the first essentials in a well-dressed window are that it should be fairly low, that it can be looked right into, from a somewhat elevated point, that it should be well lighted, and, above all, the glass kept scrupulously clean (to stimulate the latter it would not be a bad plan for the local association to offer prizes to the errand boys who kept their glass cleanest). The articles should be arranged in "catchy" groups, sufficient of each article to be seen at a decent distance. In former days the articles were alternated—a little of almost everything—with the result that nothing attracted. The trade in cut smelling bottles, put up perfumes, and fancy toilet wrapped soaps, have all been more than retained in the hands of chemists, in spite of the former dangerous opposition from jewellers, drapers, and grocers. I believe at the present time that if anyone wanted a reliable article of the above kind they would always prefer purchasing from a smart chemist; consequently the three above articles should find a place nearly all the year round, together with seasonable requisites, influenced by local requirements, and specialties that might require particular prominence, always avoiding a tawdry or *6d.* bazaar appearance in showing seasonable articles. I would rather be a fortnight too early than a day too late; a customer will have noticed the articles, make a mental note, and mark that as the shop to purchase from.

November 7, 1898.

DEVONIAN (150/16).

IODIC-HYDRARG.—WHAT'S IN A NAME?

Sir,—You were so good as to publish my suggestion that the name Uro-Trepine might lead to a confusion with some other remedies. I now think it desirable to call attention to the name "Iodic-Hydrarg," as given by Messrs. Burroughs, Wellcome and Co. to a tabloid. One need not be an unreasoning purist in language to complain of such pigeon English as this name shows. A communication to the makers on behalf of a physician whose telegraphed request had not resulted in what he desired, brought the following reply: "The difference between mercuric iodide and iodic-hydrarg. is as follows: the former is, as its name implies, the higher iodide of mercury, having the formula HgI_2 , whereas the latter is a double iodide of potassium and mercury, having the formula $2(HgI_2KI)3H_2O$. Were the substances synonymous they would be entered in our list under both names." Now, the list of tabloids does not say a word about the composition of "iodic-hydrarg.," and one is entitled to ask, By what authority has potassio-mercuric iodide received this new and strange name, certainly not suggestive of a double salt, but which might more reasonably be supposed to be a new way of describing mercuric iodide? Trusting that the makers will adopt such a change of nomenclature as shall remove this stumbling-block from the path of physicians and pharmacists.

Leeds, November 7, 1898.

RICHARD REYNOLDS.

VISUAL OPTICS IN THEORY AND PRACTICE.

Sir,—I think Mr. Laurance has entirely missed the points I took against what I considered to be a careless and inaccurate description of the efforts of chemists to cater for and correct visual defects, and that whatever he may say or do, the bulk of sight testing will always be done by ophthalmic surgeons, for a number of reasons, which I think I could give, and which he appears to me to corroborate. I should be one of the first if it were, as he appears to think and say, that the majority of chemists know nothing of visual optics, to agree the condition of things should be altered. His assertion is a very tall one, and would without doubt be most vigorously contested; and

I am sure, as he fails to give either facts or figures in support of what at present (leaving out his satire) is his mere statement, his reply will fail to impress the members of our profession.

London, November 7, 1898.

D. JONES.

THE PROPOSED POISON REGULATIONS.

Sir,—Please allow me to express my satisfaction at the prospect there seems to be of the question of the storing and dispensing of poisons being raised from within our ranks. If I understood aright, our President deprecated the discussion of this matter during the time the late Bill was before Parliament, otherwise I should have ventured to write to you at the time, suggesting the necessity of reform from within. First, let me confess my ignorance of the regulations upon this matter, which are said to be found in the Calendar. What Mr. Cross said is but too true. He stated a fact very mildly when he said that "no doubt all pharmacists did not possess a copy of the Calendar." Doubtless our Secretary could give information upon that point. I should like to see those regulations printed in the Journal [They were reprinted in the *Pharmaceutical Journal* for July 2 last.—ED., P. J.], and also I should like, as a preliminary to discussion, to have that table of mortalities from scheduled poisons printed again. In reading that table I was particularly struck by the fact that sixty deaths had occurred in two years from prussic acid. This presumably includes deaths from poisonous cyanides generally, but some cases were certainly due to prussic acid. The sale of this might, I think, very conveniently be prohibited *in toto*, except, of course, to medical men. My experience, I know, is limited, but during sixteen years as assistant and principal in various places I have as yet not met a case in which there was any real necessity to sell prussic acid. Would there be any objection, sir, to a regulation ordering that strychnine should be coloured in the same way as arsenic? I know of none, nor of much occasion to sell undiluted strychnine at all, but that would come out in discussion. Such a regulation would have probably averted one recent death at least in a case which must be fresh in the mind of every pharmacist. Some regulation might be made, too, with regard to the sale of opiates. I am aware that there is much difficulty in restricting the sale of those poisons which have a *bona fide* and legitimate use in arts, manufactures, or domestic economy; but I am convinced that a discussion of the problem and a serious effort to diminish the number of deaths from the poisons which are restricted to us pharmacists can be productive of nothing but good, both to the public well-being and to the reputation of the persons entrusted with the duty of safeguarding the public welfare in this direction.

Bristol, November 8, 1898.

E. F. YEUNG.

COMPANY TRADING.

Sir,—The remarks *re* company trading made by the President at the recent Council meeting are sensible and timely, and should be carefully kept in mind when the perplexing problem of company pharmacy is being considered. The general tone of his remarks would, however, give the impression that the resolution passed by the Nottingham and Notts. Chemists' Association was, to put the matter mildly, a little wide of the mark, and I shall, therefore, be glad if you will afford me a little space in which to present an aspect of the Nottingham meeting which the incomplete report in the *Pharmaceutical Journal* overlooked. The members of the Nottingham Association were practically in complete accord on several points, viz. :—

1. That any matter of legislation can be considered only from the standpoint of how it affects the public welfare.
2. That it appears logical to assert that if it is not legal for an unqualified individual to carry on the business of a chemist and druggist it ought also to be illegal for an unqualified company to do so.
3. These unqualified companies generally employ a registered chemist as manager of each branch, and, therefore, the crucial point of the whole question is, Is the employment of a registered chemist, who is simply a salaried assistant to an unqualified company, a sufficient public safeguard? On this question the whole issue rests, and unless it can be answered with a definite negative, we need not seek any reform.
4. The question of company trading is rendered more difficult of solution by the fact that several chemists have turned their businesses into companies, and conduct them in a manner to which no exception can be taken.

On these points most pharmacists will be agreed, but when we come to consider whether the case against unqualified companies is sufficiently clear to warrant us seeking further legislation, and

if so, on what lines we shall proceed, then it requires some body of men in touch with the whole question to give a definite answer. Several suggestions were laid before the Nottingham meeting, but none were considered to be sufficiently practical to crystallise into a resolution, and it seems to me that instead of asking local associations to discuss the matter and report to the Federation it would be far better for the Council of the Pharmaceutical Society to carefully consider the matter, formulate some plan which it considers to be practical and submit that to the local associations for consideration and ask their assistance in furthering the plan. The Nottingham resolution was, therefore, not an abstract one, but the most practical one that could be passed, and unless the Pharmaceutical Society (or its Council) does formulate some scheme I fear the whole agitation will simply end in smoke.

207, Radford Road, Nottingham,
November 8, 1898.

WILLIAM GILL.

THE CHEMISTS' ASSISTANTS' UNION.

Sir,—In placing before the chemists' assistants of Great Britain a proposed policy of the Chemists' Assistants' Union through the medium of your columns, perhaps a few remarks on its constitution and on the difficulties to overcome in its construction would not be out of place. A point that has caused a considerable amount of discussion at all meetings of the Union, and which is one of great importance, has been: Should membership of the Union be open to every assistant in the drug trade, or only to those who have served an apprenticeship with and are employed by a registered chemist? The Committee (*pro tem.*) have, after protracted deliberation, decided that the Union shall be composed of the latter only. And as a further check against unsatisfactory membership, the Council have the power to refuse any application from an assistant whose business principles are detrimental to the interest of the calling. It may be intimated that a prominent wholesale firm has kindly placed its register of situations vacant at our disposal, and that a number of chemists have already been supplied with assistants by the Union. The Union has met with considerable favour in the eyes of many prominent medical men, and several chemists have been enrolled as patrons. The Committee submits the following to the notice of your readers, and invites criticism for the perfection of its policy. This draft is respectfully brought to the notice of all provincial chemists and chemists' assistants' associations for their consideration:—

PROPOSED POLICY OF THE CHEMISTS' ASSISTANTS' UNION.

1. To combine against the unjust system of unqualified company trading, to do our utmost to secure the co-operation of our fellow-assistants.
2. To avail ourselves of the privileges given to qualified assistants by the Pharmacy Acts Amendment Bill, 1898, and by combination to secure direct representation on the Council of the Pharmaceutical Society.
3. To establish in London an institution or club, to be the headquarters of the Union, where members can meet for social or business purposes, and where provincial members can apply for information, etc.
4. To establish at the headquarters an Engagements' Register, with the object of facilitating the securing of worthy employment and employes.
5. To strengthen the parent Society by our combined support to the suppression of illegal competition and trading.
6. To appoint at every large centre a local secretary, and so establish branches of the Union in touch with the London headquarters.
7. To consider, and if practicable to form a mutual benefit institution, with the object of providing aid in sickness.
8. To bring what weight we may possess to bear on Members of Parliament for the extension of the power of the Society in the protection of our calling.
9. To promote good fellowship in a hitherto alienated body of workers, and to seize all opportunities for the promotion of our welfare.
10. To secure by the above policy a healthier condition both financially and socially of the employer, and thereby ensure to assistants a remuneration and hours of labour consistent with the higher educational training of the present.

These few lines in conjunction with the rules published after the second public meeting of the Union, which have been revised, No. 19 now reading "shall not" instead of "is recommended not to" sell his services to improperly constructed companies, will give to assistants generally some idea of the intentions of the Union. A smoking concert will be held at an early date, and we cordially invite all employers and employed in the trade, when there will be a full opportunity of discussing the proposed policy.

Headquarters (*pro tem.*), The Formative Committee,
Horse Shoe Hotel, Pp. J. LLOYD ROBERTS,
Tottenham Court Road, W.C., Hon. Secretary.
November 8, 1898.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

STAND DEVELOPMENT.—Yes, the method of development described at p. 446a can be used with cut films, provided they are kept upright and apart from one another. [*Reply to GAMMA.*—18/19.]

FORMULÆ AND REACTIONS.—Thanks for the suggestion. The matter has already been under consideration, and will not be lost sight of. [*Reply to H. G.*—151/37.]

CONTINENTAL PRESCRIPTIONS.—Yes, both solids and liquids are weighed as a rule. Your second question is not comprehensible as it is written. [*Reply to INQUIRER.*—18/33.]

BOOK ON PHYSICS.—You cannot do better than procure Aldous' 'Elementary Course of Physics' (Macmillan, 7s. 6d.); though not "a small book," it deals with the subject more satisfactorily than any other we know. [*Reply to E. A. S.*—18/29.]

SOLUBILITIES.—You quite miss the point of the communication you refer to. The writer did not attempt to convey that one set of figures was more accurate than the other, but merely that one was not in accordance with what he regarded as the recognised standard. [*Reply to A. M.*—152/44.]

MODERN WORKS ON VETERINARY MEDICINE.—Gresswell's 'Equine Hospital Prescriber'; the same author's 'Bovine Prescriber'; each published at 2s. 6d.; Hoare's 'Veterinary Therapeutics and Pharmacology,' 10s. 6d., and Gresswell's 'Veterinary Pharmacopœia,' 10s. 6d., are all useful works. [*Reply to J. H. G.*—18/23]

MICROSCOPIC CHARACTERS OF LEAVES.—There is no recent book on the subject, but the structure of several medicinal leaves has been dealt with in the *Pharmaceutical Journal*: hyoscyamus, stramonium, senna, and jaborandi (October 27, 1894), aconite (February 27, 1897), belladonna (July 17, 1897), buchu (September 11, 1897), and cannabis indica (January 8, 1898). For others you should refer to 'Pharmacographia.' [*Reply to H. L. S.*—18/30.]

INDIGO CARMINE.—No, this is not the same as sulphate of indigo; it is the sodium salt of indigotin disulphonic acid, $C_{16}H_8(HSO_3)_2N_2O_2$. The reagent, consisting of so-called sulphate of indigo, is really a solution of this acid in a great excess of sulphuric acid. Indigo carmine is largely used by dyers; although wholesale druggists may not include it in their lists they would procure it for you if asked. [*Reply to APPRENTICE.*—18/21.]

DISINFECTANT FOR OLD CESSPOOLS.—Probably Tuson's patent disinfectant fluid, which consists of a mixture of zinc chloride and corrosive sublimate, together with sulphurous acid, is what you refer to. You can procure this through any wholesale house. Crude commercial sulphate of copper is also useful for the purpose. For special compounds apply to Messrs. T. Tyrer and Co., Stirling Chemical Works, Stratford, E., or to Messrs. May and Baker, Garden Wharf, Battersea, S.W. [*Reply to F. R.*—18/32.]

BACTERIAL TREATMENT OF SEWAGE.—You will probably find all you require to know in Dibdin's recent work on sewage. A patent was granted to D. Cameron and F. J. Commin, of Exeter (No. 21,142, November 8, 1895), for this method of treatment of sewage, which has been successfully carried out at Exeter and many other places in this country. If you obtain a copy of the specification of this patent, it will give you full information on the subject. Notes on the process have also appeared in the *Journal of the Society of Chemical Industry.* [*Reply to ENQUIRER.*—18/34.]

Pharmacy and the Allied Sciences.

REVIEW OF CURRENT WORK.

Drs. H. W. G. Mackenzie and W. E. Dixon

Physiological Action of Podophyllin. publish an interesting paper on the physiological action and therapeutic properties of podophyllin, with special reference to Indian podophyllin. They find that *Podophyllum emodi* is an active purgative and a useful therapeutic agent, and that it may be substituted for *P. peltatum*. The Indian drug, however, is nearly twice as effective, physiologically, as the American. The active principles contained in the crude resin of Indian podophyllum—crystalline podophyllo-toxin and podophyllo-resin—both act as excellent laxatives in small doses, without secondary constipation or other objectionable symptoms. Although both those substances act very similarly on the alimentary tract, it is only the podophyllo-resin which exerts a true cholagogue effect, and that shows itself "rather by a large increase of the solids secreted than by an increased quantity." Both the active principles exert their specific activity when injected hypodermically in alcoholic solution, but in man so much irritation is produced as to forbid their employment in this manner.—*Edin. Med. Journ.*, November, 1898.

Eucalyptol Determination. L. F. Kebler recommends the following assay process for eucalyptus oil:—Place 8 Gm. of the oil in a beaker cooled in ice-water, gradually add 4 C.c. of phosphoric acid (s. g. 1.75) with agitation, and again cool the contents of the beaker by means of ice-water. After cooling, slowly but thoroughly mix the contents of the beaker by means of a glass rod, remove the eucalyptol phosphate formed by placing it between folds of filter paper and subjecting it to heavy pressure, then weigh and decompose it by treatment with hot water. The phosphoric acid is liberated and can readily be determined by titration with potassium hydroxide; the eucalyptol can then be determined by difference. As a method of assay, the above process does not give absolute results, but those obtained are close approximations. Working with pure eucalyptol, the percentage by difference came out at 103.75, whilst Scammell's direct process indicated 62.14 per cent. only.—*American Journal of Pharmacy*, lxx., 492.

Nutrition of Yeast. Dr. A. L. Stern has undertaken an investigation to determine the amount of inorganic and nitrogenous nutriment required to produce the largest crop of yeast, the greatest assimilation of nitrogen, and the most complete fermentation in a fixed time. The yeast employed was a pure form obtained from a Burton pitching yeast, the sugar was *d*-glucose, the nitrogenous nutriment asparagin, and the inorganic nutriment of two kinds—the first prepared from a yeast ash and free from sulphur, the second a mixture of potassium phosphate, magnesium sulphate, and calcium sulphate. Each experiment consisted in fermenting 500 C.c. of a 10 per cent. solution of the sugar, to which varying amounts of the nitrogenous and inorganic nutriment had been added. The author finds that sulphur is an essential constituent of yeast nutriment, and that in the absence of other more suitable forms of sulphur nutriment, sulphates can supply the yeast with this element, a portion of the sulphate being invariably reduced to sulphuretted hydrogen. Attempts were made to find a substance of known constitution which could supply yeast with sulphur

without the evolution of sulphuretted hydrogen, but without success. No evidence could be obtained in support of the statement that iron is an essential constituent of yeast nutriment. The author has examined the effect of variation in the amount of (1) nitrogen nutriment and (2) inorganic nutriment respectively on the amount of nitrogen assimilated, the percentage of nitrogen nutriment assimilated, the percentage of nitrogen contained in the yeast, the percentage of sugar remaining unfermented, and the weight of the yeast crop, and draws the following conclusion:—Any increase of nutriment beyond a definite limit will not materially increase the amount of nitrogen assimilated by the yeast, the percentage of nitrogen in the yeast, the weight of the yeast, or the amount of sugar fermented. This limit, called the normal supply, is the largest quantity that the yeast can assimilate under the conditions employed in the experiments, and is approximately 0.025 Gm. of inorganic nutriment per 100 C.c., and the same weight of nitrogen supplied as asparagin.—*Proc. Chem. Soc.*, 198, 182.

Extraction of Nickel. Dr. Ludwig Mond has devised an ingenious process for extracting nickel from its ores, by combining the metal with carbon monoxide. The process is of exceptional interest because nickel is a very refractory metal, having a melting point of over 1000° C., and is yet able to combine with carbon monoxide at a temperature of over 50° C. to form a gaseous compound—nickel carbonyl. That gas, on heating to a temperature of 150° C., becomes completely dissociated, pure carbon monoxide being given off and metallic nickel deposited on the sides of the vessel in which the gas is heated. Nickel ores, most of which contain sulphur and arsenic, are first roasted to convert them as far as possible into oxides, and the resulting oxides are treated with reducing gases so as to reduce the oxides to finely-divided metallic nickel. The reduced nickel is then transferred to a suitable tower, which is maintained at a temperature not exceeding 100° C., and carbon monoxide passed over the material. The nickel carbonyl thus formed is then passed into a suitable chamber or vessel containing granules of commercial nickel or iron, and on being heated to 180° C. the nickel carbonyl is immediately decomposed, and metallic nickel deposited on the granules of metal, whilst carbon monoxide is set free. The carbon monoxide thus liberated in the process is returned to the volatiliser, where it attacks a fresh quantity of nickel, so that the process is continuous.

Lubricants for Glass Stop-Cocks. F. C. Phillips has experimented with a view to producing better lubricants for glass stop-cocks than those in ordinary use, and he finds that the following mixture lubricates well, is translucent, adheres to the glass, and is not saponifiable:—Pure rubber, 70; spermaceti, 25; soft paraffin, 5. The materials were thoroughly mixed while hot, the rubber being melted first and the other ingredients stirred in. A little more soft paraffin should be used in winter than in summer. Still better results were obtained by mixing pure and fresh rubber, 70, with yellow beeswax, 30. The rubber was heated in a covered vessel until thoroughly melted, the wax added, and the hot mixture well stirred. This lubricant is quite translucent in thin layers, and protects stop-cocks from sticking, even when used for concentrated solutions of caustic alkalies. To keep the rubber mixtures in the best possible condition, they should not be exposed to air longer than necessary when heating, and they ought to be preserved in closed bottles. The stop-cocks should occasionally be thoroughly cleaned and re-coated with the rubber mixture.—*Journ. Am. Chem. Soc.*, xx., 678.

PHOTO-MICROGRAPHY.—VIII.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

The photo-micrographer may occasionally be asked to produce photographs about 200 or more diameters to illustrate pathological specimens which are violently stained in contrast colours, of which red is often a large component. If these be photographed by the ordinary methods it will be found the resulting prints are full of severe contrasts, the red stained portions coming out violently black if the rest of the print be fully developed, whereas if under-developed to render these less pronounced and to show details which exist in the negative, the rest of the structure appears faint and ill-defined. No amount of "shading" in making the print will cure the trouble. To render a more uniform photograph resort must be had to the power which exists in the hands of the photographer to lessen contrast, viz., he must use a coloured glass of the same wave-length as the predominant colour of the specimen. If, for example, it is one of those specimens, where red stained parts abound and are so troublesome, he must reduce the contrast by employing a red glass, which will increase the exposure for the parts not red, whereas it will not materially affect those so stained, anyhow to the same amount. In other words a more balanced negative will result. To take such photographs he must, it need scarcely be pointed out, use a red stained plate, such as a Cadet Spectrum or Lumière's Panchromatic, or the red and yellow plate. He must develop in the dark, only looking at his picture by fits and starts with a subdued green light if possible. If he is unable to have this green light he must look at his plate as little as possible or, of course, it will get fogged; and he must recollect also to place it in the slide in the absolute dark. Having then produced a much flatter negative, but one full of detail without much contrast anywhere, he had better print from it, either by the platinotype process with daylight or by the use of platino-bromide paper and the gas. Let him develop too with weak developer and over-expose the print. He will then get a grey print not unlike a pencil drawing.

How to make lantern slides from the negatives obtained photo-micrographically is the next process to be explained. Plates ready made are sold by most makers, and each claims superiority of manufacture. They are primarily of three kinds: Ordinary gelatin, printing-out gelatin, and collodion. Of these the gelatin are by far the easier to work, as they possess much latitude on exposure, whereas the collodion type, whether ready made or manufactured by the photographer himself, must have exactly the right time given them, or they are of no use.

With respect to plates made with gelatin emulsion, they may again be divided into rapid and slow. It is not easy to define accurately the advantages or disadvantages of either, but speaking generally the rapid type give black images, whereas the slow are more amenable to treatment and produce pictures much more warm and soft. Almost any colour may be obtained with them if the directions enclosed in each box are carefully carried out. Then, again, if one is unable to obtain detail known to exist in a negative with a quick plate, the prudent experimenter will surely try a slow one, and if unsuccessful again, try his luck with one of the printing-out type.

For the subject in hand—the production of lantern slides from photo-micrographically obtained negatives—seeing they are more dense, and require such careful exhibition of detail—and as there are many who consider that rapid emulsions give more gradation than slow ones—although this is not a universally accepted statement—so it has mostly been found that the rapid series of lantern plates suit the purpose the better. As to the finest maker, the

reader cannot expect to be advised here, but what I have used and can find no fault with are those prepared by the Paget Prize Company, the "Rapid" series.

Let one be placed on the negative as it lies in the printing frame, having first carefully examined its film to see that no little pieces "stick up" from the edges—an attempt at "frilling" of the plate. If these bits are present they will be found to be very hard, and will resist the accurate contact of the lantern plate against the film of the negative so effectively as to prevent the best result being obtained. Let them be scraped off with a sharp knife. Seeing that the lantern plate lies in sharp contact then, the frame is held in front of the gas flame at a distance of a foot, taking care to move it about as mentioned when explaining the exposure of Nikko paper. A good negative of the proboscis of a blow-fly will require about thirty seconds, forty-five will not hurt it, as there is so much latitude with these lantern plates. This ended, remove the plate and flow over it a developer consisting of equal parts of the hydroquinone and soda solution, which happens to suit the emulsion admirably.

In a few seconds the positive will commence to appear, growing in density and definition with exceeding rapidity. Attaining sufficient definition and blackness, the developer is poured back again into the measure (for it can be used over and over again, as when using it for Nikko paper), and the slide allowed to drain for four or five seconds, when it will be found to grow distinctly foggy. Wash quickly and sharply—not losing much time, as development is apt to go on notwithstanding the washing—and plunge into the hypo bath, which is of the same strength as that employed for fixing negatives.

In a few minutes—a much shorter time than that required for fixing negatives—the positive image will appear quite free from yellowness. Let it rest in the bath for a few minutes longer than appears actually necessary, just the same, only for a shorter time, as was recommended when dealing with negatives. If now the background appears perfectly transparent and the image bright and black, the operator may be satisfied, but if brown it has been over-exposed. Try half the former exposure. If, on the contrary, it is everywhere faint and shows lack of detail—the hair points hardly out and the ends of the suctorial tubes deficient in continuity—the time before the gas has been too short—remedy: double it.

But should the slide appear with a muddy ground, so very common and so very unsightly, one of three faults have caused it. Either the negative is too thin—remedy, intensify it in a manner to be yet explained—or the slide has been over-exposed or over-developed. To ascertain which of the three, first look at the negative. If too thin the gas-flame will be too easily seen through it. If the fault is over-exposure of the slide, try less; and if over-developed, do not be so slow over the process. Suppose, after trying again, the background of the slide still appears dirty-looking and overcast, then glance at the original specimen and note if the mounting medium is clear or yellow. If yellow, there is no remedy but taking a fresh negative with more exposure. But here a most troublesome difficulty may arise. Suppose a more exposed negative is taken and it is found on development that the background is sufficiently dense and black so as to produce a clear, clean positive, but at the same time the proboscis itself is much over-exposed; all its details being choked up with deposit. Thinning will be of no service, because the background will be thinned at the same time as the proboscis, and the final result will be the same as if the whole negative had been all over-exposed less. Admittedly the difficulty is great, but it can be very often got over to a great extent in the following manner:—Consider the circumstances: a yellow interceptive background

from the colour of the mounting medium, which increases the exposure, and a brilliant proboscis, which has only absorbed enough of the yellow mountant to clear it and make it more transparent. An increase of exposure has been found to increase the density of the background, it is true, but at the same time to cause over-exposure of the proboscis itself. The only way generally known is to use a glass screen of some colour to render the contrast in exposure less severe. A green pot glass, about one-eighth of an inch thick and of medium density, will increase the total exposure, it is true, some five or six times, but will often produce a more equally balanced negative. Sometimes a yellow screen is preferable, and with certain specimens a still better result is obtained. Let the photographer try the effect of each colour and judge for himself. When the contrast is not pronounced enough, as often found with photographs of bacilli, exactly the opposite treatment is required, and a glass used to increase it.

The lantern plate should be washed after leaving the hypo for at least an hour, and then be dried on the hot water tank, after having wiped the back. Wiping the front of any lantern plate is not a good thing to do. It is very useful in the case of negatives, but with lantern plates certain markings sometimes occur if the fabric be too severely pressed on to the emulsion.

One more matter should be mentioned, which sometimes gives rise to a large amount of trouble and experiment, and which will occasionally occur in warm weather with these and other lantern plates, namely, a distinct and fatally pronounced yellowing of the clear portions of the film, which shows itself after fixing. It seems to resist all treatment, and it was a long time before I ascertained the cause. At first, common hypo was thought to be the cause, and that the yellowness was only due to imperfect fixation. This was ascertained to be an error, and all the solutions were alike called to book for the trouble. The emulsion was then blamed, and the manufacturers called upon to explain. After a very considerable time was spent, and after the most courteous attention of the Paget Company was well-nigh exhausted, the trouble was discovered to arise from a staining by the developer when the process was carried on too slowly, and to an insufficient subsequent washing before fixing. The trouble never occurs in winter, but sometimes, though rarely, it occurs in summer. Considerable soaking in water after development will remove it, but it is better to expose a little more, risking a browning of the final image, which will occur from over-exposure with lantern plates as with Nikko paper.

The slide is mounted by bending it against another slip of glass the same size, a mask of paper of suitable shape being interposed to prevent the film touching the surface of the opposing plate.

The "printing-out" slide needs but little description. It is made with a very transparent emulsion, and is placed in the frame and exposed to artificial or other light like an ordinary piece of printing-out paper. One side of the frame can be lifted, and owing to the transparency of the film the depth of printing can be easily estimated. The subsequent processes are fully set out in the printed directions with each box, and need not be narrated here.

With respect to collodion plates, the best ready-made ones I know are sold under the name of "Hill-Norris Dry Collodion Lantern-slide Plates." They require about a third more exposure than the rapid Paget previously described, and they may be developed with the same hydroquinone and soda solution, as it suits them very well. Great care is necessary in the use of the plates by contact, as the film is so delicate the slightest touch will scratch them. They also require the most exact exposure, as they flash up in development to a certain pitch which can never be made deeper or more dense by any length of development. They have the advan-

tage, however, of being able to be fixed by a watery solution of any strength of cyanide of potassium, which does its work immediately and only requires a few seconds' washing to remove. They can be dried, too, in front of the fire or over a spirit lamp with impunity in a few minutes.

Seeing, however, that so many collodion slides are made by the so-called "wet-plate process," it would be an omission on my part if I neglected to mention how these can be manufactured by the photographer himself. It is first necessary to obtain what is called a bath and dipper, which can be procured for small-sized plates very cheaply. Into this is placed a solution of re-crystallised nitrate of silver from 40 to 60 grains to the ounce of distilled water. The glass plate to be used should be first most scrupulously cleaned both sides, and this must never be neglected, for if so the penalty paid for the mistake will be a severe one—the film will float off after its development, or after it is fixed in one or other washings.

To make this less likely I have always adopted the following plan in times past, when the wet-plate process was freely used for negatives, even on the field. It is to pour over the plate a preliminary coating of albumin in some form. There are many formulæ, but the one used was always effectual, easy to make, and kept well. The solution was made by mixing 1 part of white of egg in about 500 to 700 parts of water, to which was finally added 3 or 4 drops of commercial carbolic acid. The plate, carefully cleaned with spirit and water and plenty of rubbing, the albumin solution is poured over it, several plates being done at one time, and drying afterwards effected spontaneously in a dust-proof cupboard. When coating these plates with the bromo-iodised collodion, each one is held in the left hand, whilst the right one is occupied with pouring the collodion from its specially-capped bottle on to the centre of the plate in a little pool. The plate is tilted so as to flow the collodion in one wave—and only one—all over it equally, the surplus being quickly returned to the bottle, which is instantly covered. The operator is careful now not to incline the plate more in one direction than in another, or there may result a crease from this cause on the film. Presuming he accomplishes this satisfactorily, he watches for the material to "set," and just when it has—let him try the edge at one corner to make certain—he places it into the silver bath, resting it on the dipper. When on lifting the slide out he sees no greasiness of the film, which is generally effected in about three minutes in summer, and six in winter, he places it on the slide, which, by the way, should be made for wet plates, having silver wire corners. It is needless to say contact is out of the question, so all transparencies of negatives must be taken with the camera and lens, the lime-light condenser already explained being used if daylight, which is much quicker, cannot be utilised. Development with one of the many formulæ is carried out in the usual manner, great care being exercised in pouring the fluid over the plate to do so with one sweep of the hand. The following recipe is a very good one:—

Ferrous Sulphate	10 grains.
Glacial acetic acid	15 minims.
Alcohol	15 to 20 minims.
Water	1 ounce.

As the silver bath gets old—more and more silver crystals being added from time to time to keep up its strength, more and more alcohol is required in the developer to make it flow evenly. This hint should not be forgotten.

Washing, fixing, and drying are carried out in the same manner as with the dry-plate collodion plates.

As all collodion films are so tender every lantern-plate must be varnished. Rouche's transparent variety for wet plates I have always found to be excellent, but most dealers supply varnish equally good.

If the slide after development appears rather flat, intensification may be resorted to, and this is done at once by pouring over the film some of the following, to which has been added a few drops of silver nitrate dissolved in distilled water (about 2 per cent.).

Pyrogallic acid	2 grains.
Citric acid	3 grains.
Water	1 ounce.

After fixing, intensification may also be performed, but the solution is different and the effect very often prohibitive, as the film nearly always turns yellow or of an ugly colour. In my experience it is quicker and far more satisfactory to make another exposure rather than tinker with a lantern slide. With a negative it may be different.

The faults that may arise by this process are many. The following are the leading ones:—

1. If the plate, after development, appears foggy in patches, probably the plate has not been properly coated with albumin, or is not clean.
2. If patches are transparent in bubbly-looking spots probably bubbles have been present, and so have prevented the plate being properly sensitised in the bath.
3. Streaks and irregular markings suggest a damp plate in parts.
4. Streaks all over and general irregularity in the film; some parts much more coated than others; usually arise from badly coating with the collodion, and parts drier than others before putting in bath.
5. Comets and pin-holes often come from dirt either in the collodion or on the plate.
6. Marks of deposited silver on the edges arise nearly always from a dirty slide.
7. Flat pictures nearly always mean a dirty bath. To remedy expose it to the sun and filter. Avoid a too acid bath, but equally so an alkaline one.

A short while back I mentioned that I would describe intensification of a gelatin plate. It is easily done. The dried negative is re-wetted and placed in a concentrated solution of perchloride of mercury. It turns completely white. When white all the way through, let it be well washed for half an hour, and then returned to the developing dish, into which should be poured some of the hydroquinone developer. The negative will turn rapidly black. When this is seen on looking through the negative to be complete, more washing must be carried out for an hour. Streaks and spots arise nearly always from too short and inadequate washing.

BACILLUS SUBTILIS IN LIQUOR POTASSII CITRATIS.*

BY WILLIAM A. CHAMBERLIN.

Pharmacists are often annoyed by growths of micro-organisms in the aqueous solutions of certain chemicals. While many of these are comparatively harmless from a therapeutical point of view, they spoil the appearance of the preparation, and often excite a fermentation that ultimately renders it worthless.

Many dispensers find it convenient to keep separate solutions of citric acid and potassium bicarbonate for preparing the official "liquor potassii citratis" extemporaneously.

In examining, recently, a solution of citric acid kept for this purpose I noticed a heavy flocculent deposit or growth. I collected some of the growth and added it to agar-agar in a test tube, which had been allowed to gelatinise in an oblique position in order to extend the surface of culture, if any occurred.

The tube was permitted to remain in a closet at an ordinary temperature. After twenty-four hours there were no signs of development, and it was concluded that the growth, if any, would grow only in an acid media, for the agar-agar used had been made distinctly alkaline, since most bacteria thrive better in an alkaline media. After forty-eight hours, however, a decided growth appeared. Two spreads of the organisms were made on cover-glasses, one being stained with gentian violet for three minutes, the other with carbol fuchsin for five minutes. They were mounted in Canada balsam, and examined with a one-twelfth inch oil immersion objective.

The organisms were distinctly recognised as *Bacillus subtilis*, or hay bacillus.

Bacillus subtilis is ordinarily found in water, air, and infusions of hay. It has locomotive powers, and grows at ordinary room

temperatures in all culture media, whether acid or alkaline. It is aerobic, that is, it requires the presence of oxygen in order to develop. It reproduces its species by producing spores and by fission. It is non-pathogenic, but is saprophytic, i.e., it lives on decaying organic matter, causing putrefaction and fermentation.

From this it can be plainly seen that a preparation with the usual "liquor potassii citratis" as an ingredient—subjected to the above conditions—would be liable to decompose in a very short while, or, at any rate, it would be anything but a permanent preparation.

There is, however, a remedy for the difficulty. In the first place, distilled water should be always used for making the solution, and the salt and acid should be dissolved in it while hot.

Then, if decomposition takes place, the bottles holding the solutions should be placed in a water-bath, or in a steriliser, twenty minutes a day for three days, and all the bacilli that have been developed will be killed, for but a few spores are killed at 100° C.; they must be allowed to form into bacteria before they can be destroyed by sterilisation. Of course, this eliminates all carbonic acid gas, but it inhibits further fermentation, and yields a sterile solution.—*Alumni Report*.

TIME LIMITS IN THE U.S. PHARMACOPEIA.*

BY JOSEPH FEIL, PH.G.

All drugs are essentially chemicals, and as chemicals are all prone to decompose under a vast variety of conditions, it is natural to expect that galenicals, always containing several substances in intimate contact and frequently a large number, should decompose to a greater or less extent from the moment that their preparation has been completed.

In a large percentage of the pharmaceutical preparations used to-day, deterioration or detrimental changes are so guarded against that they remain in almost perfect condition for a long time; but in another class, containing important medicaments, it has been found impossible to preserve against destruction and serious regression, that not only render them worthless but even dangerous substances when used as drugs.

In the case of this class of galenicals the pharmacopœias should establish not only clear methods which tend to prevent decomposition, but also state a time limit beyond which their use should be prohibited.

I showed last year that tincture of iodine will remain about U.S.P. strength for a month, if kept in an ordinary shelf bottle exposed to light, but two months when kept in a dark closet; hence such a time limit ought to be appended to the description of this preparation and instructions added to prepare a quantity not larger than sufficient to supply the ordinary demand for this period.

Spirit of nitrous ether remains of fair strength for about three months after preparation, yet I have known a sample of this preparation manufactured by one of our best manufacturing pharmacists to assay only one-eighth strength and, on investigation, discovered that the jobbing house from whom this article was purchased had had it in stock for two years, selling it only when the particular make was specified; with a date on the package all interested would have used proper caution.

Diluted hydrocyanic acid deteriorates to one-half strength in six months and it is so easily prepared by the second process of the U.S.P. 1890 that no excuse can serve the dispensing of this important substance, having practically no value: a time limit would serve to prevent such action.

I have frequently noticed sulphurous acid in pharmacies with no odour. How long this preparation remains useable I do not know.

Among other galenicals that could profitably be marked with time limits in addition to all other precautions to preserve quality, may be enumerated syrup of wild cherry, syrup of althæa, solution of lead subacetate, camphor water, fennel water, anise water, diluted nitrohydrochloric acid, solution of hydrogen dioxide, certain cerates and ointments and others.

It would seem quite desirable likewise to order the yearly replenishing of the stock of such crude drugs, oils and chemicals that cannot be made by ordinary methods to retain their virtues, this is practically accomplished in some European countries at present.

* Read before the American Pharmaceutical Association, at Baltimore.

The British Pharmacopœia, 1898.

At a meeting of the Glasgow and West of Scotland Pharmaceutical Association, held on November 10, Mr. THOMAS DUNLOP read a paper on

The British Pharmacopœia, 1898.

He said the Association had taken such a lively interest in its production that he thought the members should not seem to be indifferent to it now that it was an accomplished fact. It was gratifying to find that several suggestions forwarded from Glasgow had been considered worthy of adoption. At the Conference it had been stated that in the production of the book the medical profession and manufacturers had been more studied than pharmacists, and on that account pharmacists might the more readily be excused if they were its principal critics. It had been generally and rightly admitted that it was an advance on any of its predecessors. Its qualitative chemistry and the physical and chemical tests that were appended to fixed and volatile oils and other articles of *materia medica*, placed in the hands of the pharmacist weapons of defence that were invaluable. Whilst redundancy had been avoided in the text, that was not the case in the index, which had now assumed dimensions that could not serve any useful purpose. For example, three pages were taken up with the acids arranged alphabetically, first in English and then in Latin. Similarly two pages were taken up with the extracts, one page with the infusions, one and a half pages with the pills, one page with the syrups, and five pages with the tinctures. The cross references were not more numerous than in the 1885 Pharmacopœia, but the fact that dosage and composition (or percentage strength), were repeated in each case made it more cumbersome. Although there was only one page more in the text of the volume, the index took up sixty additional pages, and in all comprised nearly one-sixth of the volume. The section of it, however, with which they came or should come most closely into contact was pharmacy. He said "should come" because it had been enunciated at the Conference, presumably in the interests of manufacturers, that the pharmacist of the future was likely to stand in the same relation to galenicals as the pharmacist of to-day did to chemicals, viz., be able to guarantee their quality whilst he relegated to another the manufacture of them. When that time came the examination schedule would require modification, as it would only be a waste of time for students to acquire a practical knowledge of processes they would never practise. It was to be hoped, however, that the "traditional pharmacist" and "the pharmaceutical purist" would not become extinct species, but that as education advanced their numbers would increase. Coming to the text, his first observations referred to CONCENTRATED LIQUORS.—Although those were not meant to supersede fresh infusions they gave in a concentrated form official preparations which should be uniform instead of the heterogeneous products that were commercially called concentrated infusions. Those of them he had were more limpid than any concentrated infusion he had ever handled. The menstruum being an alcoholic one would contribute much to this result. OINTMENTS.—The ointments with a paraffin base have been much improved by the re-arrangement of the relative proportions of the two paraffins. The more limited range of the paraffin melting points, as well as the reduction in the percentages of the active ingredients, also tend to make them much more plastic. Having changed the solvent in the alkaloidal ointments they could not now be rightly designated by their old title, as neither the Latin nor the English name was in keeping with the chemical constitution, oleate. Sulphur ointment was a very watery looking preparation, and one wondered what called for it being altered. OXYMEL OF SQUILLS.—The making of this without evaporation was an improvement. The formula admitted the practicability of a double strong diluted acetic acid exhausting the squill, therefore, why not have acetum scillæ made the same strength and dilute when required for syrupus scillæ? SYRUPS.—Many of these had been improved through the quantity of sugar having been reduced. It should be noted that syrup of codeine was stronger in alkaloid than it had been heretofore. The unofficial syrup contained 1 grain of alkaloid per oz.; the official syrup contained 2 grains of the phosphate per oz. This, calculated according to the new atomic weights, was equal to about

1½ grains of alkaloid, 40 grains phosphate representing 29.9 grains of alkaloid. The new phosphate for syrup of lemon was a decided improvement. The addition of syrup of glucose was of doubtful utility, syrupus giving satisfactory results where the compound syrup was ordered. Having said this, further reference to pills was obviated. TINCTURES.—These had attracted his attention most, not that he questioned the soundness of the judgment that led to the changes, but looking at them comparatively with the 1885 B.P., and in view of the fact that the changes might, as formerly, only be temporary. On Mr. Farr's authority they were informed that in cases where a weaker menstruum had been ordered the drug was equally well exhausted, a stronger spirit only removing more extractive. But no reason was given for increasing alcoholic strength where a weaker spirit had not failed to do its duty. Although they were informed in the preface that "90 per cent. alcohol is almost identical with the rectified spirit of the 1885 Pharmacopœia," the use of it for the same purposes was not justified by the experiments of Farr and Wright, whilst it entailed an outlay beside which there was no corresponding advantage. Mr. Martin was right when he, at the Conference, took exception to increasing alcoholic dosage for the sake of unifying medicinal dosage. The inclusion of an 80 per cent. alcohol (from 90 per cent. to 70 per cent. was a big gap) would, in his opinion, have been very judicious, as it could have taken the place of the 90 per cent. in many cases where such a strong alcohol was not required, e.g., spt. camph., spt. chlorof., spts. of the ess. oils, and tinctures generally, where S.V.R. of the 1885 Pharmacopœia was used. Under ol. menth. pip. they were informed that "it should dissolve in four times its volume of 70 per cent. alcohol," and yet nine times its volume of 90 per cent. alcohol was ordered to make spt. menth. pip. Similarly one volume of ol. lavand. dissolves in three volumes of 70 per cent. alcohol and ol. rosmarini in twice its volume of 90 per cent. alcohol, whilst nine volumes of 90 per cent. alcohol were ordered for the respective spirits. Asafetida, on the other hand, they were informed "should contain not less than 65 per cent. of matter soluble in 90 per cent. alcohol" (it did not say how much alcohol would be required to dissolve this 65 per cent.), and yet the tincture, although it has been increased in strength from 1 in 8 to 1 in 5, is ordered to be made with 70 per cent. alcohol. In this connection it would be interesting to know if manufacturers to whom they were asked to pin their faith observed the standards of crude drugs before making galenicals, as they must do the standards of officially standardised pharmaceutical preparations? That was where the extractive residues of the tinctures would give an approximate indication of the quality of the drugs that had been used in their manufacture. This question had been suggested by an experience of his own in making tr. asafet. since the issue of the new B.P. The gum resin, so far as appearance and aroma went, seemed good, but it only yielded 46 per cent. of soluble matter—a deficit of 19 per cent.—and the ash amounted to 31 per cent., an excess of 21 per cent. Moreover, although it had been such a poor specimen the menstruum only removed 43 per cent. of the soluble matter, which showed that 70 per cent. alcohol was not sufficiently strong. This was further proved by the tincture, which was bright, producing opalescence when it was mixed with some 1885 tincture. A glance at past pharmacopœias with reference to that drug showed how capricious an authority the Pharmacopœia was for the time being. In 1867 asafetida was said to "dissolve almost entirely in rectified spirit"; in 1885, "50 to 60 per cent. should be soluble in rectified spirit," and now the percentage, without variation, had been raised to 65. An analysis of the changes that had been made in the tinctures showed that 41 had been strengthened in alcohol:—

No. 11	Menstruum	S.V.R. 1885	Trs.,	are now made	with 90 p.c. alcohol.
" 3	"	Pr. Spt.	"	"	90 "
" 6	"	"	"	"	70 "
" 21	"	"	"	"	60 "

Of these 6 had been weakened in active ingredients, 19 were unaltered and 16 had been strengthened. On the other hand 18 tinctures had been weakened in alcohol:—

No. 7	Menstruum,	S.V.R., 1885	Trs.,	are now made	with 70 p.c. alcohol.
" 11	"	Pr. Spt.	"	"	45 "

Of these four have been weakened in active ingredients, three are unaltered, and 11 have been strengthened. The omission of tr. zingib. fort. when it is still required for making tr. zingib. *per se*—when both it and the syrup would have been conveniently made as dilutions of the strong tincture—were equally inexplicable. Six proof spirit tinctures and four S.V.R. tinctures had been omitted and three tinctures had been added. The *modus operandi* in the percolation process also called for remark, inasmuch as the relation of menstruum and drug in the initial process had been reversed. The quantity now ordered was inadequate for the purpose of damping, his experience being that to thoroughly moisten a drug it required double the volume of menstruum for the weight taken. On the chemical side, it might be noted that the tests for essential oils would have had their usefulness increased had colour reactions, as well as physical changes, been uniformly observed. In the ammonia test for ol. caryoph. and ol. pimentæ, the colour of the "semi-solid" was stated in the case of the former, but not of the latter. In the latter there were two strata, the lower being orange-yellow, and the upper amber coloured, which ultimately assumed the original colour of the oil. Then the phosphoric acid test for ol. cajeputi and ol. eucalypti acted differently on these oils. In the former the green colour was discharged, and a pale, straw-coloured mass resulted; while in the latter, as stated by Helbing, the addition of the acid produced "a dark reddish coloration." Then the nitrite test applied to ol. eucalypti produced a beautiful emerald-green colour, but according to Baker and Smith, of the Technological Museum, Sydney, the oil of the eucalypt. globulus does not give this coloration (*P. J.*, October 22, 1898, p. 437). If that were so, the importance of that colour reaction could easily be seen, seeing that globulus was official, and commercially was the higher priced oil. Several samples he had examined all gave the green colour, and they were bought as globulus. If these were constants they would be better for being authoritatively stated, rather than that they should seem to be accidental or give rise to doubt. Ol. cadini is stated to be "soluble in ether and chloroform, partially soluble in cold, almost entirely in hot alcohol, 90 per cent.," but in what proportion was not stated. These were a few of the points that had arrested his attention in perusing the B.P., 1898, and they served to indicate what a fertile field it presented for a varied expression of opinion. In view of the fact that the object of the paper was to introduce a discussion, he had purposely left untouched many points that were sure to be raised during the progress of the discussion, which he trusted would be as enthusiastic and profitable as it was to be prolonged.—Mr. SUTHERLAND thought there was a distinct improvement in regard to the index, especially from a student's point of view, but at the same time he thought it more profuse than it really ought to be. He should have liked to have seen one or two more syrup formulæ. Easton's syrup, according to the new formula, showed no distinct improvement. It deposited in a short time, and required a small amount of free acids to keep the salts in solution. The colour tests of the essential oils might well have been added. Most of them were coming to the conclusion that quite a number of things were beyond the capabilities of the ordinary pharmacist. Take the standardised preparations. There was no doubt a distinct improvement in having these placed on the market with a uniform strength; but at the same time he should have liked to have had a simpler method of determining the strength of these drugs, so that the average pharmacist could prepare them in his own place. While he did not doubt that these were supplied by the wholesale houses at the pharmaceutical strength, it was desirable that these should be manufactured by the pharmacists themselves. He was only thus expressing what many of the recent examiners in pharmacy had been saying. The new concentrated liquors were not, in his opinion, equal to the old-fashioned infusions. He did not think a uniformity of doses a step in the right direction. Doses might have been kept within a limit of 5 to 10 minims or 10 to 30 minims, and at the same time have a pretty uniform system of strengths from which they were prepared.—Mr. MACMILLAN thought the uniformity of doses a very great mistake. It was a Glasgow production, and he had done what he could to show the absurdity of it at the time, but the idea had been that it would be such a saving to the younger men. The difficulty with the whole of them was the number of doses on the border lines of safety. He had searched out about a dozen of these, and he defied any man to say whether they were strong or ordinary doses.—The PRESIDENT failed to see why the alteration of doses had been gone into to so large an extent. He was certain, for instance, that many medical

men who now ordered tincture of nux vomica were not aware that they were getting a stronger dose.—Mr. MACMILLAN said it was absurd that they should dispense prescriptions according to the new B.P. when it was not the thing ordered by the prescriber. He understood that there was a difficulty about this, but that it might be overcome by publishing the book, say, in the middle of summer, and not gazetting it till January 1. Might there not be some pronouncement sent by the Association now to the General Medical Council, or whichever body was responsible for the publication?—Mr. SUTHERLAND thought that would be remedied in the next edition, as he had no doubt the Committee would, in the next edition, publish the book some time before they made it legal.—The discussion was then adjourned to the next meeting.

At a meeting of the Manchester Pharmaceutical Association, held on November 9, the chair was taken by Mr. G. S. WOOLLEY, and a paper was read by Mr. J. H. HOSEASON on

The Standardisation Processes of the B.P.

The author criticised many of the official processes at length. He said the lead oxide quantitative test for phosphoric acid might have been replaced with advantage by the method of determination with magnesium pyrophosphate. In the present test, other acids (except nitric) and salts occurring as impurities will be reckoned as phosphoric acid. Ammonium phosphate is assayed by the magnesium test, but not sodium phosphate. The salts of quinine and morphine are not to be quantitatively determined, but in the case of all other alkaloids and their salts no assay process is given. It seems desirable that those compounds and preparations obtained from them should answer to suitable volumetric tests. The present titration method for ammonium carbonate is fallacious, especially in the hands of an unskilled operator, and the quantitative tests are incomplete in spt. ammon. aromat. The total ammonia is to be determined by acid, and a minimum limit is fixed for ammonium carbonate, but there may be no free ammonia present and the preparation yet answer the test. The following process is suggested:—(1) Determine the total ammonia; (2) add excess of barium chloride, filter into excess of decinormal hydrochloric acid, wash the precipitate with three quantities of distilled water, add the washings to the acid, and finally titrate with decinormal soda solution. A simple calculation gives the correct amounts of free ammonia and carbonate. These should vary within small limits. Suitable processes for the quantitative determination of the arsenic preparations are necessary. In the case of iron arsenate the ferrous iron is to be determined, but not the arsenic. The method for sodium arsenate, in which magnesium pyro-arsenate is used is distinctly better than precipitation with lead arsenate, as in the latter case the presence of free acid or ammonia vitiates the result. The belladonna assay process of the Pharmacopœia is due to Cripps. Wilson has criticised the process, and his (Mr. Hoseason's) experience in great measure coincided with Wilson's. He found the loss due to alcohol to be from 1 to 2 per cent. of the total alkaloid present. In working with belladonna there is less tendency to emulsification if the first lot of chloroform added is rotated gently and withdrawn. The washing of the chloroformic solution is quite unnecessary, but whether a preparation is assayed by the B.P. process or by Wilson's method, the analytical results are substantially the same. Baryta or lime water would be preferable to soda solution in the B.P. assay process. The end reaction is much sharper, owing to the absence of carbonate. Hæmatoxylin is preferable as an indicator in this process. The assay process for ext. cinchona liq. is practically that of the B.P. of 1885, with the addition of a purification process. The results are lower than by the earlier process, and are undoubtedly nearer the truth. The addition of a check by titration might be advisable, and a limit of variation, based on the average proportion of mixed alkaloids found in cinchona, should be allowed. The B.P. test for calx. sulphurata allows a 50 per cent. or a 99 per cent. sample to pass indiscriminately. Total precipitation and weighing of the sulphide would be preferable. The preparations of cantharides might well have been made from a standardised fluid extract. The assaying of cantharides should not present any great difficulty. The assay process for fluid extract of ipecacuanha is one of the most unsatisfactory in the Pharmacopœia. Wilson had found that process faulty in precipitating alkaloid along with the lead compound formed by the addition of sol. of subacetate of lead. He (Mr. Hoseason) had not been able to obtain such close results as those of Wilson, and he thought Wilson's method open to improvement. In jalap extract no definite quantity of resin is required,

and an assay might be added with advantage. In lead salts the determination by total precipitation is unsatisfactory. By precipitation from neutral oxalate solution of known strength and subsequent determination of the residual oxalate by permanganate correct results are obtainable. The sulphate in magnesium salts is determined, but the oxides and carbonates, which are more likely to be variable, are not. In assaying *nux vomica*, strict adherence to the pharmacopœial quantities is absolutely necessary to obtain correct results. The new process for opium is a distinct improvement; the final titration and addition of an average loss makes this assay almost absolutely accurate. Potassium permanganate is estimated by oxalic acid, which is not official, neither is it a substance that can be taken as a constant. The B.P. process of assaying pepsin is inadequate. Nothing short of a method for assaying the peptone formed under given conditions of time, dilution, acidity, agitation, should have been inserted. With the present test, solution is regarded as digestion. *Strophanthus* preparations might well have been made from a standard fluid extract. Barclay has suggested a very easy and apparently accurate means of determination, but the pharmacopœial authorities seem to have overlooked his paper.

Mr. GRIER next read a paper on

The Pharmacy of the B.P.

Beginning with the nomenclature of the book, he drew attention to the changes which have been made, and referring to the Latin names, which were now declinable, expressed wonder at nouns, such as thymol, menthol, chloral, etc., being still treated as indeclinable. With regard to the chemical names he saw no reason why, since chloroform was a sufficient title for chloroform plus 1 per cent. of alcohol, that ethyl alcohol was not sufficient for alcohol plus 1 per cent. of water. Further, he thought that phenol should have been the official name of ac. carbol., and carbolic acid the synonym. In the case of calcium hydroxide he failed to see any reason for this new title, inasmuch as it was not pure $\text{Ca}(\text{OH}_2)$, and potassium hydroxide was defined as $\text{K}(\text{OH})$, plus combined water and impurities. Coming to pharmacy proper it was noted that considerable alterations had been made in the processes for exhausting drugs: (1) In the degree of comminution; (2) in the solvent employed; and (3) in the methods of exhaustion, as well as in the strength of doses, and, generally speaking, he thought all were distinct improvements on what had gone before, whilst he thought they by no means represented the utmost that British pharmacy could do. He took exceptions to the application of the name liquor to such preparations as the new liq. *calumbæ*, etc., thinking it should be reserved for solutions of definite substances, such as strychnine or caoutchouc; and on the same ground he thought the term misapplied in the cases of liq. *thyroidei* and liq. *pancreatis*, which were not solutions of the substances themselves but of their soluble constituents only. Dealing with the extracts he thought that cold re-percolation would be more suitable for ext. *cocæ* liq., seeing that cocaine readily decomposes in hot solutions, and that process might have been extended with advantage to some other liquid extracts. On the other hand a distinct improvement had been made in the methods of exhausting *jaborandi* and *rhubarb*. He expressed surprise that no change had been made in the preparation of extract of chamomile, as he considered a much better process would be exhaust with weak alcohol, and after recovering the alcohol, continue evaporation *in vacuo*, as he had advocated elsewhere. Referring to the *aceta*, he noted the improvement in the process of making *acetum canthar.*, but thought the new process of making *acet. ipecac.* a rather roundabout one. In the matter of wines, seeing that the presence of tannin and free acid was objectionable, he was of opinion they should be detannated, or that a weak flavoured alcohol should be used instead, as recommended by the U.S.P. Revision Committee. Passing to the tinctures, he did not think the substitution of liq. *ammonia* for *spts. am. arom.* a good one, and questioned the necessity of pressure in many cases where now ordered. In the cases of tinctures made by the maceration process, and which were now to be made up to a definite volume, he pointed out that, as considerable loss of spirit by evaporation might occur during filtration, the final products might vary considerably. In the solution of *indiarubber*, too, he considered that the volatile nature of the solvent employed was such as to render necessary some statement as to the volume of the final product, and he showed two samples—one a clear brown solution, and the other more of the nature of an emulsion. Speaking next of the syrups, he suggested that liquid extract of

rhubarb and *senna* should be made official, and also the respective syrups made therefrom. Referring to the waters, his opinion was that, as calcium phosphate is slightly soluble in cold water, a better medium would be teased filter paper. He then briefly referred to the more important changes which had been made in other classes of preparations, and disapproved of the use of dried sulphate of iron in *pil. ferri*, as the pills so made showed a tendency to crack. The Pharmacopœia authorities having done away with descriptive methods for preparing chemicals, and having gone still further in giving two general processes for the preparation of the tinctures, leaving the details and minor variations in their preparation to the judgment of pharmacists, the speaker wondered if the same principle would be extended in future pharmacopœias to other classes of preparations, such as extracts and infusions.

Discussion.

In the discussion which followed the reading of the papers, Mr. FRANKLIN said he agreed with almost everything Mr. Hoseason had said, but in regard to the standardisation of, say, belladonna plaster and ointment, this would entail very great difficulty to working pharmacists to do this with every preparation. It seemed to him the object had been achieved in having one standardised basis for the whole lot. In regard to ointment bases generally, he thought there was great room for improvement, and he himself thought that petroleum jelly was a typical ointment basis.—Mr. BATTLE agreed that there was a lot of waste in the lead process, and if another were brought out, it would be better all round.—Mr. HOSEASON said that Mr. Grier had had the same difficulty as he had. Concentrated infusions of *senega* were liable to deposit, and he spoke of the large amount of solvent required for moistening the drug. He (Mr. Hoseason) thought it might be added to the Pharmacopœia, stating at what standard oleate of mercury could be evaporated.—Mr. WALTON agreed with Mr. Franklin's remarks on the wholesale and retail pharmacopœia. He did not, however, see the necessity of standardising three or four preparations of belladonna. If they could not do it in their own pharmacy they should certainly be able to buy the standardised preparation and make their own from it.—Mr. KIRKBY said he came expecting to hear some criticism of the Pharmacopœia and its methods. Most of them, as far as printed matter was concerned, had been almost surfeited with particulars of the new Pharmacopœia, what it did and what it did not contain. They could not help feeling when they heard the voices of fellow pharmacists that there was another interesting side to the subject. He felt thankful for the two papers, and he thought Mr. Hoseason's suggestions with regard to the Pharmacopœia appeared to the point, and might very well be adopted. The questions which had been raised as to a wholesale and a retailer's pharmacopœia must be considered in connection with standardising processes. If they were made too elaborate the chances were they would not be undertaken at all, and in a pharmacist's retail establishment it was almost certain they would not be undertaken. The present Pharmacopœia had thrown into the hands of the manufacturing pharmacist a great many things which might have been made by the pharmacists, and he deplored that this should be so. He thought the time had come when the Pharmaceutical Society might devise some means of getting somehow into touch with the members of the General Medical Council, to see if the Research Laboratory could not be made useful for working out the formulæ which should come into the new Pharmacopœia.—Mr. KEMP also agreed with Mr. Franklin and Mr. Walton that it was a mistake to have a standardised preparation to start with in the making of such things as belladonna plasters and belladonna ointment, and then being under the necessity of still further standardising. He inferred if they started with an already standardised preparation in all these things, given all reasonable care, they were bound to get what was practically a uniform preparation as a result.—Mr. HOSEASON and Mr. GRIER having briefly replied, the meeting terminated.

REACTION FOR VANILLIN.—Bounema has found, while working on santal oil, that a little vanillin, dissolved in a few centimetres of acetic acid containing 10 per cent. hydrochloric acid, gives immediately, on the addition of 2 drops of santal oil, an intense cherry-red colour, which changes to dark bluish-violet on heating. At ordinary temperatures the bluish-violet colour changes to green in the course of twenty-four hours.—*Pharm. Centralh.*, xxxix., 357, after *Pharm. Weckblad.*, 1897, 24.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

The annual dinner of this Association was held at the Café Royal, Regent Street, W., on Wednesday, November 16, the retiring president, Mr. J. H. MATHEWS, in the chair. He was supported by Mr. WALTER HILLS, President of the Pharmaceutical Society, Mr. J. F. Harrington, the newly-elected President of the Association, Dr. A. P. Luff, Dr. B. H. Paul, Mr. F. W. Gamble, President of the Chemists' Assistants' Association, and other gentlemen well known in pharmaceutical circles.—After dinner and the usual loyal toast, the CHAIRMAN proposed

The Western Chemists' Association.

Mr. MATHEWS said he was very interested and pleased to bring this toast before them that evening, inasmuch as he had taken a deep interest in the Association from its formation. The number of permanent members was now about one hundred, and on the whole the Association could boast a successful career. It had been the means of bringing together not only the chemists of the West-end but others from all parts of London, and as a result they were on more friendly terms than was the case eight years ago. He believed it was the only Association formed to discuss purely trade matters in London, except, of course, the Pharmaceutical Society. He was sure they would all wish with him that the Association should continue to prosper, and he hoped they would support it at all times. That occasion would be the last on which he would address them as President of the Association, but he was pleased to know that the lot had fallen upon one fully capable and worthy in every way of occupying the position. He coupled with the toast the name of the new president.—Mr. HARRINGTON, in reply, thanked those present for the way in which the toast had been proposed and received. There was one matter on which he was desired to speak that night. He understood that if the Association were to invite the British Pharmaceutical Conference to visit London in the year 1900, there was every reason to believe the invitation would probably be accepted, and it was desired to send a cordial invitation to the Conference from the Association. The matter would be brought forward at the December meeting, and he hoped they would be prepared to accord the Conference a good welcome, such as the pharmacists of the metropolis ought to give. With regard to the Association itself, they all wished to see it grow. When the Association got the name of the Western Chemists' Association he believed it was not intended that it should be confined to the chemists of the West-end, but that it should include chemists from all parts of London. Already they had a number of members from many parts outside the western district, and if in the future it was thought desirable to alter the name of the Association no doubt it would be done. He hoped there would be a large attendance at the December meeting, as several things of interest to pharmacy in general, and London chemists in particular, would be brought forward.

The CHAIRMAN next proposed the toast of

The Pharmaceutical Society of Great Britain.

He said it had always been customary to propose that toast, and he might perhaps be allowed to say that the Western Chemists' Association as a body is perfectly loyal to the Society, and is prepared in every possible way to support the Council with its sympathy and practical help in everything it might think proper to do for the general good of pharmacy and the advancement of education. He coupled with the toast the name of the President of the Pharmaceutical Society.—The toast was drunk with musical honours and, in reply,

Mr. HILLS said he thought the speakers that night laboured under a considerable disadvantage, for with such a good musical programme as had been provided those present would not wish to listen to long speeches. Still he felt that on the present occasion it was necessary that he should say a few words on matters pharmaceutical. First, however, he would like to thank the Chairman for the very kind way in which he had proposed the toast of the Pharmaceutical Society, and all present for the very enthusiastic way in which it had been received. The duties and responsibilities attached to the position he had the honour to hold at the present time were very considerable, but they were very much lightened by the kind reception that he received at meetings of the character of the gathering that night. Wherever he went he was received as President of the Society with the utmost cordiality. He was always glad to attend meetings of associations similar to theirs, because he was of opinion that such associations were of great

service to the parent Society, which he had the honour to represent. Since he last had the pleasure of addressing them twelve months ago the Society had gone through a little excitement, and several things had happened of very considerable importance. He need only refer to what had taken place in Parliament during the past session. They would recollect that during the last session the Council of the Pharmaceutical Society was successful in carrying through the Pharmacy Acts Amendment Bill, which is now on the Statute, and during the same session the Poisonous Substances Bill was successfully opposed. He took credit for the Pharmaceutical Society entirely for the first feat, and he took a very large amount of credit to the Society for the successful opposition of the Poisonous Substances Bill. The Pharmacy Acts Amendment Bill was one which, he believed, received the almost unanimous support of the members and associates of the Society throughout the country. They had not in that case to fight against anything like public opinion, but they had a fair unanimity amongst the Society's own members and associates, and so were able to carry that Bill through Parliament. With regard to the Poisonous Substances Bill, they had a very strong argument to urge; that was that poisonous substances should only be sold to the public by those who know their qualities and those who know the responsibilities which accompany such sales. He wished to refer more particularly, however, to what took place towards the end of the passage of the Pharmacy Acts Amendment Bill through the House of Lords. It would be remembered that when the Bill came before the Upper House, the Lord Chancellor and Lord Herschell pointed out the anomaly that exists at the present time with reference to the carrying on of the practice of pharmacy by

LIMITED COMPANIES AND CORPORATIONS.

Those remarks caused a considerable flutter in the ranks of pharmacy and consternation amongst those connected with such companies and corporations. Lord Hardwicke, however, who had charge of the Bill, very wisely asked the Lord Chancellor to frame an amendment on the lines of the remarks made by himself and Lord Herschell. But after their views were put upon paper, the Council felt that they did not give much encouragement to proceed in the matter. They were, in fact, such as would have legalised the practice of pharmacy by limited companies and corporations. He thought the Council did well, therefore, that on the part of those whose interests were affected—if for no other reason—the Lord Chancellor was asked to withdraw that amendment, and that the Bill passed without it. They had been told, by one organ at least, that the Council did a very unwise action by asking the Lord Chancellor to withdraw that Amendment. He (Mr. Hills) had no evidence of that except from that organ, which does not always represent the opinions of chemists throughout the country, but he thought that the Council's action was justified and advantageous under the circumstances. After the Bill had passed and become a Statute, he had a very pleasant interview with the Lord Chancellor at the House of Lords. He did not propose to tell them all that passed on that occasion because it was of the nature of a private interview, and he did not wish to say anything which was not intended to be made public. There were two points, however, which struck him with reference to that conversation (1) The Lord Chancellor strongly advised that in any action the Pharmaceutical Society took to regulate the practice of pharmacy, only such measures should be proposed as would be favoured by public opinion, and which would receive the support of Members of both Houses of Parliament. (2) The Lord Chancellor said he thought that the public have some right to know that its medicines are compounded and dispensed by qualified persons. Those were the two points which particularly struck him with reference to that interview. Of course, the interview was asked for by him (Mr. Hills) because of the companies question, and that was the point to which he wished to refer. He thought they would believe him when he said that personally he was utterly opposed to company pharmacy. He believed it to be contrary to the spirit of the Pharmacy Act, and it had been of very great disadvantage to the progress of pharmacy. He thought and felt that the great obstacle to progress was the dreadful bane of companies carrying on the practice of pharmacy. He was inclined to think it was to the interest of every community that there should be in it a good parson, a good physician, and a good pharmacist. It might also be advantageous

to have a good lawyer. Those men should be above the carking cares of poverty. Certainly there should be a good pharmacist, who ought to have sufficient remuneration for his services to enable him to do generous actions in cases of real need in any particular community. But company pharmacy has interfered with that ideal. Such is the problem facing pharmacists at the present time, and it is one which has been suggested by the Federation of Local Associations for discussion during the coming winter. It has already been discussed at Nottingham, and he desired to impress upon that and other associations the desirability of discussing it from a practical point of view, not from an ideal standpoint, but to deal with it as they found it to-day. In connection with the resolutions sent up from the Nottingham meeting, he was not altogether correctly reported when he last spoke at the Council meeting. What he wished to say was that he thought that the remarks—as reported to have been made—by some of the speakers at that meeting were not in accord with the unanimous passing of the resolution which was afterwards sent up to the Council, because some of the gentlemen said it was almost impossible to prevent companies trading in pharmacy from carrying on their business. Now, there were three ways or lines of policy which might be pursued. The first was what he might call the *laissez-faire* policy, and that was the policy which had been pursued during the last eighteen years, it being about eighteen years since the House of Lords gave the judgment which made it possible for companies to carry on the practice of pharmacy. The objection he had to that policy was that matters were getting worse and worse. Companies are pressing pharmacists on every side, and the rights that those companies have are increasing. Moreover, the Pharmaceutical Council has no means at the present time of taking proceedings against companies, the only course it can pursue is to find out and prosecute the unqualified seller of poisons. Another objection to the *laissez-faire* policy is that the Government itself may bring in a measure dealing with the question, and it is not likely to bring in one which is as good as one pharmacists could bring in themselves. The second policy would make it

ILLEGAL FOR ALL COMPANIES

to carry on the practice of pharmacy. He was bound to say that if the matter was being discussed at a debating society he should like to throw in his lot with that policy. But they would have to make it perfectly clear to the members of the House of Commons that it is to the interest of the public that the practice of pharmacy should be under the control of qualified persons, and that there is no safety in company pharmacy. He thought, however, that in the present state of public opinion they would have a very powerful opposition against which to fight, to obtain legislation to carry out that policy. Of course, they would have the opposition of companies, there could be no doubt about that, and not only that, but to be of any use to pharmacists a proposition of that kind must be retrospective in its action. Now, if there is one thing about which the House of Commons is very strong it is its regard for existing rights, and he thought it was very obvious that if pharmacists were to make any suggestion of that kind there would be a very strong feeling on the part of the House of Commons to place on some kind of register those companies which have been in business for some length of time. In spite of that he believed that if there were, say, 90 per cent. of the trade in the Society, it would be possible to go to Parliament on the question. But even if they had 90 per cent. of the trade with them, they would certainly have public opinion against them in the matter. The third thing that might be done would be to draft a Bill which would in some way regulate company trading, and ensure that there is a qualified man in all places where medicines are sold, dispensed, or compounded, and it might with advantage include qualified managers in branch shops of qualified proprietors. He was inclined to think that such a measure could be framed, and he did think that it was quite possible that some Bill might be framed which would under present circumstances be of advantage to registered persons. It would certainly place difficulties in the way of what he called bogus companies, who would have to say from time to time whether a registered man was in charge of their business places. But he was bound to say that that action would be met by a considerable amount of opposition from many of their own friends. He believed, however, it was possible that a Bill drafted on those lines would be accepted by the Government and would be, under present circumstances, advantageous to the craft. He should say that any Bill which they drafted for the consideration of Parlia-

ment should most certainly contain a clause restricting to qualified persons the compounding and dispensing of medicine and the sale of pharmaceutical preparations. It should be a *sine quâ non* that the sale should be restricted to those who have passed the necessary qualifying examination; and that pharmacy should not be taken up and practised by persons who are simply banded together without taking that qualification. He had thrown out these views in the hope that it might help associations in their discussions, and he would urge associations to treat the matter from a purely practical point of view. There are many things pharmacists want, but which they are unable to procure. He found that there was an opinion current that the companies have now got such a long-established right to practise pharmacy that it is almost impossible to stop the practice altogether. They would have to fight public opinion, and they must recollect that many pharmacists are now engaged by companies; moreover, there are many chemists who have formed themselves into companies, as had been ably pointed out by Mr. Gill in the last issue of the *Pharmaceutical Journal*. But if chemists were all united in this matter, they would not need any fresh legislation, because if they were all bound together companies could not be carried on. He did not blame those persons for lending themselves to companies. There might be circumstances in their case which rendered it necessary, but so long as persons did lend themselves to companies, the difficulty would always be very considerable. He did not intend to speak about the Poisonous Substances Bill, nor about poison regulations, but both those subjects were of importance at the present time, and were worthy of consideration by local associations. He thanked the Association for the very kindly response to the toast that evening, and he trusted that it would continue to flourish, and that it would help to strengthen the Pharmaceutical Society, for that Society required strengthening, and it was hoped that the Pharmacy Acts Amendment Act would be the means of bringing many into the Society. He hoped that in the coming spring they would have a considerable accession of members to the Society, and the Council would then be better able to deal with such matters as had been mentioned. It could not go to Parliament with any measure unless it had the great body of chemists with it, and he hoped that during the coming winter local associations would let the Council know what were their views on the question of company trading, and on other subjects to which he had alluded.

Other Toasts.

The next toast was that of the "Visitors," which was responded to by Mr. F. W. GAMBLE, President of the Chemists' Assistants' Association.—Mr. A. G. WORSLEY then proposed the toast of the "Chairman," Mr. MATHEWS replying.—Mr. J. F. HARRINGTON proposed a supplementary toast to the "Dinner Committee," which was replied to by Mr. H. CRACKNELL, the Hon. Secretary, and Mr. G. S. TAYLOR.—The toast list was interspersed with an exceptionally good musical programme, while the dinner itself left nothing to be desired.

DENTAL NOTES.

PROPERTIES OF VULCANITE.

Vulcanite is easily cut by dipping the chisel in oil. It packs clean and easily if used warm and wet. Warped vulcanite plates can be made to fit by using a fresh model of the mouth, warming the plate until quite pliable, then press well home on model and dip in water.

REPLACING A BROKEN TOOTH.

An easy and quick way to replace a broken tooth on a rubber base is to remove all pieces of tooth and pins, cut retaining form where pins were with engine bur, place new tooth in position, and stick it to approximating teeth by placing sticky wax over the labial surfaces. Then fill the retaining form and around the pins of the new tooth with amalgam. Leave the wax in place until amalgam has hardened.—*Ohio Dental Journal*.

LIQUID BORAX FOR SOLDERING.

Use a saturated solution of borax for soldering. The piece to be soldered is painted with solution where the solder is wanted to flow. The solder will be found to run much quicker and easier than if the borax powder is used.

THE STUDENTS' PAGE.

EXPLANATORY NOTES ON THE B.P.*

Extractum Belladonnæ Alcoholicum.—By simply evaporating a given bulk of the liquid extract to dryness we should obtain a solid extract whose weight, and consequently whose potency, would vary with the amount of extractive matter, other than alkaloid, contained in different samples of the liquid extract. Moreover, a solid extract so obtained would obviously contain several per cents. of alkaloid and would be too strong for general use, since the dose would have to be a very small fraction of a grain. To avoid these objections the Pharmacopœia directs a small trial portion to be evaporated to a moderately firm extract to determine the total solids contained in the liquid extract. *Extractum belladonnæ alcoholicum* is required to contain 1 per cent. of alkaloids. The liquid extract, from which it is made, contains 0.75 part of alkaloids in 100 fluid parts; hence to obtain a solid extract containing 1 per cent. every 100 fluid parts of liquid extract must yield 75 parts by weight of solid extract. This explains why the weight of total solids from the trial portion, one fluid ounce (or 50 C.c.—*vide* B.P. directions) is to be subtracted from three-quarters of an ounce (or 37.5 grammes). The figure so obtained shows the weight of milk sugar required to produce, with the solids derived from the liquid extract, a solid extract having the required relationship to the liquid extract. In making the solid extract, it is better to add the required weight of milk sugar to the liquid extract before evaporation. We obtain thus an intimate and uniform blending of milk sugar with extractive matter more easily than we could by triturating the sugar with the solid residue produced by evaporating the liquid extract by itself.

Extractum Cinchonæ Liquidum.—The assay process for this extract has been elaborated. In the B.P., 1885, the residue of the benzolated amylic alcohol solution, obtained by agitating the extract with this solvent after addition of alkali, was weighed and reckoned as alkaloid. In order to effect further purification before weighing, the alkaloids are "shaken out" from the benzolated amylic alcohol, as hydrochlorides, by acidulated water. They are then transferred, as free alkaloids, to chloroform after addition of ammonia to the acid aqueous liquor. Colouring matter will be eliminated at each of these additional operations, and assuming that no appreciable quantity of alkaloids are simultaneously lost, the chloroform residue should yield a more accurate index of the alkaloidal contents than the crude residue of the benzolated amylic alcohol.

Extractum Filicis Liquidum.—Note the alteration in the official dose. It is now in accord with medical practice, for the dose given in B.P. 1885, was much too small to have the desired anthelmintic effect.

Extractum Nucis Vomiceæ Liquidum.—The method adopted for the preparation of this extract is followed in principle in the case of several others in the official formulary. The drug is moistened and percolated with the menstruum. A certain portion of the percolate first obtained is set aside. Since this contains the greater portion of the substances extracted by the menstruum, it is not subjected to evaporation. The weaker portion of the percolate obtained subsequently in completing the exhaustion of the drug is concentrated to a small bulk and added to the stronger reserved portion.

The assay process now adopted aims at the determination of strychnine only—not strychnine and brucine. Compare the notes on this subject in the last series of "The Students' Page." The extract is first evaporated to remove alcohol, then after suitable dilution the alkaloids are liberated by sodium carbonate and shaken out with chloroform. From the chloroform they are transferred as sulphates to water. The separation of the two alkaloids is based upon the fact that strychnine forms an extremely sparingly soluble ferrocyanide, while the corresponding brucine salt is only precipitated from comparatively strong solutions, and, therefore, not at all from the dilute solution as described in the Pharmacopœia. The strychnine ferrocyanide is washed free from brucine by acidulated water, in which the precipitate is less soluble

than in plain water. The washing is stopped when the bitter taste of brucine is no longer distinguishable in the wash liquor. The determination of the strychnine cannot be satisfactorily effected by drying and weighing the precipitate, since this undergoes decomposition during drying. A hole is therefore made in the point of the filter and the moist precipitate washed into a separator by a jet of water from a washing bottle. To the strychnine ferrocyanide thus suspended in water some solution of ammonia is added. Ammonium ferrocyanide remains dissolved in the water, from which the liberated strychnine is removed by repeated agitation with chloroform.

Extractum Nucis Vomiceæ.—The production of this from the liquid extract is conducted on lines quite similar to those already described under *extractum belladonnæ alcoholicum*. Here, however, the total solids of 500 C.c. of liquid extract, containing 7.5 grammes (1.5 × 5) of strychnine, must be made up by the addition of milk sugar to a total weight of 150 grammes in order that the finished solid extract may contain 5 per cent. of strychnine; for 5 : 100 :: 7.5 : 150.

Extractum Opii Liquidum.—The strength of this is now reduced so as to make it of the same potency as *tinctura opii*.

Extractum Pareiræ Liquidum.—The solid extract of *pareira* from which the liquid extract was prepared in the B. P. 1885 is now omitted. By careful comparison of the processes in the 1885 and 1898 Pharmacopœias it will be found that the new process for the liquid extract is a combination of the processes for both solid and liquid extracts in the former edition. The omission of the solid extract is probably due to the impracticability of giving the dose required (10-30 grains) in the pilular form for which solid extracts are generally adapted. The new process for the liquid extract provides a preparation practically identical with the 1885 liquid extract.

Extractum Physostigmatis.—This is now diluted with milk sugar to make the dose more manageable, and uniform with the other potent extracts of the Pharmacopœia.

Extractum Sarsæ Liquidum.—In making this extract maceration successively with proof spirit and water is replaced by repercolation with dilute alcohol (20 per cent.). Note that only the strong percolate up to the required amount is collected, probably because belief in the medicinal virtues of sarsaparilla has long since disappeared, and the value of the substances obtained by complete exhaustion are not considered worth the time and trouble their extraction involves.

Extractum Stramonii.—By omitting the preliminary treatment with ether to remove oil the yield of extract is increased, with a corresponding decrease of potency in the extract obtained. The dose of the new extract is therefore larger, and is now uniform with the other potent extracts.

Extractum Strophanthi.—The maximum dose of *strophanthus* seeds is about half a grain. It is therefore obvious that the residue produced by the evaporation of the alcoholic percolate (obtained by following the official directions) would be extremely potent, and its dose would be inconveniently small. It is diluted with a comparatively large quantity of milk sugar to produce from 1 part of seeds two parts of extract, the dose of which will therefore be one-quarter to 1 grain. The oil is removed from the seeds by previous treatment with ether. The presence of this oil would prevent the production of a dry extract in powder form, as described in the Pharmacopœia.

Ferri Sulphas.—Solution of ferrous sulphate is not precipitated by sulphuretted hydrogen on account of the solubility of ferrous sulphide in the sulphuric acid which would be produced at the same time.

In the case of ferric salts a precipitate of sulphur is produced. This is due to the oxidation of the H₂S by the ferric salt, which is thereby reduced to ferrous salt. This fact should be carefully remembered in qualitative analysis, since the precipitate of sulphur, caused by the presence of ferric salts in the solution analysed, is often mistaken by students for one of the yellow sulphides.

Ferri Sulphas Exsiccata.—Note that this substance still contains one molecule of water which is not expelled at a temperature of 100° C. If it be heated above this temperature the ferrous sulphate undergoes decomposition with formation of an insoluble oxy-sulphate.

* NOTE.—This series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P. J.* during 1897 and the earlier portion of the current year.

PHARMACEUTICAL JOURNAL.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, NOVEMBER 19, 1898.

THE CHIEF PROBLEM FOR CHEMISTS.

No one, we imagine, will be found in the ranks of pharmacy to deny that the most serious difficulty with which the craft is faced to-day is the growing tendency to render a proprietary qualification in pharmacy a non-necessity. Judicial interpretation of the Pharmacy Act of 1868 has all tended in the direction of upholding—as a substitute—the personal qualification of the individuals who sell poisons by retail to the public, and that personal qualification is now more effectually protected by Statute than any other qualification known to British law. But whilst the public is thus ostensibly protected by the Legislature and confirmed in its claim to such protection by the courts of justice, it has been gradually drifting into a position of extreme danger by reason of the utter inadequacy of the Pharmacy Acts to regulate the practice of pharmacy. If unqualified persons as companies—being outside the Act—can lawfully keep open shop for the sale, dispensing and compounding of poisons for medicinal purposes, the practical effect of that interpretation is to make the business free to everyone without restriction. It is not even requisite that the actual dispensing and compounding of poisons should be performed by or under the supervision of a duly qualified person. All that is really requisite is that the dispensed and compounded poisons shall be handed to the purchasers by a person registered under the Pharmacy Act. That position would be absurd if it were not so serious. Thirty years ago an Act was passed by Parliament, the preamble of which states that “it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business.” But though the legislators agreed as to what was expedient, the portion of the Act referring to those points—as since interpreted by lawyers—has been held not to apply to corporations consisting of seven or more persons, all of whom may be lacking as regards competent practical knowledge of the business they conduct.

Moreover, a company or other corporation consisting of unqualified persons may—according to that judicial interpretation—not only keep open shop for the sale, dispensing, and compounding of poisons; but, for the same reason, it may, apparently, appropriate the titles which the Pharmacy Acts were supposed to restrict to duly qualified persons; it need not observe any regulations with regard to the keeping and dispensing of poisons, nor is it obliged to compound medicines of the British Pharmacopœia in strict accordance with the formularies of that book. Poisons may be dispensed and compounded by errand boys or porters in establishments owned by corporations, without the supervision of a registered chemist and

—according to the same view—so long as the packages of medicine are handed to the purchaser by a duly qualified person, the law is fulfilled. Such is the absurd position in which matters now stand, and such is the position in which they are likely to remain unless active steps are taken to amend the existing Act, so as to effect the objects stated in the preamble more thoroughly. At present there is no protection for the public, except in regard to the mechanical sale of some few poisons. By the public spirit of chemists and druggists, as represented by the Pharmaceutical Society, a certain measure of protection has been established, as the result of half a century's work in improving the training and qualifications of the recognised retailers of poisons. But proprietary qualification in pharmacy—the chief essential for public safety—was attacked with fatal results when the decision of the House of Lords was given in the case of the London and Provincial Supply Association and, at the present time, an insidious attack is being made on the personal qualification of registered chemists, through the appropriation by limited liability companies of the titles which the Pharmacy Acts have been supposed to protect.

Unless registered chemists are willing to acquiesce in this state of affairs—which reduces British pharmacy law to a delusion and a mockery—they must resolve to dispute the conclusions which have led to it. They must therefore be prepared to fight again for their position, unless they are content to witness the loss of everything which they have acquired by years of persevering and hard work in the public interest. Having realised how miserably insufficient is the protection afforded by the Pharmacy Acts, and especially by the 1868 Act which opens with the declaration that so much is requisite “for the safety of the public”; recognising also how unsatisfactory is their own position, registered chemists as a body should take measures to secure the proper regulation of the practice of pharmacy, and insist that it shall not be open for any combination of unqualified individuals to do what the law prohibits one, two, or six persons from doing. When a person is compelled by the State to devote time, labour, and expense to the acquirement, in the public interest, of a special qualification, it is reasonable to expect that the State should for that reason prohibit unqualified persons—however many may combine together for the purpose—from exercising the business for which that qualification is held to be requisite, and it is also reasonable that unqualified persons should be effectually prevented from usurping the titles attaching to that qualification. If, further, a person submits to the regulation of his business by the State, also in the public interest, he is entitled to ask that no person or combination of persons shall be in a position to do what he may not do. There should not be one law for individuals and another for corporations, and if registered chemists will only combine to ask for the proper regulation of their business on a logical and common-sense basis, they can present so good a case that the result can hardly fail to be satisfactory to them and advantageous to the public. In conclusion, attention may profitably be directed to the offer made by the President of the Pharmaceutical Society (see p. 532) to take the lead in working for an amendment of the existing law if he is properly supported. Registered chemists can only give the support needed by joining the Society of which Mr. HILLS is the head, and the sooner they recognise that fact the better.

ANNOTATIONS.

THE FIRST EDINBURGH EVENING MEETING of the Pharmaceutical Society will be held in the Society's House, 36, York Place, on Wednesday next, November 23, at 8.30 p. m. The chair will be taken by Mr. J. Laidlaw Ewing, and the inaugural sessional address will be delivered by Ralph Stockman, M.D., F.R.S.E., Professor of Materia Medica and Therapeutics in the University of Glasgow. The subject of the address will be "Arrow and Ordeal Poisons: their History, Sources, and Constituents," and the lecturer's remarks will be illustrated by an exhibition of specimens.

THE PHARMACEUTICAL SOCIETY, according to certain newspapers which are not usually well informed regarding the Society's methods of procedure, has recently issued a circular to its local secretaries bearing on the sale of certain "patent" medicines. Vendors of the articles referred to are accordingly warned to be on their guard where a question of poison is involved, and it is suggested that, perhaps as a consequence of the circular, many inquiries for prohibited goods have recently been made at shops selling "patent" medicines. No circular of the special nature indicated has been issued by the Society, and the alleged effects of the hypothetical document must, therefore, be due to some other cause, possibly the working of conscience in the case of individuals who have been selling poisons illegally. In any case, the warning addressed to such persons by the *Grocer* and other papers cannot fail to be useful, and the public should reap the benefit by a diminution in the number of infringements of the Statute.

THE PHARMACEUTICAL SOCIETY OF IRELAND has failed to convince the Judges of the High Court that there was not a good reason for a writ of mandamus to be granted in the case referred to a fortnight ago (see *ante*, p. 496). It will be remembered that the applicant, Mr. Conyngham, sought a mandamus to compel the Council of the Society to admit him to their examination for the pharmaceutical licence. That they had declined to do on the ground that he had not served a full term of four years' apprenticeship to a pharmaceutical chemist or a firm of legally qualified pharmaceutical chemists, a portion of his term having been served to a limited liability company. On the part of the applicant the contention was that the regulation requiring four years' apprenticeship was *ultra vires*; but that even if it were not, his apprenticeship was a compliance with the regulation, as all the members of the limited company with whom he had served part of his term were duly qualified pharmaceutical chemists, and that none others could belong to that company. The judges were all of opinion that the Court was not precluded from examining into the validity of the regulation; that the regulation went outside the powers conferred by Section 15 of the Act of 1875 to make regulations, and consequently was originally *ultra vires*; that it had, however, been set up by Section 10 of the Amendment Act, and was consequently operative; and, finally, that the apprenticeship of Mr. Conyngham was a compliance with the regulation, the limited company in question fully answering the description of a "firm of legally qualified pharmaceutical chemists," which the regulation contains. The writ of mandamus was therefore granted.

THE DIPLOMATIC PRINCIPLE of using language to conceal one's thoughts has within recent years been extended to the selection of names intended to be registered as trade marks which must not have any descriptive significance, and, to that extent, fairly good reason can be assigned for this practice. But in connection with

articles used for medicinal purposes caution is necessary to avoid a resemblance of names which might lead to possible mistakes, such as that pointed out a few weeks ago by Mr. R. Reynolds as arising from the confusion of a preparation described by the word "urotropine" with a drug so widely different as atropine. The further instance, given by Mr. Reynolds in last week's Journal (see p. 523), of a designation that fails to convey a definite indication of the article to which it is applied, shows how readily mistakes may result from the use of defective or unmeaning nomenclature. With such a multiplicity of articles as the pharmacist has to handle more or less frequently at the present time, the necessity of avoiding names that are at all misleading cannot be too forcibly insisted upon.

ECONOMY MAY BE EXAGGERATED, and it certainly appears to be so when medicine is administered to healthy individuals in order that it may not be wasted. Judging from the remarks of the Flintshire coroner at an inquest held last week, that was the position of affairs which had resulted in a child's death. The child had been taking medicine, but the supply had been exhausted for some days, and the erstwhile patient had since been playing about and quite happy. The mother was using a lotion containing atropine for the eyes, and, before paying a visit to Liverpool Infirmary, she emptied what was left of her lotion into the bottle that had contained the child's medicine, so that she might take the lotion bottle to be replenished. Next day she noticed the liquid in the child's medicine bottle and—forgetting what it was, and ignoring the fact that the child was not ailing—she administered to the poor infant a dose of the poisonous lotion. Death ensued, and was shown to be due to poisoning with atropine; the coroner said it was clear from the evidence that the mother had been most negligent, but the jury returned a verdict of "Death from misadventure," apparently without comment. Possibly, the jurymen are enthusiasts on the subject of economy, and prefer that their pet virtue should be persisted in, under all circumstances, even at the cost of a life.

THE DOOM OF THE RETAILER is suggested by a communication in the *Times*, the writer of which suggests that if the consumer can procure, by the simple expedient of a postcard, a trade article delivered at his door straight from the manufacturer, with less trouble and at a lower price than from the middleman, the needless labour involved by the use of the intermediary is, surely, so much loss sustained by the State. Accordingly, he proposes that the State should become the universal middleman, and that the policy at St. Martin's-le-Grand in this matter should be "to lead by its example the nations of the world—not sluggishly to halt in the background while others show it the way across country." He argues that lower cost means usually more production; and more production, at the same profit, greater activity and wider employment in remunerative trade. Why then, he says, waste (say) ten per cent. of the cost of manufactured goods, when by utilising a national establishment the ratepayer may save it? "He may at one stroke benefit himself and those who depend on wholesale manufacturers." Fortunately for the dismal science, this would-be revolutionist's object is not so much to touch the fringe of political economy as to urge that our Post Office should in no respect lag in the rear of the Continent and our dependencies, but be encouraged to develop "its still limited potentiality."

A PECULIAR COMPANY CASE came before the Deputy Judge in the City of London Court this week. It was sought to enforce payment of money, due from a defendant, who said he was the Chairman and a Director of the United Watch and Jewellery

Company, Limited, but that he received no remuneration from the Company. There were seven shareholders in the Company, but his wife, who had paid one hundred pounds, was the only shareholder who had paid for any shares. The Company had only been in existence for two months, and employed seven people. Defendant said it was not correct to say that he was virtually the Company. He held no shares, but he and another director signed the cheques. The latter were not countersigned by the Secretary, because there was not one. The premises in which the Company carried on business were tenanted by defendant, and the Company paid seventy-five pounds a year rent. Only a small business was done. The opinion of the Deputy Judge about the case was rendered sufficiently clear when he remarked that, after a decision in the House of Lords, no amount of fraud would justify him in getting at the defendant behind the Company. The defendant was evidently well acquainted with the Companies Acts, and he (the Deputy Judge) could not see any way to help the plaintiffs. He wished he could, and hoped that Parliament would before long consider such a case, and enable such companies to be dealt with.

INCUBATION OF BABIES BY GAS is the somewhat misleading heading of a news paragraph in the daily press, in which the use of gas for heating incubators is referred to. Gas plays a very valuable part in modern life, and new uses are found for it every day, but it is not yet directly available in the incubation of infants. Electricity, which has taken the place of gas very largely in the kindly office of dispensing light, might equally replace it in this newer direction, so that the *Daily Telegraph* is hardly justified in assuming that gas need not fear for its future on that account. At the same time, it is difficult not to sympathise with the journalist who has found a small vein of humour in the story of the proprietor of gas-heated incubators at Earl's Court, the Crystal Palace, and in other parts of the country. The gentleman in question had failed to pay his gas bill, the reason for the delay in payment being some dispute about the meter. Under such circumstances a deadlock might be most dangerous, the *Daily Telegraph* thinks, and it shudders to think what might happen if the gas were suddenly "cut off" from the disconsolate babes. "It would be a 'nice' point as to who was responsible for the result. After this we shall look at a street lamp with moistened eyes, knowing that it contains the foster-parent of some of our future citizens. It would be interesting to watch the effect of such early training on the inmates of these gas incubators. Will they grow up politicians or religious reformers, or merely light-headed?"

A HOSPITAL NURSE has accidentally caused the death of a patient through administering an overdose of tincture of opium in an enema. The written instructions left by the medical man in charge of the case were to the effect that if no relief were obtained by the patient by a certain time, an enema was to be administered, containing six ounces of starch and half a drachm of tincture of opium. The ordinary medical signs appear to have been used to indicate the quantities, and the nurse, unfortunately, misinterpreted the drachm sign, taking it for that of the ounce. Accordingly, half an ounce of the tincture was administered, with a fatal result. As might be anticipated, newspaper comments on the case have not been lacking, and much printing ink has been wasted in the endeavour to show that if the signs for the ounce and drachm were not so much alike the patient's life would not have been sacrificed. Lay writers have also enlarged on the possible dangers incurred by the regular employment of such signs in prescriptions. The more obvious moral would seem to be that if the technical signs and other abbreviations were

reserved for the exclusive use of persons trained in a knowledge of the properties and uses of dangerous drugs, a more effective check would be placed on the risk of accident than by simplifying matters for hospital nurses. The person most at fault in the case referred to appears to be the medical man who used signs in directions that should have been written in plain language. No similar mistake would be likely to occur with a properly trained dispenser, for even if a wrong sign were employed his knowledge of the properties and doses of dangerous remedies would suffice to prevent him sending out a wrong quantity. Most mistakes in connection with prescriptions occur in writing them, and the public would be surprised, and might be alarmed, if it were known how frequently registered chemists act as a check on prescribers in that respect.

THE CHEMICAL SOCIETY celebrated, last week, the continued existence of six of its past-presidents, all of whom have been Fellows for half a century.—Sir J. H. Gilbert, Sir E. Frankland, Professor W. Odling, Sir Frederick Abel, Dr. A. W. Williamson, and Dr. J. H. Gladstone.—The chair was taken by Professor Dewar, the President of the Society, who, in proposing the toast of the evening, remarked that it included the health of six of the Society's most distinguished past-presidents. It was admitted on all hands that the cultivation of chemical science had added enormously to the resources and power of mankind, and that its successful cultivation involved the exercise of every faculty of the human mind. Those men had laboured for half a century in the public interest, and they had added enormously to our knowledge of chemistry. It was almost impossible to over-rate the work they had executed. The width of it was something appalling, for amongst them they had recorded four hundred and fifty separate contributions to chemical science, many of which were of the highest importance, and they had really exercised an extraordinary influence on the development of chemistry. It was well that the Chemical Society of London—the oldest chemical society in the world—should have inaugurated that dinner, and it had been held because it was felt that the opportunity might probably never again occur. The sympathy of every chemist in the world was with them that evening, and their guests had the warm congratulations of the learned men in chemical science in France, Holland, Germany, Sweden, Austria, Russia, the United States, and other countries, which showed that Continental chemists appreciated the honour that it was desired to confer. Professor Dewar then proceeded to give a brief epitome of the work of the guests of the evening, and subsequently each of the six past-presidents responded

A LADIES MEDICAL AND PHARMACEUTICAL ASSOCIATION has been registered with a capital of three thousand five hundred pounds, its object being the advancement of the interests of gentlewomen who are qualified to act as doctors, dentists, and chemists, or who are desirous of acting in those capacities; to form a preliminary school of pharmacy; to establish a registry for general, midwifery, and surgical nurses; to open a consulting room where "women" may have the advice and attention of "gentlewomen" duly qualified in medicine and dentistry, and to carry on the business of pharmaceutical chemists, druggists, etc. The first subscribers and directors are all women, the qualification for directorship is ten pounds, and the directors are to share among them one hundred pounds per annum. It may be wondered why female patients are referred to in the prospectus as "women," whilst the members of the Association who wish to make a living out of those patients are "gentlewomen," but the prefix is doubtless justified by the great superiority of the joint-stock article.

CHEMISTS' ASSISTANTS' ASSOCIATION.

One of the most attractive and pleasant features of the weekly meetings of the C.A.A. is the gathering together of old school chums and fellow pharmaceutical students, now engaged in various parts of London, for a few minutes' chat over a cup of coffee prior to the scientific or practical business of the Association. On Thursday, November 10, there was a much larger assembly than usual at 73, Newman Street, W., that fact being largely accounted for by the presence of Prof. J. Reynolds Green, F.R.S., who had attended to deliver a lecture on

The Biology of Yeast.

Professor GREEN briefly sketched the work of the early investigators of yeast from the time of Leeuwenhoek down to that of Pasteur, and descanted at some length on Pasteur's famous theory that fermentation is an expression of life in the absence of oxygen. The lecturer, referring in detail to the complex composition of the yeast cells, pointed out that they are in some respects as highly organised as the animal body, inasmuch as many enzymes, among others, diastase, maltase, and invertase, have been found in them. In fact, the various functions performed in the yeast cells gave a picture on a small scale of what goes on in the human body. Professor Green enlivened the lecture by occasional characteristic flashes of humour, and narrated several incidents in connection with experiments conducted by himself, on the lines laid down by Buchner and other workers.—The PRESIDENT (Mr. F. W. Gamble) said they must all have listened with the greatest possible pleasure and interest to Professor Green's account of most of what is known concerning yeast. All present would doubtless have a wider view of what they had previously looked upon as a very insignificant organism. The fact that yeast cells form matter for their own use from time to time seemed to indicate that there must be some nervous mechanism in the plant which suggests to itself means to an end. The heartiest thanks of the meeting were due to Professor Green for the trouble he had taken to prepare the lecture, which must have cost a great amount of time and labour, even to one possessed of such an ample range of knowledge of the subject as the lecturer.—Mr. H. E. MATTHEWS, the Hon. Secretary, seconded the vote of thanks moved by the President, and said they had been charmed with the lecture, and he was sure all had benefited by the account of the personal experiments of the lecturer.—The vote was then put to the meeting and carried most enthusiastically.—Professor GREEN, in reply, expressed the pleasure it had given him to come amongst his old friends, even though some of them had new faces. He could assure them that if it had been any pleasure to listen to his remarks, it had been a greater pleasure for him to talk.—The meeting then adjourned.

BURNLEY PHARMACEUTICAL ASSOCIATION.

A meeting of chemists and druggists in Burnley and district, convened for the purpose of considering the desirability or otherwise of forming an association, was held at the Bull Hotel, Burnley, on Thursday, November 10. In response to invitations sent out by Mr. J. Brown, there was a fairly good muster at the meeting. Mr. J. A. Heaton, a member of the local Board of Guardians, was voted to the chair. At the outset of the meeting Mr. BROWN read a number of letters from chemists in the town and district who were unable to be present, yet who signified their intention of supporting any association which might be formed.—Councillor CRITCHLEY, President of the Blackburn Association, who was introduced by the Chairman as the "father of Blackburn chemists," spoke of the great benefits which had accrued to chemists in Blackburn as a result of forming an association. One of their chief aids to success had been a dinner, which was held once a year, and brought the members together. By doing this they believed they were creating a really good feeling amongst the trade, a feeling which enabled them all to be friends one with another.—Mr. R. LORD GIFFORD, Secretary to the Blackburn Association, also addressed the meeting. He was of opinion that all pharmacists should be alive to the fact that the time had come for altering the laws of the land, and putting pharmacy on a proper basis. There was no man amongst them who lived by pharmacy only, they depended on trade almost solely. In Blackburn they did not wish to interfere with another man's

business. Chemists there worked on the principle that they had to earn their bread and butter to-day; but that this should not prevent them working for to-morrow. They all agreed as to what ought to be, but they should quarrel at once on what is. In other words, he would not tolerate any interference from persons who could not properly appreciate his difficulties and, therefore, he had no right to interfere with others. However, they would not find many chemists who were not straightforward honourable men. This was an age of progress and everything was tending towards specialisation. That ought to apply with special force in pharmacy. It must be supposed that in 1868 it was intended to give to the body of men required to qualify, certain duties which no one else should exercise. It was ridiculous to suppose that a time was not looked forward to when a natural growth would have made those duties extensive and consequent privileges tangible. To-day there are more stringent examinations and fewer privileges than then. Why? Because the Pharmaceutical Society incorporated by Royal Charter had not fulfilled its charge. It had partly fulfilled its charge in that it had made examinations more stringent. It had, however, absolutely failed in making the position of chemists more secure. They were attacked on every side by unqualified practitioners of pharmacy in the shape of grocers, drug stores, and herbalists; and now also by the unqualified medical assistant who, turned away by the doctor, naturally falls back on the drug trade. What they wanted was a remedy. Their livelihood ought to be the first thing to be considered, and if there was a meeting of chemists they ought to attend that before doing anything else. *Esprit de corps* was wanted, and they demanded that those who were not qualified should not act as chemists and druggists.—Mr. W. HOLT, also of Blackburn, gave an account of the Belfast Conference, at which he was present, and reverted to several lessons learned from it, stating that chemists themselves were to blame for the present condition of trade.—Mr. WILKINSON (Colne) expressed his sympathy with the proposed movement. He said the calling of the chemist and druggist had become a by-word and a reproach, and until by united and concerted action they asserted their true position in the country they were little more than a rope of sand. Mr. Gifford had spoken of them as a body of honourable men, but he was afraid many did not come up to that standard when they would sell a P.A.T.A. article for 2s. 6d. though the minimum price was 3s. Others would sign an agreement with the proprietor of a preparation and then sell the article at cost price. The "craft" had become so demoralised that nothing but union and legislation could help them. Why should the State inflict upon them severe examinations and not give them some equivalent more than they had? The doctor, lawyer, and dentist are to a large degree protected by the State, and the artisans, with their "trade unions" and "labour leagues," could vindicate their rights, and why not the chemist? He referred to the Teachers' National Union by way of illustration to show what a power it had become in the country during the last twenty-five years by continued effort, and how the just claims of teachers were met by the Education Department. The crass ignorance of the position and of the legitimate duties of chemists is daily noticeable in the unjust censures cast upon them by magistrates and coroners and other public men. In fact, their want of union and combination prevents them from making their influence felt in Parliament, and thus enlightening the public on these matters. Mr. Holt had said the Pharmaceutical Society was their only representative and could not do much. Why? Because the trade as a whole did not give the Society its support. He (Mr. Wilkinson) was glad to hear Mr. Critchley recommend all members of local associations to become members of the Pharmaceutical Society, and thus support that body. He was also pleased that in the Blackburn Association they did not recognise qualified managers of drug stores. Such were traitors to the craft. What did the General Medical Council do with men who hired themselves to such as Munyon? Why they were struck off the roll. Companies robbed the legitimate chemist and his family of their livelihood, and it should not be allowed for a syndicate elsewhere to reap the benefit. That was an open violation of the Pharmacy Act, and if the chemists of England were only united they could compel the British Parliament to remove the iniquity and protect the vested interests of the chemists. Members of Parliament were ignorant as a whole of the grievances chemists, as a technical trained class, laboured under. If a body of them, say 100 strong, could wait upon their member, Sir Ughtred Kay-Shuttleworth, he would be open to reason and admit the justice of their claims. They must agitate and seek legislation to redress their wrongs, and the Executive of the Pharmaceu-

tical Society must be backed up by local associations of qualified men.—Mr. COLLINS (Nelson) at this juncture moved that an association be formed.—Mr. WILKINSON seconded, and the motion was unanimously adopted.—It was also decided that the Association be affiliated with the North-East Lancashire Association with certain reservations. A vote of thanks to the friends from Blackburn was proposed by Mr. BROWN and seconded by Mr. COATES, after which the following officers were elected:—President, Mr. J. A. Heaton; Treasurer, Mr. C. E. Dodsley; and Honorary Secretary, Mr. J. Brown. Messrs. Hitchen, Walker, Clarkson, Shepherd, Lawton (Nelson), Stuttard, and Wilkinson (Colne) were elected a Committee with power to add to their number.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At a meeting held on November 9, Mr. G. H. C. ROWLAND, President, was in the chair, and the first paper read was by Miss FLORA C. MADGSHON, being a

Note on Glycerin Suppositories.

In making glycerin suppositories by the B.P. method there are invariably some pieces of gelatin which remain undissolved and in a hardened condition. To obviate this place the gelatin in a weighed evaporating dish with sufficient water to cover it, let it stand for two minutes, pour off the excess of water, set aside till the gelatin is quite soft, add the glycerin, and dissolve on a water bath. If, instead of adding the glycerin to the soaked gelatin before applying heat, the softened gelatin be dissolved on a water bath in the water of hydration and the glycerin is then gradually added, the result is also completely satisfactory, and accomplished without loss of time or material. A point to be observed in dissolving the gelatin is not to stir so vigorously as to introduce much air into the solution, or inconvenient frothing will ensue. Gentle stirring is all that is necessary, and if performed with little breaking of the surface, aëration need be very little.—Mr. RUTHERFORD HILL said there was a formula for preparing glycerin jelly as a mounting medium in microscopic work, and it was made in the way suggested by Miss Madgshon, which seemed obviously the best way. It would appear that the error in procedure arose somehow in connection with Squire's process for gelatin suppository basis, from which the official formula was copied.—Mr. BOA said the matter arose from a frequent trouble in making suppositories—especially on short notice—by the official method, and a little investigation proved that the method suggested in the paper obviated all difficulty. This was one point that rather indicated something that was more theoretical than practical in the compiling of the Pharmacopœia.—Mr. GEORGE SINCLAIR said he had found the same difficulty in making Unna's gelatum zinci.—Mr. COWIE said he did not agree as to the explanation of the insolubility of the gelatin. It was due to hard pieces of gelatin, which ought to be picked out, and not to the dehydrating effects of the glycerin.—Mr. DUNCAN said the finest sheet gelatin was used, and he did not think the difficulty was due to the presence of hard pieces. If 1 oz. of glycerin and 1 oz. of mucilage of acacia or simple syrup were mixed there would be a separation of gum or sugar, because the glycerin took up some water. The same thing happened in this case, and he thought it was clear that Miss Madgshon's explanation was correct.—The CHAIRMAN said he had found the same difficulty in making ichthyol suppositories, and had found that they could be made without any difficulty by following Miss Madgshon's method.

Mr. J. RUTHERFORD HILL then read a paper on

The Dispensing of a Strychnine Mixture.

The following prescription was dispensed in two different pharmacies, and in both instances the dispensers added a suspending agent, in one case two drachms of mucilage of acacia, in the other the same quantity of glycerin:—

℞ Liq. Strychninæ Hydrochloratis (1885) ʒiii.
Potass. Iodidi ʒiiss.
Aquam ad ʒiv.

When acacia was used there was very little separation of any precipitate for several hours. It looked, indeed, as if precipitation had been prevented, and a careless dispenser might send out the mixture without any direction to shake the bottle. But, ultimately, of course, there was a separation of the compara-

tively insoluble strychnine hydriodide (see *P. J.* [4], vi., 389), and after twelve hours the strychnine salt settled on the bottom of the bottle, to which the acacia caused it to adhere, so that it could only with difficulty be detached, and then only in pieces, which could never be properly diffused. Moreover, decomposition had taken place, owing to oxidation. The mixture assumed a dirty brownish-yellow colour, and the addition of starch solution indicated that this was due to free iodine. Acacia seems to facilitate oxidation, probably because, being always acid, it liberates hydriodic acid from the potassium iodide. Even in the case of ferrous salts acacia seems to facilitate oxidation. When glycerin was used, there was a separation of strychnine hydriodide in a few minutes, but it easily diffused; the mixture remained for months perfectly colourless, and the glycerin apparently prevented the oxidation that takes place when the mixture is dispensed without any suspending agent. Glycerin is in every sense superior, and either it or simple syrup should be used rather than mucilage of acacia.

The third paper was by Mr. WILLIAM DUNCAN on

Lotio Hydrargyri Nigra.

The author thinks the new B.P. preparation is an example of very bad pharmacy. The addition of glycerin as a preservative of mercurous oxide may be unobjectionable provided it does not induce reduction of the oxide to metallic mercury. The addition of tragacanth as a suspending agent, on the other hand, simply spoils the preparation, the oxide clotting with the insoluble gum. Samples that have been made for about a month conclusively show that the tragacanth addition is not a success, and the sooner a return is made to the old formula the better.

The next paper was by Mr. WILLIAM DUNCAN on

Magnesia in Mixtures.

The tendency of magnesia and similar salts to cake into hard non-diffusible deposits when dispensed in aqueous mixtures is well known. Recently the following was brought under notice:—

℞ Magnes. Calc.
Sp. Ætheris Nit. aa ʒvi.
Sacch. Alb. ʒss.
Ol. Menth. Pip. ℥lxx.
Aquam ad ʒviii.

Dispensed in the usual way the magnesia in a few days becomes a hard, solid mass, which refuses to break up by agitation. In order to ascertain if this objection could be obviated or mitigated, the following experiments were made:—The prescription was dispensed in the usual way, triturating the magnesia with water, adding the sugar previously dissolved, and finally the oil and spirit. In two days the magnesia had formed a solid undiffusible mass at the bottom of the bottle. The mixture was dispensed as above and the hard cake when formed was removed, thoroughly rubbed smooth in a mortar, and returned to the bottle. This showed a slight tendency to aggregate, but was diffusible on shaking. In a third experiment the magnesia was allowed to stand for twenty-four hours under water, with occasional agitation, and then the other ingredients added. This method, like the preceding, was successful. As these, however, take time, a fourth method was tried. The magnesia was boiled in half the water, the sugar added, the boiling continued for a few minutes, and after cooling the other ingredients added. This gave the best result, the magnesia being freely diffusible on shaking, and remaining so. A similar series of experiments were made with the following mixture:—

℞ Magnes. Sulph. ʒi.
Magnes. Calc. ʒss.
Aquam ad ʒviii.

This mixture frequently causes trouble to the patient from caking. In this instance the results were the same. The caking is due to the fact that magnesia absorbs water to form hydrate. In doing so it aggregates, especially in presence of certain salts, much in the same way as calcium sulphate does. The hardness and rapidity of the caking largely depends on the other constituents and on the shape of the bottle. In a mortar or flask with a rounded bottom allowing free expansion the hardening is not so great as in an ordinary dispensing bottle. If previously hydrated magnesia is used the difficulty does not arise. Most samples of magnesia absorb water more or less readily—especially light magnesia—and show a tendency to aggregate into a gelatinous mass. This property, however, is not constant and seems due to the temperature to which the salt has been exposed during calcination. Much attention has lately been given as to the rapidity

with which magnesia absorbs carbonic anhydride. With magnesia and other similar oxides the absorption largely depends on the presence or absence of moisture. The better hydrated the substance the more rapid is the formation of carbonate.

LIVERPOOL CHEMISTS' ASSOCIATION.

A largely attended meeting of this Association was held in the Royal Institution on Thursday evening, the 10th instant, the PRESIDENT, Mr. John Bain, in the chair.—In addition to the usual business, the SECRETARY reported the receipt of a letter from Mr. Edward Evans, of Wrexham, expressing his willingness to accept the office of President for next year and thanking the Association for the honour done him. One new member, Mr. W. Parry, of Waterloo, was elected.—Mr. R. C. COWLEY read a paper on a

Simple Laboratory Arrangement for Drying Alkaloidal Residues in Organic Assays.

According to the new Pharmacopœia the alkaloidal residues in the assay of opium preparations must be dried at 110° C. for two hours before determining their purity by titration. To the pharmacist this entails considerable trouble, which he does not encounter in drying other alkaloidal residues. The time also is an item to be taken into consideration by the busy man. When the new B.P. was published the following simple contrivance was adopted to overcome these difficulties, and in practice it works remarkably well, enabling the operator to dry the alkaloid to a constant weight in a much shorter time than the B.P. demands. A 50 per cent. solution of calcium chloride, or a corresponding weight of the crystallised salt will boil at a temperature of 110° C. If water is added from time to time to make up for evaporation, this gives a means of obtaining and retaining the requisite temperature. By fixing a thermometer in the bath and keeping the flame of the Bunsen low after the required temperature has been reached, the frequent addition of water will not be necessary. The alkaloid to be dried is folded up in the enclosing filter papers and placed in a small wide-mouthed bottle furnished with a rubber bung, having two perforations. Two pieces of glass tubing, bent at right angles, pass through these holes; one tube passes to the bottom of the bottle, the second terminates just within the bung. The bottle with the alkaloid is now placed in the calcium chloride bath. The longer tube is connected with a drying tube containing quicklime; the other is attached to a Geissler's filter pump. Heat is applied to the bath and the pump is started working; dry air is sucked through the whole apparatus. Since the longer tube passes to the bottom of the wide-mouth bottle, the air will be somewhat heated. Thus the moist air in the bottle will be continually displaced by warm dry air. At first a condensation of moisture will be noticed beyond the bend in the short tube, and when this disappears it has been experimentally proved that the alkaloid is dry. A similar method was adopted in drying other alkaloidal residues, using, of course, a water bath. Where a number of assays are made, the loss of the alkaloidal solvent is a consideration. Instead of evaporating the solution in a tared dish, as is usually done, the solution was collected in a small tared flask, from which the solvent was distilled off; this distillate may be repeatedly used, thus entailing but a small loss even on a number of assays. The moisture left in the flask is removed by attaching the flask to the drying apparatus previously described in the place of the wide-mouth bottle. A few minutes in the drying oven will then be sufficient to remove the moisture that adheres to the outside of the flask.—In the absence of Mr. Catford, Mr. COWLEY proceeded to read that gentleman's communication on

The Determination of Alkaline Cyanides and Copper.

The cyanide process for the volumetric estimation of copper has been much used during the last fifty years in technical assaying, the writer of this note used it daily more than twenty years ago in South America. Although easy and convenient, it is not strictly accurate, because the quantity of cyanide required to discharge the blue colour of ammoniacal copper solution depends upon the amount of ammonia, free and combined, which varies according to the amount of free acid to be saturated, and so varying quantities of secondary products, such as urea, formate of ammonia, etc., are formed. Fleck attempted to minimise this, and also introduced a second indicator, potassium ferrocyanide, so that as the blue is discharged there remains the red of the cupric ferrocyanide, which in turn is decomposed by more KCN. This suggested to the writer

to leave out altogether the disturbing element—the ammonia—as follows:—If the cupric solution is acid, add caustic fixed alkali until a slight permanent precipitate of cupric hydrate is produced—

add a drop or two of 1 per cent. solution of potassium ferrocyanide, and run in the KCN until the greenish cupric cyanide at first precipitated is re-dissolved—

and the solution becomes pink from the minute quantity of cupric ferrocyanide—

It is best to stop at this point to be sure that too much KCN has not been added. On standing, the cupric ferrocyanide will deposit, leaving the solution colourless. The KCN reacts equally on the cupric hydrate and on any carbonate produced by impurities in commercial cyanide—

The slight amount of free alkali does not prevent the appearance of the cupric ferrocyanide, and experiment proves that the addition of fixed alkaline salts does not affect the amount of KCN required. Thus an acid solution of pure copper becomes a reliable means of standardising cyanide solution, preliminary to using it for volumetric assays, or, for example, to check the strength of the No. 1 Fehling's solution, the new B.P. formula, for which, by-the-by, is one of the instances in which the old atomic weights have been used in the calculations. In the absence of ammonia, a cupric salt reacts with KCN in the proportion of one molecule of the cupric salt to four of the cyanide—

Silver reacts in the proportion of one molecule to two—

but the various and considerable impurities in commercial cyanide render its determination by silver difficult; whilst copper is not interfered with by chlorides or carbonates, the latter again interfering with the estimation by iodine, which is generally used for the purpose. Fresenius recommended soda water to be used to convert the carbonate into bicarbonate, but this not being among the reagents on the laboratory shelves, recourse might be had to liberating CO₂, as in the B.P. process for estimating arsenic. But a decinormal cupric sulphate would not require any such precautions.—A good discussion followed, and votes of thanks were accorded to the authors of the papers, which were of considerable pharmaceutical interest. A fine collection of

Medicinal Plants

was then exhibited by Mr. J. Gutteridge, Curator of the Liverpool Botanical Gardens, whilst Mr. T. H. WARDLEWORTH pointed out their chief characteristics and points of interest. Ginger rhizome, grown in the gardens, reminded the lecturer of the fact that some specimens of ginger had been met with on the Liverpool market so badly cured that it was possible to cause them to grow under favourable circumstances. *Kola acuminata*, the ordinary variety yielding the dicotyledonous seed, was shown, as well as *Stillingia sebifera*, a Euphorbiaceous plant, from whose seeds the Chinese vegetable wax or tallow is prepared. The following are the other plants exhibited:—*Coffea arabica*, the Liberian or large-leaved variety; *Psychotria ipecacuanha*, the true ipecac. root; *Cinchona succirubra*; *Piper nigrum*, a strikingly handsome plant; *Cinnamomum verum*; *Maranta arundinaca*, or arrowroot; *Manihot glaziovii*, from which the Ceará rubber of South America is obtained; *Hevea brasiliensis*, the source of Pará rubber; *Physostigma venenosma*; *Sarracenia purpurea*, or pitcher plant; several specimens of *Strophanthus* plants, and some of the dried follicles; *Bixa orellana* or annatto; *Andropogon schænanthus*, which yields the ginger grass or roussa oil; *Saccharum officinarum*, or sugar cane; *Ipomea purga*, jalap; *Dioscorœa sativa*, or yam; *Luffa ægyptica*, or loufah; *Gossypium barbadense*; *Abrus precatorius*, or Indian liquorice, whose leaves, as well as root, taste of glycyrrhizin; *Garcinia mangostana*, the mangosteen fruit found as an adulterant of bael; *Persea gratissima*, or Avocado pear; *Kicksia africana*, whose seeds are met with amongst those of *Strophanthus Xanthochymus pictorius* yielding;

a variety of gamboge, and *Lagenaria vulgaris*, which furnishes the peculiar calabash or bottle gourd.—In the course of his remarks Mr. Wardleworth gave as the reason for the present extreme price of ipecac. root, that the demand for Pará rubber had increased to such an extent since the advent of rubber-tyred cycles that the native collectors had neglected the ipecac. in order to bestow their whole attention to the search for rubber.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

The first of the monthly meetings of the present session was held on November 10. Mr. W. L. CURRIE presided, and there was a good attendance.—The CHAIRMAN said he had consented to occupy the chair for another year, and he hoped the success which had attended their past session would be as prominent in this. Between the sessions matters of considerable importance to the trade had happened.

The Pharmacy Acts Amendment Bill

had become law, and its passing had removed every possible objection which a registered chemist and druggist could have to becoming associated with the Pharmaceutical Society of Great Britain. Previously it had been said by those not members, What is the good of becoming associated with the Society when there are practically no benefits resulting from it? We certainly have the privilege of voting, but that is the extent of it. Now, no one could point the finger of scorn at the Society, and say nothing could be obtained, because every office which was open could now be had by registered men. He hoped that during the approaching year they in Glasgow, at all events, and particularly because the Bill had its origin in Glasgow, would in large numbers, employers and assistants who were qualified, become associated with the Pharmaceutical Society. By so doing not only would they have a voice in the election of Members of Council, but would be eligible for election to that honourable position. That, he thought, was a very great advance upon past times. He need not say that the very best way to obtain that result was for every member to buttonhole his friends who were not connected with the Society, and point out to them that so long as they remained outside they could not possibly expect it to have that power it ought to have, and which if they were all members they could wield with much greater effect than at present. He supposed there were 15,000 chemists and druggists on the Register, and at the present time there were only between 4000 and 5000 connected with the Society. That was not sufficient. If they had 10,000, he made bold to say, they could approach Parliament with a Bill asking for almost anything, and he was sure they would meet with a very large amount of success. During the last Parliament they had shown what could be done by united action, for he had no hesitation in saying that the Poisons Bill had been rejected simply on account of the unanimity of the expressed opinion of the chemists and druggists throughout the country. If they wanted to improve their position they had now the opportunity of doing so, and by strengthening the hands of the Society they could rely upon getting what they had been aiming at for a long time.—Mr. THOMAS DUNLOP then read a paper on "The British Pharmacopœia, 1898," a report of which will be found at page 529.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

At the third meeting of the session, held on November 9, at the Exchange Rooms, Birmingham, the chair was taken by Mr. J. SELBY, and there was a good attendance of members.—Mr. J. F. LIVERSEEDGE in a paper entitled

Health and Occupation,

submitted some statistical tables compiled from the last census relating to the comparative mortality pertaining to various occupations. He pointed out as the most striking circumstance the excessive mortality of those associated with the liquor traffic, not only in respect of alcoholism separately considered, but in the aggravation of various diseases. Mr. Liverseedge went on to show how, through lack of ventilation, cutlers and potters suffered from dust, and how plumbers and file-makers suffered from lead-poisoning. The deduction the reader of the paper drew was the great importance of thorough ventilation.—Mr. Liverseedge was heartily thanked for his paper.

PHARMACEUTICAL SOCIETY OF IRELAND.

At an evening meeting of this Society, held at Dublin, on Monday last, a lecture on

Plants and Insects

was delivered at 67, Lower Mount Street, by Professor F. W. MOORE, M.R.I.A., Royal Botanic Gardens. There was a large attendance of ladies and gentlemen, the spacious examination hall being crowded to inconvenience. The PRESIDENT, Mr. Robert J. Downes, occupied the chair, and amongst those present were the following: Dr. J. A. Walsh, M.C.P.S.I., Dr. J. Evans, Dr. W. G. Smith, Dr. J. C. McWalter, M.P.S.I., Messrs. J. Smith, M.C.P.S.I., D. M. Watson, L.P.S.I., J. Forde, Deakin, Simpson, M.C.P.S.I., Evans, Smylie, Monroe, G. Grindley, M.C.P.S.I., Beggs (Vice-President), W. F. Wells, M.C.P.S.I. (ex-President), P. Kelly, M.C.P.S.I., A. T. Ferrall (Registrar), Brady, H. O'Connor, M.P.S.I., Miss Ada Wyatt, M.P.S.I., etc. An apology for non-attendance was received from Mr. J. Tyrie Turner, M.P.S.I.—The PRESIDENT, in a few well-chosen words, introduced the lecturer, who said the title of his subject covered a very large field. He proceeded to speak on its various aspects, namely, insects which were injurious to plants, and plants that destroyed insects. The mutual beneficial relations between insects and plants were explained, and the adaptability of plants to their surroundings illustrated. There was hardly a single plant in which there was not some special structure. The lecturer enumerated a number of curious phenomena connected with the growth of plants, and dwelt at some length on the functions of certain peculiar fleshy stems thereon. He afterwards demonstrated his remarks by a choice collection of slides prepared from living plants and obtained from the College of Science, and instanced Sir John Lubbock as an authority in connection. Ants played an all-important part in plant life. Four genera of plants were described, viz., *Myrmecodia*, *Myrmedoma*, *Myrmephytum*, and *Hydnophytum*, of which there were numerous species. The history of ant plants afforded one of the most striking instances known of the advance of botanical knowledge within so recent a period. In 1874 two imperfectly known genera, with four or six ill-defined species, were known. Beccari in 1884 published his work, enumerating four genera and upwards of fifty species. The cinchona family then came under notice, and the habitat of this plant was given and also its general features. The pitcher plant and Fuller's teasel were shown on the screen, and the head of the common thistle commented on. There was hardly a living plant that did not possess an affinity between itself and certain of the insect world. The opening and closing of flowers by day and night respectively formed an interesting part of the lecture, and the explanation of the two-fold process was listened to with marked attention, frequent outbursts of applause testifying the appreciation of Mr. Moore's hearers. The methodical habits of insects were next touched upon, and the necessity of the ant as a botanical life-giver in the cases named impressed on the audience. The difficulty of importing cinchona in a living condition was pointed out, and the lecturer stated that all plants associated with ants were very difficult to cultivate. Some beautiful specimens of plants mounted on slides for the lantern were then thrown upon the screen by Mr. George Beggs, the Vice-President, who kindly acted for the occasion as honorary lanternist, chief amongst the specimens so exhibited were orchids, pineapple, and others. The "bull's horn" acacia, the thorns on the stems of which served as a protection for the plant as well as a home for the ants, was seen in various stages, as were also three different kinds of palms and the compound leaf of the acacia. The transmission of pollen by bees and the functions of the night-flying moth were explained in a clear and lucid style. A feature in the lecture were the slides of the "Bucket" orchid, which were commented on in appreciative terms. Illustrations of flowering plants were next shown. It was interesting to find that in the other great section of the vegetable kingdom equally remarkable structures were found. Some descriptions of ferns would not grow unless by the assistance of ants. A specimen in connection was shown, and the difficulties experienced in gathering it mentioned. The stems of this fern were compared. Mr. Curtis, of the Botanical Department of the Straits Settlements, collected the specimen in question, which was named *Polypodium patelliferum*, but could not succeed in cultivating it. The study of orchids next came under notice, and the special formations of the flower were described and commented on. Darwin's researches in connection were quoted, and the observations of Rodway described minutely. The flowering

plants of British Guiana were reviewed, and the lecturer concluded by giving an interesting description of the fertilisation of plants by insects.—On the motion of Mr. P. KELLY, seconded by Mr. J. SMITH, a warm vote of thanks was passed to Mr. Moore for his able and instructive lecture, and in conveying the same the PRESIDENT said it was unfortunate that chemists nowadays did not give as much attention to botany as they did some thirty years ago. The study of plants was essential to the chemist, and they would do right if they oscillated in that direction to the past. He hoped Professor Moore would again favour the Society with a similar lecture.—Professor MOORE suitably replied, and the proceedings terminated with a hearty vote of thanks to Mr. Beggs for his kindness in acting as honorary lanternist on the occasion.

NEWCASTLE-ON-TYNE AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of this Association was held in the Hôtel Métropole on Wednesday evening, November 9, at 8 o'clock. There was a full attendance of members, and in the absence of Mr. F. E. Schofield (President), Mr. KERSE occupied the chair. Six new members were elected, and the SECRETARY intimated that the President and himself had received invitations to represent the Association at the annual dinner of the Sunderland Pharmaceutical Association on November 30.—Routine business having been disposed of, Mr. T. MALTBY CLAGUE, pharmaceutical chemist, proceeded to tell his hearers all about X-rays. Commencing with the inception of the science of radiography, and touching briefly upon currents, coils, and batteries, Mr. Clague proceeded to sketch minutely the apparatus he was to operate with, using a black-board to illustrate by means of diagrams the various points in his lecture. A number of very interesting practical experiments were given, the audience taking part in many of them. Some relics of bygone days—mostly of metallic nature—in the form of foreign bodies located in various parts of the human anatomy by the lecturer in the course of professional work, proved of interest to the meeting. "This," said Mr. Clague, holding up a piece of steel of about the diameter of a sixpence, "is a piece of H.M. battleship 'Victoria,' which for many years was in the possession of one of the workmen in the Elswick Works (unfortunately, however, its then owner could not lay his hands upon it). The large piece of the same vessel was kept by Admiral Sir George Tryon, and is now at the bottom of the Mediterranean." The workman had been injured during the building of the vessel at Armstrong's, and for years the metallic invader had baffled the surgeon until unearthed by the aid of the X-rays. Much interest was evinced by members, and many questions were asked the lecturer at the close of his experiments. The meeting was one of the most successful held by the Association. A hearty vote of thanks was accorded Mr. Clague and his assistant, Mr. T. S. Herd, who operated the apparatus during the experiments.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

This Association held the annual meeting at Dale's Assembly Rooms, on Friday, November 11, the PRESIDENT, Mr. Ald. Deck, in the chair. There were present Messrs. A. Sidney Campkin, E. Saville Peck, P. McAvoy, C. S. Addison, W. L. White, H. F. Cook, W. Spencer Turner (Willingham), T. Sidney Campkin, H. A. Hancock, P. A. Barker, B. S. Campkin (Hon. Sec.).—The Treasurer's report by Mr. H. F. Cook showed a balance in hand of £1 13s. 2d., and a reserve fund of £2.—The Secretary showed the work done by the Association to be profitable to the senior and junior members.—The following officers were then elected: President, Ald. Deck, F.C.S.; Vice-Presidents, Mr. A. Sidney Campkin, J.P., Mr. E. Saville Peck, B.A.; Hon. Treasurer, Mr. H. F. Cook; Hon. Secretary, Mr. Bernard S. Campkin, Mill Road, Cambridge; Committee, Messrs. Addison, McAvoy, Parson, Harris, W. L. White, and Spencer Turner. It was decided to hold a *conversazione* during the winter.

MERCURIAL OINTMENT FROM COLLOIDAL MERCURY.—P. Suss suggests that colloidal mercury may be used for the preparation of mercurial ointment, the process being rendered less tedious and laborious. From experiments which he has conducted, it would seem that the ointment so prepared is at least equal to that made by trituration with metallic mercury.—*Ph. Cent.*, xxxix., 553.

BRADFORD AND DISTRICT CHEMISTS' ASSOCIATION.

In connection with this Association, on November 15 Dr. C. E. WADDINGTON delivered a lecture on "Nerves," with lantern and microscopic illustrations. The lecture was of a most interesting nature and was listened to with great attention by those present. Speaking first of the simplest form of animal life, the ameba, the Doctor went on to say that nerves consisted of cells in which the protoplasm was the sensitive part. He then described the structure of nerve fibre, saying that in the centre is a very fine thread called the axis cylinder, which runs along the whole length of the nerve. This axis cylinder, except at its origin and termination, is covered by a medullary sheath or the white substance of Schwann, a white substance of a peculiar fatty nature. Certain constrictions occur at intervals called the nodes of Ranvier, and are supposed to allow of the percolation of lymph to nourish the axis cylinder. Dr. Waddington then told how the nervous system was divided into voluntary and involuntary nerve fibre. The voluntary consisted of brain and spinal cord, while the involuntary consisted of ganglia. Voluntary nerve fibre ended in muscle or skin, while the involuntary ended in intestines, blood vessels, heart, and lungs. The Doctor fully described the chief features of the spinal cord, medulla oblongata, and described the chief functions of the brain.—At the conclusion of the lecture Mr. SILSON proposed a vote of thanks for the treat the Doctor had given the Association.—Mr. HARVEY (of Bourne, Johnson, and Latimer), who was present, seconded, and it was carried in a very hearty manner. The meeting then terminated.

EXTRACTS FROM CONSULAR REPORTS.

PROPRIETORS OF TURF MOORS in Scotland and Ireland, Consul Powell is of opinion, might start briquette factories with profit to themselves and the community at large. His reason for thinking so is that a briquette factory at Langenburg, Germany, which has been in existence for two years has proved a complete success. Turf is cut from an adjacent moor and is ground into mull or a fine powder, and then pressed into briquettes for fuel. The factory turns out eighty briquettes a minute or thirty-five tons per day, with an average output of about 12,775 tons per annum. The demand for this fuel is far greater than the supply, the reason being that the briquettes are so marvellously cheap, an average price being 6½d. per 130 briquettes. This "poor man's fuel" burns slowly but gives a fairly good heat, one briquette, in a closed oven, remaining in a glowing state for twenty-four hours. In an open grate it burns quicker, but remains alight for a longer time than any coal, giving a good red heat. The machinery for making briquettes is patented in England, and can be employed either by purchase or royalty.

TO CHECK THE ADULTERATION OF OLIVE OIL with cottonseed oil the Council of Government of Malta has passed a new Ordinance (No. VI.), which regulates the duty on oil. The duty now established is (a) 6d. per caffiso (4½ imperial gallons) on oil of every description, with the exception of linseed oil, of other oils used as medicine, and of any oils which, being unfit for food, are intended for industrial purposes; and (b) 1s. per caffiso on cottonseed oil or any oil containing any mixture of cottonseed oil. This measure originated in a report made by the Chamber of Commerce to the effect that cottonseed oil was being mixed with olive oil and sold as olive oil. The Collector of Customs, in supporting the report, called attention to the loss that the Revenue suffered by such mixture in connection with the duty on olive oil. To prevent importers of cottonseed oil deceiving the public and defrauding the Treasury, it was considered that a 1s. duty on cottonseed oil or any mixture thereof, compared with a 6d. duty on olive oil, would be sufficient to check fraud.

A BACTERIOLOGICAL LABORATORY was started in Colombia, Panama, in 1896, under Government auspices in conjunction with the poor asylum. In a recent session, the Legislative Assembly granted a further vote towards the purchase of additional apparatus. Great results are expected from this institution, and it is hoped that much benefit will accrue if the facilities for research are placed in the hands of competent observers.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

THE NEW TEXT-BOOK OF PHARMACY.

Sir,—The various instances mentioned by Mr. Lucas in last week's Journal, so obviously fail to support his complaint of having been misinterpreted that my reply to his remarks need only be short.

1. Presuming that Mr. Lucas will assent to the view that an error of five grains is not admissible in a weighing machine to be used in pharmacy for quantities under one ounce, a table of errors relating only to liability to penalty should not have been quoted without comment.

2. This remark does not clear up the confusion of ideas. Mr. Lucas' words are, "If fed by a pump the distilled water nearly always contains traces of oil used for lubricating the working parts of the engine." There is no objection to his straining the gnat out of the distilled water, but he still overlooks the camel which the engine introduces. I had no intention of being hard upon Mr. Lucas, either for want of engineering knowledge, or want of critical accuracy in the use of his words, and would not have noticed these points had it not been that, with similar laxity on the part of his readers, they might take his statement to be "If a boiler be fed by means of an injector, the condense water may be used in place of distilled water"—a statement of much greater laxity than Mr. Lucas intends.

3. The statement is a crude one, and Mr. Lucas does not much improve his position by sheltering behind the names of Wagner and Alder Wright, except by showing that he errs by authority.

4. If the dried ferrous sulphate is of B.P. quality, that is, 92.5 per cent. of $\text{FeSO}_4 \cdot \text{H}_2\text{O}$, or a little more (in fact, any point between this and absolute purity), he should have told the student how much syrup was the right quantity to mass it with, and that was the main point of the comment on this article.

The other "remarks" as to the criticism complained of being based on "misinterpretation," seem to indicate inability to perceive that bleaching powder is something more than $\text{Ca}(\text{OCl})\text{Cl}$, that ethylic alcohol cannot be always a product of vinous fermentation, as it is also a product in other ways, or that the words "being set free" are equivalent to "evolved together," as shown by the equation at p. 169.

November 12, 1898.

THE REVIEWER.

Sir,—Since the appearance of Mr. Lucas's letter in your last issue, I have had a visit from an expert engineer, in whose works there are twelve Lancashire boilers, each capable of

vaporising six hundred gallons of water per hour; they work all the twenty-four hours, but not all the twelve boilers at once, so that his dealing with condense is a considerable one, say sixty to one hundred thousand gallons per day. The condense contains oil which it is desirable to separate before returning the water to the boilers, as the presence of oil causes pitting and injury to them. Consequently, precautions are taken to avoid contamination as far as practicable. The condense water is passed through sawdust filters or other appliances for the separation of oil, including a centrifugal cream separator, capable of dealing with five hundred gallons per hour. To this engineer I submitted Mr. Lucas's statement, and his reply was: "He says 'the engine' when he means 'the pump,' but it is really in the passage through the engine where it gets the oil. The pump is not lubricated on the valves, only on the piston rod and stuffing-box. The engine is lubricated through all its working parts, and the oil is carried forward by the steam from the high pressure, through the triple expansion and the condenser and exhaust pumps to the filters, where the oil is absorbed and the water passes on, in comparative purity, to the boilers again. Injectors are not so much used as pumps, but when they are used it may be either with high pressure or exhaust steam. If the latter be used, of course it might carry a little oil back to the boiler, but the main contamination is the oil introduced into the engine cylinders."

November 15, 1898.

AQUA DEST. (154/38).

OUR LAST BALL IN THE EIGHTEEN HUNDREDS.

Sir,—I am requested by my Committee to inform you that the Chemists' Ball will take place at the Portman Rooms, Baker Street, W., on Wednesday, January 18, next. The Committee, consisting of Messrs. Atfield, Bowen, Bremridge, Carteighe, T. H. Francis, W. Hills, W. H. Mathews, A. J. Phillips, A. C. Preston, J. C. Umney, and W. Warren, was formally appointed at a meeting held on November 7. At the first Committee meeting, Mr. Walter Hills, President of the Pharmaceutical Society, was elected Chairman. A letter was received from Mr. T. C. W. Martin announcing his retirement from the Committee, and a resolution was passed expressing high appreciation of his services as M.C. over such a lengthened period. Intimation of these facts was duly sent to you last week, but I regret to find that my letter has miscarried in the post. I wish now, with your permission, to point out that this is the last time the Chemists' Ball will be held in the eighteen hundreds—a period which has been so marvellously full of history and progress in all directions, and not least in pharmacy. The Committee asks for the active co-operation of Stewards in getting together an assembly worthy of the occasion. I shall be glad, therefore, if all who may be willing to act as Stewards will intimate the fact to me without delay, as I wish to publish the first list of Stewards as soon as possible. The liability of each Steward is limited to the taking of two tickets—one gentleman's (17s. 6d.), and one lady's (12s. 6d.).

24, Russell Street,
Covent Garden, W.C.,
November 8, 1898.

W. WARREN,
Honorary Secretary to the
Ball Committee.

THE POSITION OF PHARMACY.

Sir,—I fully endorse the opinions of Mr. Jas. Reid in last week's Journal. The time has certainly arrived for the chemists throughout the country to unite and do all in their power to remedy the injustice under which they labour. It is against all common sense of justice and reason that unqualified companies should be permitted to do that which it is illegal for individuals to do. To remedy this evil ought to be the main object of the next "Pharmacy Bill," and the sooner steps are taken the better, especially as we have now some of the great legal authorities on our side. The very existence of the individual chemist is threatened by these limited but unqualified grocer companies, who thus call themselves chemists, and improperly impose on the public. It is the duty of every chemist, whenever he has the chance, to enlighten the public on these matters, by explaining the difference between the real chemist and the unqualified limited company who call themselves chemists and trade on other men's qualifications. It is surprising how qualified men can lend themselves to these limited companies and help to swell the coffers of the great capitalists, to the detriment of their fellow-craftsmen.

November 14, 1898.

A COUNTRY CHEMIST (154/3.)

THE SOLUBILITY OF BORIC ACID.

Sir,—I sincerely hope that all the solubilities of the new Pharmacopœia are as soundly practical as that given for boric acid. Chemists will esteem it all the more for this further—among several—concession to common sense which has appeared in the new edition. Assuming, with Martindale and Lucas, that boracic acid has an extreme limit of solubility 1 in 25, most dispensers will agree with Squire and the B.P., 1898, that 1 in 30 is the only standard by which their operations can be satisfactorily guided, and I have seen it despatched by the ounce and the gallon. But there is no reason that I can divine why such memoranda should not include at the same time the extreme and the practical limit of solubility of such substances, which, in the case of that under review, would read 1 in 25-30; due recognition being given to the fact that readers of a work on practical pharmacy naturally attach greater importance to a faithful indication of the practical limit.

November 14, 1898.

D. F. C. A. (153/44).

PHARMACEUTICAL PROBLEMS OF TO-DAY.

Sir,—I read with interest your admirable leading article in the current issue of the Journal, and am sorry it did not happen to be one of those numbers which are sent to every chemist and druggist on the Register. There can be no doubt that unless a considerable increase of membership takes place speedily the efforts made to procure the passing of the recent Act of Parliament will, to a large extent, be thrown away. Like the great majority of pharmaceutical chemists I was cordially in sympathy with the main feature of the Act, but as we all know, opening wide the door is unhappily not sufficient. We have excellent authority for saying that very many require much persuasion, and almost coercion, to make them enter, so, having a good deal of leisure this summer, I made a point of seeing several acquaintances in different parts of the country who are not connected with the Society and urging them to take advantage of the opportunity created and become members. Perhaps I induced half-a-dozen to promise definitely they would do so, and I hope, sir, it will not be thought egotistical or superfluous if I suggest that others should do likewise, and personally, if possible, or by letter, press those of their friends and acquaintances who content themselves with playing the congenial part of candid friend outside the Society to strengthen it by their membership and co-operation. One too often hears the remark, "What has the Pharmaceutical Society done for the great body of chemists and druggists?" Of course, the retort is obvious and just, "What have the chemists and druggists as a body done for the Society?" Grumbled at it—certainly, reviled it not infrequently, but as to helping it, by subscribing to the funds and becoming associated with it, that was the last thing they thought of. The state of things at present is an anomaly as discreditable as incomprehensible, and one may almost despair of the future if the number of those connected with the Society is not largely increased during the next few months. At any rate, let those of us who are members do our best to bring this about. As regards what is to come next, it is not easy to be sanguine. Those familiar with the practice of pharmacy in other countries have no difficulty in pointing out the scandalous laxity which exists in England. Unfortunately, the British public has for so many years been accustomed to the privilege of procuring, or at least of being able to procure, its drugs and medicines, with a few insignificant exceptions, from the grocer, draper, hair-dresser—in short, from anyone who chooses to supply them—that it is more than doubtful whether the sweet reasonableness of choosing the better part will appeal to it. I certainly think that one of the first steps in future legislation should be to give the Pharmaceutical Society power to set its own house in order and exercise proper disciplinary measures where its licentiates are concerned. Then, again, exemption from jury service can be claimed with a better grace by chemists than by any other class, since they are, after all, entrusted by the Legislature with certain functions, and the risks so plaintively enumerated by the chemist juror in the famous trial of *Bardell v. Pickwick* are not yet entirely removed. Of course, however, the question which suggests itself to everyone is that of what is loosely defined as company trading, and this, in spite of an easy optimism in some quarters which seems to think we have only to ask in order to have, bristles with difficulties. Vested interests are still precious and almost sacred in the eyes of a British House of Commons, and there are some wrong ones to be encountered. Be this as it may, however, it is

clear that a united and powerful society will be better armed, both for aggressive and defensive purposes, than a feeble and divided one. And to bring about the first-named state of things is the immediate object desirable.

Chard, November 15, 1898.

T. EDWARD BARRASS.

* * The article referred to by Mr. Barrass has been separately reprinted, and any reader who will undertake to distribute copies judiciously may have any reasonable number he chooses to apply for free of cost. [Ed. P. J.]

LOYALTY TO THE CRAFT.

Sir,—I was extremely disappointed with your last issue. I fully expected to be so utterly "pounded and pulverised" by Mr. Young's battle-axe that I should have been precipitated to the gutter never to rise again—and instead thereof he appears, like the Arab, to have folded his tent and silently (and valiantly) stolen away. With regard to my accusation of unfairness against you, you publish his *suggestio falsi* against me, but when I retort with a *tu quoque* you suppress that, and then you allow us to infer that your comments are based upon the parts of my letter that you have deleted. Is that fair? Is not my word as good as Mr. Young's? But if it is a question of accuracy I will make Mr. Young an offer. Warrington, Manchester, and Liverpool have together a population of something over 1,000,000; now, if out of these three towns Mr. Young will furnish (in confidence) the President of the Pharmaceutical Society with the names of six chemists' assistants in the receipt of £200 per annum, I will undertake to escort him to the "living room, about four feet square." I have not indulged in personal recollections out of vanity or egotism, but simply to show your readers how a fairly average specimen of an assistant, whose whole education and experience tended towards (or, if you like, prejudiced him in favour of) the legitimate trade, was absolutely forced out of it, against his most cherished convictions. Now, to turn from the personal to the general, I would ask your readers who know anything of the subject, who are the young men who keep the stores going, especially the big ones? I do not refer to counter-men, who are not chemists and druggists, and never will be, but to the qualified men. Heaps of them are men whose fathers are in business, and who go for a few months "just to get an insight into the store trade." And how about that ever-increasing body of individuals who long ago recognised that they must either do a store trade or go under, and how about that fairly large (and dishonest) class who put up "Drug Stores" outside their shops and charge the old-fashioned prices, and, moreover, where are the British public sending their boys to be apprenticed? Why, where they see the business being done, viz., the stores; and what is the consequence, that a large and constantly increasing body of men are growing up to whom the old traditions are a fond thing vainly invented; and do the authorities dream that abuse will ever induce them to enter the true fold? I trow not.

November 15, 1898.

C. P. (154/27).

IMPURE TARTARIC ACID.

Sir,—You go into considerable detail in discussing the reactions of sulphate of alum in the presence of carbonates (Nov. 5, p. 501). Have you ever experienced the difficulty of detecting alum in the presence of an acid like tartaric, where it may occur as an adulterant? Some of our students here were puzzled to obtain satisfactory proofs in the ordinary way, and the only solution of the problem at which we arrived was obtained by adding (1) liq. calcis and (2) liq. ammonia to the impure salt, which gave, when examined under the microscope, satisfactory indications of the presence of (1) tartrate of lime, (2) sulphate of lime, and (3) the amorphous hydrate of aluminium. In the case of the impure commercial crystals which formed the subject of the investigation, the presence of alum was distinctly evident to taste, but could not be discovered by the ordinary reagents of the text-books.

November 14, 1898.

STUDENT (153/43).

* * There should be no difficulty in detecting alum in tartaric acid, owing to the fact that barium sulphate is insoluble in hydrochloric acid, while barium tartrate is easily soluble. If to a solution of the tartaric acid contaminated with alum some hydrochloric acid be added and then barium chloride solution, a white precipitate of barium sulphate will be produced. If the tartaric acid be pure no precipitate is produced owing to the solubility of barium tartrate in dilute hydrochloric acid. It is safer to rely upon this test than upon any indications yielded by the taste of the substance or the microscopical appearance of a precipitate produced under the conditions mentioned. Our correspondent does not state what were the appearances under the microscope which led him to infer the presence of calcium sulphate and tartrate in the precipitate examined. [Ed. P. J.]

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Oxidation of Iron. Experiments have been performed by Robert Meldrum with the view of ascertaining whether the oxidation of pure iron takes place in chemically and biologically pure water; also if the general rule that iron is unacted upon by alkaline solutions holds good. Polished piano-wire was used for the experiments. It was found that the oxidation of iron takes place in the absence of bacteria and other forms of life, of ammonia, and of carbon dioxide. In the most carefully conducted experiments, however, oxygen and nitrogen must have been present in the water to a very small extent; it is therefore still an open question as to whether it is the water or dissolved oxygen that acts on the metal. The saline solutions were all alkaline, and prepared from pure substances. With saturated calcium hydroxide solution, the liquid was clear after four weeks, and a 1 per cent. barium hydroxide solution had no effect on the iron after ten days. On the other hand, a 1 per cent. sodium pyrophosphate solution had an immediate action; there was an orange precipitate in twelve hours, and in six days the wire was coated with a deposit. Hence all alkaline salts do not prevent the oxidation of iron. It is remarkable that sodium peroxide should have no action, whereas potassium carbonate in six days produced a large growth of rust on the metal. From this it appears that alkaline salts of potassium act on iron to a greater extent than those of sodium. The bicarbonates are decomposed very rapidly, with the formation of large white precipitates, which eventually turn yellow.—*Chem. News*, lxxviii., 202.

Selenium and Tellurium Compounds. An exhaustive examination of compounds of selenium and tellurium has been carried out by R. Metzner. In the case of tellurium he was able to re-determine the atomic weight by two different methods; (1) by the use of tellurium sulphate; (2) by the reduction of tellurous acid with carbon monoxide in presence of silver. He gives the atomic weight of tellurium as 127.9. Among the various new compounds which the author has prepared are two hydrates of selenic acid, well crystallised selenious sulphate, two oxyfluorides and the fluoride of tellurium, a hydrate of hydrofluoric acid, and a compound of tellurium bichloride and phosphorus perchloride. Methods are also given for preparing large quantities of selenic acid, either by electrolysing seleniate of copper or by oxidising selenious acid by means of permanganic acid.—*Ann. de Chim. et de Phys.*, xv., 203.

Free Hydrogen in Air. A. Gautier finds that free hydrogen is a constant constituent of the atmosphere; it is only present in very minute quantities, from 11 to 18 C.c. in 100 litres of air, or on an average about 0.015 per cent. by volume. Its volume is therefore nearly one half that of the normal amount of carbonic anhydride present in pure air.—*Comptes rendus*, cxxvii., 694.

Deodorised Opium Tincture. E. L. Patch reports on a process which has been suggested for preparing deodorised tincture of opium; it consists mainly in the use of benzine (petroleum ether) in place of the more costly ether for the removal of narcotine, etc., and the employment of a granulated opium

instead of the fine powder. The investigation was extended, in order to test the relative merits of acetone and methyl acetate as solvents of narcotine. As a result he considers that benzine is not adapted for use in washing narcotine, etc., from opium in making the deodorised tincture, on account of its uncertain character (*i.e.*, varying specific gravity, boiling point, etc.), its low range of solvent power (narcotine being scarcely soluble in it, whilst in ether it is soluble 1 in 166), and its disagreeable odour. Methyl acetate and acetone are better for the purpose in regard to their greater uniformity and higher solvent power, but they are inferior to ether on account of their objectionable smell.—*Amer. Journ. Pharm.*, lxx., 552.

Strength of Camphor Liniment. Norman Leonard and H. Metcalfe Smith have published a simple process for determining the strength of camphor liniment, which consists in finding the loss in weight experienced by the sample on heating. For this purpose 3 to 5 grammes of the camphorated oil are heated for two hours at 120° in a flat-bottomed dish or flask. Olive oil under the same conditions gains in weight to the extent of 0.15 per cent. This figure, therefore, should be added to the loss in weight on heating the sample in order to obtain the true amount present. An even simpler plan gives an approximate indication of the strength of the sample, *viz.*, by multiplying its specific gravity by 0.00045. The reason for this is that every 1 per cent. of camphor that is added to olive oil raises the specific gravity of the mixture by about 0.00045. It is important to note that this figure was obtained with olive oil of the specific gravity 0.9165, so that unless the gravity of the oil from which the sample was made nearly corresponds with 0.9165, the results will be of little use. Mineral oil, which is frequently used instead of olive oil, may be detected by its fluorescence, also by removing the vegetable oils by saponifying with alcoholic potash in the usual way.—*Analyst*, xxiii., 281.

Fluid Acetracts. Professor Remington has given an account of the keeping qualities of certain fluid extracts prepared with an acetic aqueous menstruum, to which he applies the name "fluid acetracts," the word acetract being a contracted form of acetic extract. The strength of the acetic acid menstruum varied, according to the drug; some were exhausted by a 5 per cent., others by a 10 per cent. menstruum; of the latter ergot is an example. Those, *e.g.*, of sanguinaria, which, according to the author, kept clear and in good condition for a period of about six years, were prepared with 60 per cent. acetic acid, while a fluid extract of ipecacuanha, prepared with the same strength of acid is in excellent condition after two years. He has received from Dr. Charles F. Squibb nine samples of similar preparations, including digitalis, cascara sagrada, aconite root, nux vomica, belladonna leaf, compound gentian, gelsemium, and coca. Those were made from coarsely powdered drugs by repercolation with dilute acid, the strength of which is not stated.—*Amer. Journ. Pharm.*, lxx., 543.

Gelatin in Gum. A. Trillat employs commercial formaldehyde solution to render gelatin insoluble, so that it may be detected and the amount present determined, in mixtures containing gum, sugar, or other bodies not precipitated by formaldehyde. The substance to be tested is dissolved in water, and the clear solution evaporated to a syrupy consistence; a little formaldehyde solution is then added and evaporation continued until a pasty consistence is reached. The residue is finally washed by decantation with boiling water, dried, and weighed.—*Comptes rendus*, cxxvii., 724.

IODINE IN THYROID GLANDS.

BY EDWARD C. C. STANFORD.

The paper on this subject by R. S. Swinton, published in your impression of November 5, p. 482, calls for some remarks from me. The author disputes my statement made at the Belfast meeting of the British Pharmaceutical Conference, that the B.P. process of making the liquor thyroidei does not dissolve out all the thyroidin. He endeavours to prove that it does. The method of proof does not appear to be conclusive. He takes the average usual estimated proportion of 0.3 per cent. of iodine, as present in the fresh gland. He then finds in one small experiment of only twenty-four glands, weighing 104 grammes, or 1605 grains, that the amount of iodine in the B.P. liquor made from these equals 0.293 per cent. of the fresh glands. He assumes, therefore, that all the organic iodine must have been removed from the glands, and that there could have been no iodine in the residue.

I need scarcely point out that this is a pure assumption, for these glands may be quite abnormal, as, indeed, they are, weighing only 15.43 grains each. In all my pretty long experience I have never met with any so small. In my B.P. Conference paper it is stated that in my experiments the weight of the glands differed as much as from 24.2 grs. to 136 grs. each, and that my average was 33 grs. This average was taken over 5000 glands. The iodine in each differs almost as widely.

He also finds, what was known before, that cold water dissolves out as much as the glycerin-phenol water of the B.P., but here he states that it completely extracts the iodine, and that he could find none in the residue.

I always find about one-fourth of the total iodine in the residue from cold water extraction.

In one lot of glands the following amounts were actually found, the amount of iodine being unusually high:—

In cold water extract	0.5358 per cent.
In soda extract of residue	0.1786 „
Total	0.7144 „

This is equal to 0.1786 per cent. in the fresh gland.

I must therefore examine and criticise the author's method of analysis, and see if it be fairly adapted to the detection and estimation of minute traces of iodine.

Having been continuously engaged in the pursuit and determination of these minute traces of iodine for about forty years, my experience in this subject is somewhat exceptional.

In this experience nothing has been more striking than the extreme ease with which small traces of iodine can be lost in the process of burning into ash.

In delicate experiments, where only small traces are expected, I never burn the sample into ash, but always into charcoal in the presence of a slight excess of caustic soda, and in a covered crucible. I certainly should never incur the risk of adding the No. 3 to promote oxidation, as in the experiment quoted. I consider the process of analysis adopted to be roundabout, cumbrous, and ill adapted for small traces of iodine. It offers means of losing iodine at almost every step. The mixture of the solution to be tested with concentrated sulphuric acid is objectionable, as it sets some iodine free, the use of phenol is also unnecessary and objectionable, as it floats on the surface, and ultimately reduces the gravity of the chloroform. Bromine water is not a good agent for setting iodine free; it often contains traces of iodine, which are very difficult to discover and eliminate, and it combines readily with the iodine set free. Chloroform is not a good solvent for iodine, as it is soluble in water, about 1 in 200. I find by experiment that after all the iodine has been apparently removed by chloroform in this process

it is quite easy to detect it in the solution. There is no occasion to titrate the chloroform solution with sodium thiosulphate, the comparison of the colour with a standard solution is more accurate. I consider, therefore, that this method of analysis for minute traces of iodine is misleading. My experiments with it give very low results.

I need not take up space by referring to the simple method I have long adopted. A reference to my papers on "Iodine in Cod-liver Oil and Other Marine Products" in the 'Year-Book of Pharmacy,' 1883, p. 528, and 1884, p. 568, will find a full account of it. The method had then been employed for many years, and it still leaves nothing to be desired. I described it there as "a delicate process of very general application."

I claimed that 1/250,000th part of iodine is easily detected and measured, and that up to 1/100,000th part the determination is very accurate. There is no other method so reliable, simple, sensitive and accurate. It is, of course, a colour process, but these are the most sensitive and accurate of all analytical processes if in experienced hands. The Nessler test is very accurate, although the colour is not a favourable one for comparison. In our largest copper producing works, although electrolysis is used to precipitate the copper, the last traces are left in the liquid, ammonia is added, and the blue colour is the final standard to complete the analysis; the accuracy of the result is extraordinary. But the crimson colour of iodine in carbon disulphide the solvent I employ, is capable of even greater accuracy, when compared with a standard solution.

In following carefully the B.P. process of making the liquor I find that thyroidin can be extracted from the residue, and that much iodine remains with it.

I would remark also that the B.P. liquor is not an elegant preparation, either in appearance or taste, and that it keeps badly. I think chloroform water as a solvent would be preferable. With regard to the vexed question as to whether the therapeutic effects of the thyroid gland depend on the presence of iodine, I think the balance of evidence goes to show that however small the proportion it is a necessary constituent. According to Baumann, the discoverer of iodine in the thyroid, it is proportional to the thyroidin—and therefore to the iodine—in it. According to other makers the therapeutic effects are entirely dependent on the peculiar principle which they prepare for sale. Probably none are altogether right.

Ernest Roos (*Journ. Chem. Soc.*, vol. 74, p. 612, November, 1898) has shown that the administration of iodine increases the amount contained in the thyroid gland, but that when the glands or thyroidin were treated with iodic acid and potassium iodide, substances containing a large amount of iodine were produced, but these were found to be "physiologically inactive."

TREATMENT OF ANÆMIA WITH URTICA DIOICA.—Fresh nettles eaten cooked as we eat spinach, or nettle tea prepared from the dried plant, are popular remedies in Sweden, where a form of anæmia is prevalent in spring-time. This has suggested to H. Agner to employ the remedy in the ordinary course of medical practice, and by its aid he has succeeded in curing cases of anæmia which were intractable to iron, mineral waters, and other treatments. He regards *Urtica dioica* as one of the best remedies in such cases. To prepare the plant for use the young tender shoots should be selected and gently boiled, then minced to a fine paste or made into a thick soup. The infusion is made from a handful of the dried herb in two litres of water; two or three glasses of this may be drunk per diem.—*Bullet. Gen. de Thérap.*

MYRRH AND BDELLIUM.

BY E. M. HOLMES, F.L.S.,

Curator of the Museums of the Pharmaceutical Society of Great Britain.

Myrrh and bdellium have been known from the earliest times as articles of Eastern commerce, and are mentioned by the oldest historians, but our knowledge of their exact botanical source is, even at the present day, exceedingly imperfect. From time to time specimens of plants supposed to yield myrrh have been brought to Europe, but in so fragmentary a condition that it has been impossible either to describe the plant or to determine whether it really yielded myrrh or one of the allied gum resins which are usually more or less mixed with it in imported packages of the drug.

As long ago as 1859 Mr. Daniel Hanbury directed attention to this subject in the 'Admiralty Manual of Scientific Inquiry,' and pointed out "the desirability of determining with accuracy the plants which afford the several sorts of myrrh" ('Science Papers,' p. 175). In 1873, this appeal having met with no response, he made another attempt to enlist the interests of travellers in the matter by publishing a paper in 'Ocean Highways' (April, 1873), with illustrations of the plant supposed to yield myrrh, at the same time indicating the state of our knowledge of the subject at that date. Further attempts to elucidate the matter have been published in the *Kew Bulletin* in 1878, 1880, and 1896, but the only advance really made has been to render more clear than before the source of Habaghadi, or perfumed bdellium.

Of late years an increasing number of travellers have visited Somali-land and Southern Arabia, and it may therefore be hoped that, ere long, the problem will be solved. It seems absurd that the botanical source of a product which has been in commerce for the last 3000 years should still remain unknown.

The failure to identify the drug with the tree producing it is probably due to the fact that some of the travellers who have visited the myrrh countries have not been botanists, and those who were botanists were not familiar with the appearance and physical characters of myrrh and bdellium and their varieties. In the hope, therefore, that some members of this Society may induce friends or acquaintances who are visiting Somali-land or Southern Arabia to bring home herbarium specimens in flower and fruit of the plants yielding myrrh and the allied gum resins, an attempt is now made to give such an account of the drugs and of the plants of the myrrh genus already known to occur in the districts producing myrrh as may enable travellers who are not botanists to know what to look for, and to identify the products with the trees yielding them. On this account botanical terms are as far as possible replaced by ordinary English words in the descriptions here given.

The Drugs.

Those included under the name of myrrh are :—

1. Somali myrrh ("mol-mol" of the Somalis) collected on the mountains between Zeila and Cape Gardafui.
2. Fadhli myrrh, collected in the Fadhli district to the east of Aden.
3. Yemen myrrh, collected still further east, in the province of Yemen.

Those included under the name of bdellium are :—

1. Perfumed bdellium, apparently collected in north-east Africa, between Harrar and Wady Nogal, south of Cape Gardafui, the tree extending probably much further inland than the myrrh tree.
2. African bdellium.
3. Opaque bdellium.
4. Hotai. The tree yielding it is found apparently growing with the Somali myrrh trees.
5. Non-aromatic acrid gum resin.

These drugs may be described as follows :—

1. SOMALI MYRRH.—This occurs in irregularly rounded pieces, one to three or more inches in diameter, brownish externally, often dull, with a brownish powder on the surface, having a translucent brownish fracture, often with white opaque streaks, and externally, sometimes, with exuded drops of oil, forming when dried concretions of minute tears of a reddish-brown colour. The flavour is strongly aromatic, and the taste very bitter. The almost immediate and powerfully bitter taste is characteristic of true myrrh. The name, indeed ("môr" or "mur"), is the Arabic, etc., for bitter.

So far as is known, Somali myrrh is collected between Zeila and Cape Gardafui, on the slopes of the Ahl and Serrut, and probably other mountain ranges near the coast line. It is brought to the great fair at Berbera in November, December, and January.

2. FADHLI OR ARABIAN MYRRH.—This differs from the first in occurring in smaller, more gummy-looking pieces, presenting a more polished and less powdery surface and in being more evidently made up of small tears. The pieces are rarely more than 1½ inches in diameter. The flavour is less strong than that of myrrh, but resembles it, and the taste is decidedly bitter. It never, however, presents white streaks on the fractured surface nor oily excretions on the exterior. It is said to be collected on the hills about Shugræea and Sureea, east of Aden, by Somalis, who cross over for the purpose, and carry it to Aden.

3. YEMEN MYRRH.—This myrrh is often in large pieces, like the Somali myrrh, 1 to 3 inches or more in diameter, and irregularly rounded. It is characterised by its dark reddish-brown colour and a reddish-brown powdery surface. Internally the fracture is also reddish-brown, and has an oily appearance, but there is no trace of external exudation of drops of oil nor of whitish streaks in the fractured surface. The odour resembles that of myrrh, but is stronger and ranker. The taste is very bitter and the flavour is strongly but somewhat disagreeably aromatic.

Yemen myrrh is exported from Makulla to Bombay and Aden.

4. PERFUMED BDELLIUM, OR "HABAGHADI" OF THE SOMALIS.—This drug closely resembles Somali myrrh in shape, size, and appearance. It has also white streaks in the fractured surface. The taste is less bitter and more acrid. The flavour is, however, entirely different, recalling that of some fungi, and once tasted, the flavour can never be mistaken for that of myrrh.

5. AFRICAN BDELLIUM.—This occurs in hard, roundish pieces sometimes of pale and sometimes of a dark greyish-brown colour (possibly derived from different species). The fracture is resinous without white streaks and is dotted over with glistening points, more evident in the dark pieces. The fragments are translucent. Externally, the darker pieces are often partially covered with an opaque powdery coat. It has not the flavour or odour of myrrh, but a slight flavour recalling that of cedar pencils. The taste is not bitter but slightly acrid.

6. OPAQUE BDELLIUM.—This is at once recognised by its dull opaque surface when broken. It is of a pale brown colour, in roundish pieces, usually 1 to 1½ inches in diameter, and rather tough. The taste is very bitter and slightly acrid, and the flavour is slight, but cedar-like.

7. HOTAI.—This resembles opaque bdellium, but is much more brittle. The taste is slightly soapy, but it has no aroma and is not perceptibly bitter.

8. TRANSLUCENT GUM RESIN.—This occurs in brownish-yellow pieces, like myrrh, but is more translucent and without white streaks. The taste is slightly bitter, but very acrid, and it has no definite flavour.

All the bdelliums here described, Nos. 4 to 8, are apparently collected in Somaliland, or perhaps also in the Shoa country, and as far south-west as Ogadayn.

The Plants.

The genus *Commiphora* (or as it is sometimes called, *Balsamodendron*) includes, according to Engler, more than sixty species, natives of Africa and Arabia only, so far as is known at present.

The plants are small trees or large shrubs, in some species thorny, and in habit and size recall the English hawthorn tree. The leaves, in the species from which myrrh and bdellium are supposed to be collected, are usually formed of three leaflets, of which the two lateral ones are in some species much smaller than the central one, or in others may be

FIG. 1A.—COMMIPHORA MYRRHA, NEES.—Collected by Ehrenberg near Gison, on the borders of Arabia Felix. Half natural size. After Nees.

minute or even not developed at all. In some species the leaves are hairy and in others free from hairs. The margin of the leaves varies considerably, being sometimes minutely and in some species strongly toothed, in others not at all. The flowers are small and inconspicuous, in most species forming small clusters in the axils of the leaves (Fig. 7), but in a few species the flower stalks are elongated and once or twice forked, and these are usually produced in tufts at the tip of the branchlets (Fig. 16). The fruits are small, usually more or less oval, often pointed, about one-third of an inch long or more, fleshy externally, and contain a hard stone enclosing a single seed when mature.

The shape and markings of the stone of the fruit are characteristic for each species of which the fruit is known.

The yellowish milky juice, which is apparently of buttery consistence when it first exudes, forms, when solidified, the gum resins of commerce. It appears to exude in the early autumn after the rains, since the drugs are brought to Berbera in November.

Owing to the thorny character of the branches in some species, they are very difficult to dry without the leaves, flowers, and fruits becoming detached. On this account, in collecting specimens, a few leaves, flowers, or fruits should be placed in an envelope marked with the same number as the twig from which they are derived, and a piece of the bark of the same tree with the gum-resin attached should be collected at the same time and labelled also with the same number. In this way only is it possible to positively identify the plants with the drugs. The character of the soil or rock should be noted, whether calcareous, silicious, or clayey. Some guide to the particular species from which the gum-resins are obtained will be afforded by the traces of scars on the trees where the bark has been incised by the natives.

The trees found in the districts producing myrrh and bdellium may be conveniently divided into groups as follows:—

- I. Leaves rarely exceeding 2 centimetres in length ;
flowers in small lateral clusters.**

This includes *Commiphora myrrha*, Nees, and its variety *mol-mol*, Engl. ; *C. playfairii*, Hook. f. ; *C. opobalsamum*, Engl. ; *C. quadricincta*, Schwf. ; and *C. robecchii*, Engl.

- II. Leaves rarely exceeding 4 centimetres in length ;
flowers in small axillary clusters.**

This includes *C. abyssinica* and its variety *simplicifolia* ; *C. schimperi*, Engl. ; *C. rostrata*, Engl. ; *G. gurreh*, Engl. ; *C. riva*, Engl. ; *C. samhariensis*, Schwf. ; *C. africana*, Engl. ; *C. hildebrandtii*, Engl. ; and *C. serrulata*, Engl.

- III. Leaves 4 centimetres or more in length. Flowers
on elongated branched flower stalks, usually at
the apex of the branchlets.**

This includes *C. kataf*, Engl., *C. erythraea*, Engl., and its var. *subpubescens*, Engl.

(To be continued.)

ARROW POISONS: THEIR HISTORY, SOURCES, AND CONSTITUENTS.*

BY RALPH STOCKMAN, M.D.,

Professor of Materia Medica in the University of Glasgow.

At the present time, except in the darkest places of the earth, the gun has completely ousted the bow as an instrument of warfare and of the chase. Even in those places which, by comparison with the darkest, we may call dark and darker, the enterprise of traders has introduced guns and gunpowder, and as soon as this happens it becomes the ambition of every savage to be the proud possessor of a weapon which at once gives him a superiority over his neighbour as a fighter and hunter. As with ourselves, superiority, or at least equality, of armament is a necessity for self-preservation and national existence, a state of matters which the savage is as quick to appreciate as his most civilised brother can possibly be. As a result, we are within measurable distance of a time when the bow and arrow will have disappeared as a serious weapon of offence and defence except in the most inaccessible parts of the world. This has already happened in many countries, and in some parts of Africa within living memory, while in others we can observe the process going

* Inaugural sessional address to the North British Branch of the Pharmaceutical Society, delivered November 23, 1898.

on. Already in certain nations and tribes skill with the bow is a thing of the past, the making of bows and arrows is a neglected art, the preparation of poisons to render them more deadly is no longer practised, and in many cases will have been forgotten before we have become accurately acquainted with their ingredients. Nevertheless, the bow and arrow have had a long and fateful career, and their history is intimately bound up with the fortunes of great nations.

The battles of Hastings, Cressy and Poitiers, not to mention others nearer home, were decided by superior archery, while English and Scottish kings and parliaments have in the past frequently taken measures, and enacted stringent laws with the view of developing and improving the national skill, and of ensuring throughout their realms a sufficient supply of well-made bows and arrows.

The arrow is a weapon of the greatest antiquity, as cave remains, the oldest sculptures, and its use at the present day by the most primitive tribes all go to show. Nor was it a weapon to be despised. The range of the English archer was from 120 to 360 yards, his accuracy was deadly, and the force such that the arrow easily penetrated an inch thick plank. Stanley, after an encounter with the Avisibbas, in which he lost several men, found that with one of their bows he could easily drive an arrow through both sides of a large biscuit box, and that he was able to shoot another over a high tree 200 yards distant. He adds that at short range such an arrow will go completely through a man, and it is said that in his palmy days the North American Indian occasionally drove one through a buffalo. Few of the tribes with which we are acquainted are capable of using them with deadly effect at longer ranges than from 50 to 100 yards, but their penetrating power is very great, especially if they have a heavy shaft, and they make a dangerous punctured and incised wound. The English archer drew the shaft to his ear and took deliberate aim, but savages, especially in the excitement of battle, hold both arms more or less extended and only draw the bow-string a certain distance towards the body. A number of arrows are held in the bow hand with a reserve in the quiver, and under these conditions they are able to fire off about six per minute with good aim. If the archers are numerous, therefore, a shower of arrows is not an exaggerated metaphor.

The typical arrow consists of three parts, the head made of iron, bone, flint or other stones, the shaft, in the fashioning of which great skill is necessary to have it straight and true, and some sort of clamp or cord to unite these. Many, however, consist of a simple wooden shaft sharpened at one end and hardened by fire, and the small darts used for killing birds and lesser game are always of this description. The head itself is often barbed, or barbs are placed behind it or are cut in the wood, to prevent extraction, and some of these look truly murderous weapons. As nowadays with gunshot wounds, so to the ancient surgeons arrow wounds were of supreme interest, and such authors as Hippocrates, Celsus, and even Ambroise Paré devoted a large space to the consideration of their effects and proper treatment.

The practice of smearing arrow-heads with poison to enhance their deadly effects must be very ancient, although until quite recent times the accounts given of it have been very vague and meagre. Lagneau states that in cave remains of the palæolithic period in France arrow and spear heads have been found made of bone and marked with depressions for containing poison. These, he thinks, were certainly used to destroy such large animals as the bison and reindeer, and were probably also employed in warfare. To the Greeks arrow poisons were well known. Their word "toxicon"—whence we derive "toxicology"—was a poisonous

substance into which the arrow—"toxon"—was dipped. Hercules is fabled to have used poisoned arrows; Homer mentions them in the 'Odyssey,' and Alexander the Great, in his conquest of Asia, met with peoples who employed such missiles against his troops.

Ovid, who lived on the shores of the Black Sea during his banishment from Rome, speaks of the bile and blood of vipers as being used to poison weapons, while Horace, in his ode to Aristins Fuscus, enumerates poisoned arrows among the evils which the man of upright life and free from crime need not fear. The widespread nature of the idea, however, may be better grasped from the prevalent belief that pestilence was due to arrows shot by one or other of the offended gods, while even such an impalpable feeling as love was conveyed into the heart by means of Cupid's darts. The Scythians were well known to use arrow poisons, and they and the tribes of the Caucasus were commonly supposed to use viper poison mixed with putrefied human blood serum.

As regards the use of poisoned arrows and other weapons in Europe, Aristotle and Strabo mention the practice as common among the Celts. In hunting, the Gauls are stated (Pliny) to have employed arrows dipped in hellebore juice, and before eating the animal to have cut out the part around the wound, a practice similar to that of African and Asiatic peoples at the present day.

Celsus states that the poison used by the Gauls was not deadly if swallowed, and remarks that in this respect it resembles the venom of serpents. If this be correct, it points to the use of snake poison rather than of hellebore, but both may have been employed. In ancient Germany similar customs seem to have been in vogue, for Quintilian (A. D. 338), having crossed the Rhine with his troops, was met in battle by the natives with arrows which caused mortal wounds, no matter which part of the body they struck.

Public opinion, however, in Europe early turned against the use of poisoned weapons, for in the fifth century we find the Salian Franks making it a crime to use such arrows, and in the seventh century the Bavarians passed a similar law. Up to the seventh century poisoned arrows were common among the Dacians and Dalmatians and along the shores of the Danube. As late as the thirteenth century, at least, poisoned daggers and swords were used in Europe for assassination purposes, and very much later, even to the sixteenth century, poisoned arrows and other weapons were well known in Spain. These, however, were probably prepared by experts in poisons, and their use was not common among the people.

There is also contemporary evidence that during the later middle ages poisoned arrows were occasionally employed for killing large wild animals in the remoter districts of France and in Switzerland.

It is very difficult at the present time to determine exactly what poisons were employed in Europe, as the meaning of many of the names has become totally lost. The different species of poisonous hellebore—*H. niger*, *Veratrum album*, *V. viride*—were certainly used, as was also aconite, and probably belladonna, besides the venom of the viper and other snakes. But none of the other plants named by different authors can be identified, the descriptions being for the most part rather vague, and probably derived from hearsay evidence only. In the sixteenth and seventeenth centuries it became widely known in Europe that the aborigines of South America and Western Africa were in the habit of employing poisoned arrows in warfare and in hunting, and now for a long time past these poisons have been objects of great interest to explorers and pharmacologists. A very large number of the different poisons used by tribes all over the world have now been more or less carefully examined physiologically, the botanical sources of many of

them have been accurately determined, and the plants have even in some cases been grown in Europe, while we have also, as regards a few of them, detailed accounts by Europeans of the exact methods of preparation in use among the savages. Such information has proved very difficult to obtain, as the secret is always most jealously guarded, and in some tribes is only known to certain families or chiefs, who pass it on to their successors. Some of the poisons are still quite unknown to us and others very imperfectly so, but in their mode of preparation and in the kind of ingredients commonly used there is a certain family resemblance all over the world. Thus we find that snake poison, poisonous insects, poisonous fish, and other animals are commonly employed, while plant juices or watery decoctions inspissated to the consistence of thick tar by heat form the basis or the sole ingredient of the majority. Many of them are mixtures of different poisonous vegetable products, some again are mixtures of animal and vegetable poisons, and this complexity of composition often makes it most difficult to determine the real nature of the poison. When freshly made they have generally the consistence of thick tar, and are carefully put up in neatly constructed receptacles made usually of vegetable fibre or in small calabashes, such as I now show you. In some cases the poison is smeared over the arrow-head, in others it is laid on thickly just behind the head for a distance of two or three inches. Among all savage tribes the head is very loosely attached to the shaft, so that the poisoned portion cannot be drawn or knocked out, but remains firmly fixed in the tissues, no matter what happens to the rest of the arrow. In the case of wooden arrows the shaft is sometimes partially cut through near the poisoned end, so that attempts at extraction by man or violent contact with bushes in the case of an animal which has been hit, snap it off short, and leave the poisoned part in the wound. I also show you some darts from Borneo, made of wood and poisoned at the point, these being shot through a blow tube. It is very noticeable that the quivers both for arrows and for darts are most carefully made with a cover for the poisoned heads, so as to avoid any accidental wounding of the owner or his friends. When carried in an open quiver they are either put head downwards or each head is wrapped in a separate leaf.

The poisons used by different tribes differ much in deadliness, and even the same poison is not always equally effective. The active principle may tend to decompose, and thus the virulence is lessened; if the poison be fresh and moist it is rapidly absorbed from the wound and is speedily fatal, but if old and dried it dissolves much more slowly in the body fluids. Its action is thereby more slowly developed, and if it can be removed in time the wounded man may recover. Some of them must retain their virulence unimpaired for a very long time, as Lewin found a Bushman arrow-poison still active which had lain for ninety years in the Museum for Anthropology at Berlin.

(To be continued.)

DETERMINATION OF NITRITES IN WATER.—L. Robin titrates the iodine set free by the action of nitrous acid on solution of potassium iodide acidulated with acetic acid. Fifty C.c. of the water is mixed with 2 C.c. of 20 per cent. solution of chemically pure potassium iodide and 2 C.c. of glacial acetic acid. After standing for exactly thirty minutes, the liberated iodine is determined in the customary manner with thiosulphate, using starch as an indicator. By this means 0.0001 gramme of nitrous acid per litre may be determined. Waters containing sulphuretted hydrogen should be precipitated with silver sulphate and then distilled, 50 C.c. of distillate being collected from every 100 C.c. of water taken.—*Journ. de Pharm.* [6], vii., 575.

ESSENTIALS OF VEGETABLE HISTOLOGY AS APPLIED TO PHARMACOGNOSY.

The Management of the Microscope.

ILLUMINATION.—Few pharmacy students have the opportunity of pursuing their microscopical studies during the hours of daylight. They must therefore, as a rule, have recourse to artificial light. The light reflected from a bright cumulus cloud is certainly

of exquisite quality for the microscopist; but so rarely is it to be obtained, and so rapid are the changes in the aspect of the sky, that he is quite reconciled for the most part to carry on his work with a source of illumination more uniform and rather more under control. A good petroleum lamp giving a small clear flame is a necessity, and may be obtained from any dealer in microscopical accessories. The most comfortable kind to use is one having a shallow glass reservoir attached to a lateral brass supporting column fixed in a heavy circular foot (Fig. 1). It may be raised or depressed by sliding on the column. The chimney is made of metal and pierced by an opening with side slots, in which can be placed either plain or coloured glass slips. The metal chimney screens the eyes from unnecessary light, and, of course, is not liable to the disasters which so frequently overtake glass ones. Upon a good supply of proper light depends not only

FIG. 1.

the worker's comfort, but also the continued efficiency of his eyesight. The light derived from an ordinary lamp or gas flame is intensely fatiguing and should be scrupulously avoided unless it has been passed through a suitable medium. A blue tinted glass slip in the lamp chimney may be used if care is taken that the colour is not so intense as to produce a decided blue field in the microscope. The aim should be to obtain a field in which the predominant yellow of the oil flame is just overcome, the result being a cool very faint blue colour which in a short time the eye accepts without being impressed with any colour sensation. Often it may be found desirable to concentrate the light upon the mirror by means of a condensing lens. A device which supersedes the blue glass chimney and the condensing lens may be made by taking a round-bottomed twelve or sixteen ounce flask and filling it almost quite full with a dilute solution of ammonio-sulphate of copper, adjusted to the proper tint, and securely corking the neck. This may be then placed upside-down in a wooden support slightly hollowed to receive the globe and having a cylindrical hole in the centre to receive the neck (Fig. 2). Judgment should be exercised in the use of the mirrors, the plane one being always used when it gives a sufficiency of light, and the concave one only when really necessary; the light from the latter may be nicely varied by adjusting its distance from the stage, when the microscope fitting permits of it. It is not always

desirable to have the light focussed upon the object, as better results are sometimes obtained by having the light diffused. It is often overlooked that a large amount of control over the light is to be obtained by an intelligent use of the diaphragms, and it is a pity that in so many microscopes these are not concentric with the microscope tube. A cheap iris diaphragm with a simple means of centering is a desideratum. That the object under the microscope is seen in only one plane should be constantly remembered; but

this drawback can be compensated for in some slight measure by examining the object under varying conditions of light, as by varying the distance of the mirrors as well as by throwing beams of more or less obliquity upon it. Dark ground illumination sometimes assists in the elucidation of obscure structures. It may be obtained by the use of the spot-lens, by the use of the

black central stops supplied with the Abbe illuminator, by paraboloid illuminators, or, in the case of low powers, by directing a beam of light upon the object, of such obliquity as not to impinge upon the front lens of the objective. Whatever the means used the end to be attained is to direct light upon the object at the same time that all other light than that refracted by the object is prevented from entering the objective. The appearance gained is that of an apparently incandescent object seen against a black ground.

DRAWING AND MEASURING.—Anyone who is proficient in free hand drawing will find but little difficulty in making satisfactory drawings of microscopical images; but something more than a pictorial representation is needed for pharmacognostical purposes. It is necessary that the drawings should bear a definite relationship in size to the original object. To secure this two pieces of apparatus are almost essential—a camera lucida and a stage micrometer. The latter, which is indispensable, should be ruled in the tenths and hundredths of a millimetre, because microscopic measurements are usually expressed as multiples of the micron (μ), the thousandth part of the millimetre, which was formerly and sometimes still is designated a micromillimetre (Mkm). For measuring purposes the micrometer may be used in three ways. The simplest and quickest, requiring some little practice, is to place the micrometer upon the microscope stage and accurately focus the objective upon it. Then place a piece of drawing paper upon some body elevated to exactly the same height as the stage upon the right-hand side of the microscope. After a little practice it will be found possible to view the micrometer through the microscope with the left eye and at the same time see the paper and a pencil with the right eye. It will then appear, if the microscope is sufficiently close to the paper, as though the micrometer were projected upon the paper, and the pencil may be used to mark the micrometrical divisions. Upon now replacing the micrometer with the object to be measured and viewing it in the same way it can be noted how many divisions of the scale on the drawing paper it covers and its measurements duly recorded. By applying a millimetre rule to the drawn scale and noting how

many millimetres are included in, say, the magnified tenth (0.1 Mm.) of a millimetre and multiplying by ten, the magnification in diameters of the particular microscopical combination (objective, ocular, and tube-length) will be obtained. Should it only be desired to measure the object without reference to the magnification of the microscope, it is not necessary to be careful to place the drawing paper upon the same level as the stage. In the same way drawings of small objects, such as starch granules, pollen grains, and crystals may be drawn. This method is not suitable for large objects, because of the difficulty of keeping the eyes in one position, and thus keeping the different parts of the object in register with the parts already drawn.

Several useful devices exist for the purpose of aiding the draughtsman to transfer to paper with accuracy a representation of the object. As a treatise on the microscope is not what is in contemplation, it will suffice to indicate the instruments which best accomplish the purpose.

The Abbe camera lucida (Fig. 3), makes it possible for the observer to see the magnified image and the pencil at the same time with one eye and, further, it causes no more fatigue than ordinary microscopical observation. Over the eye-piece is fixed a prism, the upper inclined surface of which is silvered, with the exception of a small round portion in the middle which allows

the magnified image to reach the eye. Suspended on a lateral rigid arm is placed a moveable plane mirror; the face of it is directed downwards towards the drawing paper at an angle parallel to the silvered surface of the prism which receives the reflection of the drawing paper and pencil. Thus the image of the object and the paper and pencil are seen coincidentally by the eye. The amount of light proceeding from both image and paper require the most careful adjustment if the two images are to be seen with equal distinctness. Smoke-tinted glasses are supplied with Abbe camera lucida for the purpose of regulating the brightness of the paper. For accurate work, it must be noted that when the mirror is not strictly parallel with the silvered surface of the prism, more or less distortion will occur. The amount of it, however, is so small as to be negligible for many purposes; but it cannot be ignored when making small measurements. For this reason it is preferable to have a camera lucida with as large a mirror and as long an arm as is convenient, and thus remove the tendency which sometimes arises to depress the mirror. Another piece of apparatus used for the same purpose is the camera lucida with two prisms. A type of this instrument (Fig. 4) is made by Messrs. Swift and Son. In this instrument the moveable mirror of the Abbe camera lucida is replaced by a prism, the long arm is abolished and no provision is

FIG. 2.

FIG. 3.

FIG. 4.

made for tinted glasses. In other respects and in principle the instruments are alike, total reflection of the paper being made by the inclined inner surface of the outer prism, whence it is received upon the inclined silvered surface of the inner prism. The outer prism it will be seen can be moved by means of a lateral milled head. In consequence of the close proximity of the two prisms distortion is always present when the microscope is upright and the paper horizontal. To obviate this defect the microscope may be inclined towards the observer at a proper angle and the drawing paper placed so as to be under the inclined instrument. Because of the difficulty of suitably lighting the drawing paper in this position a better plan is to use the microscope erect and have the paper placed upon a board inclined at an angle which is found to produce the least distortion.

CHAPTERS IN ORGANIC CHEMISTRY.

Æther Aceticus.—Ethyl acetate is one of the most familiar examples of the class of bodies known as esters. These are compounds derived from acids by replacing the characteristic hydrogen (or replaceable hydrogen) by organic radicles. They are, therefore, comparable to inorganic salts, which are similarly derived by replacement of the hydrogen by metals:—

Acid.	Metallic salt.	Ester (Ethereal salt).
ClH	ClK	ClC ₂ H ₅
CH ₃ COOH	CH ₃ COOK	CH ₃ COOC ₂ H ₅

The organic radicles are less strongly basic (electro-positive) than the metals. They are, therefore, displaced by metals, and most easily by the strongest electro-positive metals, the alkali metals—when they are submitted, under appropriate conditions, to the action of the metallic hydroxide. This saponification of esters may also be produced by water alone, which may be regarded as hydrogen hydroxide H·OH. The process has quite a general application, and is known as “saponification” from its earliest application in the manufacture of soap. For example, olein, the glyceryl ester of oleic acid, and the chief constituent of olive and almond oils, is decomposed when boiled with solution of potassium hydroxide.

This is precisely similar to the action of potassium hydroxide upon other esters, *e.g.*, ethyl acetate.

or in the form of an ordinary equation—

and hence the term is now of general application to such reactions. The product of saponification is therefore not necessarily a “soap” in the popular sense of the word: it resembles a soap only in chemical constitution. In a popular sense the term soap is applied to the alkali salts of the fatty acids having a high molecular weight, such as palmitic, stearic, and oleic acids, which are characteristic constituents of commercial soaps. Between formic and acetic acids, the first and second members of the fatty acid series, and the higher homologues, such as palmitic and stearic acids, there is a connecting series of intermediate acids, and passing up the series we observe a gradation in certain properties (as in all other homologous series of compounds). Thus, in the series of fatty

acids, the lower members are soluble in water, and this property decreases with increasing molecular weight, the melting and boiling points at the same time rising, while the specific gravity decreases. The alkali salts of the lower acids are neutral salts dissolving in water without decomposition and crystallising readily therefrom. On the other hand, the ordinary soaps, *i.e.*, the alkali salts of the higher fatty acids, do not crystallise from water, but form homogeneous amorphous solids containing more or less water. When dissolved in water they give an alkaline reaction due to a partial dissociation of the neutral soap into alkali hydroxide and fatty acid, the reaction of the fatty acid being much feebler than the opposite reaction of an equivalent amount of alkali. The use of soap as a cleansing agent depends partly upon this dissociation and partly upon the familiar emulsifying property of soap solution towards fats. For the dirt upon the skin and clothes is not removed easily by plain water, because it is surrounded by a protective film of insoluble oily or fatty matter. The free alkali of the soap solution attacks this grease, which is partly saponified and then emulsified, while the lathering of the soap removes the mixture of dirt, grease, and soap from the surface of the skin or fabric.

The process for the preparation of ethyl acetate mentioned in the Pharmacopœia is one of the general processes for the preparation of esters, *viz.*, the reaction between an acid and an alcohol with elimination of water.

The process, however, is not so simple as the equation indicates, because the production of water leads to a reversal of the reaction, *i.e.*, the reproduction of acid and alcohol by saponification of the ester.

If molecular proportions of an acid and alcohol be mixed, the formation of ester proceeds at first rapidly, then more slowly, and finally stops. This occurs when a certain proportion of the alcohol and acid have reacted, and the condition of equilibrium thus attained is explained by the statement that the rate of formation of the ester is just equalled by the rate at which it is saponified by the water already produced. Reversible reactions of this kind are much more common than the student may at first sight imagine. The subject is worthy of careful consideration in order to impress upon students the necessity of comprehending the course and conditions of a reaction, in addition to knowing the final products obtained. The use of equations without this sort of knowledge leads only to a superficial and slipshod acquaintance with chemistry. The general reaction for the formation of esters, given above, may be expanded to express the fact that the reaction has a limiting value. Thus:—

This shows that if x molecules of acetic acid react with an equal number of molecules of ethyl hydroxide a certain number, represented by y , of molecules of ethyl acetate and water are produced, leaving the remaining $(x-y)$ molecules of acid and alcohol unchanged. The actual value of x and y must be determined for each reaction. Confining ourselves to this reaction between ethyl alcohol and acetic acid, the “limiting value,” *i.e.*, the quantity of the mixture transformed, is equal to about 66 per cent. In this case, if $x=100$ $y=66$ and $(z-y)=34$. The limiting value is not

affected by the temperature of the reaction. The velocity of the reaction is increased by raising the temperature; that is, the higher the temperature the sooner is the limiting value attained. The term "initial velocity" is used to express the amount of the reacting substances converted during the first hour. In the case of equi-molecular proportions of acetic acid and ethyl hydroxide at a temperature of 154° C. the initial velocity is about 47 per cent., while the limiting value of 66 per cent. is only attained after seventy-two hours. It is therefore obvious that the velocity of reaction diminishes rapidly from the outset, since 47 per cent. of the mixture is transformed during the first hour, while the remaining 19 per cent. requires seventy-one hours for completion. In practice, however, we can realise almost completely the reaction expressed by the equation—

by adjusting the conditions so that the ethyl acetate and water are removed from the sphere of reaction as quickly as they are formed. This is accomplished by adding some dehydrating substance, like sulphuric acid or zinc chloride, to combine with the water while the mixture is heated to remove the ethyl acetate by distillation. By this means we can obtain about 97 per cent. of the acetic acid in the form of ethyl acetate, since the reverse reaction cannot take place owing to the removal of the substances on the right hand side of the equation. In the process mentioned in the Pharmacopœia the sulphuric acid serves a double purpose: it removes the water and also furnishes acetic acid by reacting with the sodium acetate. This salt is directed to be previously dried, to expel for obvious reasons the water of crystallisation which the ordinary salt contains ($\text{CH}_3\text{COONa}, 3\text{H}_2\text{O}$).

With regard to the reverse reaction, viz., the saponification of ethyl acetate by means of water:—

it is obvious that the limiting value of the reaction will be attained when 34 per cent. (100-66) of the mixture of equimolecular proportions of ethyl acetate and water have been so transformed, under the conditions already discussed. If, however, we can remove the products on the right hand side of the equation, this reaction will proceed until the whole of the ethyl acetate has been decomposed. We can accomplish this by adding an alkali hydroxide which combines with the acetic acid, forming potassium or sodium acetate, which do not react with the ethyl hydroxide. Under these conditions the equation holds good. The equations for such reversible reactions are sometimes written thus:—

The arrows are used to show that the reaction may proceed in either direction, according to the conditions under which it is carried out.

DETECTION OF YELLOW AZO DYES IN ARTIFICIALLY COLOURED FATS.—Geister states that ordinary Fuller's earth gives a pink-red colour with certain azo dyes, which have now largely superseded annatto in the colouring of dietetic fats. The dye may be precipitated from the fat by the earth as a violet-red precipitate; this is washed with naphtha to remove the fat, and the dye may then be extracted by boiling alcohol and identified.—*Journ. Amer. Chem. Soc.*, xx., 110.

HOW TO MAKE SILVER MIRRORS.*

BY FRANK EDEL, DES MOINES, IA.

Some time ago, in a short article on silvering glass, I gave the formulæ for making two solutions which, when mixed in equal parts and immediately poured on the glass, had been found by experiments to give most satisfactory results. By using the formulæ then given I have succeeded in plating perfectly hundreds of feet of glass for mirrors. While never having experienced trouble with the process, I have long been convinced that the reducing solution, while depositing the silver without the application of heat much more uniformly than any other I have tried, did not reduce the full amount of the silver held in solution. In this belief I was borne out by experiments made both before and after adopting the formula recommended. In my earlier experiments I had used Rochelle salt alone, and had been able to cover the glass with less than half the amount of silver I was obliged to use with the other reducing agent, but the deposit was not even and it also varied in colour, although at times I had on small work secured some very good results. While with Rochelle salt alone I had succeeded in covering the glass with a solution which contained only 100 grains of silver nitrate to 26 ounces, with the reducing agent given in the article above referred to it required 200 grains. But however much I tried, I did not succeed in getting uniform results with the Rochelle salt alone, while with the other solution I had no trouble in plating glass of any size.

On one or two occasions my attention has been called by those who have tried the process to the fact that the plate was streaked and full of black spots. This, in my opinion, was due to some imperfection in the solutions or to the fact that the glass was not chemically clean, for I have on at least two occasions made as much as 20 gallons of the solutions in lots of 1 gallon and over in a week's time, and never had any trouble with it from this source.

Lately, however, a Russian Jew has been travelling around this part of the country and plating mirrors, doing the work from house to house, and while his work was no better than that which I had succeeded in doing for a prominent furniture dealer, I was satisfied that he did not use nearly the amount of silver which was required by my own process. I satisfied myself that he used exactly the same chemicals, so that in order to do the work more economically he had to combine them differently. I asked him about the combinations used, but he did not have the slightest idea of the chemistry of his process. He was very uncommunicative, but I found that he had no knowledge of the proper methods of cleaning glass, and so I gave him full instructions. Later on he came to me and thanked me for the information, saying that he now had no more trouble in getting his glasses clean. He then wanted to know what kind of solution I used to reduce the silver, and when I told him, he said it was nearly the same as his own, only he used more Rochelle salt and less silver, and that he calculated to use only one-fourth as much salts in the reducing solution as there was silver in his silver solution. He also told me that he made up his solutions in concentrated form and diluted them with distilled water to the proper strength when ready to use them.

As this was exactly the information I was looking for I began to experiment again, with a view of securing a solution which would precipitate the whole amount of silver. While I have not had the time to give the matter the fullest attention, I have found the following solutions to be, to all appearances, just what I desired. I have only tried them on small glasses, but they did the work nicely and at the same time economically.

* From the *Western Druggist*.

SOLUTION No. 1.

Silver Nitrate.....	1 oz. av.
Distilled Water	8 fl. ozs.
Ammonia Water	enough.

Dissolve the silver in the water and add ammonia water gradually until the brown precipitate that is thrown down at first is just dissolved, being extremely careful not to add too much ammonia. But for fear that too much ammonia has been added, drop into the solution a crystal of silver nitrate and shake; if this makes the solution turbid, it is all right; if not, and it clears up, add more silver until it remains turbid. Then filter through a double paper filter, turning back until clear, and add distilled water through the filter till the filtrate measures 16 fluid ounces. Place this in a clean bottle, cork, and keep in a cool, dark place over night.

SOLUTION No. 2.

Sodium and Potassium Tartrate	$\frac{1}{4}$ oz.
Distilled Water.....	10 fl. ozs.

Dissolve the salt in the water, place in a porcelain-lined dish and heat to boiling; then add 10 grains of silver nitrate and stir thoroughly with a clean glass rod; then boil gently for ten or fifteen minutes or until the solution becomes a grey colour. Filter this through a paper filter and turn back until it comes through clear; then add enough distilled water through the filter to make the filtrate measure 16 fluid ounces. Put in a clean bottle and cork, then place in a dark place for five or six hours.

When wanted for use, mix:

Solution No. 1.	1 fl. oz.
Solution No. 2.	1 fl. oz.
Distilled water	4 fl. ozs.

Immediately pour this mixture over the glass, which has been previously cleaned and levelled on some firm support. Then allow to stand until the solution has deposited its silver, about one hour being long enough. Then dip off, rinse by sprinkling, and stand on edge to dry. Lastly, protect with a coat of asphalt varnish.

PYROXYLIN VARNISHES.*

Solutions, the main constituent of which is a nitro-cellulose, have long held an important place in photographic technics, the now almost superseded bromo-iodised collodion being, it need scarcely be said, the most conspicuous example. Since the comparative disuse, however, of this once indispensable liquid, nitro-cellulose as a varnish base has come into very general favour, the particular form most affected by photographers being the amyl-acetate solution of celluloid, which, as is well known, consists mainly of so-called gun-cotton and camphor. Incidentally, it may be remarked that the extent to which photography has become a power in the land may be gauged by the effect which the demand for celluloid (largely photographic) has had upon the market price of camphor. One grave defect of this particular solution is the penetrating odour of the amyl solvent, which, not by any means unpleasant of itself, becomes very objectionable when the presence of its vapour pervades the whole of the premises where it is used. It may be argued that, if the odour is objected to, there are many other solvents free from any offensive character of this kind, and such an argument would be sound were it not for the fact that other defective qualities are attached to many of the solvents. We may take, for example, the di-methyl-ketone, usually known as acetone, the substance so recently introduced as a developer constituent

it will readily dissolve celluloid, but, when the liquid is then tried as a varnish, it will be found wanting, from the fact that it dries to an opalescent or papery-looking film, quite useless for the purpose.

As some of the lore of the old collodion-workers is in danger of being lost to modern workers, it may be well to point out some of the peculiarities of pyroxyline when dissolved. This chemical has been termed a tri-nitro-cellulose, but its exact formula varies according to the degree of nitration it has attained, and its physical properties are equally varied, according to the heat at which it was made and the extent of dilution of the acids. With a maximum dilution the fibres of the cotton will be short and powdery and soft to the touch. With less water the fibre is stronger and quite unbroken, and feels quite harsh when handled. An expert can almost tell with his eyes shut what kind of solution a particular sample of the gun-cotton will make. The first described will give a beautiful limpid solution, flowing well and showing no structure when dry. If a certain maximum of water has been passed in its manufacture, the film left after drying will be dead and papery-looking. When the other class of pyroxyline is dissolved, it will be found that a far smaller quantity has to be dissolved before the liquid becomes too thick to pour and flow. Further, the harder and harsher the fibre of the cotton, the more will the film dry with a "grain" or structure, though it will be very clean and brilliant. Exactly the same peculiarities attend the collodion, as the solution in ether and alcohol is called by photographers, and upon the nice adjustment of these various qualities depends the working character of the collodion. A mixture of this liquid with ordinary alcoholic varnish will also not dry clear—will produce, indeed, a dead white film, which has been proposed as a substitute for ground glass.

If we now pass from these better-known solvents to others of more recent introduction, we find very marked differences in the solutions of the nitrated celluloses. Thus Herr Hugo Flemming, in a foreign journal, finds both dichlorhydrin and epichlorhydrin excellent solvents for the pyroxyline and for such compounds of them as celluloid. Herr Flemming explains that gun-cotton (presumably the photographic kinds, as the true gun-cotton—di-nitro-cellulose—is quite insoluble) is readily soluble in epichlorhydrin, but that even a 20 per cent. solution is so thick that it requires diluting with alcohol before being used as a varnish, though the resulting varnish possesses several advantages over the usual solvents for nitrated cellulose products; but in this regard it is necessary to draw attention, before arriving at any decision on this point, to our remarks upon the nature of the pyroxyline and its effect upon the solution. An ether-alcohol solution would be, with the very best sample obtainable as regards free-flowing character and complete transparency of film after varnishing, very thick indeed, and quite useless as a varnish. Hence Herr Flemming's objection is really without grounds.

In conclusion, we may now recapitulate the characters a good nitro-cellulose should possess if it be desired to use it as a varnish. It should have short, broken fibres, and feel soft to the touch. Such a kind dissolved to the extent of five grains to the ounce will give a clear, limpid liquid, free-flowing and bright-drying.

MYDRINE.—Under this name a mixture of the hydrochlorides of ephedrine and homatropine has been introduced by Merck. Stevenson has experimented with this as a mydriatic, and finds that it acts well. Dilation of the pupil satisfactorily reaches its maximum in thirty minutes, and quite disappears again in three hours. The accommodation was not affected.—*Pharm. Zeit.*

* From the *British Journal of Photography*

THE PHARMACEUTICAL SOCIETY AND ITS PRESIDENTS.

MICHAEL CARTEIGHE.—1882-96.

THAT this is not an obituary notice, *Deo gratias*. But to say something, in short compass, about a living man who for more than thirty years has had a directing share in the fortunes of the Pharmaceutical Society is a yet more difficult task. An appreciation of Michael Carteighe should be drawn with strong lines and not toned down to an average depth of colour. Capable, self-reliant, vigorous in body and mind, gifted with keen perception and generous sympathies, his fervid masterful energy would have ensured him prominence in any capacity. A leading actor amongst British pharmacists, he has played many parts well elsewhere, and to say that, in his whole pharmaceutical career, he has typified the ideal of the Society's founders, is neither flattery nor mere compliment.

Mr. Carteighe's connection with pharmacy may very probably be traced to the circumstance that his elder brother, the late John Carteighe, while engaged as assistant to Michael Faraday at the Royal Institution, accepted the offer of a position in the establishment of Mr. Charles Dinneford, somewhere about the time that the Pharmaceutical Society was being founded. After the death of Mr. Dinneford in 1846, John Carteighe entered into partnership with his friend John Edward Stuart, and the Bond Street business was continued by them under the style of Dinneford and Co. Towards the end of 1863, Michael Carteighe was admitted into the firm after having in the meantime qualified as a pharmaceutical chemist. With a different object in view he had studied chemistry under Williamson at the University College, London, and after an apprenticeship of three years with Mr. C. J. Radermacher of New Cavendish Street, he entered the Society's School of Pharmacy under the impression that it was a necessary part of the pharmaceutical curriculum, and before the close of the session he passed both the Minor and Major examinations.

Let us now go back to a prize distribution at Bloomsbury Square in October, 1863, when Thomas Hyde Hills, as Vice-President, occupied the chair in the absence of Mr. Sandford. Redwood made his annual declaration. The School, he regretted, was numerically small; but the conduct and attainments of the students were all that could be desired. Two especially had entirely outstripped the rest—and were able to answer the questions given almost as well as the Professor. These were Michael Carteighe and Charles Umney. Then came Bentley with his familiar praise; he could endorse all that the previous speaker said, and he did so. Never had there been, it appeared, such an exhibition of devotion to school studies, and in his own department he had to mention first the subject of this sketch, of whom he predicted that his future career would bring him distinc-

tion. Mr. Radermacher also spoke of his late apprentice as deserving honour at his hands, as being a pattern for punctuality, attention and method in making the best of his time. The Pereira Medal was also won by Michael Carteighe. On that occasion, at the close of the proceedings, "Mr. Carteighe begged to say a word" and he proceeded to inform the assembly that he did not approve of the mode of action of the authorities in the conduct of the examination for the Pereira Medal. Moreover, he suggested to the Council how, in his opinion, matters should be conducted. Since that evening, when he made his first recorded speech, Mr. Carteighe has had to face many an audience and deliver innumerable discourses on pharmaceutical affairs, and he has always taken the same intense interest in every detail of the Society's work that he manifested on the occasion referred to.

In the early part of 1864 Mr. Carteighe became a member of the Pharmaceutical Society, and at the twenty-third anniversary meeting he was elected one of the auditors. In 1866 he was elected on the Council and appointed a member of the Board of Examiners, positions which he continued to occupy until 1870, when in consequence of the altered arrangements under the Pharmacy Act he resigned his seat on the Council, but continued to act as an examiner, until in 1881 he gave up that position on being again elected a member of the Council. There are still a few who can remember that when Mr. Carteighe first became a member of Council, the uncompromising candour with which he expressed his views, as representing the younger generation, rather shocked some of the more conservative members; but that impression did not last long, and his untiring capacity for work soon increased his influence.

About that period chemists and druggists, unconnected with the Society, were beginning to recognise the disadvantage of being unorganised, and were seeking to obtain legislative incorporation, while the attention of the Legislature was drawn [to the necessity of more efficient regulation of the chemist's business, in consequence of the public alarm occasioned by various cases of poisoning and by the publication of reports on that subject by the medical officer of the Privy Council and Dr. Swaine Taylor. Prior to the passing of the Pharmacy Act, 1868, Mr. Carteighe was actively engaged with Mr. Sandford, then President, in the difficult negotiations relating to that measure, and he thus acquired an intimate acquaintance with the intention and origin of its several sections. At the meeting of the British Pharmaceutical Conference held at Norwich in August, 1868, Mr. Carteighe was, on that account, requested to give an exposition of the new Act, and explain the manner in which its several provisions would operate.

When next elected a member of the Council in 1881, Mr. Carteighe soon took the position of predominant partner and, in

MICHAEL CARTEIGHE.

the following year, he was elected President. It is impossible in this place to enter into particulars of all the work carried out by him while acting in that capacity, but in regard to its general tendency it may be stated that—notwithstanding the liability of a democratic institution to lapse into despotism under prolonged individual control and notwithstanding ribald jokes about the “boss” and his “team”—Mr. Carteighe occupied the position of President for fourteen consecutive years without in the least degree losing the respect and esteem of his colleagues. No higher compliment could possibly be paid to him than is conveyed by the bare statement of that fact.

During his long term of office he has devoted himself chiefly to administrative work, and has materially helped to consolidate the organisation of the Society. The work of the Council has been carried out with harmonious concurrence, and though that condition does not imply absolute identity of opinion among twenty-one men of business, only a distorting mirror could reflect their unanimity as “deadly.” Mr. Carteighe’s great influence is largely due to a mastery of detail, a memory for precedents, and a perfect acquaintance with legal technicalities and matters bearing on legislation. His knowledge in that respect is complete and places him at a perpetual advantage. One of his greatest triumphs, of which he may reasonably be proud, is the readjustment of conditions relating to the Society in Scotland. It was altogether to the credit of both North and South. The informal presentation of an address to Mr. Carteighe at the Liverpool Conference (1896) embodying the terms of a resolution passed by the Executive of the North British Branch, forms a happy conclusion to this page of Scottish history. Mr. Laidlaw Ewing, Chairman of the Executive Committee, supported by Mr. W. L. Currie, Vice-Chairman, speaking on behalf of the other members of the Executive, acknowledged their indebtedness to Mr. Carteighe for the efforts he had successfully made in order to advance the interests of the Society, to promote loyalty to one another, and a cordial feeling of unity and sympathy among pharmacists both north and south of the Tweed.

Mr. Carteighe’s Council work includes the various transitions and remodelling of the scholastic and examination systems, the better organisation concerning local secretaries and the establishment of a body of divisional secretaries in the metropolis. He has encouraged a bolder and more liberal award of annuities from the Benevolent Fund and greater reliance upon the generosity of those who can contribute to it. He has succeeded in persuading the Privy Council to agree to the increase of the fee for the qualifying examination. The reconstruction of a large portion of the building at 17, Bloomsbury Square, and the provision of suitable premises for the Society’s work in Scotland furnish material proof of the activity characterising the period referred to. The curriculum scheme has for the present been withdrawn, waiting for a more convenient season when the interests of students shall be more benevolently considered. During Mr. Carteighe’s reign the official Journal was reconstructed, and has emerged in a more attractive form, conserving its scientific character, but better representing general interests. The later years of his presidency have been marked by more vigorous enforcement of the provisions of the Pharmacy Act, and one decided indication of Mr. Carteighe’s useful personal influence is the enhanced regard and consideration shown for the Pharmaceutical Society as an important public institution.

During the course of Mr. Carteighe’s presidency, he has undertaken missionary work, not exactly in dark places, but at such reputed centres of light and leading as Manchester, Liverpool, Birmingham, Edinburgh, Sheffield, Exeter, Plymouth, Cardiff,

Dover, Carlisle, Hull, Leeds, Aberdeen, and various other English and Scottish towns. On those occasions his personal popularity has generally secured him a cordial reception, and he has invariably preached the doctrine that there is an essential difference between the trade service to be expected from an intelligent, well-informed chemist and druggist, and that rendered in the mechanical sale of packeted goods by the grocer or general store keeper. He has contended that if protection of trade interests be possible, it must be provided from the point of view and through the agency of the Society, as an organisation—co-extensive with the register of legally qualified persons—by which education is promoted, so that the claim to the title of chemist in connection with the exercise of their business may be justified. He has always strenuously urged upon chemists that—in place of sacrificing the advantage of personality in their business, for the sake of running branch shops, or enabling executors to carry on the business of a deceased chemist indefinitely; instead of assimilating their business to that of the bazaar or general store, and instead of assisting, or taking the designation of, the most destructive form of competition the chemist has to contend with—the true policy of protection is to establish a distinct line of demarcation from other traders and to show that its maintenance is obviously conducive to the safety and general interest of the public. That teaching has probably not been wholly ineffective though there is too much reason to believe that the good advice given has been less followed than is desirable.

The various ways in which Mr. Carteighe has taken an active part in promoting a feeling of good fellowship and social intercourse among chemists are minor, but by no means unimportant, instances of the good service he has rendered to the pharmaceutical community. Besides the Chemists’ Ball, of which he has been a constant supporter, the anniversary dinner of members and friends of the Pharmaceutical Society is another established institution which owes its existence mainly to the contagious enthusiasm with which he took up its organisation in 1872. The Pharmacy Club, in like manner, established very largely through Mr. Carteighe’s initiative, has acquired success by the zeal with which he has, as a member of the Committee, assisted in its management. Lastly, as the first “corner-stone” of a Masonic Lodge founded especially for promoting fraternal principles among pharmacists, Mr. Carteighe has helped to give the bonds of fellowship wider reach and efficacy.

As a speaker Mr. Carteighe is both ready, logical, and effective, rarely failing to impress his audience, though sometimes rather weakening the force of his argument by reiteration. Never is he heard to greater advantage than when giving an account of the career of some departed friend—the remarks convey a surprising amount of information, while the commendation is in excellent taste. One of his most effective efforts was an address at an opening session of the School of Pharmacy Students’ Association; it was wholly unpremeditated, genial in expression and sensible throughout. He spoke as oneudent to another, and won the affectionate esteem of his young audience. It is matter for regret, that being extemporaneous and unexpected, the address was not reported verbatim.

Mr. Carteighe’s attention was attracted at an early date to the yearly provincial meetings inaugurated mainly by Schacht and Reynolds, with the aid of their personal friends, as a collateral development of the Pharmaceutical Society, under the title of the British Pharmaceutical Conference. He attended the Conference meeting held at Nottingham in 1866, where opportunity was afforded for making the personal acquaintance of many prominent pharmacists. Under the fascinating influence of John Cargill Brough

a number of congenial spirits—including Brady, Carteighe, Ekin, Giles, Groves, Ince, Reynolds, and others—became more intimately associated, and for many years afterwards continued to assemble together at the Conference meetings. In the autumn of 1868 the meeting was at Norwich under the presidency of Daniel Hanbury, simultaneously with that of the British Association. The gathering was remarkable on its own account, and it became historical owing to the oration pronounced by Dr. Magee in the cathedral. One of the surviving members of the usual group of friends tells of their forming daily a social circle at a restaurant during the sitting of the Conference, and that at a final lunch Mr. Carteighe, after sitting for a time abnormally silent, suddenly rose, and saying that he had an engagement, left the room. Half-an-hour afterwards, Schacht came in and announced that their departed friend's engagement was of a permanent character—it was one which made the domestic happiness of his life. In 1867 Mr. Carteighe was elected a member of the Conference Committee at Dundee, was a Vice-President from 1883, Southport, to 1896, Liverpool; and in 1874, when the Conference meeting was held in London, under the presidency of T. B. Groves, he was Local Secretary.

The friendships formed at these Conference Meetings were in several ways productive of good results, and one of the most immediate was the publication in the *Chemist and Druggist*, then under the editorship of Brough, of several articles, which had for their object to familiarise English readers with French pharmacy based on the Paris 'Codex' of 1866. The contributions towards this end, commencing January, 1867, were meant to give an insight into Continental usage, specially when differing from that adopted by ourselves. The essay on "La Matière Médicale" was written by Henry Bowman Brady; "Chemistry," by the Editor, and "Pharmacy," by John Watts. The "Explanatory Introduction," written by Mr. Carteighe, was a commentary and review of the chapter entitled "Notions Préliminaires." The concluding sentences may be quoted as conveying a sentiment in which most are now agreed. "We would express our great satisfaction" (observed the writer) "that in such a work as the French Pharmacopœia one uniform system of weights and measures has been introduced, to the exclusion of every other—the metrical system, admitted to be at once the most simple, accurate, and complete that has ever been devised; one which has been in actual use for many years in a considerable part of Europe; which is rapidly extending and will become, before many years, the one recognised system in use throughout the world. . . . Nor must a fact be forgotten which the most casual acquaintance with the Continent will demonstrate, that the use of the decimal system brings the practice of computation within the reach of the humblest individual." An active life has led Mr. Carteighe astray from literature, but he has occasionally ventured upon authorship. In a letter addressed to the *Pharmaceutical Journal* in March, 1865, he informed his brethren that unless they carefully considered the nature of their fire insurances, complications might ensue, and they were warned not to distil ether unadvisedly. At the Exeter Conference Meeting in 1869 he read a paper on "Syrup of Iodide of Iron," and continued the same class of subject on March 25, 1871, when there appeared in the *Pharmaceutical Journal* a communication on "Syrup of Phosphate of Iron and other Syrups Containing Phosphoric Acid." Mention may also be made of a lecture on "The Diffusion and Occlusion of Gases," delivered before the Bristol Pharmaceutical Association in April, 1873, being a summary and explanation of Graham's researches in that department of physics.

When the Fifth International Pharmaceutical Congress was held in London, in 1881, Mr. Carteighe was the English Secretary, a

post which involved great personal work and proved no light task. So many details, both as regards the conduct of the deliberations and superintendence of the social arrangements, were sufficient to try the most determined energy. The Congress was a strange gathering of all manner of nationalities. The leading feature of its proceedings was the establishment of uniformity in the preparations of the various national pharmacopœias, of which a complete and permanent record was printed and published. The concluding banquet, when each delegate spoke in his own language, was a study curious in the extreme.

On numerous occasions Mr. Carteighe has been the recipient of appreciative tokens of recognition. In addition to the address presented at Liverpool and a complimentary dinner in his honour at Edinburgh in 1891, his portrait, painted by Mr. Foster, was presented to the Society in October, 1890, having previously been exhibited in the Royal Academy, and it now hangs in the Council room with those of other officers of the Society. Honorary membership of a number of societies has been conferred on Mr. Carteighe. He has been twice on the Council of the Chemical Society; in 1877 he was one of the Founders of the Institute of Chemistry, and in 1885 one of the signatories of its Charter; Vice-President, Censor, and Councillor until 1896; Visitor, for two periods of three years each, of the Royal Institution; Member of the Council of the Society of Arts, 1888-91, then Vice-President, 1890-96, and as such constituted a member of the Royal Commission to the Chicago Exhibition in 1893.

No trace of weakness mars the full enjoyment of his later years or has diminished his varied and remarkable activities. His strong vitality remains as fresh as ever; long may it contribute to advance the public interests and the social standing of the community with which the career of Mr. Carteighe has been so conspicuously identified.

RECENT WORK IN BOTANY.

FORMATION OF ALBUMINOIDS.—According to Dr. B. Jacobi, the synthesis of proteids in plants is effected in the leaves. Under otherwise normal conditions of growth this process may commence in the dark, a reaction taking place between the carbohydrates and nitric acid, ammonia, or amides. The extent to which this process can proceed in the dark depends on the amount of disposable carbohydrates. If these are present in large quantities, proteids are formed, but if the supply of these substances is small, the process is arrested in the dark at the production of amides. Light contributes only indirectly to the formation of proteids by increasing the supply of carbohydrates. The true source of energy, therefore, is in the carbohydrates.—*Biol. Centralblatt*, vol. xviii., p. 593.

POLYPOROID FORM OF MUSHROOM.—M. N. Patouillard describes (*Bull. Soc. Mycol. de France*, 1898, p. 46) a specimen of *Agaricus campestris* bearing, on the under side of the pileus, a polyporoid hymenium, closely resembling that of a *Polyporus* or *Boletus*. The basids and spores were normal in size and structure. He believes that many so-called species of the Polyporeæ are really polyporoid forms of Agaricineæ.

STREAMING OF PROTOPLASM.—Herr M. Heidenhain has made a series of observations on the streaming of protoplasm in the hairs on the flower of the common gourd, from which he concludes that the ordinary statement that solid particles are passively carried along in the currents is incorrect. The streaming of the granules is a phenomenon quite distinct from the local movement of masses of protoplasm, though the two kinds of motion may take place in the same cell. The movement of the granules may, however, take place equally when the protoplasm is at rest. *Sitzber. phys. med.-Gesell. Würzburg*, 1898, p. 116.

NOTES OF NOVELTIES.

The "Fram" Microscope.

A high-class microscope, the "Fram," which is admirably adapted for the purposes of the bacteriologist, student and amateur, has been recently introduced by Messrs. W. Watson and Sons, 313, High Holborn, W.C. It has been designed to yield at a very moderate cost the advantages that are usually associated with the most expensive instruments. It is exceedingly strong, solid, and rigid, while the working parts, being all skilfully fitted and finished by hand with the utmost care, yield the smoothest and most precise action.

FIG. I.—THE "FRAM" MICROSCOPE.

The foot is of the well-known tripod pattern, having a spread of seven inches, so that the instrument is absolutely steady at whatever working position the body may be inclined. It has Watson's diagonal rack and pinion coarse adjustment, which ensures an exquisitely smooth movement, and an entire absence of backlash. The fine adjustment is of the Watson noted lever pattern, as applied to all microscopes of their manufacture. One revolution of the milled head moves the body $\frac{1}{300}$ th of an inch, rendering it exquisitely exact for high power work. It is unexcelled for its accuracy of working and freedom from lateral motion, while it is not subject to depreciation in consequence of use, because all the dovetailed fittings of this movement and of all working parts in the microscope are provided with compensating screws working through spring slots, by means of which any slackness that may arise after an extended period of use can be at once remedied by the worker.

The stage is of the Nelson's horse-shoe shape, size $3\frac{3}{8}$ in. by $3\frac{3}{8}$ in. But if desired this may be of the usual pattern with central aperture. The fittings are of universal size throughout, so that objectives, condensers, and eye-pieces (0.92 in. diameter) by other makers can be employed. The body length is 152 m/metres, or with the draw-tube extended 250 m/metres. Objectives corrected for both the Continental and English tube-lengths can therefore be used. The fitting for under-stage apparatus is attached to a strongly-constructed collar, upon which it may be turned aside out of the optical axis (leaving the mirror free for use) and replaced as required. If desired, a compound sub-stage may be had instead of the under-fitting, or this can be adapted subsequently by the user, the fittings being interchangeable. The mirrors are both plane and concave, with sliding tube fitting for adjusting. The height of the instrument when placed vertically is 11 inches; to underside of stage, $3\frac{3}{4}$ inches. The Watson Parachromatic Series of objectives are used, which are constructed almost entirely of specially selected and durable Jena glass. Having a

FIG. II.—STAGE OF THE "FRAM" MICROSCOPE.

FIG. III.—DUST-PROOF TRIPLE NOSE-PIECE.

large ratio of aperture to their power they are specially suitable for biological and general work, their performance being brilliant, crisp, and free from colour, whilst they are so mounted as to be approximately in focus when revolved on a nose-piece. The eye-pieces have nickel-plated tubes, and are all arranged to work in the same focal plane, the initial magnifying power being engraved upon each eye-piece. The price of the microscope stand only, as figured, with one eye-piece (no objective) and mahogany case is £4 15s. With objectives of the Watson Parachromatic Series ($\frac{1}{6}$ th in. and 1 in., or $\frac{1}{2}$ or $\frac{2}{3}$ rd in.) eye-pieces (Nos. 2 and 3, or 4), the Abbé illuminator with iris diaphragm and carrier for coloured glass and darkground, etc., stops; in mahogany case £8 5s. If in addition it is fitted for bacteriological work with a $\frac{1}{2}$ th in. oil immersion objective 1.25 N.A., and Watson's dust-proof triple nose-piece for three objectives, as shown in the illustration, the price complete with case is £14 5s.

A New Concentrated Toning Bath.

Mr. J. E. Lockyer, 87, Evelyn Street, Deptford, S.E., has recently brought out a new specialty in toning baths. The composition is identical with "Lockyer's 1s. 6d. Concentrated Toning Solution," which has been in the market for some years. The bath (sulpho-cyanide of gold) is put up in 2-drachm bottles, this quantity requiring to be diluted with 10 oz. of water for use. The baths are neatly packed in small cartons, and sent out 1-dozen in box to retail at 4s. per doz. Each separate bath is priced $4\frac{1}{2}$ d., and should make a good selling line to introduce to beginners and junior photographers. The "Concentrated Toning Solution" mentioned was primarily introduced for the convenience of amateur photographers and others wishing to tone only a small number of prints at a time; it also obviates the necessity of weighing small quantities of gold and sulpho-cyanide of ammonium. It has been well spoken of by the photographic press.

A New Concentrated Toning Bath.

Aseptic Catheter Stand.

Messrs. Reynolds and Branson, Ltd., have specially designed an aseptic female catheter stand for use in female hospital wards. It consists of a heavy plate-glass slab with nicely rounded corners, having a $\frac{1}{2}$ inch frosted strip running along the whole length of it, upon which the patients' name may be easily written with a pencil. The ringed support for holding the six strong glass test tubes is made of metal thickly tinned, so that the whole apparatus is quite aseptic.

New Quarter Plate "Frena."

The "Frena" cameras of Messrs. R. and J. Beck, Ltd., of 68, Cornhill, E.C., are known to everyone who is interested in photography. Messrs. Beck have now introduced another of the series of $\frac{1}{4}$ -plate size at the price of £5 8s., and this price includes the forty celluloid films with which it is loaded. The new camera is equal to the others in design and workmanship, and practically it differs from the ordinary one for $\frac{1}{4}$ -plates in having a single achromatic lens fitted instead of a rapid rectilinear. This form of lens allows the price to be reduced, and the only disadvantage is that theoretically straight lines falling at the margins of the picture are represented as slightly curved. This distortion is, however, so slight that unless attention were drawn to it, it would escape notice. The definition given is equal to that of the more expensive lens, and there is naturally a gain rather than a loss of brilliancy of image. The new cameras are fitted with a patented form of brilliant view finder in which the prominent defect of the usual "brilliant" finder has been eliminated. With the latter there is some uncertainty as to the actual picture that the camera lens will record, on account of the fact that the view shown on the finder varies according to the position of the eye in viewing it, and unless the eye be exactly above the centre of the finder it will not represent exactly the amount of view included on the plate. In the present finder this defect is remedied, and the image is stationary and the same from whatever position it is viewed, and moreover, it is sunk in the case so that unpleasant reflections are avoided.

New Quarter Plate "Frena."

The "Frena" cameras of Messrs. R. and J. Beck, Ltd., of 68, Cornhill, E.C., are known to everyone who is interested in photography. Messrs. Beck have now introduced another of the series of $\frac{1}{4}$ -plate size at the price of £5 8s., and this price includes the forty celluloid films with which it is loaded. The new camera is equal to the others in design and workmanship, and practically it differs from the ordinary one for $\frac{1}{4}$ -plates in having a single achromatic lens fitted instead of a rapid rectilinear. This form of lens allows the price to be reduced, and the only disadvantage is that theoretically straight lines falling at the margins of the picture are represented as slightly curved. This distortion is, however, so slight that unless attention were drawn to it, it would escape notice. The definition given is equal to that of the more expensive lens, and there is naturally a gain rather than a loss of brilliancy of image. The new cameras are fitted with a patented form of brilliant view finder in which the prominent defect of the usual "brilliant" finder has been eliminated. With the latter there is some uncertainty as to the actual picture that the camera lens will record, on account of the fact that the view shown on the finder varies according to the position of the eye in viewing it, and unless the eye be exactly above the centre of the finder it will not represent exactly the amount of view included on the plate. In the present finder this defect is remedied, and the image is stationary and the same from whatever position it is viewed, and moreover, it is sunk in the case so that unpleasant reflections are avoided.

Bacteriological Lantern Slides.

We referred recently to an admirable work 'The Atlas of Bacteriology,' by Charles Slater, M.A., M.B., etc., and Edmund J. Spitta, L.R.C.P., M.R.C.S., and had occasion to praise the photo micrographs with which the volume is illustrated. Messrs. Newton and Co., of 3, Fleet Street, E.C., are now prepared to supply lantern slides printed direct from the original negatives made by Mr. Spitta for illustrating this work. The series consists of 111 slides. In pointing out that, for the purpose of the study of such a subject as this, a lantern slide shown by optical projection is far more valuable than a printed impression, however good, we must not be taken to depreciate the illustrations which appear in the book, which, as we have already acknowledged, are very fine.

The "English" Kinematograph.

An instrument of this kind is naturally extremely difficult to describe in detail, but a good idea of its general appearance may be obtained from the illustration. Some of the points

claimed for it are:—By the use of a substage condenser, which is fixed, and therefore gives no trouble to the manipulator, a much more brilliant illumination is obtained. The difficulty of adjusting the film so that the picture shall coincide with the mask is overcome by an eccentric movement, which allows adjustment to be made even while the film is running and without altering the position of the disc on the screen. The apparatus allows the film to be reversed without the introduction of a prism. It can be worked from either side, and the films are wound up automatically as they are used, and the spools are made large, so that several films may be joined together and run through without the delay of removing the exhibited

film and fitting and adjusting a fresh roll of film and a receiving spool. No one, so far, has made a perfect instrument, or perhaps we ought to say a perfect set of instruments, for the production and projection of kinematographs, but in this apparatus Messrs. Newton and Co., of Fleet Street, E.C., have certainly overcome some of the difficulties which had to be surmounted, and if we cannot say their results are absolutely perfect, we can at least say that they are well abreast of the times.

Table Resistance for Arc Lamp.

This is an adjustable resistance bobbin mounted on a slate bed, and in such a form that it can be placed on a table or anywhere else that may be convenient. The resistance is regulated by means of a brass contact maker, which slides up and down, and according to its position the resistance is increased or diminished, so that the amount of current supplied to the lamp is perfectly under control. Newton and Co., of 3, Fleet Street, E.C., are the makers. The price of the single bobbin, 2 ohms resistance, is £1 15s. For a greater resistance two or more are mounted together on the same base at proportionate price.

Newtonian "Universal" Science Lantern (Newton and Ive's Patent).

This lantern, which is also manufactured by Newton and Co., of 3, Fleet Street, E.C., is designed for the use of science lecturers. On reference to the illustration it will be seen that there are three fronts. These are mounted on a stage which slides horizontally across the condenser, thus allowing whichever is required for use to be brought into position in the simplest possible manner. The central front consists of a lantern objective of the usual kind, and is for showing lantern slides. The second front, that on the far side in the woodcut, consists of a microscope attachment fitted with a sub-stage condenser and a microscopical objective. That supplied with the apparatus is of low power, but higher powers can be used, and if required polarising prisms and other apparatus can be fitted. The third front is for spectroscopic work, and is fitted with a slit, direct vision spectroscope, and achromatic focussing lens, which enables a spectrum to be projected directly on to the screen

without the necessity of placing the lantern at an angle. By the side of the slit a comparison prism is fitted, and, by an ingenious arrangement provided, the beam from it is projected by means of the central objective on to the screen, thus allowing a direct image of any medium of which the absorption spectrum is being shown to be also shown by alternately uncapping the spectroscope and the lantern lens. The stage carrying the fronts can be removed, and, if necessary, the platform upon which it stands, leaving the space in front of the condenser clear for any purpose. The condenser is mounted on a hinge, and can be removed or put into position instantly. Either limelight or the electric arc can be used. We have no hesitation in saying that this is an admirably designed piece of apparatus, every detail seems to have been carefully thought out, and the workmanship is of very high class. The price of the lantern with the three fronts, etc., as illustrated and described, is £18.

Marion's New Quick-Print Paper.

This paper is put on the market by Messrs. Marion and Co., 22 and 23, Soho Square, W. It is not, as its title would suggest, a paper that will print out, but more of the nature of an extremely slow bromide paper. Its distinguishing feature is that it can be opened and handled by ordinary gas-light, or even by weak daylight, provided the latter be filtered through a yellow medium. Placed in a printing frame behind a negative of average density the exposure required by diffused daylight is from one to ten seconds, or, when printing by gas-light, two to three minutes when the negative is held about 4 inches from the gas flame. The developer recommended is either metol or amidol, and the operation of development may take place by gas-light; of course, not too close to the light. As it is not necessary to employ non-actinic light a dark room may be dispensed with, and all the operations carried on in an ordinary room. With a correct exposure the image appears a few seconds after the application of the developer, and development is completed in about sixteen seconds. Fixing and washing are conducted in the usual way. The paper is supplied in packets and in two grades—glossy and rough mat; 1s. being the price of thirty carte de visites, twenty-four quarter-plates, twenty 5 x 4's, sixteen cabinets, or twelve half-plates, other sizes in proportion.

The British Students' Microscope.

Messrs. R. and J. Beck, Ltd., of 68, Cornhill, E.C., having spent a large amount of capital in the most modern forms of labour-saving machinery, are now enabled to manufacture instruments for which there is a large demand at prices which would otherwise be impossible. The British Students' Microscope in its simplest form has for its stand a heavy tripod with a spread of six inches between each foot. It has a joint for inclination, and the form of the stand allows the tube to be brought into the horizontal position for photo-micrography, etc., without becoming unsteady. The coarse adjustment is a sliding tube, and a micrometer screw with milled head is provided for fine adjustment. The large square stage has a distance of $2\frac{1}{2}$ inches from centre of stage to limb, thus allowing a large culture plate to be examined. The understage is provided with a fitting of the full size, and is furnished with an iris diaphragm with a handle for enlarging or contracting. There is both a plane and a concave mirror. The price of this instrument, that is to say, the stand as described, with iris diaphragm, in mahogany case, but without eye-piece or object glasses is £2 11s. 6d. With an eye-piece, a $\frac{3}{8}$ rd-inch (14 Mm.), and a $\frac{1}{6}$ th-inch (4 Mm.) object glass, the price is £4 18s. 6d. In this simple form it is a very useful instrument. The addition of an Abbé condenser converts it into a very efficient microscope for bacteriological and other high-power work.

The second form, illustrated here, in addition to the micrometer screw fine adjustment, has a spiral rack and pinion for coarse adjustment. The draw tube is engraved in the Mm. scale for recording the exact amount of mechanical tube length in use. The tripod stage, stage fittings, and mirror, are the same as last described. The price is £3 12s. 6d., or £5 19s. 6d. with eye-piece and $\frac{3}{8}$ rd and $\frac{1}{6}$ th objectives. The third form differs from the second only in having a focussing and swinging substage arm to carry condenser or other apparatus. Price £4 7s. 6d., or £6 14s. 6d. with eye-piece and object glasses. The fourth form is an instrument which will efficiently do the work of the advanced student and the medical man. The various adjustments and fittings exactly correspond to those of the last-mentioned form, but, in addition, there is a rack and pinion focussing and screw centring substage. The requirements for the highest power work are here met, and the best condensers and highest power object glasses can be successfully manipulated.

Price for stand as described, in mahogany case, £5 12s. 6d. For use especially with these microscopes Messrs. Beck have designed a new cheap double nose-piece, somewhat smaller than the ordinary model but in every way as good, except that, not being provided with a loose collar, the entire nose-piece must be turned round to screw it on the microscope; with sliding adjustment microscopes this is no detriment, but with a rack and pinion adjustment it may

screw up into an inconvenient position unless specially fitted. No extra charge is made for fitting if ordered with the microscope. Price 9s. Messrs. Beck and Co. have also designed and introduced a new cheap form of Abbé condenser, especially suitable for the medical student. It has an aperture of N. A. 1.0. The iris diaphragm shown in the figure is that supplied with the microscopes we have described, and the condenser fits in a fitting provided for the purpose. Price 10s.

Baron Hubl's Developing Powder.

Messrs. Isenthal Potzler and Co., of 85, Mortimer Street, W., have submitted a sample bottle of a new developing powder for gelatin plates prepared from a formula of Baron Hubl, for which they are sole agents for the United Kingdom. The powder, when dissolved in water, forms a complete developer, and requires the addition of neither bromide nor alkali. It is claimed that the various constituents are presented in such a form that even in moist air there is hardly any reaction between them, and when kept dry in a well-corked bottle no change whatever takes place. Each bottle is supplied with a metal capsule which serves as a measure, so that no scales and weights are necessary. This is, of course, a great convenience, especially in travelling. The instructions for use are: For correctly exposed plates, dissolve 2 capsules of the powder in 100 C.c. of water; for extreme over-exposure use 1 capsule of the powder to 250 C.c. of water. The same solution may be used for a larger number of plates. This is not a very favourable time of year for experiments in developing, but having made up a quantity of developer according to instruction, we tried it first on an extremely rapid plate which had had barely sufficient exposure in a bad light and obtained a negative, which was very satisfactory under the circumstances. We do not think we should have obtained a better negative with any other developer with which we are acquainted. We next made a couple of lantern slides, using the same solution. These were admirably clear and of a pleasant colour. The solution was then left in the developing cup, uncovered, and freely exposed to the air for three days. At the expiration of this time the solution was found to be quite clear and hardly coloured. On using it to develop some plates we could not detect that any deterioration had taken place. It seems, therefore, in practice this would not be by any means an expensive developer, although the initial cost appears rather high. The price is 2s. a bottle.

Photographic Chemicals.

The tendency of modern photography is towards the employment of some of the newer reducing agents in the development of plates and paper and the abandonment of our old friends, pyroferrous oxalate, etc. The new developers are almost invariably the subject of patents, and are not obtainable except through their special agents, but we have no cause to complain that they are not obtainable in convenient forms to suit all classes among those who practise photography. Messrs. Fuerst Bros., of 17, Philpot Lane, E.C., have submitted a number of samples comprising some of the newer developers and various combinations, or rather mixtures in which they form part, and other chemicals. As ortol, the newest developing agent, seems to possess properties which unite the advantages of the older and the newer reducers of silver, we will mention that in addition to the simple substance, which is packed in 1, 4, 8, and 16-oz. bottles, we have ortol cartridges, each containing a definite quantity of the substance, tubes containing ortol

and metabisulphite of potass., each tube containing sufficient, when dissolved in water, to make 20 ozs. of stock solution, and soda cartridges similarly making 20 ozs. of the stock alkaline solution. We have also concentrated pyro solution and acetone solution for Lumière's acetone pyro developer. The acetone solution is also supplied alone in 16-oz. bottles. There are also toning and fixing cartridges, a convenient form for those who prefer toning and fixing in one operation. The cartridges are supplied in two sizes, to make 5 and 10 ozs. of solution respectively. We were glad to have the opportunity of experimenting with persulphate of ammonia as a reducer of over-density. The ordinary reducing methods have the disadvantage that they attack the half-tones more strongly than they do the high light, and when the negative already possesses too much contrast the result is that the contrast is increased rather than diminished. We found persulphate of ammonia to have the opposite effect; the solution distinctly reduces the high lights in greater proportion than the half-tones. This valuable property will no doubt bring the salt into common use in every photographer's laboratory.

The Pocket "Presto" Camera.

There seems to be a great demand just now for cameras of diminutive size and the apparatus manufacturers are not allowing the demand to exist without a corresponding supply. One of the neatest cameras of the kind is the "Presto" supplied by Messrs. Marion and Co., of 22 and 23, Soho Square, W. Its general appearance may be judged from the illustration. The whole of the camera is of metal, oxidised on the outside, and the mechanism consists of an exceedingly simple form of roll holder capable of carrying sufficient film for twenty-five exposures. The roll holder, however, can be removed and a "magazine" holding four glass plates substituted. The magazine is supplied with the camera.

The outside measurements are $3\frac{1}{4}$ by $2\frac{1}{8}$ by $1\frac{3}{8}$ inches, and the pictures made $1\frac{1}{4}$ by $1\frac{1}{4}$ inches. The shutter is both novel and ingenious. To set it the camera is held upside down and the button pressed. After turning the camera back to position, pressure on the same button releases the shutter and makes the exposure. By inclining the camera in the direction of the arrow indicating "time," the shutter adapts itself to time exposures. The price of the camera, fitted with a roll of film for twenty-five exposures and including a plate magazine, is 10s. Half-a-crown more will purchase a solid leather case with sling strap. Extra rolls of film for twenty-five exposures 1s. 6d.

CHEMICAL SOCIETY.

A meeting was held on Thursday, November 17, at 8 p.m., the PRESIDENT, Professor Dewar, in the chair. The attendance was fairly good, and the papers dealt with a variety of subjects. The first paper was by A. W. CROSSLEY, Ph.D., and H. R. LE SUEUR, B.Sc., on

The Determination of the Constituents of Fatty and other Organic Acids.

The process briefly consists in obtaining the free acid by hydrolysis from the mono-bromo derivative, and then treating with quinoline or diethylaniline. The product (an unsaturated acid) is oxidised first with potassium permanganate, which yields a dihydroxy acid, then with chromic acid, by which the molecule is split up at the double linkage, giving a fatty acid or ketone containing two carbon atoms less than the original acid. The process has been employed, with satisfactory results, in the case of valeric, iso-valeric, iso-butyl-acetic and other acids.—The PRESIDENT, who considered the method an ingenious one, hoped that the authors would carry their investigations further.—W. J. POPE read a paper on

A Crystalline Form of Iodoform.

The author pointed out that satisfactory crystals of iodoform cannot well be obtained from ether, alcohol, or benzene. He had, however, been able to produce large, well-developed crystals of this substance from acetone. He had studied the crystals so obtained in the hope of throwing light on a question which had in years often recurred to his mind, viz., "Is there any relation

cal composition?" His conclusion was that at present there is no foundation for pressing this theory beyond a certain point, owing especially to polymorphy.—There being no discussion, the PRESIDENT congratulated the author on his zeal in the study of that branch of chemical research, and requested him to read a paper by Dr. Kipping and himself on

Racemic Compounds.

The investigation dealt with the conditions under which certain salts crystallised in racemic forms. Thus a mixture of the dextro and lævo sodium ammonium tartrates, $\text{Na}\cdot\text{NH}_4\cdot\text{C}_4\text{H}_4\text{O}_6\cdot 4\text{H}_2\text{O}$, gave a racemic compound above 27°C , and the sodium potassium tartrates above 0°C .—This communication also provoked no discussion, and it was left to the PRESIDENT to testify to the value of such investigations to organic chemistry and to physical chemistry in its broadest sense.—The next paper was on

The Occurrence of Ortho-Hydroxy-Acetophenone in the Volatile Oil of *Chione Glabra*.

by WYNDHAM R. DUNSTAN, M.A., F.R.S., and T. A. HENRY.—Mr. DUNSTAN, who read the paper, remarked that the investigation was commenced on some of the bark of *Chione glabra* in the collection of the late Daniel Hanbury, which was possessed of a curious smell, partly aromatic and partly fetid. On distilling the small amount at his disposal he succeeded in isolating a minute quantity of ortho-hydroxy-acetophenone. *Chione glabra* is a large tree indigenous to Bonare, and has gained a reputation in Trinidad on account of its medicinal properties. The oil distils at 163°C , and by analysis seems to have the composition $\text{C}_8\text{H}_8\text{O}_2$. It dissolves in alkalis, forming salts. On fusion with an alkali it yields salicylic acid and phenol. The authors have applied to Mr. Thiselton Dyer, of Kew Gardens, for samples of other woods having the same smell, and have already examined many such samples. As a general rule the oil is more aromatic than the wood from which it is prepared. No reference was made in the paper to the work of Paul and Cownley, who actually discovered the presence of volatile oil in the bark of *Chione glabra* (see ante, p. 51).—In the discussion that followed, Dr. HARDEN asked whether, seeing that indole, scatole, and phenol are now generally considered to be decomposition products of proteids, ortho-hydroxy-acetophenone might not be produced in a similar manner. It was asked whether the trees possessing an unpleasant odour were normal or diseased.—In reply, Mr. DUNSTAN stated that undoubtedly the trees were normal; they bore large flowers yearly, having an aromatic and not at all a disagreeable odour. There were objections, from the botanist's point of view, to the idea that such bodies as indole resulted from the breaking down of proteid matter, seeing that they are present in the tree long before the proteids show signs of decomposition.—The PRESIDENT next asked Dr. Wynn, as Secretary, to read an abstract of a series of six papers by E. Divers, M.D., F.R.S., and, in the case of the first of the series, in conjunction with T. Haga, B.Sc., the authors being resident abroad.—The first gave a method for preparing "Hyponitrites from Nitrites through Oxy-amido-sulphonate." The yield is 60 per cent., and the operation is conducted at 60°C .—The second paper dealt with the "Absorption of Nitric Oxide in Gas Analysis." This method consists in absorbing the gas by concentrated sodium or potassium sulphite, with formation of a nitroso-sulphate. The titles of the other communications were as follows:—"The Interaction of Nitric Oxide with Silver Nitrate," "The Preparation of Pure Alkali Nitrites," "The Reduction of an Alkali Nitrite by an Alkali Metal," and "Hyponitrites: Their Preparation by Sodium or Potassium and their Properties."—These papers gave rise to an interesting discussion, in which Mr. DUNSTAN gave an account of a research on the nitrites published by Dymond and himself in 1884.—Mr. GROVES thought the author's method of preparing nitrites by passing nitrous gases (excepting NO_2) into potassium hydroxide or carbonate was not generally adopted on a commercial scale. It early was superseded by the fusion together of sodium nitrate and sodium sulphite, which method has itself given place to the lead process, by which sodium nitrate is treated with lead. He gave a ready method for preparing a solution of nitrous acid, viz., heat together arsenious oxide and nitric acid (sp. gr. 1.3) to 70°C . Pure N_2O_3 is evolved, and on passing into a mixture of ice and water gives a pure solution of nitrous acid.—The PRESIDENT expressed his satisfaction in receiving papers from members who had left the mother country, and considered it an example of genuine imperialism.—After the SECRETARY had read a paper by R. Meldola, F.R.S., on "Para-nitro Orthanisidine," the meeting was adjourned.

PHARMACEUTICAL SOCIETY.

EVENING MEETING IN EDINBURGH.

The first evening meeting of the present session was held in the Society's Hall, 36, York Place, Edinburgh, on Wednesday, November 23, Mr. J. LAIDLAW EWING in the chair. There was a very large attendance, and apologies were intimated from Professor Balfour and Messrs. Aitkin, Davidson, Seron, Nesbit, Paton, and Storrar.

The CHAIRMAN said Professor Stockman had honoured them by agreeing to give the opening address of the session. He required no introduction to a pharmaceutical audience in Edinburgh. To none did his recent appointment to the chair of materia medica in Glasgow University give greater satisfaction than to the pharmacists of Edinburgh. They had often been indebted to him, and they felt that their loss had been Glasgow's gain. He had great pleasure in calling on him to address them.

Professor STOCKMAN then proceeded to deliver his address on

Arrow Poisons,

which is printed at page 548. At the conclusion,

Professor GIBSON said he had listened, as all had done, with great interest to the address, and he had learned almost all he knew about arrow poisons that night. He moved that they accord to Professor Stockman a hearty vote of thanks.

Mr. BOA, in seconding, said they were greatly indebted to Professor Stockman for the interesting and very complete way in which he had treated the subject.

Dr. SILLARS, in supporting the motion, said the subject had a peculiar interest for him at present, because he was engaged in revising the proofs of the important research on some of these arrow poisons by Professor Fraser and Dr. Tillie. It seemed there were at least four different substances which went under the generic name of ouabain. With regard to the crystalline ouabain, it was hoped that it might become a very important therapeutic agent, and they proposed to call it "acokantherin." He was much interested in the description of the aborigines who used these poisons. They seemed highly trained in diabolical ingenuity, and had found out all the most powerful poisons, as well as in many cases the appropriate antidotes. In the case of snake venom, for instance, in regard to which Professor Fraser had discovered the antitoxic serum and the immunising influence of bile, it was found that these things were well known to some natives, and when a request was made for serpent livers and gall bladders they showed reluctance to supply them, and said we were beginning to know too much. One reason why those arrow poisons were sometimes inert was due to this reluctance to divulge secrets. Those men were not only medicine men, they might be called "patent" medicine men, and when poison was asked for they made up and palmed off on the purchaser a compound resembling in appearance the poison, but with the active constituents omitted. That was a difficulty they had always to guard against. He felt very grateful to Professor Stockman, and cordially supported the vote of thanks.

The CHAIRMAN having put the vote to the meeting, it was carried with acclamation, and Professor STOCKMAN briefly replied.

The CHAIRMAN next moved a vote of thanks to those who had sent specimens, especially Professor Balfour, who had sent a most interesting exhibit, and Mr. E. M. Holmes who had taken great pains with the specimens sent from the Society's Museum in Bloomsbury Square, London.

The ASSISTANT SECRETARY then directed attention to the books recently added to the Library, and on the motion of the CHAIRMAN, votes of thanks were awarded to the donors, and the meeting then closed.

"NATRI" AS A SOURCE OF SOLANINE.—The Chilian drug "natri," a mixture of *Solanum crispum*, *S. gayanum*, and *S. tomatillo*, contains, according to Kamdohr and Neger, a considerable amount of solanine, and not, as Vasques stated earlier, a new alkaloid, natrine or hueveline. "Natri" is richer in alkaloid than native solanaceous plants, and is, therefore, recommended as a commercial source of solanine.—*Pharm. Zeit.*, xliii., 563.

REVIEWS AND NOTICES OF BOOKS.

CLINICAL LECTURES ON DISEASES OF THE HEART AND AORTA. By GEORGE W. BALFOUR, M.D., LL.D., F.R.C.P. Edin., F.R.S. Edin. Third edition. Pp. xxiv. + 479. Price 12s. 6d. London: Adam and Charles Black, Soho Square, W. 1898.

It is twenty-two years since the first appearance of Dr. G. W. Balfour's now classical work on diseases of the heart and aorta, and the present edition, the third, has been revised and entirely rewritten by the author. The titles of the various chapters are retained, but a considerable amount of new matter has been incorporated so as to bring the work thoroughly up to date. The book is divided into seventeen chapters, each chapter representing a clinical lecture on some form of cardiac affection and containing one or more fully recorded illustrative cases. Great attention is paid to the recognition and interpretation of the physical signs of cardiac disease, the author evidently laying special stress on the importance of an accurate diagnosis. He is alive to the benefit of treatment both by rest and by exercise, but objects to any routine course in cardiac disease, and considers that "the neat little diagrams we so often see propounded as proofs of the diminution of a dilated heart after a bath are most delusive. The heart is so mobile an organ, and varies so incessantly in size that any attempt to define its degree of dilatation by percussion alone, auscultatory or otherwise, cannot but be entirely untrustworthy."

The chapter on Curable Mitral Regurgitation is a specially valuable one, and cheering both to physician and patient on the question of prognosis. Treatment is described shortly with each variety of disease, and there is a lecture on the therapeutics of cardiac disease. This will be found specially valuable, as the preparations, doses, and methods of administration of the various drugs are fully described. The author has his own methods, but based as these are on a prolonged experience and careful observation, they will no doubt prove in the future, as they have proved in the past, of extreme value to the practitioner. The results obtained may be slow, but they are sure. He mentions the case of a gentleman aged seventy-seven who presented all the signs of extreme cardiac debility. "After taking for four years ten minims of tincture of digitalis night and morning, he developed a firm forcible apex beat, and an excellent pulse, and he also ceased to alarm his friends by fainting. In short, instead of dying from a so-called fatty heart, as had been predicted, he lived to be over ninety years of age, and finally did not die from his heart at all, but from senile asthenia." We do not know whether to admire more the patience and perseverance of the physician or of the old gentleman.

There is a charm of style about Dr. Balfour's writing which makes the book pleasant reading, and even difficult subjects are handled in a manner which enables the reader to follow easily the argument. We heartily commend this work both to the student and the practitioner as one of the best works on the subject of heart disease in our language.

NEW SUGAR SUBSTITUTE.—Under the name of "sugarine," methylbenzene-sulphinide, which is stated to possess five hundred times the sweetening power of sucrose, has been patented in this country as a dietetic sweetening agent. It is obtained by saponifying toluol-cyano-sulphamide with caustic potash, and liberating the new product with sulphuric acid; the crystals which form are then purified by crystallisation from dimethylbenzene.—*Pharm. Zeit.*, xliii., 573.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, NOVEMBER 26, 1898.

NATURAL VERSUS ARTIFICIAL PERSONS.

As is well known to our readers, the break-down of the Pharmacy Act, 1868, eighteen years ago, was due to the fact that joint-stock companies and other corporate bodies were held by the House of Lords to be outside the scope of the first fifteen sections of the Act. But, judging from the reports of meetings that have recently been held, it is not at all clear to the minds of many registered chemists why that judgment was given. For example, at the meeting of the Nottingham and Notts Chemists' Association on October 26 last (see p. 468*a*), an idea seemed to prevail that joint-stock companies are outside the Act because the word "person" is used throughout the Statute instead of the plural "persons." But that is not so; if that had been the case Lord BROUGHAM'S Act—providing that in Acts of Parliament "the singular shall include the plural"—would have applied. Neither is it correct to imagine that, in law, the word "person" cannot include a corporation, for, in Act 7 and 8, Geo. IV., c. 28, it is definitely provided that, in any statute relating to an offence punishable upon indictment or summary conviction, the word "person" shall include bodies corporate. A similar provision is found in the Interpretation Act, 1891. But offences under Section 15 of the Pharmacy Act are not punishable upon indictment or on summary conviction; the penalties must be sued for by civil process. Offences under Section 17 are punishable upon indictment or on summary conviction, and companies are undoubtedly amenable to the provisions of that section. But though such bodies can be sued by civil process in other instances they cannot be so sued by the Pharmaceutical Society for any of the offences created by Sections 1 and 15 of the Pharmacy Act, 1868, the reason being that a corporation—or artificial person—has been held not to be a person within the meaning of those sections.

The idea that prevailed most with the judges in the House of Lords was that the object of including corporations within the scope of the measure was not avowed on the face of the Act. Lord BLACKBURN said he had no doubt the word "person" might very well include both a natural person—a human being, and an artificial person—a corporation. Moreover, he expressed the view that unless there be something to the contrary in an Act of Parliament, the word ought probably to be held to include both. He did not think, however, that the Legislature thought of bodies corporate at all when considering the Pharmacy Bill, and he held that—inasmuch as a corporation could not possess the competent practical knowledge of the business of a chemist and druggist

mentioned in the preamble to the Act, or be examined—there is reason for the inference that only natural persons are referred to in Sections 1 and 15. Whether those who promoted the Act had any idea of preventing unqualified persons from benefiting by the profits to be derived from selling, dispensing, or compounding poisons, Lord BLACKBURN said he could not tell, but they certainly had not brought that intention forward, or put it in such words as would at all lead the Legislature to think of it. He also thought that it was exceedingly improbable, if the promoters of the Act had boldly said "bodies corporate and joint-stock companies shall not deal in poisonous drugs," that the Legislature would have agreed to the measure in those terms. But that was pure assumption on Lord BLACKBURN'S part, though his suggestion that the Legislature was not thinking at all of bodies corporate when the Bill was being considered was most probably correct, but for a reason that does not appear to have occurred to the learned judge.

When the Bill was under consideration, and for long after it became law, no incorporation of unqualified persons was known to carry on the business of a chemist and druggist; considering, then, that the Houses of Parliament are not in the habit of legislating for conditions that do not exist or appear likely to come into existence, it would have been somewhat surprising if bodies corporate had been mentioned in the Act. Undoubtedly, companies were not thought of at all in connection with the measure and, as argued before the House of Lords in July, 1880, this particular case of a corporation was a *casus omissus*. In acquiescing with that argument, the judges were very largely guided to their decision by the reflection that, inasmuch as the actual seller of poisons must in any case be a person duly qualified under the Act, no harm could accrue to the public, in the case of a joint-stock drug store, from the fact that its proprietors were unqualified persons. But, if that be a correct view of the matter, there would be equal reason for raising the question—What harm could arise if the "open shop for retailing, dispensing, or compounding poisons" belonged to a firm of unqualified persons, or even to a single unqualified person, so long as a duly qualified person was in charge? Yet the Legislature has definitely provided that individuals keeping open shop for the sale, etc., of poisons, as well as the members of firms, must be duly qualified, even though they employ qualified assistants. Where, then, is the logic of that provision? Why should proprietary qualification be insisted upon in one case and not in another? It cannot be because duly qualified proprietors are allowed to delegate their duties to unqualified persons, for the judges, in the House of Lords case referred to, were unanimously of opinion that the actual seller must, in all cases, be a duly qualified person. Accepting the view that the lack of reference to corporations in the 1868 Act was an omission, the logical conclusion to be arrived at is that it was an error, and one leading to results so inconsistent with the admitted object of the Act, that it should have been remedied by the Legislature as speedily as possible. It is, of course, unfortunate that chemists have not resolved upon seeking a remedy earlier; but at no time within the past eighteen years has the Pharmaceutical Society been sufficiently strong to move in the matter with any prospect of success. Whether the requisite strength and agreement will now be forthcoming remains to be seen; but it will certainly be impossible to proceed far, if at all, without those conditions.

WORK FOR LOCAL PHARMACEUTICAL ASSOCIATIONS.

THE local pharmaceutical associations of this country are to-day faced with two important tasks—first, the taking of such steps as may best serve to bring within the Pharmaceutical Society the chemists and druggists now outside the ranks; and, second, the holding of trade conferences in their respective districts with a view to devising the best possible means of securing satisfactory regulation of the exercise of their business. The Pharmaceutical Society offers the only available nucleus for complete organisation, and it must of necessity take the lead in any attempt to amend the existing pharmacy and poison law. But, for its attempts to be effective, its leaders must be in a position to say that they represent the great bulk of the trade. The Society cannot reasonably approach Parliament with a comprehensive scheme for regulating the practice of pharmacy and remedying all the defects in the Pharmacy Acts, until it comprises at least twice as many registered chemists as belong to it at present. That position attained, the drafting of a satisfactory Pharmacy Acts Amendment Bill need not be long deferred.

An ideal Bill would contain a clause making the word "person," wherever it occurs in the Pharmacy Acts, include a corporation, and no unqualified persons acting as trustees to a deceased chemist would be permitted to carry on the business of a chemist and druggist in perpetuity. It would also provide that registration as a student must precede entrance for the qualifying examination by at least three years, and that a definite term of pupilage should be spent with a registered chemist actually conducting a pharmacy on his own account. Attendance at certain courses of lectures and laboratory instruction would also be made compulsory in the case of all persons seeking qualification as chemists and druggists. Provisions would be made to extend the list of scheduled poisons sold for medicinal purposes, and to enable the Pharmaceutical Council to strike off the Register of Chemists and Druggists the names of any individuals proved guilty of "covering" unqualified persons, or other conduct "infamous" in a professional sense. Then the dispensing and compounding of medicine and the sale of pharmaceutical preparations would naturally, as suggested by Mr. WALTER HILLS, be restricted to duly qualified persons, and other useful provisions would be included in an ideal Bill, with the two-fold object of establishing the practice of pharmacy on a right basis, and so providing for the public safety in the matters of dispensing or compounding and retailing medicines.

Such an ideal Bill, though pleasant to contemplate, may never be wholly realised in Great Britain. But some of its provisions—especially those relating to interpretation of the meaning of the word "person," the registration of students, a curriculum of study, and the prevention of "covering"—may with advantage be recommended to the thoughtful consideration of all registered chemists. A Bill containing those clauses, at least, should prove fairly popular in the trade; but it would require strenuous efforts to carry it through Parliament, such efforts indeed as the most zealous support of the entire trade would be required to justify. A favourable opportunity now presents itself and it remains for the registered chemists of Great Britain to take advantage of that opportunity. Will they do so or not? The local associations must reply.

ANNOTATIONS.

THE PHARMACEUTICAL PROBLEMS recently referred to in the Journal are evidently occupying a prominent position in the minds of many registered chemists in all parts of the country, judging from the numerous applications received for copies of the article reprinted from our issue of November 12. The whole of the copies printed had been disposed of by Saturday last, but as applications continue to arrive a further supply has been prepared, including, as additions, the article entitled "The Chief Problem for Chemists," printed in last week's Journal, together with the recommendations for the keeping, dispensing, and selling of poisons, adopted at a general meeting of the Pharmaceutical Society on May 17, 1871, and reprinted in the *Pharmaceutical Journal* for July 2 last. A reasonable number of copies of this reprint will be supplied gratis to any local secretary or other member of the Society who will undertake to distribute them among registered chemists not at present connected with the Society. There is obviously not the same necessity to distribute copies to persons already in touch with the Society and receiving the Journal regularly, as they can refer to recent back numbers—those for July 2, November 12 and 19—for the whole of the matter now reprinted.

THE CLEAN SWEEPING of the Society's Council Chamber—suggested by a correspondent in this week's Journal—is sufficiently heroic to create a suspicion that the proverb relating to new brooms might be applicable in that case. We cannot say that it is so, but since there is some reason for believing that the view expressed may be entertained in other quarters, it may not be inappropriate to point out that, before the task of selecting men capable of effecting the objects specified by our correspondent, a preliminary proceeding would be desirable and even necessary, viz., that of ascertaining how many among the number qualified to undertake the onerous task of carrying on the business of the Society and the administrative work connected with the Pharmacy Act, may be willing to give their time and attention to the performance of those duties. Another point to which attention may be directed, is the mention of the Society as though it were merely an official metropolitan establishment and not really an organisation of members spread over the entire kingdom. This is a common mistake, but it is one which should be displaced by a more correct appreciation of the real nature of the Pharmaceutical Society.

THE NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION appears to be in a condition of exceptional activity at the present time and the good work of organising chemists and druggists is proceeding apace in various busy towns in the district included within the Association's sphere of influence. The report of the Committee, published last week (p. 534a), was a somewhat remarkable one, and if the chemists of North-East Lancashire can manage to keep up to the concert pitch which they have now attained, much good to the craft ought to result. One not unimportant feature of the Lancashire meetings is that chemists in different towns exchange visits, and thus do much to widen their ideas and secure unanimity of action within a wider area. There is one thing, however, which the North-East Lancashire Association omitted to do at the meeting—that is to indicate on what lines the proposed Pharmacy Acts Amendment Bill should be drafted. The President and Council of the Pharmaceutical Society await the views of the trade on that point, as well as some indication of what measure of support they may look for in promoting fresh legislation. It is

not enough to wait for the Pharmaceutical Council to draft a Bill, and then "promptly back it up or veto it as it deserved," but possibly at the next meeting of the Association the deficiency referred to will be remedied.

THE NORTH STAFFORDSHIRE ASSOCIATION is to be congratulated upon the excellent speech in which Mr. Edmund Jones supported his proposition that the Association should strongly recommend all registered chemists, not at present connected with the Pharmaceutical Society, to join at once and so increase the ability to promote legislation for the good of pharmacy. Mr. Jones pointed out, as clearly as ever has been done, the one obvious remedy for the grievances under which registered chemists now suffer, and he showed how much greater the chances of success would be in approaching Parliament or Government Departments upon matters of special interest to the craft, if the membership of the Society were double or treble what it now is. Increased parliamentary powers, as Mr. Jones indicated, can only be obtained by a larger membership, and now that every registered chemist can enter the Society on an equal footing with other members, there should be no hesitation in deciding to join what is, after all, the only national body that makes for progress in pharmacy.

ANOTHER NOTEWORTHY SPEECH was that delivered at Liverpool on the 17th inst. by Mr. R. C. Cowley, Secretary of the Federation of Local Pharmaceutical Associations. The pharmacist of the present day, he pointed out, starts life under much more advantageous circumstances than his predecessors, and he will not have done his duty if he does not assist in further elevating the calling to which he belongs, emulating his predecessors in the attempt to leave his profession in a better position than he found it. The "policy of drift," as exemplified in the career of so many individuals, was severely criticised. Thus, allusion was made to the folly of young men who "have entered the calling, passed their examination, and have become old men, often before their time, without ever attempting to inquire whether they themselves could do more than lift the spoon to their own mouths." In an attempt to answer the question why pharmacy should have fallen into the condition it has, Mr. Cowley referred to the fact that we are accustomed to hear of the lack of energy on the part of the body "which, to a certain extent, presides over our own destinies, and which should by right play the part expected of Hercules by the woman in the title." Some critics, he pointed out, have made a strong point of want of suitable pharmaceutical education, as tending to produce the effect complained of, and others suggest various defects in our system, but the great necessity of the time is that "the parent Society must be fortified by a majority of the chemists throughout the country."

MYRRH AND BDELLIUM are exhaustively dealt with in a monograph by Mr. E. M. Holmes, the first instalment of which appears in the present issue of the Journal. The intention of the author is to supply a comprehensive summary of what is known on the subject, in the hope that it may interest travellers visiting the myrrh districts, and assist them in securing such fresh information as may throw light on many obscure problems. Myrrh as imported into this country, it may be pointed out, consists of a mixture of true myrrh with several other gum-resins obtained from trees of the same genus. Those impurities are picked out when the myrrh arrives in England, "gum myrrh elect" being free from them. The chief foreign gum-resins so found in myrrh are opaque bdellium, African and Indian bdelliums, and "bissabol," known in commerce as "opoponax," and used in the production of oil of opoponax. Bissabol also goes to China, and is the kind of

"myrrh" usually found in that country. Bdellium, especially the African and Indian varieties, is sometimes in demand among varnish makers.

THERE WAS A LARGE GATHERING at Somerset House on Tuesday afternoon last, when Mr. Richard Bannister was the recipient at the hands of Dr. Thorpe, the Chief Chemist to the Inland Revenue Department, of a handsome testimonial, subscribed for by numerous friends, on his retirement from the position of Deputy Superintendent of the Laboratory at Somerset House. Dr. Thorpe, in making the presentation, gave a résumé of the distinguished career of Mr. Bannister in his official position at Somerset House during the last forty years, not only referring to his championship for the removal of official grievances, but to his efficient control of an important State Department. Mr. Bannister, in returning thanks for the honour done to him, sketched out the important changes that have taken place in the duties of the Somerset House Laboratory since he entered the Laboratory under Mr. George Phillips, who was then Superintendent. The enormous amount of scientific and analytical work now required in the Laboratory, not only in connection with the Excise but with other State departments, has been added to by official references under the Foods and Drugs Act. Referring to the last matter, Mr. Bannister showed how his anxiety had always been, like blind Justice, to hold the scales righteously between advocates who would prejudicially strain analytical results, on the one hand, and the honest trader on the other hand. Amongst those present were Dr. Thorpe, Dr. Jas. Bell, Dr. Paul, Mr. George Lewin, and the heads of several departments. Mr. Bannister on his retirement deserves the thanks of scientific men, chemists in particular, who have always received at his hand courteous assistance on any point with which, from his great experience, he was familiar, and of public analysts generally, in guiding them and restraining them in many difficult cases of reference under the Food and Drugs Act.

DR. STOCKMAN'S ADDRESS to the North British Branch of the Pharmaceutical Society (see p. 548), deals with a subject of peculiar interest, but as it is being reproduced at length in the Journal there is no need to refer to it in detail here. It may be pointed out, however, that the address was illustrated by specimens from the Society's Museum in London, from Dr. George Smith, C.I.E., Foreign Missions Secretary, Free Church of Scotland, from Dr. Woodhead, Dr. Felkin, and the lecturer. In addition, living plants of *Strophanthus*, *Acokanthera*, *Strychnos*, *Antiaris*, *Tanghinia*, and *Erythrophloeum*, were kindly sent by Professor Isaac Bayley Balfour, Regius Keeper of the Edinburgh Botanic Garden.

THE GENERAL MEDICAL COUNCIL met this week, and the President—Sir William Turner—in his opening address, said that since the previous meeting, he had been in communication with the Lord President of the Council with regard to the practicability of obtaining such an amendment of the law as would effectually prevent the holder of a medical diploma or degree from using the title thereof after his name had been erased from the Medical Register, for so long as the erasure continued in force. Certain clauses have been drafted, in regard to this matter, and may be embodied in a Bill. Meanwhile, however, it becomes necessary to ascertain if the universities would offer any opposition to amendment of the Medical Act, 1858, in the direction indicated. It was also explained by Sir William Turner that the committee appointed to take steps to induce the Government to insert a clause in the Companies Act Amendment Bill, with the object of preventing the registration of companies to carry on medical, surgical, and

dental practices, had again met and arranged that suitable clauses should be drafted and placed in the hands of the Lord Chancellor. That had accordingly been done. It is much to be desired that the registration of companies to carry on the business of a chemist and druggist might be prevented in a similar manner to that proposed by the medical authorities.

THAT THE BRITISH PHARMACOPEIA, 1898, is not absolutely free from error is well known, and it is doubtful whether the official list of corrections, just published, includes all the inaccuracies that exist in the book. Limited, however, as they are in number, the official "Corrigenda" are here placed on record, in order that readers of the Journal may mark their copies of the new Pharmacopœia accordingly:—

Page 237, line 31, for 0·0235 read 0·0233.

Page 266, line 3, omit chlorides.

Page 462, fourth col., line 6, for 1 grm. read 0·5 grm.

Page 495, third col., line 12, for 5 to 10 m. read 2 to 8 m.

Page 511, first col., line 35, insert Compound after Tincture of.

Page 519, first col., line 25, for Spirit Compositus read — — Compositus (=Spiritus Ætheris Compositus).

We are informed that, as the 20,000 copies of the British Pharmacopœia, originally printed, have already passed into circulation, a reprint has been ordered, and the opportunity has been taken to indicate the above few manifest errors and misprints. Anyone desiring to possess a copy of the corrigenda slip may obtain one on application to the publishers of the Pharmacopœia—Messrs. Spottiswoode and Co., 54, Gracechurch Street, London.

PRESENTATION TO THE SOCIETY'S LIBRARY.—We are requested to note that Professor Dr. August E. Vogl has presented to the Library of the Pharmaceutical Society a copy of his work, 'Nahrungs- und Genussmittel.' The distinguished donor is K. K. Hofrath und Universitäts Professor and Präsident des Obersten Sanitäts Rathes. He was elected Hanbury Medallist in 1895, and is an honorary member of the Pharmaceutical Society.

A UNIVERSITY FOR BIRMINGHAM is Mr. Joseph Chamberlain's latest idea. He has suggested that the well-known Mason College should be absorbed in a new University, and at a meeting held at Birmingham on Friday last a resolution was adopted authorising the Council of the College to take the necessary measures to obtain a Royal Charter for a great academic institution in the Midlands, to be called the University of Birmingham. Provincial colleges and universities, which are fast becoming a common feature in the educational life of the country, discharge a valuable function, such as the older seats of learning at Oxford and Cambridge cannot fulfil. But Mr. Chamberlain's design for the Birmingham University, as the *Daily Telegraph* remarks, does not run on merely familiar lines. Whilst there is to be room for all the more ancient disciplines, a great trading centre requires novel features in addition. Naturally, science, in all its branches, is to be encouraged, and a school of medicine is to be organised with thorough-going completeness. Apart, however, from this, commerce, for the first time on record, is to take its place as a distinct faculty, with an equipment of professors and lecturers and special schools of instruction. There is to be systematic instruction in all the theoretical and practical aspects of that great industrial expansion of which Great Britain has been in the past the conspicuous example. Modern languages are to be studied in accordance with definite principles and a clearly-recognised aim, and lectures are to be given in commercial geography, in commercial law, in commercial economy, and other kindred subjects, so that the whole province

of industry may be surveyed by precise and scientific methods. The provisional scheme shows that, in addition to the endowment of Mason College, a further endowment of about a quarter of a million pounds will be required, but subscriptions already promised amount to about half that sum.

THE 'YEAR-BOOK OF PHARMACY' FOR 1898 is now published, and appears altogether in a more healthy condition than its immediate predecessor, including as it does forty-four pages more than the volume for 1897. The introduction is briefer than usual, but that is no loss, for it is doubtful if many persons ever trouble to read that portion of the book. The abstracts are as good as ever, and practically as numerous as formerly; the notes and formulæ are up to the usual standard, and the proceedings of the Conference at the Belfast meeting are reported in full. The general verdict will certainly be that the 'Year-Book' is now steadily improving again, and that the latest addition to the series of handy green volumes is in nowise inferior to any of its predecessors.

THE RÖNTGEN SOCIETY appears to have scored a distinct success with the conversazione held in St. Martin's Town Hall on Monday last. The President of the Society and Mrs. C. Mansell-Mouillon received the members and their friends, among those present being Admiral Sir John Dalrymple Hay, the Hon. Sydney Holland, Sir William Crookes, F.R.S., Mr. W. H. Preece, C.B., Sir J. N. Dick, Sir Gervase Glyn, Sir Thomas Smith, Professor Gladstone, F.R.S., Major-General Jameson, Mr. Justice and Lady North, Mr. John Aird, M.P., and Sir F. and Lady Carden. All the latest improvements in the apparatus concerned in the production of the mysterious X rays were on view, as well as some of the most successful of recent radiographs, indicating the extent of injury to bones or presence of foreign substances. Professor Gladstone showed an apparatus for testing the grade of rays; and although not exhibited for the first time, much interest was manifested in the experiments conducted [by] Professor Sylvanus Thompson with the Tesla Oscillator, by which luminous phenomena are produced in vacuum tubes placed within the scope of its electrically-charged field. Among other demonstrators and exhibitors were Messrs. Watson and Sons, Mr. Dean, Mr. Apps, Mr. Watson Baker, Mr. Conrad Cooke, Mr. Cossor, Professor Gladstone, Dr. Maw, Dr. Schwind, and Mr. Wimshurst. Among the radiographs were several of the human body, sent from Munich by the Voltohm Society. Mr. E. Payne, of Brighton, showed the results of an examination of rheumatoid arthritis, in which the bone, which ought to have been black when in a healthy state, came out in the radiograph as white. Mr. Swinton's radiographs were taken with a pinhole Röntgen Ray camera, and a series of radiographs of hands was shown by Mr. Griffith Wilkins to illustrate the application of the X rays to the identification of criminals.

PHARMACY ACT CASE.—In the case of the Pharmaceutical Society of Great Britain v. Hogben, which came before the Registrar at the Westminster County Court, on November 24, the plaintiffs sued the defendant, Howard Hogben, of the Palace Drug Company, 8, Bridge Street, Westminster, for three penalties of £5 each, for having sold poisons, contrary to the provisions of Section 15 of the Pharmacy Act, 1868. Upon the case being called it transpired that defendant had confessed judgment for the penalties claimed, and had made an offer to pay by small instalments. Mr. Flux, on behalf of the Society, stated that the offer could not be accepted, and an order was made for the payment of the full amount with costs within three months.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of this Association held at 73, Newman Street, W., on Thursday, November 17, Mr. F. W. GAMBLE, President, took the chair. There was a good attendance. In the absence of the Hon. Secretary the minutes of the previous meeting were read by Mr. J. FOTHERGILL and were confirmed. The President then called upon Mr. T. Morley Taylor to read a paper written by Mr. W. ANDERSON on

Advertising.

The author commenced by observing that the word advertisement—from the French *advertissement*, a giving notice or announcement—denotes in a general sense any information publicly communicated through the press or otherwise. The first known to have been published in a newspaper occurred in the 'Mercurius Elenticus' of October, 1648, while it was reported that posters made of vellum and painted in various colours have been found in the mummy cases of Egypt dating as far back as 3800 B.C. In England, previous to 1853 they were subject to duty at so much per advertisement. He did not propose to go further into the history of advertisements, although it in itself would form the basis of a very interesting paper. In pharmacy there are two classes of advertisers, (1) one whose business is largely dispensing and high-class retail and (2) the other who supplies the multitude. The best advertisement of the former was said to be the class of people who trade with him. The second class, however, which comprises the great bulk of the trade, has a great opportunity for using advertisements, inasmuch as his business consists largely in distributing proprietaries, with a varying amount of dispensing. There are, said the author, few chemists of this class but have some proprietary article or articles upon which they pin their faith. It was that article or series of articles he wished to consider. He then proceeded to show that they should be articles in daily demand, neatly and attractively got up, and that the advertiser must not be disheartened if the sales at first did not come up to expectation. The preparation of the advertisement was discussed, and the would-be advertiser was told never to despise a suggestion, no matter from what source, as a chance phrase very often proved a most attractive headline, and it must be remembered that the first point of an advertisement was to attract attention. The use of bold type, borders, illustrations, photographs, etc., was referred to, and the importance of giving reasons why such and such an article should be purchased, showing, if possible, why it is better than others of the same nature in the market. The language of an advertisement should be convincing, not flowery, plain, not ambiguous, and the whole sense of it should be directed straight to the point, and not devoted to generalities. The use of testimonials was referred to as a strong point in connection with convincing arguments. Another point was that the price should always be stated, as the omission stops all purchasers through the post, while of course the address should in all cases be given. A list of "What not to do" was then given, and the advantage of booklets as a paying investment when well got up and distributed was mentioned. In regard to newspapers, the best medium was said to be the one with the largest circulation among the class it was desired to reach. But wherever an advertisement was placed, it was of the greatest importance to ensure that it stands out well. Amongst the various methods of advertising quoted as helping to bring good results, the first place was given to neat and effective window dressing with frequent change; then a plain price put on goods where it can easily be seen. That attention to customers pays was illustrated by the words of an American specialist, who said: "Remember that the tongue of a well-pleased matron is always a good advertising medium." A neat and clean shop was the last-mentioned method of effective advertising. The author then concluded by quoting a number of amusing advertisements, mostly from America, which he said must be taken *cum grano salis*.—The PRESIDENT said Mr. Anderson's paper had been not only instructing but extremely amusing. Personally he was not an authority on advertising, so he should leave it to several gentlemen present, whom he believed did know something about it, to adequately discuss the paper.—Mr. JAMES felt that he was not competent to criticise the paper, but he thought several points in advertising had been missed by the author. In his opinion, the distribution of free samples, although very expensive, was a method which paid. Then in advertising in magazines, such as the

Strand, he believed that an advertisement placed in the centre of the advertisement pages was of little use; to be effective it should be either near the text or the cover. The advantage of catch lines and testimonials from public personages of repute and good standing were other points worth noting. With regard to manufacturers and wholesale dealers in pharmaceutical preparations, he thought it was of no use to advertise unless they got the co-operation of chemists by offering a good profit and by a certain amount of supplementary work.—Mr. G. PEARSON suggested that as advertising has become such an art that it is almost expert work, it was next to impossible for them to advance views on the matter. Still, if he were a retailer, he thought he should try to create a style of his own, and he was of opinion that at the present time there is a good opening for chemists to push really good quality toilet preparations, as he believed the trade in such articles is largely in the hands of French chemists.—Mr. BURRELL pointed out that the author of the paper had not dealt with counter advertisements, such as handbills.—Mr. CURRY was inclined to think that advertising in newspapers and magazines is of secondary importance, and that the future of advertising lies in some more unique and novel method than has hitherto been adopted. Free samples, illustrated books, etc., are, in his opinion, good methods.—Mr. GEORGE ROE seemed to think that advertising has been a curse to pharmacy in the past, and he regretted that now-a-days it is almost a necessity for chemists to advertise, for no body of men, he said, have suffered more from advertising than chemists. He referred, of course, to proprietary articles and so-called patent medicines. He found no fault, however, with chemists bringing their own toilet preparations before the public.—Mr. FULLERTON found himself perfectly in accord with Mr. Roe with regard to the injury done to chemists by advertisements of proprietary articles. He did not think, however, that legitimate advertising is undignifying and derogatory to chemists, but he was of opinion that many of the advertisements of the present time are simply endeavours to trade upon the gullibility of human nature.—The PRESIDENT strongly condemned misrepresentation in advertising. He approvingly referred to that style of advertisement posters which were at one time used asking, "Who's So-and-so?" and the subsequent reply. He expressed his regret that the author of the paper, Mr. Anderson, had not been present to hear the whole of the discussion, but as he was now in the room he would ask him to reply to such points as he had heard raised.—Mr. ANDERSON having replied, a vote of thanks was accorded by acclamation, and the meeting terminated.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held on Thursday night the 17th inst. at the White Bull Hotel, Blackburn.—Mr. COUNCILLOR CRITCHLEY presided, and there was a very good attendance.—The TREASURER (Mr. Howarth) reported that there was a balance in hand of £6 10s. 8d. against £7 8s. 0d. last year, but they had had a very busy and expensive year, in which good work had been done. He proposed the adoption of the balance sheet.—Mr. GRIMSHAW seconded, and the motion was agreed to.

THE WORK OF ORGANISATION.

The HON. SECRETARY (Mr. Gifford) reported that Mr. Williamson, Secretary of the Preston Association, had written, stating that, although he could not get any Preston members to that meeting he would try to secure a meeting of Preston chemists on December 1, if he (the Secretary) would go over with a few members of the Blackburn Association and lay their views before them. He tendered his fullest sympathy to the Blackburn Association in its endeavours to unite the trade. Mr. J. Rymer Young, of Warrington (one of the Lancashire members of the Pharmaceutical Council) wrote that he would try to conform to the wishes of the Committee and give them an address during the winter, but not before Christmas.—The CHAIRMAN stated that on the previous Thursday Mr. Gifford and he visited Accrington and Burnley, having previously asked the chemists of those towns to meet them, so that an interchange of views might take place on the question of professional combination. At Accrington, Mr. Furness had called a meeting of all the chemists in the town, and they were all present except three, and things went so well that the same night they resolved to form an association, and only the night before they had held their inaugural meeting. The chemists in Accring-

ton had previously been almost fit to cut each other's throats, but at last Thursday's meeting they got the principal cutter of the town in the chair, and he was quite agreeable to conform to their wishes. At Burnley Mr. Brown had got together about twenty chemists from all over the district, and the meeting was most enthusiastic, a resolution being passed in favour of forming a local association before the deputation left. That alone was very good work for the Association, independent of all the other good work done throughout the year. During the last few months their Secretary had been pushing things ahead and the prospect was much more favourable.

PHARMACY ACT AMENDMENT.

Mr. GIFFORD read the annual report of the Committee, which was published in these columns last week.—Mr. GRIMSHAW proposed a vote of thanks to the Committee for their excellent report, which was seconded by Mr. HARRISON.—Mr. GARLAND, referring to the report, said that if Mr. Gifford would try to draft an amended Pharmacy Bill he would find it a difficult task. He would have to encounter the opposition of all such places as the Army and Navy Stores, and the big firms, whether Liberals or Tories were in power.—Mr. HOWARTH said he thought Mr. Garland wanted to give the Committee a hard job. As to drafting a Pharmacy Bill, he quite agreed with the Secretary that it was not work for them. If the Pharmaceutical Council would do its duty and draft a Bill, they would promptly back it up or veto it as it deserved.—Mr. GARLAND thought the times were hardly ripe for such a Bill.—Mr. HOWARTH: Have you read the leader in this week's Journal.—Mr. GARLAND: No.—Mr. HOWARTH: Then do so, and tell me if you ever knew the *Pharmaceutical Journal* so well express the views of country chemists before. Burnley is going to affiliate with us, Accrington may do the same, and when we have Blackburn, Preston, Darwen, Accrington, and Burnley all united together, we shall be able to speak with no low voice.—Mr. GARLAND: I quite agree with action on those lines.—Mr. HOWARTH: As to our drafting a Bill and expecting the Council to follow us, I do not think it will. The new Committee, however, may follow your advice, but for myself I have had three or four years' service on the Committee, and I decline.—Mr. GIFFORD said he might remark, as an illustration of the work of the Committee during the year, which was not mentioned in their report, that during the agitation on the Poisonous Substances Bill they had an interview with Mr. W. H. Hornby, M.P.; and their explanation of the chemists' position was nothing less than a revelation to that gentleman. Personally, he thought every chemist ought in private life to discuss this question of pharmacy with his intelligent friends, as by that means they could quickly secure public appreciation of their position, and so do a great deal towards obtaining relief from their grievances. To show the earnestness with which the Committee had worked he might say that while the matter of drafting resolutions on the Belfast report was before it, the Committee held seven meetings before they finally decided upon their wording.

THE NEXT SESSION.

The HON. SECRETARY said that the Committee had drawn up a suggested list of fixtures for the winter session for the guidance of the new Committee. In the first place they suggested a general meeting in December to discuss the resolutions drawn up by the Federation. Then they proposed that a member of the Pharmaceutical Council should be asked to address them. Mr. J. Rymer Young had kindly promised to do that, and it was suggested that a special meeting should be held for the purpose. The third item was the annual dinner. Then Mr. Councillor James Law, who took a great interest in the Society, had offered to conduct the members over the Corporation electricity and gas works, and also over the sewage works at Samlesbury—two most interesting excursions. Finally, Mr. J. D. Baxter, B.A., had offered to give them a paper later in the season.—Mr. LOMAX said he thought the programme very interesting. It was most important that the work of the Association should be maintained and that every effort should be made to unite the whole trade for the purpose of their agitation. If the chemists of the country did not now realise the necessity for combination when things were about as bad as they could be they never would learn. They would lose nothing by publicity—it was time they pushed themselves to the front without fear of other people. It had been the case in the past that they had been frightened of what the big companies

might do. They had such companies at Darwen. In this matter, as in the others, they had everything to gain by a bold attitude and speaking their minds. The North-East Lancashire Association had already been the means of doing good work. It set the ball rolling at Belfast, as several propositions were there brought forward on its instigation, and first and foremost the matter of company pharmacy. The public men of the country would, he was convinced, be on the right side when they knew the facts.

ELECTION OF OFFICERS.

—Mr. GARLAND proposed the re-election of Councillor Critchley as President for the year.—The proposition was seconded by Mr. PICKUP and supported by Messrs. HOLT and SHORROCK, and carried with acclamation. Councillor Shorrock (Darwen) was elected Vice-President in place of Mr. Wells, who retired owing to the distance he now lives away from Blackburn.—Mr. R. LORD GIFFORD was re-elected Hon. Secretary on the proposition of Mr. GARLAND, seconded by Mr. LOMAX.—Mr. GIFFORD, who was heartily applauded, remarked that the laws relating to pharmacy appeared to him to be altogether anomalous and senseless for a country like England. Such a state of things has been brought about by the apathy of the rank and file of the profession, and he accepted the position of Secretary determined to do his utmost to alter the existing condition of affairs.—Messrs. Howarth, Holt, Highton, Eatough, Lomax, Wells, Pickup, Pickworth, and Grimshaw were elected on the Committee, with instructions to form a sub-committee to deal with trade matters purely.

MIDLAND PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held at Mason University College, Birmingham, on the 17th inst., the PRESIDENT (Mr. Jeffrey Poole) in the chair.—Mr. JOHN BARCLAY, F.C.S., read the following notes on

Some of the New Standards of the 1898 Pharmacopœia.

PHENOL.—The acid of the new Pharmacopœia is a purer variety than the old, but a margin of impurity is still allowed.

CITRIC ACID.—A specific test for the presence of lead in this acid, as also in tartaric, is now included in the Pharmacopœia, but the test is worthless if a trace of iron be present. Sulphuretted hydrogen is directed to be added to a solution of the acid made neutral with ammonia. No doubt a better method of testing would be to add sulphuretted hydrogen to the acid solution, or to use Warrington's test, neutralising the acid with ammonia, and adding a little potassium cyanide.

AROMATIC SULPHURIC ACID contains the same proportion of acid as heretofore, but the percentage now stands at 13.8, the correct figure.

PURIFIED ETHER now "has most of the alcohol and water removed" instead of being absolutely pure as previously.

ABSOLUTE ALCOHOL is required to be purer than heretofore, the specific gravity being lowered from 0.797–0.800 to 0.794–0.7969.

WOOD CHARCOAL.—The amount of ash allowed to be present in this has been raised from from 2 per cent. to 7½ per cent.

CHLOROFORM has its specific gravity lowered from 1.497 to 1.490, which indicates the presence of more alcohol.

SAFFRON.—The Pharmacopœia now states that dry saffron yields about 7 per cent. of ash, and should not lose more than 12½ per cent. of moisture when dried at 212° F.

ELATERIUM.—There is an improved method for assaying elaterin, the chloroform solution being evaporated and the residue washed with ether instead of ether being added to the chloroform solution as formerly.

IPECACUANHA.—There is now a liquid extract, which must be made from Rio or Brazilian root only, and contain from 2 to 2¼ per cent. of alkaloid. That this alkaloid shall be at least half emetine is provided for by the exclusion of Cartagena root, which contains a larger proportion of cephaeline. The process of preparing the fluid extract is a somewhat tedious one, but the long-continued evaporation of acid alkaloidal solution involved in the 1885 process has been done away with, and undoubtedly a more perfect removal of alkaloid ensured. The wine of ipecacuanha made from the fluid extract now contains 1/10th per cent. of alkaloid. This is a decided improvement. It seems a pity that no standard for alkaloid in the root itself has been fixed, for the

powdered drug is, and will no doubt continue to be, largely used.

NUX VOMICA.—An advance has been made in respect of distinguishing between strychnine and brucine, the standard preparations being required to contain a definite percentage of the former. It is, however, a great question whether the liquid extract is in any way an improvement on the old solid preparation of the 1885 Pharmacopœia.

OPIUM.—The low limit of morphine allowed in opium from which tincture and extract may be made produces some peculiar results. For instance, the Pharmacopœia states that half a pound of extract made from a pound of this class of opium shall contain 20 per cent. of morphine, which, of course, is impossible. It is added that stronger extracts may be mixed with weak ones to obtain the right strength. Then, again, to make a tincture, any opium containing 7½ per cent. and upwards of morphine may be used, thus allowing an enormous variation in the amount of extractive present in the tincture. The further statement that for purposes other than that of making extract and tincture a 10 per cent. opium must be used, implies, of course, that morphine cannot be made from any drug deviating from that standard, which is also absurd.

EXSICCATED IRON SULPHATE.—The standard for this salt has been reduced, but the change appears unnecessary, as there is no difficulty in obtaining a salt up to the old standard if good sulphate be used.

REDUCED IRON.—The proportion of metallic iron required has been raised from 50 to 75 per cent., and there is here an improved method of assay. The standard might well be even higher.

GLYCERIN.—The specific gravity has been raised.

SOLUTION OF HYDROGEN PEROXIDE is a newly introduced preparation.

CINNAMON OIL must contain 50 per cent. of aldehyde, and adulteration with leaf oil and terpene-like bodies is thus prevented.

PEPSIN is now the soluble variety in the form of either scale or powder. The time of treatment with egg-albumin has been lengthened, and the temperature of digestion lowered from 54° C. to 40° C. It is notable that the new pepsin is at least ten times as strong as that of the old Pharmacopœia, whilst the dose is doubled.

ACID POTASSIUM TARTRATE is now required to be rather more than 5 per cent. purer than heretofore. The method of assay is also altered, direct titration with an alkali being adopted. The most satisfactory method of testing the salt is to use the new method and the old in conjunction.

QUININE SULPHATE.—Reference has been made to the new methods of testing this, by Cownley in the *Pharmaceutical Journal* of April 30 last. He alludes to the inutility of tests for cinchonine, quinidine, and cupreine alkaloids, which, as he points out, are rarely, if ever, present in the quinine of commerce. He also alludes to the fact that the official method of estimating cinchonidine present does not give the amount of that alkaloid actually contained in the salt, but the Pharmacopœia does not state that the whole of the cinchonidine is obtained by this method, and a more complicated process of assay is inadvisable.

SODIUM NITRITE has been introduced for the purpose of making a solution of ethyl nitrite.

SOLUTION OF ETHYL NITRITE.—This is a new preparation, somewhat stronger than the old spirit, and is required to be free from the aldehyde and those "other substances" said to be contained in the older preparation.

PRECIPITATED SULPHUR is required to be free from fixed mineral matter.

SYRUP OF IODIDE OF IRON.—The method of determination of the iodide present is not a very fortunate one, since any quantity of chloride and bromide might be present and escape detection.

TINCTURE OF CINCHONA is now required to contain a definite proportion of alkaloid, as also is the compound tincture.

BELLADONNA.—The method of standardisation adopted for belladonna preparations is far from satisfactory. A liquid extract prepared by repercolation is made a base for standardising all the galenicals. This liquid has, of course, to be prepared with rectified spirit, the use of which means loss. To make a methylated liniment of belladonna under the new regulations, a fluid extract containing rectified spirit has to be used. The new tincture is probably quite double the strength of an average tincture made according to the old Pharmacopœia, whilst the dose is only slightly altered. The liniment, too, is stronger than formerly. The variable green extract is allowed to remain, and no method of standardisa-

tion is given. This preparation is no doubt still largely used, and will continue to be used, in spite of the introduction of the 1 per cent. alcoholic preparation intended to supersede it. Seven samples of the liquid extract obtained from various first-class wholesale drug houses gave the following results on examination:—

No.	S.G. at 15.5° C.	Total Solids per cent. dried at 100° C.	Alkaloids per cent. by Weight.	Alkaloids per cent. by Titration.	Absolute Alcohol per cent. by Volume.	Relative Depth of Colour.
1.....	0.9180	14.07	0.801	0.772	72.08	144
2.....	0.8685	6.21	0.829	0.817	82.64	100
3.....	0.9190	13.00	0.710	0.688	73.40	163
4.....	0.9760	23.41	0.709	0.660	64.38	2530
5.....	0.9610	20.03	0.741	0.706	67.62	225
6.....	0.8775	8.73	0.816	0.816	82.64	125
7.....	0.9090	6.50	0.778	0.733	69.80	370

The official assay method was adopted in each case. The points to be noted in the table are the variations in the amount of solid matter, alkaloid, and alcohol present, and the variation in colour of the samples. It might be expected that the samples having the largest percentage of solids would show correspondingly high proportions of alkaloid, but that was not the case, nor did the relative depth of colour vary with the amount of extractive present. Samples 4 and 5 were remarkable for the very large proportion of sugary extractive matter present in them, and it was difficult to believe that the whole of it can have been derived from belladonna root. Although the extractive matter present in these two samples was approximately equal, No. 4 was more than ten times darker in colour than No. 5. The variation in the amount of extractive matter and in colour must have the effect of making the liniment, tincture, etc., vary in the same ratio, a state of things which might have been avoided if the standard extract had been of the solid class, as advocated by the author. With regard to alkaloid, the variation noted was much greater than should be permissible. The amount of alcohol present also varied more than it should, and samples 2 and 6 had evidently been prepared from an alcohol stronger than that required by the Pharmacopœia.

MISCELLANEOUS.—In conclusion, regret was expressed that advantage had not been taken of the opportunity of obtaining reliable preparations of many powerful drugs. Thus, the tinctures of aconite, colchicum, conium, henbane, jaborandi, lobelia, stramonium, and gelsemium are still allowed to vary according to the varying percentage of alkaloid present in the drugs from which they are prepared, and many important tinctures of the non-alkaloidal class, such as those of Indian hemp, foxglove, sumbul, ginger, and strophanthus, should have had standards fixed. The Pharmacopœia should also contain standards for total extractive in such articles as tincture of rhubarb, senna, etc. Though tolu is required to contain a definite percentage of acids, no such standard is fixed for benzoin, an equally important drug. Extract of Calabar bean is without a standard, as also are the liquid extracts of ergot and male fern. There is no doubt that our knowledge of the chemistry of drugs must be much further extended before thoroughly satisfactory standards can be fixed for galenical preparations, but such knowledge as we have should be made use of, and it can scarcely be denied that the compilers of the new Pharmacopœia have not made the most of their opportunities. The author expressed his thanks to Mr. E. W. Mann for help in preparing his paper.

Discussion.

Mr. A. W. GERRARD opened the discussion by congratulating Mr. Barclay upon the practical way in which he had dealt with the subject. Taken generally, he had little hesitation in saying that the new B.P. was a distinct advance from a pharmaceutical point of view upon any of those that had preceded it. As pharmacists they had very little to do with the preparation of previous B.P.'s, and it was a matter of congratulation that they had so much to do with the present one. Many pharmacists had been brought into association with members of the medical profession in the preparation of the work, and he hoped that in the future they would take a still larger part. Upon the question of standardisation, Mr. Gerrard said he did not complain of it as a whole. Where it could be carried out in a thoroughly practical manner he approved of it, but one tendency of it was to throw

pharmacy proper out of the hands of the retailer into the hands of the wholesale houses. Personally he should prefer to see a very much larger number of manufacturers throughout the country—men who would interest themselves in the manufacture of pharmaceutical productions. Then, again, they knew the drugs varied very considerably. There was great natural variation. They might, for example, have belladonna root which would give an extract containing 5 per cent. of alkaloids, and they might perhaps have another specimen which contained no more than 1 per cent. The extractive in both cases was the same. Supposing they had standardisation of these two extracts, in the one case they would have to add considerable foreign matter, whilst in the other none would be required. The result was a great variation in the appearance of the product, and the chemist and druggist who had to deal with variations in the drugs he dispensed knew the difficulty of the position. They looked for uniformity in the preparations. It was not always possible, but an effort should be made to avoid getting away too much from the natural to the artificial. If they were able to get natural products which would give alkaloids within a certain range, and made preparations from these, they were on as safe ground in the manufacture of the products as they would be if they attempted standardisation from drugs which varied considerably. Belladonna plaster was a preparation which had varied very much. He was constantly hearing complaints during his hospital career of the irritating effects produced by the application of belladonna. He had never seen an actual blister, but he had seen a good deal of redness and irritation, due in many cases to the fact that there was a large excess of alkaloid in the plaster, which became absorbed and produced the local therapeutic action of the drug. Looking at the figures in connection with alkaloids in Mr. Barclay's table, there certainly should not be the amount of variation which was represented between the figures 0.81 and 0.66. He was also surprised to find there was so wide a difference between the alkaloid yielded by titration and that determined otherwise; it might be due to the colouring matter. He did not attach so much importance to the difference in specific gravity. This would be accounted for by the amount of matter which it was necessary to add to bring the preparation up to the alkaloidal strength. With regard to phenol, it was a wise change in the B.P. to improve the quality of the article by altering the melting point and, of course, increasing its solubility; and there was no better test for the pharmacist in connection with phenol than the proportion in which it was soluble in water. The alteration of the specific gravity and variety of ethers was also very essential; they must be careful as to quality of ether produced in the market. So far as saffron was concerned he thought it proper that the Pharmacopœia should give a fair range, because however carefully storage might be carried out they could not avoid moisture getting away when parcels were opened. He did not think the public authorities should be too strict with the pharmacist on a matter like this. As to Mr. Barclay's statement that the old pepsin contained peptone, he should have thought it was the new pepsin, and that the old one was more likely to be free. The soluble pepsin was generally made by the self-digestion of the stomach of the pig. In that case they were dealing really with peptone, and he had found that peptone would digest almost as well as pepsin. With reference to precipitated sulphur and the old milk of sulphur, he observed that if a person asked for a certain article and preferred to have it with sulphate of lime in it, he was entitled to it; but if the chemist pointed out to the customer that in one case he was buying the pure sulphur, and that in the other the mixture contained sulphate of lime, the purchaser would generally prefer the pure product. The public wanted educating in this respect.

Mr. SPILSBURY concurred in the opinions expressed by the previous speaker with regard to standardisation. He did not, however, advocate the preparation of tinctures from liquid extracts, because the preparations did not represent the constituents of the drugs as efficiently as tinctures made direct. It was tending to dependence on the presence of the alkaloids only, whilst it was a prevalent opinion, especially with regard to cinchona and nux vomica, that the physiological effects of a well-prepared tincture were more satisfactory than those produced when the alkaloids alone were administered. The process for the liquid extract of belladonna was, in his opinion, incomplete and wasteful, and according to Mr. Barclay's figures, the results were subject to much variation, especially in the amounts of solids, the larger quantities of which, he pointed out, might probably be due to the presence of an excessive proportion of the

inorganic constituents of the root. He had prepared a standardised tincture direct from the root, and found it yielded 70 per cent. more solids, whilst its physical characters were more satisfactory than one made from the liquid extract. Nor could he conceive why the tincture of nux vomica had been increased in strength whilst the dose remained practically the same. Toxic effects had already been reported to him from its use, and he thought that for further security in both practice and dispensing it would have been preferable rather to decrease the strength and increase the dose than otherwise. The instructions for testing balsam of tolu he also considered somewhat indefinite. No percentage requirement was quoted, and the residue from the bisulphate of carbon solution remained an unknown quantity. Yet the Pharmacopœia added that it should require not less than one-third its weight of potassium hydroxide for its saponification, indicating the presence of a sufficient proportion of benzoates and cinnamates. Mr. Spilsbury concluded by expressing the opinion that until recent investigations were thoroughly corroborated by other and independent workers, it was inadvisable to extend the number of standardised tinctures.

Mr. ALCOCK considered the Pharmacopœia as an individual sitting side by side with pharmaceutical students. Although the student was not quite capable of discussing the new B.P., he must be looked upon as the future pharmacist, and see how he behaved with these processes. They had an instance that night of the difficulty the retail pharmacist would have in dealing with the determinations of the standards. It was ever thus, and there was no doubt that the battle of the standards would continue until the end of time. There could be no doubt that the Pharmacopœia was a bit in advance of the retail pharmacist, and this meant throwing difficulties upon the wholesale house. The pharmacist did not attempt such important things in his business as assays of tincture of opium, extract of nux vomica, and similar things. The pharmacist, he argued, ought to be able to make his tincture of opium. Otherwise he became a huxter, which would be a most deplorable state of things. If the pharmacist could not make the preparations of the Pharmacopœia, if he could not make his pilula hydrargyri and unguentum hydrargyri, he was not doing the right thing to himself. The figures quoted by Mr. Barclay called for serious attention. They related, he took it, to products of houses of repute, and there was a most remarkable difference which should not be found in preparations of the kind. Thoughtful men really did not know what to say concerning them. He agreed that specific gravity was not of much account, but it was one of the first things the pharmacist would ascertain. Take, again, the great difference in the amount of solids, yet the alkaloid was practically the same. In one or two instances there was a great variation, and one could scarcely understand how it was brought about. Some of the modes of determining the standards were open to criticism. For instance, the method of assaying extract of ipecacuanha would, in inexperienced hands, be a failure. The Meysey (?) process, again, took a long time, and if great care was not exercised they would not get the exact amount they anticipated, but that was the process which the public analyst would be obliged to follow. Then, again, the Pharmacopœia ordered very large quantities for the processes of assay, when, in his opinion, less than (as in the liquid extract of ipecacuanha) 20 C.c. could be used. By the use of a much smaller quantity—even 1 C.c.—in these days of good balances, fairly accurate results could be obtained. It should not go forth that the official solution of hydrogen peroxide was of 20 vol. strength, because half the oxygen obtained was produced by the test used. It was curious that a solution of ethyl nitrite of definite strength was introduced, apparently to supersede the spirit of nitrous ether, when that was acknowledged to be an article that would deteriorate, as the test showed. In the standardisation of extract of nux vomica they were told to take 11 ozs. of liquid extract, use 1 fluid oz. to ascertain the solid matter in it, and throw it away, and from the remaining 10 ozs. get the product. No doubt Mr. Barclay threw his 1 oz. away.

Mr. SHORHOUSE remarked that, looking at the figures Mr. Barclay had brought forward, showing the various analyses of the liquid extract of belladonna purchased from houses of repute, he thought it was very deplorable that there should be such a variation in composition. The specific gravities of the preparations they might completely overlook, but the percentages of alkaloids varied considerably. Was this due to errors in standardisation, or had they been carelessly prepared? Again, throughout his determinations had Mr. Barclay observed any standard of ratio between the determinations made gravimetrically

and the results obtained by titration? With reference to the percentage of alcohol contained therein, was it not more probable that the belladonna had been exhausted with alcohol of varying strengths rather than that the loss was due to evaporation or carelessness in manipulation? With Mr. Spilsbury's remarks that the amount found by different operators varied considerably he was not inclined to agree, as he had frequently made determinations against other analysts, and had invariably obtained concordant results. He thought it would be to the interest of pharmacy if such a preparation as fluid extract of belladonna could be made more constant in colour, as many people were apt to judge the strength of a preparation from the colour. In his own experience he had found samples to vary both in colour and strength, and in one or two instances he had found the preparations to contain more alkaloid than was specified in the B.P. Personally, he thought it was practically impossible for the majority of retail pharmacists to prepare their standardised preparations, inasmuch as they required considerable time and attention in the laboratory, and during this time the chemist had to leave his customers in the hands of his assistants or apprentices.

Mr. BARCLAY, in replying, said he thought that even if the use of standardised preparations should place the manufacture of galenicals more in the hands of the wholesale trade, standardisation was both desirable and necessary. Minor considerations should be sacrificed to public good, and it would be absurd to arrest the progress of scientific pharmacy because of the incompetence of retailers to perform the processes required by the Pharmacopœia. He, further, did not think that retailers should find the difficulties alluded to by Mr. Gerrard and Mr. Spilsbury, since if a man passed his Minor, he ought to be well able to undertake all the work required. It was true that standardisation of alkaloids in galenicals might, in some cases, produce a variation in the amount of extractive and colour present, but he did not agree with Mr. Spilsbury that these factors were of importance compared with the main point, viz., a uniformity in percentage of active principle. The difference between the figures obtained for alkaloids by weight and alkaloids by titration were unavoidable, and a reference to the figures would show that the relation between them was fairly constant. With regard to pepsin, when he referred to the presence of peptone and other animal matter in the preparation of the 1885 Pharmacopœia, it was because he wished to draw attention to the insoluble animal matter which it contained. Referring to Mr. Spilsbury's experiment with tincture of belladonna made direct from the root, instead of from liquid extract, he pointed out that the test would scarcely be valuable unless both tincture and liquid extract were made from the same sample of root. Furthermore, he did not attach any considerable importance to the presence of matters other than alkaloid in belladonna preparations. As to the researches of one worker not affording sufficient ground for the fixing of standards by the Pharmacopœia Committee, he did not agree with Mr. Spilsbury, since the Committee had it in their power to investigate any suggested process and determine its value before adopting it. He was surprised that Mr. Alcock thought the new Pharmacopœia in advance of the pharmacist. It was the pharmacist's fault if it were so, and the sooner he became competent to deal with it the better. He agreed with Mr. Alcock that the process of assaying liquid extract of ipecacuanha would be an expensive one, but here again the difficulties of individuals should, in his opinion, be subordinated to the public good. He was glad to find that Mr. Perry agreed with him in the matter of standardisation, and as a retail pharmacist was satisfied with the new Pharmacopœia in this respect. In reply to Mr. Shorthouse, he remarked that there was in the figures given in the table a certain amount of correspondence between the strength of spirit found and the amount of extractive present.

ALKALIES IN SKIN DISEASES.—P. G. Unna, commenting on the increasing use of alkalies in dermatology (*Monatsch. f. Prak. Dermat.*, 898, 27, 65), prescribes the following formula for a caustic paste:—Potassium hydroxide, lime, soft soap, and water (equal parts), to be made into a paste. This may be diluted with glycerin, so as to modify its action. Water should not be used to the parts while this dressing is being used. It is applied on a small piece of cottonwool, over which a bandage moistened with water is placed. To moderate the pain caused by the first application 5 or 10 per cent. of morphine alkaloid may be incorporated with the paste. This is found to be more efficacious than cocaine, eucaine, and other local anæsthetics.—*Pharm. Centralhalle*, xxxix., 562.

BOURNEMOUTH PHARMACEUTICAL ASSOCIATION.

The members of this Association met for supper on the evening of November 16 at the Grand Hotel, Bournemouth, Mr. JOHN TOONE, President, in the chair.—After the toast of "The Queen" had been given from the chair, and that of "The Pharmaceutical Society" by Mr. G. E. BRIDGE, "The Bournemouth Pharmaceutical Association" was proposed by Mr. E. WORTH, who commented on the advantage of a local organisation, not only from a social point of view, but also for purposes of discussing trade questions and of influencing proposed legislation. He thought men employed in common work, brought together by meetings of such an Association as theirs, could not fail to learn from each other.—Mr. TOONE, in reply, referred to the work the Association had recently done, a meeting being called, as members would remember, to discuss the Poisons Bill, and they had sent a letter to the local Member, pointing out objections to the proposed measure.—A good programme of music and recitation was provided by members and visitors, proceedings being closed by a vote of thanks to Messrs. Bilson and Williams, who had so well organised a successful and pleasant evening.

DERBY AND DISTRICT CHEMISTS' ASSOCIATION.

The annual general meeting of this Association was held at Smith's Restaurant, Derby, on Wednesday, November 16, Mr. J. A. COPE, President, being in the chair. All the retiring officers were re-elected, with the exception that Messrs. Stevenson and Readman take the places of Messrs. Heath and Hefford on the Committee. Three new members were elected, and the Hon. Treasurer's balance sheet showed cash in hand to the extent of £2 19s. 6d. This satisfactory state of things obtaining, it was decided that old members' subscriptions for the current year should be in abeyance.—The presidential address was one of true loyalty to the parent Society, Mr. Cope urging those present to join the Pharmaceutical Society as members, pointing out the main features of the new constitution, and how that, if chemists are to expect any legislation to effectually prevent company pharmacy and to control the sale of carbolic acid and other poisonous substances, they must all unite as one body, and that can only be by unanimously supporting the Society at Bloomsbury Square.—Other business on the agenda having been disposed of, the meeting resolved itself into a social gathering, the President greatly interesting and instructing the company by a practical exposition of the Freck tablet machine. Light refreshments and smokes being provided, a very pleasant and enjoyable evening was spent.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The opening meeting of this Association was held on Friday, November 18, at 7 p.m., Professor GREENISH in the chair.—Mr. E. W. LUCAS addressed the meeting on the subject of

Pharmaceutical Education.

Describing the course of instruction given in the School of Pharmacy fifteen years ago, he contrasted it with that at present adopted. Alluding to the changes that have occurred in the practice of pharmacy during the last few years, Mr. Lucas drew conclusions as to the probable tendency of the further changes that might be expected during the next few years, and based upon them his opinion that in the future the assay of crude drugs and galenical preparations will play a much more important part than it does at present, and that accordingly the education of the pharmacist should be extended in that direction. Mr. Lucas gave an encouraging account of the Minor examination from an examiner's point of view, and expressed himself in favour of students who have passed the examination taking a situation abroad, in order to extend their knowledge of their business and the world, before settling down to the life of a pharmacist at home.—Mr. Lucas' address, which was accompanied by amusing anecdotes, was listened to with attention, and received hearty applause. At the conclusion of the address, on the motion of Mr. F. A. UPSHER SMITH, seconded by Mr. H. PAYNE, a vote of thanks was awarded to Mr. Lucas for his interesting and humorous address.—The voting for the

ELECTION OF OFFICERS

for the ensuing session then took place, with the following result: President, Professor J. Norman Collie; Vice-Presidents, F. A.

Upsher Smith and J. Evans; Treasurer, H. S. Durbin; Secretaries, H. Finnemore and P. B. Gray; Committee, C. Battle, W. Ransom, E. W. Ewell, T. Wallis, E. Dyas, and H. Payne.—It has been thought that as this is a students' association it is desirable that students should fill all the offices except that of President. As will be seen, this change has now been effected, and it is hoped that the change will be beneficial.—After the result of the election had been declared, Professor COLLIE took the chair, and thanked the students for electing him as President. Subsequently a vote of thanks was accorded Professor Greenish for his services as Chairman during the past two sessions.

NORTH STAFFORDSHIRE ASSOCIATION.

A monthly meeting of this Association was held at the Copland Arms Hotel, Stoke, on Thursday last. Mr. J. Averill, J.P., presided, and there were also present, among others, Messrs. W. Poole, Treasurer (Newcastle), Edmund Jones, Hon. Secretary (Hanley), E. H. Croydon (Newcastle), W. Marson (Stafford), R. Prince (Longton), A. P. Tiley, W. Oldham and Bates (Burslem), T. H. Jenkins (Stone), and W. Allison (N. S. Infirmary).

NEW MEMBERS.

On the proposition of A. P. Tiley, seconded by Mr. Jones, Mr. W. Oldham, the father of the retail trade of the district, was elected a member of the Association.—Mr. OLDHAM, in reply, said he was a member of the first chemists' association in the district twenty-eight years ago. That was not a success, but with the young blood in it he did not see why the present Association should not be of great service.—On the motion of Mr. JONES, seconded by the PRESIDENT, Mr. William Hartle, of Shelton, was also elected to membership.—Mr. ALLISON then read a paper on

Emulsions.

which was listened to with the greatest interest. The author also described numerous experiments made by him on the subject, and produced varied samples of emulsions and white oils.—An interesting discussion took place on the paper, and on the motion of the PRESIDENT, seconded by Mr. JONES, a hearty vote of thanks was accorded to Mr. Allison.

EVENING CLASSES.

Mr. JONES stated he had made arrangements with the headmaster of the Hanley Higher Grade School, Mr. Wilson, M.A., and Mr. Audley, B.A., teacher of botany, for classes to be held in botany for the benefit of pharmaceutical students.—A vote of thanks was passed to the Hanley School Board, which had granted free use of a room, for its kindness in the matter.

The Advantages of Membership of the Pharmaceutical Society.

—Mr. JONES, in accordance with notice, moved—

That this Association strongly recommends every pharmaceutical chemist or chemist and druggist, who is not already a member, in his own interest to join the Pharmaceutical Society, and thereby increase its powers to legislate and operate for the good of its members and the progress of pharmacy.

Mr. Jones said: I move this resolution in accordance with a resolution passed by the Federation of Local Associations at Belfast, and supported by suggestions of the Editor of the *Pharmaceutical Journal*. The passing of the Pharmacy Acts Amendment Bill, in my opinion, has removed the gross inequality which caused much grumbling and dissatisfaction amongst those who were associates of the Society and many who remained outside the Society. Formerly the associates in business paid the same annual subscription as members, but had not the same privileges. This state of things is now altered, and the wise democratic policy of the Council will, I trust, be actively appreciated, and at the new year we shall, I hope, see a large increase in members. It is not my intention to-night to discuss the question, What has the Pharmaceutical Society done for the trade? I have very strong convictions upon that point with which you might not all agree, and should refer you to the condition of the drug trade prior to the foundation of the Society and the passing of the Pharmacy Acts, and tracing its history since to prove to you that the Society has done much to elevate and improve our calling. My object in moving this resolution is to plead to those outside upon the advantages now offered, and those we might possess by making the Society larger in numbers and more fully representative of the

trade. There are several very important questions which occupy the mind of the trade at the present time, and which many desire the Council to take up with a view to legislating on them. The one which appears to be most prominent is company trading, and the cry is, "Why doesn't the Society do something to try to stop this pressing evil amongst us?" Now, gentlemen, this cry comes mostly from those who have no connection with the Society and have no *locus standi* in the Society. I consider it unfair and unreasonable for such outsiders to so harshly and unpardonably criticise the Society. What would those gentlemen think if a stranger walked into their shops and commenced to criticise and find fault with the way their stock was kept, their poisons stored, their glass cases arranged, and the general conduct of their business? I think they would strongly and justifiably resent it; but the Society—and when I say the Society I mean not the Council only, but its rank and file—does not adopt such a resentful attitude, as is proved by its conduct of the Benevolent Fund, which is encouraged and employed for the benefit of all chemists on the Register. As a Freemason and a great believer in that grand and noble principle, charity, I feel that the trade has very greatly lacked in its support of the Benevolent Fund, which since its creation has been the means of administering relief and consolation to less fortunate members of our craft in their misfortune and old age. Surely this is a work which in itself ought to gain for the Society greater sympathy and support from the trade. Apart from this, is it not most desirable to increase the members and fighting strength in view of the legislative possibilities which the trade is devoutly wishing for? I take it that there is scarcely a chemist on the Register who does not desire to see an amendment to the present anomalous condition of the Pharmacy Act of 1868. This granted, how are we to get the Act amended to our satisfaction? The Pharmaceutical Society is a thoroughly democratic body, even more so now than hitherto. Every member of the trade who has a grievance which he would like to see remedied, or a policy carried out, can, by becoming a member of the Pharmaceutical Society, and in a proper and legitimate way, impress his grievance or policy upon the Council, which would be compelled, under pressure from the electorate, to carry out the desired reforms, if possible. Surely no one can wish for a more democratic constitution of the Society. In the face of these facts, can the Society be said to represent the trade? Although it is practically the National Pharmaceutical Society—I was hoping to see it made "Royal" this year—and has our best and brightest pharmacists on its roll of members, it does not contain a majority of the chemists on the Register, and many good and able men remain outside and appear to take little or no active part in pharmaceutical politics. If the Society, instead of a membership of about 4000, had 10,000 or 12,000, how much greater the chances would be of inducing the Privy Council and Parliament to take up Bills drawn up and submitted to them by the Society? The drug trade is certainly in a very unfavourable and lamentable condition to-day, speaking generally, and we frequently hear it spoken of as "rotten." Still, in spite of this, I for one believe in its future, and I love pharmacy so much that had I my time to go over again I think I should enter the same calling, but desire to see a better and happier state of things than at present prevails. During the passing of the Pharmacy Acts Amendment Bill and the introduction of the Poisonous Substances Bill in Parliament early this year it was evident what great advantages accrued from a united and active interest in those matters concerning the trade. We passed one Bill and successfully opposed another; how much greater our advantage would be if we had a stronger Society? It would be a good thing if we could form a society for dealing with the limited company question. These consolidated and increased powers can only, in my opinion, be obtained by a larger membership, and now that the Society offer additional advantages I trust that every chemist on the Register will seriously consider the advisability of becoming a member. Let me especially express the hope that every member of this Association will do his best to induce non members in the district of the town where he lives to avail themselves of the advantages and privileges the new Act confers. If this is done and done successfully we shall ere long see a happy and bright condition of pharmacy never dreamt of in our philosophy.—Mr. MARSON seconded the resolution. He endorsed every word Mr. Jones had said, and expressed his intention of joining the Society at once. He considered it the duty of every member of the trade to put forth every effort

and support the Society and local associations, which, if containing a majority of the members of the trade, could approach the local M.P.'s with some confidence, and almost demand that they should give their support in aid of the Association's aims.—Mr. CROYDON supported, and said that under the new constitution he would be glad to join the Society. Speaking of the low state of the trade, he considered that if the Society had a charter empowering it to strike members off the rolls who had been guilty of unprofessional-like conduct, it would do more than anything to improve the condition of the trade.—Mr. WESTON POOLE considered that reforms had to come from within as well as without. Nice conduct between chemist and chemist would do something, but when one tried to "best" the other it was not a matter for wonder that they could not get all they required from the public, and which the public, was prepared to give them if they acted in a consistent manner. He believed there was a time when the public was prepared to put them upon a professional footing. At the time they were getting reforms conceded to them he thought every chemist should try to purify the craft from within and live up to the privileges they were endeavouring to obtain.—Mr. OLDHAM further supported the resolution. He had been a member of the Pharmaceutical Society for twenty-eight years, and he was astonished that so few had entered its gates. There was no doubt that for the evils that existed they had themselves to thank in a large measure. Underselling had been encouraged and had grown, whereas, had the chemists put their foot down on the practice, it would not have increased to nearly its present extent.—The CHAIRMAN, in putting the resolution to the meeting, said: Gentlemen, you all know that during the last session of Parliament powers were obtained by which every registered chemist and druggist can become a member of the Pharmaceutical Society with all the advantages attached to former membership. It now rests with us whether we embrace that opportunity and elect a thoroughly representative Council, which will be able to state the opinion of the trade, and thereby have a more direct influence on legislation than at any former period during the history of the Society. It is absolutely necessary that a very large proportion, if not all, of the chemists and druggists should be members of the Society, and that the trade should be unanimous in any line of action which it may be thought desirable to take for the welfare of our class. No real good can be done unless we are united. The Council of the Pharmaceutical Society must have the support of the members of the craft, otherwise it is hopeless to expect any real benefit to accrue. One of the first things, I think, for the Council to take in hand is the enforcement of the statutory qualification in the case of all persons connected with the business, and that in Section 15 of the Pharmacy Act, 1868, the word person should include a "corporate body." The Lord Chief Justice, at the official reception of the Lord Mayor of London at the Law Courts, spoke on the necessity of further regulating company trading by special legislation. We have also had the opinion of the Lord Chancellor during the last session of Parliament, so that if we can speak as a body on our special grievance we may reasonably hope some good may result to ourselves. I ask you, then, to join the Society, and I hope every member of this Association will, and show to all similar associations throughout the country that the North Staffordshire Association is in earnest and determined to do the best it can to help the Society in bringing about such reforms as may be for the benefit of the trade generally.—The resolution was passed unanimously, and Messrs. Allison and Jenkins also promised to join the Society.

IRISH PHARMACISTS' ASSISTANTS' ASSOCIATION.

At Dublin, on Friday evening last, the usual fortnightly meeting of this Association was held at 67, Lower Mount Street, the PRESIDENT, Mr. Henry Hunt, M.P.S.I., in the chair. There was a good attendance, and amongst those present were:—Miss Ada Wyatt, M.P.S.I., Miss C. E. Jessop, Miss Walsh, Messrs. Yoxall, Savage, McCarthy, Preston, Bowles, Hogan, Dempsey, Taylor, O'Farrell, J. Jessop, etc., etc. The minutes of the last meeting were read and confirmed. The question of securing a club room and an employment agency office was discussed, and the report of the sub-committee on the matter was regarded as satisfactory. Two central places were agreed to be seen after, and a further report was called for. January 20 next was settled as the date of holding the first lantern evening of the session, and it was hoped this date would be convenient for the Pharmaceutical Society to allow the

use of the Examination Hall. A letter on the subject was directed to be written to the Council respectfully asking for the use of the large room on the occasion. It was stated that the limelight would be worked by a member of the Association, who had kindly promised his services as honorary lanternist.—The arrangements for the approaching concert in the XL Café, on December 14, were entrusted to Mr. Turner.—The following were elected to membership: Messrs. A. J. Byrne, R. D. Russell, J. H. Davis, C. E. Warner, P. Wright, and J. Winckworth. A discussion was then held on

The Proprietary Articles Trade Association and Its Influence on Pharmacy.

—Mr. TAYLOR led off the discussion by the statement that he considered the P.A.T.A. was an excellent institution, in that it helped to keep up the standard prices and enabled chemists to obtain a reasonable profit on their goods. Personally he had little to say as to the practice of that Association, but from what he gathered by hearsay its objects were laudable.—Mr. O'FARRELL spoke at some length on both sides of the question. Circumstances and locality, in his opinion, materially altered the cases, and what suited one class of house would be most unsuitable for another. In some instances it was absolutely necessary to make some reduction in prices of patents and proprietaries. Customers were apt to say they could get such and such an article in the house round the corner at so much cheaper, and if the public became possessed of the idea that high prices ruled all round they would simply transfer their custom to the stores. It was foolish to sell goods at starvation profit, but he thought if the vendor could get from 15 to 20 per cent. profit all round it would pay very well. To charge 1s. 1½d. for a box of pills and insist on getting the full price was to drive trade to the stores. It was a wiser policy to meet the public on reasonable terms than to send them to the cutters.—The PRESIDENT spoke on the influence of assistants in pushing a particular line of goods. The wholesale houses sometimes did not realise that the assistant had it in his power to recommend special remedies. He referred to correspondence on the subject which had recently appeared in print, and spoke on the gratuitous distribution of manufacturers' advertisements in the shape of hand-bills used as wrapping paper. He instanced a well-known wholesale house which sent out tons of advertising matter, and commenting on the splitting-up of regulation-sized packages of pills, saw nothing wrong in the proceeding.—Following this came a further discussion on "Infusions New and Old," in which most of those present joined, after which the proceedings terminated.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.

The first general business meeting of the session took place on Thursday evening, the 17th inst., at the School of Pharmacy, Sandon Terrace, the PRESIDENT, Mr. R. C. Cowley, in the chair. There was a good attendance, particularly of the younger members, and useful miscellaneous communications were a strong point in the evening's work.—Mr. H. B. MORGAN led off with a relation of his experience of the want of solubility of much of the bicarbonate of soda used for seltzogene charges. He had experimented with various samples and found that they all became hard in the globe on contact with the acid and water, with the exception of one lot of Chance's make. This turned out to be the general experience of those present, and was considered to be due either to excess of soda or impurity in the acid or soda. Mr. Morgan was asked to work on the subject and report later.—The variability of calf lymph, both ordinary and glycerinated, was commented on by Mr. W. COOKE, who had a customer who was unaffected even after repeated trials of both varieties. It was thought to be a case of idiosyncrasy, the patient being possibly immune to vaccine. The new B.P. tincture of strophanthus, Mr. MARSHALL said, did not mix clear with water, showing that even the weaker alcohol now used dissolved some of the fixed oil present in the seeds, which in the B.P. 1885 was removed by percolation with ether previous to making the tincture.—Mr. DAVIES thought with Mr. Marshall that the opalescence produced on mixing with water was due to dissolved fatty matter.—Mr. PROSPER H. Marsden had made tincture of squill, B.P. 1898, and although it was bright when finished, on standing it deposited a heavy, gummy precipitate of a pectinous nature. Messrs. Kesterton and

H. B. Morgan had also noticed it, and Mr. Jenner said it was usual in the old B.P. tincture.—The President advised that the tincture should be allowed to stand at least twenty-four hours before filtering.—“A Note on Peroxides” was then contributed by Mr. COWLEY, who, after speaking of Mendeléeff’s classification of such oxides as superoxides and polyoxides, according to whether they yielded H_2O_2 or O on the addition of an acid, said that any peroxide when shaken up with dilute sulphuric acid and then with ferrous sulphate, starch paste, and iodide of potassium, would give a blue colour, due to iodide of starch formed from the action on the starch of the iodine liberated from the KI by the H_2O_2 in the case of peroxides, and nascent oxygen, or perhaps O_3 in the polyoxides. This was an extremely delicate test for peroxides, and would answer for all.

Mr. R. C. COWLEY then delivered an address on

Some Pharmaceutical Problems of the Present Day.

He said: Time works numerous changes. Years pass by and numerous new societies spring into existence. During our own experience we have seen considerable changes, and if the members of this Society were old men instead of young ones, what a store of useful experience we should have. The members of the present-day pharmaceutical students’ societies possess advantages that those of fifty years ago scarcely dreamt of. The pharmacist of the present day has become an educated man. Starting life as we do with all these advantages, we shall not have done our duty if we do not assist in elevating the calling to which we belong and in trying to leave it in a better position than that in which we found it. It therefore behoves us all to do what lies in our power towards furthering this end. The policy of drift has been too much in evidence ever since the calling of pharmacy possessed a charter. Young men have entered the calling, passed their examination, and have become old men, often before their time, without ever attempting to inquire whether they themselves could do more than lift the spoon to their own mouths, if I may speak figuratively. The folly of this is very evident, we must not expect everything to be done gratuitously for us. Now, the question arises, what has been the cause of this lethargy which permeates our body? Why should pharmacy have fallen into the condition it has? This question has arisen time after time, and has been answered as often, but I venture to think that no one has answered the problem correctly though many have expressed opinions containing no doubt a substratum of truth. We are accustomed to hear of the lack of energy on the part of the body which, to a certain extent, presides over our own destinies, and which should by right play the part expected of Hercules by the woodman in the fable. Some have made a strong point of want of suitable pharmaceutical education as tending to produce the effect complained of. We are now passing through an experimental stage which no doubt will produce good results in the future. This is a point on which I am myself very sanguine and one on which I should have something to say had I time this evening, but for the present I will confine myself to the business side of the question which, after all, is the most important. It would appear to me that this is a very suitable time, in a meeting of pharmaceutical students, to give expression to an opinion I have held for several years. As a young man I may be considered presumptuous in addressing remarks of the kind I am about to make to other young men, but I think for several reasons the occasion requires it, and in it may be found one of the reasons which tend to produce the present condition of pharmacy. I am sufficiently presumptuous in saying that it is worth your while this evening to sift the matter well in your mind, and to ponder carefully over it. A subject that is uppermost in the thoughts of every right-minded individual is the idea of bettering one’s position in life. At the outset of our career we are inclined to believe that the most rapid move in this direction is guided by an all-wise providence, and is certain of attaining the result aimed at. The endeavour to better one’s position is praiseworthy, but still young men are often without the experience and cool judgment which can only come from age. Unfortunately, we are unable to begin where our fathers left off, and since this can not be so, it is well for us to seriously consider the step we are about to take. I refer especially to the wild hurry some men are in to go into business for themselves and to enter matrimony. Business is a necessity to matrimony, and matrimony seems to be a necessity to business. We may have had a great deal of dispensing experience and we may have acquitted ourselves creditably during our student career,

but still, we may lack the business training that is necessary to become a successful business man. The “Minor” certificate is not a sufficient guarantee that a man is qualified to conduct a business. It is to be deplored that so many pharmacists are wanting in this essential respect. I have often heard it remarked that the pharmacist is the poorest business man in the street, and it often happens that the scientific pharmacist is the one most wanting in this respect. But I am at a loss to know why this should be so. I attribute this lack of business qualities to the hurry to become the proprietor of a pharmacy, which does not give the individual time to obtain the necessary qualifications, and he becomes handicapped. It is unfortunate that these shortcomings do not attain finality in the individual, but are always propagated and transmitted to future generations, and at the time they affect the interests of pharmacy in general, for with fewer men in business better salaries to the assistant would result, and many who at the present time are earning in their own business but a mere pittance would, without anxiety, be much better off as employés. If the much maligned store proprietor has injured pharmacy he has at the same time shown what a business training can do, for wherever has anyone found a thorough-going store chemist but who was a good business man. It is a fact which may at once be realised that the business of the future will not be the business of the past. Sharp, keen intellect will be required, and education alone will not do this. Another point I wish to emphasise is the necessity of insufficient recreation. I am justified in saying there are dozens of pharmacists throughout the country who leave their shop for bed and their bed for the shop. Man is a gregarious animal, and the society of our fellow men is good for us. It takes us out of ourselves, it cleans the cobwebs from our brains; we will have greater sympathy with our fellow creatures, and, what is more, it will make us better business men. The society of our pipe and the contents of our little back room make us misanthropic without the correcting influence of outside society, and this, I take it, is the best possible reason for the creation and continuance of such societies as ours, where from the particular character of our business, we are prevented, to a certain extent from enjoying the freedom allowed by more favoured callings. The lateness of business hours is another subject to be deplored, and this, I am sorry to say, is the fault of the pharmacist himself. It must be allowed that the lateness of the hours of business will depend on the character of the business catered for. The labourer, the clerk, the city man, and the fortunate individual possessed of sufficient means to please himself whether he works or not, may all have their leisure at different times, but the fact still remains that late hours are often cultivated by pharmacists themselves. Now, I am sorry to say, the young man who opens a suburban business is the individual most to blame. He begins life with the idea that keeping his shop open longer than the man along the street obliges customers, and he himself is cultivating a connection. We must remember that while we are young men we can do more than when we are older, and in a comparatively few years we shall begin to want the advantage of shorter hours of business. Servility is not business, and politeness is not servility. We can retain our individuality although our position is behind a chemist’s counter. Manliness and character are features which go to make a successful man of business. While we are engaged in business let us do it well, and when we are away from business let us endeavour to forget all about it. In all cases we must endeavour to become proficient pharmacists. This state cannot be arrived at by a course of instruction in a school of pharmacy only; systematic previous training is necessary, and this will count in an examination room. Slipshod pharmacy has led to the advantage of those who conscientiously followed the wishes of the medical man, and rightly so. It has been one of the factors that have led to the spread of factory pharmacy, which every right-minded pharmacist should discourage. I am not one who takes a pessimistic view of the pharmacist’s business but rather otherwise. I think we are turning the corner and are beginning to see the way the land lies. The utterances of the Lord Chancellor during the last session of Parliament on company pharmacy and of the Lord Chief Justice last week before the Lord Mayor of London, regarding company promoting, are hopeful signs, and it behoves us all to act simultaneously. The confirmation of the Bye-law in accordance with the Pharmacy Act, 1898, by the Privy Council places us in a better position than ever we were in before, as the

removal of an anomaly is likely to lead to increased membership of the Pharmaceutical Society; still I think a little consideration on the part of the Society's Executive would be an advantage, for I fear that many will not spontaneously give their support. The admirable suggestion of Mr. J. Smith, our local secretary to the Pharmaceutical Society, in his recent paper on "The Duties of a Local Secretary," would, I am sure, result in an immediate increase in the number of supporters of the Society. At the present time there is an appeal before the various local associations throughout the country to consider suitable subjects for pharmaceutical legislation. In considering the Federation programme we must weigh matters up carefully and not pass rash resolutions. The parent Society must be fortified by a majority of the chemists throughout the country. They have been wise during the last session in being modest in their demands. We all know what we want, but at the same time we must not ask for what we cannot have. Pharmacists themselves are not likely to have any special privileges granted to them, unless it can be shown that these privileges will at the same time benefit the public at large. Before we can ask to become the guardians of public welfare in the distribution of drugs, we must show that, by a justification of confidence reposed in us in the past, we are a suitable class in whom fresh confidences may be placed; in other words, we must show a clean sheet. Are we prepared to sacrifice any advantages we already possess? For instance, are we prepared to sacrifice the doubtful privilege of storing the laudanum bottle alongside the black draught? I fancy I hear you say "Yes," but this is a very crucial point, although seemingly so simple. Company pharmacy is a very difficult subject to deal with, and I will leave it for those better able to discuss it. It is sufficient to say that companies may be divided into two classes, viz., those conducted legitimately by qualified owners and those run by an association of individuals whose calling and station in life may be of the most widely divergent character. These individuals are very useful in their proper sphere of work, but I cannot see that they are suitable persons in whom to repose the responsibility of the distribution of drugs, even though whatever virtue in this respect they may possess be transmitted through a qualified manager. In the main I agree with Mr. Rymer Young respecting the second class of companies. At the present time there is no visible means of distinguishing the former class from the latter except through their historic associations. This, I think, is an anomaly that should be corrected, and which is likely to result in advantage to legitimate companies. I have introduced the programme of the Federation of Local Associations in my remarks, as this Society is one of the affiliated bodies, and the programme is before us for consideration during the present session. At the same time, as Secretary of the Federation, I wish, through this meeting, to place the Belfast resolutions before other associations in the light they were intended, hoping that they will receive the attention they deserve. I am pleased to notice that pharmaceutical politics are taking up the attention of associations throughout the country, and it points to the conclusion that pharmacists are ready to amalgamate for their combined benefit. I had intended to introduce some remarks on education, but trade subjects have taken up so much of my time I fear I cannot further trespass on your time and patience in giving expression to ideas that may be dogmatic. In conclusion, I congratulate this Society on the increased membership and new lease of life it has apparently taken, and on the programme that has been arranged for the social and educational advantage of us all by our energetic Secretary.—A discussion followed, and a vote of thanks was accorded the PRESIDENT on the motion of Mr. H. WYATT, jun., and seconded by Mr. T. H. WARDLEWORTH and Mr. P. H. MARSDEN, for the interesting and practical nature of his remarks.

PURITY OF VANILLIN.—Welmans states that the best criterion of the purity of vanillin is its melting point, which should be 82° C. Admixture with a considerable amount of vanillic acid may give a lower melting point than this, although the acid alone melts at 207° C. The amount of vanillin in a mixture of sugar or of acetanilide may be determined by direct titration. A known weight is shaken with alcohol, a measured volume of normal alcoholic alkali added in excess, and, as soon as solution is complete, the uncombined alkali is titrated back with normal acid, using phenolphthalein as an indicator. When acetanilide is present the mixture is less soluble in alcoholic alkali than pure vanillin.—*Pharm. Zeit.*, xlii., 633.

OPTICAL EXAMINATION OF THE WORSHIPFUL COMPANY OF SPECTACLE MAKERS.

The following is the list of successful candidates at the examinations held on November 1, 2, and 3 at the Guildhall, London, E. C., in connection with the new diploma scheme of the Worshipful Company of Spectacle Makers:—

Aitchison, J., London
 Bateman, F. W., London
 Bond, R., Morecambe
 Bunker, C. J. G., chemist, London
 Butterfield, H. H., Bradford
 Cæsar, J., chemist, London
 Campkin, F. S., chemist, Cambridge
 Cave, S. A., Deal
 Chalmers, R., Newcastle-on-Tyne
 Cooper, F. R., chemist, Manchester
 Cornell, H. C., Maidstone
 Cornish, J. R., chemist, Tottenham
 Crowhurst, H. A., Sheffield
 De la Cour, G. H., Chatham
 *Dixey, W. A., London
 Dixon, E. R., chemist, Leeds
 Ellis, G. E., London
 Francis, A. L., chemist, Wrexham
 Green, F., London
 Harris, A. T., London
 Hayden, E., Great Yarmouth
 Heywood, E. A., Leeds
 Holland, C. L., Birkenhead
 Horsey, F. S., chemist, London
 Hunt, J. F., Hull
 Jameson, W. R., London
 Knaption, E., London
 *Laurance, Lionel, London
 Lyon, H. M., London
 Mackinney, F. W., London
 Maker, T. M., Harrogate

* Passed with distinction.

Marlow, J. H., Harrogate
 Marsden, R. A., Preston
 Moles, R. S., London
 Mumford, L., London
 Overstall, J., London
 *Overstall, W. T., London
 Oxbrow, A. W., Norwich
 Palmer, S. W., London
 Percy, W., London
 Ranken, R., Kilmarnock, N.B.
 Read, F. J., Bradford
 Ritson, F., chemist, Carlisle
 Rossiter, A. T., Canterbury
 Selby, J., Nottingham
 Smith, E. T., Huntingdon
 Spiegelhalter, E. K., Malton
 Tilley, J., Manchester
 Troulan, Miss F. S., Torquay
 *Truscott, R. I., Tenby
 Turner, A. R., Crewe
 Turtle, W. G., chemist, Chatham
 Walmsley, A., Northampton
 Ward, J., Kirkham
 Werner, C. H. F., Australia
 Wood, A. A., Liverpool
 *Wood, A. E., London
 Wood, J. J., Liverpool
 Wood, W. R., London
 Woolley, S. W., chemist, London
 †Wright, T. H., chemist, Leeds
 Young, J. B., Newcastle-on-Tyne

† To be examined in full syllabus.

This was the first examination conducted by the Worshipful Company of Spectacle Makers, in accordance with their new scheme for the registration of dealers in optical goods. The *viva voce* examination on the first and second days was conducted by Dr. Lindsay Johnson, Professor Silvanus Thompson, and Mr. George Paxton, who examined the candidates in visual optics and practical lens work. This part of the examination occupied about twenty minutes in the case of each candidate. The time allowed for the written examination on November 3 was two hours. The questions set are given below, together with model answers furnished by Mr. Lionel Laurance, instructor in visual optics at the classes conducted by the Spectacle Makers' Company.

Question No. 1.

How would you determine the focal length of a simple bi-convex lens with faces of equal curvature? Give all the practical methods you know of.

ANSWER.

1. By means of a spherometer.
2. By measurement of the distance between the lens and the image on a screen of a luminous object placed at infinity.
3. By measurement of the distance between a flame and its image on a screen, when both are of equal size. The object and its image can only be of the same size when both are equally distant from the lens, and conjugate foci are so situated when the object is in front of the lens at a distance equal to twice the focal distance. Hence the distance between object and image divided by four gives the focal length of the lens. This is the most perfect although the longest method of those given.
4. By neutralising the positive refractive power with a negative lens of known focal length, that of the latter is equal to that of the former.

There are also other methods of great accuracy employed by scientific instrument makers.

Question No. 2.

In what way is the position of the principal focus of a lens dependent upon the choice of the curvatures? Illustrate your answer by reference to the positions of the front and back foci of a plano-convex lens of +20 D. Does it matter which surface you turn towards the source of light as regards definition?

ANSWER.

The position of the principal focus depends on the position of the two nodal points, but it is sufficiently accurate to consider that it depends on the position of the optical centre, and the latter depends on the nature of the two surfaces of the lens.

In a double Cx. lens of equal curvatures the optical centre lies on the principal axis midway between the two surfaces. In an unequally double Cx. lens it lies nearer to the more curved surface. In a meniscus it lies outside the lens.

In a plano-convex lens the distance of the focal point changes as the one or the other surface is exposed to the light. The anterior focal distance is calculated from the first nodal point and the posterior focal distance is calculated from the second nodal point; therefore, these must be located. Now, the first nodal point of a plano-convex lens lies at the apex of the curved surface, and the second lies at a point determined by the thickness of the lens divided by the index of refraction of the glass, which, taking the index as $\frac{3}{2}$, equals two-thirds the thickness of the lens.

A plano-Cx. lens may be considered as a series of rectangular prisms, their bases coinciding with the principal axis, and so that there be a minimum of spherical aberration these imaginary prisms should be in the position of minimum deviation. Then for parallel rays the Cx. surface should be exposed to the light, and for rays diverging from the principal focus the plano surface should be so exposed.

Question No. 3.

Are two lenses, say, for example, a + 3 D S and a + 5 D S (placed together behind one another in a trial frame), exactly equivalent to a single lens (in this case a + 8 D S) whose power is numerically equal to the sum of their separate powers? If not, why not?

ANSWER.

No. Two lenses added together cannot be exactly equal to the sum of their individual powers; the interval between them even if their centres be in actual contact prevents it.

Provided that the lens nearer to the eye be stationary, and if the + 5 D be in front, the combined powers would be equal to 8 D + the value of the distance, d , between the lenses. Let the interval be, say, 5 Mm., then:—

$$\begin{array}{r} \frac{1000}{5} = 200 \\ 200 - 5 = 195 \\ \frac{1000}{195} = 5.125, \text{ and} \\ 5.125 + 3 = 8.125 \text{ D} \end{array}$$

Question No. 4.

What proofs are there that the human eye is not achromatic? What kind of combination of lenses would be required to correct its chromatic aberration?

ANSWER.

Practically speaking the eye is achromatic, although not so actually. A proof very frequently met with is the perception of coloured fringes to the astigmatic bars, the rays from which are not in focus at the retina. This proves first, the chromatism of the eye, secondly, that it is only noted under exceptional circumstance.

The most notable proof is that of the chromatic disc which has the property of excluding the green ray and transmitting only the red and violet rays, the latter appearing as deep blue.

If a circle of flame—say, an Argand burner, covered by a screen, and having a round aperture of about the size of a shilling—be looked at through the chromatic disc by an ametrope, the light is seen blue with red border; or *vice versa*. Even in emmetropia the flame is seen as a light purple, a mixture of red and blue, with a distinctly blue border. The violet rays come to a focus in the vitreous and diverge impinging on the retina in a wider area than that occupied by the red rays which have reached the retina before coming to a focus. Hence the blue border. It is impossible with any single lens added to the eye to do away with the deeply coloured border, although it can be changed from blue to red.

Another proof is that a myope sees better through a red glass and worse through a blue glass. A hypermetrope sees better through a blue and worse through a red.

If red and green letters or lights be looked at, they do not appear equally distant.

If black bars against bright light be looked at, the lower half of pupil being occluded, coloured fringes to the bars will be seen.

For the correction of the chromatism in an emmetropic eye there is needed a negatively chromatic lens of no refractive power. For this purpose, I should think that a combination of pebble Cx. and crown Cc., both of the same radius of curvature, would serve.

Pebble has an index of refraction of 1.545 and an index of dispersion of .014. Crown glass has an index of refraction of 1.54 and an index of dispersion of .018. So while the indices of refraction are the same, the indices of dispersion vary, and solar rays converged by the pebble Cx and dispersed positively would after divergent refraction by the Crown Cc. emerge parallel as regards the mean ray, but slightly divergent as regards the violet ray, and slightly convergent as regards the red ray. The negative chromatism of the lens would correct the positive chromatism of the eye so that all the rays would unite in a single focus at the retina.

Pebble and crown glass should be selected in preference to crown and flint glass, because the former pair have practically equal indices of refraction, and so can be of equal radii of curvature, and the difference in their indices of dispersion is not so marked as between crown and flint glass.

Question No. 5.

A person requires for the R eye only - 6 DS for distance and - 3 DS for reading, but only wants one pair of spectacles. State the various ways in which this can be managed. Which method do you prefer?

ANSWER.

There is seemingly only one eye that has vision; therefore:—

1. A frame having - 6 in the one eye and - 3 in the other, and with an X bridge or perhaps a K bridge and with straight sides. This frame can be reversed so as to bring as required either lens in front of the one eye which has sight.

2. A frame with lenses as above and with a straight C or arch bridge, and with curled sides on reversible joints. This frame can be turned either side to the front.

3. A frame in the form of a D eye spectacle with lenses of - 6 for distance, and with + 3 in the flaps or wings, which can be brought forward in front of the distance glasses when required.

There are several other forms of frames which might be utilised for the same purpose.

The wording of the question excludes eye-glasses, pincenez, or grab fronts.

4. By means of split bi-focal lenses, - 6 above and - 3 below.

5. By means of perfection bi-focals, the large lenses being - 6 and the small ones inserted below being - 3, or the larger lenses - 3 and - 6 being inserted above.

6. By means of cement bi-focals, the whole lenses being - 6 and the added segments being of the power needed to reduce the - 6 to - 3. The segments would vary, as the - 6 are bi-concave, plano-concave, or periscopic concave; also the original lenses might be plano-Cc. - 3, and segments of - 3 added above.

7. By means of a solid bi-focal, the two curvatures being ground on the same piece of glass.

8. Also, perhaps, by grinding flat half of one surface of a bi-concave - 6. This would reduce - 6 to - 3.

I prefer No. 6 method, the cement bi-focal of the first form.

Question No. 6.

A prescription is given you as follows: - 3 DC axis horizontal \ominus + 1.5 DC axis vertical R and L. State the different methods of working such a lens and give reason for your choice of curves.

ANSWER.

1. - 3 D Cyl. Axis Hor. \ominus + 1.50 Cyl. Axis Ver.
2. - 3 D Sph. \ominus + 4.50 Cyl. Axis Ver.
3. + 1.50 Sph. \ominus - 4.50 Cyl. Axis Hor.
4. A toric lens—

$$\begin{array}{r} \text{On the one side} \quad - \quad 4 \text{ Sph.} \\ \text{On the other side} \quad + \quad 1 \text{ Cyl. Axis Hor.} \\ \quad \quad \quad \quad \quad \quad + \quad 5.50 \text{ Cyl. Axis Ver.} \end{array}$$

Or by other similar combinations.

I prefer for lightness and thinness No. 3 form, but if eyes or lashes were prominent, or nose flat, I would prefer No. 2, as with it I could obtain a closer location of the lenses to the eyes. No. 4 would also serve this purpose well, but the form is not in general use, and is expensive.

Question No. 7.

What are pebble lenses? State the relative advantages of pebbles over glass, or *vice versa*. How can you distinguish between them?

ANSWER.

Lenses made of rock crystal.

Advantages of pebble :—

It does not scratch.

It has a lower index of dispersion.

Disadvantages of pebble :—

It is more brittle.

It has a lower index of refraction than flint glass (about the same as crown).

It possesses double refraction.

To distinguish :—

1. By the polariscope. Light is transmitted by a pebble placed between two plates of tourmaline cut parallel to their axes and placed at right angles to each other; it is not transmitted by glass.

2. By a file. No impression can be made on pebble.

3. By contact with the tongue, pebble feels colder.

Also to a certain extent by the ring and colour, but these are not very definite or exact.

Question No. 8.

An emmetrope, aged 60, has had his lens removed for cataract. What glass would you give for reading, and what for distant vision? Could he see clearly with either glass at a metre?

ANSWER.

I would give for distance about +10 D Sph. placed at 15 Mm. from the cornea for distance, and +13 D for reading at 33 Cm. If visual acuity be lowered I would give $\frac{1}{2}$ or 1 D stronger for reading at respectively 28 or 25 Cm.

He could see clearly with neither glass at 1 metre, but by moving the distance lens out further from the eye to, say, 25 Mm., he would be enabled to see at 1 metre distance.

Question No. 9.

A boy aged 12 has vision = 6/9, but with a concave lens of 1.25 he has a vision = 6/6. What test would you employ to ascertain the nature of his defect?

ANSWER.

This might be a case of astigmatism or it might be spasm of accommodation. For the one, I should use the astigmatic chart, for the other, the near point measure. It cannot be M of 1.25 D because in that degree of M V cannot be equal to 6/9, in fact, it can safely be said that it is not M at all. It is a case, most likely, of simple myopic or of simple hypermetropic or even of compound hypermetropic astigmatism, and if not it is spasm of accommodation, and it is very likely, indeed, that there are both the refractive error and the accommodative trouble. The data are insufficient for just estimation, but generally I should think it is not a case for an optician.

Question No. 10.

An oculist has prescribed for a man, aged 60, for distant sight :

R	- 1.5 DS	L	- 4 DS
	- 2 DC Axis Hor.		- 0.75 DC Axis 45.

He requires glasses for about 15 or 16 in. reading distance; write the formula.

ANSWER.

Age 60. Amplitude of accommodation is 1 D. Of this I reckon half is available for constant near work.

For reading at 16 in. additional refractive power of 2.50 D is needed, and the accommodation providing .50 D the lenses to be added for close work must be +2 D, therefore the R for reading is

R	+ 0.50 D Sph.
	- 2.00 D Cyl. Axis Hor.
	- 2.00 D Sph.
L	- 0.75 D Cyl. Axis 45°

Some might prefer for the right eye :—

	- 1.50 D Sph.
	+ 2.00 D Cyl. Axis Vert.

Question No. 11.

A youth, aged 12, sees best with — 14 D S R and L. Would you give him this correction on your own responsibility, and if not state your reasons?

ANSWER.

This is a serious condition, as high myopia is a disease, and it is especially serious when found in a child, because the tendency to increase is great in proportion to the youth of the myope.

As an optician I should not think of supplying glasses except under the prescription of an oculist. The case requires medical and hygienic treatment as much as, or more than, optical correction.

Question No. 12.

A boy aged 10 has vision = 20/40, and with — 2.5 DS he sees 20/30, but on testing, his P.P. is found to be at 12 Cm. What is probably his defect? and give your reason.

ANSWER.

At 10 years of age amplitude of accommodation is 14 D, and the P.P. is at 7 Cm.

In M. 2.50 D at this age it should be at $\frac{100}{14 + 2.50} = 6$ Cm.,

but here it is found to be at 12 Cm. showing $\frac{100}{12} = 8.50$ D,

and $14 - 8.50 = 5.50$ D of hypermetropia. The M. is false and not real, and there is spasm of accommodation amounting to 8 D and causing 5.50 D hypermetropia to appear as 2.50 D myopia.

It could not require — 2.50 D Sph. to improve V from 20/40 to 20/30, and indeed in M of 2.50 D vision is equal to at best 20/200.

The case requires treatment with atropine, and advice to this effect should be given by the optician, so that the needed medical treatment be obtained.

Question No. 13.

What do you understand by the terms "Amplitude of Accommodation" and "Range of Accommodation"? Illustrate these terms in the case of an emmetrope aged 20, a myope of 3 DS, aged 20, and of a hypermetrope of 3 DS of the same age. Where would the P.P. be situated in each case?

ANSWER.

Amplitude of accommodation is the total accommodative power possessed by the eye. It varies with age, being greatest in youth and gradually decreasing. Amplitude is expressed in diopters.

Range of accommodation is the distance over which accommodation is exerted. That is, the distance between the P.P. and the P.R. The former being the nearest place to the eye at which any accommodation (the smallest quantity) is exerted, and the latter being the nearest place to the eye for which it can be adjusted, this being where the total amplitude of accommodation is exerted. Range is expressed in Cm. or inches.

The amplitude is the same in all the cases mentioned, viz., 10 D, as it depends (except in high M.) on age, but the range varies considerably, as the P.P. and the P.R. vary, both being more distant in hypermetropia and nearer in myopia than in emmetropia.

In Em. 20 years of age.

P.P. is at $\frac{100}{10} = 10$ Cm., and the P.R. is at (infinity),

In H. 3 D at 20 years of age.

P.P. is at $\frac{100}{10 - 3} = 14$ Cm., and the P.R. is at (infinity),

it being brought there by the exertion of 3 D accommodation for distance.

In M. 3 D at 20 years of age.

P.P. is at $\frac{100}{10 + 3} = 8$ Cm. (approx.), and the P.R. is at

$\frac{100}{3} = 33$ Cm.

With a full correction, the range becomes in all cases of ametropia of low degree the same as in emmetropia.

Question No. 14.

Explain the importance of having spectacle lenses correctly centred. What would (roughly speaking) be the effect on a customer of having his spectacle lenses of — 10 DS, each decentred 4 m.m. inwards, supposing that he had binocular vision?

ANSWER.

If lenses be not centred they act as if prisms were added to them and they cause heterophoria, and they may be the cause of strabismus and diplopia if strong enough and sufficiently decentred.

Cx. decentred inward and Cc. decentred outward act as prisms bases in and throw strain on the external recti.

Cx. decentred outward and Cc. decentred inward act as prisms bases out and throw strain on the recti.

— 10 D. Sph. decentred 4 Mm. has a prismatic effect (roughly) of

$$10 \times 4$$

$$\frac{\quad}{10} = 40 \text{ base out each eye.}$$

They would, therefore, cause exophoria, but as in M. of 10 D. there is almost certainly exophoria already, it is very probable that the decentration of the lenses would bring about a divergent strabismus and crossed diplopia.

NEW REMEDIES.

CREOSOTE IN CHRONIC CONSTIPATION.—Commencing with doses of single drops increased to 7 or 8 drops in a glass of milk or beer after lunch and dinner, Vladimir (*Semaine médicale*) has found creosote to be a valuable remedy in chronic constipation. Its use is not accompanied by any pain or discomfort, and it appears to act by neutralising an intestinal toxine which causes the malady by paralysing the digestive canal.—*Bull. Gén. de Thérap.*, cxxxv., 15.

LINIMENTUM EXSICANS, PICK.—Lupp recommends the following method of preparation, thus:—Take tragacanth, coarsely divided, 12, and cover with 15 of glycerin; rub down well with a pestle, and add distilled water, with continual stirring, in portions of 100, until the whole amounts to 500 grammes. If the liniment is used with lanoline, heat the mixture until the lanoline melts, and stir until cold.—*Zeit. d. allg. oest. Apoth. Ver.*, li., 525.

METALLIC IODINE IN SYPHILIS.—Bouveyron (*Bullet. Med.*) recommends the treatment of syphilis with metallic iodine, which is prescribed thus: Iodine, 1 gramme; potassium iodide, sufficient to dissolve; glycerin, 5 to 10 grammes; citric acid, 5 grammes; simple syrup, to 1 litre. Two teaspoonfuls are taken to commence with, the dose being gradually increased to 6 or 9 teaspoonfuls. These are taken on an empty stomach half an hour before a meal.—*Bull. Gén. de Thérap.*, cxxxv., 799.

PHENOSAL AND PYROSAL.—Phenosal is the aceto-salicylic ester of phenetidine and occurs in white needles, sparingly soluble in water. When taken, it is split up into its components, and it acts as an antipyretic. Pyrosal is the corresponding salt of antipyrin; in each case the secondary action of both the salicylic acid and the base is stated to be modified.—*Pharm. Centralh.*, xxxix., 621.

MERCURIAL OINTMENT INTERNALLY IN SYPHILIS.—The treatment of syphilis by the internal administration of mercurial ointment finds many followers in continental practice. It is stated that the metal is better absorbed in this form. L. Silberstein prescribes it in pills thus: Mercurial ointment with lanolin basis, 4.5 grammes; powdered liquorice root, 5 grammes; glycerin, 5 drops; mucilage of acacia q.s. to mass. Divide into 60 pills; each pill contains 0.025 gramme of mercury.—*Therap. Monats.*, xii., 397.

XEROFORM IN CORNEAL ULCER.—Marcinowski finds that xeroform is much preferable to iodoform in the treatment of corneal ulcer. Having succeeded with xeroform in a case which had previously given bad results with iodoform, he has since relied solely upon the former, with uniformly good results, both in ulcerations, and in dressings for corneal injuries. Wounds heal quickly under its influence without leaving a scar.—*Therap. Monats.*, xii., 38.

SELECTED PRACTICAL FORMULÆ.

AROMATIC SACCHARIN SOLUTION.

Refined saccharin, 2.5; vanilline, 5, are dissolved in alcohol (90 per cent.), 95, and Ceylon cinnamon oil, 2, added.—*Pharm. Cent.*, xxxix., 460.

MOUSE AND RAT POISON.

Lard, 500 grammes; salicylic acid, 5 grammes; one fried onion; beef tallow, 50 grammes to 100 grammes; barium carbonate, 500 grammes, in 20 per cent. solution of verdigris; ammonia, 50 grammes. The onion is cut into slices, which are fried to a dark brown in the fat. Salicylic acid is added and the mixture stirred until partly congealed. The barium carbonate is now added, and finally the solution of verdigris.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 360, after *Sudd. Apoth. Ztg.*

CAPSICUM OPODELDOC.

Alcohol (90 per cent.), 40; tinct. capsic., 10; castile soap, 6; camphor, 4; solution of ammonia, 2; menthol, 1; ol. spilanth. olerac., 1, are dissolved together in the cold and filled into tubes.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 35, after *Bull. f. Ph.*

PILOCARPINE AND QUININE HAIRWASH.

Pilocarpine hydrochloride, 6; quinine hydrochloride, 12; tincture of cantharides, 100; Cologne water, 200; distilled water to produce 1000. Digest together for twenty-four hours then filter.

PILOCARPINE AND QUININE POMADE.

Pilocarpine hydrochloride, 2; quinine hydrochloride, 4; precipitated sulphur, 10; balsam of Peru, 20; beef marrow, 500. Mix.—*Pharm. Post*, xxxi., 343.

NON-POISONOUS WEED-KILLER.

A solution of calcium sulphide is stated to be an effectual weed-killer, both for weeds on paths and on the beds. Six pounds of recently-slaked lime and 1 pound of flowers of sulphur are boiled with 17 gallons of water for some time. The mixture is diluted with an equal volume of water before using, and sprinkled freely over the weeds.—*Pharm. Zeit.*, xliii., 607.

LAC VARNISH FOR ELECTRIC CELLS.

(a) Resin, 80; gutta-percha, 20; boiled oil, 25; melt together. Or (b) Burgundy pitch, 150; gutta-percha, 35; pumice stone powder, 25. First melt the gutta-percha, then add the powder and lastly the resin. After applying, a smooth surface is obtained with a hot iron. For small cells a good lac is obtained by macerating broken fragments of celluloid in acetone.—*Eng. and Min. Journ.*, lxx., 699.

TOOTH POWDER FOR DISCOLOURED ENAMEL.

Potassium chlorate, 1; powdered boric acid, 2; magnesium carbonate, 2; prepared chalk, 2. Flavour with peppermint or any desired perfume.—*Odontology*, through *Zahn. Rundsch.*, vii., 4703.

FOR CHAPPED HANDS.

Glycerin of tragacanth, 480; boric acid, 36; zinc sulphocarbonate, 4; glycerin, 150; otto of rose, q.s.—*Zeits. des alg. oest. Apoth. Ver.*, lii., 518.

RED STAINS FOR WOOD.

Pernambuco Wood Stain.—The wood to be stained is first heated for sixty to ninety minutes with a 12½ per cent. alum solution, then dried for twenty hours, and finally coloured with an alcoholic liquid extract of Pernambuco wood. **Brazil Wood Stain.**—The stain is prepared by digesting Brazil wood chips, 16; and potassium carbonate, 2; in water, 64; for four days. The liquid thus obtained is applied to the wood to be coloured in successive portions until the desired depth of tone is reached; before the last lot of stain is put on, the coloured surface must be gone over with a 20 per cent. solution of alum. **Cochineal Stain.**—Boil together cochineal, 1; cream of tartar, 2; and water, 20; dissolve zinc, 17; in hydrochloric acid, 8. Add the zinc chloride solution to the boiling cochineal liquor, and add sufficient ammonia to produce a good carmine colour. The stain thus obtained is applied direct to the wood.—*Pharm. Centralh.*, xxxix., 611, after *Neueste Erfind. u. Erfahr.*

DENTAL NOTES.

REFINING GOLD SCRAPS.

Experience teaches most dentists that it pays them to refine their gold scraps rather than rely upon the assayer. The scraps should be dissolved in a small quantity of nitro-muriatic acid—warming hastens the solution—the solution should then be diluted with about three times its volume of water and nearly neutralised by adding a small quantity of sodium carbonate. The solution should remain slightly acid or the gold will be precipitated, in that case redissolve by adding a few drops of nitro-muriatic acid. Filter the solution, washing it through with water, then add slowly while stirring a concentrated solution of ferric sulphate, acidulated with a little sulphuric acid. Set the solution aside for twenty-four hours, so that all the gold is precipitated, then decant the liquor through filter paper to catch any particles of floating gold, wash the precipitate out of the vessel into the filter paper, roll up the paper and fuse with plenty of flux.

USEFUL HINTS.

Oxide of zinc for the final polishing of gold plates gives a beautiful polish, and does not soil the hands. The true working qualities of cohesive gold are best obtained by heating it on a sheet of mica. Direct heating in the flame of a spirit lamp injures its cohesiveness. When filling an incisor or cuspid that has a thin labial wall with cement or gutta percha, line the wall with four thicknesses of No. 4 gold-foil, it gives the tooth when finished a very nice appearance. In waxing up, oil the surface of wax before using blowpipe to give final finish to case.

THIN RIM DISCS.

Thin rim discs can be made at a moment's notice by placing a disc on the mandril in the engine and revolving it rapidly, holding an instrument against the part nearest the mandril and gradually passing it outwards to about an eighth of an inch of the edge. This wears off the grit on the central surface, but leaves fresh grit on the rim.—*Items of Interest.*

DURABILITY OF OSTEO FILLINGS.

The durability of an osteo filling is greatly increased by condensing it thoroughly by pressure while it is setting. This is best done with a smooth round-headed hand burnisher, kneading it, so to speak, into the cavity. The rubber dam should be used, and as much care taken in shaping and finishing the cavity as for a gold filling. A stopping so treated with melted paraffin flowed over, using the hot air syringe to keep it melted while it soaks into the cement will be found (the conditions of the mouth being favourable) to last for many years, even in the most exposed positions. It is as remarkable as it is true that the walls of carefully prepared cavities that have been filled with osteo seldom show any signs of re-occurring decay, although the stopping may be worn away considerably below the enamel edge.

REPAIRING THE FACE.

It sometimes comes within the province of the dentist to restore portions of the face that have been lost. What appears to be an ingenious and practical method of making an artificial nose is copied by the *Dental Record* from an article by Herr Bruck of Breslau, in the *Monatsschrift*. Having obtained a cast of the remains of the nose and of the surrounding parts, a model of a suitable nose is carved to this and duplicated in zinc or lead. This is painted over with gum arabic and then a layer of damp kid leather is smoothly laid on. A piece of white transparent celluloid, 1 to 2 millimetres in thickness, is softened in acetone and is then carefully pressed to shape on the model as prepared. When the celluloid has hardened the latter can be readily torn away from it. But should the celluloid have become separated from the model, because of the latter drying, it can readily be pressed into place if it be softened by slightly warming the model. When cold the celluloid nose is trimmed to shape, its edges are trimmed and the surface gloss is removed by rubbing it over with powdered pumice. Gold springs are attached to the portion between the anterior nares, these carry small ivory plates which grip the remains of the septum. The springs are fastened to the nose by celluloid dissolved in acetone. When finished the nose is handed to an artist, who paints its under surface to match the complexion of the face. Herr Bruck claims that the colour seen through the celluloid produces a most natural appearance.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

THE CHIEF PROBLEM FOR CHEMISTS.

Sir,—Your editorial article of to-day points to the necessity of combination on the part of chemists with the Pharmaceutical Society, to strengthen the hands of the Council to obtain more pharmaceutical legislation. If the Council cannot obtain more powers than the last amendment of the Act confers I do not think it will need—nor will it get—the disaffected ones to join. As an earnest of the Society's wishes to benefit chemists and druggists, I think it is time they sought powers to license and control the keeping open of chemists' businesses, and as the intention or spirit of the 1868 Act was to have shops kept open only by qualified men, to see that no one carries on such business either for himself or in partnership with any one but a qualified chemist. The way businesses change hands from one person to another without the Society's "ken" has long been a wonder to me, and it is evident that many proprietors give over their businesses to others without returning their certificates of membership or diplomas, and those who purchase may in some instances be trading upon the reputation of a qualified man without the Society's knowledge. This is one reason why an old-established business is of so much value to the purchaser, but still I hold the Society in all cases should be cognisant of such sale, and I think licensing would effect that purpose. Now, sir! if the Society will seek the power to license, and only recognise the right of each individual to carry on business for himself, or in partnership with any other qualified persons, and get the legal authorities to back them, as it seems evident they are willing to, then we may hope to do away with this system of company pharmacy. There also should be licensed assistants as well as proprietors, who should be under the control of the Society, and hold situations under the eye, as it were, of the secretary (local), just as curates are licensed to curacies. If this were strictly carried out "The Widow's Clause" need be no obstacle. By this system of licence, the Society should know if a deceased system of licence, the Society should know if a deceased licensee was married, and if by will he desired his widow to carry on business solely for her benefit, and if so, permission should be granted to her to carry on the same only during her widowhood by a duly qualified licensed assistant, whose name should appear as the manager, and whose appointment and vacation of the same should be ratified by the local secretary or the Society. This licence should be paid for by the widow and renewed yearly, and due notification of intended change of state should be given to the Society so that they might revoke such licence and appointment. This to my idea is the only practical solution of the company pharmacy question, and should be set about ere the bulk of those in business convert their establishments into company pharmacies.

Torquay, November 19, 1898.

WM. JNO. RAWLING.

Sir,—The editorial remarks made in the two last numbers of the *Pharmaceutical Journal*, as well as the speech made by the President (p. 532), give hope that with an energetic and decided policy, combined with an increased support of the Society by the trade generally, there may yet be a future for pharmacy. I remember it was said in the House of Commons last year that before the Pharmaceutical Society could expect to get greater privileges it must put its own house in order. The point I wish to emphasise now is the folly of expecting to get the principle of proprietors' qualification recognised as long as the so-called "Widows' Clause" stands. We may close our eyes to it, but our opponents will not be slow to point out that that clause legalises the very thing we are fighting against. What is the difference between the unqualified widow or executor and the unqualified corporation? In my judgment the clause should limit the time to a period (say a year) necessary to wind up the estate of the deceased chemist. I am aware of the apparent injustice of this suggestion, but I am inclined to think the injustice and hardship are more apparent than real, for it seems to me that the estate would in the majority of cases be better off if the business were sold at once. I know of several cases where a great loss has ultimately been sustained, and of none where the arrangement has been a success. But, however that may be, the only logical course to pursue, in the event of attempting legislation, is to make up our minds that the widows' clause is one of the things we shall have to abandon.

Bristol, November 19, 1898.

B. KEEN (15/30).

LOYALTY TO THE CRAFT.

Sir,—If C. P. will be good enough to communicate with me privately, or through the President of the Pharmaceutical Society, I shall be very glad to furnish him with the information he desires.

40, Sankey Street, Warrington,
November 21, 1898.

J. RYMER YOUNG.

Sir,—In your issue of to-day C. P. says, "How about that fairly large (and dishonest) class who put up 'Drug Stores' outside their shops and charge the old-fashioned prices?" How about the well-known drug company who puts up perfumes in a bottle looking like a large 2-oz. if not more, but which, filled to the stopper, holds only 10 drachms, and charges it store price 2s. 6d., also enemas 5s. 6d., which can be obtained anywhere for 3s. 6d. or at most 4s.? Oh the gullibility of the British public.

November 19, 1898.

BELGRAVIA (155/10).

Sir,—I have read the *Pharmaceutical Journal* regularly for some sixteen years now, and have been frequently amused with the difference of opinions expressed from time to time by correspondents on the inexhaustible "stores" question. The enthusiastic exponents of professional pharmacy entreat all the assistants connected with the drug trade to remain "Loyal to the craft." I do not dispute for a moment but that chemists would find their businesses greatly improve if all the qualified men could be induced not to sell their services to unqualified companies, but then so long as this is a free country and the law is respected a qualified man is at liberty to engage with whom he pleases, and he naturally chooses the field of labour which pays him best. In the same way you will always find smart business chemists buy their goods from sources which pay them best, and under ordinary circumstances an active chemist like a skilled trader adopts the principle of buying in the cheapest and selling in the dearest market, no matter whether the wholesale dealer or agent is qualified or not. There is another more powerful factor at work than the assistants who engage themselves to the stores, but which is sometimes lost sight of. Perhaps it will surprise a good many of your readers to know that most if not all the high-class leading houses in London do a lot of their business with stores. Many houses supply their specialties on wholesale terms to any limited company or firm who will take goods to the extent of their wholesale limit, and as business men they execute such orders for prompt cash and send them to their destination carriage paid or otherwise, according to their terms. Now what I contend is this: The man who sells his services to the stores is in no worse position than those leaders of pharmacy who sell their goods in this way. The only difference is that the assistant makes all his living by this means, while the high-class houses make only part of theirs, but the principle remains the same. In the event of supplies being cut off from the stores by the makers, as occasionally happens when the P.A.T.A. prices are departed from, it is only fair to state that company traders can

always obtain any quantity of proprietary articles of any firm from patent medicine houses at a trifle over wholesale cost. In order for a large company to be highly successful the ship must be steered with one brain power only, and the systems of carrying on business must be those of the utmost simplicity and business-like uniformity, while the quality of all goods supplied by the branches must be of the highest standard possible. In any case the chemist, firm, or company with energy, method, and tact will always succeed *omnibus paribus*, but without those qualities no one can reasonably expect to get a living during those times of keen competition from which every trader more or less suffers.

November 19, 1898.

KING'S HEATH (155/11).

SUGGESTIONS FOR A MORE FORWARD POLICY.

Sir,—Almost a clean sweep of the present Council should be made at the next election. One can almost perceive the broom. Radical change is necessary, a forward policy pursued, dwelling on the past forgotten, the dry but respected bones of our founders left buried and exhumed no more. Our present Council contains some pre-eminent men. Keep these, but the nonentities let us once and forever brush aside. Our future policy should be "war to the knife" with companies and no half-hearted triflings. This cancer must be extirpated. Let all chemists see to it. Chemists of Great Britain between now and next May should select men capable of securing the rights for which we have studied and paid, and willing to make the requisite effort. To increase the favour that the Society ought to enjoy amongst our craft it has been suggested that it should throw open its London premises, like its Edinburgh house, to all chemists, supplying suitable accommodation for purposes of business and social intercourse, and so keeping the immediate interests of our craft in sight. By so doing many who are not now of the Society would become its members. Transform this head centre into a kind of ark where our brethren may rest and become familiar with the Society's ways. There is nothing more conducive to a strengthening of the bond which should bind us together than to have a spot where all may meet freely and fraternally to discuss topics of mutual interest. Asperities would be softened down, and many chemists would be drawn from their objectionable ways, thus affording a fair and reasonable mode of living for us all. In the past without question the poor remuneration of assistants, when employers were having their fill of good things, has been a potent factor in the present chaos. Our assistants should command a higher rate of pay, commensurate with the position they hold in the community, and as compensation for their expenditure of money, time, and brains for their studies. Loyalty would then step in and companies be crushed, by the assistance they now receive from qualified men being withheld.

London, November 17, 1893.

DUM SPIRO SPERO (155/8).

THE IMPORTATION OF COLONIAL PRODUCE.

Sir,—I take the opportunity offered by the extensive colonial and foreign circulation of your Journal to direct the attention of pharmacists and others who reside abroad or in the British Colonies to a few facts which bear an important relation to the sale of colonial products in this country.

1. *Drugs*.—It is absolutely necessary, in order to avoid loss, to be well informed as to the state of the large European markets, especially London, Liverpool, Hamburg, and New York, etc. As an instance I may point to the genuine or Pernambuco jaborandi, *Pilocarpus jaborandi*, which is now, I am told, realising 7s or 8s. per lb., against 1s. 6d. per lb. for the Rio Janeiro jaborandi, *P. pinnatifolium*; Pernambuco jaborandi, which is now the only official kind, having practically disappeared from the market. The reason of this is that, when the genuine jaborandi was last sent to this country, the market was overstocked with the Rio Janeiro kind, and there were no buyers for the genuine, except at a price that entailed a decided loss on the exporters. Consequently, the exporters having lost money, sent no more, and the drug gets scarcer and scarcer and the price goes up. Drugs are not like provisions. There is not room for an unlimited supply, and the export to European markets, if it is not to entail loss upon the producer and exporter, must bear a direct relation to the state of the market. But it is to the interest of the buyer to buy cheaply, and early information is not likely to be obtainable except through colonial agents in Europe, paid to look after the interests of their respective colonies.

2. *New Vegetable Remedies*.—Frequently specimens of native remedies are sent home on speculation, without any details as to

their botanical source and in very small quantities. Under these circumstances it is useless to hope that they will receive attention. It requires at least 14 lb. or 28 lb. of material to ascertain if any definite active principle is present, and unless the drug possesses decided properties and differs from other drugs already in use in its remedial effects, it is not likely to be experimented with. Thus, pure bitters, simple purgatives, or emetics are not needed; but remedies that are known to be actually of service in skin diseases, malarial fevers, or zymotic diseases (and which do not owe their properties to the hot water in which they are administered), might receive a trial if sent in sufficient quantity and if a portion of the plant having leaves, flower, and fruit be sent with them for identification. Medical men are chary of trying remedies of which nothing but the native name and use is known. It may, therefore, be taken as a rule that not less than 28 lb. to 1 cwt. is worth sending for a trial.

3. *Drugs other than Medicines.*—Gums, resins, oils, fats, dye woods, tanning materials, and other economic products, if sent over in the form of samples of 14 lb. or more, should be sent with full information as to possible regularity of supply, and uniformity, or otherwise, of quality. Thus, on offering a new fat or oil to a soap boiler, the first inquiry will be: "Can I get this by the ton? and is there a regular supply to be had?" It will not pay me to introduce a new article to the public and when a demand is created to find there is no supply." With respect to gums, it should be recognised that it pays the exporter to sort the gum into qualities where labour is cheap; a uniform white gum fetching a much better price in proportion than a mixed or dirty product.

4. *Packing.*—Doubtless in tropical climates there is some difficulty in drying drugs properly, so as to avoid mouldiness. It must be recognised, however, that the value depends very largely on proper drying. There should be no difficulty in drying many drugs under the roof of a dwelling where the air is hot and a current can be easily established, and where the drug is protected from the heavy dew. Many drugs, such as coca leaves, lose much of their alkaloid if packed before being properly dried. The question of packing fruits also is one of great importance to colonists. Thus, Jamaica oranges packed unassorted in boxes, even if of very superior quality, will fetch only a very inferior price, for the reason that the wholesale fruiterer cannot see inside the barrels, and thus has to buy, so to speak, "a pig in a poke." But oranges that are packed of uniform size and quality, each in tissue paper, a definite number in a box of definite size, with air spaces between the box boards and protected by transverse ribs from crushing, and thus allowing circulation of air, will, he knows, pay him to buy, because he can see something of their state and knows what each contains. In other words, the exporter who wishes to ensure a profitable transaction must first learn the requirements of the market to which he sends them, and must keep himself as well informed as possible as to the state of repletion or depletion of the stock in the market.

London, November 23, 1898.

E. M. HOLMES.

THE POSITION OF PHARMACY.

Sir,—I have read with interest your recent editorials upon pharmaceutical problems, and also the speech of the President of the Society. I agree with you in thinking that it will be difficult to fix upon a suitable course to pursue in regard to legislation. The first step to be taken, however, is to try and rouse chemists throughout the country from the lethargy into which they have fallen. Nothing can be done until they are thoroughly roused. I do not wonder that they have long since lost all heart, and all hope, and are now reduced to a condition in which they can only sit in sackcloth and ashes and mutter "Ichabod." If a trumpet from heaven were to sound in the ears of those men it would scarcely arouse them, and yet they must be led to understand that even an angel from heaven could not help them unless they will make some effort to help themselves. They must, if they are to follow the lead which the President has promised to give, and make their influence felt as a compact force behind him, join the Society, form local associations which are associations in something more than a mere name, read the reports of what is going on in the world of pharmacy, and keep themselves informed upon matters pharmaceutical generally. Our case is not hopeless, and we have everything to gain by dragging the whole circumstances into the light. Our strength lies in this, that we are suffering from a real and very pressing injustice, and not an imaginary one, and in this also lies the weakness of the

enemy, and the enemy knows it. It is easy to humbug the public by publishing false and calumnious statements (in some cases I think actionable) about chemists when only one side of the question is presented, but it will not be so easy to humbug the House of Commons when both sides are presented, and the enemy has already had a taste of this fact. Now, as to method of procedure, I am quite sure that chemists will have nothing to do with a Bill which only forces unqualified men to keep qualified men for their various branches. This would only be legalising what is at present of doubtful legality, and it would be a miserable selling of our posterity in the pharmaceutical world into the most abject and contemptible slavery. Such a Bill would be easy to pass, but we will have nothing to do with it at any price, or else I have quite failed in my attempt to gather the feeling throughout the drug trade. I do not think that it would be a wise act to bring in a Bill for the closing of unqualified companies either. In fact, until we can widen the scope of the Pharmacy Act this is impossible. Through the courtesy of the lay press, I have been enabled to express my opinion upon several occasions, and I shall now do so briefly here. I think our best course is to try and get a measure through the House of Commons, empowering the Pharmaceutical Society to erase from the Register of Chemists the names of those qualified men who cover unqualified men, whether these men exist as individuals or as companies. In order that the opposition from qualified men in stores might be overcome, and also in order that the vested interest question might be toned down, I would have the Bill drawn in such a manner that it would only come into operation, say five years after the date of its passing through Parliament. Such a long period is certainly an objection, but we must allow something to adverse circumstances. I am of opinion, I may say frankly, that such a measure would meet with tremendous opposition from people who are interested and others who are ignorant, but the rascality which has been sheltered under the Companies Acts generally is being so well exposed in influential quarters, that our task would be easier now than it would have been two years ago. Besides, even if we fail the first, and the second, and the third time, we will still be educating the people, and the opposition with which we are sure to meet will educate the people even better than our action. It must not be understood that I am censuring men who have taken situations in stores. I sympathise with these men, knowing as I do that many of them are there much against their inclinations, but with them it has not been a question of more or less pay, but one of work or no work. I can see no good service to be done in inveighing against them, unless we wish to drive the work into the hands of the worst kind of assistants, and leave the best out in the cold. We must bring the work into a legitimate channel, and the question of honour in qualified men will rectify itself. We must also remember that whatever steps we take must be taken under sound legal advice. These unqualified men will leave no legal subterfuge untried in order to wriggle through an Act of Parliament. Indeed, I am informed that in some cases they took legal steps to enable them to wriggle through an Act which has never become law, and in all human probability never will become law. So far as the widening of the scope of the Pharmacy Act goes, I think we may well leave that for future consideration. One thing at a time is enough. Sir, will you allow me to say, in conclusion (and I wish I could shout it in the ear of every chemist in the country), that we have everything to gain by bringing the whole case before the public, both in Parliament and out of it, and the enemy has everything to lose. The front door of honour is ours, the back door is for them.

Dumfries, November 14, 1898.

JAMES REID.

A CORRECTION.

Sir,—On page 534*d* of this week's issue you state that Mr. A. Urwin has taken over my business at 114, Westgate Road, Newcastle-on-Tyne. Now I may tell you this is incorrect. I am still the owner, and have not sold the business, nor am I negotiating for its sale.

Newcastle-on-Tyne, November 19, 1898.

JAMES DAVIDSON.

* * We regret that the erroneous statement referred to by Mr. Davidson should have been published in the Journal and tender him an apology for any inconvenience or annoyance he may have been caused in the matter. Mr. Urwin had written, stating that he was "now in a business" at the address stated, but it appears that he is only manager of the business referred to. [Ed. P. J.]

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

BOTANICAL.—(1) Probably a white form of *Campanula latifolia*. (2) Pink, pale lilac, and white varieties are found in Kent. (3) We are not acquainted with such a book. [Reply to R. D.—19/13.]

CUDBEAR.—This colouring matter is obtained from lichens, including various species of *Roccella*. It may safely be used for the purpose you mention. [Reply to NEMO.—19/11.]

SUPPLY OF MEDICINES CONTAINING POISONS.—He is not entitled to "sell, or keep an open shop for the retailing, dispensing, or compounding poisons," unless he is a registered chemist. [Reply to R. H. R.—19/2.]

LANTERN SLIDES.—Procure water-soluble aniline dyes, make concentrated aqueous solutions of the same, and add a little mucilage of acacia. When the slides are quite dry, varnish them with a thin, transparent spirit varnish. [Reply T. H. D.—19/4.]

BELL SCHOLARSHIP EXAMINATION.—Refer to the special article on the subject in the Journal for September 11, 1897. Full particulars are given there regarding books, the course of study, etc. [Reply to W. J. H. T.—19/21.]

DECOLORISING HONEY.—This is a difficult matter. Try gently warming with granular animal charcoal and filtering while hot through a column of the same substance in a cylindrical percolator. Honey is generally very dark in colour this year. [Reply to W. S.—19/6.]

COLOURING OF EASTON'S SYRUP.—This is due to oxidation. Keep the syrup well corked up in full bottles. Exposure to light will not hinder this preparation from colouring, as it will in the case of syrup of ferrous iodide or bromide. The addition of a little citric acid is sometimes recommended. [Reply to A. K. H.—19/3.]

IODOFORM SUBSTITUTE.—Probably there are more substitutes for iodoform than for any other drug. Look through the "New Remedies" column in our pages during the past three years, and you will easily find a score of such substitutes. You may then select which seem most suitable to your special requirements. [Reply to WHITE ROSE.—19/5.]

ANALYTICAL CHEMIST.—The amount of the premium will vary greatly according to the circumstances of the case. There is no special period, nor is there any necessity for you to pass an examination prior to practising as an analyst. It is an advantage, however, to be connected with the Institute of Chemistry, 30, Bloomsbury Square, W.C., and you should write to the Secretary, at that address, for full particulars regarding the examinations, etc. [Reply to J. R. A.—19/9.]

UNGUENTUM ALTHEÆ.—The following is the formula official in the Codex: Infused oil of fenugreek, 8; yellow wax, 2; resin, 1; Venice turpentine, 1. Melt resin and wax in the oil, add the Venice turpentine, strain and stir until nearly cold. The infused oil of fenugreek is prepared thus: fenugreek, 1; olive oil, 10. Digest on the water bath for two hours with occasional stirring; strain, press and filter. You will note that this contains no althea root; the old London Pharmacopœia (1746) formula, however, is made with "oil of mucilages," which does, thus: Oil of mucilages, 24; beeswax, 6; resin, 3; Venice turpentine, $\frac{1}{2}$. Mix with heat. The oil of mucilages is prepared from fresh marshmallow root, 6; linseed and fenugreek, of each 3; water, 24; olive oil, 48. Gently boil the bruised seeds and root with the hot water for 30 minutes; then add the oil and again boil until the water is evaporated. Allow to settle and decant the oil. [Reply to J. W. H.—18/27.]

CAUSTICUM B. H. P.—Impure solution of calcium hydroxide is formed and subjected to distillation. The distillate may contain traces of ammonia, and may also be expected to contain "homœopathic" quantities of potassium hydroxide carried over mechanically during the operation. [Reply to W. B. W.—19/19.]

SOLUTION OF MENTHOL.—To make the solution strictly according to the particulars you send, you should take 48 grains of menthol and add sufficient olive oil to make 480 grains, or one ounce, Apothecaries' weight. Presumably, however, a fluid ounce of solution is required, and in that case you should take 43.75 grains of menthol and make up to 437.5 grain-measures, or one fluid ounce, with oil. [Reply to R. McC.—19/20.]

CORRECTIONS.

PHARMACEUTICAL PROBLEMS OF TO-DAY.—In the letter by Mr. Barrass, published last week, the word "wrong" in the last line of column 1, page 544, should read "strong." The type was accidentally broken in printing and not properly replaced.

MR. DUNLOP'S PAPER.—At page 529, column 2, line 2, for "phosphate" read "formula." At the same page and column, line 20, for "Martin" read "Martindale." At page 530, column 1, line 3, before "tr. zingib." read "syr. zingib. and the making of."

DISPENSING PROBLEMS AND NOTES.

COCAINE HYDROCHLORIDE IN OINTMENT.

Sir,—Please say how the following prescription should be dispensed?—

℞ Ung. Ac. Borici ʒii.
Lanolini ad ʒii.
Addē Cocain. Hydrochlor. 10 per cent.
M. ft. Unguentum. Sig.: To be used as directed.

"NEMO" (19/7).

NOTE.—As the prescription stands it implies that two drachms of boric acid ointment are to be mixed with 14 drachms of lanolin, and sufficient cocaine hydrochloride added so that the finished ointment shall contain 10 per cent. of the alkaloidal salt. In order to accomplish this we must add to every 9 parts of the ointment and lanolin 1 part of cocaine hydrochloride. Since the two ounces (ʒii.) of ointment weigh 960 grains, 106 $\frac{2}{3}$ grains of the hydrochloride will be necessary. The total weight (1066 $\frac{2}{3}$ grains) of ointment will then contain $\frac{1}{10}$ th its weight, or 10 per cent. of alkaloidal salt. If the cocaine hydrochloride be rubbed carefully with the ointment it will dissolve in the water contained in the lanolin. There is, therefore, no necessity to dissolve the salt in water before mixing. It is not very often that ointments containing 10 per cent. of cocaine are employed; still, they are sometimes, and the correct interpretation of the prescription is the one indicated. It is just possible, however, that the prescriber intended a certain quantity of 10 per cent. solution of cocaine hydrochloride to be added but omitted to name the quantity. If there is anything to suggest the possibility of this, your only plan is to communicate with the prescriber.

ZINC OXIDE IN A LOTION.

Sir,—Is it possible to send out the following lotion perfectly smooth and non-separable?—

℞ Zinci. Oxid. ʒvi.
Glycerini ʒiii.
Ol. Olivæ ʒvi.
Aq. Calcis. ad ʒvi.

M.

How should it be dispensed?

TYRO (18/28).

NOTE.—We have not succeeded in making a non-separable combination according to your prescription. The cause of this is the insolubility, in water or lime water, of the lime soap formed by the partial saponification of the olive oil. Since this is insoluble it cannot form an emulsion with the unsaponified oil, as is the case with the soluble potash, soda, or ammonia soaps. The curdy precipitate of lime soap separates, whatever be the order of mixing, and carries with it the zinc oxide and unsaponified oil, forming greasy masses suspended in the aqueous fluid. If the prescriber is willing to substitute an equivalent quantity of potash, soda, or ammonia, a more presentable product can probably be made.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Lithium Ammonium. When pure lithium is exposed in a tube to the dry vapour of ammonia, according to H. Moissan it quickly assumes a reddish-brown colour, and rapidly liquefies with evolution of considerable heat. The liquid continues to absorb ammonia. When absorption ceases, excess of ammonia is driven off by quickly heating the tube to 70° C. A red-brown solid results, which takes fire on contact with air. If lithium be immersed in liquefied ammonia, and the tube containing it be allowed to gradually revert to normal temperatures, the deep blue liquid at first formed gradually thickens and becomes reddish brown. The constitution of this body, as determined by both synthetical and analytical methods, corresponds with the formula NH_3Li . In contact with water, it is decomposed into lithium hydrate, ammonia, and hydrogen, thus $\text{NH}_3\text{Li} + \text{H}_2\text{O} = \text{NH}_3 + \text{LiHO} + \text{H}$.—*Comptes rendus*, cxxvii., 686.

Lithium Amide. The above lithium ammonium dissolved in pure ammonia is slowly transformed at ordinary temperatures, and rapidly at 63-80° C. into lithium amide, NH_2Li , in the form of brilliant transparent crystals, very slightly soluble in liquefied ammonia.—*Comptes rendus*, cxxvii., 690.

Calcium Ammonium. H. Moissan has also prepared calcium ammonium in a similar manner to that followed for the lithium compound. As soon as calcium comes in contact with ammonia gas, each crystal of the metal assumes a fine yellowish-brown colour, and increases in volume, with a notable rise of temperature. If the temperature be maintained at between 15° and 20° C. only a solid body, $(\text{NH}_3)_4\text{Ca}$, is formed, and no liquefaction takes place. This body takes fire and burns with a brilliant flame in contact with the air. In liquefied ammonia it dissolves, forming a pasty mass, which is not soluble in the liquid. Calcium ammonium is of a deeper bronze colour than the lithium compound. It gradually decomposes at ordinary temperatures, forming crystals of calcium amide, $(\text{NH}_2)_2\text{Ca}$, and evolving hydrogen and ammonia. From the formula for calcium ammonium given above, it would appear that calcium here exerts a tetratomic valency, unless the formula be assumed to be $(\text{NH}_3)_2\text{Ca} + 2\text{NH}_3$, in which the metal preserves its diatomic character. The investigator, however, docs not favour the latter hypothesis, since he has been unable to obtain any intermediate compound of ammonia and calcium containing two molecules of ammonia.—*Comptes rendus*, cxxvii., 690.

New Fruit Pest. There appears to be grounds for fear that a troublesome insect pest, a scale insect *Diaspis amygdali*, Tryon, may have gained a footing in this country. In January of the present year, a consignment of Japanese cherries was imported, and ultimately dispersed over the country; later on it was discovered that many of them were badly infested with this scale. As the insect is quite hardy, and likely to flourish in this country, and is, moreover, very resistant to insecticides and most destructive to fruit trees, all those who happen to have Japanese cherries, presumably of this consignment, are requested to communicate with R. Newstead, Grosvenor Museum, Chester. Figures of the insect are given in *Gard. Chron.*, xiv., 245.

A False Sarsaparilla. Hartwich, of Zurich, calls attention to the occurrence of a false sarsaparilla which outwardly greatly resembles the genuine drug, and shows also a similar anatomical structure, but is distinguished by its constituents. The false drug contains no calcium oxalate and no starch. Instead of the latter sugar is present. The root comes from the Amazon River. Its exact botanical source cannot be definitely fixed, but it is undoubtedly derived from a liliaceous plant.—*Pharm. Ztg.*, lxxvii., 684.

Properties of Calcium. The following properties, characteristic of pure metallic calcium, are recorded by H. Moissan. It melts at 760° C. to a brilliant liquid, which, on cooling, may be cut with a knife, but is less malleable than potassium or sodium. The surface, when perfectly free from nitrogen, is brilliantly white, like silver. The density is 1.85. Its crystals are hexagonal tablets or secondary rhombohedra. It is not acted upon by chlorine in the cold, but combines with it at about 400° C. with incandescence. It does not combine with liquid bromine, but burns in its vapour below a low heat. In oxygen when heated to 300, it burns with a dazzling flame, evolving sufficient heat to melt and volatilise part of the lime produced. It also combines directly, when heated, with sulphur, phosphorus, arsenic, antimony, and bismuth. When heated with lamp-black, it forms calcium carbide below a red heat. A long series of experiments has been conducted to investigate the action of acids on the metal.—*Comptes rendus*, cxxvii., 585.

Solubility of Camphor in Hydrochloric Acid. In the course of their researches on the synthesis of camphor, C. Istrati and A. Zaharia have observed that camphor is markedly soluble in concentrated hydrochloric acid. On adding water a precipitate is formed, which, however, dissolves on adding more water. It is considered probable that there is a definite chemical combination between the hydrochloric acid and the camphor, forming a chlorhydrine, since on evaporation *in vacuo* the solid obtained has a markedly lower melting point than pure camphor. It is noteworthy that camphor is much more soluble in hydrochloric acid at a lower than at a higher temperature, a few degrees making a very marked difference. Thus a concentrated syrupy solution may be prepared at 0° C., containing over 40 per cent. of camphor, and if a flask of this be held in the hand it speedily becomes solid, but is again liquefied on cooling to 0° C.—*Comptes rendus*, cxxvii., 557.

Colocynth Fruiting at Kew. The *Citrullus colocynthis* may now be seen in fruit in one of the houses in Kew Gardens. The fruits are about as large again as an ordinary orange, and are of a rich golden hue (*Garden*, November 26, p. 439). The orange colour is apparently assumed when the fruits ripen, since fresh fruits from Mogador, brought home some years ago by the late Dr. Learedo, had a green colour variegated with white.

Cassia Marilandica. This plant, the leaves of which are used in the United States like senna, and are known as American senna, has long been regarded as a greenhouse plant in this country, but it has flowered freely this season out of doors against a wall. Plants of the sub-order *Cesalpinea* that are hardy in the open air in this country are very difficult to obtain for botanical purposes, and the *Cassia marilandica* should prove a useful addition to the very limited number obtainable. Even the flower buds of *Cercis siliquastrum* often drop before opening in this country.

PRACTICAL PHARMACOGRAPHY.

CINNAMOMI CORTEX.

Cinnamon Bark.—Cannelle, Fr.; Ceylonzimmt, Germ.

MACROSCOPIC CHARACTERS.

It should be noted that in Austria, Germany, Hungary, and Russia, cassia bark is official under the name of cinnamon, and that in the Danish, Dutch, Spanish, Swiss, and United States Pharmacopœias, both cinnamon and cassia are official under the name of cinnamon, which in this country is restricted to the bark of *Cinnamomum zeylanicum*. The bark, which is prepared from the shoots of truncated stocks by removing the corky layer, and rolling

a number of quills one inside the other, occurs in commerce in compound quills, about 100 Cm. in length and about 6 to 9 Mm. in diameter. The usual length of each separate quill is about 30 Cm., the pieces being made to overlap in order to make up the uniform length of the bundles, and the smaller pieces being placed in the interior. There are four commercial qualities in this country, distinguished by the thinness and smoothness of the compound quills, the finest variety being in the smallest quills. Besides these the broken pieces, usually of the fourth quality, are sold as quillings, and are of inferior colour and appearance. The trimmings of the shoots enter commerce under the name of cinnamon chips. These have usually small portions of the whitish wood attached to them. They are chiefly used for distilling the oil, and probably for powdering. More rarely a very thick bark enters commerce, but it has comparatively little aroma, and may possibly find its way into inferior varieties of mixed spice. The quills during the process of preparation lose the corky layer, and thus present a smooth appearance, only traces of the cork cells remaining. The quills are thin, with a splintery but not fibrous fracture, are of a light yellowish-brown colour, marked externally with faint, shining, slightly paler, wavy lines, and with little scars or holes, indicating the position of lateral twigs or leaves. On the inner surface the colour is rather darker. Cinnamon has a sweet,

Cinnamon. Cassia.

biting, aromatic, and somewhat astringent taste, and a characteristic agreeable odour. It is not adulterated, but occasionally the bark of other species of *Cinnamomum* is offered for it. The one most resembling it externally is that of *Cinnamomum obtusifolium*, but this is in larger quills, has a very fibrous fracture, and the flavour recalls that of cinnamon mixed with coriander.

Powdered cinnamon bark is sometimes replaced by the cheaper cassia bark, but the flavour of the latter is so distinctly different, that it is easily recognised by taste. Cassia bark itself is distinguished by the thicker quills, usually simple, but rarely one inrolled in another, by the presence of an imperfectly renewed cork, and by the shortness and irregularity of length of the quills. The variety known as Saigon cassia, but which is collected in Annam, occurs in straighter and smoother quills, and has none of the corky layer removed. It has a sweeter and more pungent taste than ordinary cassia. It is little known in this country, being chiefly exported to the United States.

MICROSCOPIC CHARACTERS.

Stereom Sheath.—As the cork and primary cortex have been removed from the bark in the process of preparation for the market, it happens that the outermost tissue is a stereom sheath, taking the form of a completely closed ring of short sclerenchymatous cells and scattered bundles of fibres. The ring is three or four cells broad. The cells are markedly extended tangentially, have strongly thickened porous walls, and the deposits are fairly uniformly disposed upon both the outer and inner walls as well as upon the lateral ones. Upon the outer verge of the ring are placed the narrow bundles of bast fibres, to which is due the delicate anastomosing tracery observable upon the outer surface of the drug.

Phloem.—Immediately within the stereom ring is situated the proto-phloem represented by narrow tangentially extended masses of obliterated sieve elements placed in a matrix of parenchyma with somewhat tangentially extended cells; in this region isolated bast fibres are not uncommon. The inner portion of the bark is occupied by broad masses of phloem tissue separated from each other by distinct medullary rays. In the phloem masses there are to be found, in addition to the ground tissue, numerous bast fibres, isolated and in small tangentially extended rows, narrow bands of sieve tubes and soft phloem tissue, and large mucilage receptacles. The latter vary in diameter from 45 to 75 μ or even more. The fibres have strongly thickened walls and gradually taper towards the acute

ends. The medullary rays are usually two cells broad, and in the inner portion the elements are radially extended, but in the outer portion they are tangentially extended; many of the cells contain very small raphides of calcium oxalate which are not always readily detected. The fundamental parenchyma contains large quantities of small starch granules varying in size from 5 to 10 μ ; some of the cells contain volatile oil and others contain similar raphides to those found in the medullary rays. The cell walls are charged with colouring matters which should be removed by treatment with a solution of chlorinated lime in order to obtain good microscopical preparations.

Cinnamomi Cortex. — A. Transverse section of a roll of cinnamon quills. B. Transverse section. r. Medullary rays. g. Phloem masses. g. Sclerenchyma ring. $\times 65$. (After Berg.)

Distinctive Characters.—The completely closed sclerenchymatous ring; the tangential extension of the stone cells; the comparatively uniform thickening of the same. In cassia bark the ring is pierced here and there by radial bands of thin-walled parenchyma; the stone cells are not so strongly extended

Cinnamomi Cortex.—Fragments of powder, much magnified. *fl.* Bast fibres. *sc.* Sclerenchymatous cells. *pc.* Fundamental parenchyma. *l.* Tissue of the phloem bundles containing raphides. *a.* Starch. After Collin

tangentially and are more frequently quadratic; the thickening is generally much more pronounced on the inner tangential wall than on the outer one. The bast fibres are more numerous than they are in cassia bark, and are not infrequently in short tangential

Cinnamomi Cortex.—Transverse section. *pR.* Remains of cortical parenchyma. *gR.* Sclerenchyma ring. *scl.* Sclerenchymatous cells. *B.* Bundle of fibres. *psb.* Protophloem. *B.* Bast fibres. *obl.* Obliterated sieve elements. *scb.* Mucilage receptacles. *rst.* Medullary rays. *sb.* Groups of soft phloem. \times abt. 140. (After Tschirch and Oesterle).

rows, whereas in cassia it is most rare to find more than two together. The powder should be free from vessels the presence of which would indicate the admixture of woody tissue, which might be due to the grinding of cinnamon chips to which fragments of wood are sometimes adherent.

SOAP FOR PEDICULI.—Melt soft soap, 100; add alcohol, 50; glycerin, 15. Filter and dissolve in the mixture, naphthol, 3.—*L'Union Pharm.* after *Journ. de Pharm. de Liège.*

ARROW POISONS: THEIR HISTORY, SOURCES, AND CONSTITUENTS.*

BY RALPH STOCKMAN, M.D.,

Professor of Materia Medica in the University of Glasgow.

(Concluded from page 550.)

After this slight introductory sketch we may now glance at some of the more interesting or better-known poisons which are at present in use in different parts of the globe, and I shall first consider two of animal origin as being distinctive in their character and of great interest in their action. One of these is the arrow poison of the Kalahari Bushmen (S.W. Africa). The Bushmen live in scattered tribes over the whole of S. Africa from the Cape to the Zambesi, and as they use local poisons for their arrows, these differ a good deal in different districts. In the Kalahari district Livingstone states that the natives were seen applying to their arrows the entrails of a small caterpillar, which they termed 'Nga. When the caterpillar is drawn over a small sore it causes the most excruciating agony, and men wounded with the arrows die slowly in the most violent delirium. Baines gives a more detailed description. There was brought to him a small bagful of the cocoons of an insect, brown in colour, oval, and about half an inch long. On breaking the cocoon a small cream-coloured grub was found coiled up inside. The Bushmen squeeze the grub gradually between the forefinger and thumb, when a colourless fluid exudes, which is smeared over the arrow-head. It is then almost imperceptible and no mixture is used. The insect is a small beetle, the *Diamphidia locusta*, which deposits its eggs on the leaves of a large tree on which the caterpillars feed, and then in due time they drop on to the earth and form their cocoons. Boehm has recently investigated the chemistry and action of the poison. He found that it is an albuminous substance very soluble in water, the solutions becoming rapidly decomposed under the action of putrefractive organisms and losing their poisonous properties. By precipitating the toxic albumin with alcohol or ammonium sulphate and drying the precipitate, he obtained it as an amorphous greyish powder, which retained its poisonous properties for an indefinite time. His pupil, Starcke, made experiments with it on animals, and found that its action had a generic resemblance to some of the snake poisons. Like them, it is not poisonous when given by the mouth, but injected under the skin it causes great local irritation, sometimes ending in ulceration or abscess, nervous depression, and bloody urine. Death was slow, from some hours to several days after administration. It somewhat resembles, therefore, abrin, snake poison, and other toxic albumoses which have been more minutely studied than it has.

Although its action is sure, it is not very rapid, and Baines states that animals after being wounded sometimes require to be followed up for a whole day. As regards an antidote, he says, the natives use a root which is chewed, and then rubbed on the wound and fat applied, but Livingstone makes a much more interesting statement, namely, that the grub taken by the mouth is considered the best cure. This bears out what we already know accurately about the immunity obtainable from the effects of abrin, ricin, and snake poison.

According to Steedman and Burchell, who both give very detailed accounts, other Bushman tribes use vegetable poisons from the *Amaryllis disticha*, various species of *Euphorbium* and *Acokanthera* alone or mixed with snake, spider, and beetle poisons. Burchell says there is no chance of surviving after a wound if the poison be fresh and well-made, but that quite superficial wounds may be scraped and scarified with a successful result. A Hottentot

* Inaugural sessional address to the North British Branch of the Pharmaceutical Society, delivered November 23, 1898.

also told him that habitual eaters of snake poison do not die from the wounds of the poisoned arrows, and no doubt this would prove a protection against the animal venoms, but scarcely against the vegetable ones.

The Choco Indians, in Columbia, South America, also use a peculiar poison, derived from a tree-frog, the *Phyllobates chocoensis*, which they hold on a stick near a fire, when the heat causes the glands of the skin to secrete the poisonous fluid. Our common frog secretes an irritating fluid from its cutaneous glands; so does the toad, the active principle of the latter having been named phrynin, and being known to act as a heart poison. The Choco Indian poison is innocuous when given by the mouth; a few experiments have been made with it in France, but its exact action remains rather doubtful. It is capable of killing large carnivora.

Of the vegetable substances used for poisoning arrows those which paralyse the heart after the manner of large doses of digitalis occupy a foremost place as regards deadliness and widespread use. As you are doubtless aware, digitalis and bodies of the same pharmacological group, of which there are many, paralyse the heart muscle, at first causing irregular and feeble action followed by complete stoppage and death. The final effect is preceded by great muscular feebleness and breathlessness. The physiological action of all these substances has been carefully and successfully studied, but no antidote has yet been found, and so if one absorb a sufficient amount of the poison death is certain to occur within a short time.

The most deadly are the arrow-poisons derived from the root wood of different species of *Acokanthera*, trees about 15 feet high—*A. schimperi*, *A. deflersii*, and *A. ouabai*. From these is prepared the deadly arrow-poison of the Somalis, known now for a long time and very fully described by Burton ('First Footsteps in East Africa' 1856). The poison is known as Waba, Wabayo, or Ouabaio. It is a thick, tar-like, watery extract, the active constituent in which is a glucoside known as ouabain (Arnaud), and it is made by splitting up the root into small pieces, boiling these with water, inspissating the juice, and then adding usually snake-venom or other poisonous vegetable extracts. Burton says that cattle eat the leaves of the tree only if very hungry, and that the berries are edible.

Besides the Somalis, the Wa Nyika, Wakamba, the Massai Wa Nyamwesi, and many tribes of Eastern and Central Equatorial Africa use practically this same poison, although there are many minor differences in its composition among these different peoples. Many of the prepared poisons contain very irritating substances, which are productive of severe local symptoms in the wounded. Boehm states that the poisonous dose for a dog per kilo. of its weight is about 1/140th gr. echujin, 1/260th gr. strophanthin, and 1/430th gr. ouabain, which gives some idea of their extreme toxicity. Fitzgerald ('Travels in British East Africa,' 1898) relates of the Waboni, that each arrow-head has its owner's special mark, and is so made that it cannot drop out, and this enables them to identify the killer of big game, as elephants often live for several days after they have been hit. In German South-West Africa, the Ovambas also use a heart poison derived from a species of *Adenium*, while the *Strophanthus* is widely used on the Congo, on Lake Nyassa, the Zambesi, Gaboon, Guinea, Cameroons, and Senegambia. Various *Euphorbias* and other imperfectly known plants are also largely employed.

Mr. Crawford Angus gives a graphic account of the poisons used in Azimba and Chapitaland, in Central Africa. I am indebted for it, and for the photograph of the arrows to Dr. R. W. Felkin. The natives use an arrow, the slightest scratch of which causes death,

the poison being known only to certain chief men, who collect it and serve it out to the others. He saw a man very slightly wounded in the lip, and in fifteen minutes he fell down, twitching violently; in six hours the arms and neck began to swell, and he died in twelve hours in great agony. Large quantities of these arrows are kept in covered bins in the villages, which are opened on a war alarm and the arrows served out. The arrow-heads are made so brittle that if they miss their mark they shatter against the ground and cannot be picked up and used against their original owners.

Stanley describes some of the wounds received by members of his expedition as being "mere needle-point punctures," and yet proving fatal. Some of the wounded died at once, others more slowly, and a few of tetanus later on. Some of the cases recovered. Very careful cleansing of the wound and cauterising was the treatment adopted.

The arrow poison of the Pigmies is a mixture of a cardiac poison and strychnine poison, with some others. It is very deadly, and one arrow will kill an elephant, but Stublman states that in man, if the head be at once extracted and the wound scraped and washed, fatal consequences are frequently averted.

Another set of arrow poisons which have a similar action on the heart are those made from the juice of the famous upas tree, the *Upas antiar*, growing in Borneo, Java, and adjacent parts. It is a very large forest tree, and the poisonous sap is obtained from incisions made into the bark. I show you some of it preserved with alcohol, and also the active principle—a crystalline glucoside called antiarin—which I isolated from this very specimen. It is extremely poisonous, and experiments which I made with it showed that 1/6400th gr. was sufficient to kill an ordinary sized frog in comparison with 1/4500th gr. strophanthin and 1/2600th gr. urechitin. The sap is known as Ipoh Kayu (tree poison) among the natives. It kills guinea-pigs and other small animals in a few minutes from stoppage of the heart, and has been used in Cochin-China against the French soldiers, who died in from half-an-hour to several days after receiving their wounds. It is in use throughout the Eastern Archipelago by nearly all the native peoples, pure, or mixed with snake-poison, scorpions, centipedes, other plants and occasionally with arsenic. The different prepared poisons vary greatly in strength, and one old specimen which I examined was quite innocuous.

The most extraordinary stories have been circulated about the deadliness of the upas tree, and seem to have been believed widely, and even by such an authority as Erasmus Darwin (see the 'Botanic Garden'). These stories are traceable to an account of the tree written last century by a Dutch surgeon named Foerscher, in the service of the Dutch East India Company, whose account was copied as genuine into a number of the current periodicals of the time, and thus obtained a wide circulation. On reading it, however, one is forcibly reminded of the style of Swift, in describing the travels of Mr. Lemuel Gulliver to Laputa. As it is rather amusing I may perhaps be allowed to give some extracts from his account: "I shall now only relate simple unadorned facts, of which I have been an eye-witness. In the year 1774 I was stationed at Batavia, and during my residence there I received several different accounts of the Bohon upas, and the violent effects of its poison. They all seemed incredible to me, and I resolved to investigate this subject thoroughly, and to trust only to my own observation. . . . I had procured a recommendation from an old Malayan priest to another priest, who lives on the nearest habitable spot to the tree, which is about fifteen or sixteen miles distant. The letter proved of great service to me in my undertaking, as that priest is appointed by the Emperor to reside there, in

order to prepare for eternity the souls of those who for different crimes are sentenced to approach the tree and to procure the poison. Malefactors who for their crimes are sentenced to die, are the only persons who fetch the poison. After sentence is pronounced on them by the judge, they are asked in court whether they will die by the hands of the executioner, or whether they will go to the upas tree for a box of poison. . . . They are afterwards sent to the house of the old priest and remain some days, during which time the ecclesiastic prepares them for their future fate by prayers and admonitions. When the hour of their departure arrives, the priest puts on them a long leather cap with two glasses before their eyes, which comes down as far as their breast, and also provides them with a pair of leather gloves. The worthy old ecclesiastic has assured me that during his residence there for upwards of thirty years he had dismissed above seven hundred criminals in the manner which I have described; and that scarcely two out of twenty have returned. He showed me a catalogue of all the unhappy sufferers, with the date of their departure from his house annexed, and a list of the offences for which they had been condemned. I was present at some of these melancholy ceremonies." He goes on with great detail in the same strain, and may be compared as a historian to a mixture of Defoe and Swift, and several people have been at the trouble to gravely refute his statements.

Aconite root (*A. ferox*), under the name of Bis, Bish, Bikh, and sometimes called tiger poison, is used as an arrow poison in Nepaul and along the eastern frontiers of our Indian Empire, and on the French and Chinese frontiers also most probably. It is very active, but the effects of aconite are so well known that I need not linger over them here.

We come lastly to the different species of *Strychnos*, which are so largely used in South America, in the East Indian Archipelago, and to a much more limited extent in Africa for preparing these poisons. The most famous of them is the *Curare*, first brought to Europe in 1595 by Sir Walter Raleigh. Under various names it is used over the immense tract of country comprised in the basins of the Amazon and Orinoco and their tributaries. A very minute and interesting account of its manufacture has been given by Humboldt, from which it appears that it is a concentrated extract made with cold water from the bark of several species of *Strychnos*, and that this is mixed with other poisonous and non-poisonous ingredients to increase its efficacy and consistence. It is not poisonous when swallowed owing, it is said, to the slow rate at which it is absorbed, and Humboldt says that the Indians lick it off their fingers and use it as a stomachic tonic. Its harmlessness when given by the mouth has been frequently confirmed by exact experiment. But when injected subcutaneously it proves rapidly fatal by paralysing the ends of the motor nerves in muscle, so that movement becomes impossible and death takes place from the respiratory muscles ceasing to act on the chest wall. A large dose kills in a few minutes, and there is no antidote known. Besides this action on the nerves, which is due to curarin, it has a paralysing effect on the heart, due to a second active principle, discovered by Boehm and named by him curin.

In the Malayan Archipelago the *Strychnos* or *Upas tieute* furnishes a sap largely used for poisoning arrows, and the active principles being strychnine and brucine we get the well-known convulsant effect of these substances in animals or men struck by the arrows.

I have, however, examined the root-bark of two species of *Strychnos* used as an arrow poison by the natives of Perak in the Straits Settlements, and found that both had a marked digitalis-like action on the heart, as well as a curare-like action on the

motor nerves (*Lab. Rep. Roy. Coll. Phys. Ed.*, vol. vi.). These are mixed with a third substance called "prual," which paralyses the muscles. When these different ingredients are mixed they form a most efficient means of dealing death, seeing that they paralyse simultaneously the heart, the motor nerves, and the voluntary muscles.

In conclusion, I may just mention two other poisons, neither of which is perhaps thoroughly authenticated. The Ainos in Japan are said to use a preparation made from aconite and tobacco, while the natives of the New Hebrides are stated to smear their arrows and spears with damp earth containing the tetanus bacillus, so that a cut infects their victim with this disease. It is more probable, perhaps, that the wounds inflicted by these weapons sometimes become infected with the bacilli through the ordinary channels. The North American Indians do not use arrow poisons, nor do the aborigines of Australia, so far as is known.

In spite of the large number of arrow poisons which are known to us, the toxic actions are not very numerous, and can be roughly classed under five headings (although this does not include all, especially locally irritating substances): (1) Those which act on the heart and muscles, like digitalis; (2) those which act on the nerve-endings, like curare; (3) those which act on the nervous system and heart, like aconite; (4) those which act on the spinal cord, like strychnine; and (5) those which have an action something like snake poison.

In addition to my own specimens I have received samples of arrows and poisons from Mr. E. M. Holmes, Dr. Woodhead, Dr. Felkin, and Professor Balfour, and to these gentlemen I have to express my sincere thanks for their kindness.

PHOTO-MICROGRAPHY.—IX.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

Let us next place a half-inch objective on the microscope and use it with what is called a "projection" eye-piece. This eye-piece is made especially for projection purposes, and can be procured for achromatics as well as apochromatics. It has a considerably smaller field than the ordinary eye-piece, such being limited by a diaphragm which is meant to be focussed on the ground glass by a slight turning of the front lens. When this diaphragm is so focussed, the eye-piece performs at its best.

Let us use the same slide of the proboscis, but try this time to get details of some one or more of the smaller suctorial tubes. These should now be seen, if the objective be a good one, very sharply defined on the ground glass, but it must be borne in mind that the low power condenser used at first should be removed and one of higher N. A. substituted, otherwise the full benefit of the higher N. A. of the objective may be impaired. We must now, too, be more careful about centering the condenser, the limelight, and the auxiliary lens, for errors of no consequence when using the inch objective are now of more importance. The exact method of centering the condenser will be given when speaking of the 1/6th objective.

The exposure will have to be increased, and as attention has been called to the fact that most writers afford little information upon the subject of exposure altogether, and as I have pledged myself to make these articles as practical and instructive as possible, so I will try and make an attempt to be more explicit.

Theoretically the time of exposure in cases like this increases in the same ratio as the squares of the diameters, or directly as the variation of the areas, *i.e.*, if twice the diameter (four times the area), it will be as 1 to 4. Put another way, supposing the first picture is magnified 25 diameters, and the second 50 diameters, the exposure varies as $25^2 : 50^2$, or as 625 : 2500, which is as 1 : 4.

If then the first negative was found to require two seconds exposure, the second one should receive eight seconds.

This law holds good as a general guide, but it is not always found to be practically correct, owing to the presence of a source of error hitherto not mentioned, and one not so easy to intelligibly explain. When a specimen is photographed in its entirety any small portions of it more dense than the rest become lost and unnoticed in the photograph when taken as a whole; by which is meant the lack of sufficient exposure in these tiny parts of the specimen is unobserved. But when taking a photo-micrograph at a higher scale of magnification it is evident if we get one of these very places now so much enlarged to photograph, the law will not apparently serve us correctly, furnishing us very likely with too short an exposure. But it is not the law that is at fault; on the contrary, it is really quite correct, for the very portion of the specimen which I have said escaped the proper exposure, before now shows how clearly it was under-exposed. But this may not strike the observer until after a little consideration. Anyhow, the law furnishes us with an approximation if we have taken a photograph with a low power first as described. But what if we have not, and are asked to take a photo of a tissue at 300 diameters without any previous experience? Speaking only of the limelight mixed jet, it is a good rule to give an exposure (300 diameters being the magnification) of about twenty seconds for the first plate and sixty for the second. It will be evident then on which side of scale we shall have to proceed. If over-exposed, such is the latitude of the Edwards plate that we may most probably save the picture.

When using the $\frac{1}{2}$ inch, the Davis diaphragm must be touched with a lighter hand than before, and focussing becomes more of an art, and the head should be withdrawn from the ground glass about ten inches, whilst a good dark focussing cloth excludes all extraneous light. If any minute details are desired the coarse ground glass might be removed for the finer one, after the photographer has made sure the light is equal over the plate, and then if necessary the finest of all can be substituted, a Dallmeyer or other focuser being applied while the operator turns his focussing screw gently to and fro till he gets the best results. Great care must be exercised not to shake the apparatus, as if we are using a six projection eye-piece, a $\frac{1}{2}$ inch objective and a twenty-inch extension of the camera, which in our case is done by adding the auxiliary front, it must be remembered one is dealing with a linear magnification of 240 diameters, and, therefore, any shake is itself magnified that number of times in all directions.

It is time now for us to enter into and discuss a phase of our subject, which, although it is of a most engrossing nature and one which has a most important bearing upon things photo-micrographical, yet is very frequently overlooked, and perhaps with some photographers very slightly understood.

It has been plainly pointed out that the apochromatic objective can stand eye-piecing to almost any reasonable extent, and the effect or outcome of this excessively useful property is that magnification of the same amount may be obtained by very different combinations of objective and eye-piece, putting aside for the moment the utility of different camera lengths. As an instance, just for example sake take the following illustration. It is required to magnify an object 250 diameters. This can be obtained in the following manner:—

1. With a 1 inch apo. N. A. $\cdot 3$ and a 4 eye-piece and 60 inch camera.
2. " 1 " " N. A. $0\cdot 3$ " 24 " 10 "
3. " $\frac{1}{2}$ " " N. A. $0\cdot 65$ " 10 " 12 "
4. " $\frac{1}{4}$ " " N. A. $0\cdot 95$ " 4 " 10 "
5. " $\frac{1}{8}$ " " N. A. $1\cdot 40$ " 3 " 10 "
6. " $\frac{1}{2}$ " " N. A. $1\cdot 40$ " 2 " 10 "

Which, then, is the best? Here we have to pause and ask ourselves, first, what is required to be represented in the photograph?

(α) Is it to show the finest details that can be possibly effected in one plane, disregarding altogether the relation of any one part to the whole? or is it

(β) That a general view with as much detail as possible is required of the large objects, but not so much of the small? or

(γ) Merely a general idea of an object with just enough of the leading points to make a recognisable picture and to show as many planes in focus at one time as possible?

Before returning an answer to these questions, I must remind the reader that I have explained in a recent chapter, when speaking about lenses, that although "penetrating power" varies inversely as the square of the magnifying power, still it also varies inversely as the N. A. of the objective. Now with respect to the magnifying power in the present case before us, there is nothing to say, as with each combination the amplitude obtained is practically the same; but it is to the effect produced by change in the N. A. of the system that the attention of the reader must be directed. A word in explanation may here be given. To say that this variation is inversely as the N. A. is only another way of expressing the fact that it varies directly as the reciprocal of N. A., and as the reciprocal of the N. A. is expressed by $\left(\frac{1}{N.A.}\right)$ a ready method of comparing the penetrating power of the different apochromatic powers used is afforded by a study of the accompanying table.

For N.A. $0\cdot 30$	3·338
" " $0\cdot 65$	1·538
" " $0\cdot 95$	1·053
" " $1\cdot 40$	0·714

It is quite evident that the 1-inch gives the greatest depth of focus, and that the $\frac{1}{8}$ th and $\frac{1}{12}$ th, each of $1\cdot 40$, give the least. We can now see which of the six combinations already mentioned will best suit the conditions enumerated in α , β , and γ . If the requirements are as propounded in α , where we desire the highest possible detail irrespective of depth of focus, then small as the field would be in No. 5 or No. 6, the former in preference, will be the combination best suited for the purpose, because the details furnished will be unquestionably greater; but if (γ) where merely the general view of everything is desired everywhere, and detail a secondary object, then I should choose No. 1 or No. 2. But granted that neither the extreme of (α) nor that of (γ) suit the wishes of the photographer, then No. 3 or No. 4 will be the arrangement I should recommend for (β). Here, then, is a great opportunity for the operator to display his "individuality," for he must make his choice, and I counsel those whose experience is limited to try several of the combinations before coming to a definite conclusion.

To resume, having now focussed with the greatest care, we expose—what we think from the considerations laid down to be the correct amount—and develop and fix in the ordinary fashion.

The next class of slide which may be taken with the half-inch is a diatom. It serves to illustrate a different type of object. Before purchasing one—let us say an *Arachnoidiscus ehrenbergii*—the photographer must assure himself it is mounted perfectly flat on the cover-glass and in a highly refractive medium. I know of no mounter of diatoms in Great Britain who can surpass Mr. Firth, of Clifton Park Avenue, Belfast, and few that can equal him; but Thum, of Leipzig, and Möller, of Wedel Holstein, supply slides of exceptional merit and perfection.

In photographing diatoms, apochromatics become almost a necessity—certainly so with high powers—for the manner they seem to pick out the details devoid of all secondary spectrum colours must be seen to be appreciated.

Critical light is an absolute necessity, but the iris will usually want a small amount of closing; in other words, too large a cone is not advisable, but, if too small, the minute marking will seem to have thick cumbersome black edges. No coloured glasses or screens will be here required with these objects. Expose fully about five to twenty seconds and develop deeply, and clear afterwards if necessary. Great care in centering the condenser is obligatory, and the light must be narrowly watched to see it is quite even. If a good negative be procured it can be subsequently enlarged to almost any amount. I have experienced no difficulty in producing a secondary enlargement up to 1800 diameters on Ilford rapid bromide paper in the manner already described.

This concludes a general description of some of the leading objects for medium power work, specimens of which were recently illustrated in the Journal. I propose next to deal with high power or critical photography.

REVIEWS AND NOTICES OF BOOKS.

THE COMING OF THE KILOGRAM; OR, THE BATTLE OF THE STANDARDS. By H. O. ARNOLD FORSTER. Pp. 150. Price 2s. 6d. London: Cassell and Company, Limited. 1898.

The relative advantages of the metric system of weights and measures have never been stated more forcibly than in this modest work, nor have the facts and statistics in connection therewith ever been marshalled in a more interesting fashion. The object of the book is "to make Englishmen realise the position in which they stand in the competition of the civilised world, and to show them exactly what it is that they are risking by clinging to their present system of weights and measures while almost every other nation in the world is adopting another and saner plan." If that object is not attained it will not be the fault of the author, but to the innate contrariness of people who think they know the how and why of everything better than anyone else can tell them. It is not altogether pleasing to the English reader to be told that the book is not intended to be a manual of instruction in the use of metric weights and measures, because "we have not yet arrived at the stage when the admirable text-books in use in France, Germany, and elsewhere, can be of value to a large class in this country." Nevertheless, what is stated by the author is quite true, and he is right in condemning, by implication, the muddle-headed conservatism which prevents British Governments from declaring that the metric system shall become compulsory within some limited time. The longer the day of compulsory change is put off the worse will matters become, for it is absolutely out of the question to imagine that the British public will voluntarily go out of its way to add a knowledge of other standards to the multiplicity it is already burdened with.

Commencing with a chapter on weighing and measuring, in which he deals with the principle of measurement and standards of comparison, the author points out that weights and measures should be uniform, accurate, easily understood and used, widely known, and simple in calculation. All those requirements are met by the metric system, but by no other, and certainly not by the weights and measures in use in this country. We have different pounds, ounces, and drachms, a variety of miles, acres, etc., and an enormous superfluity of antiquated and absurd weights and measures, many of which are employed locally only. Corn is sold in different parts of the country by more than two hundred different measures, many of which agree in name, but in no other respect; a stone weight varies according as it applies to a man, an ox, or to glass; a fodder

of lead changes its weight as it goes along the coast, a pint is not necessarily a pint, nor a quart always a quart. Englishmen have not even the satisfaction of being able to say that they are not worse, in regard to the confusion of their weights and measures, than other people, for as it happens, our system, taken as a whole, is the worst of all. The United States system was as bad, but is gradually improving, though it is still the next worst to ours. But Japan, Turkey, and Venezuela are far and away ahead of us, their old systems of weights and measures having been abolished and the newer and more scientific one adopted. Russia also is about to adopt the metric system.

British weights and measures are used by some 113 millions of people in Great Britain and Ireland, Canada, Australia, Cape Colony, New Zealand, and the United States of America; and the time, money, and patience lost to that enormous number of human beings, most of whom esteem themselves rational, is simply incalculable. The 329 millions of people who habitually use metric weights and measures save time in all their calculations, they also save trouble through being able to perform mental calculation more easily, and the inter-relation of their standards affords them a great advantage over us. That this is so is clearly shown by the author in the chapters wherein he discloses "the secret of ten," and explains the principles of a decimal system. The use of illustrations is freely resorted to in the book, in which the metric system is as fully explained as it is possible for it to be, and compared with the British system to the manifest disadvantage of the latter. The book can therefore be unreservedly recommended to all readers of the Journal, and the sooner they secure copies and digest the contents the better will it be.

THE TUTORIAL ALGEBRA. PART II. ADVANCED COURSE. By WILLIAM BRIGGS, M.A., and G. H. BRYAN, Sc.D., F.R.S. Pp. 596. Price, 6s. 6d. London: W. B. Clive. 1898.

This is a much larger work than the 'Middle Algebra,' by the same authors, but, like that, it is based on the Algebra of Radhakrishnan. It is intended more particularly for the use of students preparing for the Intermediate and B.A. examinations of London University, and follows the same lines as the smaller work, though it carries the student further and goes more deeply into certain subjects. The matter is well arranged and the book clearly printed. Probably no better praise can be awarded to it than to say that it is a worthy addition to the University Tutorial Series, which now includes so many excellent text-books for students—books which contain all that is required without being overburdened with what students are not concerned about.

ELEMENTS OF PHARMACY, MATERIA MEDICA, AND THERAPEUTICS. By WILLIAM WHITLA, M.A., M.D. Seventh edition. Pp. 644. Price 10s. 6d. London: Henry Renshaw. 1898.

This is one of the most useful students' manuals, dealing with the subjects of which it treats from the medical side, and the new edition should have a large demand, considering that it is based on the new B.P., and has been entirely revised and, in great measure, re-written, in accordance with that work. The various sections of the work deal with pharmacy, the administration of medicines, materia medica, therapeutics, and non-official remedies. As an indication of the thoroughness of the revision the book has undergone it may be stated that, whilst much new matter has been introduced throughout without adding to the size of the book, the section on non-official remedies—a most useful one—contains short notices of about three hundred new drugs not mentioned in previous editions.

Pharmaceutical Problems of To-Day.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

A special meeting of this Association was held on Wednesday, November 30, at the Westbourne Restaurant, Craven Road, Paddington, to consider the question of

Compulsory Poisons Regulations.

Mr. J. F. HARRINGTON, President, occupied the chair, and there was a good attendance of members.—The PRESIDENT, having explained the purpose of the meeting, asked Mr. J. H. Mathews to open the discussion.—Mr. MATHEWS said he had to bring before the meeting a proposition relating to the making of regulations for the keeping and dispensing of poisons. He pointed out that the question has for many years been a stumbling-block in the way of better pharmaceutical legislation. Although such regulations as were recommended by the Pharmaceutical Society in 1871 were in use to a great extent amongst pharmacists, still they were not adopted by the whole trade, and he was of opinion that it was advisable that some such regulations should now be adopted, as it would strengthen the position of pharmacists considerably and do away with such opposition as they have hitherto met with from the Privy Council. He had pleasure, therefore, in moving that, in the opinion of that meeting the time had arrived for making regulations for the keeping, dispensing, and selling of poisons in accordance with the Pharmacy Act of 1868.—Mr. H. CRACKNELL, in seconding the motion, said that according to the first clause of the Pharmacy Act, 1868, pharmacists were in duty bound to have some such regulations as were recommended by the Pharmaceutical Society. It might be asked if regulations were necessary, and in many cases the answer would be that they are not. But in other cases it was necessary that regulations should be enforced with respect to the keeping, dispensing, and selling of poisons. The object of such regulations would simply be to call to book any pharmacists who by carelessness had been the means of bringing about an accident. There would be no inspectors appointed, and no need for inspection of any kind, but in cases of accident the coroner's jury would make inquiries as to the circumstances under which the poison was sold. It had been pointed out again and again by the Privy Council that, inasmuch as the stipulation in the first section of the Pharmacy Act, to the effect that regulations should be drawn up, had not been complied with, the Pharmaceutical Society had broken faith with the Government. He believed that the opposition to the regulations at the time came largely from country members, but now there is a different state of feeling in the matter. Therefore, in bringing the question forward that night, they simply wanted to make suggestions for discussion throughout the country, and not to say what the regulations should be.

Mr. R. A. ROBINSON, L.C.C., supported the motion, but wished to propose an addendum to the effect that a special meeting of the Pharmaceutical Society should be called, in order to consider the question. He said the question had been brought before the country because it had been borne upon their minds that the present Government was not satisfied with the position of affairs at the present time. When the Pharmacy Act was going through in 1868, the Government wished to make regulations for the keeping and sale of poisons, but the President of the Pharmaceutical Society (Mr. Sandford) asked that no hard and fast regulations should be laid down, but that the making of regulations should be left to the Society,—strangely enough not to the Council—and Mr. Sandford promised that regulations should be made. When the matter came before a meeting of the Society, however, in May, 1871, those present came to the conclusion that there was no occasion for regulations such as had been drafted by the Council, and they were simply adopted as recommendations. Thereupon, Mr. Sandford, he believed, resigned from the presidency. Since then the question had been laid on one side, but whenever the President of the Society had gone to the Privy Council for anything, that refusal had been brought up against the Society. Last Session the Privy Council brought in the Poisonous Substances Bill and put in a clause that it should make regulations for the

keeping and sale of poisons. That placed pharmacists in a very difficult position and was a very strong indictment, and it required some care to show the Government that it was a false position. As an individual interested in the matter, he wrote to the Government giving his views, and his letter was passed on to the Privy Council, which replied. The Bill was subsequently withdrawn, but he was not sure that they were out of the wood yet. He had an interview only that morning with Mr. Fitzroy, the Clerk to the Privy Council, and got a statement from him of some importance. Mr. Fitzroy said, in effect, that if the Pharmaceutical Society adopted poison regulations, it would certainly meet with the approval of the Privy Council, and would go a long way towards putting the Society right with the Council and with the public. In addition, he said that the Privy Council is not doing anything at present in the matter, and that the Poisonous Substances Bill would not be introduced again without a consultation with the Pharmaceutical Society. He (Mr. Robinson) urged upon him that the proper thing to do was to bring in a Bill to extend the present Poison Schedule, and Mr. Fitzroy seemed to agree with that. There was no doubt that the Lord President would be made acquainted with what had passed during the interview that morning, and he (Mr. Robinson) thought there was a better chance than there had been for some time past of the Pharmaceutical Society being brought into closer contact with the Privy Council. Personally, he was pledged to bring the matter before the Society, if no one else did, but if the proposed addition was made to the motion before the meeting, then, of course, the question would be brought forward by that Association. The law was that if thirty members of the Society signed a requisition the Council was bound to call a meeting of the Society. Mr. Robinson then read the following:—

RECOMMENDATIONS FOR THE KEEPING, DISPENSING, AND SELLING OF POISONS.

(Adopted at a General Meeting of the Pharmaceutical Society, May 17, 1871)

1. That in the keeping of poisons each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.
2. Also that in the keeping of poisons, each poison be kept on one or other of the following systems, viz.:—
 - (a) In a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or
 - (b) In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or
 - (c) In a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.
3. That in the dispensing and selling of poisons all liniments, embrocations, and lotions containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

He pointed out that there could be no difficulty in complying with such regulations, as they would be found to be applicable for either town or country, being specially made so elastic as to suit all classes of chemists. They were wise regulations and would do chemists no harm, nor would they affect their dignity in the slightest degree, seeing that they were already subject to regulations, as also were other persons in equally dignified positions. They had now an opportunity of getting on good terms with the Privy Council and the Government, and if they did not adopt regulations themselves, there could be no doubt that the Government would bring in a Bill which would take the matter out of their hands.—Mr. MATHEWS having no objection to the proposed addition to his motion, he formally withdrew it, and Mr. ROBINSON then moved:—

That in the opinion of the Western Chemists' Association (of London) the time has arrived for making regulations for the keeping, dispensing, and selling of poisons, in accordance with the Pharmacy Act of 1868, and also that a special meeting of the Pharmaceutical Society should be called in order to consider the question.

Mr. MATHEWS seconded the motion, and Mr. J. W. TAPLIN said he quite agreed with it. Of course, there would have to be some

slight modifications of the recommendations as they now stand, and there would be a great many poisons not in the Schedule, to which they would not apply.—Mr. PHILLIPS wished to know how the regulations would be enforced.—It was pointed out by Mr. Robinson and others that there would be no inspection required, but if an accident happened, then, if the regulations had not been properly carried out, the chemist implicated would be liable to a penalty.—Mr. J. C. HYSLOP spoke in favour of the adoption of regulations, and expressed the opinion that there should be some legislation with regard to dispensing, and that any regulations should order poisons to be arranged according to dosage.—Mr. G. S. TAYLOR thought it a right and proper thing to adopt some kind of poisons regulations, because if they, as pharmacists, wished to secure a better Act than they had at present, the only way to succeed with it was to get right with the Privy Council. It was really a very little concession for them to make, because he believed that most practical pharmacists do all that is necessary now, and as for compulsion, they were already subject to it.—Mr. WOOLLONS agreed that the majority of chemists do keep their poisons as they ought to be kept. He thought the fear of inspection was a bogie. He would like to see it made illegal for any poison to be supplied in unsuitable bottles, and thought that the onus should not be thrown upon the chemist of refusing to serve poisons in a wrong class of bottles.—The motion was then put and carried unanimously.—A requisition asking the Council of the Pharmaceutical Society to call a special meeting to consider the question was then handed round amongst the members of the Society present for signature, and after a few items of private business, the meeting terminated.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

A special meeting of this Association was held at the Victoria Hotel, Manchester, on Wednesday, November 30, for the purpose of discussing resolutions submitted by the Federation of Local Associations.—Mr. G. S. WOOLLEY, President, occupied the chair, and there was a fair attendance.—The CHAIRMAN said that the resolutions sent by the Federation of Local Associations contained matter of such importance that the Committee thought it was worthy of an extra-ordinary meeting being called. He was glad to notice there was a considerable revival in pharmaceutical politics throughout the country, and he was also pleased to see interest was shown in Manchester. He thought it their duty to keep the interest alive, and do what they could to stimulate their fellow-craftsmen in the district to exert themselves to assist the Pharmaceutical Society, and to do everything in their power to promote the legislation that they all so urgently desired.—Mr. HARRY KEMP introduced the discussion of the resolutions. Dealing with the first item, the importance of

FIRMS TRADING UNDER TITLES,

using the names of present proprietors in conjunction, he said he hoped the gentlemen present would take a lively interest in those matters, because he felt quite sure that what was done that night would in a great measure be reflected in other localities, and that they would have an expression of opinion from other parts of the country. On more than one occasion the President of the Pharmaceutical Society and others, as knowing something of the inner workings of the Council, had expressed themselves to the effect that they wanted to know what are the wishes of the trade generally. Sometimes it was facetiously said that it was desirable that the tail should wag the dog, and if they were the tail, and the Pharmaceutical Council the dog, the sooner they wagged the dog the better. At Belfast the matter was placed in such clear light that there was not a dissentient voice. As to the first item being carried out, it might happen that a new proprietor might come in who was not a qualified person at all. He had reason to believe that certain gentlemen, whose names he mentioned, who traded under old titles, would be willing to fall in with such a suggestion if it was thought desirable. He felt sure, if the matter were dealt with on those lines, they would have good grounds for including in the case of registered companies the name of the qualified manager on the labels, and thus see that the dispensing of poisons was in the hands of a properly qualified man. On the second item, the question of

ALLIANCE OF ALL REGISTERED CHEMISTS

with the Pharmaceutical Society, that was a matter which

could not be dealt with quite so quickly. But they were all aware, of course, that the Pharmaceutical Society had, during the past twelve months, been successful in passing into law an amendment of the Pharmacy Acts, for the consolidation of the Society. It was now possible for every member on the Register to have equal privileges with those who had been members in the past, and they had now no reason to hold aloof. There were others, again, who had the old excuse that the Society had done nothing for them, and they would not do anything for the Society. This was a short-sighted view of matters, and he trusted under the new conditions no registered person would remain outside any longer. It was essential that the Pharmaceutical Society should have a strong following, and he hoped the time was coming when the present state of things would be altered. If Manchester took the lead in that matter they would find plenty of other places ready to follow. Mr. Kemp next dealt with the Secretary's circular showing the democratic constitution of the Pharmaceutical Society, and he held that if this were carefully studied it would result in an improvement of their position. The Pharmaceutical Society took the lead in killing or scorching the Poisonous Substances Bill, and those who did not subscribe to the Society benefited equally with those who did; it was therefore desirable for all to subscribe to a society which existed for their protection and advancement. He was glad that a Committee had been formed in Manchester at the instance of the Council of the Association, and he did hope that they would in consequence have a large accession of members, as it would eventually be for the good of the whole trade. In regard to the

REGULATION OF THE KEEPING AND STORING OF POISONS,

this was one on which considerable differences of opinion existed. He urged, however, that they had suggestions on the point which were of a practicable character. When the Duke of Devonshire brought in the Poisonous Substances Bill he made a great deal of the fact that the Pharmaceutical Society had been existing for thirty years and had never done anything to get this brought in as a regulation, and he almost as much as said that they were going to take it out of the hands of the Society and place it in the hands of the medical officer of the Privy Council to say under what conditions poisons should be kept and stored, and what regulations should be made from time to time for the storing and keeping of poisons by chemists. This, in his opinion, would be an undesirable thing, because if the Act were placed on the Statute Book they would have some system of inspection, which was always repulsive to English minds. He did not think there were any pharmacists who did not comply with the regulations as to labelling poisons. Another point was that, regulation or no regulation, they ought to have some system of separating poisons from ordinary drugs. He saw no reason why those recommendations should not become regulations and subject to the penalties of the Pharmacy Act. He moved, first—

That this meeting approves of the suggestion that all registered chemists trading under ancient titles shall be required to use the name of the present owner in conjunction therewith.

Secondly,

That this meeting, believing it to be to the best interests of the trade that the present recommendations for the storage, etc., of poisons, should become regulations subject to the provisions of the Pharmacy Act, requests the Council to take early steps towards this end.

—Mr. WOODRUFF next moved—

That this meeting pledges itself to use every effort to induce all registered chemists to ally themselves with the Pharmaceutical Society, and thereby lead to the consolidation of the craft.

—Mr. PERCY KNOTT (Bolton) seconded all the three motions.—A discussion followed, the CHAIRMAN remarking that, judging from revelations recently made, it was very desirable that some amendment should be made in the constitution of limited companies.—Mr. WALTER GIBBONS urged that the Pharmaceutical Society should take friendly action to test the position of such companies trading as chemists.—Mr. RYMER YOUNG supported Mr. Woolley's motions, which were agreed to.—On Mr. WOODRUFF's proposition being discussed, the CHAIRMAN said they had seen what they could achieve with united action recently; if they got a strong body they might accomplish something which would be of use afterwards.—Mr. J. PHILLIPS (Wigan) supported, as did Mr. RYMER YOUNG, who remarked that it was not, as had often been said, a question of guineas. The Pharmaceutical Society in its normal condition was not in want of guineas, but it was absolutely necessary it should have the trade behind it.—The motion was then agreed to.

FORMULÆ, METHODS, AND REACTIONS,
KNOWN BY THE NAMES OF THEIR AUTHORS.

Supplementary List.*

Boedecker (SULPHITES).—On adding zinc sulphate solution with a little sodium nitroprusside, to a neutral liquid a rose to dark-red colour appears if sulphites be present; under similar circumstances potassium ferrocyanide gives a purple precipitate.

Boehm (BOMBAY MACE).—When an alcoholic extract of Bombay mace is filtered through pure white filter paper, the paper is only stained a pale yellow colour, and when dried the red colour of Bombay mace appears round the edge.

Boettger (ALCOHOL).—A blue coloration is produced on adding a solution of molybdic acid in sulphuric acid. When alcohol is present in essential oils, it can be removed by shaking with glycerin. Or, a piece of dry potassium hydroxide added to the oil is soon covered with a yellowish film.

Boettger (AMMONIA).—Gaseous ammonia changes the colour of alcannin paper from red to blue.

Boettger (ANIMAL FIBRE).—A piece of the fabric is treated with an alcoholic solution of rosolic acid, then with soda solution and washed. Animal fibres (such as wool) are dyed red, linen (flax) pink, but cotton remains uncoloured. Compare with Liebermann's test.

Boettger (COTTON AND LINEN FIBRES).—The fabric is dyed with fuchsine solution, washed out with water, then treated with ammonia. Cotton thus treated is decolorised, while flax retains the dye.

Boettger (FLOUR IN STARCH).—If flour be present in starch, a more or less persistent foam is produced on boiling 1 Gm. of the mixture with 180 C.c. of water, and stirring briskly with a glass rod.

Boettger (HYDROGEN PEROXIDE).—On heating a liquid containing hydrogen peroxide with a few drops of ammoniated silver nitrate solution containing no free ammonia, cloudiness is produced and the silver is reduced. See *P. J.* [4], iv., 510.

Boettger (INDICATOR).—The colour of tincture of *Coleus verschaefelti* is changed from red to green on adding to an alkaline solution.

Boettger (MANGANESE).—A red coloration is produced on throwing a little manganese into fused potassium chlorate.

Boettger (NITRIC ACID).—If nitric acid be present in potable water, a red to brownish-red colour is produced on mixing 3 drops of the water, with two drops of brucine solution, and 3 or 4 drops of sulphuric acid.

Boettger (NITROUS ACID).—A blue colour is given by nitrous acid on adding diluted sulphuric acid and cadmium-iodide starch paste. See Boettger's reagent.

Boettger (REAGENT).—This reagent consists of a solution of cadmium iodide and starch prepared thus: Starch, 1, is dissolved in water, 200, and hydrochloric acid, 1. The solution is then neutralised with calcium carbonate, 10; sodium chloride, 10; and cadmium chloride, 0.5, are then added, and the solution made up to 250 with water.

Boettger (SAFRANINE).—On adding sulphuric acid safranine turns blue, and the subsequent addition of water changes the colour to green.

Boettger (SULPHOCYANIDES).—Filtering paper dipped in tincture of guaiacum and dried, then moistened with copper sulphate solution (1:2000), is coloured blue by sulphocyanides in solution.

Boettger (WATER IN ETHER).—Ether containing water causes a milky appearance on being shaken gently with an equal bulk of carbon bisulphide.

Bogomolow and Wassilieff (PEPTONE).—The accompanying albuminoids are precipitated by means of trichloroacetic acid, and the presence of peptone revealed in the filtrate by means of the biuret reaction. See Devoto's reaction for peptone.

Bohland (URINARY DEPOSITS).—To preserve urinary deposits, decant the supernatant urine, wash the residue with physiological salt solution (sodium chloride, 4; sodium carbonate, 3;

water, 1000), then treat with Mueller's solution, renewing this three or four times in the course of 14 days. Finally harden with alcohol, frequently renewed until it is colourless.

Böhmer (HÆMATOXYLIN).—Add 2 or 3 drops of a solution of hæmatoxylin (1 p.c.) in absolute alcohol to a watch-glassful of an aqueous solution of alum (0.5 p.c.), leave the sections in the mixture for half a day to a day, then pass them in succession through absolute alcohol, alcoholic solution of tartaric acid, absolute alcohol again, then through benzol or turpentine. Finally mount in castor oil.

Böhn (NEUTRAL CARMINE).—Rub up in a mortar 3 or 4 Gm. of carmine and 200 Gm. of water; then add ammonia, drop by drop, until the solution acquires a cherry-red colour. Next add acetic acid until the solution becomes of a sealing-wax red, and filter. To intensify the colour add 2 drops of ammonia before filtering, and expose in an open vessel until the odour of the ammonia disappears. Stain tissues in this for 24 hours (or longer if they exceed 1 Mm. in thickness), after which wash out with a mixture of equal parts of glycerin and water, acidulated with 0.5 p.c. of hydrochloric acid.

Bolas (NITRIC ACID).—Mix 10 parts of sulphuric acid with 1 of ferrous sulphate solution, heat, and pour the suspected liquid cautiously on top. A brown zone is produced in the presence of nitric acid.

Borne (MACERATION FLUID).—Mix 10 p.c. sodium chloride solution, 5, with absolute alcohol,

Bornstein (SACCHARIN).—The substance is extracted with ether, and the residue, on distilling off the solvent, is heated with resorcin and concentrated sulphuric acid. If saccharin be present a marked fluorescence is produced on saturating with caustic soda.

Borntraeger (INDICATOR).—A concentrated tincture of fresh orange peel, shaken up with ether, is not affected by acids, but turns lemon-yellow with alkalis.

Borodin (SOLUBLE PRECIPITATES).—This process consists of treating the precipitate with a saturated solution of the body with which it is considered to be identical. For instance, a vegetable microscopical preparation, containing a substance, suspected to be asparagin, is treated with a saturated solution of that body. If it be asparagin, it will be insoluble, whereas if it be not it will probably be dissolved.

Borsarelli (ALCOHOL).—On heating essential oils containing alcohol with dry calcium chloride a dense solution is formed.

Böttcher (STAINING METHOD).—Preparations are treated with Müller's fluid, followed by alcohol, then stained with rosaniline nitrate dissolved in glycerin and water, washed out with alcohol, cleared with creosote or clove oil, and mounted in balsam.

Boudet (OLIVE OIL).—Note the colour produced on adding 3 parts of a mixture of equal volumes of sulphuric and nitric acids to 10 parts of the oil, and the change in consistence caused by the addition to the oil of fuming nitric acid. See also *P. J.* [4], iv., 510.

Bourgoin (NITROBENZOL).—On shaking 15 drops of essential oil of bitter almonds with 8 drops of potash solution, a green colour is produced if nitrobenzol be present, and on subsequently adding 20 drops of water two layers are formed—the upper one green, the lower one yellow.

Bourne (BORAX CARMINE).—Mix a saturated solution of carmine in 4 p.c. borax solution with an equal volume of 70 p.c. alcohol. Let the mixture stand for a week, then filter, and if carmine should be deposited subsequently, filter again. Leave tissues in this stain for 1 to 3 days, according to size, then immerse them in acidulated alcohol for 3 to 6 hours until bright and transparent.

Bourreau (ALBUMIN).—See Koch's reagent.

Boussingault (NITRIC ACID).—This depends upon the decolorisation of solution of indigo in sulphuric acid in the presence of hydrochloric acid. A little of the latter is heated in a test tube, a few drops of very dilute indigo sulphate solution are added, then the substance to be tested. In the presence of nitric acid the blue colour is discharged.

Bouvier (AMYLIC ALCOHOL).—Alcohol containing fusel oil acquires a yellowish colour on adding a few crystals of potassium iodide and agitating gently.

* After Wilder, Schneider, Altschul, Lee, Squire, Crookshank, etc. Continued from p. 487.

Braconnot (ARSENIC).—Extract the arsenic with alcohol and test with sulphuretted hydrogen.

Bradford (OLIVE OIL).—The production of a reddish colour on shaking olive oil with solution of lead subacetate indicates the presence of cotton-seed oil.

Brand (ABRSTOL IN WINE).—The wine is first treated with lead peroxide and sulphuric acid to eliminate other colouring matter; it is then shaken out with chloroform. On evaporating off this solvent any abrastol present is left and may be identified by its giving a green colour reaction with sulphuric acid.

Brand (THALLEIOQUIN).—As modified by Hyde this reaction consists in acidulating a solution of quinine containing 5 Mgm. of the alkaloid, with one drop of sulphuric acid (1 : 4), passing through a small filter and adding solution of chlorinated lime until the bluish fluorescence at first visible is destroyed. A few drops of dilute ammonia (1 : 3) are now added when, if quinine be present, a bright green colour is obtained. On the addition of dilute sulphuric acid this changes to red.

Brandberg (BENZOL-BENZINE).—Pitch dissolves in benzol, but not in petroleum spirit.

Branson (ASSAY OF GOLD CHLORIDE).—Take about 15 grains of the salt dissolved in water. Add 25 C.c. of normal oxalic acid solution. Set aside for 36 hours at about 21° C. and expose to light for 12 hours, then boil, collect the precipitate, dry, incinerate, and weigh the metallic gold.

Brantlecht (POTABLE WATER).—To detect organic impurities in potable water, treat 100 C.c. with 5 drops of aluminium sulphate solution (aluminium sulphate, 1; hydrochloric acid, 1; water, 8), and add 1 or 2 drops of ammonia. Filter off the precipitate, dissolve it in 10 or 15 drops of diluted acetic acid, and examine under the microscope before and after the addition of safranine.

Braun (CHLORATES).—A cherry-red colour is produced with chlorates on adding a solution of aniline sulphate containing toluidin and hydrochloric acid. On neutralising, the colour changes to blue.

Braun (MOLYBDIC ACID).—A yellow to flesh-coloured precipitate, which soon becomes violet, is formed on adding to a very dilute solution of molybdic acid containing a little nitric acid, an aqueous solution of potassium ethyl-sulpho-carbonate.

Braun (NICKEL).—A rose-red to deep brownish-red colour, almost black, results when a solution of potassium sulphocarbonate is added to a solution containing nickel.

Braun (NITRIC ACID).—Add to 1 C.c. of sulphuric acid, drop by drop, 0.5 C.c. of aniline sulphate solution, prepared by mixing 10 drops of aniline with 50 C.c. of diluted sulphuric acid. Place a little of this reagent on a porcelain plate and draw through it a glass rod dipped in the suspected liquid. If nitric acid be present a reddish fringe is produced on breathing upon the surface of the mixture.

Bremer (GLUCOSE IN BLOOD).—Equal volumes of saturated solutions of eosin and of methylene blue are mixed, the resulting precipitate collected on a filter, dried, finely powdered, and mixed with 1/24th its weight of eosin and 1/6th of methylene blue. When required for use from 2 to 5 centigrammes of this mixture are dissolved in alcohol (33 p. c.), 10 grammes. A cover-glass with a drop of the blood to be examined is immersed in this solution for 4 minutes. The production of a blue-black colour indicates glucose.

Bremer (SESAME OIL).—To a cooled mixture of 50 C.c. of absolute alcohol and sulphuric acid add 10 drops of furfural. When 1 drop of this reagent is stirred with sesame oil (or with margarine containing that oil) it develops a red colour in 1 or 2 minutes. Pure butter and albuminoids are not thus coloured. Compare Villavecchia and Fabri's reagent.

Brieger (STRYCHNINE).—Pure chromic acid gives a violet colour with strychnine.

Brösicke (STAINING METHOD).—Treat tissues with 1 per cent. osmic acid solution for 1 hour, then wash out carefully and immerse for 24 hours in cold saturated aqueous solution of oxalic acid. The tissues should not be allowed to blacken in the osmic acid bath.

Brown (COPPER).—The copper salt in solution is treated with excess of potassium iodide and cuprous iodide precipitated. The iodine in this is determined with a standard solution of thio-sulphate.

THE STUDENTS' PAGE.

EXPLANATORY NOTES ON THE B.P.*

Ferrum Redactum.—This is now required to contain 75 per cent. of metallic iron. Fuge's process is adopted for the determination of this constituent: It is the one mentioned in the previous article on Reduced Iron (*vide P. J.*, June 12, 1897), as being more satisfactory than the old iodine method. The reactions involved are as follows:—

The filtrate will contain ferrous sulphate and a small excess of copper sulphate. It is acidulated and titrated with vol. sol. of potassium bichromate (or with potassium permanganate):—

Since the potassium and chromium of the bichromate form the sulphates K_2SO_4 and $\text{Cr}_2\text{3SO}_4$, corresponding to the oxides K_2O and Cr_2O_3 , it is evident that one molecule of bichromate yields three atoms of available oxygen in this and similar cases where bichromate is used as an oxidising agent. This will be more easily understood if we split up the formula thus:—

Since three atoms of oxygen are equivalent to *six* atoms of hydrogen, a *normal* solution (*i.e.*, a solution containing one gramme of replaceable hydrogen, or equivalent quantity of some other element, per litre) of potassium bichromate contains $\frac{1}{6}$ th M. Wt.

$$\text{K}_2\text{Cr}_2\text{O}_7 \left(\text{or } \frac{292.3}{6} = 48.7 \text{ grammes} \right)$$

in grammes in one litre. The official volumetric solution contains 4.87 grammes per litre, and is hence a N/10 solution. In the equation already given it will be seen that $\text{K}_2\text{Cr}_2\text{O}_7 \equiv 6\text{FeSO}_4$, or 6Fe in terms of metallic iron.

Now 1 litre of N/10 $\text{K}_2\text{Cr}_2\text{O}_7$ contains 4.87 grammes $\left(\frac{\text{K}_2\text{Cr}_2\text{O}_7}{60} \right)$
 $\therefore 1 \text{ ,, ,, ,, is equivalent to } 5.56 \text{ grammes of iron.}$
 $\left(\frac{6\text{Fe}}{60} = 5.56 \right)$
 $\therefore 1 \text{ C.c. ,, ,, } \equiv .00556 \text{ gramme of iron.}$

Consequently the 33.7 C.c. mentioned in the official test indicate 0.187 gramme (0.00556×33.7) of metallic iron in the 0.25 gramme of ferrum redactum, or 74.95 per cent.

Glusidum.—The preparation and reactions of this compound provide material for illustrating a number of reactions having general interest in organic chemistry. It is made from toluene (methyl benzene). The first step is to prepare toluene sulphonic acid by the action of strong sulphuric acid on the toluene:—

The facility with which the benzene hydrocarbons can be thus sulphonated distinguishes them from the paraffin hydrocarbons. Since toluene sulphonic acid is a di-derivative of benzene it can exist in the three varieties, distinguished by the three prefixes ortho-, meta-, and para-, according to the relative positions of the two substituting groups in the benzene nucleus. When, as in the formation of toluene sulphonic acid, a mono- is converted into a di-derivative, it has been found that the position taken up by the entering radicle is dependent upon the nature of the substituting radicle *already present* in the benzene nucleus and only in a slight degree upon the nature of the second radicle to be

* NOTE.—This series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P. J.* during 1897 and the earlier portion of the current year.

introduced. Thus, speaking generally, if the group already present be (HO), (CH₃), or other hydrocarbon residue, Cl, Br, or (NH₂), the second entering group takes up partly the ortho-, and partly the para-position relatively to the first. On the other hand when the mono-substitution product contains the following groups (NO₂), (COOH), (SO₂OH), (C·O·H), then the meta-di-derivative is obtained. These rules may be easily remembered by observing that the substances obtained by adding hydrogen to the groups of the first class are all difficult to oxidise, viz., H₂O, CH₄, HCl, HBr, and NH₃; while in a similar way we obtain from the groups of the second class substances easily oxidised, viz., HNO₂, H·COOH, H₂SO₃, HC·O·H. By the action of sulphuric acid on toluene, we should expect therefore to obtain a mixture of ortho- and para-acids, but none of the meta-toluene sulphonic acid. The relative proportion of these two acids obtained in this and analogous cases varies in each case and with the conditions under which the reaction is carried out. It has been found that by sulphonating toluene at a temperature not exceeding 100° C., the ortho-acid is formed in greater quantity than the para-acid, and since the para-acid is useless (for reasons which will be explained later on) for the preparation of gluside, the reaction between toluene and sulphuric acid is carried out below 100° C. The mixture of ortho- and para-toluene sulphonic acids are then converted into their sodium salts by neutralisation with sodium hydroxide :—

The sodium salts are next converted into the acid chlorides by the action of phosphorus pentachloride. This change essentially consists in the replacement of the hydroxyl of the acid by one atom of chlorine—behaviour which is quite typical of the reaction of phosphorus pentachloride (and trichloride) with bodies containing hydroxyl groups.

At this stage the para-compound mostly crystallises out, leaving a fluid residue containing chiefly ortho-toluene-sulphonic chloride. This compound by treatment with ammonia is converted into ortho-toluene-sulphonamide :—

This reaction is quite typical of the behaviour of acid chlorides with ammonia. By oxidation with potassium permanganate in neutral solution the methyl group of the toluene residue in the sulphonamide is oxidised to carboxyl, giving, therefore, a derivative of benzoic acid, viz., ortho-sulphon-amido-benzoic acid :—

Oxidation of benzene derivatives containing alkyl side chains (methyl, ethyl, propyl, etc.) always finally results in the complete oxidation of these down to the last carbon atom connected with the benzene nucleus. Benzoic acid, or some derivative thereof, if the compound oxidised contained already some other substituting group or groups (as in the case under discussion), is consequently obtained. Thus methyl-, ethyl-, or propyl-benzene all yield benzoic acid :—

The ortho-sulphamido-benzoic acid immediately loses water—

forming gluside, or benzoyl-sulphonic-imide.

The latter name is obtained by regarding gluside as a derivative of benzoyl, C₆H₅CO (the acid radicle of benzoic acid C₆H₅CO·OH) containing the sulphon (—SO₂—) and imido (=NH) groups. It belongs to a class of bodies known as *inner* anhydrides, which

are so-called because they are obtained by the separation of a molecule of water from *one* molecule of the acid. Compare equation (vi.). Ordinary anhydrides are derived by the removal of water from two molecules of acid :—

In describing the preparation of gluside, it has been mentioned that only the *ortho*-toluene-sulphonic acid was desired. The reason for this is that only the *ortho*-sulphamido-benzoic acid, containing the sulphamido and carboxyl groups linked to *contiguous* carbon atoms in the benzene nucleus, forms this inner (or intra-molecular) anhydride. The corresponding meta or para in which the substituting sulphonamide and carboxyl groups are separated by one or two carbon atoms do not form inner anhydrides, and have, moreover, no sweet taste. With regard to this formation of inner anhydrides compare the behaviour of phthalic and succinic acids, and the formation of lactones from the γ -oxy-acids of the fatty series. The hydrogen atom combined with nitrogen in gluside can be easily replaced by electro-positive metals or groups. The acidic nature of this hydrogen is due to the influence of the closely associated electro-negative carbonyl (CO) and sulphonyl (SO₂) groups. Typical organic acids which contain the carboxyl group CO·OH, owe their acid properties to the association of the hydroxyl with the carbonyl group. When aqueous solutions of gluside are treated with sodium bicarbonate the sodium compound or "soluble saccharin" is formed :—

The reason why gluside is not readily charred by warm sulphuric acid can be easily seen by inspecting its formula. The side chains contain only one carbon atom and that closely associated with oxygen, while the carbon in the aromatic nucleus is not easily disturbed by sulphuric acid, as is shown by the formation of such compounds as benzene sulphonic acid from benzene.

When *boiled* with potassium hydroxide *solution* the anhydride formation is broken up, the potassium salt of the corresponding acid, ortho-sulphamido-benzoic acid, being formed :—

When this solution is evaporated and *fused* with the excess of hydroxide the sulpho-group is eliminated and replaced by hydroxyl, the potassium salt of ortho-hydroxy-benzoic acid (salicylic acid) being formed. The fused mass dissolved in water, and the excess of potassium hydroxide removed by neutralisation with hydrochloric acid, gives the characteristic test with ferric chloride for salicylates. The elimination of the sulpho-group by fusion with caustic alkali is quite typical of the benzene-sulphonic acids and their derivatives. Compare the practical process in your text-book for the synthesis of phenol from benzene by means of the potassium benzene sulphonate—

In the case of glucoside, the nitrogen in the side chain is evolved as ammonia, while the sulpho group appears as potassium sulphite.

The sulphamido-benzoic acid referred to in the last official test is probably the *para*-variety derived from the corresponding *para*-toluene-sulphonic acid (*vide supra* process for preparing gluside). As a rule, inner anhydrides in the aromatic series can only be formed from bodies having the groups, from which the water is eliminated, in the adjacent or ortho-position. Consequently *para*-amido benzoic acid will not eliminate water with formation of an imide, like the corresponding ortho-acid.

PHARMACEUTICAL JOURNAL.

LONDON : SATURDAY, DECEMBER 3, 1898.

COMPANY TRADING AND THE PHARMACY ACT.

THE proceedings of local associations appear recently to have given evidence that the imperative necessity for the incorporation of all persons carrying on the business of chemists and druggists—so much talked about forty years ago—is now more really appreciated as being a prime condition of their welfare and even of their continued existence. This circumstance gives encouragement to consider, again, the claims that chemists registered under the Pharmacy Act are entitled to make, as legally qualified members of a body recognised by the State and, in that capacity, individually authorised, to perform certain functions. The Act of 1868, like all arrangements that are the result of compromise, has manifold inherent defects, which have been only partially mended by subsequent judicial constructions. As a means of adequately regulating the practice of pharmacy the Act fails altogether; from its deficiency, even in regard to the business of chemists and druggists in the wider sense, it has well earned the designation of being merely a “wretched poison Act” and it has given rise to general dissatisfaction. Judicial construction has upheld the object of the Act—so far as the public are concerned—by affirming the necessity of personal qualification of the mechanical seller of poisons within its meaning; but there is still difference of opinion as to the necessity of the complementary condition, viz., that the keeping open shop for the sale, dispensing, or compounding of poison in connection with the use of a distinctive title, requires the same individual qualification. In that respect the construction of the Act, relating to the position of companies and to the exercise of the chemist's business by them, is unquestionably most unsatisfactory from every point of view but that of companies which have thus acquired some apparent recognition of their claim to be “above all law,” as Mr. Newton put it when hearing the case of the Pharmaceutical Society *v.* the London and Provincial Association, in 1878, at the Marlborough Street Police Court. Since the object of the Pharmacy Act, 1868, was to establish a legal qualification and new conditions for the exercise of a business which had previously been uncontrolled and open to anyone, provision for conserving the interests of persons already known as chemists and druggists had of necessity to be made and such persons as could show they had been so engaged were placed upon the Register of Chemists and Druggists as entitled to keep open shop under the designation of chemist and druggist. There is no record of any application to be registered having been made by a corporation or limited liability company; that circumstance may therefore be taken as evidence that no such companies were at that time carrying on the business. The absence of reference to companies, in the Act, is consequently intelligible, as such companies were non-existent at the time as keepers of shops for the sale, dispensing, or compounding of poisons. Moreover, the only persons indicated as capable of becoming qualified under the Act are those capable of undergoing examination, there is, therefore, no ground for supposing that the contingency of a company, consisting of unqualified persons, carrying on

that business, as an artificial person, was overlooked, indeed a provision that such exercise of the business would be unlawful, would have been superfluous and absurd. In this connection it is interesting to refer to the terms of the declaration to be made by applicants for registration (Schedules C and D) as showing that the provisions of the Act apply to, and were intended to apply specifically to, individual persons, even in the case of firms carrying on the business. Moreover, the one prospective qualification, established by the Act, relates to “persons keeping open shop,” and that qualification is to be acquired by them “before commencing such business,” clearly showing that the qualification was intended to apply to persons engaged in business on their own account, and not to persons acting in the capacity of assistants or servants.

The position now existing is that in face of a statutory enactment which, in its principle, distinctly points to the necessity for qualification of the individual proprietor or proprietors of a chemist's business and, in its details, affords evidence that such individual proprietary qualification was contemplated by the Legislature and intended to be the essential condition for exercising the business; in face also of the judicial construction which has, at least, recognised the qualification of individuals, performing the functions to which the Act relates, as being essential in the public interest, there is the practice which ignores all these indications. Combinations of unqualified persons—incorporated as limited liability companies—carry on the business of chemist and druggist with no further pretext of justification than the plea that the artificial person, thus constituted, being incapable of qualifying as the Act requires, is outside the scope of the Act and, therefore, not amenable to its provisions. That, in itself, is but a one-sided view and the more rational inference would be that such an artificial person is necessarily disqualified for the performance of functions requiring individual personal qualification as the Act provides. Even the view taken by the House of Lords, in the case above referred to—that personal qualification of the individual selling, dispensing, or compounding poisons, as the servant of a company, satisfied, in that particular case, all the requirements of the Act, as a public measure, so far as the safety of the public was concerned—cannot be regarded otherwise than as partial and one-sided. The safety of the public was, no doubt, the chief object of the Act; but the imposition of conditions on the exercise of the chemist and druggist's business, with that object, carries with it, even in the interest of the public, the implication that the persons keeping open shop for retailing, dispensing, compounding etc. and known in that capacity as chemists and druggists, are to possess competent practical knowledge of their business and to be certified accordingly, as the Act provides. Unqualified persons, combined to constitute a limited liability company, do not fulfil those requirements, either individually or in their corporate capacity. The members of a company, being unqualified, are in either capacity, incapable of legally keeping open shop as, or assuming the title of, chemists and druggists. It may, therefore, be contended that, by reason of inherent disability to qualify in that respect, such a company keeping open shop as, and using the designation of, chemists and druggists is not merely exceeding its capability; but is actually committing an infringement of the Pharmacy Act, 1868.

It has been suggested that one of the difficulties to be encountered, in attempting to deal with company trading, is

that of making any legislative enactment in regard to the practice retrospective in its action.' The idea that such difficulty would arise seems to be based on the assumption that companies, in carrying on the business of chemists and druggists and assuming that designation, have acquired a prescriptive right to do so. But if the view put forward above is capable of being supported, what else is the position of such companies but that of law-breakers? They have not even a hope of the only salvation possible for wrong-doers of not being found out. Their offence is flagrant. It surely cannot be contended that twenty years' continued infringement of a statute converts wrong-doing into a right, or that defiance of the law to that extent creates immunity in regard to its provisions! Arguments to that end also imply the assumption that the principle of limited liability is not only to be applied to commercial transactions, but extended also to the application of a statutory enactment intended to promote public safety and, with that object, to establish conditions under which the exercise of a particular business is to be carried on. Any question there may be on those points still claims the consideration of the Legislature and—if chemists unite in the effort to defend the position they believe to be maintainable from every point of view—there is reasonable prospect of offering successful opposition to the plea of vested interest as being sufficient to warrant continuance in unlawful procedure. If the Pharmaceutical Society is to undertake the task of endeavouring to obtain such amendment of the Act, its membership must first be augmented so as to comprise, at least, the majority of those who desire that reform. In any case the task will be a difficult one, requiring hearty support both moral and material.

PARLIAMENTARY OPINION ON POISON.

WHEN the Pharmacy Acts Amendment Bill was before the House of Commons last June, the most remarkable feature of its chequered progress was the discussion which took place at the third reading of the Bill when—in the absence of Mr. ALEXANDER CROSS, the member for the Camlachie Division of Glasgow—Dr. CLARK, acting on his behalf, proposed to move the addition of a clause that would have the effect of rendering persons selling poisonous preparations for destroying vermin or weeds, etc., and for use in connection with the arts, agriculture, or other trade purposes, exempt from the provisions of the Pharmacy Act, 1868, in regard to the sale of poisons. Dr. CLARK argued that the use of poisonous articles in large quantities for such purposes takes place under conditions so different from those under which poisons are employed for medicinal purposes, that there should be a corresponding difference in the regulations to which the sale of poisons for those respective purposes should be subjected for the sake of public safety. He maintained that the provisions of the Pharmacy Act—which the Pharmaceutical Society is now compelled to enforce—operate prejudicially in restraint of trade, by preventing farmers, cattle dealers, and others from conveniently obtaining their supplies of sheep dressings, antiseptic solutions, etc. The discussion that followed was especially interesting; for, though entirely irrelevant so far as the object and purpose of the Bill under consideration were concerned, it led to expressions of opinion from several members of the House that should be borne in mind as having important bearing upon the general question as to regulation of the sale of poison for the safety of the public and upon legislative regulation of the practice of pharmacy.

The speakers on that occasion were unanimously of opinion that the present condition of things in regard to the sale of poisons is very unsatisfactory and that the restriction of their sale should be much greater than it is. On that point Mr. CHANNING spoke of the present lax regulations as being very undesirable, and he referred to a recent case of murder as illustrating the danger arising from the facility with which scheduled poisons can be obtained, even in a chemist's shop. Mr. BURNS also regarded the existing regulations for the sale of poison as most unsatisfactory in many respects. He expressed a belief that the average chemist and druggist, as a mixer of poisons, is capable of much education and that chemists and druggists have not, as a body, fully recognised the duty they owe to the public. Dr. CLARK was of opinion that legislation on this subject should be directed to preventing the sale of drugs, for medicinal purposes, either by companies or by individuals who are not qualified for that purpose, while at the same time it should not interfere with the supply of poisonous articles, under proper regulations, for agricultural or commercial purposes. Mr. BURNS agreed with him that legislation is requisite in this respect, in order that the true purpose and object of the Pharmacy Act may be carried out. Having regard to the special nature of the Bill then before the House, as enabling chemists and druggists and the Pharmaceutical Society to put their own house in order, Mr. BURNS also expressed a hope that, after accomplishing that object, they would act upon the various suggestions which had been made in the House and use their powers with greater courage and greater discretion in the interests of the general public as well as of registered chemists and druggists.

It was evident throughout this discussion that members of Parliament, in speaking of the Pharmaceutical Society, regarded it as representing chemists and druggists: they also assumed the Society to be a body comprising all chemists and druggists registered under the Pharmacy Act, 1868 and, in that sense, fully capable of exercising the powers conferred upon it. That idea certainly seems to have prevailed with Mr. BURNS, and to have induced him to support the general object of the Bill, as being a means of educating chemists and druggists, improving their status as members of the Society, and enabling the Society as a representative body to assist the House of Commons in the endeavour to put the regulations for the sale of poisons on a satisfactory footing. That, indeed, is the position which must be taken in the future and it is encouraging to find members of Parliament expressing confidence in the Pharmaceutical Society, as well as appreciation of its past work in trying to put a stop to the system—referred to by Dr. FARQUHARSON as a great and growing evil—under which associations calling themselves drug stores are able to elude the provisions of the Pharmacy Act. In future attempts at legislation the question will probably be raised whether at the present day the place of business of the chemist and druggist should be exclusively the poison shop, or whether, disregarding old associations, some more rational conception of pharmacy, as a professional occupation, should not now be made the basis of a law regulating the practice of that art. The remarks made by Mr. LORD GIFFORD at the recent meeting of the North-East Lancashire Chemists' Association point in that direction, as evidence of a wholesome, though tardy, awakening. He has wisely taken up the propagation of that gospel with much prospect of success, and there is good reason for believing that a similar opinion is held by many chemists throughout the country.

ANNOTATIONS.

THE NEXT EVENING MEETING of the Pharmaceutical Society will be held at 17, Bloomsbury Square, London, on Tuesday, December 13, when Mr. W. Murton Holmes will deliver a lecture on "Deep-Sea Deposits." Mr. Holmes proposes to give a short account of the principal microscopic organisms found at the bottom of the sea, and to compare them with certain deposits which are now found on land. The lecture will be illustrated by lantern slides, and members are invited to bring any friends who may be interested in the subject. The meeting will open at 8 p.m. sharp, when the chair will be taken by the President of the Society—Mr. Walter Hills.

THE INVERNESS CHEMISTS' ASSOCIATION has commenced its winter session with an illustrated lecture by Mr. W. Lamond Howie, on Mont Blanc and the Matterhorn, and the Hon. Secretary, Mr. Lewis MacLeod, informs us that several of the local medical men have intimated their willingness to assist the Association in its work. Already a discussion on the new B.P. has been arranged for, and one of the members of the Association will initiate that discussion by reading a paper on the subject. Presumably, also, though the fact is not stated by Mr. MacLeod, the members of the Association will meet to discuss the Federation programme, and more especially the subjects of compulsory poison regulations and company trading in pharmacy, which are more prominent and better fitted for discussion at the present time than any other problems of special pharmaceutical interest.

IT IS EXTREMELY IMPORTANT that the subjects referred to should be seriously considered, with a view to fresh legislation, by every pharmaceutical association in Great Britain before Christmas, in order that the views of the whole trade may be put before the Council of the Pharmaceutical Society at its first meeting in the new year. As we point out elsewhere, to a correspondent who seems to fail to grasp what is necessary at the present moment, chemists and druggists generally have to consider in the first place whether it is desirable that steps should be taken to secure further alteration in the existing pharmacy and poison law. If that point be decided in the affirmative, the next steps will be for the trade to agree what alterations should be attempted, and to furnish the President and Council of the Pharmaceutical Society with the support necessary for enabling them to proceed with a suitable measure.

A DRAFT PHARMACY BILL may be an attractive thing to criticise, especially to registered chemists who are without the pale of the Society, but unless a sufficient measure of support is forthcoming from that class, in addition to what is furnished by the existing members, it is improbable that much room will be afforded for criticism, except it be criticism of the non-existent. It must be clearly understood that the probability of any attempt being made by the Society to promote fresh legislation will be strictly limited by the numerical strength of the Society. The greater the increase in strength during the next few weeks, the more likelihood will there be of measures being attempted for the regulation of the practice of pharmacy, but it would obviously be absurd for the Society to attempt what is at present, utterly beyond its capacity as a representative body.

THAT THE SOCIETY should at once set about drafting a Bill and spending money freely, in an attempt to limit the sale of drugs

to duly qualified persons, might gratify many who do not contribute in any degree to the expense of promoting such a Bill. And if it were passed, some few registered chemists might join the Society. But under existing conditions there is no reason why the Society should embark in enterprises of the nature indicated for the sake of such a possibility? Is it not infinitely more logical that those individuals should join the Society first, and thus give it the benefit of their direct support during the struggle? The Society has two special duties and two only—one to protect the public in the matter of the sale of scheduled poisons, and the other to advance the interests of its members. It is under no obligation whatever with regard to registered chemists outside its ranks, and if they wish to influence its policy or stimulate its action their obvious course is to become members forthwith.

A CIRCULAR IS IN COURSE OF BEING ISSUED by the Secretary of the Pharmaceutical Society to the Society's local secretaries throughout the country, pointing out that the official confirmation of the new Bye-laws—giving effect to the provisions of the Act passed last session—places every person on the Register of Chemists and Druggists in a position to become a member of the Society. The circular also requests local secretaries to bring this fact under the notice of the chemists and druggists, in their several districts, who are still unconnected with the Society, and personally to urge upon them the pressing necessity of general organisation as a means of providing the protection which is now felt to be more requisite than ever. Attached to the circular is a memorandum for distribution, stating the nature of the advantages enjoyed by members of the Society, the principal one being representation in the executive body, which not only manages the private affairs of the Society but is entrusted by the Legislature with the administration of the law relating to the exercise of the business of chemists and druggists and with the conduct of the qualifying examination. The possibility of making that position serviceable for the purposes of defence, or for advancing and protecting the interests of registered chemists and druggists—either by the internal self-government, which the Society's democratic constitution admits of, or by appealing to Parliament for an amended Pharmacy Act—is now absolutely at the command of all registered chemists who, as members of the Society, can decide upon the policy to be pursued in their interest and can accordingly elect their representatives to carry out a line of action commanding general support.

THE USE OF SYMBOLS IN PRESCRIPTIONS is referred to by a correspondent of the *British Medical Journal*, who has noticed how the use of the customary symbols in prescription writing has been denounced, because a hospital nurse accidentally poisoned a patient through misinterpreting one such symbol. The fact of that fatal misadventure having recently occurred prompted one medical writer to suggest that, "at this time of the day, we can afford to dispense with these symbols considering the danger to human life." But, the present writer asks, would he not also think it advisable to dispense with the "opium," which was shown to be the cause of death in the case in question, for the very same reason? "The mishap referred to was caused simply by the fact that the prescription came into the hands of a person for whom it was in nowise intended, and to whom it should naturally be quite unintelligible. What has a 'nurse' to do with the reading of prescriptions? They are meant solely and exclusively for a qualified chemist, and if they are invariably transferred to his hands, all the directions necessary for nurse, etc., will appear in plain English on the label attached to the medicine, and mistakes cannot occur." The

writer also remarks that he sees no reason for the change suggested, and he expresses the opinion that, should such a change be adopted, it would lead to very much greater danger in the same direction. Life is too short to enable the busy practitioner to write his prescriptions always in plain English, and abbreviations would naturally result, increasing very materially the probability of such mishaps. In conclusion, it is said to be more than probable that every medical man who is a master of the art of prescription writing will rigidly adhere to the symbols which experience has proved to be exceedingly convenient, thoroughly efficient, and absolutely safe—"if used only by those who know how—from ages past to 'this time of day.'"

LIEUT.-COL. AND SHERIFF PROBYN was entertained on Tuesday last at a dinner which took place in the Victoria Hall of the Hotel Cecil, and was arranged by a large number of his masonic friends, for the purpose of congratulating him on his election as one of the Sheriffs of the City of London. The chair was taken by the Earl of Euston, and the number of those present at the dinner was upwards of a hundred. Mr. Probyn is well known to most readers of this Journal as a member of the pharmaceutical body, and to many as an enthusiastic freemason, upon whom the high office of Grand Treasurer has been conferred. He is also a distinguished member of the Volunteer force, has taken an active part in public affairs, as a member of the London County Council, and has recently been elected to the office of Sheriff. After the customary loyal toasts Lord Euston proposed the health of Mr. Probyn and presented him with a piece of plate as a memento of the occasion. In returning thanks, Mr. Probyn said he was deeply touched by the kind feeling his numerous masonic friends had manifested, and in a brief, unaffected speech he expressed, on behalf of himself, his wife, and sons the gratification afforded by being the recipient of such a mark of esteem.

THE REGISTRATION OF MEDICAL COMPANIES continues, and at the meeting of the General Medical Council on Tuesday, Mr. Tomes directed renewed attention to the matter in moving the adoption of a report from the Companies Acts Amendment Committee in regard to the proposed amendment of the Companies Acts, with the object of preventing the registration of companies to carry on medical, surgical, and dental practice. The Committee, after mentioning that deputations had waited upon and submitted memorials to the President of the Board of Trade and Sir Kenneth Muir Mackenzie (on behalf of the Lord Chancellor), stated that it had been advised to have a draft of a Bill prepared which would meet the case of the Medical and Dentists Acts. Accordingly, the Committee had requested the standing counsel to the General Medical Council to do so, in order that the draft might be submitted to the Lord Chancellor. That had now been done, and the Committee asked the Council to approve its action. Mr. Tomes having pointed out that the evil was still going on, three companies having been formed since the Committee communicated with the Lord Chancellor, the report was adopted, and a resolution passed reappointing the Committee and requesting it to continue its efforts for the improvement of the law upon the subject of companies formed to carry on professional functions.

THE REPORT OF THE PHARMACOPŒIA COMMITTEE of the General Medical Council, presented and adopted on Wednesday, states that up to the present time 20,500 copies of the first issue of the British Pharmacopœia of 1898 have been sold, and as only 1000 copies now remain in stock the Committee thinks it is desirable that a further

issue of 5000 should be ordered. It is remarked that the new Pharmacopœia seems to have proved acceptable to the medical profession generally, and has likewise been well received by pharmacists. The Committee is of opinion that some of the criticisms of the Pharmacopœia should be investigated and reported on by experts, suggests that arrangements should be made for carrying out such investigations and also for accumulating information for the next publication of a Pharmacopœia, and recommends that Dr. Attfield be asked to report on the criticisms passed on the Pharmacopœia, and on the progress of pharmacy and pharmaceutical chemistry during the years 1897 and 1898. It is further recommended that the Pharmaceutical Societies be invited by the General Medical Council to co-operate in these inquiries and investigations. They might, it is suggested, be invited to appoint representatives to confer with members of the Pharmacopœia Committee, and the Pharmacopœia Committee should have the power to appoint experts in pharmacy and pharmaceutical chemistry to report upon matters deemed worthy of investigation. The Committee also suggests that Dr. Tirard should be requested to act as reporter to the Pharmacopœia Committee on advances in pharmacology and therapeutics bearing on the Pharmacopœia.

THE INDIAN AND COLONIAL ADDENDUM is specially referred to in the report, which recalls the fact that twenty-eight bodies sent in recommendations and suggestions through the Privy Council, relative to new remedies or to changes in descriptions and processes desired for recognition in India and the Colonies. Many of the suggestions were adopted in the British Pharmacopœia of 1898; others were dealt with in an appendix. The remainder, connected for the most part with recommendations concerning new drugs, were reserved to be dealt with in connection with an Addendum. Some progress has since been made in the matter; the drugs recommended for introduction have been carefully examined and described under the direction of the Pharmacopœia Committee, and suggestions have been drawn up with regard to preparations which may be required. It is proposed that those descriptions and suggestions, embodied in a Report from the Committee, shall be forwarded to the Indian and Colonial Medical Authorities, through the Privy Council, and also to other medical and pharmaceutical experts in India and the Colonies, with the view of obtaining further suggestions and criticisms prior to the production of the Indian and Colonial Addendum.

A SPECIAL REPORT ON THE PROPOSED ADDENDUM, advance copies of which have been supplied to us by Dr. Attfield, states that whilst a large number of the suggestions received from India and the Colonies have been embodied in the new Pharmacopœia, and others dealt with in an appendix to that work, many remained which it was thought best to treat separately in an Addendum. Monographs have therefore been prepared, and the respective Indian and Colonial authorities are now invited to criticise and amend the descriptions given of the various drugs, in order that such descriptions may apply to satisfactory commercial specimens. They are also invited to supply certain complete descriptions which have not yet been obtained, to express an opinion as to the suitability of the preparations proposed, and to state the doses of the preparations; further, to make suggestions respecting such additional drugs and preparations as may be deemed desirable, in order that the completed Addendum may meet the requirements of the Colonies and Dependencies. The aim of the Medical Council is, we are told, to produce, sooner or later, a Pharmacopœia which shall be equally useful in every part of the British Empire, but it is desired to recognise special articles for particular

Colonies or Dependencies in such a manner as to avoid undesirable substitution of one drug for another in other parts of the Empire.

THE DESCRIPTIVE LIST OF DRUGS, proposed by Indian and Colonial authorities for official recognition, covers twenty-three pages, similar to those of the B.P., 1898. It includes suggestions for pharmaceutical preparations, and further suggestions and comments are invited. The drugs, etc., proposed for official recognition are arranged under the names of the Colonies or Dependencies from which the recommendations of the articles have been sent; in certain instances, however, identical suggestions have been received from two or more places, and in such cases the descriptions are not repeated. Hong-Kong recommends for official recognition *Agropyrum* (the rhizome of *A. repens*), and its decoction, together with *Belæ Fructus* and its liquid extract, *Daturæ Folia*, and a spirituous extract of liquorice. India has a more lengthy list, including *Acaciæ Arabicæ Cortex* (as a substitute for *Quercus Cortex*), *Acaciæ Gummi* (the gums exuded from *A. catechu*, *A. leucophloea*, and *Feronia elephantum*); the juice of *Acalypha* (the juice of *A. indica*, recommended as an equivalent of senega); Acetic Acid (a proposal to prepare it by mixing one part by weight of glacial acetic acid and two parts by weight of water); *Andrographis* (the dried plant, *A. paniculata*), its infusion, concentrated solution, and tincture; *Aristolochia* (the stem and root of *A. indica*), its infusion, concentrated solution, and tincture; *Aurantii Cortex Indicus* (from other varieties of orange than that official in the B.P.); *Berberis* (the stem of *B. aristata*), its concentrated solution and tincture; *Belæ Fructus* (the dried, half-ripe fruit of *Ægle marmelos*) and its liquid extract; *Betel* (the leaves of *Piper betel*); *Buteæ Gummi* (an exudation from the stem of *Butea frondosa*), its compound powder and tincture; *Buteæ Semina* and their infusion; *Cambogia Indica* (from *Garcinia morella*).

THE WORD "CAMPHORODYNE" has been suggested by the Indian authorities as a suitable name for *Tinctura Chloroformi et Camphoræ Composita*, but it is not thought to be desirable. Other items in the Indian list are the following:—*Catechu Nigrum* (an extract from *Accacia catechu*), its compound powder, tincture, and lozenges; *Cissampelos* (the root of *C. pareira*) and its extract; *Coscinium* (the stem of *C. fenestratum*), its infusion, concentrated solution, and tincture; *Crinum* (the bulb of *C. asiaticum* var. *toxicarium*, suggested as a substitute for squill in the various official preparations of the latter); *Cinnamomi Lignum* (the wood of *C. glanduliferum*); *Datura Folia* and *Semina* (the leaves and seeds of *D. fastuosa*) and their respective tinctures; *Embelia* (the fruit of *E. ribes*); *Exacum* (the dried plant of *E. bicolor*); *Fœniculi Fructus* (the Indian fruit); *Glycyrrhiza Radix* (the root of *Abrus precatorius* is suggested as a substitute); *Gossypii Radicis Cortex* (the root bark of *G. herbaceum*, recommended as a substitute for ergot); *Gummi Indicum* (a gummy exudation from *Anogeissus latifolia*) and a mucilage prepared from it; *Ispaghula* (the seeds of *Plantago ovata*, recommended for use in making demulcent drinks); *Jasminum* (the flower of *J. sambac*, recommended as a lactifuge); *Mudar* (the root-bark of *Calotropis procera* and *C. gigantea*, recommended in place of ipecacuanha); *Mylabris* (the dried beetle, *M. phalerata*), its ointment, plaster, tincture, and vinegar; *Myrobalanum* (the immature fruits of *Terminalia chebula*), recommended as a substitute for galls in making the official ointments of the latter); *Oleum Ajowan* (oil distilled from *Carum copticum*, recommended for use in place of the oils of caraway, anise, dill, and peppermint); *Oleum Arachidis* (oil expressed from the seeds of *Arachis hypogæa*, recommended in place of olive oil); *Oleum Graminis Citrati* (oil distilled from *Andropogon citratus*, recommended to replace

cajuput oil in croton liniment and lavender oil in compound camphor liniment); *Oleum Sesami* (oil expressed from the seeds of *S. indicum*, recommended in place of olive oil for some preparations); *Samadera* (the wood and bark of *S. indica*, recommended as a substitute for quassia); *Sappan* (the heartwood of *Cesalpinia sappan*, recommended in place of logwood) and its decoction; *Swertia* (the dried plants of *S. affinis*, recommended as the equivalent of chiretta); *Thus Indicum* (the semi-solid oleo-resin of *Pinus longifolia*, recommended in place of American frankincense); *Tinospora* (the stem of *T. cordifolia*, a substitute for calumba), its infusion, concentrated solution and tincture; *Toddalia* (the root bark of *T. aculeata*, a substitute for cusparia bark), its infusion and concentrated solution; *Tylophoræ Folia* (the leaves of *T. asthmatica*, a substitute for ipecacuanha); and *Valerianæ Rhizoma Indicum* (the rhizome and rootlets of *V. leschenaultii*, var. *brunoniana*).

THE INDIAN MONOGRAPHS IN MANY CASES are accompanied by notes, in which objections are pointed out, suggestions made for further investigation to be made, or questions asked as to whether certain preparations, etc., are desirable or not. As may be imagined, the monographs originating in the Indian suggestions constitute the greater portion of the draft Addendum, but there are also a few suggestions from Australasia. Thus, Queensland asks for *Alstonia* (the bark of *Alstonia constricta*) and its tincture; *Beilschmiedia* (the bark of *B. obtusifolia*) and its tincture; *Duboisia* and *Duboisine*; *Euphorbia* (*E. pilulifera*) and its preparations. Victoria, in turn, desires the description of *Acaciæ Cortex* to cover commercial samples of the barks of *A. mollissima*, and *A. decurrens*. With regard to *Aconiti Radix*, information is required whether aconite root grown in Victoria corresponds exactly to that described in the B.P. *Duboisia* (the leaves of *D. myoporoides*), its tincture and ointment, and *Duboisine* are recommended for inclusion by the Victorian authorities, and attention is directed to some kindred drugs—*Anthocercis viscosa* and *A. tasmanica*, both of which contain an active principle similar to duboisine. *Duboisia hopwoodii* is also referred to. In a note on *Eucalypti Gummi*, it is stated that the Victorian authorities recommend that the official gum be limited to the product of *E. rostrata*, and that suppositories, syrup, tincture and lozenges prepared from that gum should be official. The last-mentioned articles in the Victorian list are *Fœniculi Fructus Victoriae* (the fruit desired for official recognition is that of *F. officinale*), *Grindelia* (the dried leaves and flowering tops of *G. squarrosa*), and *Kino Eucalypti* (varieties having the characters and responding to the tests of kino).

THE BOARD OF CHARITY COMMISSIONERS FOR ENGLAND AND WALES gives formal notice that an Order is proposed to be made by them after the expiration of one calendar month, establishing a scheme for the administration of the Chelsea Physic Garden, and for the further modification of the scheme regulating the charities called "The City Parochial Foundation." Any objections to the proposed Order or suggestions thereon should be transmitted to the said Commissioners in writing twenty-one days after the 23rd day of November, 1898, addressed to the Secretary, Charity Commission, Whitehall, S.W. Printed copies of the proposed scheme may be inspected free of cost on each week-day during a period of fifteen days from the first publication of this notice, between the hours of 11 a.m. and 5 p.m. (Saturdays excepted), at the Offices of the City Parochial Foundation, No. 3, Temple Gardens, and between the hours of 10 a.m. and 4 p.m., at the Offices of the Commissioners, where also copies may be purchased during the same period at 6d. each.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The familiar conversazione of this Association gave place this year to a smoking concert, which was held in the Grand Hall, Freemasons' Tavern, W.C., on Thursday, November 24. The concert was an unqualified success, both in point of view of attendance and also of excellence of the programme provided. Amongst those present were many well-known members of both retail and wholesale pharmacy. The chair and vice-chair were respectively filled by Mr. R. A. ROBINSON, L.C.C., and Mr. FRANK A. ROGERS. During the interval the PRESIDENT, Mr. F. W. Gamble, in a humorous and well-turned speech, proposed a vote of thanks to the Chairman and Vice-Chairman, coupling with it an allusion to the creditable manner in which the arrangements had been carried out by the Hon. Secretary of Committee, Mr. C. Morley.—The audience, in response to the President's invitation, accorded the vote with much enthusiasm, simultaneously rising and singing in a very spirited manner "For He's a Jolly Good Fellow."—Mr. ROBINSON, replying, expressed the pleasure it gave him to be of service to the Association, and incidentally remarked on the good work which was being done under its auspices.—Mr. ROGERS followed with acknowledgments, and said that he felt much gratification in renewing for a time an active interest in the Association's affairs.—The different items of the programme were well rendered by the following gentlemen: Messrs. Robert Grice (baritone), T. Wills Page (tenor), Alexander Edwards (cornet), Sam Wright, Harry Bluff, Percy Bell, and Fred Wilson (comic vocalists), Mr. Charles King (sketch artist), and Mr. Albert Jorden (accompanist). The quick change and ventriloquial contributions of Mr. King evoked very general approval, as did the performances of Messrs. Page, Edwards, and Wright. The rather well-known imitative sketch by Mr. Tompsett (whose name did not figure on the programme) also afforded considerable amusement. Interest in the programme was well sustained until the singing of the National Anthem, which marked the conclusion of a very enjoyable evening.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

The annual dinner of this Association was held in the Prince of Wales's Restaurant, Glasgow, on Thursday, November 24, when Mr. WM. L. CURRIE, the President, occupied the chair and a large company was present. The usual loyal and patriotic toasts having been given and heartily pledged,

Mr. JOHN WALKER proposed the toast of

The Medical Profession.

Referring to the relations existing between pharmacy and medical men he said, chemists did not wish to go into what was known as "counter prescribing," and thus tread on the toes of their medical friends.

Dr. EBENEZER DUNCAN, in reply, referred to the relations between medicine and pharmacy, and said it would be a great improvement if the two branches were entirely separated. They would then have no doctor dispensing medicine, nor any chemist or druggist giving advice. He thought it was a very wrong thing for a medical man, who had so much to learn in connection with his own profession, to enter into competition with any other profession. At the present moment he thought the one great danger was that they might get into the hands of certain great manufacturers of drugs. There was a danger in medical men prescribing simply certain specialties sent out by the great manufacturing firms, and it behoved their professors of materia medica in the universities to teach their students to prescribe properly and to send their prescriptions to competent pharmacists to be compounded. It was high time pharmacy was put on a footing with the other professions and registered by the Government, and no one permitted to deal with dangerous remedies unless they could show a thorough acquaintance with the nature of drugs. Dr. Duncan also expressed the opinion that pharmaceutical students should add zoology to the subjects of their preliminary studies.

Professor STOCKMAN, of the chair of Materia Medica in Glasgow University, next proposed the toast of

The Pharmaceutical Society.

In every possible way, he said, the Society is trying to advance the

art of pharmacy and the science of medicine. He was very pleased to see that the standard of the Preliminary examination was to be raised to an equality with that of medical and other professions. That was a very great advance. The higher the standard of general education—apart from technical education—which was introduced into any profession the greater would be the influence of that profession throughout the community. It would be a good thing if the Pharmaceutical Society became more powerful than it was at present, but if they were to obtain more power, and so benefit the community, they must band together. Units are never so powerful as a united number. The Society had shown by a recent enactment that there was no jealousy with regard to the admission of new members, or rather of the admission to membership with full powers, and that indicated a very great advance.

Mr. J. LAIDLAW EWING, Chairman of the Executive of the North British Branch, replied to the toast. He first congratulated the chemists of Glasgow on having in the chair of materia medica of their University one with so sympathetic a feeling to pharmacy as Professor Stockman, and augured the best results, both for the teaching of materia medica in Glasgow and for the elevation of pharmacy in that city. He referred at some length to the proceedings in connection with the recent opposition by Mr. Cross, Member for the Camlachie Division of Glasgow, to the Pharmacy Acts Amendment Bill and to the Government's Poisonous Substances Bill, and in regard to this latter measure, said it intended to do what he should strongly oppose—abolish the personal qualification of the seller of poisons. He mentioned this because it was time they should set their house in order. He saw no reason why the Society should not now carry out its intention of some years ago and regulate how the poisons should be stored in their pharmacies, and thus prevent a Government department doing what he was sure would be the invidious task of appointing men to look after their pharmacies. Having paid a compliment to Mr. Currie for the valuable assistance he had given to the Society in connection with these Bills, Mr. Ewing said they had learned from the Parliamentary work of the past session that the House of Commons was by no means anxious to relax the laws regulating the sale of poisons. He was perfectly certain that any future legislation would point rather to the strengthening than the relaxing of the restrictions on the sale of poisons. They had learned also that their trade had a greater influence in the House of Commons than they had ever dreamt of before. That had been again and again expressed by members of Parliament, and he did not wonder at it, because they must remember that the educational qualification of their members throughout the country was a very high one and those members were able to bring to bear upon their representatives the influence this gave. Another lesson they had learned was that it was necessary to have some central body at their back to attend to their interests, and the only body they had was the Pharmaceutical Society. He hoped now that the Council of the Society had been thrown open so widely to the members of the Society, that all pharmacists would join the Society and do their best to strengthen its position, because only through it could the legitimate interests of the chemists and druggists throughout the country be expressed.

Mr. J. RUTHERFORD HILL, Edinburgh, in proposing the toast of

The Glasgow and West of Scotland Pharmaceutical Association,

spoke of the excellent influence upon pharmacy in the West of Scotland which the Association had exerted. The Association had accomplished good work in advancing the professional side of the craft, on which the future of pharmacy so much depended. It was by that line of action they gained the respect and confidence of the medical profession, and also ultimately the respect and esteem of the general community. There was, however, much yet to be done. There was the great question of company pharmacy, and they had to set themselves to find out how the professional rights and the legitimate privileges of registered chemists were to be conserved in a country where companies for trading purposes seemed likely to become the rule. There was also the question of poison regulations, a question on which most were disappointed and surprised, because of the way in which it had been dealt with in the Government Bill. That represented an attempt to turn back the clock for thirty years, to the time that preceded the Pharmacy Act of 1868. Before that time a similar attempt had been made, and it was because that attempt had utterly and hopelessly broken down that another attempt had been made in the Act of 1868, founded on the principle that the

education and training of the vendor were the only possible bases for a Poisons Bill. That was the only principle likely to work, and the fact that a Government Department should have so completely forgotten that incident warned them that they must be ready to act unitedly and promptly to conserve that principle.—Mr. DAVID WATSON, the Hon. Secretary of the Association, in acknowledging, said that the membership of the Association at present was about 200. It had been suggested that the Association should be made more of a trade organisation, and while he trusted that the scientific side of the Association would not be overlooked, he quite agreed with the feeling that a more general interest in the proceedings would be aroused if it were more like the Edinburgh Chemists' Trade Association.

PRIZE PRESENTATION.

—Mr. RUTHERFORD HILL next presented to Mr. Martin Meldrum, assistant with Mr. John McMillan, the Kinninmont prize, competed for annually by pharmaceutical students in Glasgow and the West of Scotland. The prize was in the form of a gold medal with a suitable inscription. Mr. Meldrum was complimented on the splendid work he had done in his examination papers, which were the most satisfactory Mr. Hill had ever had through his hands.

Other Toasts.

The remaining toasts on the list were then dealt with: "The Guests," given by Mr. Thos. Dunlop, Dr. A. Wood-Smith replying; "The Croupiers," given by Mr. Charles Kerr, Mr. McMillan responding, and "The Chairman."—During the evening Dr. Mehan, Messrs. Kilpatrick, Orr, W. L. Currie, Dykes, Lorimer, Moyes, and Cairneross (ventriloquist) contributed to the harmony of the proceedings.

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.

The opening meeting of this Association for the session was held on Tuesday November 29, when the chair was taken by the President, Mr. DAVID MACLAREN, who devoted his opening address to a consideration of

The Duties and Privileges of a Chemist and Druggist.

He said: As the subject of a few introductory remarks, I have fixed upon that of the duties and privileges of a chemist and druggist. The scope of such is of very wide application, and can be looked at from many a standpoint. It is a very ancient trade, as we heard in Glasgow on Thursday night, and, having many high and honourable traditions attached to it, it must be the aim of every one to hand down to our successors in office pure and unsullied the good name that has been given to ourselves. We meet here as members of a society anxious to promote the improvement of the art of pharmacy. I feel sure that every one here present is desirous of doing his best to cultivate this Art, and by every means to further and promote its usefulness and raise it as an essential department of the practice of medicine. It is our privilege to be humble ministers in the work of healing the sick. We do not aspire to that higher state which enables the physician to search out and determine the nature, the seat, and the cause of disease; nor do we profess to be able to indicate what are the agents best suited for the relief of those who suffer from its effects. Yet we have a province distinctly our own, a sphere of action which, if closely adhered to, will materially serve the end the physician has in view in the treatment of the ailments of his clients. The duty of a chemist and druggist is to dispense, in strict accordance with the instructions of the writer, all and every prescription handed to him. This, of course, is subject to the usual reservation clause, that everything on the part of the doctor (to use a church phrase) has been done decently and in order; the ingredients compatible, and the dose within the bounds of reason. Should a particular preparation by a particular maker be so ordered, and in our own establishment we have a preparation which to our mind is infinitely superior to that ordered, it is not our duty to put such in the place of the one ordered. I have no sympathy with those who, in their desire to get rich, seek in season and out of season, by copying parrot-like, the ideas of others, or, to use a stronger phrase, with those who "pick the brains of others," thus trading at the expense of the thought and energy of some poor fellow who, if left alone, would find a "triumph of pharmacy." The all-absorbing cry is heard on

every side that the number of patent and proprietary articles is such that no ordinary drug shop can hold them. Far be it from me to dare to tell you that, when little liver pills are asked for, you should not give a box of your own. Yet I feel that way, and would like to tell you so. Your so doing is only adding another to the numerous array of quack remedies. "Never mind the cash" used to be the motto of a certain place in Cockburn Street, and for all that is really to be made from so substituting is it really worth minding? Let us try to raise our position by a careful selection of the finest drugs and chemicals; and by skilful manipulation of the same to provide for the use of medical men preparations on which they can rely with almost absolute certainty, and our position will be such as we can stand by and defend. Do not let us give way to

THE CALL FOR CHEAP PHYSIC.

Let it be of the proper quality, and we need not be afraid to name a reasonable price. Do not try to undersell your neighbour, or even sell at the same price as him. Fix your own price, and your customers and friends will like you the better. I speak in this connection more particularly with our dispensing charges, and I feel sure that, in ninety-nine cases out of a hundred, he who has a fixed line of conduct in charging, never caring where or by whom this or that recipe was prepared formerly, put his own price thereon, will surely in the end have the confidence and earn the respect of his customers. Patent and proprietary articles—let them go. We have no Charter for the sale of such. In connection with this matter it has been put to me, Has the time not come when we, the chemists and druggists of Edinburgh, should issue a list of patent and proprietary and other articles in daily consumption, and quote therein bottom prices, and send the list broadcast throughout the city? I leave the answer to the collective wisdom of you, fathers and brethren. We have, no doubt, great responsibilities, yet, if we have, we have high privileges. A Charter was granted to our craft in 1843, and confirmed by the Acts of Parliament in 1852 and 1868, giving to those who, by having attained a certain standard of education, a certain specified training in the service of a chemist and druggist, or, might I be permitted to say, in the service of a member of the Pharmaceutical Society, and passing a qualifying examination, the sole right to sell certain retail articles specified. This is the spirit of the Act of 1868, but "the best-laid schemes of mice and men oft gang a-glee," and, while the spirit is there, the flesh is wanting. By careless drafting of what was intended to be for us a good Bill, the very provisions desired to be reserved for our exclusive benefit have been so interpreted as to admit of others who have no right to benefits such as these. How are we to regain these privileges and conserve them? Is it by taking advantage of the 1868 Act, by passing our Minor examination and thus, having acquired the privilege of going into business as a chemist and druggist, determine that, so far as we are concerned, we will have nothing more to do with

THE PHARMACEUTICAL SOCIETY;

a Society that has done so little for raising the status of the profession to which we belong? This is from our own selfish little standpoint, and at the first blush may seem right. What can the Society do for us? It has limited, might I say very limited, powers conferred upon it; the power of examining, the power of conferring the right to open a shop on him who doth successfully pass the ordeal of the examination room; the right to use the title of chemist and druggist, or the higher title of pharmaceutical chemist, with all the rights and privileges of such as conferred on them by the Act of 1868. But here it must stop. What can it, in the present divided state of the drug trade, do more? It has not the power, the more the pity, to compel all who pass the examination to become members of the Society. This, I am convinced, is the weak spot, or at least one of the weak spots, in the Act so carelessly drawn. A condition of the opening of a shop should either have been the payment of a lump sum or the payment of an annual subscription into the funds of the Society. Failure to pay said sum being a barrier to the starting or carrying on of business. This naturally leads up to the vexed question of limited liability companies and their right to the title of chemist and druggist, or, what is of more importance than the name, the right to sell and to dispense poisons, under the meaning of the Act, either by themselves or as parts of the prescriptions of medical men. The court has decided that such corporations have the right to do so if they employ qualified men,

Can this decision of the court be overturned? Yes, by an Act of Parliament. In the present temper of the House of Commons, and needless to say, the House of Lords, I feel sure that the chemists and druggists, if united, would get such support as would pass any Bill that had for its purpose the public safety. The passing of the short simple Act this year, or, to put it more correctly, the Cross opposition to its passing, showed the true temper of Parliament, and proved conclusively, to me at least, that they were ready and willing to redress any seeming injustice that had been intentionally or unintentionally done by the Act of 1868. Are we united? 4,741 in the Society, 10,474 outside of the Society. A united body! Truly we are not. If

THOSE WHO STAND OUTSIDE THE SOCIETY

and cry—Give! give! would only become part and parcel of the Society, pay their just dues and feel that on them, as individuals, rested the power to demand, from the powers that be, the rights that were really intended to be conferred on them by the Act of 1868, I feel sure that such a pressure would be brought to bear on this question that no Government would be able to withstand. The expressed opinion of the Houses of Parliament is with us, the voice of the medical profession is with us, and I feel certain that the universal voice of the intelligent public is with us, in asking great powers to deal in dangerous medicines. Why, then, should those who depend upon our trade for their daily bread be so apathetic? United we stand, divided we fall. Let us, as individuals, do all that in us lies to reclaim our lapsed masses and get them to become members of one united body, and we will realise that we have power which, if legitimately used, no other power can resist. Four thousand can do but little with 12,000 outside, but let the 16,000 act as one man, and the victory will be ours. I had intended saying something as to the storage of poisons, but I have not been able to get any new light on the subject. Various plans have been suggested—poison cupboards, bottles with patent stoppers, and other modes too numerous to mention. If poisons, in the broad sense of the word, are to be isolated, it would require a room of no small dimensions to contain them all. To my way of thinking, while being very careful to have all bottles duly labelled, the best way to secure the safety of the public and the prevention of mistakes is by a careful supervision and a thorough course of drill to the young men who come to serve as apprentices. If their training was at this early stage looked after we should have a better race of men in our profession. I would humbly suggest that no one should be allowed to begin an apprenticeship till he or she has gained the preliminary qualification of the Society. They could then enter upon their duties in the shop free from any thought of outside influences. Had time permitted I might have called attention to the question of compulsory attendance on classes for a lengthened period, the question of the style and title of a firm. Should the old name be kept on the place of business and on the labels on the bottles and packets sent out? But I leave the solution of these problems to wiser and better men. I am jealous for the honour of the trade of which I am a humble member, and would desire to do all in my power to further its interests. I feel sure that, were we a united body striving for one great good, the triumph of pharmacy, putting aside all petty jealousies and working for the good of all, our trade would yet become what we would wish it to be, and occupy that high place that our legislators by the Charter of 1843 and the Act of 1852 and 1868 desired it to be raised up to.

Discussion.

Mr. LUNAN, Vice President, in moving a vote of thanks, said he hoped the address would be published and read by a much larger audience than they had there that day. The Chairman had rightly emphasised the importance of manipulative skill in dispensing, so as to render it irreproachable. By strict integrity in that department and careful attention to the quality of materials, pharmacists would best secure public confidence and recognition. He thought the Pharmaceutical Society was wise in paying heed to the higher education and training of the pharmacist, and with the general trend of the Society's policy he believed they were all in hearty sympathy, though they might occasionally differ as to details.—Mr. BOA having seconded the vote of thanks,

Mr. J. RUTHERFORD HILL said reference had been made to the spirit of the Pharmacy Act, 1868. It was unquestionably the spirit of that Act that the dispensing of all medical prescriptions should be limited to the hands of a body of men specially trained for such a delicate and responsible duty. That idea entered

into the very substance of the Act, and yet the Act failed to accomplish its own obvious purpose in that respect. This anomalous condition was emphasised by the fact that by the Irish Pharmacy Act of 1875, the exclusive right of dispensing all physicians' prescriptions is conferred on persons registered under that Act. It seemed absolutely absurd that the State should establish a statutory class of persons who had given a public guarantee of their competency to discharge a highly responsible duty and then allow any Tom, Dick or Harry to dispense any prescription for any case, however important and critical, provided only the prescription contained none of a few articles that were scheduled as poisons. Public health and public safety demanded a rectification of this anomaly, and he thought no Legislature would refuse to pass a measure having that object as its aim. With regard to the necessity of combination among chemists, isolated units could do very little, but units in combination might be all-powerful. He felt convinced that whenever pharmacists turned their minds seriously and resolutely to the question of combination, they would inevitably come to the conclusion that the Pharmaceutical Society was the only body which they could join with any reasonable prospect of doing effective work. In Scotland it was a very thankless and expensive task for the Pharmaceutical Society to prosecute under the Pharmacy Acts, since even when the offence was clearly proved and a conviction secured the practical upshot was that the Society was fined some £10 or £12, while the real delinquent got off with a small fine, or in many cases scot-free. That was a most absurd position for a public prosecutor to be placed in. But it ought to be known that the Registrar never lost any opportunity of arresting an evil and obviating an offence, even although in many cases the proceedings never came before a judge. He was glad to say there was now in Scotland a more wholesome conviction that the Society was justified in its efforts to restrain and put down offences against the Pharmacy Acts, and recent experience had shown that those means, short of prosecution, had been more successful than hitherto in securing a better observance of the law. With regard to the storage of poisons, he thought the Privy Council had some reasonable ground for their complaint that the Society had in a sense broken faith in not passing into statute law what were merely adopted as recommendations in 1871. No doubt trained chemists had some justification for their disinclination to be compelled to adopt any particular method of storage, and they very reasonably felt that their training and education were the only really effective protection to the public. But there is really nothing in the recommendations but what every prudent pharmacist carries out in daily practice at the present time. Moreover, they are sufficiently elastic to allow reasonable freedom of action. He thought, therefore, that it was an eminently wise proposition that the Society should now remove a stumbling block out of the way, by giving these recommendations the force of law in accordance with the provisions of Section 1 of the Pharmacy Act, 1868. This, of course, brought them at once face to face with the question of joint-stock companies and other corporate bodies which carried on the business of chemists and druggists. Those storage regulations would not apply to any of them. They would not even apply to ordinary firms (*sic*), nor would they apply to either apothecaries' or doctors' shops, but only to individuals. That was an important additional reason why something should be attempted to bring the practice of pharmacy by all such concerns within the scope of the Pharmacy Acts. It was, however, a very difficult problem to deal with. Many favoured a policy of ignoring companies. Others favoured the securing of legislation to suppress them. Was there any prospect of success in either direction? It looked very much as if they would be compelled to recognise them and take effective steps to bring them under such conditions and restrictions as public safety and public health demanded. The anomaly, injustice, and danger of the present situation had been recognised and admitted in very high quarters, but the practical question seemed to be—How can the legitimate rights and privileges of registered chemists and the safeguards provided in the public interest by the Pharmacy Acts of 1852 and 1868 be adequately conserved, protected, and enforced, even in a social system in which large combinations for commercial and financial purposes seem to be rapidly on the increase and likely to become universal? Many were chiefly concerned about the question of prices and trading interests, but in that aspect he believed they would just have to submit like other traders to the well-known laws of political economy by which all such questions were inevitably determined.

—Mr. C. F. HENRY said he agreed with what Mr. Hill had said about poison regulations. There was nothing in the recommendations that need unduly harass anyone, and their adoption as compulsory would remove a cause of long-standing distrust and enmity between the Privy Council and the Society, which had shown itself on several occasions. It would be observed that in the recent Poisonous Substances Bill the Privy Council proposed to assume powers to enforce some such conditions apart from the Pharmaceutical Society. That might come to be a very serious grievance, and he thought it was wise to avoid such a danger by showing that they did not object to any of the recommendations adopted in 1871.—Mr. LUNAN put the motion to the meeting, and it was cordially and unanimously adopted.

DISCOUNT OF PROPRIETARY ARTICLES.

—The SECRETARY reported that he had received a reply from Mr. R. Adrian Smith, S.S.C., on behalf of the wholesale chemists, intimating that they had considered the proposal made by the Association, and their decision was embodied in a circular issued to the trade, in which they acceded to the request of the Association for discount of 15 per cent. and one month's credit on all orders for proprietary articles, in place of the restriction to not less than £5 orders and cash in seven days as formerly.—A letter was also read from the Board of Inland Revenue, declining to do anything in the way of removing the mineral oil from methylated spirits, and stating that it was added in consequence of many persons drinking the spirit, and no circumstances had arisen to justify any departure from the present arrangement.—On the motion of Mr. BOWMAN, seconded by Mr. McDougall, it was agreed to give a donation of £2 2s. to the Benevolent Fund, and £1 1s. to the Orphan Fund of the Pharmaceutical Society.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

At Mason University College, Birmingham, on Tuesday, Nov. 29, Mr. DENCER WHITTLES, L.D.S., R.C.S., gave to members of this Association a demonstration with an electric projecting microscope. The President for the evening was Sir JAMES SAWYER, F.R.C.P., who was accompanied by Lady Sawyer, and there was a large attendance of members, accompanied for the most part by lady friends. In his opening address Sir James congratulated Mr. Dencer Whittles upon the distinguished honour recently conferred upon him by his appointment of first dental surgeon to the Birmingham General Hospital. That institution had been slow in recognising special work, and whilst it was a fact that at many other places dental surgery had been represented for many years, this was the first occasion upon which the authorities at the Birmingham General Hospital had recognised this great field of surgical work. Referring to the Chemists' Assistants' Association, Sir James said he knew assistants were inclined to be migratory, but he was sure there was a sufficient number in Birmingham and the Midland counties to form one large association. The objects of the existing Association, tending in the direction of intellectual and social development, he warmly commended, and said it would give him extreme pleasure to become an honorary member.—Mr. DENCER WHITTLES' demonstration, which was much enjoyed by all present, consisted of views of an infinite variety of insects thrown upon the screen and minutely described. The insects were photographed from life and enlarged by electricity.

PUBLIC DISPENSERS' ASSOCIATION.

At a meeting of this Association, on Tuesday, November 29, Mr. WELFORD (Colney Hatch) in the chair, others present being Messrs. Miller, Trison, Smith, Langford, Moon, Armitage, Meister, Howard, Smith, Clark, etc., an exhaustive paper was read by Mr. S. B. DONNAN, on

Urine and its Analysis.

After the paper a vote of thanks was proposed by Mr. CLARK (Marylebone), seconded by Mr. MEISTER, of Windsor. A discussion on the

New Bye-Laws

was then started by the Secretary, G. F. FORSTER, in which Messrs. Miller, Welford, Smith, Langford, Moore, Clark, and Donnan took part. All joined in cordially welcoming the changed conditions, and wishes were expressed that the Pharmaceutical

Society might see its way clear to obtain the revoking of the Local Government minute permitting Army compounders, etc., to take Poor Law Appointments, and other points. Ultimately it was agreed to forward the following resolution to the Pharmaceutical Society, proposed by Mr. G. F. FORSTER and seconded by Mr. MILLER:—

That this meeting desires to thank the Pharmaceutical Society for its efforts in obtaining the passing of the Amended Bye-Laws and Act, and hope they will see their way to make it possible for the new members to attend by altering the time of the annual meeting from afternoon to evening.

SUNDERLAND CHEMISTS' ASSOCIATION.

On Wednesday evening last, November 23, a meeting of the Sunderland Chemists' Association was held to consider the proposed Defence Fund, submitted by the P.A.T.A. The scheme was very favourably received, and the meeting dealt with the proposals, clause by clause. It was decided to send the following suggestions to the Council of the P.A.T.A. :—

1. To add to the list of Acts, under which members were to be defended, the Pharmacy, the Poisons, and the Employers' Liability Acts.

2. That compensation be given to subscribers to the Fund in the event of damage to goods, through the breaking of the window from outside agency, in a case where damages could not be claimed from the person or persons who broke the window.

3. In reference to the clause in the draft scheme stipulating that a subscriber would be entitled to the costs of his defence up to the amount of £10, whether guilty or not, but that the Association, in the event of a conviction, would not pay any fine incurred or costs of prosecution, the Association simply guaranteeing the best possible defence, it was suggested that the costs of the prosecution should also be paid in the case of a conviction where the total costs do not amount to £10.

4. That the Association pay the costs of any appeal which they undertake.

5. To add to the last clause—namely, "That the retail membership of the Defence Fund be only open to *bona-fide* chemists"—the words "on their own account."

NEW REMEDIES.

VALERIAN TEA FOR INSOMNIA.—G. Schmidt finds valerian tea is a valuable remedy for insomnia due to nervous excitement, etc., especially for female patients. He recommends $\frac{1}{4}$ litre of boiling water to be poured on 1 tablespoonful of crushed valerian root. One or two cups of the tea to be drunk with or without sugar about an hour before bedtime. The addition of a little potassium bromide increases the action.—*Pharm. Centralh.*, xxxix., 456, after *D. arzt. Pr.*, 1898.

VANADINE AS A STOMACHIC ANTISEPTIC.—Vanadine is a liquid combination of vanadium with sodium chlorate, which, on account of its powerful oxidising action on ptomaines and toxines, Weber considered might be useful in the treatment of tuberculosis. With guinea-pigs this was found to be the case, and the results obtained were so satisfactory that the investigator submitted human beings to the same treatment. Here, however, although the results were less satisfactory as regards the primary disease, the effect upon those cases which showed gastric fermentation, so frequently concomitant with a tubercular condition, was so remarkable, and the benefit derived from the drug so great, that fresh possibilities of its usefulness are suggested. The dose given varied from 6 to 30 drops per diem, and the remedy was found to be free from the least indication of toxicity.—*Nouv. Rems.*, xiv., 340.

MONO-CHLORO-PHENOL IN RINGWORM.—The following application: Mono-chloro-phenol, 20; alcohol, 80; oil of lavender, 10; has been found by Barbé to be an excellent remedy for tinea tonsurans of children. A little of this mixture is rubbed daily on the affected area, which is afterwards covered with a small piece of tafetta. The lavender oil is added to mask the unpleasant odour of the chloro mono-phenol.—*Bull. Gen. de Thérap.*, cxxxvi., 190.

URSAL.—The favourable results which have attended the use of urea as a diuretic has led to experiments with other urea derivatives and salts as to their value in therapeutics. Of these ursal is a combination of urea and salicylic acid, and has proved to be a valuable remedy in gouty and rheumatic ailments. It can be used in all such cases with advantage. Ursal is a good substitute for sodium salicylate and other similar preparations. The dose is the same as that of sodium salicylate, and should be taken in the form of lozenges or powder.—*Pharm. Zeit.*, xlii., 828.

DISPENSING PROBLEMS AND NOTES.

PRECIPITATION OF ALKALOIDS.

Sir,—Within the past week the following prescription has come under my notice :—

℞ Potass. Iodid. grs. v.
Syrup. Eastonii ʒi.
Mitte ʒiij. t. d. s.

For two days the mixture kept quite clear, and then on being stirred a dense crystalline precipitate was thrown out. What is the nature of the precipitate and would it contain strychnine and quinine iodides?

South Lambeth, November 23, 1898.

W. J. C. (19/27).

NOTE.—Without making an investigation of the precipitate it is impossible to state what is the exact composition of it. In all probability it contains strychnine hydriodide, which is a sparingly soluble salt, and probably quinine hydriodide as well. Deductions drawn by calculation from the solubilities of these two alkaloidal salts *in water* cannot be immediately applied, because in this case the solvent is syrup containing phosphoric acid. Probably the mixture would not precipitate if the drachm dose were diluted with water to one fluid ounce, but it would be advisable to try it before making the statement.

ZINC OXIDE IN A LOTION (18/28).

Sir,—I am sending you ʒiij. of the lotion dispensed according to the form given in the Journal of November 26, viz. :—

℞ Zinci Oxide ʒvi.
Glycerini ʒiij.
Ol. Olivæ ʒvi.
Aq. Calcis ad ʒvi.

As dispensed this is quite smooth, and can be evenly applied to the skin. Though not an absolute emulsion, it does not separate into greasy masses. It was prepared as follows :—The olive oil is thoroughly stirred in a measure with an equal quantity of lime water until completely saponified; then add about as much more lime water gradually, still stirring. Rub down the oxide of zinc in a mortar, add the lime water and oil emulsion to it, first in a small quantity, so as to make a thick cream when rubbed with the pestle; add the remainder, then the rest of the lime water and the glycerin.

Plymouth, November 29, 1898.

J. DAVY TURNER.

A CORRECTION (19/7).

In some copies of last week's issue, the number 16 appears instead of 14, in the second line of the note on the communication sent by "Nemo," page 582.

PROCEEDINGS UNDER THE PHARMACY ACTS.

PHARMACEUTICAL SOCIETY *v.* EDWARDS.

On the 25th ult., at the Portsmouth County Court, before His Honour Judge Gye, the Council of the Pharmaceutical Society sued Harry Gordon Edwards, of 30, Fratton Road, Portsmouth, for three penalties of £5 each for offences under the Pharmacy Act, 1868.

Mr. R. E. Vaughan Williams appeared for the Society and defendant appeared in person.

In reply to a question of His Honour, defendant stated that he would admit his liability for the offences with which he was charged.

Having regard to this admission, Mr. Williams said it would be unnecessary for him to call the witnesses who were in Court to prove the facts. The defendant had carried on the business of a chemist and druggist at 30, Fratton Road, Portsmouth, under the style of "Gorfett's Pharmacy." On September 20 the Society sent a person to the shop, who purchased from the defendant one pennyworth of white precipitate, and on September 29 the same person was served with one pennyworth of oxalic acid by defendant's wife. The title "Chemist" appeared in two places on a red lamp outside the shop, and it also appeared on the entrance door. Reference to the Burgess List showed that defendant was the occupier of the premises. He understood that defendant has on two occasions presented himself for the Preliminary examination, but had failed to pass.

His Honour, in giving judgment for the penalties claimed, with costs, severely censured the defendant.

LETTERS TO THE EDITOR.

THE BENEVOLENT FUND ELECTION.

Sir,—The time is drawing nigh for the election of annuitants, and there have appeared in the Journal, I think, but three responses to Mr. Hampson's assertions and expression of opinion regarding the method of conducting the elections. Whether indifference or other feelings is the cause of the silence it is difficult to judge. So, thinking some other answer than those which have appeared is better than absolute silence, I venture to make a few remarks on Mr. Hampson's very strong expressions, which I object to, for, though willing to admit the kindness of his motives, I do not acknowledge that he, or those who agree with him, have a right to claim an extra feeling of humanity, one surpassing others. He says the method of procedure is "unchristian." I object to dragging in the word "christian," which is totally unnecessary, the word being already sufficiently profaned. Then he tells us it is "inhuman" to compel a candidate to canvass for votes. This is the first time I have heard that canvassing is compulsory, and think there must be some error here. It must be one of the exaggerations. But, putting that aside, it is stated that the system of giving people a chance of receiving an annuity is an inhuman one, because carried out in the most customary manner. I rather think there is a vast number of people who would gladly accept the possibility, with the inhumanities involved in the procedure. For myself, though indifferent to the application of the epithets in my case, yet I strongly object to the application in the abstract. How does it sound: "The Pharmaceutical Society in its management of the Benevolent Fund is both unchristian and inhuman"? Being rather matter of fact, and disliking exaggeration as much as hyperbolic language, I feel more disgust than I express at the designation. Hyperbolic language is allowable in poetry, both sacred and profane, so when we read "men were stronger than lions and swifter than eagles," we look upon the words as expressing the love or admiration of the speaker, and excuse it. So also when we tell a woman "she is the sweetest thing on earth," if she is a sensible woman she does not believe it, but understands it as an expression of our love and admiration. This again is allowable. But in the present matter I find no excuse. Never using the vulgar expletives which some utter, I simply say the assertions are wholly unjustifiable and wrong. Furthermore, I think with that Association which sent an opinion adverse to the proposed change, that loss would occur to the Fund, judging from experiences which are patent to all. One question I should like to ask Mr. Hampson—What name does he give to the many who do not subscribe a trifle to the Fund, even though it is administered in a so-called iniquitous manner?

November 23, 1898.

PONDO (156/9).

THE POSITION OF PHARMACY.

Sir,—Not many chemists in Scotland have as yet come forward to define their views on this question. In scattered districts of England there have been a few who have done so, but they can scarcely be classed under the heading of men of light and leading. The President, it is true, recently spoke on current problems. He certainly is a leading man, and his declaration has weight. But why the indifference of all the others? The reason is not far to seek. We are all, in England and in Scotland alike, so much concerned about the loaves and the fishes, that we forget, and, I grieve to say, sometimes even speak with disdain of, the position of pharmacy. Were this not so, the young men of our craft, educated in our pharmacies, would not do those things we deprecate. It is scarcely conceivable that a young man trained in a good establishment, and by a man who had other thoughts than those merely connected with £ s. d., would let himself out for hire, for the sake of a few extra coppers a day, to an unqualified company of traders, to a store, or, worst and most degrading of all, to a co-operative store. Were we all, who are masters, animated by a nobler spirit, greater loyalty to the craft, and higher self-respect, there would be no need to recommend that our assistants, when they leave and take service in a store, should by their fellows be sent to Coventry. There could by no possibility be a drug department in a store, because there would be no man to run it. Do we ever find any young medical assistant willing to attach himself to a quack or charlatan? Has any store, however powerful, ever yet had a doctor of medicine as one of its appendages? I trow not. Then

why should a chemist so degrade himself? As the servants of pharmacy and the allies of the medical profession we do well frequently to call to mind that ours is no mean calling. Among the world's faithful workers I hold that our position is a high one, and our reward is not alone silver or gold. Did all of us, in even a small measure, try to live up to this ideal it is not at all likely that anyone from our ranks would prostitute his profession and his own service to any unqualified company of traders, whose sole and avowed *raison d'être* is merely gain. Legislation in this matter is not, I fear, of much use. You cannot suppress company trading. The real cure is "educate, educate, educate."

Dunfermline, November 29, 1898.

JOHN H. FISHER.

Sir,—You ask in effect in your leader of last week, "Will the trade back a Bill securing to the qualified members their bare rights?" Why ask such a question? The trade has shown promptly on very recent occasions, when asked straight questions, that it can and will unite to back up honest attempts to secure its rights. Formulate a Bill securing the sale of drugs to the qualified druggist, barring out companies of unqualified men equally with the unqualified man, and the whole trade will rise up and back it for all they are worth; but add clauses dealing with the widow, the orphan, the student, etc., and you open points for discussion. Let us have one chance to vote for one thing, the one desirable thing, the *summum bonum* and the one thing only, and from all parts fullest support will be accorded to the Council. There is no need to beg chemists to join. Give us bread and not stones, and the membership of the Pharmaceutical Society will mount by leaps and bounds. "Drugs for the Druggist" is the battle cry.

Cardiff, November 28, 1898.

A. HAGON.

. Our correspondent somewhat misses the point, and ignores the fact that we have, for some weeks past, been asking the trade "straight questions." The registered chemists of the country are asked, first, whether they are really anxious for fresh legislation, and have an idea as to its object; secondly, whether they can agree upon the provisions for a draft Bill and, thirdly, whether they will co-operate in taking the action necessary for the purpose. That support must be tendered in advance, not after the event to procure which support is required.—[Ed. P. J.]

THE B.P. AND THE MINOR.

Sir,—Mr. Lucas, one of the Pharmaceutical Society's examiners, in a speech reported in the *Chemist and Druggist* last week, is represented to have said: "No examiner would require to know what were the constituents of Gregory's powder or confection of senna, but he might reasonably expect to be told without hesitation the dose of tincture of nux vomica or of the preparations of ergot." Would a candidate be justified in the conclusion that the limited knowledge specified would satisfy other examiners, or is it possible they would require information as to the processes for making tinctures, extracts, etc.?

Clapham, S. W., November 29, 1898.

LEX (157/14).

. The scope of the (Minor) examination in pharmacy is clearly defined in the Regulations of the Boards of Examiners, and to those our correspondent is referred for information on the subject. Assuming the accuracy of the report quoted from, it would yet be beyond our province to say how other examiners would regard the statement quoted, but there is good reason for believing they do not usually interpret the Regulations in a narrow sense.—[Ed. P. J.]

MELLIN'S EMULSION OF COD-LIVER OIL.

Sir,—I should be glad if you will spare me a little space in the Journal to air a little grievance I have. A month or two ago Messrs. Mellin's representative called on a grocer friend of mine, introducing the above-named preparation, and offering, if he took a sample dozen, to pay for his stamped medicinal licence. Now, this grocer had never taken out a licence before, for the reason, to use his own words, "that as he had three chemists within two hundred yards of him, and knew how prices were cut, he did not think the game worth the candle." For all that, he promised to take a dozen on the conditions mentioned, package duly arriving with invoice at usual price, 17s. 6d., with allowance 5s. for licence, which really came to 12s. 6d. for a dozen emulsions, at which price the grocer sold them to me. Needless to say, he did not take out the licence. Now, if Messrs. Mellin are prepared to give grocers 5s. and only allow chemists such profits as they are known to do, I think it is time something was done. We country retailers, after carriage is paid, get the handsome remuneration of sixpence per dozen on Mellin's food, [for stocking, retailing, and in other ways advertising the article. I wish chemists would shun such proprietors, and refuse to stock their goods until they can fix a minimum price, leaving us a living margin. Could not some of the local associations take the matter up and combine against such a practice?

November 29, 1898.

DEVON (157/24).

RECTIFIED SPIRIT, B.P.

Sir,—With reference to Mr. Fletcher's inquiry in your issue of October 15, and to Mr. Kirkby's reply in your issue of October 29, allow me to point out that all the spirit strengths mentioned in the B.P., 1885 and 1898, closely accord with Stevenson's alcohol tables except in the case of alcohol 90 per cent., the specific gravity of which, according to Stevenson, should be 0.83375, and of proof spirit, the figures of which, given in the B.P., 1885, are in "round numbers." Allen in his 'Commercial Organic Analysis,' adopts a table the figures of which are of slightly different value, hence the discrepancies. Blyth in his book on 'Foods,' favours Allen's figures in the table he gives as "sufficient for ordinary purposes," but recommends either Hehner's or Stevenson's tables for accuracy. The differences will be clear on reference to the following table:—

Strength by volume.	P. B.		STEVENSON.			ALLEN.			HEHNER.		
	By wt.	Sp. gr.	By wt.	Proof	Sp. gr.	By wt.	Proof	Sp. gr.	By wt.	Proof	Sp. gr.
90 per cent. . .	85.65	.8340	85.65	157.75	.83375	85.65	157.71	.8340	85.65	157.71	.8340
70 " "8900	62.50	122.7	.8399	62.46	122.7	*.8398	62.36	122.53	.8900
60 " "9135	52.15	105.2	.9135	52.23	105.27	.9130	52.00	104.87	.9135
45 " "9436	37.85	78.8	.9436	*37.82	78.8	*.9436	37.89	78.93	.9436
20 " "9760	16.30	35.1	.9760	16.25	35.14	.9762	16.46	35.47	.9760
(88.65) " . . .	84.00	.838	84.00	155.4	.8380	84.00	155.45	.8382	84.00	155.44	.8382
(88.75) " . . .			84.10	155.5	.8378	84.08	155.55	.8380	84.08	155.55	.8380

*Calculated.

The question, therefore, resolves itself into whether Stevenson's tables are correct or not. A communication from Somerset House some months ago said that they differed very little from their own. London, November 30, 1898.

S. J. LEWIS.

. The discrepancies in the above tables mainly arise from having no absolutely reliable standard for absolute alcohol and the measure of contraction in mixtures of alcohol and water. The figures given are supposed to be in nearly all cases experimental, and cannot therefore be verified by calculation. Fletcher's 88.76 per cent. volume is deduced from Allen's table, the B.P., 1898, 88.65 is from Stevenson's. Neither of them is quite in agreement with the Revenue table at .8380 gravity, though all three are practically concordant at .834 (Stevenson's varying a little). The B.P., 1885, says that alcohol of .833 gravity contains 84.0 per cent. by weight. The calculation of the B.P., 1898, is thus arrived at—

	Vol. per cent.	Weight per cent.
1898.....	.834	= 90.00
1885.....	.838	= 88.65
Difference	1.35	1.65

Which table is strictly correct can only be proved experimentally.—[Ed., P. J.]

CHEMISTS' ASSISTANTS' UNION.

Sir,—Will you kindly allow me, through the columns of your Journal, to ask all those gentlemen whose letters have not been answered to communicate with the Secretary. The delay is not due to a want of courtesy, but to Mr. Pickering's illness, which has prevented him attending to the correspondence. A coming event is the C.A.U. "smoker" on Tuesday next.

Horse Shoe Hotel, Tottenham Court Road, J. LLOYD ROBERTS, Secretary.

RETAIL CHEMISTS AND THE P.A.T.A.

Sir,—The retail trade ought to be more than ever determined to avoid the P.A.T.A. after the recent exposures by Mr. Rowed and Mr. Glover (Mr. Beecham's representatives). The majority of the listed articles of the P.A.T.A. are on the black list of the majority of chemists, that is to say, they are avoided as bad stock. The prominence afforded their proprietors by the free monthly advertisement in the P.A.T.A. Journal may be worth the subscription (that is a matter for the proprietor); it does not alter the fact that they are still "bad stock." I defy any man to prove that Mr. Beecham has fixed the profit at less than 3d. in the shilling. If a customer comes in and asks for a 1s. 1½d. box of Beecham's pills, does Mr. Beecham say, we are not to take the full money thus offered, not likely! Mr. Beecham is too much of a gentleman in his actions to do this, and would far prefer to help us to larger profits, but I can understand in these days of 'cute competition when Lord Chancellors, judges, and millionaires go into trade, love for the British public or their grab-everything policy, prompts them to cut down the profit to what they consider a good percentage on their annual turnover. So Mr. Beecham is doing his utmost to bring them into line with the ordinary chemist, and

he is trying to secure us a living profit. He is more powerful than we are, and more likely to secure the benefits for us by persuasion than the P.A.T.A. (who are an insignificant minority of the chemists of the country) by force. Our profits on P.A.T.A. goods (even the saleable ones) are less than they were formerly, because the cost prices have been advanced since the P.A.T.A. entered the arena and stirred up strife. Therefore, I intend to avoid the P.A.T.A., and support as far as I am able Mr. Beecham, to whom we owe thanks for bringing to light some of the "dark spots" on this Association.

Portsmouth, November 29, 1898.

HERBERT H. BAILEY.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

BOTANICAL DIAGRAMS.—Kny's 'Botanische Wandtafeln' are published by Paul Parey, Berlin. [Reply to W. W.—19/32.]

BOTANICAL.—Your specimen has been handed to Mr. E. M. Holmes, who will communicate with you. [Reply to J. A.—19/25.]

CHEMIST'S COMPENDIUM.—It is published by Whittaker and Co., 2, White Hart Street, Paternoster Square, London, E.C., at 3s. 6d. net. [Reply to LASCAR.—19/33.]

MATERIA MEDICA, B.P.—We do not know that any such list has yet been published. Why not compile one for yourself? [Reply to W. S. B.—19/26.]

SPECIFIC GRAVITY OF SYR. FERRI PHOS.—We have not yet seen any published statement as to the sp. gr. of the syrup you mention. Why not make some yourself and determine the sp. gr. of the product? That would be a useful exercise. [Reply to STUDENT.—19/23.]

METHYLATED SOAP LINIMENT.—Methylated spirit may be used in the composition of soap, compound camphor, aconite and belladonna liniments, if they are otherwise made in accordance with the Pharmacopœia formulæ. [Reply to B. AND F.—19/30.]

TINCT. BENZ. CO., P.L.—B. Coarsely powdered benzoin, ℥iiss.; scraped storax, ℥iiss.; tolu balsam, ℥x.; coarsely powdered cocotrine or hepatic aloes, ℥v.; rectified spirit, Oij. Macerate for seven days, and strain. [Reply to A. E. S.—19/34.]

SALE OF POISONS.—Sulphocyanates are not poisons within the meaning of the Pharmacy Act, 1868, but it is as well to label them "poison." Any medicinal preparation containing strychnine in appreciable quantity should be dealt with in accordance with the special regulations referring to Part 1 of the list of scheduled poisons (see Pharmacy Act, Sec. 17). [Reply to ERASMUS.—19/17.]

STERILISED GELATIN VACCINATION SHIELD.—We do not know of any such article. What you refer to is probably boric gelatin, which has been employed by Dr. Sinclair White (*vide Brit. Med. Journ.*, January 1, 1898, p. 18, and November 12, 1898, p. 1519), to cover the skin after vaccination. The skin is first sterilised for some distance around the vaccine site, the lymph introduced, and the skin covered, over and around the parts, with hot boric gelatin. [Reply to F. A. W.—20/1.]

QUANTIVALENCE.—You will find the information you want with regard to sodium phosphate under Acidum Phosphoricum in the Students' Page of the Journal for September 17 of this year. You do not seem to have grasped the proper meaning of the term quantivalence. Chlorine is univalent, and hence the formula for calcium chloride is CaCl_2 , because calcium is bivalent. We cannot understand your reference to ferrous chloride and page 116 of the book you mention. Compare the statements on pp. 56 and 136. You should read Remsen's 'Theoretical Chemistry' or Scott's 'Introduction to Chemical Theory.' [Reply to W. M. B.—19/18.]

ARTIFICIAL RASPBERRY AND LIMES.—We have no formula for this preparation, and doubt if you could make it satisfactorily. [Reply to J. C. S.—19/14.]

GINGER WINE ESSENCE.—Soluble essence of ginger, 3 fl. ozs.; soluble essence of lemon, $\frac{1}{2}$ fl. oz.; tartaric acid, 1 oz.; liquid caramel, 2 fl. ozs.; tincture of capsicum, 1 drachm; oil of ginger, 20 minims; syrup to produce 8 fl. ozs. [Reply to W. W.—19/16.]

POISON REGISTER.—The space should be left blank, except when the purchaser is unknown to you and introduced by some person known to both of you. [Reply to S. H.—20/4.]

ANTI-NEURALGIA Mixture.—Quinina sulphatis, 3 grains; acid hydrobromic dil., ℥ 30; tinct. gelsem, ℥ 5; aquæ camph. ad ℥i. pro dos. To be taken every three hours until the pain ceases. Exalgine in doses of two grains in a little wine will give relief in many cases. [Reply to W. W.—19/16.]

ALCOHOLIC STRENGTHS OF TINCTURES.—You ought to be conversant with the differences in alcoholic strength, and should not find much difficulty in the matter if you classify the tinctures in groups. Moreover, since each menstruum has been selected with special reference to the physical properties of the drug, the practical acquaintance with those properties which you should possess, will afford you considerable assistance in fixing the data permanently in your mind. [Reply to E. T. S.—19/15.]

CUCUMBER EMULSION.—White castile soap, shredded, 1 oz.; cucumber pomade, 2 ozs.; tincture of quillaia, $\frac{1}{2}$ fl. oz.; distilled water, 6 fl. ozs.; rose water, to 60 fl. ozs. Dissolve the soap in the water; melt the ointment; then add it and the quillaia tincture to the soap solution and mix thoroughly. Finally, add the rose water gradually in a tepid condition, and continue to mix until cold. Leave in the mortar for some hours, and then again well mix. [Reply to GENTUMBER.—19/12.]

CONCENTRATED INFUSION OF GENTIAN.—No concentrated infusion can be made which entirely reproduces the aroma of the well-prepared fresh infusion, but the following will give you a useful preparation: Infuse 2 ounces of sliced gentian root in 14 fl. ozs. of boiling water for two hours. Strain and press. To the cold liquid add soluble essence of lemon, 2 fl. ozs.; soluble essence of orange, 2 fl. ozs.; alcohol, 90 per cent, $1\frac{1}{2}$ fl. oz.; water to produce 20 fl. ozs. Filter until bright through powdered pumice stone. [Reply to GENTUMBER.—19/12.]

COCA WINE.—Coca leaves, 4 ozs.; tartaric acid, 2 drachms; Malaga wine, *q.s.* to produce 20 fl. ozs. Reduce the coca leaves to No. 40 powder, dissolve the acid in 20 fl. ozs. of the wine, percolate the leaves with this menstruum, and continue percolation with more wine until 20 fl. ozs. is obtained. This wine will not, if prepared from good coca leaves, require a wine licence. If you wish to prepare a more pleasant tasting wine, you should use 1 fl. oz. of the B.P. fluid extract of coca made up to 1 pint with wine. This preparation, however, can only be sold by the holder of a wine licence. [Reply to E. E. F.—19/8.]

SEPARATION OF PHOSPHORIC ACID.—The mixture is boiled with strong nitric acid, and to the nitric solution, after decantation from any insoluble matter, excess of metallic tin is added, and the boiling repeated. Stannic acid is formed by the action of the nitric acid on the tin and combines with any phosphoric acid present to form an insoluble precipitate of stannic phosphate. This precipitate is filtered off, washed, and dissolved in strong potash solution. The potash decomposes the stannic phosphate, forming soluble stannate and phosphate of potassium. The solution is saturated with sulphuretted hydrogen to convert the tin into sulphide, which remains dissolved in the alkaline liquor. This is next acidified with acetic acid, which precipitates the tin sulphide. The phosphate remains in the filtrate, and may be detected by the molybdate reaction or determined by precipitation as ammonio-magnesium phosphate. The tin and nitric acid method is very useful for some technical purposes, but phosphates are usually separated by the molybdate process, which does not necessitate the use of sulphuretted hydrogen. You will find directions for applying the molybdate process in any work on quantitative analysis. [Reply to STUDENT.—19/23.]

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Sensitiveness of Dry-Plates.

Dr. W. J. Russell has detailed the results of investigations to which he was led when repeating experiments with regard to uranium, originally performed by Becquerel, who showed that the metal uranium and some of its salts are capable of acting upon a photographic dry plate in the dark. Printing-ink has an action upon the photographic plate, not only when in contact with it, but also at a distance, the action in this case, and generally, being influenced to a very great extent by temperature. When a sheet of printed paper is kept in contact with a plate for two or three weeks at ordinary temperature, a perfectly sharp and clear reproduction of the printed matter appeared upon development; the printing on the reverse side of the paper being also shown less faintly; but at a temperature of 55° C. the same result is produced in five hours. Pieces cut from three different daily papers showed a marked variation in the action of different printing inks. The action was caused by the drying oil which formed an ingredient of the ink. Speaking generally, vegetable oils are the most active, the animal oils coming next, while the mineral oils seem to be altogether inactive. If printed paper is heated, the activity of the ink disappears. This peculiar property of printing ink is capable of being retained for a very long time. Copal varnish acts similarly, the active substance being turpentine, and all the terpenes are exceedingly active in this respect; the same is the case with all the essential oils of commerce, which contain terpenes. Alcohol and ether, when pure, are not active, and a means is thus afforded of testing their purity. Deal, spruce, oak, and mahogany possess the property of affecting a dry plate, the grain and markings of the woods being accurately and sharply reproduced. Charred wood is exceedingly active, but loses its activity if heated for some time in a crucible. Such bodies as glass, fluorspar, mica, etc., allow no trace of this activity to pass through them; but writing-paper, gelatin, and gutta-percha tissue are transparent. Of the metals, zinc is one of the most active; if dulled by exposure to the air, it is quite inactive; if the surface be quite smooth and bright, it is slightly active; but, if rubbed with sand-paper, its activity becomes very great. The activity of metals is approximately in the following order: Magnesium, cadmium, zinc, nickel, aluminium, lead, bismuth, tin, cobalt, and antimony. Mercury is quite inactive, but a trace of zinc—so small a quantity as 1/300th per cent.—makes it exceedingly active.—*Brit. Journ. Phot.*, xlv., 764.

Properties of Gelatin. R. Child Bayley recently read, before the Royal Photographic Society, a communication on the Melting and Setting Points of Gelatin Solutions and Their Modification, in which he detailed the results of some investigations carried out with the aid of an apparatus he described to the Society some two years ago (see *P. J.* [4], ii. 425), and dealt with the various influences which can be brought to bear upon gelatin, with a view to altering the temperature at which its solutions solidify and melt. It was pointed out that the setting and melting points are not identical, the setting point being generally about 8° Centigrade below that of melting. The stronger the solution in gelatin the higher is the temperature at which it will set and melt, the rise being most marked in the case of the most dilute solutions capable of solidifying at all, and the effect gradually tailing off in the case of very strong solutions. The

setting and melting points are lowered by prolonged boiling, and that eventually altogether destroys the power of setting. The author has invariably noticed that in the better grades of gelatin the effect of boiling is first to raise the melting point slightly. Prolonged boiling has a marked effect upon the colour of the jelly; however white it may be at the commencement, it soon takes on a distinctly yellowish tinge, and to such an extent that the time of boiling may be readily estimated by the colour alone. The effect of the addition of a large amount of potash alum is rather an alteration of the character of the melting and setting processes than a simple raising of the temperature at which they take place; the gelatin solution then ceases to have a definite melting point, and although for complete liquefaction a higher temperature is necessary, a partial action sets in at a temperature which is actually lowered by increasing the amount of alum present, while a still further increase gives total insolubility. With chrome alum, the effect produced by adding 1.2 Gm. per litre of five per cent. gelatin solution is about the same as that caused by 5 Gm. of potash alum, and anything over 140 C.c. of commercial formalin per litre entirely destroys all power of remelting.—*Brit. Journ. Phot.*, xlv., 764.

T. Bolas describes a tallow lamp for glass-blowing, which is free from many of the disadvantages attending the use of older forms. **New Lamp for Glass-Blowing.** The new tallow lamp consists merely of a tin-plate tray open at the top, 1 inch deep, 1½ inches wide, and 3½ inches long, through the bottom of which five flat air-shafts ¼ × ⅜ inch rise, and those air-shafts terminate level with the top of the tray. The tray being filled with tallow (or any fat oil) pieces of the compact cotton wick used for mineral oil lamps, cut to a length of 1 inch, are placed between the air-shafts and lighted. Though there are six wicks, only one large flame is formed; but the air rising through the shafts so breaks up the central hollow, and so far brings the combustion into a smaller area, that little difficulty is found in so adjusting the air jet or blast as to obtain a good blowpipe flame, whilst the hard wicks, being well within the flame, scarcely suffer after many hours use. The soft wick ordinarily found to be essential for use with the tallow lamp is undesirable in this case. All six wicks should be used, with the air-jet projecting over two of them, when the largest blowpipe flame which can be maintained by one person's blowing is required, the air jet in that case being nearly a quarter of an inch in diameter; but for smaller flames fewer and narrower wicks should be used. For example, an air-jet one twenty-fifth of an inch in diameter will require three wicks, each wick being one-fourth of an inch wide. The spaces between the air-shafts are so wide as to allow the wick to be easily removed or changed by a small pair of tweezers, but so close as hinder any tendency to shift and disturb the adjustment. A slight adjustment of one wick or more can be made with the tweezers instantly and while the blast is maintained, so that the adaptation of the fuel to the air becomes almost as easy as with coal-gas and a stopcock. The lamp stands in an outer tin plate tray about a foot square, and the bottom of the lamp is an inch and a-half or so above the tray. The front of the tray carries the air-jet with universal motions for adjustment, and a plain cover fitting loosely over the lamp, serves not only as a general extinguisher, but also to extinguish any burning wicks which may be taken out of the lamp and laid on the tray. It is found convenient never to trim the wicks, but to soak the stock of wick in paraffin wax, and then cut it into one-inch lengths; replacement of an old wick by a new one is far quicker and more convenient than trimming the old wick.—*Journ. Soc. Arts*, xlvii., 52.

ON STORAGE OF POISONS.*

BY B. S. PROCTOR, F.I.C., PH.C., BRADFORD-ON-AVON.

Nearly thirty years ago when this subject was forcibly brought under the consideration of chemists by the Privy Council, urging upon the Pharmaceutical Council that they were bound by the Act of 1868 to formulate regulations for keeping poisons, which should be binding upon all chemists, Mr. J. W. Swan and I were deputed by the chemists of Newcastle to attend, along with many other chemists from all parts of the country, at Downing Street, and protest against the Privy Council putting a compulsory meaning upon a permissive expression in the Act under consideration.

The Act provides that chemists should "conform to such regulations as may be prescribed by the Pharmaceutical Society."

Before the Act passed, I had its wording under my critical consideration, and remarked to our late friend H. B. Brady: "It is very well they say 'may' and not 'must,' for I do not think it possible to lay down strict regulations that could be reasonably adopted in all shops alike." I should have felt bound to oppose a Bill which would compel the Council to draw up regulations which we should be compelled to observe unless I saw a probability of the regulations being workable. During the visit to London, Mr. Swan and I interviewed various of our north-country members of Parliament, notably the Right Hon. T. E. Headlam, as he was not only our representative, but one of Her Majesty's Ministers and the chief pilot of medical and pharmaceutical Bills in Parliament. The discussion I had with him was interesting and enlightening both to him and to me. He gave it as his opinion that any regulations would have to apply to all things that came within Schedule A, and not to any other drugs. I urged that each chemist could best decide what was desirable and workable in his own place, and it should be enough to throw the responsibility and penalty upon him in event of an error occurring through faulty keeping. I pointed out to him that by making the Schedule the criterion of the regulations, all scheduled articles bearing the danger signal, and all other substances being free from it, would lead to absurdities and to danger. We should be bound to put a danger mark on comp. tinct. camphor, and by its absence on tinct. stramonium imply the absence of danger. Oil of ergot, though inert, would be marked dangerous and croton oil safe. Extract of poppies dangerous and ext. calabar safe. He acknowledged that such would be unwise, but that it would be law until these dangerous things not then on the Schedule were added to it. Then I put it to him that it would be a danger which the pharmacist would fall into through his carrying out the legal requirements. Would the law hold him free from penalty if an accident occurred through a poisonous substance not on the Schedule being without the danger signal? But he said "No, that could not be accepted."

As Mr. Headlam was a law man with some knowledge of medicine, the conversation was pleasant and effective, and we walked together from his chambers to Downing Street quite prepared to support, if need be, the protest against hard and fast regulations.

The sufficiency of education as a safeguard was urged by Mr. Schacht, and supported by chemists from various parts of the country. But after various spokesmen had made their speeches, Mr. Headlam and I were satisfied that enough had been said. So also thought Mr. Forster (President of the Council), for he admitted that he could not compel us to read "may" into "must."

Thus the matter dropped, and the Pharmaceutical Council, feeling that there was a tacit understanding that regulations should be drawn up, proceeded to formulate and publish such, as recommendations to the trade, and these after discussion by the general meeting of the Society held on May 17, 1871, were agreed to, and you will find them in the Society's Calendar.

After these years of discussion and consideration, what chance is there that we shall agree upon anything better than is there set out?

The whole procedure was an example of legislation in a panic and the folly of it.

A druggist's porter by mistake sold seven pounds of arsenic instead of plaster of Paris, to be used for adulterating cheap sweets, these were sold in the streets and poisoned people by scores. The arsenic and plaster of Paris were in casks without any labels and stood near together in the cellar. The sentiment of Parliament and of the public was: "These dreadful druggists! They ought all to be hanged."

Druggists and sundry-men caught the fever, and absurd proposals came up like mushrooms; and the skeletons of the said mushrooms may be detected fossilised in "a," "b," and "c," of No. 2 recommendation.

No. 1 recommendation is common sense, but common sense was not satisfactory so long as the delirium continued. I do not feel sure that the ghosts of the mushrooms have been yet safely laid. Our good friends Walter Hills and Charles Symes, at the November Council meeting talked of getting the recommendations passed as "regulations," thus giving them the force of law. The President thinks they would meet with the support of their friends throughout the country; and it is with the view of having this question considered before it is submitted to a general meeting of the Society that I now draw your attention to it.

It might be an easy thing to get unworkable regulations accepted by the Privy Council, but very difficult to get them deleted.

At the time of the panic I recommended and adopted a set of labels to attach to various articles, stating the usual adult dose, red paper for dangerous poisons in Part 1 of Schedule A, or such as ought to be there; green paper for those in Part 2 of the Schedule; and white for drugs not scheduled and not essentially dangerous. Thus strychnine would be labelled on red paper:—

Usual Adult Dose:

$\frac{3}{16}$ to $1\frac{1}{4}$ grain.

Dover's powder, a similar label on green paper:—

Usual Adult Dose:

5 to 15 grains.

And ipecacuanha a white paper label:—

Usual Adult Dose:

$\frac{1}{4}$ gr. to 2 grains.

Emetic: 20 grains.

Powdered opium and laudanum are sufficiently dangerous to justify their having a poison label on red paper, or the red dose label, but in the light of what Mr. Headlam told me if regulations prescribed a dose label as the indication of a scheduled poison, it might become illegal to modify the labels in this way according to the best of our judgment and discretion.

* Read before the Newcastle-on-Tyne and District Chemists' Association, on Wednesday, December 7.

During the quarter of a century which has elapsed since I first adopted this plan I have not seen any system which has possessed an equal number of advantages, and it is only a modification of this which I would now advocate and submit to your discussion.

Accepting Mr. Headlam's dictum, that every poison on the Schedule should have a distinctive mark on the package or containing vessel, which should not be applied to any poisonous substance not scheduled, we should adopt some simple but characteristic mark conveying a definite meaning to the pharmacist, but not to his customer, such as—

signifying "Poison Schedule, 31 and 32 Victoria, cap. 121," as the Pharmacy Act of 1868 is designated in the Calendar, etc.

I am not set upon any particular design provided that it is distinctive, does not mean too much, and meets the requirements of being applicable to all things which are poisons by law, and is not used for other materials.

The law being thus satisfied, the next point should be to make such additions as would be practically useful and not interfered with by parliamentary inspectors or outside critics. These we have in the dose labels already sketched, in which case we should not be bound to classify drugs into poisons which are dangerous and others which are not, and substances which are non-poisonous according to law but which are dangerous. If the design simply were registered as the Government mark, the pharmacist might have it printed on various coloured papers, any or all of which would fulfil the requirements of the law, but the colour of which might convey something more to the initiated. Thus the pharmacist could apply the Government mark printed on red paper to his strychnine, and the same mark printed on green paper to Dover's powder. This would be a simple step in the right direction, but it would not cover all the ground, because it would not be applicable to the dangerous substances excluded from the Schedule. Cantharidine, elaterium, extract of calabar, etc., would not be covered, hence the necessity of a distinctive label which we could use according to the dictates of common sense and would be useful for the protection of ourselves and our customers. A poison label on a stock bottle from which medicine was being dispensed might alarm a nervous patient who would take little heed of a label stating the dose to be $\frac{3}{4}$ to 2 grains, or 5 to 15 grains, but this "mem." would be a valuable check to a dispenser or salesman. If the definition of "the distinctive mark" left the colour and size as open questions, the size might range from that of a threepenny piece to a few inches, the former to suit a tube of esserine, the latter for a cask of arsenic. And if the law-men would allow the word "poison" as an alternative to the distinctive mark, which, however, is a glorious uncertainty, it would give additional facilities with no less security. We should use the Schedule label where we wish to avoid alarming our customers, and the poison label when it suited our convenience better. Thus, Winslow's syrup would bear the poison label rather than the Schedule label, because, as the Act requires this to be sold with a poison label upon it, that should suffice in its storage. It might be one desirable regulation that poisons stored packed ready for sale, such as proprietary medicines and vermin killers, are sufficiently protected when each package bears the poison label required for its sale. The recommendations as drawn by the Council and tentatively accepted by the Society, do not provide rules conveniently

applicable to proprietary medicines, vermin killers, belladonna plaster, antiseptic dressings, etc.

The No. 2 recommendation, which is an addition to the labelling required by No. 1, has three alternatives, but no one of them quite suitable for packed goods, "a" in a vessel tied over, locked etc., "b," in a vessel distinguishable by touch, "c," in the poison cupboard. If the recommendations are passed as regulations, we should be bound to store paregoric, morph. 1 oz., bell. suppos., gall and opium ointment, Winslow's syrup, bell. plasters, rat poison, sheep dip or weed killer, and a multitude of miscellanea under one or other of these three regulations, many of them not conveniently stored under any one of these three. Proceedings in the law courts during recent years have taught us that a compound containing a poison is a poison in the sight of the law. If that ruling applies to storage as well as to sale, and I do not see why not, the list would become so extensive that we might put a lock on the shop door, paint out the word "Pharmacy" from the sign-board, and put up "Poison Cupboard." But the lawyers would still be down upon us, for, as Mr. Headlam objected, this would be bringing unscheduled materials under one of the regulations which are required to distinguish scheduled poisons from other drugs, whether safe or dangerous. The dose label as previously described would work harmoniously with the Schedule label and the poison label, and should be arranged to have the same colour; thus strychnine would have the red Schedule label, the red dose label, and the red poison label. Dover's powder would have a green Schedule label, a green dose label, and not necessarily any poison label, so long as it remained in the pharmacist's keeping, but would require to have this attached if sold otherwise than by doctor's prescription. Even with this reasonable elasticity a dose label might occasionally be found unnecessary upon some of the materials the official dose of which is small. Thus we might say that all liquids the B.P. dose of which is less than $\frac{3}{4}$ ss should have the dose label attached, to reduce the chance of giving an overdose, and in most of these we should say the red dose label would be desirable, but the B.P. would thus guide us to classify the tinctures of cochineal and of saffron with the more dangerous liquids, tr. nux, tr. aconite, ol. crotonis, etc. I think I should rather attach no dose label at all to the former than use one the colour of which would be understood to imply a poisonous quality in an innocent preparation. But I would rather see this left to the discretion of the pharmacist. There would be nothing unreasonable in marking the tinct. saffron 5 to 15 drops for a dose, so long as the Pharmacopœia gives it so, nor would there be any inconsistency in omitting the dose label where there is no toxic property. The object of the dose label is to save us from the chance of giving more than a safe dose without noticing it.

Now let us suppose these suggestions or some others have been agreed upon, how is their observance to be enforced?

Probably the Pharmaceutical Society would be required to appoint an inspector whose duty it would be to make visits of inspection periodically, and defaulters when caught would be liable to a fine of £5 and costs, as indicated in Section 15 of the 1868 Act and Section 12 of the 1852 Act.

Mr. Moon or his satellites would no doubt be as agreeable as usual to all pharmacists desirous of observing the law and protecting Her Majesty's subjects from danger. I never saw him but with a pleasant face, and his light would shine into the dark corners of our shops and dispel the mist of our mismanagement. Though we elect the stars of pharmacy to be our Council, and they have shed no new light on the old recommendations as fixed in 1871. I have no doubt that Mr. Moon while moving in his orbit would both gather and reflect the light and wisdom of the world.

Thirty years ago the anticipation of an inspector was one of the dark things which we dreaded would follow if regulations were to be enforced, and Mr. Brady agreed with me that an inspector's visits might be very unpleasant; but we did not know that the services of a heavenly body could be at the disposal of the Council, though we quite thought that the inspector might carry light from one pharmacy to another, as well as from our back shops to Bloomsbury Square or the police courts. There are some materials which I feel at a loss how to treat rationally. Syrup of red poppy flowers would legally require the Schedule label, though inert; and capsules of the white poppy, though the source of preparations coming into the Schedule, are not themselves scheduled. The only ground for feeling any anxiety regarding these would be the chance that some one not on the Register, having suffered by the poison law, might retaliate by giving information of any laxity in the observance of the law by a pharmacist. This I do not think is a source of much risk so long as the enforcement of the law is in the hands of the Pharmaceutical Council, who would see in such a case that the spirit of the Act had been observed.

In adopting any code of regulations it will be necessary to make it suitable to prospective additions to the Schedule, such as carbolic acid. I have no doubt Mr. Hills and Dr. Symes have advocated this addition. Did they consider whether a cask of carbolic acid would come under "a," "b," or "c," of No. 2 recommendation? I do not think any of them are sufficiently elastic to fit it. If the carbolic acid be stored in the cellar or warehouse can these places be said to be "set apart for dangerous articles"? Probably a law-man would say that if you store soda water in the warehouse, poisons must not be stored near it. A place set apart for dangerous goods must contain dangerous goods only, otherwise it is not set apart. Some other definition must be found for the poison cupboard if it is to be a workable institution.

I should quite advise the use of a poison cupboard which should contain the most dangerous poisons used in dispensing, or for sale in small quantities. It might be for all the articles in part I of Schedule A, though in that case it might have to include vermin killers and possibly sheep dip, and I would rather have it left to the judgment of the pharmacist as to what he would keep there. His own safety and convenience would be his best guide, and would lead to different results according to many varying circumstances in different pharmacies. Every pharmacy may be expected to have a front counter for sales, where poisonous substances will be few, except the popular cough remedies, belladonna plasters, gall ointment with opium, etc. These might all bear the Schedule label. In the dispensing department a great many of the articles would be more or less poisonous in overdoses, but being little seen by the patient, might have in addition to the Schedule label, the dose label, poison label, or caution label according to the danger which was judged to be involved in their use. Then, going a step further, there would be a poison cupboard from a foot square to any number of feet required by the business, and into it would go the poisons of the criminal court, savin, ergot, cantharides, etc.; the poisons dangerous to adults in small doses, hydrocyanic acid, morphia, strychnia, cantharadine, etc., and in some few pharmacies we might have to provide for the Crichton Browne poisons, bacterial cultures, and ptomaines, which should be kept away from such innocent things as arsenic and strychnia, and consigned to a chamber of horrors only accessible to the principal of the establishment. Thus we have classified legal poisons, baby poisons, adult poisons, criminal poisons, dangerous poisons, and dreadful poisons.

It would require almost a small volume to contain all particulars of regulations to suit each individual poison under the various

circumstances of different neighbourhoods and different classes of trade, the regulations for the sale of poisons provided by the Act itself, and the definitions of poison are so crude and unreasonable as to afford no encouragement to attempt final regulations at present.

Section 17 of the Act lays down definite regulations for the sale of poisons, which it may be presumed are not to be subtracted from by the Pharmaceutical Society, but Sections 1 and 15 provide that regulations for keeping, dispensing, and selling may be prescribed by the Pharmaceutical Society presumably in addition to those contained in the Act. Had the power of subtraction as well as that of addition been given us we might have avoided some of the absurdities of the law without subtracting from its value. If a chemist labels paregoric "Poison, a teaspoonful to be taken when the cough is troublesome," it is calculated to bring the Act and the word poison into contempt. Or if we adopt another of the suggestions and label it "Poison by Act of Parliament" it is too like poking fun at the law and the law-makers. If we leave out the word poison we are open to a penalty. It becomes a problem how we can obey the law without making ourselves or our legislators ridiculous in the eyes of the public. We might fairly accomplish it thus:

Paregoric Elixir.

Dose for adults, a teaspoonful.

It is unsafe to give it to young children,
and to infants it is

Poison.

This, however, is a provision for its sale and only comes now under our consideration as an illustration of how much thought and work might be required to bring every dangerous article under reasonable regulations. Our present subject is storage, though we may subsequently be called upon to draw up further regulations for dispensing and selling. The whole task would be better accomplished if we could work under a better definition of what a poison is. I hope this paper may be submitted to discussion, and I summarise its contents in form suitable for being put to the vote. I think anything your meeting might agree upon would be desirable for publication in one or other of the trade journals.

1. That the first recommendation (see Calendar) in the opinion of this meeting is acceptable.
2. That the application of a poison label to all articles when stored, which come under the legal definition of a poison, would render the poison label too common, and thus destroy its value as a caution where most needed.
3. That there are many articles now coming under the legal definition of poison which could not be conveniently stored under any one of the three alternatives coming into the second recommendation in the Calendar.
4. That some label to be called the Schedule label be defined and adopted as the distinctive mark—

indicating that the article thus labelled comes under the legal definition of a poison according to the Pharmacy Act, 1868, and that this mark be conspicuously placed near the name of the article.

5. That the size and colour of the Schedule label be variable to suit the size of the package to which it is to be applied, and the degree of virulence of the contents.

6. That, in correspondence with the dose label, the Schedule label be on red paper for dangerous poisons; and on green for those only dangerous in larger doses.

7. That poisons kept packeted ready for sale be stored with a poison label attached to each packet as required by the Act, in the retail sale of the same. And that this meets the requirement of the storage of proprietary medicines, disinfectants, antiseptic dressings, vermin killers, weed killers, sheep dip, etc.

8. That poisons, whether scheduled or not, if judged by the pharmacist to be powerful and dangerous, shall when kept for dispensing or for sale in small quantities be stored in a poison cupboard guarded by locking, and shall have red paper labels attached beside the name of the article indicating its usual adult dose.

9. That poisons of a less dangerous kind in the judgment of the pharmacist, whether coming within the Schedule or not, shall be kept in the dispensing department, and shall have a green paper label attached, beside the name of the article, indicating its usual adult dose.

10. It is suggested that the red label should apply to dry materials the dose of which is one grain or less, and to liquids the dose of which is 20 M. or under.

11. That the green dose label should apply to dry materials the dose of which is from 1 to 10 grains, and to liquids the dose of which is from 20 to 120 M.

BRITISH PHARMACOPEIA, 1898.

THE PROPOSED INDIAN AND COLONIAL ADDENDUM.

The following is the list, with descriptions, of drugs already proposed by Indian and Colonial Authorities for official recognition in the British Pharmacopœia, and suggestions for pharmaceutical preparations. Further suggestions are invited by the Pharmacopœia Committee of the General Medical Council from any British Dependency where the drugs of the British Pharmacopœia of 1898 are insufficient for local requirements, and comments are invited from readers of the Journal in India and the Colonies.

Acaciæ Cortex.—Acacia Bark.—[A description is wanted which will satisfactorily cover commercial samples of the barks of *Acacia mollissima*, Willd., and *Acacia decurrens*, Willd. Oak Bark, which the Acacia Bark seems to represent, does not appear in the British Pharmacopœia of 1898. Is it desirable now to make Acacia Bark official?]

Acaciæ Arabicæ Cortex.—[This bark is suggested as a substitute for *Quercus Cortex*. As the oak bark is no longer official, does the Indian Government Committee still desire official recognition for the bark of *Acacia arabica*?]

Acaciæ Gummi.—[The exudation from *Acacia Catechu*, Willd., *Acacia leucophlœa*, Willd., and *Feronia elephantum*, Corr., suggested by the Indian Government Committee to take the place of official gum acacia, vary greatly in colour and differ somewhat in their reactions. Hence it seems desirable to limit the official recognition to one common Indian gum; for preparations made with different gums would differ from one another, and from those made with gum acacia. Might official recognition be confined to the gum derived from *Anogeissus latifolia*, which can be obtained of a pale colour? It gives a good mucilage and affords reactions similar to those of the official *Acaciæ Gummi*. The gum might be made official under the name of *Gummi Indicum* (q.v.)]

ACALYPHA.

Acalypha.

[The juice of *Acalypha Indica* is recommended by the Indian Government Committee as an equivalent of *Senega*. Information is desired as to whether the fresh juice or a preserved juice should be supplied. A description of the herb from which the juice is obtained is also desired.]

ACIDUM ACETICUM.

Acetic Acid.

[Reference to the British Pharmacopœia of 1898 will show that nothing prevents this acid being prepared by mixing one part by weight of Glacial Acetic Acid and two parts by weight of Distilled Water; the mode of preparation desired by the Indian Government Committee.]

Aconitum Napellus.—Aconite Root.—[Information is required as to whether the Aconite Root grown in Victoria corresponds exactly to the Aconite Root described in the Pharmacopœia. Should it correspond exactly, it will only be necessary to indicate that Victorian Aconite Root is officially recognised for use in the Australasian Colonies. Should it not correspond, the Victorian authorities are requested to furnish a description.]

ALSTONIA.

Alstonia.

The bark of *Alstonia constricta*, F. v. M. []].

CHARACTERS.—In curved pieces or quills attaining a width of two and a half inches (sixty-three millimetres) or more, and half an inch (twelve millimetres) in thickness. It is covered with a thick periderm varying from one-tenth of an inch to a quarter of an inch (two and a half to six millimetres) in thickness; of an earthy or rust-brown colour, strongly rugose, and marked with large deeply fissured reticulations, and sometimes bears small white foliaceous lichens. Internally the bark is of a cinnamon-brown colour and is marked with strong coarse longitudinal striæ. On transverse section the bark exhibits the dark-brown periderm covering the inner orange-brown tissues, in which may be observed, with a lens, numerous small shining particles. The fracture is short and granular in the outer layers, but fibrous in the liber portion. It has a faint aromatic odour and a very bitter taste.

PREPARATION.

Tinctura Alstoniæ. (Formula as *Tinctura Calumbæ*, 1898.)

[The bark is suggested for official recognition by the Medical Society of Queensland, and the preparations of extract, pill and tincture by the Queensland Pharmacy Board.]

ANDROGRAPHIS.

Andrographis.

The dried plant, *Andrographis paniculata*, Nees [Bentl. and Trim., 'Med. Pl.', plate 197].

CHARACTERS.—Stem one to three feet high (three decimetres to one metre), obtusely quadrangular and, in the upper portion, slightly winged, longitudinally furrowed, smooth, and of a dark green colour. Leaves opposite, shortly petiolate, lanceolate, entire; the upper surface is dark green and shining, the lower surface somewhat paler and finely granular; they vary in size, the larger ones attaining a length of three inches (seven and a half centimetres), and a width of about one inch (twenty-five millimetres); they are thin and brittle. Calyx small, hairy, deeply five cleft. Capsules somewhat cylindrical, tapering towards the ends, about five-eighths of an inch (fifteen millimetres) long, and one-eighth of an inch (three millimetres) wide, two-valved, with a deep furrow passing longitudinally down the face of each valve. Root simple, fusiform and woody. The dried plant is without odour; its taste is intensely bitter.

[*Andrographis* has been proposed by the Indian Government Committee for use in India as a cheap equivalent of *Himalayan Chiretta*.]

PREPARATIONS.

Infusum Andrographidis. (Formula as *Infusum Chiratæ*, 1898.)

Liquor Andrographidis Concentratus. (Formula as *Liquor Chiratæ Concentratus*, 1898.)

Tinctura Andrographidis. Formula as *Tinctura Chiratæ*, 1898.)

AGROPYRUM.

Couch Grass.

The rhizome of *Agropyrum repens*, Beauvois (*Triticum repens*, Linn.). [Berg und Schmidt, 'Off. Pflanz.', plate 139.]

CHARACTERS.—Rigid pale yellow rhizome from one-twelfth to one-tenth of an inch (two to two and a half millimetres) in diameter, usually in sections from one-eighth to one-quarter of an inch (three to six millimetres) long. Strongly furrowed longitudinally, hollow in the middle excepting at the nodes. It should be free from the remains of leaves and rootlets. Couch grass has no odour; it has a faint sweetish taste.

[Recommended by the Hong Kong authorities.]

PREPARATION.

DECOCTUM AGROPYRJ.

Decoction of Couch Grass.

	Imperial.	Metric.
Couch Grass, cut small	1 ounce	50 grammes.
Distilled Water	A sufficient quantity.	

Boil the Couch Grass with twenty-four fluid ounces (or twelve hundred cubic centimetres) of Distilled Water in a suitable vessel for ten minutes; strain. Pour enough Distilled Water over the contents of the strainer to make one pint (or one thousand cubic centimetres) of the strained Decoction.

[Recommended by the Hong Kong authorities.]

ARISTOLOCHIA.

Aristolochia.

The stem and root of *Aristolochia indica*, *Linn.* [Wight, 'Icones,' plate 1858].

CHARACTERS AND TESTS.—The stem attains a diameter of about five-eighths of an inch (fifteen millimetres); it is in more or less cylindrical pieces, marked with the projecting scars of leaves and branches, covered with a greyish-yellow bark, having shallow longitudinal furrows and reticulations in the younger pieces, and a rather warty appearance with a few transverse fissures and longitudinal furrows in the older pieces. On transverse section it exhibits a rather thick bark, enclosing a woody cylinder composed of well-defined wedge-shaped portions of xylem containing large vessels, and separated from each other by evident medullary rays, which are usually fissured radially. The root is undulated, of a dark orange-brown colour, and bears well-marked transverse constrictions; the bark is easily separable from the wood, and in many places it is removed and shows the underlying twisted woody bundles. The odour is spicy and camphoraceous, and the taste bitter and camphoraceous. The cooled decoction yields the characteristic reaction for starch with *solution of iodine*.

[*Aristolochia Indica* is proposed by the Indian Government Committee for use in India instead of *Aristolochia Serpentaria*.]

PREPARATIONS.

Infusum *Aristolochiæ*. (Formula as Infusum *Serpentiariæ*, 1898.)

Liquor *Aristolochiæ* Concentratus. (Formula as Liquor *Serpentiariæ* Concentratus, 1898.)

Tinctura *Aristolochiæ*. (Formula as Tinctura *Serpentiariæ*, 1898.)

Aurantii Cortex Indicus.

Indian Orange Peel.

[The recognition of fresh and dried orange peel, from varieties of orange other than that official in the British Pharmacopœia of 1898, is desired for India. The names of the varieties, and descriptions of their peel, fresh and dried (if differing from the official descriptions), should be supplied by the Indian Authorities.]

BEILSCHMIEDIA.

Beilschmiedia.

The bark of *Beilschmiedia obtusifolia*, *Benth. and Hook.* (*Nesodaphne obtusifolia*, *Benth.*) [

CHARACTERS.—In flat pieces attaining eight inches (two decimetres) or more in length, and one and a half inches (thirty-seven millimetres) or more in width. It is covered with a coarsely granular periderm of a deep orange-brown colour marbled with patches of a yellowish-brown hue; the tissues beneath the periderm are of a deep umber-brown colour. The inside of the bark is of an umber-brown colour, and has a close satin-like surface marked with very fine striæ. It has a close fracture, slightly fibrous in the liber portion. Odour aromatic and spicy, recalling sassafras and camphor; taste agreeably spicy and camphoraceous.

PREPARATION.

TINCTURA BEILSCHIMEDIÆ.

Tincture of Beilschmiedia.

	IMPERIAL.	METRIC.
Beilschmiedia, in No. 40 powder ..	2 ounces	100 grammes.
Alcohol (90 per cent.)	A sufficient quantity.	

Moisten the powder with one fluid ounce (or fifty cubic centimetres) of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (or one thousand cubic centimetres).

[Recommended by the Queensland authorities for official recognition. Under which name should it be known, *Nesodaphne* or *Beilschmiedia* ?]

BERBERIS.

Berberis.

The stem of *Berberis aristata*, *D C.* [Bentl. and Trim. 'Med. Pl.,' plate 16].

CHARACTERS.—In undulating pieces from one to two inches in diameter (two and a half to five centimetres), covered with an orange-brown periderm which in some places is removed displaying the darker brown underlying tissues of the cortex; marked with slightly wavy longitudinal striæ and occasional shallow transverse depressions. The transverse section shows an outer narrow brown periderm surrounding a broad dark brown liber traversed by somewhat lighter medullary rays; the woody cylinder is composed of numerous narrow vascular rays, containing numerous vessels, separated by narrow paler coloured medullary rays. The wood is of a bright yellow colour; the portion in contiguity with the liber is somewhat lighter than the other portions. It has a faint odour and a bitter taste. A cooled decoction gives the characteristic reaction for starch with *solution of iodine*.

[Recommended by the Indian Government Committee as a *Berberis indigenous to India*.]

PREPARATIONS.

Liquor *Berberidis* Concentratus. (Formula as Liquor *Hydrastis* Concentratus, 1898.)

Tinctura *Berberis*. (Formula as Tinctura *Hydrastis*, 1898.)

BELÆ FRUCTUS.

Bael Fruit.

The dried half-ripe fruit of *Ægle Marmelos*, *Correa* [Bentl. and Trim. 'Med. Pl.,' vol. i., plate 55].

CHARACTERS.—Fruit roundish, about the size of a large orange, with a hard woody, nearly smooth rind; usually imported in dried more or less twisted slices, or in fragments consisting of portions of the rind and adherent dried pulp and seeds. Rind about one-eighth of an inch (three millimetres) thick, hard, and covered with a nearly smooth pale brown or greyish firmly adherent epicarp; the pulp firm and brittle, and of an orange-brown or cherry red colour externally, but when broken is seen to be nearly colourless internally. It has no odour, and its taste is simply mucilaginous and very slightly acid.

PREPARATION.

EXTRACTUM BELÆ LIQUIDUM.

Liquid Extract of Bael.

	IMPERIAL.	METRIC.
Bael Fruit.....	20 ounces	1000 grammes.
Distilled Water	15 pints	15 litres.
Alcohol (90 per cent.)..	A sufficient quantity.	

Macerate the Bael for twelve hours in one-third of the Distilled Water; pour off the clear liquor; repeat the maceration a second and third time for one hour in the remaining two-thirds of the Distilled Water; press the marc; and filter the mixed liquors through flannel. Evaporate to fifteen fluid ounces (or seven hundred and fifty cubic centimetres), and, when cold, add sufficient of the Alcohol to produce twenty fluid ounces (or one thousand cubic centimetres) of the Liquid Extract.

Dose.—1 to 2 fluid drachms.

[For use in India. From the British Pharmacopœia of 1885, but with the proportion of alcohol increased as desired by the Hong Kong authorities.]

BETEL.

Betel.

The leaves of *Piper Betel*, *L.* [Wight, 'Icones,' plate 2926].

CHARACTERS.—The leaves are broadly ovate, acuminate, obliquely cordate at the base, five or seven nerved; coriaceous and glossy on the upper surface; they have a warm aromatic bitter taste. In commerce they are frequently tied up or stitched together into packets.

[Recommended by the Indian Government Committee for use in India. Suggestions are required as to the preparations of Betel.]

(To be continued.)

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, DECEMBER 7, 1898.

Present :

MR. WALTER HILLS, PRESIDENT.

MR. G. T. W. NEWSHOLME, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bateson, Bottle, Carteighe, Corder, Cross, Grose, Harrison, Johnston, Martindale, Park, Savory, Southall, Symes, Warren, and Young.

The minutes of the previous meeting having been read and confirmed, Mr. MARTINDALE thanked the Council for the honour done him in his absence by electing him to the office of Treasurer, which he should endeavour to fill to the best of his ability. He had had many illustrious predecessors, amongst those whom he had known personally being Mr. Daniel Bell Hanbury, Mr. Cornelius Hanbury, Mr. Thomas Hyde Hills, Mr. John Williams, Mr. Thomas Greenish, and lastly, their esteemed friend and colleague, Mr. Hampson, whose resignation they all regretted, as was very properly stated at the last meeting. He had been connected with pharmacy for forty years, had had a great deal to do with the working of the Society, and he hoped his colleagues would judge of his future by the past, though he must confess that he had not the same capacity for work that he once had. However, he would endeavour to do his best, and try to conserve the funds of the Society as much as possible, but it must be borne in mind that he would be bound to pay whatever money the Council voted. He trusted that when the new Bye-laws came into force with reference to increased fees for the Minor examination, there would be a better prospect for the Society. He thanked the Council very much for the honour done him.

CORRESPONDENCE.

The PRESIDENT said he would mention, arising out of the minutes, that a letter had been received from Mr. Hampson, thanking the Council for the resolution passed at the last meeting, and also for the kindly sentiments expressed by the members of the Council on that occasion. Mr. Storrar had written regretting his inability to attend the Council, and also at not being able to attend the Conference of the Divisional Secretaries to be held that afternoon, and expressing his intention of backing up whatever course of action might be resolved upon at that meeting. Mr. Storrar went on to express the opinion that any further legislation could not be attempted by the Society with any chance of success until they could say that the Society represented the whole trade, therefore the first thing to do was to increase the membership of the Society, and a determined personal canvass should convince most of their friends of the advisability of joining the Society. A letter had been received from Dr. Baildon, who was an old colleague of the members of the Council, stating that he had again commenced his studies abroad, and that he had recently taken the degree of Doctor of Philosophy at the University of Freiburg. Dr. Baildon had lately been appointed Professor of English literature in the important University of Vienna. He (the President) had sent his presidential card of congratulation, and in the reply which had been sent Dr. Baildon asked him to convey to his old colleagues his thanks for their good wishes.

THE LATE MR. T. W. HORSLEY.

The PRESIDENT said they had lost by death one of their divisional secretaries. Mr. Thomas W. Horsley, who was a pharmaceutical chemist, and had been connected with the Society for twenty-eight years. As divisional secretary for North Kensington, the deceased gentleman had done much to advance the interests of the Society, and had done specially good service to the Council in obtaining support for the Pharmacy Acts Amendment Bill. Mr. Horsley's son was now a student in the Society's School, and when personally entering his son's name, Mr. Horsley expressed his intention of making known to every registered person in his division the possibilities which the Act opened up. It was much to be regretted that the services of such a very active supporter should be lost to the Society.

THE NEW BYE-LAWS.

The PRESIDENT announced that a letter had been received from the Clerk to the Privy Council Office acknowledging the receipt of the letter from the Society, and stating that he had been directed to notify the Council of the approval of the Privy Council of the

Bye-laws for the better regulation of the Society's business and for the better administration of the public duties imposed upon the Society by Statute.

ELECTION OF ASSOCIATES AS MEMBERS.

The PRESIDENT then moved

That the persons who, on July 25, 1898, were registered as associates in business be now elected members pursuant to Bye-law 2, Section 1.

He said he could not allow this opportunity to pass without saying one word with reference to the motion. In the first place the Council would not wish him to read the very long list of names, amounting to some 1700 or 1800. He was very glad to have this opportunity of proposing those gentlemen as members of the Society under the new Pharmacy Acts Amendment Act, and he thought that both the Society and those gentlemen were to be congratulated. It was a good thing for the Society to have such a large accretion of members, and he trusted that the gentlemen who were now to be elected would continue that loyal help as members which they had hitherto afforded as associates in business.

The VICE-PRESIDENT seconded the proposition.

Mr. BATESON said he had asked the local secretary in his town to call upon the associates in the district and ascertain those who were willing to become members. The first gentleman called upon at once expressed his willingness, and all the others immediately followed suit.

Mr. PARK said that everyone he had called upon in Plymouth had expressed his intention of joining the Society.

The PRESIDENT said there were very encouraging reports from other centres as well as those just mentioned, and there was every reason to believe that next year there would be a very large addition to the ranks of the Society. He then put the proposition for the election of associates in business as members, and it was carried unanimously.

ELECTION OF MEMBERS.

The following having tendered their subscriptions for the current year were elected "Members" of the Society:—

Franklin, Arthur Cawte ; Titchfield.	Hodgson, John Edward ; North Cowton.
Gale, George Thomas ; Barnstaple.	Hovenden, Sydney Churcher ; Croydon.
Garnett, John Benbow ; Manchester.	Sharp, William Ashton ; Owston Ferry.

RESTORATIONS TO REGISTER.

The names of the following persons who have severally made the required declaration and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

William Spiers, 73, Great Ormond Street, London, W.C.
 Richard John Williams, 7, Guildhall Square, Carmarthen.
 William Woodhouse, 15, Elizabeth Street, West Gorton, Manchester.

ELECTION OF A MEMBER OF COUNCIL.

The PRESIDENT moved that Mr. John Fredk. Harrington be elected a member of the Council in place of Mr. R. Hampson resigned. It had been felt that it was very desirable to select for this vacancy some gentleman out of the long list of those who were once associates in business and who had just been elected members. He was pleased to say that Mr. Harrington, who was personally known to many present, had expressed his willingness to serve if elected; he was at the present time the President of the Western Chemists' Association of London, and it was hardly necessary to say anything further, because a man who was elected to such a post must possess the confidence of those who knew him best. Mr. Harrington was one of those who had just been elected to membership, and they would be glad to welcome him to that table as a representative of that large number who had been loyal to the Society in the past, and who he trusted would continue to show the same loyalty in the future. Mr. Harrington was in business in London, and would therefore be available for work on committees when required, but he had also had considerable experience of country practice.

The VICE-PRESIDENT seconded the motion. He had not the pleasure of knowing Mr. Harrington personally, but from all he had heard about him he felt sure that he would prove a desirable member of the Council. It was an important point, in his opinion, that Mr. Harrington was resident in London, seeing that the number of gentlemen who were within easy reach of the building was small, and, he thought, had been getting less of late years.

The resolution was agreed to unanimously.

SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

The PRESIDENT moved the election of the gentlemen named in the following list as Superintendents and Deputy-Superintendents of written examinations during the coming year. He

believed the names of the Superintendents who were the Local Secretaries were the same as for the current year, but in some cases the deputies had been altered.

Centre.	Superintendent.	Deputy.
Aberdeen	Strachan, Alexander	Cruickshank, John
Birmingham	Thompson, Charles	Jones, William
Brighton	Gwatkin, James R.	Savage, William W.
Bristol	Kcen, Benjamin	Allen, Benjamin
Cambridge	Deck, Arthur	Coulson, Horace
Canterbury	Bing, Edwin	Amos, Daniel
Cardiff	Munday, John	Coleman, Alfred
Carlisle	Hallaway, John	Pattinson, Michael H.
Canarthen	Lloyd, Walter	Phillips, George
Carnarvon	Jones, John	Davies, Robert
Cheltenham	Barron, Wm.	Palmer, Frank T.
Darlington	Robinson, Jas.	Hutchinson, Rev. E.
Douglas (I. M.)	Radcliffe, John C.	Young, John
Dundee	Kerr, Charles	Hardie, James M.
Edinburgh	Stephenson, John B.	Henry, Claude F.
Exeter	Lake, John Hinton	Milton, Thomas C.
Glasgow	Currie, Wm. Little	Moir, James
Guernsey	Nickolls, J. Bate	De La Rue, F. H.
Hull	Bell, Charles B.	Stoakes, Benj. M.
Inverness	Ogston, William	Bethune, W. J.
Jersey	Cole, George	Baker, John T.
Kirkwall	Stewart, Duncan	Webster, Rev. D.
Lancaster	Vince, James	Arkle, William
Leeds	Reynolds, Richard	Branson, F. W.
Lincoln	Birkbeck, John T.	Elmitt, George
Liverpool	Smith, John	Buck, Anthony S.
London	Taylor, Geo. S.	Allen, Charles B.
Manchester	Kemp, Harry	Moon, Harry
Newcastle-on-T.	Clague, Thos. M.	Swinn, Charles
Northampton	Bingley, John	Owen, Alfred E.
Norwich	Sutton, Francis	Mayer, W. D.
Nottingham	Sergeant, F. Ross	Corder, Octavius
Oxford	Prior, George T.	Beverly, R. H.
Penzance	Symons, Netherton H.	Thurland, Henry
Peterborough	Heanley, Marshall	Buckett, A. H.
Plymouth	Hunt, Freeman W.	Heanley, A. V.
Sheffield	Squire, George	Woods, Wm. H.
Shrewsbury	Cross, William G.	Pater, Joseph B.
Southampton	Dawson, Oliver R.	Blunt, Thomas P.
York	Sowray, Joseph	Wilson, Harry
		Kendall, Edwd. B.

The motion was agreed to unanimously.

REPORT OF THE FINANCE COMMITTEE.

The report of this Committee, which recommended various accounts for payment, was read.

The PRESIDENT in moving the adoption of the Report and recommendations, said the receipts and payments were of the usual character and needed no special comment. During the month a donation of 100 guineas had been received from Mr. Arthur Trentham Maw. That was another mark of the great interest taken by Mr. Maw and his family in the Benevolent Fund.

The report was adopted unanimously.

REPORT OF THE BENEVOLENT FUND COMMITTEE.

The report of this Committee included a recommendation of grants to the amount of £68 in the following cases:—

The widow (63) of a chemist and druggist, who has had three previous grants. (Deptford)

The widow (68) of a pharmaceutical chemist member and founder (1841-1859), and subscriber from 1889 to 1897. The husband had a grant in 1886. The applicant is unable to work and has no means of support. (Middlesex.)

A registered chemist and druggist (79), who has had three previous grants. Applicant is hopelessly invalided. (Cheltenham.)

A registered chemist and druggist (66) and former subscriber, who has had four previous grants. (Shirley.)

A registered chemist and druggist (75), who has had five previous grants. He has an allowance of £40 a year conditionally on receiving some assistance from the Fund. (London.)

A registered chemist and druggist (65), who had a grant last year. He acts as temporary assistant, but cannot do much, and has an invalid wife. (Liverpool.)

The SECRETARY reported the death, on November 19, of Mrs. Kate Keziah Chenery, aged 64, who was elected an annuitant in December, 1886.

Mr. BOTTLE moved the adoption of the report and recommendations. There were six cases, all of the average type, and it appeared that when once their unfortunate friends got on to the list they seldom got off it again. Most of the applicants had previously received grants, and they had evidently been of great service to them.

The report and recommendations were adopted.

REPORT OF THE LIBRARY, SCHOOL, AND HOUSE COMMITTEE.

The report of this Committee stated that the Librarian had presented his usual report, including the following particulars regarding attendance at the Library:—

Attendance.	Total.	Highest.	Lowest.	Average.	
					Day
October	432	33	5	17	
	81	9	1	4	
Circulation of Books.		Total.	Town.	Country.	Carriage paid.
October	193	103	90		15s. 11½d.

The Committee recommended that the undermentioned books be purchased:—

For the Library in London:—

Slater and Spitta, Atlas of Bacteriology, 1898.

For the Library in Edinburgh:—

Attfield, Chemistry, 17th ed., 1893. Second copy.

Scottish Medical and Surgical Journal, 1899, and continuation.

The Curator's report had also been received, and included the following particulars:—

Attendance.	Total.	Highest.	Lowest.	Average.
October	392	35	5	15
	34	5	1	1

Several donations to the Library and Museum had been received (see *P. J.*, November 12, p. 511), and the Committee had directed that the usual letters of thanks be sent to the respective donors. The PRESIDENT, in moving the adoption of the report, said the fact that several items had been adjourned for further consideration showed that though the report was not long, the Committee had not been idle, in fact, it was a very hard-worked Committee, and generally sat some hours, though on this occasion there was very little to call attention to. They had received from Professor Vogl, who was recently the recipient of the Hanbury medal, a copy of a work which he had just published, on a subject on which he was one of the highest living authorities, which would be a valuable addition to the Library, and a special letter of thanks had been sent him. The report was unanimously adopted.

REPORT OF THE LAW AND PARLIAMENTARY COMMITTEE.

The following report from this Committee was read:—

The President was requested to address a communication to the Lord Chancellor to the following effect:—

1. That it has come to the knowledge of the Council through the public press that the General Medical Council has placed in the hands of the Lord Chancellor a draft Bill to prohibit the assumption by incorporated companies of the professional privileges of persons qualified to practise medicine or dentistry.

2. That the Council is desirous of obtaining the assistance of the Lord Chancellor in extending this prohibition in favour of persons qualified to practise pharmacy in Great Britain.

3. That the object of the Council may be attained by the insertion of a provision in the Draft Bill to the effect that (a) the word "person" in the Pharmacy Acts should be made to include an incorporated company as well as a natural person, and (b) that the compounding and dispensing of all medical prescriptions should, for the protection of the general public, be restricted to persons possessing the statutory qualification under the Pharmacy Act, 1868.

4. That the Council is informed that an alteration of the law in this direction is desired by registered chemists and druggists throughout Great Britain; and the Council further desires to direct the attention of the Lord Chancellor to the circumstance that such alteration has become essential in the public interest in order to prevent the practical repeal of the Pharmacy Act by incorporated companies. It is notorious that in a large number of cases unqualified individuals who have paid penalties for infringement of the law have immediately placed themselves "above the law" by converting themselves into limited companies, and thus becoming able to continue with impunity the business which as natural persons they could not lawfully carry on.

5. The Council is desirous of obtaining his Lordship's assistance, as it is felt that there is no possibility of passing into law in the form of a private Bill such a prohibition as that above indicated.

6. Bearing in mind the remarks which the Lord Chancellor made in the House of Lords on the third reading of the Pharmacy Acts Amendment Bill in July last, and the interview which he was good enough to give the President in August, the Council feels assured of the interest which his Lordship takes in this important question.

The PRESIDENT, in moving the adoption of the report and recommendations of the Committee, said he wished it, in the first place, to be thoroughly understood that this very important subject had received constant attention from the Council, though it was not always advisable or even possible to publish the result of deliberations in committee. Going back some few years, it was well known that the Council, even in the time of his distinguished predecessor, did all that was possible at the time to deal with what most of them considered a great evil, but there were great difficulties in attacking the subject. He would ask all interested in the matter to read the account in last week's Journal of the proceedings at the General Medical Council, or the fuller report in the

Lancet of December 3, because a certain amount of light was thrown on what they themselves had done in the past in connection with the medical, dental, and veterinary bodies. An attempt was made some two or three years ago to bring joint pressure by those bodies on the Departmental Committee of the Board of Trade to obtain an amendment to any Companies Act which might be introduced, the object of which should be to prevent companies being formed for the purpose of carrying on a profession or business for which a personal qualification was necessary. Great difficulties, however, occurred in dealing with the matter on those lines, and it would be noticed that at the General Medical Council it was stated that the chances of any Companies Act Amendment Bill becoming law within any reasonable time appeared uncertain, and it therefore seemed expedient to make an attempt in some other direction. It therefore seemed good to the General Medical Council to apply direct to the Lord Chancellor, and bearing in mind the remarks he made in the House of Lords last July, and to himself personally in August, the Law and Parliamentary Committee came to the conclusion that it would be wise to appeal directly to him to help them in the present difficulty. He believed almost all registered persons were agreed on two points, first, that the Legislature, in passing the Pharmacy Act of 1868, contemplated that those who kept open shop should be qualified persons, *i. e.*, natural persons who could become qualified and registered, and that this was necessary for the safety of the public. Now, with all respect to the judgment of the House of Lords, in the case with which they were all familiar, it did not seem to be consistent with the intention of the Legislature in the Act of 1868. Great stress should be laid on the expression "keep open shop," he thought it meant that the person who kept open the shop was not only the person who financed it, but who had the direction of it, and was responsible for it. But however that might be the majority of registered persons felt that the proprietors of shops in which poisons were sold, dispensed, or compounded should be qualified natural persons. Another opinion in which they were pretty unanimous was that it was always impossible in the present condition of things to get any alteration of the law in that direction without the help of the Government. He believed that, if they were united almost to a man, much might be done to carry out the views he had expressed. It was obvious, as had been recently pointed out, that limited companies could not carry on business if there were not qualified persons willing to aid them. Referring again to the Report of the Proceedings of the General Medical Council, which appeared in the *Lancet* last week, it would be observed that the Companies Act Amendment Committee of that Council came to the conclusion that it was advisable to approach the Lord Chancellor direct, and later on the Chairman of that Committee said the General Medical Council were not promoting the Bill, but that the draft which was handed to the Lord Chancellor was simply a suggestion for a Bill. The Law and Parliamentary Committee came to the conclusion, bearing in mind what had taken place, not only at the General Medical Council, but also the remarks of the Lord Chancellor, and the interest that he was known to take in the matter, that they should appeal direct to the Lord Chancellor in the terms of the resolution then before the Council. He trusted that the Council would see its way to adopt the report, and hoped that the result might be beneficial to all those who practised pharmacy. Of this he was assured, that it was not from any want of sympathy with their friends whether in London or in the country that they had not been in the past apparently more active in dealing with this great difficulty. He trusted that the proposal would not only be adopted by the Council, but would be accepted by those they represented throughout the country as an indication of their desire in every possible way to deal with this great difficulty.

The VICE-PRESIDENT, in seconding the adoption of the report, said it was hardly necessary to add anything to what the President had said, more particularly because the report spoke for itself. It had been said over and over again that they wanted a more united body; if they had the support of all the chemists of the country there would be very little difficulty in carrying out the suggestions of the Law and Parliamentary Committee.

Mr. CARTEIGHE wished to refer back to the year 1895, to place on record the fact that the Council of the Society had been the moving spirit in raising the question before the Government in regard to both pharmaceutical and medical matters. As bearing this out he referred to a statement, bearing his signature as the

then President, submitted to the Departmental Committee on the Companies Acts 1862 to 1890, calling attention to the anomalies of the Acts as bearing upon the practice of pharmacy. In the appendix to this statement many instances were given of "one-man companies." Some difficulty had been experienced in getting Lord Davey to receive the statement and give it his consideration. When they succeeded in getting the statement before the Committee a statement was made with regard to it which he thought was the strongest indictment that had ever been made against the Companies Acts, both in regard to pharmacy and finance. He called attention to this principally as an answer to their friends, who thought they had been doing nothing for many years. The Departmental Committee he had referred to did not think that the specific amendment of the law asked for by the Pharmaceutical Society fell within their scope, and were of opinion that any real grievance ought to be carried out by an amendment of the Pharmacy Act. It was very gratifying that at last the Lord Chancellor had been approached on the matter.

Mr. ATKINS gave the proposition his most hearty support. He had a strong conviction that the resolution which he believed would be passed unanimously that day, would not be marking time but making history. Referring to what Mr. Carteighe had said, those who knew how long and how arduously they had worked in Committee, often despairingly, at this measure, felt in their consciences that they were not open to the charge of having neglected their duty upon this question. They all knew how acutely the question pressed upon hundreds and hundreds of the best and most conscientious men in their calling. Sometimes in the Committee of the Benevolent Fund they had the question practically brought before them. Those who were acquainted with the districts in which company trading flourished knew perfectly well how painful the results were to their brethren. He was glad they had gone in for something big this time. It might be fairly stated that one thing, which, as prudent men, kept them back, was the feeling that they had to get through a measure of consolidation for themselves; but as this had now been accomplished, they might at once fearlessly go in for a very big order. No doubt there were many vested interests in the way, but whatever happened, certainly the kudos of having raised the question might fairly be claimed by the Council. They would, at least, be able to say to their many friends who were going down steadily financially, that they had done the best for them, and if they had not succeeded they had at least their sympathy.

Mr. HARRISON said he thoroughly approved of the action the Committee had recommended. He had taken an interest in this subject for many years, and found it bristled with difficulties, there being large vested interests involved which yearly became larger and more difficult to attack. He was extremely obliged to Mr. Carteighe for his remarks, because he had shown conclusively from the Blue Book that they had done what they could in the matter. When some years ago the question of company trading was referred to a Committee of the Board of Trade, not to deal with matters affecting pharmacy, but mainly on the financial ground, and on that Committee after some difficulty they obtained a hearing, and facts were placed before the Committee which illustrated their position admirably. They were not in a position to go to Parliament and demand a remedy, and unfortunately they did not then represent, as regarded numbers, the interests of chemists and druggists, but they had now consolidated their forces and were in a position, such as they had never occupied before, to go to Parliament, representing such an amount of pharmaceutical opinion as would entitle them not only to a hearing, but to fair consideration. The position to-day was unique; they had had an expression of opinion from the highest legal authority that there was a great grievance with regard to company trading, and though the remedy proposed was inadequate and could not be accepted, he thought it was a wise thing to appeal to one who had so clearly appreciated the grievance, and say—here is a remedy which we believe will meet the evil. He could not but think that going with their medical and dental friends, who were suffering in the same way, with a fair and reasonable statement of the case, they were bound to meet with a respectful hearing, and he trusted some attempt would be made to redress the grievance under which they suffered. He hoped it would be the President's good fortune at the end of the next Parliamentary session to have to report that a deliberate and successful attempt had been made to remove the great evils which at present existed under the Limited Liability Acts.

Mr. MARTINDALE said the document it was proposed to send to the Lord Chancellor seemed to be only a corollary to his statement in the House of Lords last July, and the natural sequence of it, and it might be pressed with even greater force by them than by the Medical Council, because his remarks had been addressed to the pharmaceutical question, and his words had been supported by Lord Herschell.

Mr. YOUNG said the discussion seemed to have rather wandered into the question of what sort of Bill should be brought forward, but he concurred with Mr. Harrison and Mr. Atkins in hoping that a broad and comprehensive measure would be brought forward. There might be some difficulty in getting the attention and consideration of the House of Commons, but they had right and justice on their side, and if they could only get a hearing good must result. He hoped the measure they eventually decided on would be a broad one, and worth working hard for.

The PRESIDENT said he was glad Mr. Carteighe had called attention to what took place in 1895, and he would emphasise the fact that this question had been very sympathetically considered, not only by the Council, but very specially by Mr. Carteighe, who took an infinite amount of pains in the matter, and who succeeded in getting placed on record some very valuable information for the benefit of those who would have to deal with the subject later on. With reference to Mr. Young's remarks, he must point out that in the action now proposed they were not drafting a Bill—they merely pointed out that the remedy for the existing state of things lay in the carrying out of the principle underlying the Pharmacy Act of 1868, and they asked the Lord Chancellor to be good enough, bearing in mind the remarks which he had made in the House of Lords, to do what he could to carry out that principle.

The resolution was then put and carried unanimously.

POISON REGULATIONS.

The PRESIDENT announced that the following requisition had been received, signed by thirty members :—

We, the undersigned members of the Pharmaceutical Society entitled to vote at any meeting of the Society, hereby require the Council of the Society to convene a Special General Meeting of the Society for the purpose of prescribing regulations within the meaning of Section 1 of the Pharmacy Act, 1868, for the keeping, dispensing and selling of poisons, and we make this requisition pursuant to the provisions of the Charter of Incorporation, 1843.

In accordance with the Charter of Incorporation it would be their duty to arrange for a special meeting of the Society within a reasonable time.

Dr. SYMES then moved :—

That a Special General Meeting of the Society be held at 17, Bloomsbury Square, at 3 p.m., on Wednesday, January 11, 1899, to adopt regulations for the keeping, dispensing, and selling of poisons, in conformity with the requirements of the Pharmacy Act of 1868.

He said it might astonish some people that any portion of the Pharmacy Act, now thirty years old, should still remain unfulfilled, and a little explanation might be necessary on his part. For this purpose he referred to the preamble and Sections 1 and 15 of the Act of 1868, and, continuing, said, when a meeting was called to draw up regulations, objections, partly sentimental and partly founded on a substantial basis were made. If they looked at the operation and bearing of the regulations embodied in the Act and the details of some of the regulations they were asked to make, he was quite sure they would feel that having swallowed a camel they were straining at a gnat. The sentimental objections were that they would apply only to qualified men, and would not apply to a large number of persons who were semi-qualified, and would still have to handle poisons. He could respect the argument of men who felt that qualified men should not be trammelled with regulations whilst unqualified men should go free; but they had to take the Act not as it was then read, but rather as it had been interpreted by the judges. Since they had been told that "seller" in every portion of the Act except in Clause 17 meant the man who actually sold and handled the poison; that being the case any regulations which they made must apply to the person who sold. There was no particular form prescribed for these regulations, but those which were offered to the Society some twenty-eight years ago had been voluntarily adopted by some 80 per cent. of the registered men throughout the country, and would no doubt form the basis of any regulations which might be made at the meeting which he proposed should be called. The details of the regulations would probably be considered in the meantime, but he thought there would be a

little advantage in altering the earlier part and providing that the man who dispensed poisons should have the environment of safety contemplated by the Act. He merely threw that out as a suggestion that was worthy of consideration. After all it would depend on whether their resolutions were accepted by the Privy Council. If it were thought that the Privy Council could not fall in with the view that these regulations should attach to a greater surrounding than their own people, then the absurdity of legislating for a small section, and leaving the larger portion still untouched, would be so apparent that the Privy Council would give them assistance in any legislation they might attempt to correct that state of things.

Mr. ALLEN said although the recommendations, as printed in the Calendar, might possibly form a basis of any proposed regulations, he hoped that they would not be bound to adopt them, because in his opinion they wanted revising and strengthening in many points.

Mr. HARRISON felt unable to support Dr. Symes' proposition. There had already been a meeting of the members of the Society to consider this matter, at which meeting the members deliberately refused to accept the suggestion now made by Dr. Symes. There were only two circumstances justifying the Council in again calling a meeting of the members to consider this question. The first was a strong desire manifested by their constituents to have the question re-opened; or, secondly, if from the number of accidents occurring in the several pharmacies of Great Britain there seemed to be some negligence in the business conducted there as to call upon them to make some regulations. Neither of these conditions had been entirely fulfilled. There had been some fulfilment of the first condition perhaps from the fact they had received a requisition to summon a meeting to consider the subject of prescribing regulations. Dr. Symes had failed to make perfectly clear the difference between the two positions—selling and keeping. He felt that the proposal indicated a retrogressive policy, and having regard to the fact that the number of accidents occurring in pharmacies had been so small during the last thirty years, they would be forging a chain to bind themselves, for which there was no reasonable ground whatever. He should propose as an amendment :

That in compliance with the requisition received from thirty members of the Pharmaceutical Society, a Special Meeting of the Society be held at 17, Bloomsbury Square, at 3 p.m., on Wednesday, January 11, 1899, to consider the expediency of adopting regulations for the keeping, dispensing, and selling of poisons in conformity with the provisions of the Pharmacy Act, 1868.

Mr. YOUNG said he thought they had got past the necessity of discussing the expediency of the matter.

After a little discussion, on the suggestion of the PRESIDENT, Mr. Harrison framed his amendment as follows :—

That in compliance with the requisition received from thirty members of the Pharmaceutical Society, a Special Meeting of the Society be held at 17, Bloomsbury Square, at 3 p.m., on Wednesday, January 11, 1899, to consider, and, if thought fit, adopt regulations for the keeping, selling, and dispensing of poisons in conformity with the provisions of the Pharmacy Act-1868.

This amendment, having been accepted by Dr. Symes, was put and carried.

The PRESIDENT said a resolution had been forwarded by the Western Chemists' Association, passed at a meeting on November 30, to the effect that in the opinion of that Association the time had arrived for making regulations for the keeping, dispensing, and sale of poisons, in accordance with the Pharmacy Act of 1868, and that a Special Meeting of the Society should be called to consider the question.

Mr. PARK said the Association at Plymouth passed a similar resolution in April last.

The PRESIDENT said he had received from the Manchester Pharmaceutical Association a resolution passed on November 30, that the Council of the Pharmaceutical Society be requested to take early steps to promote legislation for an amendment of the pharmacy law on practical lines, as it affects limited companies. He had also received from Manchester copies of three resolutions, passed on November 30, as follows :—

1. That this meeting suggests that all registered chemists trading under ancient titles shall be required to use the name of the present owner in conjunction therewith.
2. That this meeting pledges itself to use every effort to induce all registered chemists to ally themselves with the Pharmaceutical Society, and thereby lead to the consolidation of the craft.

3. That this meeting, believing it to be for the best interests of the trade that the present recommendations for the storage, etc., of poisons, should become regulations subject to the provisions of the Pharmacy Act, 1868, requests the Council to take early steps towards this end.

He suggested that these resolutions should be referred to the Law and Parliamentary Committee.

This was agreed to.

THE SALTERS' COMPANY RESEARCH FELLOWSHIP.

The PRESIDENT said a letter had been received from the clerk to the Salters' Company approving the nomination of Mr. Thomas Tickle to the Salters' Company Research Fellowship for the ensuing year. A letter had also been received from the Assistant Secretary to the Marine Department of the Board of Trade, saying that in view of the new Pharmacopœia, the medical scales for merchant and passenger ships would require to be amended, and asking if the Pharmaceutical Society would nominate some one to act on a Committee for that purpose in conjunction with two members of the medical staff and nominees of the Royal College of Physicians and Surgeons respectively. He suggested that the matter should be referred to the Library, etc., Committee, with power to make the nomination. This was agreed to.

THE CHELSEA PHYSIC GARDEN.

The PRESIDENT said a letter had been received from the Charity Commissioners enclosing a draft scheme for the management of the Chelsea Physic Garden, and asking if the Society would be prepared to nominate a member of the Committee which it was proposed to form. The Committee was to consist of fifteen persons, eight nominated by the Trustees of the London Parochial Charities, and the remaining seven by the Treasury, the Lord President of the Council, the Technical Education Board, the London County Council, the Royal Society, the Society of Apothecaries and the Royal College of Physicians in turn, the Pharmaceutical Society of Great Britain, and the Senate of the University of London respectively. He thought it was satisfactory to note that the Society was asked to take a part in this work, and he suggested that he should be authorised to reply that they would be happy to make a nomination when the time came.

This was agreed to.

Mr. MARTINDALE remarked that the name of the Gardens as inscribed on a tablet on the wall was Hortus Pharmaceuticæ.

The PRESIDENT said a letter had been received from the Privy Council saying that the Russian Ambassador had applied for copies of any regulations in force in this country with regard to chemists, and asking if any further regulations were in force beyond such as had been supplied on a former occasion to the Belgian Government. He took it the Council would leave it in his hands to supply the necessary information.

This was agreed to.

REPORT OF THE GENERAL PURPOSES COMMITTEE.

The report of this Committee, so far as it dealt with the appointment of local secretaries, examiners, etc., was read.

The PRESIDENT said he regretted that replies had only been received from five places with regard to the appointment of local secretaries, but it was open to the Council to make appointments at any time, and he still hoped that further replies would be received. In the meantime he moved the appointment of the following:—

Local Secretaries.

Enfield	Goldby, Frank.
King's Lynn	Palmer, W. J.
Leominster	Sandiland, R. B.
Richmond (Yorks.)	Walton, E. Bridges.
St. Helens	Wallbridge, J. G.

Assistant Local Secretaries.

Birmingham (North)	Poole, Jeffrey.
„ (South)	Jones, Wm.
Dundee	{ Russell, J. W. Park, Wm.
Glasgow	{ Moir, James. Russell, J. Anderson. Boyd, A.
Liverpool	{ Buck, Anthony S. Grace, W. A. Walker, F. Hudson, T. H. Thompson, C. J. S.

Divisional Secretaries.

West Kensington	Worsley, Albert Geo.
South St. Pancras	Churchyard, Robt. L.
Greenwich	Parsons, Wm.

The PRESIDENT explained that Mr. Parsons, of Greenwich, had been appointed in place of Mr. A. J. Brown, who had been obliged to retire owing to ill-health, but who they would all hope would soon recover his strength, and to whom they were much indebted for his services in the past.

APPOINTMENT OF EXAMINERS.

The PRESIDENT moved, on the recommendation of the General Purposes Committee, that the following be appointed Examiners for the ensuing year:—

ENGLAND AND WALES.

Arkininstall, William; London.	Phillips, Alfred James; London.
Farmer, John Bretland; London.	Saul, John Edward; London.
Farr, Edward H.; Uckfield.	Tanner, Alfred Edward; London.
Harvey-Gibson, John; Liverpool.	Taylor, George Spratt; London.
Kipping, F. Stanley; Nottingham.	Thomson, John Millar; London.
Lucas, Edward William; London.	Wright, Robert; Buxton.

Also, on the recommendation of the Executive of the North British Branch, that the following gentlemen should be appointed Examiners for the ensuing year in

SCOTLAND.

Balfour, Isaac Bayley; Edinburgh.	Jack, James; Arbroath.
Davidson, Alexander; Montrose.	Lunan, George; Edinburgh.
Dobbin, Leonard; Edinburgh.	Maben, Thomas; Hawick.
Ewing, James Laidlaw; Edinburgh.	Nisbet, John; Portobello.

The PRESIDENT moved a vote of thanks to each member of the Board of Examiners in England and Wales and in Scotland for their services during the past year. He said this was by no means a formal vote in any case, but he wished specially to mention three gentlemen, Professor MacLeod, Mr. A. G. Seward (Cambridge), and Dr. Gibson in Scotland, who, under the regulations adopted in 1894, were ineligible this year. These gentlemen came on the Board when the new regulations were made, and by their urbanity and courtesy had done much to make things work smoothly and to advance and maintain the standard of the examinations.

The resolution was carried unanimously.

NEW SCHEDULE FOR THE EXAMINATIONS.

The PRESIDENT moved that the recommendation of the General Purposes Committee with regard to new examination schedules be adopted, and that they come into force as from September 1, 1899. These had been considered very fully by a sub-Committee and by the General Purposes Committee, and the subject of a revision of the schedules had been for a long time under the consideration of the Boards of Examiners, because in such a matter absolute unanimity was required, and that necessarily caused delay. The great object kept in view had been rather definition than increase of stringency, and if the new schedules were carefully examined he thought it would be found that that was the result. The only point to which he thought it desirable to call attention was in connection with the practical examination in chemistry, where this sentence was added, "To analyse a mixture containing not more than two metals and two acid radicles." One of the examiners in chemistry, in reference to that, said he did not think it would be a hardship to the candidate, as they were already prepared for it by being required to detect one substance in the presence of another.

The motion was agreed to unanimously.

CONCLUDING BUSINESS.

The Council then went into committee to hear and consider the report of this Committee on legal matters.

On resuming, the report and recommendations were adopted, and resolutions passed authorising the Registrar to take proceedings against the parties named therein.

METHYL SALICYLATE IN GONORRHOEA.—Durange finds that the following injection rapidly effects a cure in cases of gonorrhœa in all stages of the disease: Methyl salicylate, 1; bismuth subnitrate, 20; liquid vaselin, 100; to be employed in three injections per diem. The liquid should be retained as long as possible in the urethra.—*Bullet. de la Societe de Pharm. du sud-ouest*, xx., 257, after *Semaine Med.*

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

'THE PHARMACEUTICAL FORMULARY,' edited by J. Oldham Braithwaite (London: J. and A. Churchill. Price, 6s. 6d.), is an old friend with a very new face, being the twelfth edition of Beasley's 'Pocket Formulary.' Inasmuch, however, as the work has been entirely re-written, it is a new book. As stated by the editor in the preface, the object kept in view in compiling the book has been to bring together, in a compact and convenient form, the whole of the formulæ in the British, French, German, and United States Pharmacopœias, together with those of the chief unofficial formularies in common use in this country and abroad, and such other medicinal formulæ as experience has proved to be of more than merely local importance. That object would appear to have been very thoroughly effected, and it would be difficult to mention any medical formula of real importance that is not included in the book. It embodies the whole of the British Pharmacopœia, B.P.C. Unofficial Formulary, Codex Medicamentarius, Arzneibuch für das Deutsche Reich, Arzneimittel die im Deutschen Arzneibuch nicht enthalten sind, U.S. Pharmacopœia, and National Formulary, with judicious selections from other works, boiled down into one small compact volume of less than five hundred pages, in which are presented "all that is best in what is practically the world's pharmaceutical practice." No more useful addition to the library of the modern pharmacist could well be conceived, for in addition to supplying so much definite information, it is also packed with suggestions for the production of new and elegant formulæ, and Mr. Braithwaite is to be congratulated upon the completion of a difficult and most praiseworthy task.

IN 'PLYMOUTH AS A TOURIST AND HEALTH RESORT,' by F. M. Williams, M.R.C.S., D.P.H., the members of the British Pharmaceutical Conference will find a plain and trustworthy account of the attractions offered by the town selected for their next meeting, and by its beautiful surroundings. The book commences with a concise historical summary, contributed by the Plymouth Borough Librarian, and subsequent sections treat of Plymouth as it exists to-day, objects of interest in and about the town, the facilities offered to tourists who make Plymouth a holiday centre, the climate of Plymouth, and places and objects of interest in the neighbourhood. There is no doubt that the more persons who read this well-illustrated little book, the larger will be the attendance when the Conference visits Plymouth next July. Mr. A. D. Breeze, Hon. Secretary of the Plymouth Incorporated Mercantile Association, is therefore doing his town good service in offering to send a copy of the book to any chemist who will remit 2½d. in stamps to cover postage.

THE XMAS 'PHOTOGRAM' contains several features of interest, and is printed in the first-class style with which readers of the *Photogram* are now familiar. The Holy Shroud of Turin is reproduced in two supplements, the larger—measuring 20 in. by 5½ in.—being intended for framing. It represents the shroud exactly as it appears, with the distinct impress of the front and of the back of a body. The smaller (full-page) reproduction shows the face and front of the body as they would appear on Signor Pia's negative which has been so much referred to in the daily press. A special article in this issue directs attention to the many objects of historical interest and natural beauty which are threatened with destruction, and calls upon photographers to resist, where possible, the destruction, or, failing this possibility, to faithfully record the scene. "Hand-Camera Work in Winter" is

shown in the course of an illustrated article by Paul Martin to be both possible and enjoyable, and altogether the Christmas number of the *Photogram* is most attractive and useful.

THE 'LONDON UNIVERSITY GUIDE' for the year 1898-9, published at the University Correspondence College Press, London, and supplied gratis to anyone applying for a copy, is probably the most useful book intending candidates for the London University examinations could refer to for information. There is a brief but interesting account of the history and constitution of the University, and full particulars are given as to the requirements for all the examinations. Then follows a list of the special subjects for 1899 and 1900, detailed and well-considered advice regarding the choice of text-books, and short descriptive articles on special subjects for 1900. The new regulations of the University of London, which come into force next year, are fully explained in this issue of the Guide.

'NATURAL SCIENCE' closes the first stage in its career with the December issue, which contains a criticism of Mr. Herbert Spencer's biological hypotheses by Professor C. Lloyd Morgan; the second part of a contribution on the artificial formation of a rudimentary nervous system, by Professor A. L. Herrera; an illustrated article on the neuration of Rhopalocera, by A. Quail; the presentation of a theory of retrogression, by G. Archdall Reid, M.B., and a paper on the movements of diatoms, with a full-page plate illustrating the structure of those organisms, by F. R. Rowley. Notes and comments on scientific affairs of current interest, notices of new books, and other matters of interest help to make up a most entertaining number of a publication that is well worthy of support. *Natural Science* will henceforth be published by Mr. Young J. Pentland, Edinburgh, and the subscription is thirteen shillings per annum.

DR. BLAKE'S BOOK on "The Hand" (London: Henry J. Glaisher. Price 2s. 6d. net.) treats of the study of that organ for indications of local and general disease. It is well-known that when the aid of a European physician is sought for a female member of a Mohammedan family of distinction, a hand, thrust through a small opening in a curtain, is the only part of the patient which the doctor is permitted to see. That such a course of procedure is not altogether absurd is shown by Dr. Blake, for he clearly demonstrates how a large amount of general information may be gleaned from a patient study of the hand. The book is illustrated by photographic reproductions of hands affected in various ways, and much curious information is imparted by the author.

LETTS'S 'MEDICAL DIARY' for 1899 is a most useful book, containing much information compiled expressly for the use of the medical profession, besides ruled pages for noting obstetric engagements, vaccination, nurses' addresses, thermometrical or other fluctuations, monthly cash account, etc. It can be obtained with space for 54 or 108 patients' names daily, and in various styles, at prices ranging from 2s. 6d. to 5s. 6d.

'THE MEDICAL AND SURGICAL REVIEW OF REVIEWS,' edited by Nathan E. Boyd, M.D., which has now reached its second number, purports to be a monthly summary of "the best in the medical and surgical periodical literature of the world," and already it goes far to justify that description. All the abstracts included in the paper are accompanied by full references to original sources, and the busy man can have no better guide to what is worth consulting in the numerous publications that appear every week and month.

THE PHARMACY OF THE ORGANOID.*

BY DR. J. C. MCWALTER.

An organ is a part which has a determinate function in the animal economy. By an organoid is meant a medicine which is supposed to fulfil the function of the organ from which it is prepared. The organs of most interest to therapeutics are those which modify the condition of the blood stream by adding, or extracting, some ferment or otherwise influencing it. The problem for pharmacy is two-fold—on the one hand to isolate, elaborate, and present in active and agreeable forms those secretions or ferments on which the activity of the various organs depend, and on the other to investigate their nature and conditions of action. Many pharmacists seem to think that professional etiquette should restrain them from the prosecution of researches in physiological chemistry lest they should seem to be trespassing on the physician's territory, but surely it is a hopeless task to endeavour to make a preparation of the active principles of an animal gland if one has not the remotest idea of what that principle might be. The impudence of the advertising person who seeks to persuade the medical profession that his preparation must represent the active principles of a gland because he has powdered a dead gland and pressed it into tablets seems on a par with the countrywoman described in one of Ian MacLaren's stories, who, being ordered by her doctor to administer three leeches, toasted them carefully and swallowed them down. The process of ratiocination by which that excellent lady concluded that by swallowing the leeches whole she was certain of the benefit of any virtue they possessed is very similar to that of certain manufacturers who give the assurance that if some desiccated portion of a gland be swallowed its properties must thereby be gained, and the relief which follows in many cases is probably due to the same causes as in the case of the Lady of the Leeches.

The science of therapeutics must be grounded on the effects which certain medicines exercise on the blood cells. Every blood cell contains a nucleus, and the chief constituents of these nuclei are called nucleins. They are highly complex phosphorous compounds whose number and complexity depend only on the variety of the cells. These nucleins are found in both animal and vegetable tissues, in yolk of eggs, yeast, liver, spleen, and in the thyroid and thymus glands, cow's milk, etc. The nucleins correspond to the empirical formula, $C_{29}H_{49}N_9P_3O_{22}$, and, besides phosphorus, most nucleins contain also sulphur. The power of the body to resist the attacks of pathogenic microbes and the ravages of epidemic diseases depends on the property which the blood cells possess of exercising a bactericidal or phagocytic action on these micro-organisms, and that power which suffices for the preservation of health under normal circumstances is found to be dependent on the integrity of the blood cells, and these in their turn must rely on the condition of the nuclei. When, therefore, the nuclei of the blood cells are unable to discharge their normal functions it is an obvious rule of therapeutics to refresh and invigorate them by the introduction into the blood stream of healthy nucleins. Such nucleins have been prepared from yeast, and taken either by the mouth or hypodermically, with considerable success. They are found to possess powerful therapeutic properties, and to have the power of stimulating an increase of the white blood cells. They require for their solution a weak alkaline preparation, and it has been found by direct experiment that the bactericidal power of certain of the nucleins is due in a large measure to the carbonate of soda necessary to dissolve them. Now, to pharmacists a detail of that nature is what renders their work at once necessary and interesting. It has been seen that an alkaline solvent is necessary, and only a skilled pharmacist could have suggested such a solvent. If the experimenters had relied on some desiccated preparation, some tablet or alcoholic solution, their efforts would have been in vain. Nucleins are found to be useful in assisting the organisms to combat disease, and it behoves the pharmacist to help the physiological investigator by suggesting what solutions will give the substance the greatest efficacy. A simple alkaline solution is found to be best, but unless the pharmacist has some *à priori* knowledge of the constitution and properties of the cells, he will not be in a position to help the doctor, and the latter will be reduced to blind empiricism in trying one solution after another. Pepsin of the B.P. is an organoid, and the suggested test in the Pharmacopœia is utterly impracticable for ordinary purposes, and very liable to

mislead unless strictly followed. The test laid down in the the 1885 edition demands only half an hour's trial, while the present B.P. requires six hours' attention. It would be very erroneous to assume that, because the test of the new Pharmacopœia requires pepsin to dissolve fifty times as much albumin as did the old, that the former is fifty times as strong. The fact is that acidulated water will dissolve white of egg without any pepsin, if only it be left long enough at the proper temperature. A pepsin, therefore, of which 1 grain would cause solution of 250 grains of albumin in half an hour, would probably be of greater digestive power in the human stomach than one which dissolves 2500 grains in six hours. Passing onto the liquor pancreatis, it will be observed that there is not the slightest admonition to observe aseptic precautions. It is not stated whether the pancreas must be hot from the animal or otherwise, neither are any particulars as to the appearance of the liquor given. We are told that it is a liquid, but beyond that no hint as to colour or consistency is conveyed. That muddy preparation depositing greyish flakes so familiar in some pharmacies might claim to be the liquor pancreatis of the British Pharmacopœia, if only it answers the very modest test given in the book, and that test is a perfect farce as a criterion of potency. It has been suggested by Mr. C. Umney that liquor pancreatis may be made by digesting an ounce of pancreatin in a pint of 20 per cent. of alcohol, but there is a pancreatin on the market of which a grain will peptonise more milk in half the time than twenty times the quantity of the liquor pancreatis. Moreover, nothing is stated as to the milk in the directions for testing pancreatis. Complete directions are given as to boiling the egg, removing the membranes, etc., but as to whether the milk should be fresh from the cow, alkaline and warm, or many hours old, charged with bacteria, and undergoing lactic fermentation, not a word is said. Mr. Umney gives the credit for the formula for liquor thyroidei to Mr. E. White, a pharmacist to one of the London hospitals, and who had done much work on the subject, but Dr. Murray, of Newcastle-on-Tyne, appears to regard it as his offspring. There are complaints that this preparation does not keep, but this is probably due to the proportion of carbolic acid being too small, and to the want of specific instructions as to sterilising the mortar, flask, etc., in which it is supposed to be prepared. Instead of the carbolic acid should be substituted a little common salt, which—pharmaceutically—should suggest itself as a solvent for the serum globulin and iodine compounds. Pharmacists accustomed to microscopic work may have noticed the wonderful effect of a few drops of salt solution on blood cells in preserving their vitality and preventing necrotic changes. Some discussion has recently been raised about testing for iodine in thyroid tablets. Certain tablet makers complain that the ordinary test for iodine, consisting of the addition of a few drops of hydrochloric acid to the solution and the subsequent agitation with chloroform to which the iodine gives the characteristic violet tint, does not demonstrate iodine in their preparations, and it certainly is difficult to do so; but it has been observed that if a tablet which contains iodine be subjected to the test, and the test solution allowed to remain in the light for some hours, a very notable quantity of chlorine is evolved. This is apparently due to the conversion of the chloroform and iodine into chlorine and iodoform, but the rapidity of the change seems to be due to some ferment in the gland. On this point, however, a personal investigation should be made by pharmacists.

When the history of medicine in the last decades of the nineteenth century come to be written no more humiliating chapter can appear than that which describes how certain manufacturers seek to torture every new remedy into the form of tablets, gelatinoids, pills, or pastilles, without the slightest regard as to whether such form is calculated to preserve or enhance the properties of the gland. The gland should be extracted with sterilised glycerin, and a solution of common salt (5 per cent.) added, whilst after filtering the solution should be rendered aseptic by being subjected to a pressure of twenty atmospheres of CO_2 . With the exception of a few preparations of the thyroid, stomach and pancreas, there are very few animal extracts produced in Great Britain which at all represent the active principles of the glands or are any credit to pharmacy. This is largely due to the absurd attempts to desiccate the organs. There is, in consequence, a very wide field of work open to the scientific pharmacist in examining the functions and properties of the various organic remedies used in medicine, and ascertaining what solvents will best extract their virtue, and what are the cardinal principles governing the pharmacy of the organoids.

* Report of a lecture delivered before the Pharmaceutical Society of Ireland.

THE STUDENTS' PAGE.

EXPLANATORY NOTES ON THE B.P. 1898.*

Extractum Ergotæ.—The process for this extract is very similar to the one contained in the Swiss Pharmacopœia. When the alcoholic filtrate is evaporated and diluted with water, resinous and oily substances are deposited and removed by filtration. The addition of hydrochloric acid causes the precipitation of a quantity of the colouring matter—the so-called sclererythrin. To the filtrate sufficient sodium carbonate is added to almost neutralise the acid, and the liquid is then evaporated to a *soft extract*. The directions for evaporation are somewhat vague, but this is perhaps unavoidable in the present stage of our knowledge concerning the active principles of ergot and their relative value as medicinal agents. It must also be remembered that different samples of ergot do not yield a constant quantity of total extractive, so that evaporation of the final product to a given weight, bearing some proportionate relationship to the weight of ergot taken, would result in a product of very variable consistency.

Glusidum.—A printer's error crept into the explanatory note on this substance. At page 594, column 2, line 11 from the bottom, for "glucoside" read "gluside."

Glycerinum.—The official tests for this substance have been considerably increased. Although insoluble in ether or chloroform, it is soluble in a mixture of either of these fluids with absolute alcohol. Its solubility in these mixtures may be utilised in analysis to separate glycerin from such substances as sugar, gum, gelatin, and many inorganic salts which are insoluble in ether-alcohol or chloroform-alcohol. The specific gravity is now given as 1.260, which corresponds to about 98 per cent. glycerin. Absolute glycerin has a sp. gr. of 1.265, but the removal of the last traces of water is somewhat difficult and not necessary in the case of glycerin for medicinal purposes. When heated it is decomposed, the chief product being acrylic aldehyde, to which the irritating odour of the decomposition products is due—

The darkening with ammonia and silver nitrate would indicate substances of an aldehydic nature (*e.g.*, formic and acrylic aldehydes), which consequently reduce silver nitrate in neutral or alkaline solution (compare the behaviour of aldehydes in your text-book). Such bodies might be produced by overheating during the distillation in the process of manufacture. The addition of ammonia may be regarded as a precautionary measure to neutralise any acid present, since the black precipitate of silver cannot be obtained in strongly acid solutions. The test for butyric acid depends upon the production of ethyl butyrate. Butyric acid, $\text{C}_3\text{H}_7\text{COOH}$, is homologous with acetic acid, and the production of its ethyl ester under the circumstances described is quite similar to that of ethyl acetate (*vide* *Æther Aceticus*, *P. J.*, November 26, 1898, p. 552). The butyric acid is derived from butyrin (the glyceryl ester, analogous to olein and stearin), which is a constituent of some of the oils and fats from which glycerin is made. In performing the test for arsenic particular care should be taken to ensure that the materials and apparatus employed are free from arsenic. The best plan is always to make a blank experiment first, *i.e.*, without the glycerin.

Homatropinæ Hydrobromidum.—If atropine be heated with alkalis it undergoes hydrolysis, a base called tropine and an organic acid, tropic acid, being the products. The tropic acid combines with the alkali, and the tropine may be removed by "shaking out" the hydrolysed product with ether. If the tropine be then heated with certain organic acids (in presence of hydrochloric

acid) the acid and base combine with formation of an ester, water being eliminated. The group of mydriatic alkaloids having the constitution of esters derived from tropine, or some allied base, and tropic acid or allied acid are called tropëines. To obtain homatropine the tropine, obtained as described above, is recombined with mandelic acid. Homatropine belongs, therefore, to the group of artificial tropëines, and may be called tropine mandelate, just as atropine may be regarded as tropine tropate. The tropëines are esters because they are derived from an acid and an alcohol just like ethyl acetate, according to the general reaction:—

The esters derived from alcohols like ethyl alcohol, containing a hydrocarbon radicle, are neutral bodies. The tropëines, however, although esters, are strongly basic alkaloids, for tropine has the constitution of methyl-oxyethyl-tetrahydro-pyrine—

and while, therefore, it contains a hydroxyl group, like ethyl alcohol, it is a strong base by virtue of the nitrogen atom in the pyridine nucleus. The basic properties of this group cause the esters—the tropëines—to be also basic bodies. Homatropine is used in ophthalmic practice, because, while it dilutes the pupil, like atropine and the other mydriatic alkaloids, its effects do not persist so long. Dilatation of the pupil is required for the examination of the interior structure of the eye, but after the examination the patient suffers considerable inconvenience from the entrance of too much light through the widely-dilated pupil: hence the reduction in the after period of dilatation is an advantage. Homatropine is a homologue of atropine, the difference of CH_2 in their formulæ being due to the homology of tropic and mandelic acids. Tropic acid is α -phenol- β -hydroxy-propionic acid, $\text{CH}_2(\text{OH})\cdot\text{CH}(\text{C}_6\text{H}_5)\cdot\text{COOH}$,

while mandelic acid is phenyl-hydroxy-acetic acid, $\text{CH}(\text{OH})(\text{C}_6\text{H}_5)\cdot\text{COOH}$. It is so called because it was first obtained by the action of hydrochloric acid on amygdalin (Ger., mandel, an almond). It is now made from benzaldehyde. Like other aldehydes, this combines with hydrocyanic acid to form an additive compound—a cyanhydrin.

By boiling with hydrochloric acid the cyanide group is converted by hydrolysis into carboxyl (compare *nitriles* in your text-book) and mandelic acid obtained.

Infusions.—The changes effected in this group of preparations by the 1898 Pharmacopœia may be briefly summarised as follows: Six formerly official are now omitted, *viz.*, the infusions of chamomile, catechu, kousoo, jaborandi, linseed, and matico, while a formula for infusion of broom has been introduced to replace the decoction of the same drug. The omissions are justified by the disuse into which the six infusions mentioned have fallen. The time of infusion has been in most cases reduced, and is now fifteen minutes in all cases, except infusions of calumba and senega (half hour each), and acid infusion of cinchona (one hour). Several changes in strength have been ordered, mostly tending to produce uniformity, one infusion (cascarilla) having been reduced from 1 in 10 to 1 in 20, and four (chiretta, ergot, rhubarb, and serpentina) increased from 1 in 40 to 1 in 20. Changes of lesser magnitude have also been effected in the infusions of quassia (now 1 in 100) and digitalis (now 1 in 146). The doses have been mostly reduced, the maximum being one fluid ounce, except for digitalis (four fluid drachms), and six others, *viz.*, buchu, cusparia, ergot, hops, broom, and senna (two fluid ounces). The infusions of cusparia and chiretta are made with boiling water in place of water at 120° F.—another change in the direction of uniformity, which is justified by the absence of sufficiently good reasons for the exceptional treatment of these two infusions.

* NOTE.—This series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P. J.* during 1897 and the earlier portion of the current year.

THE COUNCIL MEETING.

AFTER the minutes of the previous meeting had been confirmed, Mr. MARTINDALE gave expression to his grateful sense of the honour done him by his colleagues in appointing him to the office of Treasurer, which has been held by so many distinguished members of the Society.

The PRESIDENT mentioned the receipt of a letter from Mr. HAMPSON, thanking the Council for the resolution of generous appreciation passed at the last meeting, and members of the Society will be pleased to learn that in a postscript he conveyed the information that his health is improving.

Mr. STORRAR, in writing to express regret that he could not attend the Conference of Divisional Secretaries, stated his conviction that any attempt by the Society to obtain further or amended legislation would have no chance of success until it represented the whole trade, and that the first thing to be done is by a determined personal canvass to demonstrate the advisability of joining the Society.

The PRESIDENT also mentioned that he had written to Dr. BAILDON, congratulating him, on behalf of the Council, on his appointment of Professor of English Literature in the University of Vienna, and had received a letter from Dr. BAILDON asking him to convey his thanks to his former colleagues for their good wishes.

Sympathetic reference was made to the death of Mr. HORSLEY, the Society's divisional secretary for North Kensington, as an unexpected loss of an active supporter.

The letter from the Privy Council communicating the confirmation of the Bye-laws, recently made "for the better regulation of the Society's business and for the better administration of the public duties imposed upon the Society by Statute," was read.

On the motion of the PRESIDENT and Vice-President, the persons who were, on July 25 last, registered as associates in business on their own account, were elected members of the Society, and thus the first step was made to give effect to the amended constitution by which opportunity is afforded for all registered persons to co-operate together, on a footing

of equality, in promoting the objects of the Society's Charter and assisting in the attempt to remedy those defects of subsequent legislation which have now become so detrimental. Mr. BATESON and Mr. PARK stated that in their districts a very general intention had been expressed to join the Society as members, and the PRESIDENT added that the numerous encouraging reports from other places led him to anticipate a very large addition to the ranks of the Society at the opening of the next year.

Mr. JOHN FREDERICK HARRINGTON was elected a Member of the Council in the place of Mr. HAMPSON, and in proposing him for election the PRESIDENT explained that it had been thought desirable to select one of the number of those who had, under the new Pharmacy Act and Bye-laws, acquired the status of member of the Society.

The Superintendents and Deputy Superintendents of Written Examinations were elected according to the lists given at page 614.

The report of the Finance Committee had no unusual features, and its recommendations were consequently adopted without remark.

On the recommendation of the Benevolent Fund Committee, six grants, amounting in the aggregate to sixty-eight pounds, were ordered to be paid. The Secretary reported the death of Mrs. KATE CHENERY, who has been an annuitant since 1886, and the PRESIDENT announced that Mr. A. T. MAW had made a donation of one hundred guineas.

The report of the Library, School, and House Committee was unusually brief, but the PRESIDENT observed that the work done by that Committee was very considerable, and that the present brief report must not be supposed to indicate that the Committee had been idle.

The report of the Law and Parliamentary Committee stated that the PRESIDENT had been requested to address a communication to the LORD CHANCELLOR, to the effect that the Council is desirous of obtaining His Lordship's assistance towards extending, in regard to persons legally qualified to practise pharmacy, the prohibition of the assumption of professional titles by incorporated companies now being sought for by the General Medical Council.

In moving the adoption of the report, the PRESIDENT said he desired that it should be thoroughly understood that the important subject referred to has not been neglected, but has received the constant attention of the Committee. Some years ago, in the time of his predecessor, everything possible had been done to deal with the evil which has become so pressing, but great difficulty had been encountered, causing delay. Now that the action of the General Medical Council has thrown some light on what the Council has done, the Committee concluded that it would be wise to appeal directly to the Lord Chancellor for help in the present difficulty. Assuming all registered persons to be agreed in thinking that the Act of 1868 was passed in order that all who kept open shop as chemists and druggists should be qualified and registered, and that its object was the safety of the public; with all due respect to the House of Lords the decision in the case of the London and Provincial Association did not appear to be consistent with the intention of the Legislature. He thought that instead of the present state of things, it was intended that keeping open shop should not be permitted for any but persons who have the actual direction of the business as proprietors—qualified natural persons responsible for its proper conduct.

Alteration of the law in that direction cannot be obtained without the assistance of the Government, but he believed that a representative Society could do much in carrying out the views he had expressed. Obviously, they could help themselves without going to Parliament, for companies could not carry on the business without assistance from legally qualified persons; but he hoped the action now taken would be accepted throughout the country as an indication of earnest desire on behalf of the Council to deal with the difficulty in every possible way, and of the necessity for the support of all registered persons.

In seconding the motion the Vice-President dwelt upon the necessity for general support from all legally qualified chemists and druggists as the most essential condition of success in carrying out the suggestions of the Law and Parliamentary Committee.

Mr. CARTEIGHE referred to the action taken in 1895, in order again to place on record that the Council has been the moving spirit in raising the question as to the legality of company trading, and he mentioned the report of the Departmental Committee of the Board of Trade as furnishing evidence to that effect. He called attention to that as an answer to the statement that the Council has done nothing. Mr. ARTINS, Mr. HARRISON, Mr. MARTINDALE, and Mr. RYMER YOUNG spoke to the same effect, expressing a hope that adequately united action on the part of chemists and druggists would be the means of awakening the national conscience to a sense of the gross injustice which legally qualified chemists and druggists have to contend with, and that the result would be a recognition of the fact that they have common sense, right, and justice on their side.

A requisition was presented duly signed by thirty members and calling upon the Council to summon a special general meeting for the purpose of prescribing regulations for the keeping, dispensing, and selling of poisons, after which Dr. SYMES moved, in pursuance, a previous notice of motion, that the meeting for that purpose should be held on January 11 next. In accordance with an amendment moved by Mr. HARRISON, a resolution was passed that the meeting should be called to consider and, if thought fit, to adopt regulations for the keeping, selling, and dispensing of poisons in conformity with the provisions of the Pharmacy Act, 1868.

BRISTOL PHARMACEUTICAL ASSOCIATION.

WE are requested by Mr. B. KEEN, Hon. Secretary of the Bristol Pharmaceutical Association, to announce that a conference of registered chemists will be held at the Grand Hotel, Broad Street, Bristol, on Thursday next, December 15, at 9 p.m., to consider the position and prospects of the retail trade. Mr. KEEN will introduce the subject, and a free discussion will be invited upon the following points:—1. The urgent necessity there is that every registered chemist should avail himself of the privilege given by the amendment of the Pharmacy Acts of becoming a member of the Pharmaceutical Society. 2. That legislation is much needed to supplement the Pharmacy Act, 1868, which is based upon the principle of personal proprietary of all retail shops, and the restricting to qualified persons of the compounding and dispensing of medicines, as well as the sale of pharmaceutical preparations. 3. That it is desirable to adopt regulations for keeping and storing poisons. 4. That the so-called "Widows' Clause" ought to be modified or abandoned.

ANNOTATIONS.

THE PROPOSED INDIAN AND COLONIAL ADDENDUM to the British Pharmacopœia is now, as explained last week, in the draft stage, and copies of the draft have been sent to all Indian and Colonial authorities interested in the matter, with a request that they will (1) criticise and amend the descriptions given of the various drugs, in order that such descriptions may apply to satisfactory commercial specimens; (2) supply a few complete descriptions asked for in certain cases in which the Pharmacopœia Committee of the Medical Council has been unable to obtain such descriptions; (3) express an opinion as to the suitability of the preparations proposed, and state the doses of the preparations; (4) make suggestions respecting such additional drugs and preparations as may be deemed desirable in order that the Pharmacopœia with the completed Addendum may meet the requirements of the various Colonies and Dependencies. It is requested that all suggestions and criticisms should be sent in within three months, and with the view of facilitating matters, the full text of the draft Addendum is now being published in the *Pharmaceutical Journal* (see p. 611). Any suggestions and criticisms that may be communicated to the Editor by readers of the Journal will receive prompt attention, and be brought under the notice of the proper authorities in due course.

THE REPORT ON THE ADDENDUM, which prefaces the draft monographs, states that it has not been deemed desirable to recognise the drugs suggested, or those which may hereafter be suggested, as mere substitutes for drugs entering into preparations now official, save in the case of a very few substances. The drugs suggested by Indian and Colonial authorities for official adoption have, as far as possible, been recognised for their own merits, and are described more or less fully in the report in accordance with the plan followed in the Pharmacopœia, the descriptions being founded on the characters of specimens at Kew and in the museums of the Pharmaceutical Society of Great Britain, of the Owens College, and of the Imperial Institute. In a few cases it has not yet been found possible to obtain satisfactory specimens, and in cases where the advisability of introducing a new drug or preparation has seemed doubtful, brief reasons for the doubt have been given. The Pharmacopœia Committee owes the description of the specimens in the draft Addendum for the most part to Mr. William Kirkby, lecturer on Pharmacognosy at the Owens College, Manchester. He has been aided by Mr. E. M. Holmes, Curator of the Pharmaceutical Society's Museums, who has written some of the descriptions.

IN A COMMUNICATION FROM DR. LEECH, Chairman of the Pharmacopœia Committee, he refers to the *Times*, for December 2, where a letter from Dr. Nestor Tirard, Secretary of the Committee, corrects certain inaccuracies in a report of the proceedings of the General Medical Council, published in the issue of the previous day. In that letter it is stated that, whilst it is true that Dr. Attfield was desired to furnish a report upon the criticisms passed on the Pharmacopœia and on the progress of pharmacy and pharmaceutical chemistry during the years 1897 and 1898, it was also felt by the Committee that it was desirable "to submit to experts for investigation and report some of the criticisms which appeared to necessitate further experimental research." We understand that periodic conferences are to be held between representatives of the Pharmaceutical Society and representatives

of the Pharmacopœia Committee of the Medical Council. All criticisms worthy of notice and all new work bearing on the Pharmacopœia will be taken into consideration by this joint Committee, which will have the power of referring to specially appointed experts such points as may seem to require investigation. Those experts will be paid by the Medical Council, and the reports furnished by them will probably be submitted to the Pharmaceutical Societies and to pharmacists generally for criticism, as suggested in the *Pharmaceutical Journal* for April 23 last. That will be a real advance, and should be cordially welcomed as such.

THE WORSHIPFUL COMPANY OF SPECTACLE MAKERS will hold its next "modified" examination for opticians on March 1, 2, and 3. Already nearly thirty candidates have entered for the examination, and we understand that an attempt will be made to enable students from the country to go through the written and the *viva voce* portions in one day instead of two. Applications must be made on the official form, and should reach Colonel T. Davies Sewell, the Clerk of the Company, at the Guildhall, London, E.C., not later than February 14 next. A revised syllabus will shortly be issued. Meanwhile, it is announced that more practical work will be required by the examiners than was the case at the last examination.

THE CHELSEA PHYSIC GARDEN, as mentioned in a note in last week's Journal, is in future to be administered in accordance with an extended scheme. The Apothecaries' Society has decided, owing to considerations of expense, to abandon the management of the garden which, it will be remembered, was founded by Sir Hans Sloane in the early part of the eighteenth century, and was subsequently transferred to that Society in trust. A scheme has accordingly been drawn up for vesting the control in the Trustees of the London Parochial Charities, but it is proposed that the actual management should devolve upon a committee of fifteen members, eight to be nominated by the Trustees, and one each by the Treasury, the Lord President of the Council, the Technical Education Board, the Royal Society, the Society of Apothecaries and the Royal College of Physicians in turn, the Pharmaceutical Society of Great Britain and the Senate of the University of London. It is intended that the existing garden should be fully maintained, a suite of rooms being provided for lectures and experimental teaching, whilst the Trustees are to be given authority, if they think fit, to erect and fully equip a physiological laboratory.

AN ANNUAL INCOME of eight hundred pounds is to be provided by the Trustees, and it is proposed in addition that the committee shall be furnished with such a capital sum as may be necessary to enable them to enforce the scheme to its full extent. The committee is to appoint a curator for the scientific supervision of the garden, and other members of the staff. Further, the committee will be authorised by the scheme to provide instruction in botany by means of lectures, demonstrations, etc., with special reference to the requirements of elementary education; to arrange for the maintenance of botanical collections of living plants for teaching purposes, and, so far as practicable, for the supply of botanical specimens for the purpose of external instruction. Students of institutions receiving aid from the funds of the City Parochial Foundation are to be eligible for admission without payment of fees; and it is provided that, so long as a yearly payment of not less than one hundred and fifty pounds is made to the Trustees out of the moneys provided by Parliament, students of

the Royal College of Science shall also be admitted to the garden without payment, while they, the professors, and teachers of the College, shall be entitled to the use of the garden, the botanical collections, and the lecture rooms for such time as may be approved by the Charity Commissioners. It will thus be seen that the scheme is of a far-reaching character, and calculated materially to increase the usefulness of the garden.

AT AN INQUEST held at Chelsea on November 30, it was stated that two cooling powders had been administered to the deceased—a child aged five years—prior to an attack of convulsions, which terminated fatally. The medical evidence showed that the cause of death was failure of the heart's action, and that the powders had nothing whatever to do with the matter. The jury, also, was satisfied that death resulted from natural causes, and returned a verdict to that effect without any comment. Nevertheless, the coroner—Mr. Luxmoore Drew—felt it incumbent upon him to rebuke the chemist—Mr. Thomas Davies—who had sold the cooling powders. He accused him of permitting an unqualified assistant to prescribe, though the evidence clearly showed that the powders had only been supplied as asked for in the ordinary course of business, and the unfortunate chemist was browbeaten in a manner that was totally unjustified under the circumstances. We understand that the powders contained calomel as the active ingredient, but one organ of the drug trade has cast an unnecessary slur upon Mr. Davies by attaching a heading to the report, which implied that he had sold poison by the hand of an unqualified assistant. That, of course, was not the case, and the sensationalism of the headline must doubtless be attributed to the fact that the numerous sub-editors of the organ in question have not yet overcome the effects of a recent convivial gathering. But it is none the less hard upon Mr. Davies, in such a case, that he should have to suffer under so unmerited a stigma.

THE NEW FRANCO-ITALIAN TREATY OF COMMERCE provides for an abatement in the Italian conventional tariff in favour of France, and a similar abatement will, according to the *Economist*, be also conceded to British products in virtue of a most-favoured-nation treaty. A list of the principal articles in respect of which reductions are made includes essential oil of roses, spices, compound medicines, scented soap, perfumery, etc., and the reduction in the duties varies from 10 to 50 per cent. in different instances. There are some other articles, not previously classed in the Italian tariff, on which a fixed duty is now established, but in connection with those a comparison between the old and new duties is, of course, not possible. France does not make any reduction on her conventional or minimum tariff in exchange for the concessions made by Italy.

THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION held a meeting at the Imperial Institute on Monday last, when Sir Benjamin Stone, M.P., the President, delivered an address in which he dealt with the proposed national photographic record. The object of that record is the collection of photographic records of objects and scenes of interest throughout the British Isles. Those records it is proposed to deposit in the British Museum, where they would be safely stored and accessible to the public under proper regulations. Such a collection, it is thought, would not only possess a great interest for the public, but it would be almost invaluable for the historian. There must be in many parts of the country customs and habits and observances of which we possess no pictorial representation whatever, and if those were

photographed they would form most important material for a social history of the people. Then, too, there are buildings, rooms, and other places of high historical and literary interest and importance. Of many of those there are pictures in the possession of individuals, but pictures fade and perish, and it is imperative that the aid of photography should be invoked to produce records of an absolutely permanent character.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, at a meeting held last week, received a report from the committee of management of the joint examining board of the Royal Colleges of Physicians and Surgeons, recommending the Colleges to adopt a synopsis of practical pharmacy which had been drawn up by the examiners in that subject in consequence of the issue of the new British Pharmacopœia, and that it should come into force on May 1, 1899. The report also recommended that the examination in materia medica and pharmacy applicable only to candidates under the old regulations, which has hitherto been conducted by papers and *viva voce*, be conducted in future *viva voce* only, on account of the small number of candidates under the existing regulations. The committee further requested that, in consequence of a desire expressed by the teachers and examiners in physiology that there should be an examination in practical physiology, it may be empowered to consider the question, and to take the opinion of the several medical schools and report to the Colleges on a future occasion. The report was adopted, subject to the approval of the Royal College of Surgeons.

MASON UNIVERSITY COLLEGE, BIRMINGHAM, may probably before long have a school of malting and brewing established in connection with it. In an appeal for funds for that purpose, it is pointed out that, whilst England has a greater interest than any other country in brewing and malting, it is the only country interested in those trades in which there is no public systematic education given in the manufacture of malt and beer. In Germany (as the *Times* points out) there is the great school at Weihenstephan, near Munich, and in addition there are others in Berlin, Worms, Augsburg, and Munich. Austria has schools at Vienna and Prague; Belgium at Liege and Louvain; and at Copenhagen the Brewing School will for ever be connected with the classical researches of Hansen on the yeasts. Brewing is one of the businesses which manufacturers have allowed to be partly taken away from this country by foreign competitors, but it is now proposed that the training to be given at Birmingham shall be of the fullest nature both for maltsters and brewers, and that neither in the character nor extent of the instruction given shall the Birmingham school be inferior to any of those on the Continent. It is intended that the instruction shall be both scientific and technical. Examinations will be held, and diplomas awarded to successful students, and a proper standard by which a maltster's and brewer's training may be gauged will thus be established. It is estimated that £50,000 will be necessary to carry out this project adequately, and of that £21,422 has already been promised.

NEW SCHEDULES FOR THE EXAMINATIONS of the Pharmaceutical Society, which come into force as from September 1 next, were adopted by the Council of the Society on Wednesday last (see p. 617). We are asked to state that the schedules have, for the present, been left in the hands of the President for final editing. When they are ready for publication they will be dealt with in the *Pharmaceutical Journal*. Meanwhile no copies of the new schedules can as yet be obtained.

ANALYTICAL NOTES.

DETECTION OF LACTIC ACID IN THE GASTRIC CONTENTS.—As a more delicate, simple, and satisfactory test than those at present in use, J. P. Arnold advocates the employment of the following method for detecting lactic acid in the contents of the stomach. Two solutions are used, the first of which should not be kept longer than a month. No. 1: Saturated alcoholic solution of gentian violet, 1/10 C.c.: distilled water, 250 C.c. No. 2: Solution of ferric chloride, U.S.P., 5 C.c.; distilled water, 20 C.c. Into a test tube put 1 C.c. of solution No. 1 and add a drop of No. 2. The violet colour changes to bluish-violet. To this mixture add drop by drop the filtered gastric contents. If lactic acid be present, the colour of the solution changes to a greenish-yellow. The test may be made roughly quantitative by comparing the tint produced by a known volume of material with that given by a 0.02 per cent. solution of lactic acid. Alcohol, butyric and acetic acids, and phosphates up to 2 per cent. do not interfere with the reaction, nor do albumoses, albuminoids, and peptones.—*Therapist*, viii., 196, after *Univers. Med. Mag.*

DETERMINATION OF ALKALOIDS IN EXTRACTS.—N. Rustig advocates the following method for determining the alkaloidal value of pharmaceutical extracts. The novelty consists in using tragacanth to aid the separation of the fluids. From 2 to 3 grammes of the extract—for instance, of cinchona—are weighed out, diluted with water 5 C.c., and then 50 C.c. of ether and 5 C.c. of 5 per cent. soda solution are added, and the mixture well shaken. In order to rapidly separate the ethereal layer 2 grammes of powdered tragacanth are added to the mixture, and the whole again shaken for thirty seconds. This fixes the watery solution, whilst forming an adhesive mass which adheres to the glass and allows 40 C.c. of the ether to be poured off; the solvent is then distilled and the alkaloidal residuc weighed. The alkaloids so extracted are stated to be free from the usual impurities. Other extracts may be determined in a similar way, employing (instead of ether) chloroform or other solvents suitable for the alkaloids they contain. In the majority of cases a mixture of chloroform, 2 volumes, and petroleum ether, 8 volumes, is recommended. The alkaloids may, if desired, be determined by titration instead of by weighing.—*Pharm. Cent.*

QUANTITATIVE DETERMINATION OF THE BITTER PRINCIPLE OF HOPS.—C. S. Lintner and G. Barth in the course of their researches on hops, found that one of the chief bitter substances, lupulinic acid, which they isolated in a crystalline condition, was capable of being titrated in the ordinary way with alkaline solutions. Since the other bitter resins have also acid reactions, Lintner now proposes that an approximation of the bitter principle in hops may be obtained as follows:—Ten grammes of hops are placed in a half-litre flask, graduated at 505 C.c., with 300 C.c. of petroleum ether, and boiled for several hours on the water bath, under a reflux condenser. The mixture is then cooled, more solvent added to bring it up to the volume, and then filtered, 100 C.c., which represents 2 grammes of the original hops, being taken for titration. This is mixed with 80 C.c. of strong alcohol, and titrated with decinormal alcoholic potash, using phenol-phthalein as an indicator. The result is expressed in terms of lupulinic acid, the molecular weight of which is 400. The process will give figures which are of value for purposes of comparison. The average figure of fifteen samples ranged from 14.6 to 12.7 per cent.—*Zeitsch. für Brauw.*, through *Chem. Zeit.*, xxii., 219.

DETERMINING TARTARIC ACID.—J. Moszczenski treats the material with dilute sulphuric acid, and then with alcohol, which removes all the tartaric and free sulphuric acids. A definite volume of the alcoholic solution is filtered off, and alcoholic potassium acetate added to it, which precipitates the sulphuric acid as K_2SO_4 , and the tartaric acid as $KHC_4H_4O_6$. The precipitate is collected, washed with strong alcohol, and titrated with alkali.—*Journ. Soc. Chem. Ind.*, xvii., 215.

DETERMINATION OF BORAX.—Heid (*Montreal Pharm. Journ.*) adds to the solution of borax an excess of hydrochloric acid and evaporates to dryness. The boric acid thus liberated is removed by washing with absolute alcohol, and the sodium chloride in the insoluble residue, equivalent to the borax, is titrated in the usual manner with silver nitrate.—*Annales de Pharm.*, iv., 920.

CHEMICAL SOCIETY.

A meeting was held on Thursday, December 1, at 8 p.m., the PRESIDENT, Professor Dewar, F.R.S., in the chair. Besides the reading of papers, the business of the evening included a ballot for the election of Fellows. The President remarked that two foreign members were present, Professor Rennie (of Baddeley) and Professor F. D. Brown (of Auckland), and announced that the rare bust of Sir Humphrey Davy, which was exhibited on the table, had been given to the Society. The first paper, by HENRY J. HORSTMAN FENTON, M.A., and HENRY JACKSON, B.A., B.Sc., dealt with

The Oxidation of Polyhydric Alcohols in Presence of Iron.

It will be remembered that Mr. Fenton showed early in the year that ferrous iron exerts a remarkable influence upon the oxidation of tartaric and certain other hydroxy-acids. The present investigation was made with a view of studying the behaviour of various alcohols under similar conditions. The substances were treated with hydrogen peroxide with and without the addition of ferrous iron. On careful comparison of the results no apparent change was observed in the case of the *mono-hydric* alcohols, but with all the *polyhydric* alcohols under examination an energetic oxidation took place in presence of iron, accompanied by a considerable rise of temperature and formation of an aldehydic substance. In the corresponding blank experiments, where iron was absent, no such effects were obtained. In the case of glycol the oxidation product is glycollic aldehyde, while glycerol appears to give glycer-aldehyde only, little or no dioxycetone being detected; erythrite gives rise to a reducing substance which yields erythrosazone, mannite gives mannose, and dulcitol and sorbitol are similarly oxidised. It was further shown that atmospheric oxygen, in presence of ferrous iron, produces in many cases similar oxidation effects on exposure to sunlight.—In the ensuing discussion, as the PRESIDENT neatly remarked, Mr. Cross expressed the opinion of every Fellow present when he warmly praised the work of the authors in generalising the reaction in which ferrous iron plays so important a part.—After the usual vote of thanks had been warmly passed, Mr. WYNDHAM R. DUNSTAN, M.A., F.R.S., communicated the result of an investigation by himself and Harold Brown, on

The Occurrence of Hyoscyamine in the *Hyoscyamus muticus* of India.

This plant, which is extensively used externally in Indian medical practice, abounds in the Punjaub, Beloochistan, Afghanistan and elsewhere. On account of its powerful excitant properties by virtue of which mania may be produced, it has also received the name *Hyoscyamus insanus*. According to Dr. Praed, of the Botanical Survey of India, the intoxicant known as "bhang," so largely used throughout India and Persia, is not prepared so exclusively from *Cannabis indica* as has been imagined, but, especially in Persia, from species of *Hyoscyamus*. It appears, also, that in Beloochistan the *Hyoscyamus muticus* alone is employed in making both this preparation and the well-known "haschish." With the assistance of Mr. Andrews, the authors have extracted the alkaloid from a sample of the drug furnished by the Indian Government. It was exhausted with alcohol, which was distilled off at a low temperature to avoid conversion of hyoscyamine to atropine, and impurities were removed in the usual way, such as was adopted by the speaker and Mr. Chaston in the case of other *Hyoscyamus* species. The gold salt was prepared with a view of separating the alkaloids by means of the different solubilities and melting points of their salts. The whole of the alkaloid, however, proved to be hyoscyamine, because only one auric chloride was produced, melting at a definite temperature. The authors have extended the investigation to a comparison of this drug with the *Hyoscyamus niger*. They find that the former yields hyoscyamine in a pure state, whereas that obtained from the official drug is mixed with varying quantities of atropine and scopolamine.—This paper gave rise to a lengthy discussion. Mr. GROVES asked whether, seeing that the authors had operated only on a small quantity of the plant obtained from one part of India, atropine might not be found under certain conditions of age and climate in other specimens of the plant. It was asked how far the alkaloid hyoscyamine represented the medicinal value of the drug, and Mr. DAVID HOWARD asked what was the proportion of hyoscyamine present.—Mr. PAGE inquired

whether the residue that remained after separation of the hyoscyamine was capable of producing any physiological action.—In reply, Mr. DUNSTAN stated that, just as in belladonna almost pure hyoscyamine is present in the *young* plant, becoming more and more mixed with atropine with increasing age, such might be the case with *Hyoscyamus muticus*. Only the stem and leaf were examined, and not the root; 0.1 per cent. of hyoscyamine was found. With regard to the medicinal value of a drug depending on the presence of one or more alkaloidal constituents differences of opinion existed, but in this case he considered that the physiological action was entirely due to hyoscyamine.—Professor Dewar temporarily left the chair in favour of Dr. W. H. Perkin, F.R.S., while he gave an account of "The Comparison of the Colour of the Vapour of Iodine at Atmospheric Pressure and in Vacuo."—After a lengthy discussion, in which Dr. Thorpe, Professor Brown, Mr. Elworthy, Mr. C. M. Jones, Dr. Travers, and Dr. Forster joined, the meeting adjourned.

SHEFFIELD MICROSCOPICAL SOCIETY.

At a meeting of the above Society held on Friday, December 2, Dr. GEORGE WILKINSON, B.A., F.R.C.S., in the chair, there was a crowded assembly of members and friends to hear a lecture by Mr. A. H. Allen, F.I.C., Sheffield city analyst, on the

Microscope in Chemo-Legal Investigations.

The lecture was illustrated throughout by lantern slides, and a series of very beautiful experiments. At the outset Mr. Allen explained the construction and manipulation of the spectroscope, and went on to describe its great usefulness in the detection of minute quantities of blood. He prepared a dilute solution of fresh blood and placed it in a flat glass trough in front of the slit of a spectroscope, and the spectrum produced was thrown on to a small screen. The characteristic double absorption bands of oxy-hæmoglobin were at once sharply defined. The solution of blood was next de-oxidised by means of a minute quantity of true sodium hyposulphite ($\text{Na}_2\text{S}_2\text{O}_4$), which gradually reduced the oxy-hæmoglobin to hæmoglobin; the double absorption bands of the spectrum were now seen to coalesce to form one single broad band. On bubbling air through the solution the hæmoglobin became re-united with oxygen, and the double banded spectrum re-appeared. These two spectra are, of course, characteristic of arterial and venous blood respectively. The decomposition products of hæmoglobin, such as methæmoglobin acid and alkaline hæmatin, hæmochromogen, etc., were explained, and the variation in their spectra was demonstrated. The manner of the formation of blood crystals was minutely described, and a number of variously shaped hæmoglobin crystals were depicted on the screen. The very important hæmin crystals (Teichmann's blood crystals) were also shown, and stress was laid on the fact that the formation of these crystals affords one of the most delicate and characteristic tests for the colouring matter of blood. The lecturer then proceeded to show how blood stains may generally be treated; thus, if the stain be on cotton, linen, silk, wool, etc., a portion of the fabric on which the stain exists should be cut out. If on wood, stone, or other porous material the stained portion should be carefully scraped away for some depth and reduced to fine powder. Stains on iron and other metals may be removed by scraping. If the stains are at all recent, water will be sufficient to extract the colouring matter. If the stain is old it should be soaked and warmed with ammonia or caustic soda. The hæmatin is thus readily dissolved, and may be detected by reducing it to hæmochromogen. Very few colouring matters yield absorption spectra which can be mistaken for that of blood. The red colouring matter of *Cineraria* petals, turacin, cochineal, soluble indigo (hot solutions only), lac-dye alkanet, madder, etc., give the nearest spectra to that of blood, but these may be absolutely distinguished by the application of reagents. Ganther's test for blood had proved useful, and this was next demonstrated. A glass trough containing peroxide of hydrogen was placed in the lantern in such a way as to allow the experiment to be seen distinctly on the screen. A slip of glass well besprinkled with dried spots of blood was now immersed in the peroxide trough, immediately numerous large bubbles of gas were developed on the blood spots. This test is of great use as a means of detecting blood stains on rusty iron. Stains on rust six months old respond to this test as sharply as when fresh. Although Ganther considered that a negative reaction proved the absence of blood, yet the

formation of bubbles is not an absolute proof of its presence, as other animal fluids behave in a similar manner with peroxide of hydrogen. Mr. Allen then went on to describe the microscopic characters of blood corpuscles, giving comparisons as to the sizes and shapes to be found in different animals. Thus the microscopic recognition of the corpuscles becomes a valuable confirmation of the spectroscopic indications, and derives its chief value from the possibility it affords of identifying the blood as of human origin. Although it might not be possible to affirm positively from the microscopic examination that a stain contained human blood, yet it was possible to differentiate it to such an extent that by a process of elimination other sources are excluded. In a case within the lecturer's personal experience a man accused of murder asserted that certain stains were caused by the blood of a sheep, an explanation which the size of the corpuscles showed to be false. In another similar case the stain was attributed to the blood of a fowl, an origin which the circular shape of the corpuscles proved to be impossible. The following diameters of the red corpuscles from eight different animals are interesting:—

Man	·0078 millimetre.
Dog	·0071 "
Rabbit	·0069 "
Ox	·0060 "
Horse	·0059 "
Pig	·0059 "
Sheep	·0052 "
Goat	·0041 "

Mr. Allen then passed on to the microscopic identification of different hairs, and showed slides of the following:—Hair of child, adult, eyebrow, spaniel, horse, goat, fox, fallow deer, and the fur of rabbit and hare, pointing out the characteristics of each. In a similar manner various fibres were also shown, such as silk cotton, jute, linen, wool, and the importance of the microscope in detecting adulterations in various fibres was commented upon.—At the close of the meeting a very hearty vote of thanks was accorded to Mr. Allen, on the motion of Mr. W. BARRACLOUGH seconded by Mr. C. F. GIDDINGS.

SOCIETY OF PUBLIC ANALYSTS.

At a special meeting of this Society, held at the Chemical Society's Rooms, Burlington House, Piccadilly, on Wednesday, the chair was taken by Dr. Bernard Dyer, when Mr. A. H. ALLEN, F.I.C., delivered a lecture on

The Use of the Micro-Spectroscope.

Mr. Allen commenced by describing and showing with the lantern the absorption-spectra of various coloured substances, including nitrous fumes, cobalt glass, and solution of potassium permanganate. He next exhibited the spectrum of blood, both in an oxidised and unoxidised condition, and described the changes undergone by the colouring matter of blood under the influence of time, application of acids and alkalis, etc. The spectrum of hæmatin, which resulted from the splitting up of the colouring matter of blood by the action of acids and alkalis was not characteristic, but if a solution of hæmatin were made alkaline and a reducing agent added, the absorption-spectrum of hæmochromogen—characterised by an exceedingly deep and well-defined band in the green—was obtained. This spectrum could always be obtained from a blood-stain, however old. The lecturer went on to describe and illustrate by lantern slides the construction of various forms of micro spectroscope, and showed the method of manipulation. He then proceeded to discuss the microscopic characters of blood and the size of the corpuscles from the blood of various animals. Illustrations of human blood and of the blood of various other mammals were exhibited, and their difference in size pointed out. Mr. Allen expressed the opinion that although the difference in the size of the corpuscles did not afford an absolute distinction between human blood and that of other animals, it served in many cases as a means of eliminating unsupported allegations. Thus, while the corpuscles of human blood could not be distinguished with certainty from those of the dog, the corpuscles of the blood of the sheep and goat were so much smaller as to render the difference striking, if not absolutely conclusive of their origin.—The discourse was listened to with the closest attention throughout and was well received by the audience, consisting largely of analytical chemists, medical practitioners and microscopists.—A discussion followed in which the President and other gentlemen took part.

MEETING OF PRESTON CHEMISTS.

An important gathering of chemists was held at the Old Bull Hotel, Preston, on Thursday, December 1, to confer on various topics of interest to the trade and to consider the advisability of forming a pharmaceutical association for Preston. Mr. Arkle (Preston) was voted to the chair, and opened the proceedings by commenting upon the lack of interest chemists exhibit in their own affairs. He said he could not help thinking that it was entirely owing to this apathy or carelessness that they were in the present slough of despond, and it was only by inducing every registered chemist to become a member of the Pharmaceutical Society that any satisfactory approach could be made to Parliament.

Councillor SHORROCK said all the Darwen chemists had joined the Blackburn Association, and had since become subscribers to the Pharmaceutical Society. They had realised that this was the right course to pursue, for unless chemists gave to the Society all the help and assistance possible, they could not expect to secure the passing of parliamentary measures dealing with their grievances. The chemists of the Empire were suffering from the effects of that unfortunate decision of the House of Lords to the effect that a company is not a "person" within the meaning of the Pharmacy Act, 1868. Since that decision the country had become inundated with companies, and chemists were now beginning to feel the pinch. It was quite time they began to put their house in order by forming themselves into associations, and so create a power which would influence members of Parliament, and thus secure a much-desired reform in the law. As one of the representatives who attended the Federation meeting at Belfast, he was astonished to find that many associations in the country were absolutely ignorant of the existence of such a useful connecting link, and he was also impressed with the want of unity amongst chemists. They seemed to be altogether out of touch with one another, and common experience proved that nothing could be more harmful to a cause than the existence of such a state of affairs. At Darwen, Blackburn, Burnley, Colne, and Accrington chemists had been brought together with advantage, and if the chemists of Preston would also form themselves into a strong association or join the North-East Lancashire Association, he predicted that the result would reward them for their pains.—After a brief discussion as to the nature of the proposed local organisation,

Mr. GIFFORD (Blackburn) said what was wanted was unity, and it did not matter in the least how that was secured. The intentions of the Legislature in 1868 had not been carried into effect, or the position of the pharmacist to-day would have been vastly different. Twenty years ago the dentists secured an Act of Parliament, and to-day they were directly interested in a Bill which the General Medical Council was introducing to prevent the registration of companies to carry on medical, surgical, or dental practice. He contended that the public was in greater need of the pharmacist than of the dentist. Yet to-day the chemist had lost what he was supposed to have gained in 1868, when there existed a well-defined body of men doing a certain work. To-day chemists had the privilege, shared by corporate bodies, of selling, subject to certain regulations, about twenty defined substances. Chemists have nothing to lose, but everything to gain, by seeking to improve the Pharmacy Acts. At any rate they should ascertain what the functions of a chemist were really supposed to be, and they hoped to make it clear that it was for the public benefit that the profession of pharmacy should exist in fact and not in name only. They needed a new and adequate Pharmacy Act which would define and regulate the practice of pharmacy. There was ample room for the profession of pharmacy, and their business should consist in the handling and distribution of all powerful herbs, drugs, and chemicals. It was the duty of the Pharmaceutical Council to draft a Bill to that effect, and it was unreasonable to expect the rank and file to take the initiative in the matter.

Mr. LIVESLEY thought it was eminently desirable that Preston should have an Association, but he was convinced that they could not persuade the governing powers to do anything for them as chemists. If, however, they could convince Parliament that it was desirable the public should be protected against the irresponsible sale of poisons, then the Legislature might be induced to move. The Act of 1868 was not passed for the benefit of chemists, but entirely for the protection of the public. He deprecated the attitude taken up by the apathetic chemist who thought more of his till than his profession.

Mr. WILLIAMSON was of opinion that the Pharmaceutical Society should follow the example of the General Medical Council, which had drafted a recommendation for submission to the House of Lords in connection with the Companies Bill. He also proposed that a committee should be formed to consider the advisability of immediately organising a chemists' association for Preston.

Mr. STUART seconded the motion, and it was unanimously agreed that the Committee should consist of Messrs. Arkle, Livesey, Stuart, and Williamson.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.

The usual monthly meeting of the above organisation was held at the Liverpool School of Pharmacy on Thursday evening, the 1st instant, the VICE-PRESIDENT, Mr. H. Wyatt, jun., taking the chair in the absence of Mr. R. C. Cowley, the President.—After the election of one new member (Mr. Patridge), an exceedingly interesting address on

Dispensing and Dispensing Problems

was delivered by Mr. T. S. WOKES, who, prefacing his remarks by a general definition of the term "dispensing business," and as to where such businesses were to be found, proceeded to discuss fully the numerous important details essential to the proper conduct of such businesses, and laid down certain well-known and generally received rules applicable to the control of the daily routine of a pharmacy with a dispensing connection. It was essential that only the best glassware, corks, boxes, and sundries should be used, and that the labels should be of a special and characteristic style peculiar to the pharmacy, which should not be changed when once decided upon, except after mature and judicious consideration.

BOTTLES.—For mixtures flat or square bottles were generally used, whilst for gargles and such preparations as were not intended to be taken, but which were not of a dangerous nature, actinic green bottles were becoming usual. Poisonous lotions and liniments should invariably be dispensed in green or blue fluted special bottles. Thick liquids for throat or mouth application were conveniently sent out in wide-mouthed bottles capable of allowing a camel hair brush or mouth sponge being introduced.

SUPPOSITORIES were normally of 15-grain size, except the Pharmacopœia glycerin, and pessaries, of 60 grains, except quinine, which were mostly 30 grains.

SALTS in mixtures when in quantities above the saturation point of the liquid menstruum should be rubbed down to a fine powder and suspended. Heat should never be used to effect solution, for the excess of salt on cooling would be deposited as crystals.

ETHER AND CHLOROFORM were best dispensed in corked bottles, glass stoppers being very unreliable and apt to be blown out on a rise in temperature. Whilst speaking of chloroform he would mention its applicability to the preservation of fresh infusions, for which it was very handy.

POWDER PAPERS could be bought ready cut and trimmed up by the printers and were neater and better than those cut by hand.

FILLING DIRECT from the distilled water bottle was risky in dispensing, for the vapour or flavour of the mixture might rise in the air space of the water bottle by displacement, and so flavour or contaminate the whole supply. He had once had a case of this sort where elixir phosphori was the cause of a bottle of medicine being returned to him, owing to its tasting of the phosphorus.

SYRUP OF IODIDE OF IRON was, contrary to general notion, improved by exposure to direct sunlight, and should always be kept in the lightest part of the shop.

COPIES OF PRESCRIPTIONS were a fruitful source of annoyance, and he should like to know under what circumstances they should be given.

As examples of dispensing problems, he submitted the following prescriptions he had recently handled:—

No. 1.	
℞ Liq. Ammon. Acet.	ʒvi.
Sp. Ætheris Nit.	ʒiii.
Sp. Camphoræ.	ʒii.
Aquæ Chlorof. ad	ʒvi.
Fiat mistura.	

The camphor was deposited, so he used spirits of chloroform, ʒii., and made up with aqua camphoræ, thus finding a way out of the difficulty.

No. 2.	
℞ Ung. Zinci	ʒi.
Aquæ Calcis	ʒii.
Fiat unguentum.	

The ointment was melted in a bottle, the aqua calcis added, and the whole shaken until a smooth cream was formed.

No. 3.	
℞ Lanolini Anhydrosi	ʒi.
Adipis Benzoati	ʒii.
Liq. Plumbi Subacet. Dil.	ʒvi.
Fiat unguentum.	

This submitted to the same treatment as No. 2, and turned out satisfactorily.

No. 4.	
℞ Ammon. Chlorid.	ʒii.
Lithii Carbonatis	ʒi.
Liq. Bismuthi	ʒi.
Sp. Ætheris Nit.	ʒss.
Aquæ Chlorof. ad	ʒviii.
M. ft. mist.	

When the ammon. chlor. and lithium carbonate were shaken with the chloroform water, the lithium salt dissolved with difficulty, but on the addition of the sp. ætheris nit. the solution became at once clear. The liq. bismuthi subsequently gave a white precipitate. He should like to ask the opinion of the President upon this and other decompositions which occurred in the prescriptions submitted to the meeting.

No. 5.	
℞ Potas ii citratls	ʒii.
Sp. Chlorof	ʒii.
Aqua	ad ʒviii.
M. ft. mistura.	

The potassium salt threw out the chloroform from the spirit.

No. 6.	
℞ Salicin	ʒi.
Potass. Chlor.	gr. ʒ6.
Syr. Limonis	ʒss.
Infusi Quassia	ad ʒvi.
M. ft. mist.	

The salicin dissolved clear after adding the syrup of lemons, though it was feared the acidity of this syrup might cause a precipitate of salicylic acid.

No. 7.	
℞ Pepsin Porel	gr. 80.
Acid Hydroch. Dil.	ʒ 80.
Liq. Strychninae	ʒ 80.
Tinct. Aurantii	ʒii.
Tinct. Zingiberis	ʒi.
Sp. Chlorof.	ʒi.
Aquæ	ad ʒviii.
M. ft. mist.	

The pepsin at first on dilution came out in clots, but these, strained out and rubbed down again, furnished a fairly satisfactory mixture. Would the use of a soluble pepsin have been allowable so as to obtain a clear and presentable mixture?

No. 8.	
℞ Pulv. Boracis	ʒi.
Alum Sulph.	ʒi.
Glycerini	ʒi.
Aquæ Rosæ	ad ʒviii.
M. ft. gargasima.	

The addition of the alum caused a white, finely divided precipitate to form. What was this?

No. 9.	
℞ Ferri et Quininae Cit.	gr. 40.
Liq. Ammonia Acet.	ʒss.
Syrupi Aurantii	ʒii.
Aquæ	ad ʒiv.

Although this when dispensed was clear a precipitate formed upon standing. To what was this reaction due?

At the conclusion of his address Mr. Wokes exhibited a press for the production of suppositories in the cold, a mould for making the pastilli of the Throat Hospital Pharmacopœia, and a pyramidal stand for round labels, consisting of a set of wood boxes of different sizes holding the labels, these boxes being placed on their sides one above the other in a pyramid-shaped box of handy size for the dispensing counter. The remarks of such a well-known dispenser as Mr. Wokes were naturally listened to with the greatest interest by a full meeting of the students, who showed their appreciation by hearty applause.—In moving a vote of thanks to the speaker, the CHAIRMAN congratulated his fellow members on having been privileged to listen to such a well-ordered and practical address

on a subject which to them was of the utmost importance. Such papers were of inestimable value to real students, and were exactly what their Society had always striven to encourage. Scientific papers were good, undoubtedly, in their proper place, but they were luxuries for which most students had no spare time, whereas it was remarkable that these really practical papers were invariably delivered to a goodly and appreciative audience, which seemed to enter into the spirit of the subject and find all its good points. He, the Chairman, was flattered that Mr. Wokes should in a way look upon him as an authority upon dispensing difficulties; it was a position to which he could lay no claim. However, he would try and explain those indicated as far as he was able to do so. The hints Mr. Wokes had given were likely to be of use to many, for instance, the use of wide-mouthed bottles for glycerin of borax. The advice concerning the filling of bottles direct from the stock bottle of distilled water had been emphasised by one of the members, Mr. Pierson, during a previous session. The ointments made by shaking were very satisfactory indeed. Now as to the difficulty with No. 4, the explanation was in his opinion this, the acidity of the spirits of nitre first carried the lithium carbonate into solution, the haze from the chloroform partly thrown out by the salts being at the same time removed by the alcohol in the spirit. The white precipitate subsequent to the addition of the liq. bismuthi, was, no doubt, bismuth subcarbonate, caused by the lithium carbonate acting as any other carbonate of the alkali group would do. The separation of chloroform in No. 5 might be obviated by using an equivalent of chloroform water instead of the spirit. In No. 6, the acidity of the syrup of lemons would assist in the solution of the glucoside salicin, from which salicylic acid could only be liberated by the prolonged action of an oxidising agent. Pepsin porci was an awkward thing to make into a mixture, and could be with advantage replaced by a soluble pepsin, if the prescriber agreed to such a course. Continental prescriptions often contained pepsine in "potions," and in France a moist pasty pepsin, known as "pepsine extractive" was used in such cases as it was easy to suspend, and made a tolerably elegant mixture, whose only drawback was its rather disagreeable smell. The cloudiness noticed in the gargle No. 8 was due to double decomposition between the alum—an acid salt—and the borax, with formation of gelatinous aluminium borate, and sodium sulphate. In the ninth formula the alkalinity of the solution of ammonium acetate was the disturbing element, giving rise to a precipitate of quinine hydrate or carbonate readily soluble on the addition of a little acetic acid.—The vote of thanks was seconded by Mr. PRATT, who remarked that the new pepsin was of the soluble variety, which would remove one of the dispenser's difficulties in the future. Anent the use of "Shake the bottle" labels he would advise their being placed above the ordinary label, so as to be more striking to the eye. Mr. Wokes's address had been of the greatest interest to the younger members present, in whose name he (Mr. Pratt) wished to second the vote of thanks.—After the vote had been unanimously recorded, and Mr. WOKES had replied, Mr. A. H. MORGAN read a paper on

Suppositories,

which consisted of a general review of the various recognised methods of making suppositories, pessaries and bougies, the most suitable bases, and the special methods of manipulation to be adopted in certain cases. The extended use of a gelatin base for suppositories was advocated; owing to its dissolving relatively large quantities of such salts as potassium bromide, quinine bisulphate, and iron salts generally, the aperient action of the glycerin could be modified by using less of it and more water and gelatin. The too ready melting of cacao butter when made into urethral bougies had been overcome by a French chemist, who, in the Bulletin of the Bordeaux Society of Pharmacists, published a formula for a plastic mass, softening, but not melting at the temperature of the body. It ran as follows: Cacao butter, 2 parts; lanoline, 1 part; white wax, 1 part. The pouring of bougie mass into moulds was difficult, because of their narrow diameter. Placing a warm wire down the mould so as to direct the flow of the melted base was one method of making things easier, but the quickest method was undoubtedly that recently advocated and followed on the Continent, which needs no mould in the ordinary sense of the term. The melted mass is drawn up by suction into glass tubes of the right diameter, and after setting is forced out as a long rod by means of an iron wire, terminated by a plug accurately fitting the tube. The bougies in this case are

naturally perfect cylinders, which can be cut to any size and pointed by rubbing down with a piece of lint. A special way of manipulating such drugs as chloral hydrate, devised by Mr. Morgan, gave good results, the suppositories when finished being all that one could desire. Cacao butter was heated in a capsule to 100° F. or 105° and poured into the carefully cleaned mould previously cooled in a freezing mixture. After standing thirty to sixty seconds, the excess of cacao butter was poured off, leaving the interior of the moulds covered with a lining or hollow suppository of chilled cacao butter. The tops were then levelled with a palette-knife, and the chloral or other drug, worked up previously with grated cacao butter in a mortar, was filled into these hollows, which were afterwards sealed by pouring a layer of butter over their bases. Removing the surplus base, a set of perfect suppositories was obtained on opening the mould. In prescribing suppositories Mr. Morgan thought doctors would be well advised if they ordered the active ingredient in percentages, for instance:

R Morph. Hydrochlor.
Olei Theobromæ
Fiat Suppos. 10 per cent. Mitte vi. 15 Gr.

for it is difficult to know how much space the drug will take up, and in the case of zinc oxide, extracts, acetate of lead, etc., this varies considerably.—A good discussion followed, the CHAIRMAN saying that the method used by Mr. Morgan for chloral suppositories was decidedly novel and, besides, of practical interest. The use of glass tubes for making bougies was not a new invention by any means, and though many good things came from the Continent, it would not do to credit their brethren across the Channel with every seemingly new idea. He had made bougies in the same way at least four years since, and obtained the notion from either the 'Art of Dispensing' or the pages of one of the trade journals. In turning out such bougies he simply re-warmed the tube slightly, after the mass had set, and then blew the rod out. Tinfoil was a good thing to make moulds from for pessaries, rolling it round sticks of various lengths and diameters. In hot weather, when pessaries were wanted in a hurry, the tinfoil moulds had advantages over the solid metal ones, first, because they allowed the mass to cool quickly and, secondly, because the pessaries did not stick to the mould, and, thirdly, because the finished pessaries could be cut down to a given weight and absolute accuracy of dose thus insured. If the tinfoil was allowed to project about half an inch above the surface of the mass when this was run into the moulds, they could be at once taken and floated on the surface of a vessel of iced water and cooled ready for finishing off within five minutes of casting.

Mr. WOKES proposed a vote of thanks to Mr. Morgan for his contribution to their evening's instruction, in which he was seconded by Mr. PICKERING, and supported by Mr. J. HARRIS BURNS, who mentioned that he had some suppositories, containing 6 or 8 minims of balsam of Peru and 10 grains of iodoform in each, whose manipulation was very difficult. He had also to make suppositories of ammonio-citrate of iron, and others of iodine and iodide of potassium where the gelatin base was of great utility.—In reply to the vote of thanks, Mr. MORGAN said he had never heard of the glass-tube method of making bougies before, so he must confess himself behind the times. The iodoform and balsam of Peru suppositories would be difficult to make with heat, and the ammonio-citrate of iron was one of the cases he had in mind when he recommended the glycerin and gelatin base.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At a meeting held on Wednesday, November 30, Mr. G. H. C. ROWLAND, President, in the chair, the SECRETARY read the report of the Prize Committee at the herbarium competition, from which it appeared that the prize had been awarded to Mr. Ernest James Pike, 139, Princes Street, who had submitted a highly meritorious collection of well-preserved and neatly-mounted specimens.—The PRESIDENT then presented to the winner a cheque for £2 2s. from the donor of the herbarium prize, Mr. J. C. Pottage, 117, Princes Street, to whom a vote of thanks was awarded on the motion of the VICE-PRESIDENT, Mr. J. D. Sinclair.—A paper by Mr. E. J. PIKE was then read, entitled—

Experiences in Herbarium Collecting.

The author gave a most interesting and humorous description of

the delights of plant hunting, and many useful practical details of the way to collect, dry, and mount specimens.—Mr. D. B. KIDD communicated a

Note on Dispensing Ferrous Iodide and Sodium Arseniate.

Complaint had been made that the following mixture dispensed in different pharmacies was sometimes an opalescent mixture, sometimes quite clear, and sometimes clear but coloured brown:—

℞ Liq. Sodii Arseniat.	℥xl.
Syr. Ferri Iodidi	ʒi.

On adding the solution of sodium arseniate to freshly made syrup of ferrous iodide there is immediate precipitation of ferrous arseniate, which makes the mixture opalescent. The ingredients are, therefore, chemically incompatible. But most wholesale houses send out a liquor ferri iodidi or syrupus ferri iodidi, to which hypophosphorous acid has been added as a preservative, and when such a syrup is used in dispensing the mixture there is no precipitation, the result being a clear, colourless mixture. This result is probably due to the fact that the free hypophosphorous acid dissolves the ferrous arseniate. But a curious circumstance is that the mixture soon acquires a brown colour and indicates free iodine, and on standing a few days again becomes colourless. The coloration may be due to oxidation of ferrous iodide with formation first of oxyiodide, and subsequently of ferric oxide and free iodine. The preservative action of the hypophosphorous acid depends on a reaction between free iodine, water, and hypophosphorous acid, with production of phosphoric and hydriodic acids. The phosphoric acid then seizes the ferric oxide formed in the previous reaction with formation of ferric phosphate, which is dissolved by the hydriodic acid formed in the preceding reaction, and thus a colourless solution results. The coloration and subsequent decoloration may be due to the fact that the iodine is liberated more rapidly than it is reacted upon, and that it takes a little time to reach the point of decoloration, but further inquiry is needed to decide. When citric acid is used as the preservative the mixture is clear, and there is no coloration.—Mr. GEORGE GRAINGER then read a paper on

Pharmacy—A Retrospect,

in which he contrasted the conditions of pharmacy at the beginning of the century with those of to-day, showing what vast strides have been made within so short a period. He illustrated the contrast by a detailed reference to the knowledge of the properties and the preparations and active constituents of opium then and now, as indicating how precision, accuracy, and rationalism had taken the place of the vagueness, indefiniteness, and empiricism of the earlier period.—The last communication read was by Mr. GEORGE MACK on

Carbolic Ointment.

The new B.P. formula for this ointment is not regarded by the author as an example of good pharmacy. The glycerin readily separates, and thus the ointment, instead of acting as a local anæsthetic, as it is often intended to do, might act as a caustic. The paraffin basis should be discarded entirely as not suitable for the application of carbolic acid. The basis suggested is yellow wax and olive oil (1 in 4), which gives a softer ointment than the U.S.P. and has the advantage over the B.P. formula that all the ingredients are soluble in one another.

Discussion.

In the discussion which followed, Mr. DUNCAN said he did not quite agree as to the suitability of olive oil and yellow wax. Hydrous wool-fat or cold cream formed the best basis for carbolic ointment. Water was needed as a solvent for the acid to prevent crystallisation.—Mr. G. SINCLAIR agreed with Mr. Duncan.—Mr. HENRY also disapproved of the paraffin basis. He was disappointed to find it retained in the 1898 Pharmacopœia. The presence of water was important, and therefore he recommended hydrous wool-fat.—Mr. HILL said the ferrous iodide and sodium arseniate mixture would probably have been best dispensed by the addition of a little citric acid. A clear, colourless mixture would have been sent out possessing all the therapeutic properties of the prescription.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held at 73, Newman Street, W., on Thursday, December 1, when a large number of members witnessed a

Demonstration of Röntgen Rays

by Mr. W. COLDWELL.—A considerable number of X-ray photographs of different parts of the human body were on view; one in particular, a skiagraph of the whole human frame, being a very fine specimen.—The PRESIDENT (Mr. F. W. Gamble) introduced Mr. Coldwell as a master in the practice of his subject, as an inspection of the examples of his work exhibited that evening would demonstrate. He also incidentally mentioned that the lecturer had the honour entrusted to him of taking a photograph of the Prince of Wales's knee during his recent illness. Mr. Gamble thought those present would better appreciate the demonstration if a short description of the apparatus to be employed were given. The source of electricity was a six-celled secondary battery charged up to 14 volts. The current passed thence to a modified Ruhmkorff coil, which gave a 10-inch spark. He went on to explain that the current from the battery was of comparatively low potential, but its tension was greatly increased in the primary circuit at each break by the direct extra current. At each make and break of the primary a powerful current was induced in the secondary coil, which, in the battery used, was about 90 miles in length. The secondary induced current was used to excite the tubes. He would leave Mr. Coldwell to speak of the particular vacuum tubes he used, and would merely explain the effect of a gradually increased vacuum upon the nature of the discharge in a glass tube. At atmospheric pressure there was a disruptive discharge, owing to the resistance of the di-electric. At about 75 Mm. pressure the discharge became linear, and was bent like a piece of string by the influence of a magnetic field. At about 1 Mm. the discharge was still linear, but was attracted to the side by a magnet and struck the glass, forming a fluorescent patch. At 1/100th Mm. pressure the discharge becoming striated, and the negative rays (or radiant matter of Crookes) are emitted from the cathode. No substance has yet been found radiable to these rays, therefore they cannot be obtained outside the tube. At a higher exhaustion cathode rays are emitted. These do not pass through the glass of the tube, but can be obtained outside the tube by the insertion of an aluminium window. At a still lower pressure there are obtained Röntgen's X rays. Scientific opinions did not agree as to the nature of X rays. The fact that they could easily be changed into light rays favoured the supposition that they were of a similar nature, and it was generally supposed that they are transverse ethereal vibrations of extremely short wave-length having their place in the scale beneath the ultra-violet rays.—Mr. COLDWELL then showed the method of using the apparatus, and explained the difference between the tubes used for photographic and screen work respectively.—The room was afterwards darkened, and by means of a fluorescent screen the movements of the bones of the hand and wrist were easily discerned, also the bones of the thorax and the beating of the heart. At the close of the experiments, questions were asked by Messrs. Hymans, Pearson, and Roe, to which the lecturer replied.—On the motion of Mr. HYMANS, seconded by Mr. T. MORLEY TAYLOR, Mr. Coldwell was heartily thanked for his interesting and instructive demonstration, as were also Messrs. Allen and Hanburys, Ltd., 43, Wigmore Street, W., for their kindness in lending the apparatus and photographs.

MIDLAND PHARMACEUTICAL ASSOCIATION.

On Thursday, December 1, in the large lecture theatre of Mason's University College, Birmingham, Mr. Hall-Edwards, L.R.C.P., F.R.P.S. (Surgical Radiographer to the General Hospital), delivered a lecture on the

Practical Application of the Röntgen Rays

before the members and friends of the Midland Pharmaceutical Association.—Mr. J. POOLE, President of the Society, introduced the lecturer, who illustrated his remarks by practical demonstrations, diagrams, lantern slides, and apparatus. After a brief scientific introduction and a comparison between the earlier methods adopted and those of to-day, the lecturer claimed that not only scientifically, but from a surgical point of view, the "X rays"

rank as one of the greatest discoveries of the century. Their practical application was being daily extended, and the full scope of their usefulness could not yet be measured. He laid great stress upon the value of surgical radiography upon the field of battle, and said that to military surgeons the discovery was only second in importance to the introduction of antiseptic precautions. He declared that after a battle far more men were killed by the search for bullets with bacteria-laden probes than would die if all bullets were left undisturbed. A radiograph of a hand was taken and developed before the audience, and a large number of lantern slides illustrating the various applications to surgery, etc., were exhibited by means of the electric optical lantern.—Mr. HALL-EDWARDS showed his localising apparatus and spoke of the value of stereoscopic X-ray pictures. He made some brief remarks upon the therapeutic effects of the X-rays in some serious forms of skin disease, but he was not in a position yet to go deeply into the question, as his experiments were not yet finished.—Mr. JONES proposed and the meeting heartily adopted a vote of thanks to Mr. Hall-Edwards for his lecture.

NEWCASTLE-ON-TYNE AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of this Association was held on Wednesday evening last, when the chair was taken by the PRESIDENT, Mr. F. Schofield, and a paper was communicated by Mr. BARNARD S. PROCTOR on

The Storage of Poisons.

The paper is printed in full at page 608.—After it had been read, the PRESIDENT called upon Mr. T. Maltby Clague to open the discussion. Mr. CLAGUE expressed the belief that no amount of legislation would absolutely prevent accidents, but in a brief historical *résumé* he showed how proposed regulations had been a barrier in the past, and how their non-adoption was an obstacle to progress at the present moment.—Mr. WEDDELL emphasised the value education had been to pharmacists in preventing accidents. He strenuously opposed Government inspection as arbitrary and impracticable in regard to poison storage regulations.—Mr. WHITEHEAD deprecated inspection, and extolled personal responsibility.—Messrs. ELLIS and BUCKLEY were in favour of regulations.—The sense of the meeting was represented in the following resolution, proposed by Mr. CLAGUE, seconded by Mr. WEDDELL, and carried unanimously:—

This meeting is of opinion that, if the Council of the Pharmaceutical Society believes that the adoption of modified regulations would improve the position of chemists under the present Acts of Parliament or for future legislation, and would conduce to the greater safety of the public, the case would be met by the promulgation of Part I. of the 1871 recommendations, but Part II. is condemned as unworkable, and Mr. Proctor's scheme is recommended as worthy of careful consideration.

IRISH PHARMACISTS' ASSISTANTS' ASSOCIATION.

At Dublin, on December 2, a meeting of this Association was held at 67, Lower Mount Street, the President, Mr. HENRY HUNT, in the chair. There was a good attendance. After a few items of preliminary business, a debate was held on the question

Should the Examinations and General Management of the Pharmaceutical Society of Ireland be conducted by the State?

Mr. JONES opened the discussion in the affirmative, and Mr. O'FARRELL followed in the negative.—Mr. HOGAN argued in the affirmative, while Mr. WILLIAMS thought the whole question *ultra vires*, and that a Government monopoly would kill pharmacy with red tape.—Several other members spoke for and against the question. The insufficiency of inspectors employed by the Pharmaceutical Society was given as a reason for the dearth of prosecutions by that body. France and America were instanced as countries that looked after pharmacy much better than in England. Hours of duty, educational facilities, and salaries enjoyed by Continental chemists were commented on, and it was held without dissent that the British pharmacist was not nearly as well off as his colleague outside the United Kingdom.—The PRESIDENT summed up the arguments, and was himself

in favour of the affirmative side.—On a poll being taken it was found that the voting on the question was equal, and by the casting vote by the President it was held that the examinations and general management of the Society should be conducted by the State.—The proceedings then terminated.

SELECTED PRACTICAL FORMULÆ.

ELIXIR OF CALISAYA.

Crushed coriander, 1; crushed cardamoms, 15; cloves, 2; orange flowers, 2; powdered red sandal wood, 2; star anise fruit, 5; cinnamon, 12; orange peel, 15; calisaya bark, 36; all in coarse powder, are macerated with 400 parts diluted alcohol (60 per cent.) and 400 water for eight days. After straining, simple syrup, 400, and saccharin 0.2 are added. The mixture is then set aside for eight days to subside, when a clear and reddish-brown fluid is obtained.—*Pharm. Centr.*, xxxix., 480.

BENZOIC ACID AS A PREVENTIVE OF MOULD.

P. Rungo finds that benzoic acid, even if diluted to 1:1000, acts as a preventative of mildew in the same manner as thymol, to which it is preferable by virtue of its being non-irritant.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 35, after *Monatsh. f. Prakt. Dermat.*

SIMPLE METHOD FOR "KILLING" MERCURY.

A mixture of vaseline, 30, lanoline, 15, barium sulphate, 100, is found by B. Bourdoursques to be an excellent means of extinguishing a large quantity of mercury. A small quantity of mercury is first added to the mixture and rubbed until killed, then more of the metal is added, which quickly loses its globular condition. The barium sulphate acts mechanically in dividing the mercury, and from its complete insolubility its presence is free from objection.—*Bullet. de Pharm. du Sud Est*, iii., 437.

PHENOL PASTILLES.

Ninety-five parts of phenol are melted on the water bath and 5 parts stearin soap are added and mixed. The mass is turned out into a cold capsule, when a crystalline paste is obtained, which may be divided into pastilles. These keep well and are convenient for use, readily dissolving in water.—*Journ. de Pharm. d'Anvers*, liv., 420, after *Pharm. de Mex.*

DENTIFRICE SOAP.

Thymol, 25; extract of rhatany, 100; warm glycerin, 600; calcined magnesium, 50; borax, 400; oil of peppermint, 100; medicinal soap, *qs.* to produce 3000. Dissolve the thymol and extract of rhatany in the warm glycerin, and add the other ingredients, mixing thoroughly.—*Form. of Bull. Gen. de Ther.*

COMPOSITION OF ANTITUSSIN.

This remedy for whooping cough is said to be composed of difluordiphenyl, 5; vaseline, 10; wool-fat, 8. This ointment is vigorously rubbed into the chest, the neck, and the back, between the shoulder blades.—*Pharm. Centr.*, xxxix., 427.

PREPARATION OF KOLA FLUID EXTRACT.

Berrégau, of Hanover, uses the following process for the extraction of kola nuts:—1 Kg. of the drug is moistened with a solvent composed of a solution of sodium phosphate, 25 Gm.; glycerin, 150 Gm.; and dilute alcohol (60 per cent.), 200 Gm., and left to stand twelve hours. It is then percolated with dilute spirit, for which 10 Kg. are necessary, and evaporated to a weight of 1 Kg.—*Pharm. Zeit.*, xliii., 683.

SIMPLE FIRE EXTINGUISHERS.

These can be produced by anybody at a slight cost, says *Technische Berichte*. Dissolve 20 pounds of common salt and 10 pounds of sal ammoniac in 30 litres of water, and fill the mixture in quart bottles of thin glass. The extinguishers thus prepared are highly suitable to smother small fires. The bottles, which should be securely corked up and sealed, to prevent the contents from evaporating, are thrown into the flames of the starting fire or its immediate vicinity with enough force to cause them to break.—*Sci. Amer.*, lxxix., 246.

LETTERS TO THE EDITOR.

"PONDO" AND THE BENEVOLENT FUND ELECTION.

Sir,—If "Pondo" will give his name and address in the Correspondence columns of the Journal, and so come out from behind his mask, I am quite willing to reply to his letter. It is scarcely courteous to withhold his name when indulging in trenchant criticism at another's expense.

"Ronaldsway," Tower Road West, ROBERT HAMPSON (159/16).
St. Leonards-on-Sea,
December 6, 1898.

THE MANCHESTER COMMITTEE.

Sir,—Having been asked for some information regarding the Committee referred to in my published remarks (*vide* p. 591), it may be of interest to others to know what has been done in this connection. Briefly it is that, having become more and more convinced of the inadequacy of one ordinary business man to do justice to the Society in the capacity of local secretary in a community so extensive as this is, I suggested to our local Council that a committee should be appointed "to act with the local secretary in watching the interests of the Pharmaceutical Society." Such a committee has been formed upon this plan. Representing the whole area as a wheel, one gentleman has been appointed to the centre of the city, the hub; others in the principal thoroughfares, the spokes; and one or two on the outskirts, the rim. Thus we have in every district a "member of the Pharmaceutical Society," who will be able, without sacrifice of much time, and almost without trouble, to keep the local secretary posted up regarding changes of ownership, deaths, new-comers, matters requiring investigation, etc., in his particular locality, which might otherwise go unnoticed for some considerable time. By an amicable division of labour, too, it is hoped to make use of the present time for canvassing all the district for new members.

Manchester, December 3, 1898.

HARRY KEMP,
Local Secretary.

SUGGESTIONS FOR A MORE FORWARD POLICY.

Sir,—Judging from the character of the correspondence that has lately appeared in your columns, it would seem there is a "shaking among the dry bones." Whether they are ever to reunite and stand up as independent men must depend on their receiving the breath of life which is essential to re-animation and the resumption of flesh and blood. It is a useless and painful task recounting manifest grievances, and more to the point to work for a removal or at least a mitigation of the evils. I would propose that a conference be held, to be attended by members of the craft, men of intellect and determined honesty of purpose, whose object should be: (1) To thoroughly ventilate the subject of company trading in pharmacy in all its bearings; (2) To evoke a power of execution—such a function is supposed to exist in the Council of the Pharmaceutical Society. The Council consists of a body of men elected by members to represent the interests of all, in accordance with the foundation of the Society, viz., to advance the science of pharmacy and to protect trade interests. The question arises, how far hence they realised these two all-important propositions? And it must be confessed that they cannot give a very good account of themselves. That there are able and worthy councillors is not denied, but that a system of progress and adaptation to the requirements of to-day exists there is no evidence. One of your correspondents advocates "almost a clean sweep of the present Council," and surely those members of that body who are out of sympathy with modern trade requirements will scarcely have the face to offer themselves for re-election after such a warning. Let us then hope that next May will bring with it the promise of rejuvenescence of legitimate pharmacy.

December 1, 1898.

NIL DESPERANDUM (158/16).

THE POSITION OF PHARMACY.

Sir,—I am glad to observe the active interest that is being taken in so many parts of the country with regard to unqualified company pharmacy. There is no doubt we have arrived at an acute stage and are already confronted, as a consequence of the evils of company pharmacy, with the serious inconvenience of a labour famine, and which is certain to become more accentuated unless prompt, bold, and comprehensive action be taken. Certainly conditions will not improve until "pharmacy for the

pharmacist" is an accomplished fact. As is well known the most successful of these companies utilise legitimate pharmacy as an advertising medium in order to secure business of a lucrative character, from which in the main the shareholders derive their dividends. As an illustration of this, some months ago a prescription was presented to me to dispense containing three forms, which from start to finish occupied myself and an assistant forty-five minutes. I was informed that 1s. 6d. had been charged by a noted company for this service, which certainly could not be regarded as other than reasonably assessed at 3s. There is no doubt we have a strong case, as it was never intended that a statutory calling should be at the mercy of the capitalist in this manner. With regard to the line of action to be adopted, I am of Mr. Gill's opinion, as expressed at Nottingham a few weeks ago, to the effect that the Council should forthwith formulate a plan and send a draft of the salient points for each local association to discuss and vote upon, and where there is no local association the local secretary should be requested to call together the chemists in his district to express their opinion as to the course future legislation should take, and forward the result to headquarters. If this course is adopted I think there is no doubt but that 1899 will witness a considerable number of those who have not hitherto felt that between themselves and the special and educational work of the Society there has been anything in common brought into line. In connection with this question of increased membership, I am glad to note that each local secretary is expected to make a special canvass of all chemists not connected with the Society residing in his district. If well worked, this should achieve most excellent results, although to my mind the main factor towards securing the united front so much discussed and desired is the formulation of a plan by the Council, as suggested above, by as early a date as possible.

Ashby-de-la-Zouch, November 30, 1898.

G. W. BULLEN.

THE PROPOSED POISON REGULATIONS.

Sir,—I should like to express my pleasure at the expressions of opinion respecting the need for regulating the storage of poisons. Let chemists set their own house in order, or else some one else will do it for them. They will thus gain the favour of the Privy Council, and make the way easier for future reforms by leaving nothing at which the enemy can point. May I suggest, whilst writing, that coming events seem to be casting their shadows before. In your issue of 26th ult. I notice two passages bearing upon the title "Royal" for the Pharmaceutical Society. One, in the (very natural) mistake of a doctor, and the other is Mr. Jones's speech at a meeting of the North Staffordshire Association. It seems to me that the Pharmaceutical Society has now arrived at that stage of development at which it might very suitably have this title bestowed upon it, and it is quite as natural and fitting that it should have it as some other societies—the Royal Photographic Society, for instance. Could not our worthy President, who has so devotedly set his shoulder to the wheel and given us such a tremendous lift ahead in the recent Act, give us the benefit of his influence in high places in this direction? It may seem apparently a small matter, but it must be remembered that as a man is taken at his own valuation, the same rule applies to societies, and the higher standing a society can obtain the more it is respected.

Southport, December 3, 1898

GLYCYRRHIZA (158/19).

MEMBERS, NON-MEMBERS, AND THE PHARMACEUTICAL COUNCIL.

Sir,—The child-like faith the Pharmaceutical Council seems to have in the efficacy of the new Bye-laws admitting chemists and druggists to membership of the Society is, to say the least, somewhat amusing. "A circular is in course of being issued to local secretaries throughout the country to be brought to the notice of chemists and druggists not connected with the Society." This and the phrase, "The greater the increase (of membership) during the next few weeks" make it appear that the Council anticipates a great increase of members at the beginning of the new year. May these anticipations be realised. But it is indeed very doubtful. Chemists and druggists are no better and no worse than other men. Those who use the difference in the title of membership as an excuse for not joining the Society will not be at a loss to find some other excuse. Here and there a young gentleman just commencing business may join for the advantage of adopting the abbreviations "M.P.S.," so as to show the public that he is as great, at the least, as some boisterous Ph.C., who may be in business near him. But that is nearly all. This would

not be so serious a matter were it not for some important statements made in the Journal last week—statements demanding the immediate attention of members of the Society. In reply to a correspondent you say “that support (meaning support of the Society) must be tendered in advance, not after the event to procure which support is required.” In your leader you say:—“If the Pharmaceutical Society is to undertake the task of endeavouring to obtain such amendment of the Act its membership must first be augmented so as to comprise at least the majority of those who desire that reform.”

These statements are clear and definite. There is to be no attempt to alter the law in relation to company pharmacy, until the majority of chemists and druggists become members of the Society. That being so, it behoves the members of the Society to consider the advisability of retaining their certificates of membership. On one side we have the Pharmaceutical Council saying, “we will do nothing for you until you send us your guineas.” Truly a dignified attitude! On the other side we have the non-members saying, “we will not send you our guineas until you do something for us.” Truly, a magnanimous attitude! Between the two stand the members who send up their guineas yearly. Truly, a most enviable position! After these pronouncements of years the atmosphere becomes somewhat clear. Shall we have it cleared thoroughly so that we can see which way to travel? I beg, through you, to ask those members of the Society who agree that this attitude of the Council is wrong, to send up their names for publication as a protest against that attitude. Or if any should think that attitude the right one, to do the same as a protest against my interference, we should quickly get at the opinion of the Society as a body—most desirable from a business point of view. If a majority go against me, I will put up both hands and cry “peccavi.” But, personally, I should like something more tangible for my subscription than this austere policy. Company pharmacy growing on us like an incubus, and the Council saying it will do nothing to relieve us from the feights (*sic*), company pharmacy seizing us like an octopus, and the victims will not lend their individual aid to the only body that can deliver them from its tentacles. It is to be hoped fresh decisions will be quickly arrived at. But if the Council thinks that by a mixture of promises and threats it will draw or force the majority of chemists to become members, it is doomed to disappointment. If we have to wait for any improvement in our legal status until we get a majority of chemists into the Society, we shall have to wait some little time yet.

You say “under existing conditions there is no reason why the Society should attempt to limit the sale of drugs to duly qualified persons for the sake of getting a few registered chemists to join the Society.” Perhaps not. But has the Society no duty to those who are already members? You say “the Society has two special duties, and two only—one to protect the public in the matter of the sale of scheduled poisons, and the other to protect the interests of its members.” I beg to suggest that the limiting of the sale of drugs to qualified persons is to my interest as a member of the Society, and I hope the other members will support me in calling on the Council to perform its duty to the best of its ability. You continue: “It is under no obligation whatever in regard to registered chemists outside its ranks.” I beg to challenge that statement. If the Society were a mere Government institution appointed to examine candidates and to prosecute for the illegal sale of poisons, it would be under no obligation to chemists at all. But it cannot be a mere Government institution, for it retains the fees of candidates, and to tell a successful candidate that it has no more concern with him, that he must go forth in the world and battle for himself, and that any body of men whatsoever—any Tom, Dick, and Harry and their pals—can set up in opposition to him without having spent any money or mental anxiety on examinations, and with impunity, is to insult him; and to tell him it will look after his interests if he will only subscribe and get the majority of his brother chemists to do the same is puerile. The duty of the Society is to protect every successful candidate against quacks, usurers, and against every inequality in the law, and to its uttermost farthing, if need be. Its duty is to bring inequalities before the law-makers, who owe a duty to the Society, and to work until it gets the inequality removed; and if the Society will issue petitions to every town Parliament will not be able to say that the trade is not united, for every chemist in the country, almost without exception, would append his name to do away with this inequality. That the Society can do a great deal with the few members it has is evident by the fact that it has recently

got an alteration in the Pharmacy Act, and that without waiting for the great majority to become members or associates. And while that was being passed that it allowed one of the greatest opportunities it ever had of benefiting pharmacists, and, in my opinion, for a mere “will o’ the wisp,” is what passes one’s comprehension. The utility of that amendment must, in the opinion of the Council, have been mighty for good. Let us hope it will not lead to disappointment.

Bury, Lancs., December 5, 1898.

T. HULME.

* * Apparently our correspondent fails to distinguish between the powers of the Legislature and those of the Council of the Pharmaceutical Society. It should not be necessary to explain that the Council is utterly unable to promise anything to registered chemists in the direction of amending the law—guineas or no guineas. Apart from that, it is a simple and logical conclusion that the power of the Council to influence legislators must be strictly proportionate to the extent that the Society represents registered chemists as a body, and to which they enable the Council to act on their behalf.—[Ed. P. J.]

RETAIL CHEMISTS AND THE P.A.T.A.

Sir,—Mr. Bailey’s letter on the above subject, in your issue of the 3rd inst., is so uncompromising as to call forth some remarks. In my correspondence with Mr. Beecham I find him a broad-minded gentleman, who agrees with the aims of the P.A.T.A., but disagrees with its methods and management. Mr. Bailey’s letter loses some effect when it is taken into consideration that the aims of the P.A.T.A. and the efforts of Mr. Beecham are towards the same end; they only differ in degree. The methods of the P.A.T.A., or of any association connected with pharmacy for that matter, are, to all appearances, far from perfect. The P.A.T.A. is an association which is endeavouring, according to its lights, to ameliorate the condition of the chemist whose lines are cast in mixed places. There is no other purely trade organisation. If this one is so injurious to some, it is time matters were mended. But it has certainly never injured me, and I should not think of refusing my support because I differed with it on certain points. I must also admit that the opinions of many of the “insignificant minority” are as good and as worthy of respect as my own or any other man’s. The P.A.T.A. has already proved beneficial. Advances in cost prices have taken place in other lines besides those on the P.A.T.A. list, and I am informed by many practical and unprejudiced business men that they look upon such advances as of some advantage to ordinary chemists. A few fixed minimum retail prices are at least something towards modifying the many counter-irritants which render the average chemist as touchy as the fretful porcupine. The standardisation of galenicals is of professional importance, but the standardisation of profits is intimately associated with the subject of serviettes. There prevails an air of animosity to things in general. Even our local associations find objectors, who refuse their allegiance because there are men and things they do not like. The Pharmaceutical Society, asking for a representative membership instead of an “insignificant minority,” is looked upon in many quarters as the origin of all evil, and curses, not loud, but deep, are showered upon it. Services rendered directly or indirectly for the well-being of the trade are marred by the narrow views of the chemist. If everything does not dovetail with the idiosyncrasies of his temperament and the conglomeration of trifles called business, he “won’t play.” Want of unanimity on any subject is the vulnerable point at which those who disparage us successfully strike. I admire Mr. Bailey’s candid criticism, it is what is required, particularly from inside, and I have replied in all friendliness because I fail to see what good his iconoclasm would achieve. At the present moment, however, charity and tolerance should form a fraternal bond, tending to make the daily business battle subservient to the higher aspirations towards ensuring the proper recognition of our honourable calling by all classes of the community.

Batley, December 5, 1898.

R. BROADHEAD.

Sir,—In reply to Mr. Herbert H. Bailey’s letter *re* above, in your last issue, kindly allow me a little space in order that I may point out where several of his statements are not quite correct. In speaking of the recent “exposures” by Mr. Beecham’s representatives, I suppose he refers to the fact that certain retailers have been enabled to buy protected goods and sell them below the P.A.T.A. list. Mr. Bailey must be aware that these certain retailers have been put to sore straits to obtain these goods, which they are selling, in many cases, below cost price. Though this may prove that the P.A.T.A. have not been able to stop supplies in every case, it does not prove the P.A.T.A. to

be a failure. The whole circumstances rather point to the fact that the opponents of the P.A.T.A., recognising the danger of its operations to their methods, are fighting it, and getting protected articles at all cost, in order to try and prove to the ordinary retailer that the P.A.T.A. is futile, and to persuade them to leave its ranks. Does Mr. Bailey really think that if the P.A.T.A. were of no effect the leading "cutters" would take the trouble they are doing to try and squash it? Would they not rather leave it severely alone? Mr. Bailey states: "The P.A.T.A. are an insignificant minority of the chemists of the country." My experience amounts to this, viz., with very few exceptions, the leading chemists in most districts have identified themselves with it. They may be a minority, but, I think, a significant one. I believe, sir, that the true reason why the wholesale price of certain patents has been advanced is because the manufacturers have wisely determined to take the profits the retailers have for some time abandoned. The advent of the P.A.T.A. has not affected the matter at all, but I fear we must thank our friends the "cutters" for this. The fact that the public has cheerfully submitted to this advance in price proves the arguments of certain manufacturers—"that the public would not submit to an advance in the price of their goods"—to be scarcely correct.

Grassendale, Liverpool, December 6, 1898. T. S. WOKES.

LOYALTY TO THE CRAFT.

Sir,—The correspondence between Mr. Young and myself has taken a direct and private course, but I should like through your columns to say, in justice to him, that he has accepted my challenge and has fully and completely answered it.

London, December 5, 1898. C. P. (158/35).

MELLIN'S EMULSION OF COD-LIVER OIL.

Sir,—We wrote to Messrs. Mellin's Emulsion Co., Ltd., asking for an explanation of their liberality to retailers other than chemists, as mentioned by your correspondent "Devon" in last week's Journal, and enclose their reply, which you are at liberty to publish.

Reading, December 6, 1898. J. CROSS AND CO.

[ENCLOSURE.]

Messrs. John Cross and Co., Reading.

Dear Sirs,—In reply to yours of the 2nd instant, I am instructed to inform you that there have been a few exceptional cases in which our travellers have offered to allow the cost of Patent Medicine Licence to grocers in such cases as where our medical friends have required supplies for their patients, and also where a demand from the general public has existed, and chemists have refused to stock our preparation, notwithstanding the fact that they obtain from us every consideration. We, therefore, have had in such cases to obtain someone to hold stocks for us as against a demand. The case mentioned in the letter, however, has never come before us, and we are astonished at any trader being so palpably dishonourable as to take such a despicable advantage. Our emulsion is protected, and shows a very handsome profit to the retailer with little or no trouble for handling it, and we are open to meet chemists on business lines at any time, and to promptly answer all inquiries from this address as received.

For Mellin's Emulsion Co., Ltd.,

London, December 5, 1898. J. OAKES, Secretary.

Sir,—The communication appearing in your current issue, signed "Devon," is curiously interesting. Perhaps "some of the local associations" might most effectively "combine against such a practice" as that in which the grocer is alleged to have indulged by disclosing the whole of the facts to the local Inland Revenue Supervisor. No doubt the grocer overlooked the fact that in disposing of the parcel of stamped goods he was incurring a penalty of £20, for selling goods liable to Stamp Duty without having a licence (42 Geo. III., c. 56, s. 9). It would seem, also, that the allowance of 5s. was accepted for the specific purpose of paying for a medicine licence, but this is rather a question for the parties by whom the allowance was made. "Devon" might even do the work single-handed, and possibly recover his "reasonable costs and charges" in "making the discovery" (43 Geo. III., c. 73).

December 2, 1898. CYCLOPS (159/1).

Sir,—I was utterly surprised and disgusted on reading the letter in your last issue signed "Devon," and await with curiosity Messrs. Mellin's reply to the same, when possibly they will explain their ideas of trade morality. The usual custom with their repre-

sentative is to get chemists in districts to stock their emulsion, with the promise that he will introduce it to the neighbouring medical men, at the same time mentioning the chemists that have supplies when required. It is evident from your correspondent's letter that three chemists within 200 yards had stocked their goods on those terms. What will chemists throughout the country think of Messrs. Mellin by their faithless conduct in planting a subsidised opponent in their midst?

December 3, 1898.

HEBE (158/31).

ARROW POISONS.

Sir,—I am especially delighted by Professor Stockman's lecture on "Arrow Poisons, etc.," and I feel as if I should like to hear more of the subject. In Robertson's 'History of America,' the author makes mention of certain tribes of American Indians employing curare, while others employ an equally deadly poison, which he calls *Manchinelle*. I have wondered if this latter arrow poison is derived from the hura, or sand box-tree, nat. ord. Euphorbiaceæ, the various species of which are found in Central and South America and the West Indies. All the species contain an acrid juice, which is irritant to the skin and to the alimentary and urinary tracts, but I have been unable to find out if this juice is nowadays employed as an arrow poison.

Leeds, December 6, 1898. GORDON SHARP, M.D. (159/10).

THE USE OF NETTLES AS FOOD.

Sir,—In reference to your note in the Journal (*ante*, p. 546) concerning *Urtica dioica*, it does not seem to be generally known that nettles were commonly used as food in the Highlands of Scotland, and are still occasionally eaten. In the spring, when the young shoots are about two or three inches high, they are collected, and after being cut or chopped up are made into a moderately thick soup. Dose, one or two platefuls per diem. The odour and taste of the soup are characteristic and not unpleasant. Many people consider it a great delicacy. I have not heard of the dry plant being used here, and do not know whether it is *Urtica dioica* or *U. urens* that is used. Both species are common.

Inverness, November 29, 1898.

D. GAIR.

IODINE IN THYROID GLANDS.

Sir,—I am glad to have the opportunity of replying to Mr. Stanford's criticism on my note on "Iodine in Thyroid Glands," as his experience in this direction is, to use his own words, "somewhat exceptional, having been continuously engaged in the pursuit and determination of these minute traces of iodine for about forty years." I am disposed to think, however, that he has not given sufficient trial to the process which I put forward for the separation of the halogens (*P. J.* [4], v., 562), and applied to this subject (*P. J.* [4], vii., 482), or he would not say that the presence of carbolic acid was unnecessary and the whole process roundabout, cumbrous, and ill-adapted for the determination of small traces of iodine, as I am aware that the process has been successfully used in London laboratories. The use of the phenol is so obvious that I did not explain in my process the reason for its presence. It is there to meet the objection as to the bromine combining with the iodine; the excess of bromine combining with the phenol to form phenol tribromide. As to the possible presence of traces of iodine in bromine water a long series of blank experiments has failed to discover any. Then as to the several other objections, as they all deal with the process after the conversion of the iodine into an inorganic salt, they can be easily refuted by simply determining, by the phenol process, the iodine in a sample of pure ammonium iodide. One advantage that this process appears to possess over Stanford's is that the iodide can be estimated in the presence of bromide, the results yielded by his (Stanford's) process under those conditions being low, since nitro-sulphuric acid made by acting on starch with nitric acid and passing the resulting gas through sulphuric acid, appears to set free bromine, as well as iodine, which necessarily combine, resulting in a too low iodine figure. Since my previous paper on this subject I have repeated my experiments, and see no reason to alter my statements as to the proportion of iodine proteids extractable from the glands either by water or the B.P. menstruum, neither do I find any defect in my process for determining iodine content. In these confirmatory experiments two quantities of 100 grammes of the fresh gland were exhausted with water, the percentage of iodine in one quantity being determined by Stanford's process; in the other portion by my own.

	FROM 100 GRAMMES.		Iodine in exhausted glands.
	Iodine in cold water extr.		
Phenol process.....	0.032 Gm.	0.0013 Gm.
Stanford's process ..	0.0295 „	0.0014 „

In my hands, therefore, there appears very little difference in the results obtained by the two processes. Another exhaustion by B.P. menstruum showed that not more than 1/20th of the total iodine remained in the exhausted glands, these results agreeing with the statement of R. Tambach (*Journ. Chem. Soc.*, October, 1898, p. 543), who says that the iodine proteids of the thyroid gland are almost completely extractable by water. In referring to my paper on this subject, it is unfortunate that Mr. Stanford should incorrectly quote my words as he does in the following instances:—

EXCERPTS FROM STANFORD'S PAPER.

Line 7: He takes the average usual estimated proportion of 0.3 per cent.

Line 9: He then finds in one small experiment.

Lines 11 and 17: Of only twenty-four glands weighing 104 grammes, or 1605 grains . . . for these glands may be quite abnormal, weighing only 15.43 grains each.

Line 43: In delicate experiments . . . I never burn into ash (the inference being that this was advised in my process).

In conclusion, I should like to emphasise the reason of my inquiry into the subject, which was done with a view to determining or eliciting any information as to whether the therapeutic value was in proportion to the amount of iodine present.

48 and 50, Southwark Street, London,
December 6, 1898.

R. S. SWINTON.

THE FEDERATION AND ITS WORK.

Sir,—The Federation of Local Pharmaceutical Associations is justifying its existence. The circular letter it recently issued shows that it has its finger on the pharmaceutical pulse, and knows when a little stimulant is needed. The hour for dealing with company pharmacy is fast approaching, thanks to the energy of the Federation and the sensible leading articles which have recently appeared in the *Pharmaceutical Journal*. Several local associations have also assisted the movement, but there is still a large amount of work to be done before the craft is fully organised. Helpful influences are at work outside the pale of pharmacy, for throughout the country there is a general feeling that limited liability companies should be made more amenable to law. The tide is, therefore, rising to the flood; let us prepare to take advantage of it, and be led on to fortune. It has been repeatedly pointed out that the first condition of success is combination, that fact cannot be too strongly or too often emphasised; every chemist should be a member of the Pharmaceutical Society. The next essential is a constituency which practically understands the question, this can be secured by an exposition of the Federation suggestions by those who have carefully studied them at meetings of local associations; then we need determination to succeed. When those conditions are fulfilled I do not think the Pharmaceutical Society will be slow to move in the matter and do what is needful, although one cannot help wishing it had taken the initiative.

207, Radford Road, Nottingham.
December 7, 1898.

WILLIAM GILL.

ANSWERS TO QUERIES.

MATERIA MEDICA.—The date is not yet announced by the publishers—Messrs. J. and A. Churchill. [*Reply to F. J. J.*—20/16.]

THYROID GLANDS.—We understand that fresh glands can be obtained from Mr. T. Williams, 2, Trafalgar Street, Liverpool. [*Reply to G. W. and C.*—20/5.]

MIRROR MAKING.—The article referred to does not appear to have been published in the *Journal*. [*Reply to G. R. T.*—20/19.]

OPTICAL BUSINESS.—The 'Optician's Handbook' is officially recommended, but no one book will serve your purpose. See reply to D. M. [*Reply to ORTOL.*—20/18.]

BOTANICAL.—It is the fruit of the strawberry tree, *Arbutus unedo* (Ericaceæ). [*Reply to W. K.*—20/22.]

TO REMOVE MARKING INK.—First go over the mark with a little dilute iodine solution, then apply freely a saturated hot solution of sodium hyposulphite. [*Reply to HAT.*—20/13.]

INDIGESTION POWDERS.—American scale pepsin, 5 grains; powdered ginger, 5 grains. Mix. For acid dyspepsia a simple mixture of sodium bicarbonate and ginger is often given. This should be flavoured with a trace of spearmint or peppermint.— [*Reply to W. W.*—19/16.]

POISON BOOK.—You are not legally bound to show your poison book to anyone, though you might be summoned to produce it in a court of law. Under the circumstances you were fully justified in not allowing it to be inspected on the occasion referred to. [*Reply to AESTAS.*—20/23.]

NON-SEPARATING EMBROCATION.—Two eggs; oil of turpentine, 9 fl. ozs.; acetic acid, 5 fl. ozs.; water, 7 fl. ozs. Mix the eggs, both yolks and whites, with the turpentine, gradually rub in the water, and, lastly, very gradually add the acetic acid. [*Reply to E. W. W.*—19/31.]

BETA-NAPHTHOL PILLS.—Beta-naphthol makes a very good mass with glycerin of tragacanth. Very little of this excipient is required if a little liquid glucose or syrup of glucose be also used. Keratin-coated pills usually receive a coating of cacao butter if they are not made with an oily excipient. We have not much experience of naphthol pills, as we have more often seen this substance administered in powders or cachets. [*Reply to EXON.*—20/15.]

TINCTURE OF NUX VOMICA.—In the proportion in which tincture of nux vomica is prescribed in mixtures only a faint turbidity results. If water be added gradually to the tincture, so that the latter constitutes a considerable proportion of the mixture, then a more distinct turbidity may be noticed, but we have not observed anything in the nature of a separable precipitate under any conditions. [*Reply to A. E. M.*—20/10.]

URINE ANALYSIS.—The appearance you mention may be due to indol or skatole in the urine. Occurrence of these bodies in the urine is indicative of various pathological conditions, which are accompanied or caused by decomposition of proteids in the intestine. Try separating the albumin by boiling the faintly acidulated urine and testing the filtrate. The urine should be tested when quite fresh, as putrefaction after it is collected may, under some conditions, give rise to decomposition products giving colour reactions. You can easily determine the presence or absence of the constituents of bile by other tests. Refer to Allen's 'Urine Analysis' if possible. [*Reply to STUDENT.*—20/12.]

SODIUM BICARBONATE AND CARBOLIC ACID.—1. No; because phenol, although forming a phenate with the alkaline hydroxides, does not decompose the alkali bicarbonates, or carbonates (into which the bicarbonates are converted by boiling their aqueous solution). See the articles on Acidum Carbolicum in the Students' Page for September 17 last, p. 334. 2. No; you should, however, remember that phenol readily volatilises when its aqueous solution is boiled. [*Reply to G. B.*—20/3.]

OPTICAL EXAMINATION.—There are two optical associations that grant diplomas—namely, the British Optical Association and the Worshipful Company of Spectacle Makers. The former consists of a body of retail opticians, which has done much good work, and a committee of that body constitutes the examining board. The Secretary is Mr. J. H. Sutcliffe, of Blackpool, Lancashire. The other examining body is a guild of the city of London, its optical committee consists of some of the leading wholesale and retail opticians, and its examiners are Lindsay Johnson, M.A., M.D., F.R.C.S.; Professor Silvanus Thompson, F.R.S.; and Mr. George Paxton. The S.M.C. diploma would appear to be the one that should be held by chemists who wish to deal in optical goods. As regards the books needed for reading up and particulars as to the examinations, syllabus, etc., apply to Colonel T. Davies Sewell, Guildhall, London; or to Mr. Lionel Laurance, 1, Vernon Place, Bloomsbury Square, W.C., either of whom will give you all the particulars you require. [*Reply to D. M.*—20/8.]

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Dr. J. Shields has been experimenting with Palladium an electrical method, with a view to determining the relations existing between palladium and Hydrogen and hydrogen. Since the discovery by Graham, in 1856, of the remarkable property of absorbing

hydrogen possessed by palladium, many researches have been undertaken with the object of throwing light upon the relations existing between the metal and the gas, but the chief result has been that there are nearly as many different views as there have been experimenters. From the theoretical discussion, there would at first sight appear to be no difficulty in distinguishing experimentally between the alloy or solid solution hypothesis and the view that a definite compound, a hydride, is formed. The pressure-concentration curve, in particular, would be expected to decide at once between these two views. But the application of this method is rendered difficult, if not useless, by the fact that the shape of the curve varies greatly with temperature. At 100° C., for instance, the horizontal portion required by the hypothesis of Pd₂H being present is well marked (Troost and Hautefeuille), but at 200° C. no trace of this is present. Dr. Shields (*Proc. Roy. Soc. Edin.*, vol. xxii., 169) has examined the electro-motive force of the concentration cell, palladium-hydrogen (weak) / dilute sulphuric acid / palladium-hydrogen (strong), where the concentrations of the hydrogen were weak and strong at the two electrodes. The electro-motive force of the cell was found to be zero, or nearly so. This is opposed to the solid solution hypothesis, and agrees better with the view that a definite chemical compound is formed.—*Nature*, lix., 107.

R. T. Baker and H. G. Smith endorse Stringybark Trees Baron von Mueller's classification of the and their trees of the genus *Eucalyptus*, to which Essential Oils. the name "Stringybark" is applied in New South Wales, and they find that an oil exists, having a specific gravity less than 0.910, containing over 50 per cent. of eucalyptol, and answering all the tests of the British Pharmacopœia of 1898, except that dealing with specific gravity. It is thus seen that the specific gravity test for eucalyptus oil, as given in the B.P., if enforced, might be the means of excluding some excellent oils. The authors also find that the phosphoric acid test is not a satisfactory qualitative one for eucalyptol in some crude eucalyptus oils, and that eudesmol, the stearopten of eucalyptus oil, exists in large quantities in the oil of *E. macrorhyncha* and can be readily purified.—*Proc. Roy. Soc. N. S. Wales*.

Frank Edel, as the result of an extended Compressed series of experiments in the manufacture of Tablets. compressed tablets, believes that careful tests of those preparations will show that in some cases they are much more insoluble than well-made pills, and have no advantage over the latter in any particular. One prominent work on pharmacy says that tablets should be compressed with the addition of as little excipient as possible. That, in the writer's opinion, is far from proper, for most of the adhesives used in the preparation of tablets are readily soluble in the stomach, and thus such addition can only contribute to add to their solubility. Especially is this so in the preparation of tablets, such as salol, for instance, and some time ago the writer suggested that it would be

VOL. LXI. (FOURTH SERIES, VOL. VII.) No. 1486.

well to incorporate into the body of the tablet a small portion of sodium bicarbonate and tartaric acid. Such an admixture would result, in the presence of moisture, in the rapid disintegration of the tablet, and could in no way be objectionable, except that the tablet would not keep in the open air, but would have to be carefully protected from moisture. The addition, while objectionable from the standpoint of the permanency of the tablet, would add greatly to its solubility. Experiments along this line have demonstrated to him that a very small amount of alkali and acid will bring about the rapid disintegration of the tablet. And he thinks that, in the great majority of combinations, its use cannot be objected to from any standpoint.—*Western Druggist*, xx., 491.

Hermann Barth deals with the micro-chemical Micro-Chemical recognition of alkaloids in commercial drugs. Recognition He finds alkaloids in different parts of plants, of Alkaloids. as, for example, in the pericarp of *Conium maculatum*; in the seed-coats in *Peganum harmala* and *Colchicum autumnale*; in the endosperm of *Areca catechu*; in both endosperm and embryo of *Aconitum napellus*; and in the embryo only of *Physostigma venenosum*. He concludes that the functions of alkaloids must be as various as their distribution; thus, when they occur in the periphery of plant organs, it is reasonable to suppose that they then act as protective substances, to prevent such parts being eaten by animals. According to Heckel, those occurring in the endosperm and embryo serve as reserve foods. It appears, in accordance with the common belief, that alkaloids may always be regarded as excretions. Reactions are described in the paper for the recognition of certain alkaloids.—*Botanisches Centralblatt*, through *Bot. Gazette*, xxvi., 365.

K. Elbs and A. Hertz give further particulars of the electrolytic method of preparing Iodoform by iodoform, which was given in outline in the Electrolysis. *Pharmaceutical Journal*, lx., p. 586. This substance is produced when the alkaline or alkaline-earthly iodides are subjected to electrolysis in presence of alcohol, aldehyde, or acetone. By the former method the electrolyte should be traversed by a stream of carbon dioxide gas during the operation to saturate the alkali set free by the electrolysis of the iodide. The authors show that the current of carbon dioxide gas is advantageously replaced by the simple addition of an alkaline carbonate to the electrolyte. The following solution answers best:—

Potassium Carbonate	5 Gm.
Potassium Iodide	10 Gm.
Alcohol	20 C.c.
Water	100 C.c.

Every hour the iodoform is removed and the strength of the solution in the several ingredients made up to standard. From many experiments they conclude (1) that, *ceteris paribus*, the proportion of hydriodic acid formed increases as the temperature rises above 60 to 70° C.; (2) that the yield of iodoform diminishes if the density of the current exceeds 1 ampère per square decimetre; (3) that increase of carbonate in the electrolyte slightly diminishes the yield of iodoform and largely increases the proportion of hydriodic acid; (4) that replacement of alcohol by acetone gives far less satisfactory results.—*Zeit. für Electro-Chemie*, through *Chem. News*, lxxviii., 257.

After an exhaustive research on the quality of Cade Oil. of juniper tar oil (cade oil), P. Adam finds that the commercial article is so variable in composition, and of such doubtful purity that he recommends that its use in medicine should be discontinued.—*Pharm. Zeit.*, xliii., 659.

DEEP-SEA DEPOSITS.*

BY W. MURTON HOLMES.

The history of deep-sea exploration is quite of recent origin. Previously to the year 1864 it was the general opinion among men of science that life did not and could not exist below a certain depth of the sea. There were, according to Edward Forbes, fixed zones of depth: (1) The Littoral zone, between low and high water marks; (2) the Laminarian zone, from low water to a depth of fifteen fathoms; (3) the Coralline zone, from the fifteen fathom line to a depth of fifty fathoms; and (4) the zone of deep-sea corals, extending from the edge of the Coralline zone to an unknown lower limit. "In this region," he says, "as we descend deeper and deeper, its inhabitants become more and more modified and fewer and fewer, indicating our approach towards an abyss where life is either extinguished or exhibits but a few sparks to mark its lingering existence."

About 1864, G. O. Sars, one of the Acting Commissioners of Fisheries for Norway, while dredging in water about 700 feet deep for the purpose of determining the condition of the sea-bed, obtained several specimens of a strange crinoid, or lily star, which at once struck him as resembling a certain stage of development of a crinoid with which he was familiar. Continuing his dredging operations at depths of from 700 to 800 feet he found abundance of animal life.

His father, Professor Michael Sars, announced the discovery to Professor Wyville Thomson, then working on the crinoids, and invited him to Christiania to see the specimens, and on talking the matter over together they came to the conclusion that the new lily star was closely allied to a genus well known in the fossil state. This was a startling discovery, it seemed now almost certain that there had been found, not only a living representative of a long-lost group, but a form that might be regarded as having lived on from the great chalk epoch.

In 1868 the late Dr. Carpenter, then one of the vice-presidents of the Royal Society, while discussing with Wyville Thomson the structure and development of lily stars, was urged by him to use his influence at headquarters to induce the Admiralty to furnish a vessel properly fitted out with dredging gear and other scientific apparatus to further examine the sea-bottom. The Admiralty very liberally fitted out the surveying ship "Lightning" and it started on a cruise in the North Atlantic Ocean, in August, 1868. The results were fairly satisfactory. It was shown beyond question that animal life was varied and abundant at depths down to between 600 and 700 fathoms; and it was further shown that many of the deep-sea forms of life were closely related to fossils of the chalk period. In 1869 the "Porcupine" was assigned by the Admiralty for surveys off the west coast of Ireland and in the Bay of Biscay. The track of the "Lightning" was also carefully worked over and previous observations checked. In the following year the "Porcupine" was again placed at the disposal of the Royal Society, and operations were carried on between Falmouth and the Mediterranean.

On the return of the "Porcupine" from her last cruise, so much interest was felt in the bearings of the new discoveries upon important biological, geological, and physical problems, that the Government was again urged by the Royal Society to dispatch an expedition to investigate each of the great oceans, and to take an outline survey of that new field of research, the bottom of the sea. The result was that, towards the close of 1872, H.M.S. "Challenger" started upon her voyage round the world, a voyage that occupied about three years and a half, and which

is certainly one of the most memorable during modern times. Between 1877 and 1880 the United States survey steamer "Blake" made three cruises in the Gulf of Mexico, in the Caribbean sea, and along the Atlantic coast of the United States. The steamer was fitted up with all the latest improvements in apparatus, and the naturalist in charge was the celebrated Alexander Agassiz, while the officer in charge of the steamer was Lieut.-Commander Sigsbee, the same, I believe, who was in command of the ill-fated "Maine" when she was blown up at Havana.

The scientific results of this survey were very important, and a valuable report was published.

Our knowledge of deep-sea forms may be said to have commenced when the results of the "Challenger" expedition were first published. The publication of these reports was not completed until 1895. They fill fifty large volumes, beautifully illustrated, but proportionately costly. It is gratifying to know that one of the best, if not the best, that on foraminifera, was the work of a member of our Society, the late Henry Bowman Brady, F.R.S.

It was my good fortune some years ago to have a series of soundings lent to me for examination. They were taken by H.M.S. "Egeria," and the locality in each case was carefully noted. They range from depths of 1242 to 4428 fathoms (a little over five miles), the latter one of the deepest spots known. It is situated in the South Pacific Ocean in lat. 24° 24' S., long. 175° 10' W. Two or three slightly deeper depressions have been noted, but their area in all cases is comparatively small. I have also been fortunate enough to obtain specimens of several of the "Challenger" dredgings, and I propose this evening to exhibit some slides prepared from these soundings, which will convey some idea of the microscopic life of the sea-bottom. The slides now shown represent *Rhizocrinus lofotensis* (28 species of living crinoids now known).

FORAMINIFERA.

Foraminifera belong to the lowest class of animal life, the Protozoa. They are further distinguished as being rhizopods, or root-footed animals, from the root-like appearance of the strands of protoplasm, by which they are enabled to adhere to surrounding objects or to move from place to place. If you imagine a small particle of structureless, jelly-like protoplasm, which is capable of emitting long thread-like processes, and if you also imagine the main portion to be enveloped in a calcareous shell, you will then have a very good general idea of what a foraminifer is. The term "foraminifera" is applied on account of the numerous perforations in the shell with which many of the species are provided. When the animal wants to feed, or to move to another place, it protrudes its delicate filaments or pseudopodia either through the mouth of the shell or through the perforations in its walls, or by both sets of apertures combined. There is a constant streaming movement of protoplasm along the filaments, which coalesce here and there, and in this manner the particles of food obtained from the surrounding water are conveyed to the central mass of protoplasm, and there digested. The majority of species live at the bottom of the sea; others are pelagic and occur in abundance at the surface. Some of the free-swimming forms are sunk in a mass of bubbly protoplasm, which serves as a float.

The most abundant genus is Globigerina, and there are several species or varieties. It occurs in immense numbers, forming what is known as Globigerina ooze, mostly at depths of from 600 to 2500 fathoms, in the Atlantic, Western Indian Ocean, and Pacific, the total area covered by its remains being estimated by Murray and Renard at 49,520,000 of square miles. The species are not considered to live at the sea-bottom, as their occurrence coincided with the area of warm surface water, no ooze being found where the surface water is too cold.

* Read at an evening meeting of the Pharmaceutical Society, on Tuesday, December 13, 1898.

RADIOLARIA.

The next group of animals are the radiolaria. These also belong to the rhizopods, but are distinguished from the foraminifera by a siliceous or a horny, instead of a calcareous skeleton, and by the presence of a membranous central capsule surrounding a nucleus. This capsule is considered to correspond to the calcareous shell of foraminifera. They are commonly floating organisms, and are often present in enormous numbers in all seas, the greatest variety of species, however, being found in the warm waters of the tropics. Many other forms are "abyssal," and are confined to great depths of the sea, while others again are "zonarial," and are restricted to particular layers between the surface and the bottom. Over large areas of the deep sea, principally at depths of from two thousand to over four thousand fathoms, the bottom is found to be covered with extensive deposits of "radiolarian ooze," estimated to cover 2,290,400 square miles. Haeckel has described about 4000 species, and there are probably many more still undescribed.

PTEROPODS.

Another deposit forming an ooze, though to a more limited extent, 400,000 square miles, is very largely made up of pteropod and other small shells, and is known as "pteropod" ooze. It occurs in the tropics round oceanic islands, and is especially abundant between Cuba and Florida Keys.

The pteropods or "winged snails" are pelagic molluscs, found swimming near the surface of the sea, the living forms being all of small size. They have no distinct head, and the mouth is placed in the fore-part of the foot, which is rudimentary. The lateral parts of the foot are, however, developed into a pair of wing-like fins (hence the name), by means of which the animal swims actively. The shell is generally calcareous and very delicate in texture, frequently taking the form of a slender hollow cone. Pteropods form the principal food of the Greenland whale. Pteropod ooze is not found below 1500 fathoms, the carbonic acid in the water dissolving the delicate shells. For the same reason globigerina ooze disappears below 2500 fathoms, the shell being somewhat thicker.

SPONGES.

The group to which I shall next call attention is that of the sponges. About 2000 species of these are known and 300 are found round the British coast. They may be either soft, stony, leathery, or horny, and vary in weight from 1 grain to over 100 pounds.

The simplest form of sponge consists of a thin-walled sac with the walls perforated by pores and the central cavity lined with flagellated cells. The constant lashing of the flagellated cells gives rise to a strong current of water which is drawn through the pores into the central cavity and passes out by the mouth of the sac.

If now we picture to ourselves a great thickening of the sac-wall with the layer of flagellated cells very much extended and folded up so as to form a series of canals leading from the external pores to the central cavity, we shall get an idea as to the manner in which the more complicated forms are built up.

In most cases some support for the jelly-like mass of cells is required, and accordingly we find either a network of horny fibres, or a skeleton composed of siliceous or calcareous spicules forming a kind of trellis-work. The common bath and Turkey sponges are examples of horny skeletons. The horny and calcareous groups live mostly in comparatively shallow water and their skeletons do not form any noteworthy deposit. It is not so, however, with the siliceous sponges. These live in depths down to 2500 or 3000 fathoms, and their skeletons not being easily acted upon by sea-water form extensive deposits. Such a deposit occurs at a depth of 3000 fathoms in the Indian Ocean off the south-west coast of Australia, and includes a great number of species.

Siliceous sponges are divided into four orders: (1) Monaxonida, has one-rayed spicules; (2) Tetractinellida, has spicules of four-rays; (3) Lithistida, are massive and stony sponges, with interlocking spicules; (4) Hexactinellida, sponges with six-rayed spicules. The slides shown here include—*Pheronema carpenteri*, from 530 to 1600 fathoms, Atlantic; *Rossella velata*, west of Gibraltar, 651 fathoms; *Semperella schultzei*, dermal framework, Cebu, Philippine Is., 140 fathoms; *Dactylocalyx pumiceus*, W. Indies.

DIATOMS.

Diatoms are one-celled plants inhabiting both the sea and fresh water. The cell-wall is hardened by the deposition of silica, so as to give rise to a glassy case, known as a "frustule," composed of two parts which fit into one another like the lid on to a pill-box. The cells may be either separate or connected into filaments, either free or attached to some other body. The separate valves are of various forms, circular, oblong, elliptical, linear, saddle-shaped, boat-shaped, undulate, sigmoid, etc., and their surfaces exhibit more or less delicate sculpturings and markings in the form of bands, lines either parallel or radiate or crossing each other, or they present a cellular appearance like honeycomb. The accumulation of these flinty envelopes gives rise to very extensive deposits, more especially in the Arctic and Antarctic regions, where they are less mixed with foraminifera and other organisms (total area estimated at 10,880,000 sq. miles). The fresh-water species give rise to the numerous varieties of "kieselguhr." The slides now shown include—*Heliopecta*; *Arachnoidiscus ehrenbergii*, *in situ*; *Pinnularia*.—Sounding "Egeria," 2479 fathoms, S.W. of Australia.

OTHER DEPOSITS.

In nearly all deep-sea deposits, with the exception of those in polar and sub-polar regions, numerous extremely minute bodies, known as coccoliths and rhabdoliths, are to be met with. Coccoliths are oval calcareous discs, having a thick, strongly-refracting rim and centre, and are the disintegrated remains of a spherical body known as a coccosphere. Rhabdoliths consist of minute calcareous rods, having a disc at one end, and are the disintegrated remains of a body called a rhabdosphere.

Coccospheres and rhabdospheres are now regarded as pelagic algae. Rhabdospheres are developed in equatorial and tropical regions, and are rarely met with where the temperature of the surface water falls below 65° F. Coccospheres, while abundant in the tropics, are found further north and south than rhabdospheres, and are present where the temperature of the surface water is as low as 45° F. (Stellate bodies in deep-sea deposits probably allied to coccoliths.)

From a depth of 2000 fathoms downwards there is a very widespread deposit of red and grey clays, the area of which is estimated at 51,500,000 square miles. These consist of silicate of alumina, with the oxides of iron and manganese. They result from the decomposition of pumice and volcanic dust, either from terrestrial or submarine volcanoes.

The extreme slowness of deposition is shown by the fact that the "Challenger" frequently procured in a single haul hundreds of sharks' teeth, some of them of gigantic size, and occasionally embedded in manganese; dozens of ear bones and other bones of whales, large numbers of manganese nodules, zeolitic minerals which have been formed and crystallised round abysmal organisms, at about the temperature of 32°, and magnetic spherules, which are believed to be the dust of meteorites, which, in the course of long ages, have fallen upon the sea. It is not possible to conceive that sharks and whales were ever so numerous at one time that their remains should form a continuous stratum. Many generations must therefore be represented.

In high latitudes a large quantity of *débris* from the land must be deposited in the sea by the melting of icebergs. A short time ago I had a small quantity of a dredging from the North Atlantic given to me. It was obtained at a depth of 2300 fathoms, but the particular locality was not noted on the label. It contained a few foraminifera, the remainder was made up of mud and rounded quartz grains of various sizes and a few angular fragments of rock. It is not likely that there could have been sufficient friction at such a depth as to round the angles of quartz, and as the depth indicated a distance from land, I came to the conclusion that the rounding was the result of ice action, and that the particles had then been carried to sea on floating ice.

Hitherto my remarks have dealt with deposits in course of formation. I will now direct your attention to certain deposits raised above the sea-level, and by comparing these with recent formations, we shall be led irresistibly to the conclusion that they also have been formed in deep water.

CHALK.

The most important of these, especially to a Kentish man, is chalk. White chalk is a soft variety of limestone largely made up of foraminifera and fragments of shells. By careful washing and decantation the foraminifera may easily be washed out and recognised, but a more satisfactory way is to wash the powdery substance from the inside of a hollow nodule of flint. This is, to all intents and purposes, a portion of the mud of the cretaceous ocean hermetically sealed up in an almost unaltered condition. In this powder will be found sponge spicules, foraminifera, the shells of minute crustaceans, and portions of echinoderms and shells. The finer portions will be found to contain numerous coccoliths.

Globigerina ooze has been called "modern" chalk, but it differs from true chalk in some respects, and there has been a great deal of controversy on the subject. An analysis of Sussex chalk shows that it contains about 98.4 per cent. of calcium carbonate and a small quantity of alumina. The Atlantic chalk-mud, on the other hand, does not contain more than 60 per cent. of calcium carbonate, and, in addition, from 20 to 30 per cent. of silica, with varying proportions of alumina, magnesia, and oxide of iron. This difference may to a great extent be accounted for by the fact that the siliceous organisms, such as diatoms, radiolaria, and sponges, have been dissolved and re-deposited in nodular masses as flint. The silica is in a hydrated condition and comparatively easily acted upon by sea-water, more especially as the bottom water is more alkaline than that near the surface. The iron is also found segregated as iron pyrites.

The Greensand, again, which is classed as a member of the cretaceous formation, is largely made up of sponge spicules in a fragmentary or otherwise altered condition, together with foraminifera, and casts of the same in glauconite, a hydrous green silicate of iron and potash generally formed in contact with decomposing organisms in comparatively shallow depths. I have also detected rhabdoliths in the upper greensand of Betchworth, Surrey.

The analyses of sea-water take no account of silica in solution. It is probable that there is a trifling quantity, but the principal source from whence diatoms and other siliceous bodies obtain their supplies is the finely divided clay held in suspension in all seas.

Most of the important sedimentary rocks will in like manner furnish evidence of marine origin.

RADIOLARIAN EARTHS.

The most famous deposit of radiolaria, or polycystina, is in the Island of Barbados. It has long been known to microscopists, with whom it has always been a favourite source from whence these objects could be obtained. This Barbado "earth" is a friable, earthy, or chalky marl which rises to heights

of over 1000 feet above sea-level, and is more or less extensively composed of radiolaria with a variable proportion of foraminifera. According to Haeckel, the number of species is not less than 400, and is probably more than 500. Many of the species are still found in the Pacific Ocean. Coccoliths are also found of unusually large size, associated with stellate bodies, probably of similar origin. Other deposits are found in Cuba, Sicily, Greece, and Northern Africa. In the Nicobar Islands the radiolarian clay reaches elevations of about 2000 feet above sea-level.

A deposit exhibited from Moron, in the South of Spain, is very rich in sponge-remains, diatoms, radiolaria, and foraminifera.

Siliceous sponges are largely represented in past time, and are of high antiquity, being known to occur in deposits as ancient as the Cambrian, and are abundantly found in the chalk. A deposit, in places 40 to 60 feet thick, which contains a large number of detached sponge spicules, of which 110 species have been definitely determined, occurs near Oamaru, in New Zealand. As in other deposits it is largely mingled with diatoms, radiolaria, and foraminifera. In fact, it has all the characters of a deep sea ooze very similar to one already noticed off the south-west of Australia at a depth of 3000 fathoms. In the primary and secondary rocks sponge spicules have lost their hydrous condition and have become converted into chalcedony, a crystalline form of silica.

A very remarkable bed of diatom-earth from 30 to 40 feet thick and some miles in extent occurs at Richmond, in Virginia.

Time will not permit me to add more. I fear that I have already trespassed too long upon your patience, but from the evidence adduced I think we can come to no other conclusion than that there are deep-sea deposits among the marine sediments that have been raised above the sea.

I must express my sincere thanks to Mr. E. W. Lucas and Mr. Baldock for so kindly preparing the lantern slides which have been used on this occasion, and to Professor Greenish for operating the lantern.

THE PHARMACY ACT OF 1868, AND ITS LITERAL INTERPRETATION.*

BY J. RYMER YOUNG.

Though the intentions of the promoters of Bills brought before Parliament for consideration are not infrequently lost sight of to a great extent, in the interpretation of the Acts into which those Bills have developed, it may not be unprofitable if, before proceeding to speak of the Pharmacy Act of 1868 as it is and may be interpreted to-day, a brief space is devoted to a survey of the intentions of those whose efforts resulted in the addition of that measure to the British Statute book. The parties concerned in the matter were four: the Pharmaceutical Society, representing the only registered chemists at that time; the United Society of Chemists and Druggists—of which I was then a member—representing the as yet legally undefined body of chemists and druggists other than pharmaceutical chemists; the General Medical Council, which desired to see the practice of pharmacy regulated in some way; and the Government of that day, which was anxious to have the sale of poisons regulated.

The Pharmaceutical Society was first in the field with a Bill which provided that it should be unlawful for any unregistered person in Great Britain to call himself a pharmaceutical chemist or a chemist and druggist, or to carry on the business of a chemist and druggist in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners. The United Society of Chemists and Druggists also produced a Bill,

* Read before the Manchester Pharmaceutical Association, on Wednesday, December 14, 1898.

which provided, in addition, that only registered chemists and medical men should supply certain dangerous drugs, that certain regulations should be observed in the sale of active poisons, and that all registered chemists should be exempt from serving on juries.

The General Medical Council was in sympathy with the Bill promoted by the Pharmaceutical Society—which, as I have stated, provided for the protection of titles and the restriction of dispensing generally to chemists—and represented to the Government the necessity of regulating by Statute the practice of pharmacy by chemists and druggists throughout the kingdom; but the Government insisted upon some restriction of the sale of poisons, and after the two measures had been read a second time, they were both referred to a Select Committee of the House of Commons. That Committee reported in favour of legislating on the lines suggested by the Pharmaceutical Society and with the Pharmacy Act of 1852 as a basis, but was averse to restricting the dispensing of medicines to registered persons, and in the end its deliberations resulted in nothing beyond a suggestion that another Bill should be brought in by the Government.

A conference next took place between representatives of the two Societies, many interviews followed, and ultimately it was agreed to unite forces, as there appeared to be no chance of carrying a Pharmacy Bill through Parliament, otherwise—an object-lesson on the necessity of unity which might well be kept in mind at the present juncture. The net result of the agreement was a Bill which, after being modified in various ways in its passage through Parliament, became the Pharmacy Act of 1868. That Act entirely failed to touch the chief objects aimed at by the Pharmaceutical Society and the Medical Council, though it met most of the views of the chemists and druggists of that day and also satisfied the Government with regard to the regulation of the sale of poisons. Bearing in mind, therefore, how imperfectly the Act represented, and has continued to represent, the views of the Pharmaceutical Society, and how completely it embodied those of the chemists and druggists of 1868—who were undoubtedly responsible for its acknowledged defects—let us proceed to consider what its provisions are understood, or may be supposed, to mean. For we must not lose sight of the fact that, until any section of an Act of Parliament has been interpreted by the highest court in the realm, the exact force and meaning of it must needs remain more or less a doubtful quantity.

The Intentions of the 1868 Act.

In the first place, it is essential to note that the Act was passed by the Legislature exclusively in the public interest, and not in any degree to enable chemists and druggists to monopolise any branch of trade. The preamble to the Act, which is most important as indicating the reason for restrictive legislation and the manner of securing the object aimed at, states definitely that it is expedient “for the safety of the public” that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent, practical knowledge of their business, be duly examined as to their practical knowledge, and also be duly registered. That is to say, the public safety requires the proprietors of all pharmacies to be duly registered. Not only so, but all persons who should become proprietors after the passing of the Act must be examined prior to registration. The sole object of these restrictions, however, was the public safety. The Legislature did not in 1868, and does not now, care one iota about the interests, vested or otherwise, of chemists and druggists; there is not a word in the Act indicating any anxiety in that direction, and whatever efforts may be made in the future to secure further legislative powers in connection with the practice of pharmacy, it

will, in my opinion, be exceedingly unwise to attempt to secure any privileges that are not absolutely compatible with, and likely to promote, “the safety of the public,” as that is all the Legislature can be expected to consider. The protection of trade interests devolves upon ourselves; that is a matter which only very indirectly concerns the public, and it cannot satisfactorily be legislated for.

But so far as insisting upon the due qualification of those who deal in poisons is concerned, the question involved is not one of trade interests. The Legislature has declared proprietary qualification to be expedient for the safety of the public, and in the public interest that qualification ought to have been maintained. By what, however, can only be regarded as a legal quibble, a joint-stock company, including several unqualified persons, was in 1880 held not to be a “person” within the meaning of the first fifteen sections of the Act, so far as regards the sale of poisons and keeping open shop for such sale. Though by common law the company was undoubtedly a legal or artificial person, yet inasmuch as it could not be duly examined as to its practical knowledge of the business of a chemist and druggist, it was held by the House of Lords to be outside the operation of the major portion of the Act. That is to say, because corporations are not specifically mentioned in the Act, it was held that they are outside of the law, and it was even suggested that there is nothing to prevent them making use of the titles supposed to be restricted by the Pharmacy Acts of 1852 and 1868 to persons duly registered under those Acts. But, without dwelling further on the chief omission of the 1868 Act, let us now proceed to consider its various sections in detail.

Section 1.—Offences under the Act.

Section 1 of the Act restricts to certain persons the selling of poisons; the keeping open shop for retailing, dispensing, or compounding poisons; and the assumption or use of the title “chemist and druggist” and kindred titles. Those persons must be registered pharmaceutical chemists or chemists and druggists, and must also conform to such regulations as to the keeping, dispensing, and selling of poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council. Here, then, are defined the offences under the Act—the selling of poisons, keeping open shop for such sale or for dispensing or compounding poisons, and the use of certain titles by other persons than registered chemists, whilst even registered chemists may not perform any of the specified acts unless they conform to certain regulations. Those regulations, unfortunately, are as yet hypothetical and exist only as recommendations. If they had reality and were properly enforced, they might constitute a powerful weapon in the hands of the Pharmaceutical Society, by enabling it to proceed in many cases of “covering,” such as are illustrated in the matter of the practice of pharmacy by unqualified corporate bodies which, as I have already stated, have, unfortunately, been held not to be “persons” within the meaning of the Act. A breach of the contemplated regulations would be an offence under the Act, and the Privy Council could, as provided in Section 26, authorise the removal of the offender’s name from the Register of Chemists and Druggists. This is overlooked by those who sigh for similar disciplinary measures to those exercised by the General Medical Council. The Pharmaceutical Society could thus, if it wished, punish the black sheep of the profession.

PROPOSED POISON REGULATIONS.

I shall refer to this matter further in dealing with Section 15, but must point out here that the prescribing of the poison regulations contemplated by Section 1 must be the act of the Pharmaceutical Society as a whole, not of its

Council (which after all, can only reflect the will of the body corporate), and up to the present the members of the Society—purblind and fatuous, to their own discredit and hurt—have not seen fit to do what is requisite to carry out the manifest intentions of the concluding words of the Section. It is worthy of note that the mere fact of providing for the making and enforcing regulations as to the keeping, etc., of poisons, seems to afford proof that the keeper or proprietor of the shop is the person the Legislature intended should be registered, as it could hardly have been contemplated that the qualified assistant of an unqualified person should be proceeded against for a breach of those regulations? A further point is that, according to the wording of this section, the regulations are not to touch "compounding." This is significant, as a recognition that the skilled portion of the calling of pharmacy must be left to the discretion of the competent, *i.e.*, registered man, without conditions. The "keeping," "dispensing," and "selling" of poisons were intended to be the subject of regulations, but the actual "compounding" of the ingredients was apparently expected to be done by a duly registered "pharmacist," the public safety depending upon his skill rather than on regulations. The section undoubtedly draws a distinction between "dispensing" and "compounding," and Section 15, as I shall presently show, emphasises that distinction. It is a question whether Section 1 could not be construed as making it illegal for a person to "compound" a poison unless he is a registered person, and the "compounding" of all official medicines is by strong implication confined to registered men. A clause to convert this strong implication into a clearly defined restriction might probably be accepted by the Legislature.

Sections 2-6.—Poisons; Registration; Examiners.

Section 2 specifies the articles which are to be deemed poisons within the meaning of the Act, and provides that other articles may be added to the list from time to time by a resolution of the Council of the Pharmaceutical Society, if approved by the Privy Council. That provision has been acted upon on several occasions, but it is to be regretted that the Privy Council has so far refused to approve of the addition of carbolic acid and other dangerous substances to the list of poisons. So far as can be ascertained, there is good reason to believe that this refusal is due in great measure to the omission of the Pharmaceutical Society to prescribe the poison regulations already referred to. That omission I trust to see remedied ere long, and we may then hope to secure the removal of the Privy Council's block. This section, I may remark, helps to define the word "article," which is somewhat vague in Section 17.

Section 3 provides that all persons who were, before the passing of the Act, in business as chemists and druggists, or registered as assistants under the Pharmacy Act of 1852, shall be entitled to registration as chemists and druggists. That provision, of course, has been fully carried into effect, with results that can hardly be deemed generally satisfactory, for those unexamined registered chemists have always been more or less of a stumbling block in the path of progress. The word "compounding" is again used in this section in the sense in which the word "dispensing" is now usually applied, whilst "dispensing" is not mentioned. Section 4 stipulates that assistants other than those registered under the previous Act may, under certain conditions, be permitted to enter for a modified examination, and Section 5 exempts certain persons from paying any fee for registration.

Section 6 confirms the provisions of the Charter, with regard to the appointment of examiners. Those individuals need not be pharmaceutical chemists or chemists and druggists, but must be "competent persons" appointed by the Council of the Pharmaceutical Society, and approved by the Privy Council. They

may not be appointed for more than five years, and an officer appointed by the Privy Council is entitled to be present during the progress of any examination conducted by them. It is clear, therefore, that the examinations are directly controlled by the Privy Council, which acts as a check upon the Council of the Society and its nominees, alike in the interests of the public and of candidates presenting themselves for examination. This point cannot be made too clear—that the Society and its Council are very far from exercising anything like absolute power in the matter of the examinations it conducts.

Sections 7-14.—Payment of Fees; Keeping the Register.

Section 7 provides for the payment of examination and registration fees; those fees are now combined in the sum payable by a candidate on presenting himself for the qualifying examination, but registration could be made the subject of a separate fee. Sections 8 to 14 deal with the appointment of a Registrar and the keeping of the Register of Chemists and Druggists. It is the duty of the Registrar to keep a "correct" Register of all persons entitled to registration under the Act, and to that end he is empowered to erase the name of any person from the Register, if he receives no answer to two registered letters, sent at an interval of six months. Experience proves that, with every care on the part of the Registrar, it is not possible to keep the Register absolutely correct, but in most, if not all, cases of error, it will be found that carelessness on the part of registered persons or their representatives is at the root of the matter. The printed Register is sufficient evidence in a court of law that a person named therein is duly registered under the Act, and absence of a name therefrom is evidence, unless the contrary be proved, that a person is not so registered. You will see, therefore, how essential it is that everyone concerned should take whatever steps may be necessary, not only to ensure that his own name and address appear correctly, but that the names and addresses of others are given with equal accuracy. Registered assistants moving from one situation to another are peculiarly apt to overlook the necessity of promptly notifying their changes of address, and at times, after failing to receive and answer letters posted to them by the Registrar, they may experience considerable difficulty and expense (a fee of one guinea being payable) in securing re-registration. But the fault is usually entirely their own, and should not be unfairly attributed to the Registrar in abusive letters communicated to trade papers. The Register, it may be stated, is kept by the Registrar under orders of the Council, in accordance with Section 9, and if those who have secured qualification put a proper value on that qualification, the Register might be more accurate and the solidarity of pharmacists more assured.

Section 15.—Offences and Penalties.

We now come to Section 15, by far the most important in the Act from the pharmacist's point of view, for it is the chief penal section, and under it action can only be taken by the Registrar, acting in the name and under authority of the Council of the Pharmaceutical Society. How it was that some twenty years elapsed before the Executive of the Society fully realised and utilised the great power it possesses in this enactment, is one of those unaccountable things which, as Lord Dundreary would have said, "no fellow can understand." The acts which Section 1 declares to be illegal except when performed under certain conditions are here recapitulated as offences punishable by a fixed penalty. We may take it that there are seven distinct offences specified in this Section (1) the illegal sale of poison; (2) keeping open shop for such sale; (3) keeping open shop illegally for dispensing poison; (4) keeping open shop illegally for compounding poison; (5) illegally taking, using, or

exhibiting the name or title of chemist and druggist, etc.; (6) failing to conform with any regulation made in pursuance of the Act, with regard to the keeping or selling of poisons; (7) compounding any medicines of the British Pharmacopœia except according to the formularies of that work.

Now, as regards selling, it has been definitely decided that the person who actually conducts the sale of poison is the seller of the article and therefore liable under the Act, whether he be the proprietor of the shop or merely an assistant or apprentice, but the Courts have never yet held that the actual person handing over the poison is the unique seller. In the Wheeldon case, the defendant was one of the persons engaged in the sale, and as he was unqualified he was hit. Both agent and principal in an illegal transaction may be made liable. The agent would perhaps have ground for action against the principal for any damage he might incur in carrying out instructions, and registered men, knowing this, should—if even for no higher motive than self-preservation—give the most careful consideration to the question of employing unregistered assistants. It is more important, however, to notice that it is the act of handing over poison to the customer, and the personal superintendence of that act, that the law takes especial cognisance of, and not the question of who benefits by any profit on the transaction. Hence the reason why the House of Lords held that there could be no risk to the public in the case of pharmacies carried on by joint-stock companies, so long as the actual sale of poison is effected by a registered person. That argument, unfortunately, was supplied ready-made to the judges by an exemption in Section 16, as will presently be seen.

DISPENSING AND COMPOUNDING.

The next point to be noted is that there is nothing illegal in an unregistered person dispensing or compounding poison unless, as already suggested, Section 1 be held to restrict compounding to registered persons, and in any case there is no penalty provided. Whilst, therefore, it is an undoubted offence for an unregistered person to keep open shop for dispensing or compounding poison, dispensers and compounders appear to incur no risk if they are not registered as chemists, though the persons who subsequently effect the sale of poison so dispensed or compounded must be registered. Here we have remarkable confirmation of the fact that it is not the practice of pharmacy which is restricted and regulated, but only the sale of poisons. No unregistered person may sell poison, nor keep open shop for such sale or for dispensing or compounding poison, but anyone apparently may, with impunity, perform the physical act of dispensing or compounding poison. A porter, coachman, or errand boy may mix the lethal draught, but a duly registered person alone is permitted to hand it over to the hapless patient or his representative.

How "dispensing" and "compounding" differ, so far as the Act is concerned, and to what extent, is not at all clear. It is possible that the words were meant as alternatives, both referring to a similar action. But the introduction of a comma after the word "dispensing" is quite sufficient in an Act of Parliament to make the two words mean totally different things. The "compounding of poisons," beyond a doubt, covers the making up of medicines containing poisons, in accordance with the prescriptions of medical men or of private recipes—and, I venture to think, even of preparations containing poison, made in accordance with the chemist's own formulæ—provided the medicine is labelled with the name and address of the seller, and the ingredients are entered in the prescription book. But the meaning of the word "dispensing," if it implies something different from "compounding," is by no means so evident. The fact that the words are separately mentioned would, I think, seem necessarily

to imply that they are not synonymous. "Compounding" would appear naturally to refer to the actual making up of the medicine; "dispensing" to its distribution or dealing out, and as it appears to me, though both acts may be performed by the same person, that does not follow of necessity. This point, I think, is worthy of further consideration. The importance of having the term "compounding" strictly defined is evident, when we consider that it is a distinct offence under the Act to "compound any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia." Not to sell, mark you, but to compound. If the word "compounding" were legally interpreted to cover the breaking of bulk involved in conveying a medicine from a stock bottle to a smaller one, and then handing the latter to a customer, the Pharmaceutical Society might do much to supplement the working of the Sale of Food and Drugs Acts by putting in force the portion of Section 15 referred to. And even if that did not apply to corporate bodies, it would apply to their assistants or managers. It may be, however, that Section 15, so far as the latter portion of it goes, is as applicable to companies or artificial persons as to natural persons. The House of Lords decision did not apply to the regulations as to "keeping, etc., poisons" or compounding Pharmacopœia medicines. This may yet prove a very valuable portion of the Section, but so far it has been neglected, though it seems to offer a chance of saving the situation by giving the Society a salutary control in the case of businesses conducted by "companies."

If the "covering" chemist and druggist should offend against the Regulations off would come his name from the Register, and the impersonal entity or artificial person would be coverless. On the other hand, if the "cover" did not offend, the "covered" might be hit. The question of examination and registration does not come in at all in the latter part of Section 15, and this may be a case where a corporation is a "person" within the meaning of the Act. The difficulty, however, if compounding invariably implies the actual preparation of the medicine, is to prove the act of compounding, and that difficulty renders it almost hopeless for the Society to take any steps in the matter, as unregistered sellers of Pharmacopœia preparations much more frequently purchase them ready-made from wholesale houses than attempt to prepare them on their own premises. Nevertheless, the point is decidedly worth looking into. I may point out that with reference to the word "compounding," the preamble and Section 1 speak of "retailing, dispensing or compounding" of poisons; Section 3 refers to keeping open shop for "the compounding of the prescriptions" of medical practitioners; Section 4 speaks of persons engaged in the "dispensing and compounding of prescriptions"; Section 15 says "retailing, dispensing, or compounding"; Schedule (C) refers to keeping open shop for "the compounding of the prescriptions" of duly qualified medical practitioners; Schedule (E) and Schedule (A) of the 1869 Act both speak of having been employed "in dispensing and compounding prescriptions" as an assistant to a pharmaceutical chemist or chemist and druggist. What is the inference to be drawn from these varied uses of the words? The puzzle is not an easy one to solve, and a judicial ruling on the point would be advantageous.

THE MISUSE OF CHEMISTS' TITLES.

The question of the misuse of titles protected under the Act is in a somewhat chaotic condition, but I am inclined to disagree with the contention that the decision in the case of the London and Provincial Supply Association absolutely covers this point. The "House of Lords" decision was of a purely negative character; it simply decided that corporations cannot be regarded as "persons" within the meaning of the Act, inasmuch as they cannot be examined; and, therefore, that they cannot be pre-

vented from carrying on business as chemists and druggists. The decision turned entirely on the question of selling poisons and keeping open shop for such sale, and it was held that, in any case, the public must be protected as regards the sale of poisons, by a registered chemist conducting and managing the sales. But if corporate bodies are entirely outside the scope of the first fifteen sections of the Act, what protection does the public possess with regard to the misuse of chemists' titles? That point was not directly raised in the case of the London and Provincial Supply Association, and it has never been raised since. Now if a corporation is not a person, and cannot be examined, I am disposed to think that the words—"any person . . . who shall take, use, or exhibit the name or title of chemist and druggist . . . not being a duly registered pharmaceutical chemist or chemist and druggist, etc., shall for every such offence be liable to pay a penalty"—should be interpreted by the Courts as meaning that none but a registered chemist shall be free to use such titles. The view taken by the House of Lords was that, inasmuch as a joint-stock company cannot undergo examination, it is outside the law as regards the sale of poisons. But that argument cuts both ways, and I think we may fairly contend that as examination is a necessary preliminary of registration, a corporate body cannot be registered and, therefore, cannot legally employ any title the use of which the Legislature intended to restrict to duly registered persons. I certainly think the presumption that such would be the interpretation of the Courts is sufficiently well-based to justify an attempt being made to test this important point. We should not lose sight of the fact that the judges who delivered the House of Lords decision, in the case of the London and Provincial Supply Association, expressed the opinion that the word "person" in the Act might be construed to include a body corporate, if the object of the Act could be shown to require that the word should have the more extended sense. In regard to the matter of titles, it seems to me that the more extended sense is certainly required, and we ought, if necessary, to have a House of Lords decision on the point, in addition to having other problems solved. Year after year the Act is being shown to be more far-reaching than was originally imagined, and there is no reason to suppose that we have yet proved the utmost it is capable of.

HOW FAR REGULATIONS WOULD APPLY.

The last subject for consideration in connection with Section 15 is that dealing with regulations as to the keeping or selling of poisons, already referred to in dealing with Section 1, though in that case the word "dispensing" is also introduced. If regulations existed, no penalty could be recovered for ignoring those relating to dispensing, since no penalty is specified for that offence in Section 15. But no regulations of any kind have yet been made obligatory, though draft regulations have existed for many years in the form of recommendations. So far, however, the members of the Pharmaceutical Society have not seen fit to make them compulsory. If they would do so, and the Privy Council approved, a powerful weapon for good would, as I have already suggested, be placed in the hands of the Society. For even if those regulations should not apply to every place where poisons are offered for sale in open shop, but only to the establishments of registered chemists, it is extremely desirable that we should be able to show very clean hands in everything connected with the storage, dispensing and sale of poisons. If corporate bodies are entirely outside the provisions of Sections 1 and 15 of the Act, the making and enforcing of regulations would not directly affect them. At the same time, it is not quite clear that such regulations would not affect corporate bodies, if only to the extent that their

directors and managers might be liable for any breach of the regulations, as the decision in the Wheeldon case—with regard to the construction to be placed on the word "sell"—would probably be held to apply.

Section 16.—Exemptions under the Act.

In Section 16, with which must be read Section 1 of the 1869 amending Act, we find enumerated the various exemptions from the provisions of the previous fifteen sections. The classes exempted are: (1) Apothecaries and other legally qualified medical practitioners who pass an examination in pharmacy. (2) Veterinary surgeons dispensing medicines for animals under their care; (3) makers of or dealers in patent medicines; (4) wholesale dealers; and (5) the executors, administrators, or trustees of the estates of deceased chemists. With regard to the first and second classes, no reasonable objection can be taken to their exemption; besides, it would be absolutely useless if we did object. But the "business of a legally qualified apothecary," I may suggest, does not involve the keeping of open shop, or it would surely be subject to regulations as to the keeping, etc., of poisons. It is not an apothecary's "business" to keep a chemist's shop. It may be observed, by the way, that dentists, as such, are not exempted from the provisions of the fifteen sections, and I quite fail to see any reason why they should be. The third class, fortunately, has been narrowed considerably of late years. For, whereas for a prolonged period, it was considered that the term "patent medicines" covered all proprietary remedies sold under the Government stamp, that bubble was at last pricked, and the term is now restricted to such medicaments as are actually sold under the authority of letters patent in force—a very limited class indeed. As a result, the sale of practically all proprietary medicines containing scheduled poisons is restricted to registered chemists, and various attempts that have been made to convert such articles into veritable "patent medicines" have been defeated by the prompt action of the Council of the Pharmaceutical Society, in asking the Court of Chancery to prevent the attempted evasion of the Pharmacy Act by the would-be patentees. That remedy or check, as I need hardly say, is expensive, but so far it has invariably proved extremely effective. So far as the third class of exemptions is concerned, therefore, registered chemists have now little cause to grumble. It is worthy of note, by the way, that the term "dealers" has not yet been legally defined. Might it not have a restrictive meaning, intended to protect manufacturers and wholesale distributors only?

"Wholesale dealers" are exempt, in the words of Section 16, when they supply poisons "in the ordinary course of wholesale dealing." Now the ordinary course of wholesale dealing is the supply of goods by a wholesale dealer to a retail dealer. That is more fully and clearly expressed in the next section of the Act, where exemption from certain conditions is granted to "sales by wholesale to retail dealers in the ordinary course of wholesale dealing." The exact position appears to me to be this—if a wholesale dealer supplies a scheduled poison to a consumer, he is not in any degree exempted from the requirements of the Act. On the other hand, it is, I think, distinctly illegal for a retail dealer to attempt to avoid the restrictions imposed by the Act, in cases where he supplies consumers with what he chooses to regard—for his own or his customer's convenience—as wholesale quantities of scheduled poisons. If the poison be supplied to a consumer, the transaction cannot be a wholesale one, and if, in the interests of the public, the letter of the law is strictly adhered to in this connection, the registered chemist is not likely to be a sufferer.

THE SO-CALLED "WIDOW'S" CLAUSE.

The same cannot be said, unfortunately, with regard to the exemption of executors, administrators, or trustees, under Section 16, for that weakest of all weak spots in the Act has been at the bottom of all our troubles. The fact that unqualified persons—acting as executors, administrators, or trustees—are permitted by the law to carry on the business of pharmacy without special restrictions, so long as a duly qualified assistant is employed to conduct the business, provided the judges in the case of the London and Provincial Supply Association with such a good reason for deciding in favour of the legality of unqualified company pharmacy as would probably—nay, almost certainly—not otherwise have been found. For the supposed interests of a few widows and heirs of deceased chemists, who might not unreasonably have been left to make a living in some sphere for which they were better fitted, the whole craft has had to suffer in sackcloth and ashes for nearly twenty years.

I may note here that this exception in Section 16 has been grossly abused; steps ought to be taken to vindicate the law where trusts have ended without the conditions under which business is carried on being altered. How long is an executor an executor? Death, completion of trust, and other circumstances terminate his or her duty, and the exemption of the Section then no longer applies. But there are cases in which no proceedings have yet been taken, although the trusts appear to have been completed, and the present proprietors of the businesses are unregistered persons. Take the case of a man whose father was a registered person, with several branch businesses. After his death, his widow carries on business under Section 16, and opens other branches—a distinct infringement, it seems to me. In the event of her death, can any reasonable man contend that her trustee—an unqualified person—is entitled to the exemption of Section 16? He would not be the trustee of a registered man, but the trustee of the deceased wife of a registered man. At the same time, he is not a registered chemist, and unless his position can be shown to be illegal he may in turn bequeath the trusteeship to another unqualified person. Every unbiased individual must agree that, whilst this Section affords loopholes enough in its legitimate sense, it is shamefully abused by those who could not legally claim its protection.

Section 17.—Regulations for the Sale of Poisons.

So much for the exemptions under the Act. Coming to Section 17, we find that it treats exclusively of the regulations to be observed in selling poisons. Those regulations, it should be needless to explain, are not identical with the regulations indicated in Sections 1 and 15, which were meant to deal with the keeping and dispensing as well as the sale of poisons. It is not generally recognised that the Society could, if it thought fit, supplement the provisions of this Section by putting into force Section 1. In Section 17 we have the minimum requirements for safety in selling, and the Legislature was confiding enough to leave the other regulations to the experts, *i.e.*, the registered persons who have so far declined to adopt those other regulations. To summarise the regulations in Section 17 briefly, the bottle, etc., containing any scheduled poison must be labelled with the name of the article, the word "poison," and the name and address of the seller. The name of the article sold is not necessarily, it seems to me, the name of the poison present in that article, but where the poisonous ingredient is present in large proportion, I should say the name of the poison ought to be stated on the label, if only to enable anyone, in case of an accidental overdose being taken, to know what emetic or antidote to administer or other treatment to adopt. The more virulent poisons must, of course, have their sale recorded in a book kept for that purpose. The

seller, for the purpose of this Section, is the person on whose behalf any sale is made, though in Section 15 of the Act the seller is the person who actually conducts the sale, *i.e.*, performs the physical act involved in a sale. This is an important distinction which should not be overlooked. The definition of the word "introduced," the exact meaning of the phrase "known to the seller," and an infinite variety of other problems crop up here, and there are, as might be expected in the case of any Act passed in a free country like this, certain exemptions from these poison regulations.

EXEMPTIONS UNDER SECTION 17.

Thus, wholesale dealers need only label packages containing poison with the name of the article and the word "poison," and that procedure need not be varied whether the articles be included in Part 1 or Part 2 of the Poison Schedule. Apothecaries and other qualified medical practitioners are not exempted from the provisions of this Section if they "sell" poisons to the public. They are only exempted as regards poisons contained in medicines supplied by them to their patients, to the same extent as registered chemists, who are not required to do more than label medicine dispensed by them and containing poison with the name and address of the seller, so long as they copy the prescription or formula in a book kept for the purpose, and also enter the name of the person to whom the medicine is sold or delivered. It has also been suggested that the last-mentioned exemption enables a registered chemist to supply any medicine dispensed by him and containing a scheduled poison—whether made up from a prescription or not—without labelling it "Poison." That is to say, by entering the requisite particulars in his prescription book, a registered chemist may supply any medicine dispensed by him and containing a scheduled poison or poisons, without being required to treat it as a poison sold under the ordinary conditions of sale. As regards corporate bodies, it has repeatedly been held that they are liable to penalties for any infraction of Section 17, and the Interpretation Act of 1891 puts that matter on a definite basis. The reason they are liable under Section 17, though they are not liable under Section 15, is that the penalties in the former case must be recovered in a court of summary jurisdiction, and not in a county court. Inasmuch as the Interpretation Act applies to Scotland, where all cases under the Pharmacy Acts must be tried in courts of summary jurisdiction, it would appear as if we could proceed under both Sections there. As it happens, however, the whole of the 1868 Act is practically a dead letter in Scotland. The decision in the Leith Depôt Case—according to which the individual members of a corporate body cannot be sued in Scotland for trading as chemists and druggists—appears to have been too much taken for granted. We ought to shake off the local paralysis induced by that decision and bring a test case under Section 15 against a Scottish limited company, arguing that the Interpretation Act renders a corporation a person within the meaning of the Section. In Scotland, by the way, an ordinary firm is held to be a corporation, though in England a decision to the contrary effect was given last year in the case of the Pharmaceutical Society *v.* Potter.

WANTED—A PROSECUTOR.

But to return to Section 17, in connection with the liability of corporate bodies under this Section, the interesting question arises, How can a joint-stock company of unqualified persons sell poisons in Part 1 of the Schedule? It has been clearly laid down that for the purpose of Section 17 the person (including a company in this case) on whose behalf any sale of poison is made by any apprentice or servant shall be deemed to be the seller. The

apprentice or servant is not employed by the manager, but by the company, and the poisons in Part 1 of the Schedule may not be sold unless the purchaser is known to, or is introduced by, some person known to the seller. How can the purchaser be known to the company which has an impersonal existence? That is another problem requiring solution. The great drawback of Section 17 is that no authorised prosecutor is named. Any one may prosecute, but the Pharmaceutical Society thinks it is not its special business. The police authorities say they are not the administrators of this Act, and so offenders go scot-free and the public suffers. It is open to question whether we can justifiably talk about "public safety" in approaching Parliament, whilst leaving practically inoperative the chief protective clause in the Act. In Scotland the embodiment of wisdom which sits under the Sheriff's hat says the Society cannot proceed under Section 17. The Procurator-Fiscal says it can, and that he will not. Hence in both parts of the island there is stagnation, confusion, and aggravation.

Sections 18-21.—Membership of the Society.

The remaining sections of the Act may be very briefly dealt with, the more especially as Sections 18, 19, 20, and 21 are now repealed. Sections 18 and 19 had the effect of rendering every registered chemist and druggist, who was in business as such at the time of the passing of the Act, eligible to be elected a member of the Pharmaceutical Society, and also to be elected a member of the Council of the Society. The number who have taken advantage of those provisions has been extremely small, comparatively speaking, though at the present time there is a very large number of unexamined men who secured registration as chemists and druggists by virtue of having been in business on their own account prior to August 1, 1868, but who have never taken any steps to become connected with the Society, or to help in forwarding its aims. The more shame to them, say I, that they should be so lacking in public spirit as to take no care for the future of their craft, and so wanting in self-respect as to stoop to share benefits which they have never moved a finger to help to attain. Those men are a disgrace to pharmacy, a standing reproach to those of us who would boast of the position of our craft, and they have ever been a drag upon the wheels of progress. The weakest link is always the measure of the strength of a chain, and the unexamined men on the Register, or those of them who have persistently refrained from assisting in the good work of the body to which they owe their registration—free of all trouble or cost—certainly constitute that link in our case.

Section 20—which rendered every chemist and druggist registered after the passing of the Act, in virtue of having passed an examination, eligible for election as an associate of the Society—has now, I am glad to say, been repealed. The amending Act passed this year provides that such persons shall be eligible for election as "members," with the same rights and privileges as other members. In this way one of the original ideas of the founders of the Society has been realised—every person possessing the statutory qualification being now eligible for election as a member of the Society. The effects of this modification of the regulations should be far-reaching, as it enables the whole trade to work together on a common footing for the general good, in a way that has never before been possible. I hope that, before long, the membership of the Society may be at least doubled by this statesmanlike change in the law; if every existing member will do his best to bring only one more into the fold, that result will not be difficult of attainment. Another section which has been modified by the new Act is Section 21; that deals with the manner of voting for the election of officers,

and provision has now been made for votes to be sent by post later than has been customary.

Sections 22-28.—Benevolence; Purging the Register.

Section 22 provides that the Council of the Society shall have the sole control and management of all the Society's property. It also authorises the existence of our Benevolent Fund and enables the Council to extend the benefits of that noble Fund to all registered chemists (and their widows and orphans), whether they are or have been connected with the Society and subscribers to the Fund or not. It is not pleasant to think of the mean spirit displayed by registered men who decline to support the Society and its Benevolent Fund, and yet are eligible to enjoy, and frequently come to need, the benefits of that Fund. Fortunately, those who have subscribed to the Society at any time, and have later fallen upon evil days, do not suffer by the generous provision which enables the Council to afford assistance to outsiders, and it is a remarkable fact that chemists who have supported the Society and its Benevolent Fund rarely require charitable assistance.

Section 23, which forbade the registration of medical men as chemists and druggists, was repealed by the Act of 1869. Even now, however, persons registered under the Medical Act cannot be registered as pharmaceutical chemists. Section 24 has also been repealed; it provided that an early Act for preventing the adulteration of articles of food and drink should extend to all articles usually taken or sold as medicines, but the Sale of Food and Drugs Act, 1875, removed the necessity for the existence of that section. Section 25 practically places the Society under the control of the Privy Council, the body which is really responsible for many of the Society's alleged shortcomings. Section 26 vests in the Privy Council the power of directing the names of registered persons who have been convicted of any offence against the Act to be erased from the Register. If the poison regulations contemplated by Sections 1 and 15 were in force, that power of purging the Register would virtually be vested in the Council of the Pharmaceutical Society, as it would only be necessary to report breaches of the regulations to the Privy Council to ensure the carrying out of disciplinary measures such as we now frequently feel the need of. Section 27 provides that the Act shall not extend to Ireland; so much the worse, in my opinion, for the chemists of the Emerald Isle, though they are better off than we are in some respects. Finally, Section 28 fixes the short title of the Act, that of the Pharmacy Act, 1868.

Brief Summary of the Act.

Now, to summarise the twenty-eight sections of the Act, we find that though it was avowedly passed—as witness the words of the preamble—to secure that "persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business," and to that end should be duly examined and registered, yet by subtle judicial distinctions it has been held to secure nothing of the sort. Any seven persons—grocers, drapers, butchers, or scavengers—can register themselves as a joint-stock company to carry on the business of a chemist and druggist, and the law is powerless to prevent them. Such mongrel and nondescript companies usurp our titles, share our sadly limited privileges, and are enabled to do all that a registered chemist can do, without the worry and expense of practical training, study, and examination. The only condition is that they must have a registered chemist in charge of the business and, by the disastrous and suicidal conduct of men in our own ranks, they have no difficulty in complying with that condition. The original purpose of the Act, then—as vouched by its preamble—has not been ful-

filled, and all that the absurdly insufficient measure does is to protect the public with regard to the sale of a few poisons. Registered chemists, wisely or foolishly, have fitted themselves to deal with those poisons by the roundabout way of study and examination, in preference to adopting the obviously more easy plan of combining in groups of seven, and getting registered as limited liability companies. It is true that scheduled poisons can only be legally sold to the public by persons registered under the Act, but since the dispensing and compounding of the poisons may be done by errand boys, porters, or any other class of incompetent persons a corporate body may choose to employ, the handing over to customers of such dispensed and compounded poisons by a person duly qualified under the Pharmacy Act, 1868, seems wonderfully akin to the operation of locking the stable door after the horse has been stolen.

Remedy for Shortcomings.

The obviously best remedy for the existing state of affairs is for Parliament to declare that the word "person," wherever used in the Pharmacy Acts, shall include any corporate body, and that unqualified persons acting as executors, etc., of deceased chemists shall only be entitled to carry on the business of a chemist and druggist for a limited period. That period might be extended at the discretion of the Council of the Pharmaceutical Society, but in any case this weak spot in our armour ought to be removed. With regard to the alleged prescriptive rights of companies now carrying on the business of chemists and druggists, such "rights" are mere evasions of the Statute. As to the fact that corporations cannot undergo examination, that has no bearing whatever upon the question. The relevant fact is that the practice of pharmacy and the use of all titles implying the carrying on of the business of a chemist and druggist should, in the public interest, be restricted to duly qualified individuals. It may be that the spirit of the times will prove too strong for us and prevent us attaining the position that, as duly qualified pharmacists, we aspire to. At the same time, it is doubtful if anything less is really worth fighting for, and if only the majority of registered chemists now outside the Society will join the ranks of those who, for more than half a century, have kept the lamp of progress in pharmacy steadfastly burning, the fight I hope to see will be a good one, and need not necessarily be unsuccessful. That fight, whilst partaking to a great extent of the nature of a struggle for existence, will also, in even greater measure, be for the public benefit. Let us then proceed to educate the public with regard to the interests involved, and at the same time consolidate our forces. If the outsiders will come in and join us, we shall surely make a brave fight, and may see a successful end to all our enterprises; if, however, the minority are left to bear the brunt of attack unassisted—and if, in any case, luck should go against us, so that each of us shall be compelled to exclaim, with Falstaff: "Company, villainous company, hath been the spoil of me"—we shall at least have preserved our self-respect. We shall also know that we have done our best, though vainly, to provide a remedy for the mistakes committed by our leaders some eighteen years ago, when they omitted to follow up the decision of the House of Lords in the case of the London and Provincial Supply Association, by striving to carry an amending Bill through Parliament at all costs. The sinews of war were doubtless lacking then; they are none too plentiful now, but it is the moral support and sympathy of the whole trade, rather than guineas that the Society needs and has a right to expect. Nevertheless, law is an expensive luxury, and I take it that in a matter of such vital importance to our craft no registered man ought to hesitate to bear his fair share of the costs of the undertaking. That can most satisfactorily be done by

becoming a member of the Pharmaceutical Society. In any case, the registered chemists of this country are now faced with the necessity of either fighting anew for what Parliament undoubtedly intended to give them in 1868, or succumbing in a seemingly vain struggle with a few unscrupulous capitalists who have ingeniously contrived to frustrate what the sanction of Queen, Lords and Commons seemed to have assured. In my opinion (and it must be distinctly understood that, on this occasion, I speak for myself only), those two courses, and those simply, are open to us, and it is for you, the registered chemists and druggists of Manchester and district, in conjunction with your fellows throughout Great Britain, to decide which course shall be pursued.

THE OFFICIAL TESTS FOR GURJUN BALSAM IN COPAIBA.

BY H. J. HENDERSON, PH.C.

The tests for gurjun balsam in copaiba are described with some minuteness in the British Pharmacopœia. The points to which I wish to call attention are small ones, yet they are of importance in the practical application of the test, which is my excuse for bringing them under notice. It is stated that when two drops of copaiba are added to twenty parts, presumably drops, of carbon bisulphide, a transient violet colour should not be produced, showing absence of gurjun balsam. It is to the word transient that I wish to call attention first. I cannot find it stated anywhere other than in the B.P. that gurjun balsam gives a transient violet when subjected to this test. Flückiger and Hanbury, in the 'Pharmacographia,' state that the colour is an intense purplish-red, becoming violet after a few minutes. The U.S.P. simply says that a violet colour is produced, and refrains from qualifying it in any way. J. C. Umney, in the *Pharmaceutical Journal* [3], xxii., p. 450, stated that a sample of gurjun balsam examined by him gave a decided and permanent violet. The following few experiments which I performed tend to show that the Pharmacopœia is wrong in describing the colour as transient. I obtained a sample of *D. turbinatus*, and mixed one part with seven parts of copaiba; I did this because it occurred to me that the presence of copaiba might have some influence on the colour. I carefully followed the directions given in the B.P., and after a minute or two a fine violet was obtained, which remained permanent for an hour, which I consider long enough for practical purposes. The 'Pharmacographia' states that the test easily detects the presence of an eighth part of wood oil in copaiba, which was my reason for mixing in the above proportions. On applying the second test several times to the mixture, no purple colour was obtained, but on increasing the proportion of gurjun balsam from one-eighth to a fourth part, a distinct purple colour was obtained after standing for an hour. The colour does not appear at once, therefore, I think the monograph would have been improved if it had stated the limit of time required to produce the effect. The sample of gurjun balsam was supplied to me by the courtesy of Professor Greenish.

EUCAINE- β IN STOMATOLOGY.—Legroind advocates the use of a 2 per cent. solution of eucaine- β for extractions, since the anæsthesia produced by a solution of that strength is complete, and the operation may be performed immediately after the injection has been made. In over sixty cases, embracing patients of all ages, of both sexes, no unpleasant after-effects were observed in any instance, the doses ranging from $\frac{1}{2}$ to 4 C.c. of the 2 per cent. solution. The extreme pallor of the face observed sometimes after the use of holocaine and other analgesics was not observed with eucaine- β .—*Les Nouv. Rem.*, xiv., 337.

COMPANY PHARMACY: ITS CAUSE AND CURE.*

BY GEORGE SQUIRE.

In dealing with a subject of such great importance as the one I have chosen as the subject of my paper, I am perfectly aware of the responsibility I have taken upon myself, and also of the many shortcomings that may be manifested in my remarks, owing to the fact that I cannot bring to bear upon the subject the knowledge that comes from experience to anything like the same extent as men who were in business long years before I was connected with pharmacy, and who have watched the growth of company pharmacy from its infancy. However, I hold certain views upon the subject and those I shall endeavour to place before you briefly; if they do not exactly coincide with the opinions held by others the opportunity offered for discussion will be all the greater.

COMPANY TRADING AND REGISTERED CHEMISTS.

During the past decade the rage for company trading has increased to such an enormous extent, and with it the attendant evils—bogus companies, and one-man companies—have multiplied so fast, that the matter is now becoming a source of great anxiety, and must soon, of necessity, be further regulated by special legislation in order to prevent the frauds that are being practised on the public daily. One would have thought that pharmacy in its quiet sphere, and with its sometimes limited turnover, would have been left severely alone by that artificial person—the joint-stock company, but no, the greed for gold has been too great for the company promoter, and pharmacy must needs take its chance with the rest.

As a consequence we, as registered chemists, have been unfairly handicapped in the struggle for existence during the last eighteen years. But the prospect of pharmacy has brightened considerably during the past twelve months, the chemists of the country having awakened from their dormant state and proved themselves a body to be reckoned with, as evidenced by the enthusiasm they displayed in promoting the passing of the Pharmacy Acts Amendment Bill and their successful opposition to the Poisonous Substances Bill. That is as it should be, and one can only regret that the same enthusiasm was not shown by the craft years ago, for then company pharmacy would have been nipped in the bud and never have assumed the gigantic proportions it has attained to now.

To-day, however, a fresh opportunity presents itself for retrieving our position. The new Bye-laws drafted in accordance with the Pharmacy Acts Amendment Act have now been confirmed and approved by the Privy Council, and there is no longer any obstacle in the way of all registered chemists becoming members of the Pharmaceutical Society, and thereby giving it their sympathy and active support in the endeavour to improve the lot of registered chemists in the future, as well as helping to present an unbroken front to all the enemies of our craft. The Pharmaceutical Society is the only legally recognised organised body in pharmacy, and it is through the instrumentality of that Society alone we can hope to obtain any amelioration of the company pharmacy grievance, which so urgently calls for early and serious attention.

COMPANIES VERSUS INDIVIDUALS.

Business to-day is very different from what it was when the Pharmacy Act was passed in 1868, and had those who were responsible for the framing of that Act foreseen the possible existence of company pharmacy they would have taken good care that the measure was so worded as to have prevented any evasion of its provisions by means of legal and judicial quibbling. But though such a thing was never dreamt of then, what have we to-day?

There are drug stores all around us, no matter where we go, and they are mostly owned by limited companies, the directors of the majority of which have never seen a pill machine, handled a test-tube, or heard of *materia medica*. But their previous business and lack of pharmaceutical knowledge is not taken into consideration by the law, be they undertakers, cabinet-makers, printers, newsvendors, or anything else whatever. Only let seven men register themselves as a limited liability company, and they can blossom out at once as chemists and druggists, and keep open shop for the dispensing and retailing of poisons, the only legal requirement being that some duly qualified person must sell his services and act as cover so that the seven unqualified persons may carry on their illegitimate business.

On the other hand, let an individual who is not registered under the Pharmacy Acts open shop and style himself a chemist and druggist, and the Pharmaceutical Society at once interferes. Now, I cannot for the life of me see why the Pharmaceutical Society should be legally within its rights in preventing an unregistered person, even though he has served an apprenticeship to the business, opening a shop and styling himself a chemist and druggist, if it be not equally possible to prevent seven unqualified persons doing the same thing. Common-sense demands that identical treatment should be meted out to individuals and to collections of individuals in this matter, and that view, in my opinion, ought to be maintained by us at all costs and to the bitter end. When we have spent time, labour, and money in obtaining a qualification which the State has made compulsory in the interest and for the safety of the public, it is only reasonable to expect the State to protect us against unqualified persons combining to form limited liability companies and engaging in the business for which the State insists that a qualification is absolutely necessary in the case of an individual, and also to prevent those companies usurping the titles associated with that qualification.

COMPANY PHARMACY A PARASITIC GROWTH.

But unfortunately, as we all know and greatly regret, that protection does not exist, and since that fatal decision of the House of Lords in the case of the London and Provincial Supply Association, company pharmacy has increased without check. That is not to the credit of pharmacy in the public eye, nor is it for the public good. Company pharmacy is a parasitic growth on the outcome of the labours of the Pharmaceutical Society, and registered chemists as a body should do all in their power to remedy the evil. Fair and square competition no chemist can object to, but trading on the qualifications of other people is not honourable, and all upright men must set their faces dead against such dishonourable trading. The business methods of company pharmacy are in many ways questionable, and in the matter of advertising nothing is too mean or too low for companies of unqualified persons to stoop to in order to gain their ends. According to their advertisements, the respectable chemists of this country are anything but gentlemen, and have carried on a system of fleecing the public for years, but companies as the pioneers of cheap and nasty physic have come to the rescue, and they pose before a much too easily gulled public as philanthropists.

That such is not the case is seen by the number of proprietary articles that are advertised by companies under the names of fictitious doctors and nurses, the 3s. 6d. sizes for 10½d., and so forth. The real position is also manifested by the numerous and common devices used to foist those quack nostrums upon the public. On purchasing one of the articles the purchaser probably receives a coupon which, on being filled in with the correct winners of cricket or football matches, entitles the owner to a prize of

* Read before the Sheffield Pharmaceutical and Chemical Society, on Wednesday, December 14, 1898.

variable amount. Or, for a change, one may be asked to guess how many of some imaginary physician's pills are contained in a certain exhibited bottle, and the fortunate or unfortunate person who is nearest the mark is rewarded for his trouble. At those so-called pharmacies (the most beautifully fitted in the country, we are informed in advertisements) one can purchase almost anything—a tin of salmon or a pot of jam, a lead pencil or a sweeping-brush, a sheet of note-paper or an oil painting and frame (if you do not care to purchase the latter you are entitled to view it free of charge), and an extra special 5s. diary may be offered for 6d. to clear. The windows of these nondescript establishments are covered with huge bills advertising foreign quack medicines, with which the public may kill or cure themselves without the aid of a medical man. And yet, I regret to say, there are medical men who deliberately send their patients to such paltry shows for their stocks of medicine.

TRAITORS TO THE CRAFT.

Such is the style of business conducted by limited companies which profess to carry on business as chemists and druggists, and those registered chemists who, by their Judas like treachery in selling their services to unqualified persons, are responsible for its existence, have degraded pharmacy, as carried on in joint-stock drug stores, to the lowest depths of mere commercialism. To have a physician's prescription dispensed in the same establishment as you would have a picture framed, or to receive a coupon for a guessing competition should hardly tend to inspire the public with confidence, and does the fact that limited companies generally employ a registered chemist and druggist, who is a salaried assistant, constitute a sufficient public safeguard? I say decidedly not, and as any matter involving fresh legislation will have to be considered from the standpoint of the public welfare, I think the points I have adduced are very important.

But these companies are not only unfit to carry on the business of chemists and druggists, they have been built up by the aid of qualified members of our own craft, without whose help company pharmacy could not exist; that is greatly to be regretted, for it is only by a unanimous combination of the chemists of this country that we can hope for any redress. How are we to set about it? Numerous suggestions have been made, many of which it is unfortunately impossible to act upon, for in dealing with a subject of such great importance we must go to work in a deliberate manner, and with due consideration for surrounding influences.

SUGGESTIONS FOR IMPROVEMENT.

My first suggestion is that all registered chemists should show their loyalty to the Pharmaceutical Society and appreciation of its work by at once joining that body if they are not already members. Such loyalty has been lacking in many quarters for a great number of years and, as a consequence, the Society has never during that time been in a position to approach Parliament with a view to any important legislation. The Society, as we all know, is now more thoroughly democratic than ever and if it is to do as effective work as we could wish, a great increase of new members is required. Since Minor and Major men will now share the same advantages they can work together for their common good. One often hears hard sayings against the Society, but as a rule it is from men who hold themselves aloof, and think they can obtain all the necessary reforms by grumbling. Those men are ignorant of the internal workings of the Society and how for years its Council has cheerfully plodded away against great odds, never flinching from its duty to the craft, and even conferring benefit on those men who have not only never lifted a finger to help, but have very often done the opposite. Will anyone deny that pharmacy

to-day is in a much better position, in spite of limited companies, than it was before the Pharmacy Act was passed? That has not been brought about by the grumbling members of the craft, but through the influence of the Pharmaceutical Society. If, as I maintain, pharmacy has progressed under such unfavourable circumstances for many years, what may we not hope for if the great majority of chemists become members of the Society, and thereby show their loyalty to their profession?

My second suggestion is that we should individually endeavour to educate the public as to our position and help people to comprehend the difference between company pharmacy and that practised in our own establishments. It is astonishing how little the public really knows regarding our training and position, but when an explanation is given to them it is appreciated and satisfactory results follow. The British public believes in fair-play, and when it knows all about a chemist's training, etc., there will be disinclination to support those who hold a false position in the matter. I am sure a great deal can be done by appeals to the public through the House of Commons and in every other possible way. In this and my former suggestion is embodied all our hope for future improvement, and, presuming those suggestions are acted upon by the majority, what can be effected? I venture to say much that will be for our future benefit, though not all we should like. The House of Commons is most particular in its regard for existing rights, and the fact that limited companies have so long had everything their own way will make the present position very difficult to alter; but "Nothing venture, nothing won," and if we are not successful in our first attempt, we shall at least be educating the public as to what ought to be, and so doing much good.

THE NECESSITY OF UNANIMITY.

A Bill making it illegal for all companies of unqualified persons to carry on the practice of pharmacy would be a very drastic measure; one that we should all heartily support, one also that would meet with tremendous opposition. I should strongly advocate such a measure if we could secure complete unanimity. The medical and dental professions are now being attacked by limited companies, which have been registered in order to evade the provisions of the Medical and Dental Acts, and at a meeting of the General Medical Council a few days ago a great deal was said about the evasion of those Acts by limited companies, and it was agreed to promote a Bill and to send a petition to the Lord Chancellor praying that something may be done to stop it. Medical men and dentists, in fact, are in the same position as pharmacists, and I think this is a splendid opportunity to go hand in hand with them. Let the Pharmaceutical Society and the General Medical Council decide to work together for the benefit of the three professions. A Bill backed up by chemists, medical men, and dentists would beyond question receive every attention.

If the Council of the Pharmaceutical Society were granted the same privilege as the General Medical Council—the power to strike off the Register any man guilty of unprofessional conduct, such as acting as "cover" to unqualified persons, something might be done to mitigate the company pharmacy evil, but it would not do away with it altogether. Any Bill drafted should certainly contain a clause restricting the compounding and dispensing of medicines and the sale of pharmaceutical preparations to persons who have obtained the necessary qualification, and make it impossible for a number of persons to band themselves together to defeat that object and carry on the practice of pharmacy. That is the law on the Continent and, as the leading country in the world, it is a pity we are far behind others in pharmacy law.

Reform is urgently needed and there is plenty of scope for a

measure which will be beneficial to the public and tend to the advancement of pharmacy. Never was there a more opportune time to advocate what we desire. Many members of both Houses of Parliament sympathise with us, medical men are also with us, and the public will equally be with us as soon as they see justice is on our side. Let the chemists of the country awake and unite as one man, rallying round the Pharmaceutical Society. Those who have not yet supported that body should begin to do so at once, and I am sure, with such a man as our worthy President—Mr. Walter Hills—at the wheel, we shall be guided on to victory. Parliament will surely grant us some amelioration of existing conditions, if not all we ask; and as a consequence the position of pharmacy in the future will be greatly improved, whilst possibly company pharmacy will be shown to have had its day.

PHARMACEUTICAL SOCIETY.

EVENING MEETING IN LONDON.

The second evening meeting of the Pharmaceutical Society of Great Britain was held on Tuesday, December 13.—Mr. WALTER HILLS, President, took the chair at 8 o'clock, and at once called upon Mr. W. MURTON HOLMES to give his lecture on

Deep-Sea Deposits.

—The lecture, which is reported in full at page 636, was illustrated by lantern slides, of which the following is a complete list:—

1. *Rhizocrinus lofotensis*.
2. Foraminifer with pseudopodia extended.
3. Deep-sea Foraminifera (outlines).
4. *Polystomella* (balsam).
5. *Globigerina*, North Atlantic (transparent).
6. *Miliolina reticulata*, Bird Island, Great Barrier Reef.
7. *Lagena*, Samarang, Java.
8. *Nodosaria subterrenata operversa*, off Ki Is, 129 fathoms.
9. *Globigerina inflata*, 1800 fathoms.
10. *Orbulina universa*, off Culebra Island.
11. *Sphaeroidina dehiscens*, "Challenger," 7° 45' N., 144° 20' E., 1850 fathoms, near Caroline Islands.
12. *Pulvinulina menardii*, 7° 45' N., 144° 20' E., 1850 fathoms, near Caroline Islands, N. Atlantic.
- 12A. *Pulvinulina pauperata*, 56° 11' N., 37° 41' W., 1450 fathoms, near Caroline Islands, N. Atlantic.
13. Radiolaria. From drawings after Haeckel.
14. " " "
15. " " "
16. " " "
17. " " "
18. " " "Challenger," 7° 25' S., 152° 15' W., 2750 fathoms, S. Pacific.
19. " " Antarctic, 1950 fathoms.
20. *Pheronema carpenteri*, Atlantic, 530 to 1600 fathoms.
21. *Rossella velata*, West of Gibraltar, 651 fathoms.
22. *Semperella schultzei*, Dermal framework, Phillipine Islands.
23. *Dactylocalyx pumiceus*, West Indies.
24. *Arachnoidiscus*, *in situ*, Mauritius.
- 24A. " " 200 drs.
25. *Arachnoidiscus*, highly magnified.
26. *Heliopecta*.
27. *Pinnularia*.
28. Sounding "Egeria" 36° 08' S., 117° 10' E., 2479 fathoms S.W. of Australia.
29. Deep-sea deposits, "Challenger."
30. *Globigerina cretacea*, Croydon.
31. Foraminifera from cavity of flint, West Wickham.
32. Radiolarian Earth, Port Jeremie, Hayti.
33. " " Moron, Spain.
34. " " "
35. Sponge Spicules, Oamaru, New Zealand.

The PRESIDENT said the thanks of the audience were eminently due to Mr. Holmes for the very interesting lecture he had given. He hardly knew which to admire most, the slides which represented Mr. Holmes' drawings, or those taken direct from nature. He should like to call attention to the fact that Mr. Holmes was a hard-working pharmacist, who devoted his leisure to the microscope and to working out such problems as those with which he had been dealing. That fact might encourage some of the students present to think that some day they also, after their day's work at pharmacy, might find delight in such studies, and that they might even make a name for themselves, like Mr. Henry B. Brady, of whom all pharmacists were proud. He was also glad to know that Mr. Holmes was recognised as a microscopist, and that his work was highly appreciated. He would conclude by proposing a cordial vote of thanks to him.

The vote of thanks was carried unanimously, and briefly acknowledged by Mr. HOLMES.

BENEVOLENT FUND GENERAL MEETING.

ELECTION OF ANNUITANTS.

A General Meeting of the Members of the Pharmaceutical Society and of Subscribers and Donors to the Benevolent Fund was held at the house of the Society, 17, Bloomsbury Square, on Tuesday, December 13, for the election of four annuitants.

Scrutineers were appointed by the meeting, and Mr. E. N. BUTT having been elected as Chairman, proceeded to examine the voting papers.

The General Meeting then adjourned until after the scrutiny had been completed.

At the adjourned meeting, Mr. WALTER HILLS, President, in the chair, the scrutineers presented the following report:—

Scrutineers' Report.

We the undersigned scrutineers appointed at the Thirty-fourth Election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following results:—

Young, James J.	5495.
Bowman, Jane.	3841.
Biggs, Walter.	3728.
Field, William C.	3528.
Bosley, Emily Jane.	2974.
Stangroom, Frederick.	2314.

3945 voting papers* were received, of which number 76 were informal (53 unsigned, representing 180 votes, and 23 incorrectly filled up, representing 69 votes).

EDWARD N. BUTT, Chairman.

LEO ATKINSON.	FRANK A. ROGERS.	A. J. BULLEN COOPER.
G. S. TAYLOR.	HENRY BATE.	C. EDWIN GARMAN.
W. PRIOR ROBINSON.	W. FRED GULLIVER.	JOHN HOLDING.
D. R. JACKS.	S. A. STURTON.	JOHN T. W. WALLIS.
THOS. HY. POWELL.	RICHARD THOMAS.	A. G. WORSLEY.
W. ARKINSTALL.	J. H. SHACKLOCK.	JOHN F. HARRINGTON.
A. J. PHILLIPS.	F. BASCOMBE.	T. TICKLE.

The PRESIDENT then declared the following duly elected annuitants:—

Young, James J.	Biggs, Walter.
Bowman, Jane.	Field, William C.

In proposing a vote of thanks to the scrutineers for their services, the PRESIDENT pointed out that although this year more voting papers were sent out than on the occasion of the last election, a smaller number had been returned, and of those a larger proportion were unsigned.—The vote of thanks was seconded and carried unanimously, and was acknowledged by Mr. E. N. Butt.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School and House Committee, on Wednesday, December 14, the Librarian and Curator presented the following reports of donations:—

To the Library (London).

Smithsonian Institution, Washington:—Miscellaneous Contributions, Nos. 1125-6.

Messrs. C. J. Hewlett and Son, London:—Notes on the New B.P., 1898, 3rd ed.

British Pharmaceutical Conference:—Year-Book of Pharmacy, 1898; 2 copies.

Mr. W. J. Clarke, South Lambeth:—Journal of Applied Microscopy, Nos. 1-8.

University College, London:—Calendar, 1898.

Mr. R. Hampson, St. Leonards:—Old English Medical MS., with transcript.

Mr. E. Duprey, Jersey:—Essai de bibliographie jersiaise, 1898.

To the Museum (London).

Mr. M. Bateman, Watford:—Living specimen of the Loofah Plant in fruit.

Messrs. Schimmel and Co., Leipsic.—Specimen of Phellandrene.

Mr. W. R. Carles, Tunbridge:—Specimen of a Chinese medicine called Chilian, employed as a vulnerary.

Dr. E. B. Ormerod, Queensland:—Specimens of the root of a Cyperus used in medicine by the natives.

Messrs. Hearon, Squire, and Francis, London:—Specimen of Persian opium in the form of an elongated cone.

Mr. C. E. Sage, London:—Specimens of crystallised Ferrous Ammonio-Sulphate and of Chloride of Sodium.

The African Lakes Corporation, Limited:—Three specimens of pods of *Strophanthus Kombe*.

To the Herbarium.

Mr. E. Lort-Phillips, London:—Specimens of *Adenium Somalense*, a plant used in the preparation of arrow poison.

*6445 voting papers were issued.

COMPANIES AND THE PHARMACY ACT, 1868.

THE common-sense consistency of the view, put forward in a previous Journal, that a combination of unqualified persons keeping open shop as, and assuming the title of, chemists and druggists, infringes the provisions of the Pharmacy Act, 1868, will be sufficiently self-evident to most persons—except lawyers—if fully conversant with the circumstances to which it relates. But that view will be disputed by some, either on account of interests in an opposite direction or other reasons. Chief among those other reasons are imperfect appreciation of the objects that the Pharmacy Act was intended to effect, and perverse disregard of the means by which its administration could have been made more effective in realising those objects. Both have had considerable influence in practically stultifying the Act and furnishing opportunity for its infringement. Some further consideration of the decisions in regard to corporate bodies and of the arguments in favour of the contention that they are not amenable to the provisions of the Act, will, therefore, be useful at the present time. The argument put forward in support of that position by the counsel for the London and Provincial Association in the appeal case, heard by Lord Chief Justice COCKBURN and Mr. Justice MELLOR, was that the *prima-facie* inference to be drawn from the terms of every provision of the Act, is that the word "person" does not apply to, and was not intended to apply to a corporate body. In proof of that he referred to the absence of any mention of corporate bodies in the provision of Section 5, that persons in business as chemists and druggists at the passing of the Act should be registered. He argued that while individuals, registered on the ground of having been in business, would, in the nature of things, die out and thus the possibly incomplete protection of the public would be terminable, companies, registered in virtue of similar vested interest, would have continued for all time, without being liable to the penalties of the Act, however much they might be incompetent to carry on the business, and since that obviously could never have been intended, the inference was to be drawn that the Act was not intended to apply to companies.

That seemingly plausible argument might have been cogent if supported by fact. But it is utterly fallacious; any hypothetical weight it has, rests on the erroneous assumption that such corporate bodies were then in existence. Moreover, if they had been, they would have continued exempt whether the Act applied to companies or not.

The unquestionable fact that every provision of the Pharmacy Act points to the conclusion that "person" is to be understood to mean an individual in the ordinary sense, might perhaps have furnished more reasonable indication of not being meant to apply to a corporate body, if the provisions of the Pharmacy Act had been conditionally permissive, viz., that a person, registered as the Act requires, may keep open shop, etc. But since its provisions are prohibitory they amount to no less than a general prohibition extending to all who are not qualified. The specified qualification being impossible for a corporate body, the object of the Act should therefore be understood as excluding combinations of unqualified persons. Though companies are outside the Act in regard to qualification, they are capable of infringing the Act and ought, at least, to be liable to its penalties, otherwise it might equally be contended that individuals, incapable of qualifying, should be entitled to do, with impunity, what the Act prohibits. The question, therefore, is not so much whether the word "person" should be taken as including a corporate body or not; but whether, having regard to the subject matter and context, corporate bodies should not be understood as absolutely shut out because incapable of qualification. That such was held to be the case in regard to the Pharmacy Act of 1852, by the counsel for the London and Provincial Association, is a notable indication of the inconsistency of his argument. He admitted that no corporate body could assume, or pretend, to be a pharmaceutical chemist, because the Act of 1852 is clearly limited to persons in the ordinary sense. But it is equally inconsistent with the provisions of the Pharmacy Act, 1868, for a company to assume the title of chemist and druggist and keep open shop in that capacity. Nothing in the Act is repugnant to the construction that the term person has the widest significance in regard to infringement; there is really nothing in it which, in that sense, requires the application of the word person to be limited to individuals. As Lord Chief Justice COCKBURN pointed out in his judgment, the fact, so strenuously insisted on by Mr. WILLS, that in all sections of the Act the word "person" is applicable only to individual persons—though tending to show that the adoption of the business of chemists and druggists by companies was not contemplated when the Act was passed—does not by any means show that companies should not be held within the penal sections. On the contrary he held that—the prohibition being general and the mischief clearly within the Statute—companies should not be allowed to break the law under the belief that they are beyond its reach. That common-sense view of the matter induced the Lord Chief Justice to decide that a breach of the law had been committed by the London and Provincial Association, that, as a corporate body, it had incurred liability to penalty by disobedience to a statutory prohibition. Mr. Justice MELLOR concurred with that view after considerable hesitation, on the ground that the great object of the Legislature was to prevent the sale of poisons or dangerous drugs by persons not qualified by skill or experience to deal in such commodities. In that sense he held that the intention as well as the scope of Sections 1

and 15 were for the future absolutely to exclude all persons other than those capable of being registered under the Act. On that ground Mr. Justice MELLOR decided that, in the absence of anything repugnant to such a construction, the interpretation of "person" as including a corporate body, was justified, that an offence had been committed and that the defendant company was liable to penalty under the 15th Section of the Act.

On the subsequent hearing of the appeal against the decision of the LORD CHIEF JUSTICE and Mr. Justice MELLOR, the duplicate signification of the words "sell" and "seller" came under consideration, and much discussion arose upon the notion originated by Mr. GEORGE LAKE RUSSELL—that the object of the Act would be secured where a sale is effected by the hand of a qualified person, although the owner of the shop were a limited company which could not be qualified. Mr. WILLS admitted having great difficulty in adopting that view; but it found favour with Lord Justice BRAMWELL, who held that the mischief to be prevented could be dealt with by prosecution of individual offenders acting as servants of a company. Lord Justice BAGGALLAY took the same view and could not gather from the general scope and purport of the Act any necessity, in the interest of the public, to interpret "person" as including corporation. Lord Justice THESIGER was undecided on that point; but taking into consideration that the motive of the Act was regard for public safety, he was disposed to think corporations should be made subject to the same conditions and restrictions as individuals. He held that a conditionally prohibited act being intended to be entirely prohibited, except under the particular conditions, it consequently cannot be done by a company, even though the conditions are, in their nature, such as cannot be complied with by a company. He also held that the penalty by which prohibition is to be enforced by civil suit is as applicable to a corporation as to individuals, though by no means satisfied that the members would not be individually liable in place of the corporate entity. But the clear intention that the word "person" was in all instances to apply to individuals, and the absence of express reference to companies in the Act, induced him to agree with the other two judges. By that decision, afterwards confirmed by the House of Lords, the necessity of qualification, as the Act provides, in order to carry on the business of chemist and druggist, and to use that title, was practically negated. As a consequence, combinations of unqualified persons have carried on the business as being outside the scope of the Act. So far as the terms of the Act specify they are not under the necessity of employing qualified persons as their assistants. If that position is maintainable it really amounts to a virtual repeal of the Act, for it means that a person desiring to carry on the business is under no necessity to qualify if, with the nominal assistance of six other persons, he forms a limited liability company. A further consequence of that decision and of the imported doctrine that, in regard to public safety, only the mechanical seller need be qualified, is that the function of the Pharmaceutical Society in conducting examinations may be reduced to providing qualified persons to act as assistants to combinations of unqualified persons. Such an absurd result of legislation "expedient for the safety of the public" cannot be spoken of in complimentary terms; but the questions may well be asked—Can that possibly have been the intention of the Legislature? Can it even be the intended outcome of a rational construction of the Act itself?

ANNOTATIONS.

LITERAL INTERPRETATION OF THE PHARMACY ACT, 1868, is not the easiest thing in the world to arrive at, as Mr. J. Rymer Young doubtless realises more than anyone else at the present moment. The attempt he has made, however, to show how certain portions of the Act have been judicially interpreted and how the remainder may be interpreted, should be productive of useful results, even if the only effect is to induce registered chemists in general, and members of the Society in particular, to study the provisions of the Act. They will then realise more fully than at present how the intentions of the Act have been entirely frustrated, except with regard to the imposition of certain checks upon the sale of a limited number of poisons. At the same time they may arrive at the conclusion that, insufficient and ineffective as the provisions of the Act have been made to appear, there are opportunities afforded by the measure which have not yet been clearly recognised. What those are a careful perusal of Mr. Young's paper will reveal, and it is unnecessary to repeat them here.

THE OBVIOUSLY BEST REMEDY for the existing state of affairs is, as Mr. Young points out, for Parliament to make the word "person," wherever used in the Pharmacy Acts, include any corporate body, but whether that remedy can be applied remains to be seen. For the present, the possibility of an attempt being made to secure the application of such a remedy is not assured, and nothing short of the support of a very large majority of registered chemists is likely to be held to justify the attempt. Resolutions in favour of the total suppression of unqualified company pharmacy afford interesting reading, and a fair number of such resolutions will doubtless come before the Council of the Pharmaceutical Society at its next meeting. But what action will follow must depend in very great measure upon the number of names submitted for election to membership of the Society at that and subsequent meetings. No good purpose can be served by masking that fact, for vastly increased support—both moral and financial—is essential if the Society is to take action on the bold lines proposed in different parts of the country, and the sooner that support is definitely tendered the sooner will it be possible to organise a satisfactory plan of campaign.

THE OBJECTIONS TO COMPANY PHARMACY, it may be well to state here, must be based on something stronger than the self-interest of registered chemists, if they are to attract and secure the attention of legislators. At the present time the two things which are legally restricted in connection with pharmaceutical practice are the use of certain titles and the sale of poisons. Owing to the accident that corporate bodies were not mentioned in the Pharmacy Acts, those restrictions have been considerably relaxed, for a corporate body can freely sell poisons by the hand of a duly qualified agent, and it is even assumed that such a body is quite at liberty to use any of the titles supposed to be restricted to the use of registered persons. Now, if the Legislature is to be asked to remedy this state of affairs, good reasons must be advanced in favour of the imposition of restrictions that do not exist at present, so far as corporate bodies are concerned. And as it may shortly be necessary for every chemist in business to communicate with his parliamentary representative in the matter, it will be as well for him to consider in advance what are good reasons and what are not.

THE CHIEF ARGUMENT that found favour with the judges who finally decided against the Pharmaceutical Society in the case of

the London and Provincial Supply Association, was that it seemed quite immaterial whether the individuals constituting a corporation were duly qualified or not, so long as the paid servant of the corporation who performed the physical act of sale was a registered person. In other words, the idea conveyed by the judicial decision was that, so far as the public safety is concerned, it is not of the least importance to whom the capital invested in the business belongs, or who benefits by the profits from the business, so long as the would-be purchaser of poison is able to deal directly with a registered chemist. Whether that registered chemist was the proprietor or part-proprietor of the business did not, in the judges' opinion, concern the public in the least degree. The logical conclusion we are driven to in considering this decision is that the State is only concerned about the qualification of assistants in pharmacies, and cares nothing whatever about that of the proprietors.

THE FALLACY underlying the argument of the judges—whose decision was fraught with such momentous consequences to registered chemists in business on their own account—is this very assumption that the qualification of the proprietor is of no moment. For it must of necessity rest with the proprietor of a business to decide to what extent the assistants employed in that business shall exercise discretion in the sale of certain articles. In the case of a joint-stock company, the only reason for the existence of which is to make money for its shareholders, it is extremely doubtful if any check is imposed upon the enterprise of assistants except that of keeping within the strict letter of the law. It is not for the soulless, artificial person, created by Act of Parliament, to put any hindrance in the way of its assistants selling scheduled poisons as freely as asked for, so long as they do all that is requisite in the way of labelling, and registration if necessary. The assistant's business is to turn over the stock as rapidly as possible, and to help the directors of the company to declare a good dividend. If a purchaser asks for a suspicious quantity of poison, it is not to the assistant's interest to object to supply it.

THE REGISTERED PROPRIETOR, however, looks at such matters in a totally different light. He recognises that he exists for something more than making money, inasmuch as he owes a duty to the public. His position as a professional man will not allow him to regard the sale of poisons simply as a means of profit, and his assistants are instructed not to supply poisons of any kind unless they are quite sure that everything is straightforward in the transaction. The amount of profit on the poison sold is not for one moment allowed to enter into consideration, and it is safe to say that every registered chemist in business on his own account in Great Britain can recall scores, if not hundreds, of cases in which he has deliberately refused to supply poisons over the counter. Some go so far as to decline absolutely to sell any quantity of such poisons as strychnine, aconitine, cantharides, and even morphine or opium, unless prescribed by a medical practitioner. And whether such extreme caution is called for or not, there is not the least doubt that a duly qualified proprietor of a pharmacy is a surer safeguard for the public than any number of qualified assistants in a drug-store carried on by a company of unqualified persons.

MEETINGS OF PHARMACEUTICAL ASSOCIATIONS have been held in most parts of the country this week, and, by an unfortunate chance, half a dozen of the more important ones were held on Wednesday evening, the worst possible time from a press point of

view. For, as a result, it has been necessary to have the Journal reports of some of those meetings transmitted by telegraph, and they are necessarily much more scanty and incomplete than would have been the case if they could have been sent through the post in the ordinary way. The fact of reports arriving just before going to press also tends to brevity in the printed accounts of what has taken place, and members of Associations who object to curtailed reports should note that the curtailment is probably due to the fact that they choose the worst possible night in the week for their meetings. It is convenient, by the way, to have the opinions of Associations so widely separated geographically as are several of those reported this week, presented simultaneously for consideration by readers of the Journal, and though some of the reports are brief, yet they contain what is most essential, *i.e.*, the resolutions agreed upon at the meetings. So far, pharmaceutical opinion throughout the country appears to be fairly unanimous, and if the opinions expressed are confirmed by the attitude adopted during the next few weeks by chemists and druggists generally towards the Pharmaceutical Society, something approaching what is so widely asked for may be secured, if not all.

THE WESTERN CHEMISTS' ASSOCIATION OF LONDON is announced to deal with the Federation programme on Wednesday next, December 21, after the delivery of an inaugural address by the new President, Mr. J. F. Harrington, who has recently been elected a member of the Council of the Pharmaceutical Society. Reference to the Federation programme leads us to direct attention to the force that useful organisation has become in pharmaceutical circles. Many registered chemists hardly comprehend yet what the Federation is, but few who take the least interest in affairs can now be ignorant of its programme for the year. To explain once more what the Federation is, we may state that it is not an association, but simply a bond of union between pharmaceutical associations in different parts of the country. Between forty and fifty such associations are now federated and so brought into constant touch with each other. The President of the Federation is Mr. W. L. Currie, of Glasgow, and the Hon. Secretary, Mr. R. C. Cowley, of Liverpool. The position occupied by the latter gentleman is that of a living clearing house, for he receives communications from any association, and communicates it to all the rest. What useful work it is in his power to accomplish is shown by the results of the numerous meetings now being held all over the country and dealing with the same important subjects at or about the same time.

A SPECIAL GENERAL MEETING of the members of the Pharmaceutical Society will be held at 17, Bloomsbury Square, London, W.C., on Wednesday, January 11, 1899, at 3 p.m. precisely, for the purpose of considering and, if thought fit, of adopting regulations for the keeping, dispensing, and selling of poisons in conformity with the provisions of the Pharmacy Act, 1868. Notices of motion for this meeting have been intimated by Mr. R. A. Robinson, the first being as follows: "That the Pharmaceutical Society of Great Britain resolves to adopt regulations for the keeping, selling, and dispensing of poisons in accordance with the provisions set forth in Section 1 of the Pharmacy Act, 1868," A second notice of motion by Mr. Robinson is to the effect that the recommendations for the keeping, dispensing, and selling of poisons, adopted at a general meeting of the Pharmaceutical Society on May 17, 1871, shall be adopted by the Society as regulations in accordance with the provisions set forth in Section 1 of the Pharmacy Act, 1868.

THE THREE RECOMMENDATIONS referred to are given in full in the official notice calling the special general meeting, and printed in our advertisement pages this week. Although Mr. Robinson's notice of motion proposes that the recommendations shall be adopted in their entirety, it will not be incumbent upon the meeting to accept that motion without amendment. In fact, it is extremely improbable that it will be so accepted, the opinion being pretty general that the recommendations are more or less obsolete. At the same time they will serve as a basis for discussion, and no difficulty can arise through the members of the Society assembling without having something definite to deal with. It is hardly necessary to say that, between now and the time of the meeting, the pages of the Journal will be open to receive suggestions for poison regulations, and as any regulations actually adopted will, if approved by the Privy Council, virtually become part of the Pharmacy Act, 1868, it should be apparent that the matter is one for the most serious consideration.

IN MR. RYMER YOUNG'S REMARKS on this subject, the curious fact is pointed out that, according to the wording of Section 15 of the 1868 Act, no penalty can be imposed for breach of any regulations that may be adopted with regard to the "dispensing" of poisons. Regulations dealing with the sale of poisons already exist, of course, in Section 17, but it may be found desirable to amplify them. It is, however, with regard to the keeping of poisons that regulations are more especially required, and that is the point on which the Privy Council is understood to be most strongly insistent. As we have on many occasions remarked in these columns, most registered chemists in business on their own account already adopt satisfactory regulations for the keeping of poisons in their pharmacies, and the only result of the formal adoption of regulations by the Pharmaceutical Society will be to make the procedure uniform in pharmacies throughout Great Britain.

THE SECRETARY OF THE PHARMACEUTICAL SOCIETY desires us to announce that, owing to pressure of official detail work involved in carrying into operation the provisions of the Pharmacy Acts Amendment Act, 1898, he regrets to find himself unable to reply very promptly to the numerous communications he is now receiving. He, therefore, begs his correspondents to excuse the unavoidable delay. All correspondence will be dealt with as quickly as possible under the circumstances.

THE CHEMISTS' BALL, as everyone connected with pharmacy ought to know, is to be held, for the thirty-third occasion, at the Portman Rooms, London, on Wednesday, January 18. The Hon. Secretary to the Ball Committee, Mr. W. Warren, is anxious to have a record list of stewards on this occasion, and desires that the date of the ball should be carefully noted in everybody's diary. The duty of a steward, it may be pointed out, is to dispose of tickets, but he is not obliged to make himself responsible for a greater amount than thirty shillings—the cost of two tickets, one each for a lady and a gentleman respectively. The Hon. Secretary, who may be communicated with, by intending stewards, at 24, Russell Street, Covent Garden, W.C., asks us to direct special attention to the fact that this will be the last Chemists' Ball "in the eighteen hundreds." Doubtless that will be considered an amply sufficient reason for the purchase of extra tickets by all our readers who are interested in the matter. The fact does not appear to be too relevant, but it is probably relevant enough.

THE NEW UNIVERSITY OF LONDON will require a suitable place of lodgment, and it is interesting to note that a resolution has

been adopted by the Council of University College, London, in which it is stated that the Council is prepared to summon a general meeting of the members of the College, and to propose to them that such steps should be taken as may be necessary for placing the site, land, buildings, and endowments of the College at the complete disposal of the reconstituted University. In making this offer the Council does not desire to throw any obstacle in the way of any other institutions in London, which may be disposed to place their resources at the disposal of the Governing Body of the University, but it will be necessary, in accordance with the precedent afforded by the Universities Act (Oxford and Cambridge), to protect the interests of the existing teachers and executive staff of the College. The existing teachers are, however, to have no claim as such to any rank in the re-constituted University, or to any vested interest, other than that they now have in the College. It is interesting to recall the fact that University College was originally founded as the University of London, with the object of providing a complete university education in London of the highest type.

THE OLD UNIVERSITY OF LONDON has under consideration a proposal to transfer its headquarters from Burlington House to the Imperial Institute. It would thereby gain laboratory accommodation for the practical parts of its examinations, and would also naturally become the nucleus of the new teaching university. In the opinion of the *Standard* the proposal is, on the whole, advantageous to the existing university, the more especially as it would provide a practical use for the stately fabric of the Imperial Institute, which for various reasons has not fulfilled the hopes entertained when it was founded. For the present, it appears, the new university is to be lodged in certain spare apartments at the Imperial Institute. With regard to any more permanent arrangements, the *Standard* suggests that a building constructed for one purpose cannot successfully be utilised for another unless considerable expense is incurred. In addition, it is urged, as a not inconsiderable drawback to the plan now brought forward, that what is intended to be a teaching university for the whole of London would be established in a position convenient only for the West-end, and equally inaccessible to students from the northern, southern, and eastern districts of the Metropolis. To carry out the purpose for which the new university is destined it seems to require something which may be described as a central situation, and that is offered by University College.

AT THE ROYAL INSTITUTION the following lectures will be delivered before Easter:—Sir Robert Ball, six lectures (adapted to young people) on "Astronomy"; Professor E. Ray Lankester, ten lectures on "The Morphology of the Mollusca"; Mr. A. Henry Savage Landor, three lectures on "Tibet and the Tibetans"; Dr. Allan Macfadyen, four lectures on "Toxins and Antitoxins"; Mr. William Poel, three lectures on "English Playhouses in the 15th, 16th, and 17th Centuries"; Sir Alexander Mackenzie, three lectures on "Liszt, Tschaikowsky, Brahms" (with musical illustrations); the Right Hon. Lord Rayleigh, seven lectures on "The Mechanical Properties of Bodies." The Friday evening meetings will begin on January 20, when a discourse will be delivered by Professor Dewar on "Liquid Hydrogen." Succeeding discourses will probably be given by the Right Hon. Sir Mountstuart E. Grant Duff, Mr. Victor Horsley, Professor H. S. Hele-Shaw, Mr. Richard R. Holmes, Sir Frederick Pollock, Bart., Professor H. L. Callendar, the Right Hon. Lord Rayleigh, and other gentlemen. The year 1899 is the centenary year of the Royal Institution, and arrangements are being made with a view to its celebration in a fitting manner. Details will be announced at a later period.

LIVERPOOL CHEMISTS' ASSOCIATION.

The usual monthly meeting was held on Thursday evening, the 8th inst., at the Royal Institution, the PRESIDENT, Mr. Bain, in the chair. Two new members, Messrs. C. W. Dalrymple and J. F. Woods, were elected, and several miscellaneous communications were brought forward.

Paraffin Bases; Robin's Syrup; Opium Assays.

Mr. PROSPER H. MARSDEN gave his experience with the various paraffin bases sold as paraffinum molle, B.P., saying that not one of the samples he had examined had a melting point within the limits of the B.P. 1898, viz., "96° to 102° F. or even somewhat higher," his experiments showing as a mean of four estimations for each sample 106°, 107°, and 108°. It was advised that Mr. Marsden pursue his investigations further and report at a latter meeting.

The PRESIDENT wished to know what should be the colour of syrup of the glycerophosphates according to Robin's formula. He believed it should be about the tint of Parrish's syrup, but he had had it of all colours, from brown and caramel-like to almost purple.

Dr. SYMES said that it was red in colour; at any rate, that made by a London firm of foreign chemists was, and he might say that the published formula known as Robin's gave a very different preparation, and one which did not remain clear.

Mr. H. WYATT, jun., had had a communication from a former member of the Liverpool Pharmaceutical Students' Society, Mr. C. Ludlow Taylor, who, whilst in Rome, wrote respecting this syrup, that what he dispensed frequently (made by a firm in Florence) was a bright red coloured syrup of light specific gravity, evidently containing, in addition to the active ingredients, chloroform as a preservative. A friend of Mr. Wyatt's recently made some of the syrup from Robin's formula and was surprised that the product turned out of a distinct violet colour. On inquiry it was found that the cherry syrup used contained salicylic acid as a preservative, and this naturally reacted with the iron salt present to form the deep-coloured salicylate. A syrup could be flavoured without the cherries by using vanilla, and almond essences with enough tincture of orris, or a flavouring of the culinary essence of maraschino might be tried instead.

Mr. COWLEY said he employed for the separation of the ethereal layer in opium assays an ordinary male syringe with an indiarubber band covering the cotton packing so as to fit the bore accurately, and yet prevent small crystals of morphine becoming attached to the cotton.

Mr. HORNBLLOWER found the same purpose was answered by a pipette with an indiarubber teat, which had the additional advantage of only requiring the use of one hand for its manipulation. Pouring off the ether, even when a larger amount than that ordered in the B.P. was used, was not a good method.

Mr. A. C. ABRAHAM had been in the habit of using ether freely, but if it were true that morphine was dissolved by it to any appreciable extent, as Mr. Cowley seemed to imply, it raised a rather serious point. He knew that "ether purus" might contain alcohol, and it was possibly the presence of this that accounted for the seeming solubility of morphine in ether.

Mr. COWLEY said, in reply, that the ether did dissolve a certain amount of morphine, therefore more ether than ordered in the B.P. should be used. Mr. Abraham had overlooked the point that ether was used, not only to keep narcotine, etc., in solution, but also to assist in the crystallisation of the morphine.

The PRESIDENT then called on Dr. Symes to open a discussion upon the resolutions passed by the Federation of Local Pharmaceutical Associations at the Belfast meeting in August last.

The Federation Proposals.

Dr. Symes commenced by referring to the usefulness and activity of the Federation of Local Pharmaceutical Associations, and expressed the hope that Associations throughout the country would readily respond to the invitation to discuss those proposals. He agreed with the suggestion that persons trading under ancient titles or any other name than their own should also use their own names in conjunction therewith. Local Associations should certainly use their best efforts to induce registered chemists to become members of the Pharmaceutical Society. It had long been his cherished hope that the time would arrive when every registered chemist would be a member of the Society. With regard to poison regulations, he felt assured that it would be

beneficial to the whole craft if such regulations were adopted. It is generally admitted that the regulation which requires that when a poison is sold it shall be labelled poison is a just one, and inflicts no hardship on the person who sells; no more can it be a hardship to demand that the same poison, if a liquid, should be sold in a poison bottle, and not in a teacup. As to the keeping of poisons, most chemists do, and all ought to take some precautions for keeping them in some way separate or distinguishable from harmless substances. There can be no hardship in compelling a few careless men to act more carefully, and do what the great bulk of chemists are doing voluntarily for the public safety. The last suggestion in the Federation circular was that during the ensuing winter session each association should consider the whole question of company trading, as it affects the legitimate interests of registered chemists and the protection of the public safety aimed at in the Pharmacy Acts, and that an effort should be made to formulate some definite line of policy on which all registered chemists could agree to act. It must be pointed out that there are large companies, such as the Army and Navy Stores, where only members are supplied; stores where the general public are supplied; companies formed by *bond-fide* chemists and druggists for carrying on a legitimate trade; and a large number of companies formed by unqualified persons to enable them to evade the Pharmacy Act. The Council of the Pharmaceutical Society had sent to the Lord Chancellor a letter in relation to companies, with a view of enlisting his sympathy and action on behalf of pharmacy, as the Medical Council has also done on behalf of medicine and dentistry. All that is asked for may not be obtained, but some good will probably result if chemists can get the ear of the Government. If, however, they hoped to do that they must first place themselves in accord with its wishes by adopting "regulations" such as had already been referred to. In conclusion Dr. Symes moved—

- (a) That any person or persons carrying on the business of pharmacy under other names than their own should use their own names or name in addition to that under which they trade.
- (b) That this Association will use its best efforts to induce registered persons to become members of the Pharmaceutical Society.
- (c) That the "recommendations" issued by the Council of the Pharmaceutical Society for the keeping, selling, and dispensing of poisons or some modification thereof, should become "Regulations" under the Pharmacy Act, 1868.

The PRESIDENT, in seconding the proposed resolutions, said that it was to the interest of old-established firms that the individuals actively engaged in conducting their business should be known to their customers. That being so, no one in such a business could reasonably complain of resolution (a). He predicted a large accession to the number of members of the Pharmaceutical Society now that the old ridiculous regulations as to membership had been done away with. The storage of poisons was a question which could only be solved by some definite regulations on the subject, regulations which would simply be reducing to order the many systems which chemists had for their own protection already adopted. In attempting to get through anything in the nature of effectual legislation with the object of limiting the operations of illegitimate or company trading he was afraid they had a hard nut to crack, and so long as such companies availed themselves of the services of fully qualified managers he was of the opinion that no Government could be persuaded to pass a Bill of the kind required by the trade. Such a Bill was almost indispensable to the well-being of the chemist's and druggist's business, yet he was forced to say their chances of getting their desire were small indeed. He had pleasure in proposing a vote of thanks to Dr. Symes for the able manner in which he had put the various points before them.

Mr. COWLEY, in a forcible speech, said the present state of affairs was due undoubtedly to the weak-kneed policy of the Pharmaceutical Society in days gone by, when it was afraid of attacking its enemies for fear of implicating its friends. The Wheeldon case, however, forced its attention to notice the corruption existing within its own body, since which time a happier and more manly policy had been adopted. Now the Society was about to make good the trust placed in it by the Privy Council thirty years ago by taking up, in a thorough manner he hoped, the question of the storage of poisons—a matter it had hitherto shamefully neglected. Mr. Cowley then went on to elaborate the views put forward by him in his recent address to the Liverpool Pharmaceutical Students' Society, already fully reported in the *Pharmaceutical Journal*.

Messrs. STOCKDALE and HOCKEN supported the expressions of opinion given vent to by the previous speaker, and Mr. Hocken, as an old member of the Society, said that his experience of the good

done by the Act of 1868 was not of a very encouraging nature; still, it appeared that the Society had now realised to the full its duty, and he believed with the support it should now receive from the bulk of the trade it would obtain that power it had so far lacked and be in a position to do something for the amelioration of the plight into which pharmacy had fallen.

The SECRETARY here read a letter from Mr. John Smith, the Society's local secretary, regretting his inability to attend the meeting, and saying that in case a Bill were presented to Parliament he personally would be in favour of an attempt to entirely remodel the laws governing the practice of pharmacy. He would let the so-called "Widow's Clause" go, and would approve of the regulation of the storage of poisons. Such a Bill should make it illegal for other than properly registered persons to keep open shop for retailing poisons or to exhibit such misleading descriptions over their shops as "drug store."

Dr. SYMES, in his reply, defended the Pharmaceutical Society from the charge of apathy, saying that none who had had the same amount of insight into the work done by the Society since 1868 as he had could in common fairness charge it with want of either energy or the desire to pass Bills of a protective nature. Such Bills had been drafted without cessation, and had mostly met the same fate. The only way to get anything done of real use to pharmacists was to set themselves right with the Privy Council in the first place by assuming their just responsibility, and then they might succeed in their modest demand to have the sole right to sell poisons and the sole right to dispense medicines.—The motion proposed by Dr. Symes was then put to the meeting, and carried unanimously.

A Note on Distilled Extract of Witch Hazel

was then contributed by Mr. HAROLD WYATT, jun.—In working recently with a variety of aldehyde reagents he had been much struck with the delicacy of that of Schiff—a solution of magenta decolorised with a sulphurous acid—which gives a violet red with even the minutest traces of aldehyde. The odour of the distilled extract of witch hazel somewhat recalls that of a weak solution of formalin, and as the extract is made from the fresh plant the presence therein of formaldehyde is at any rate probable, if one is to believe the theories of botanical physiologists. With this in view the extract was treated with Schiff's reagent, with the immediate production of a coloration. At first sight this might have been taken as fairly conclusive evidence of the presence of formaldehyde, but further examination showed that the extract was similar to that of the Pharmacopœia, being prepared with alcohol; to traces of aldehyde in which the coloration was undoubtedly due, for the application of all the known tests for formaldehyde itself failed to give the slightest indication of its presence. This confirms the result arrived at by Mr. Alexander Gunn in a similar investigation some time ago published in one of the trade papers.

Mr. Theo. H. Wardleworth then read—

A Note on Thyroglandin, its Uses and the Manufacturing Facilities Liverpool Possesses for its Production in Large Quantities.

The author said that in view of the important position preparations of the thyroid gland were assuming, and the success which attended their administration in cases of obesity, myxœdema, and kindred diseases, it was very important that the very best preparation should be employed. He, therefore, ventured to bring under their notice an article which was just appearing on the market, and which was free from many objections connected with the dried gland, namely, thyroglandin (Stanford). This preparation was really a standardised product of the thyroid gland prepared under conditions which preserved in the best possible manner all the active ingredients of the sheep glands. While the elements of the article were constant and reliable, it had the virtue of being five times the strength of the raw gland, and in use had effected results of the most satisfactory character where the simple gland had failed. In virtue of its method of manufacture it was free from the tendency to decomposition exhibited by other products of a like nature. It possessed the further merit of being made in Liverpool, where the best facilities in the country existed for securing a good supply of the fresh glands, as more sheep were killed in Liverpool in a week than in all the country beside in the same time. At present it was prepared and dispensed in the form of a powder, but the manufacturers were arranging to put it up in the form of granules for convenience of dispensing.—During the discussion following the reading of this paper Mr. PROSPER H.

MARSDEN mentioned a case they had had at the Royal Infirmary which had been relieved in a remarkable manner by the use of the ordinary thyroid powder. It was a case of sporadic cretinism, in which the continued use of thyroid caused such an alteration in the form and texture in the bone of the hand that radiograms taken before and after the treatment showed the change in an exceedingly clear and marked manner.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the above Association was held on Friday, December 9, Mr. F. A. UPSHER SMITH in the chair.—The attendance augured well for the success of the Association this year, as there were forty-one members present.—Mr. H. PAYNE, in the temporary absence of the Secretary, brought forward a proposal that the time of meeting be altered from 5.30 to 5 o'clock.—After the minutes of the previous meeting had been read and confirmed, the real business of the evening began, when Mr. P. B. GRAY opened a discussion on the proposed division of the Minor by proposing:—

That in the opinion of the School of Pharmacy Students' Association the Minor should be divided into two parts, consisting respectively of a theoretical and a practical part, the theoretical to be taken after three years' apprenticeship, the candidate to be not under 20 years of age; the practical to be taken after a lapse of one year.

Mr. Gray supported his proposition in a very able speech, in which he pointed out the benefits which would result from such a division. He argued that it would result in a class of men coming forward who would look on their apprenticeship as a time for preparing for the first examination, which would supersede that class of men who now postpone all their studies till they go to college. His plan for dividing it was as follows:—The first portion should consist of an examination in theoretical chemistry, botany, and physics, the second part in practical chemistry, dispensing, practical pharmacy, and practical materia medica, and he pointed out how utterly impossible it was to study materia medica until a student had some knowledge of botanical terms. He thought that the large percentage of failures at the last Minor examination showed clearly there was something wrong with the present system. Mr. E. W. EWELL seconded the resolution.

Mr. H. PAYNE proposed as an amendment:—

That this meeting of the School of Pharmacy Students' Association views with regret the desire in some quarters for the division of the Minor examination, and, considering the present state of that examination, it deems such a division is entirely undesirable and unnecessary, and is inimical to the welfare of pharmacy.

He went on to say that while the examination is sufficiently severe to safeguard the public, it is not above the power of men of average ability, and considering the increased facilities nowadays afforded by science classes all over the country, the examination is no harder to candidates to-day than it was to the men of thirty years ago. And if the examination were divided, the difficulty of passing it might be decreased, and we should have men entering the ranks of pharmacy of inferior mental ability, which would be extremely undesirable. Mr. Payne thought that while pharmacy is allied to trade as it now is, a higher qualifying examination would be quite unnecessary, and that the only people who supported division were a few incompetent would-be pharmacists. A further argument was that division increased expense without giving corresponding advantages.—Mr. J. EVANS seconded the amendment, and, in a few well-chosen remarks, supported the views of Mr. Payne, pointing out that theory and practice cannot be divided; they must go hand in hand, it being quite impossible to study scientific theory without the help of experiment, whilst to study practice without theory would lead to some surprises.—Mr. CHAPMAN spoke in favour of the amendment. He considered that the present state of trade did not render it practicable to increase the expense of passing the qualifying examination, considering the salaries earned by qualified men are only about £50 or £60. He thought the deplorable number of failures in the Minor was due to the low standard of men who entered the drug trade, as evidenced by the fact that out of 1414 candidates who entered for the Preliminary in the year ending April, 1898, 737 failed, and out of the 737, 311 failed in every subject.—Mr. DURBIN was in favour of the amendment, and attributed the large percentage of failures at the last Minor to the students hurrying to get through before they were examined on the new B.P.—Messrs. Perrédès, Garsed, Spurway, Wallis, Baker, and Padwick

expressed themselves in favour of division, and Messrs. Battle and Finnemore spoke in favour of Mr. Payne's amendment.—The CHAIRMAN, in an impartial speech, then summed up, and pointed out that the present Minor examination was not calculated to turn out all-round, capable pharmacists, considering that a thorough knowledge of the B.P. cannot be attained until the student has passed through a course of organic chemistry and advanced *materia medica* as required for the Major examination. Voting took place with this result: For the resolution 16, for the amendment 11.—The meeting then adjourned.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held on December 7, at the Exchange Rooms, Birmingham, the President, Mr. J. SELBY, occupying the chair.

Mr. JOHN BARCLAY, B.Sc., read some further notes on

The Standardisation of Strophanthus Preparations,

in the course of which he gave a *résumé* of the method for assaying strophanthus advocated by him in 1896, an account of which is given in the *Pharmaceutical Journal* of November 25, 1896. He alluded to the alteration in strength of the 1898 tincture and pointed out that the preliminary treatment of the seeds with ether before extraction with alcohol had been done away with in the case of the tincture, but retained as part of the process for making the new extract. From experiments which he had made he found that a tincture prepared by the new process contained more strophanthin than when made by the old, and his experiments led him to the conclusion that a percentage of 0.3 per cent. of strophanthin in the new tincture would be the most useful standard to adopt. Mr. Barclay then proceeded to discuss the new extract of strophanthus, the utility of which, he said, had already been questioned by many commentators on the new Pharmacopœia. Since, however, the extract was an official preparation, and a somewhat potent one, it seemed desirable that it should be made to contain a definite percentage of active principle, and following the lines of the method suggested by the author for standardising the tincture, the following process was recommended for the extract: Dissolve 5 grammes of the extract in water, filter, shake the filtrate with two successive 5 C.c. of chloroform; the chloroformic washings agitated with a little pure water are rejected, and the mixed aqueous washings acidified with 1 C.c. sulphuric acid (50 per cent.), and heated on water bath for one hour. After cooling, the liquid is transferred to a separator and extracted with three washings of chloroform, chloroform is washed with water (to free from acid), distilled, and the residual strophanthidin dried at 150° F. The amount of strophanthidin yielded multiplied by 20 and divided by 0.365 gives the proportion of strophanthin present in 100 grammes of the extract. With regard to the strength to be chosen for the standard, 4 per cent. was suggested as a reasonable figure, that percentage being on all fours with that chosen for the 1885 tincture made like the new extract from seeds previously treated with ether. Five samples of seeds treated according to the official method gave extracts containing respectively 2.02, 2.55, 3.28, 3.22, and 4.33 per cent. of strophanthin. The variation indicated is probably largely due to the varying temperature used in preparing the extracts. In the case of the first two sample, steam heat was employed, while in that of the other three a water bath was used. The seeds from which the fourth sample was prepared yielded, on assay, 8.02 per cent. of strophanthin, and should therefore give an extract containing 4.01 per cent. instead of 3.22 per cent., as found, proof being thus afforded that the application of heat to the limited extent ordered by the Pharmacopœia results in the destruction of some of the active principle.—Mr. BARCLAY, having expressed his thanks to Mr. E. W. Mann for assistance in preparing the foregoing paper, then proceeded to suggest the desirability of having exact standards for the tinctures of the British Pharmacopœia. It was urged to be essential for the sake both of the pharmacist and of the public that guidance as to the requirements of the Pharmacopœia should be as definite as possible, and that the margin of variation in the strength of tinctures, due to variability in the drugs used, should be reduced to a minimum. The following list—the result of numerous experiments conducted by the author—was submitted:—

Proposed Standards for Official Tinctures.

Tincture.	S. G. at 15.5° C.	Percentage.
Aconiti	0.890	0.02 ether-soluble alkaloids
Aloes	0.970	7.0 total solids†
Arnicae	0.894	0.60 total solids
A. fetidae	0.914	10.0 resin
Aurantii	0.885	2.0 total solids
*Bella tonnae	0.914	0.05 total alkaloids
Benzoini Comp.	0.900	2.5 benzoic and cinnamic acids
Buchu	0.934	4.0 total solids
Calumbae	0.920	0.8 total solids
*Camphorae Comp.	0.920	0.05 anhydrous morphine
Cannabis Indic.	0.846	4.00 total solids
Cantharidis	0.838	0.25 total solids
Capsici	0.896	1.50 total solids
Cardamomi Comp.	0.948	6.50 total solids
Cascarillae	0.900	1.60 resin
Catechu	0.977	14.50 total solids
Chiratae	0.920	0.80 total solids
*Chloroformi et Morph.	1.012	
Cimicifugae	0.924	2.00 total solids
*Cinchonae	0.918	1.00 alkaloids
*Cinchonae Comp.	0.918	0.10 alkaloids
Cinnamomi	0.904	2.40 total solids
Cocci	0.955	2.50 total solids
Colchici	0.953	0.075 colchicine
Conii	0.896	0.09 total alkaloids
Croci	0.927	3.00 total solids
Cubebae	0.840	2.00 oleo-resin
Digitalis	0.932	3.60 total solids
Ergotae Ammon.	0.934	4.00 total solids
Ferri Perchloridi	1.086	
Gelsemii	0.925	0.025 gel emine
Gentianae Comp.	0.966	5.00 total solids
Guaiaci Ammon.	0.900	15.0 resins
Hamamelidis	0.952	2.0 total solids
Hydrastis	0.925	2.5 total solids
Hyoscyami	0.953	0.008 alkaloids
*Iodi	0.878	2.5 iodine
Jaborandi	0.953	0.048 p locarpine
*Jalape	0.906	1.50 resin
Kino.	0.995	5.00 kino tannic acid
Krameriae	0.938	5.00 total solids
Lavandulae Comp.	0.836	0.60 total solids
Limonis	0.888	2.00 total solids
Lobeliae Aetherea	0.816	0.07 lobeline
Lupuli	0.938	4.00 total solids
Myrrhae	0.854	5.60 resins
*Nucis Vomicae	0.912	0.25 strychnine
*Opii	0.958	0.75 anhydrous morphine
*Opii Ammoniat	0.895	0.113 anhydrous morphine
*Poleophylli	0.850	3.65 resin
Pruni Virgin.	0.934	3.00 total solids
Pyrethri	0.900	1.60 total solids
Quassiae	0.946	0.016 quassin
Quillaiae	0.919	1.25 total solids
*Quinine	0.894	2.00 quinine hydrochlor.
*Quinine Ammoniat.	0.925	2.00 quinine hydrochlor.
Rhei Comp.	0.970	4.50 total solids
Scillae	0.960	10.00 total solids
Senegae	0.938	4.80 total solids
Sennae	0.988	10.00 total solids
Serpentariae	0.896	2.00 total solids
Stramonii	0.962	0.04 total alkaloids
Strophanthi	0.892	0.30 strophanthin
Sumbul	0.898	2.50 total solids
Tolutana	0.860	2.0 benzoic and cinnamic acids
Valerianae Ammoniat.	0.942	3.00 total solids
Zingiberis	0.835	0.40 total solids

* Officially standardised.

† Total solids in all cases to be dried at 100° C.

DOVER CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held on Thursday, December 8, Mr. H. PEAKE, J.P., C.C., in the chair.—The usual routine business having been transacted, Mr. Peake was unanimously re-elected Chairman for the ensuing year, with the best thanks of the members for past services. Mr. Ewell was also re-elected Secretary and Treasurer.

Mr. BOTTLE having put before the meeting the proposed action of the Pharmaceutical Council with regard to the poison regulations and the letter to the Lord Chancellor, Mr. W. J. BARNES said that he would propose a resolution, and in doing so he wished to point out that, before asking the support of the Government in favour of

AN ACT TO AMEND THE PHARMACY ACT OF 1868,

in accordance with the intention of the Legislature when that Act was passed, it was very necessary that chemists should first

put their own house in order. When the Society approaches the Privy Council, it is at once met with a reminder that no poison regulations have been framed, as was originally intended, and there is no doubt that the Society has been in bad odour with the Privy Council in consequence. Just now seems a very good opportunity of putting things on a better footing, and he earnestly hoped that the whole body of chemists would unite in agreeing to these regulations, and he would urge on every member of the trade the importance of joining the Society. Unless the Society can say that it represents the great majority of the chemists, its influence and power is very much weakened. One other thing he would like to mention, and that was the desirability of abolishing the so-called "Widow's Clause." Were this done, he felt sure it would help considerably to further the efforts to stop company trading. There were probably very few widows carrying on business, and there was no doubt it would be better in almost every case for the widow to dispose of the business on the death of her husband.

Mr. J. F. BROWN said the proposal of the Deputy-Mayor had his cordial sympathy, but he could not conceal from himself the belief that before reaching the position they aspired to they had a long hill to get up. He might claim for chemists that they were more highly educated than the average tradesman; they had often been the pioneers of scientific progress, and certainly in present company he could maintain that they undertook their full share of civic duty. Yet what position did they occupy in public opinion? Chemists were the Ishmaelites of the shopkeeping community—poached upon by nearly every other member. Often they were deprived of their scanty emoluments by the action of the medical profession; unjustly aspersed by coroners ignorant of law, and medicos innocent of pharmacology; libelled by those brigands of modern commerce, the cutters; whose plea for public favour was couched in the terms of St. Paul's appeal to his converts "I robbed other men to do you service." Their motives and honesty were constantly slandered by the big bullies who could spend vast sums in incessant and brazen self-assertion, and, lastly, the educated public to a large extent meet the statements of chemists about the wares they vend with habitual incredulity and invincible distrust. Before their position could be greatly improved a great change must come over the public attitude towards any privilege or monopoly granted to those who have proved their competence to serve the community in any capacity. There were indications that such a change was in progress. The action taken by the dentists, the opticians, and the plumbers showed the trend of public opinion. But the times were far from being ripe yet, and he wished to utter a word of warning against expecting too much from even the return of a member to Parliament to represent their interests.

Mr. BARNES thought it was very desirable that chemists should have

SPECIAL REPRESENTATIVES IN PARLIAMENT,

and he had for a long time hoped that steps would be taken to secure the services of chemists with the ability to advocate their cause in the House of Commons; he was certain that it would be greatly to their advantage. All Governments were much more susceptible to a body of men whose representatives got in the House; as an instance of this he would mention the case of Elementary School teachers. They had been trying for years to get a Pension Bill passed, but without success until the present House of Commons was elected. They have two representatives now, one on each side of the House, and as a consequence he believed a Pension Act was passed last session. It was the same with other associations, everybody was represented but the chemists, and if they did not get all they wanted, they all got something, except the chemists. They had it in their own hands to alter this state of things and he would remind them of the old proverb: "Providence helps those who help themselves."

It was proposed by Mr. W. J. BARNES, seconded by Mr. J. F. BROWN, and carried unanimously,

That it is desirable to have one or more chemists as members of Parliament to represent the whole body of chemists and druggists, and that the trade should provide the funds for election expenses.

Proposed by Mr. W. J. BARNES, seconded by Mr. J. F. BROWN, and carried unanimously,

That this meeting accord their approval of the proposal of the Council of the Pharmaceutical Society to make the Poison Regulations compulsory, and also of approaching the Lord Chancellor on the subject of company trading in pharmacy.

PHARMACEUTICAL SOCIETY OF IRELAND.

On Wednesday, December 7, the monthly meeting of the Council was held at 67, Lower Mount Street, Dublin. The PRESIDENT, Mr. R. J. Downes, was in the chair, and the other members of Council who attended were: The Vice-President (Mr. Beggs), and Messrs. Wells, W. D. Porter, Connor (Newry), Baxter (Coleraine), Ryan, and Dr. Walsh.—The PRESIDENT, in the course of a somewhat lengthy address, referred to

THE RECENT DECISION

in the case of the Queen (Conyngham) *v.* The Pharmaceutical Society of Ireland, argued and decided in the High Court of Justice, Queen's Bench Division, and reported that the Law Committee met at the Courts on the morning of the judgment, and also subsequently in consultation with Counsel, when the question of appeal was fully considered, and it was unanimously decided to recommend that they should abide by the mandamus. He then referred to a friendly visit he had received from Mr. Rankin, the Hon. Secretary of the Chemists' and Druggists' Society of Ireland (North of Ireland Branch), the object of which was to ascertain how the Council were disposed to the druggists as a body, and how it would receive their return. It appeared that they had been discussing the question of whether they would recommend their members to join the Society as associates. Mr. Downes expressed the hope that the year 1898 may be known as the year of reconciliation. He then mentioned that the fine imposed upon Mr. James Hogg had been reduced from £5 to £2. He considered it became an urgent question for the Council to consider whether it would continue to direct prosecutions or refer them to the Crown Prosecutor for the district and ask him to conduct them. The Council would be pleased to learn that the Medical Council had decided to recognise their Society in the review and preparation of the Pharmacopœia.

Mr. WELLS, referring to the visit of Mr. Rankin, said the pharmaceutical chemists did not want to be antagonistic in any way to the druggists. They had never been so to the law-abiding druggists, but they had been opposed to gentlemen who only got a druggist's diploma and then compounded prescriptions. Unfortunately, some of those gentlemen who had been placed on the Council had worked, not in the interests of the druggists at all, but for their own interests. But if the druggists could show men like Mr. Turkington, it would be a pleasure to work with them.

The VICE-PRESIDENT said he met Mr. Rankin at the Law Courts, and told him that they would be perfectly ready to meet the druggists if the druggists would meet them fairly.—Mr. WELLS, speaking on the subject of representation on the Pharmacopœia Committee, questioned whether they would be right in accepting any such representation as the British Society had done. He thought that if the Pharmaceutical Society of Great Britain had acted as they did, and held aloof from the General Medical Council, the Societies would now have been represented on the Pharmacopœia Committee.—The PRESIDENT said the only intimation of the matter he had was a paragraph which appeared in one of the journals, stating that some recognition was decided on.—Mr. KELLY said that "snubbing" seemed to be the portion that the Council was to receive from the Castle, and he thought that if the Lord-Lieutenant had not the power of making remissions, as in the case of Mr. James Hogg, the Council should question them. As for the druggists, he should be delighted to see druggists on the Council who would keep to the law. As to representation on the Medical Council, they should see what their rights were and demand them.—Mr. BAXTER said it was absurd that the Pharmacopœia Committee should not have on it a representation of pharmaceutical chemists. He was at one with the President in desiring to show favour to druggists who would work harmoniously with the Council. A letter from the Privy Council Office transmitted a copy of the report of Sir George Duffey, M.D., Visitor on the examinations held by the Society during the year 1898. The report stated that the examinations of the Society during the year were conducted in a satisfactory manner. The examiners were uniformly painstaking and considerate towards the candidates; the supervision was good and the several arrangements were adequate. The consideration of Sir G. Duffey's report was deferred until the next meeting.—A letter from the Under-Secretary, Dublin Castle, intimated that the Lord-Lieutenant had reduced the fine imposed on James Hogg to £2.—Mr. KELLY: How much has the Society lost by that prosecution?—Mr. WELLS: About £10.—I would be disposed to ask Mr. Field, M.P., to put a question in Parliament as to whether the Society can be expected to carry on

prosecutions under the circumstances.—Several donations of books were then acknowledged.—The VICE-PRESIDENT moved pursuant to notice that Regulation 15 be amended so as to read as follows :

Every candidate for the Pharmaceutical Licence Examination will, in addition to all other certificates hitherto required, be required to present a certificate of having attended a course of botany and materia medica, of not less than three months' duration, at some school recognised by the Pharmaceutical Society of Ireland. Such certificate must show an attendance of not less than twenty lectures of not less than one hour in each subject.

As the regulation stood, the attendance of the candidate might be only for a week or a month, and he proposed to introduce the words "not less than three months' duration" in order to spread the lectures over that period.—Mr. BAXTER seconded the motion, which was unanimously agreed to.—Other business, including reports, having been disposed of, the Council separated.

HALIFAX AND DISTRICT CHEMISTS' ASSOCIATION.

The annual dinner and meeting of this Association were held at the Old Cock Hotel, on December 8, Mr. COBB, President, in the chair. There was a goodly array of members, and there were present also the following guests: Mr. Waddington, President of the Bradford Chemists' Association; Mr. Crook, Vice-President of the Dewsbury Chemists' Association; Mr. S. Norman Pickard, local Secretary of the P.A.T.A.; and Mr. James Smith, of Hirst, Brooke and Hirst, Ltd. A vote of condolence was passed to Miss Farr on the lamented death of her father, an old and esteemed past president and member of the Association. It was explained that it was impossible to postpone the meeting, because all arrangements had been completed and delegates invited from other towns, and there was not sufficient time in which to communicate with country members and guests, and also to countermand the dinner.

The Hon. Treasurer, Mr. W. HAIGH, read his annual report which showed the Association to be in a sound financial position.

The Hon. Secretary, Mr. H. C. BRIERLEY, in his report stated that the past year of the Association had been very successful, and that it had seldom, if ever, been stronger numerically. There had been an increase of five new members, but death had unfortunately taken away two very good members in the persons of Messrs. H. Seely, F.C.S., and J. Farr. The Association had been especially active in Parliamentary work during the past session, and the Pharmacy Acts (Amendment) Bill, which was supported by the members, had since become law. The Duke of Devonshire's Poisonous Substances Bill had been opposed most strenuously, and had since been abandoned by the Government. Last month, Mr. Clement Fielding, M.P.S., was elected local secretary of the Pharmaceutical Society of Great Britain.—The election of officers resulted in Mr. Cobb being re-elected President, Mr. Haigh, Treasurer, and Mr. Herbert C. Brierley, Hon. Secretary for the ensuing year. Speeches were delivered by the visitors, Councillor Hebden, Messrs. T. Briggs, Gibson Q. Dixon, J. B. Brierley, and others.—Songs were sung by the Secretary, Mr. Tiffany, and Councillor Hebden, and selections on the piano were given by Mr. Reginald Brierley.—The dinner was catered for in an exceedingly capable manner by Mr. Talboys, the proprietor.

BRADFORD AND DISTRICT CHEMISTS' ASSOCIATION.

At a special meeting of this Association, held at the County Restaurant, Bradford, on December 13, it was unanimously agreed—

1. That in the opinion of the meeting it is desirable that members of the Council of the Pharmaceutical Society of Great Britain should be requested to visit the different centres and address meetings under the auspices of local associations where possible, submit identical resolutions, and obtain the general opinion of the trade respecting further legislative action. The following questions should be specially considered:—

1. Restriction to chemists of the sale of medicinal drugs and compounding of medicine.
2. Company pharmacy.
3. Covering of unqualified traders by registered chemists.
4. Handling of poisons and additions to Schedule.
5. Compulsory membership of the Society of qualified individuals.
6. Exemption from jury service of members of Society.
7. Exhibition of names of qualified members over their establishments.

2. In view of the passing of the Pharmacy Acts Amendment Act, 1898, this meeting suggests that members of this Association who are at present members of the Pharmaceutical Society use

their best efforts to induce all registered chemists in the district to become members of the Pharmaceutical Society, and are requested to render any assistance in their power to the local secretaries in carrying out this resolution.

3. This meeting of the members of the Bradford and District Chemists' Association records its conviction that it is not worth their while encouraging in any way the sale of such advertised specialties as bear at the current retail prices no appreciable profit. Accordingly they decline to exhibit or distribute advertising matter having for its object the popularising of such specialties, unless their proprietors become members of the P.A.T.A., or guarantee a living profit on their goods, thus showing practically their sympathy with the great body of retail chemists. Also that copies of this resolution be sent to the trade papers and the following firms: Dinneford and Co., Kay Bros., W. T. Owbridge, A. J. White, Ltd., Thomas Beecham, James Cockle and Co., J. M. Richards, Edwards and Co., G. R. Sims Hair Restorer Co., Scott and Bowne, Anglo-American Drug Co., and J. C. Eno, Ltd.

4. That this meeting of the Bradford and District Chemists' Association desires to compliment the Dewsbury and District Chemists' Association on their action in regard to the sales of unprofitable proprietary articles.

PHARMACEUTICAL MEETING AT PRESTON.

An important meeting of chemists was held at the White Horse Restaurant, Preston, on Tuesday, December 13, when Mr. ARKLE occupied the chair, and there was a large attendance of Lancashire chemists.

The CHAIRMAN said they had met to discuss the best means to remedy the existing state of things in pharmacy. The Pharmaceutical Society was helpless to assist chemists unless the latter enrolled themselves as members. If the Society went to Parliament to secure

AMENDMENT OF THE PHARMACY ACTS

its leaders were necessarily confronted with the query, "Whom do you represent?" and they could not say that they represented the bulk of registered chemists. So long as that state of things existed there was little hope of legislation, and it was owing to the apathy which existed that chemists were surrounded on every side by limited companies, who carried on the business of chemists and druggists. So far as concerned company trading, the Pharmacy Act of 1868, from Sections 1 to 15, was a dead letter, but chemists should urge the Pharmaceutical Council to introduce a new Bill, which must, however, be backed up with all the strength available. Chemists wanted the trade for the trade, but the Society could not apply to Parliament unless it received the general support of registered chemists throughout the country.

Dr. PAUL, who was introduced as being present in a private capacity said there appeared to be a strong desire to do something to meet some of the more serious difficulties under which registered chemists laboured at the present time. Competition was a thing which chemists had to face just in the same way as everybody else, but the drawback chemists chiefly complained of was that they had to contend with unreasonable competition on the part of companies carrying on business as chemists and druggists and assuming titles which were intended to be reserved by Statute to persons who had satisfied the requirements of the Pharmacy Acts. The use of the title "chemist" under those circumstances was distinctly an infringement of the provisions of the Pharmacy Act of 1868, and was one of the most detrimental influences that operated against chemists. The sale of poisons and the dispensing of medicine afforded other aspects of what chemists suffered in competition with stores, and here the grievance was not that an unregistered person was competing unlawfully and unfairly with them, but that some of their own fellow qualified men were assisting the stores to carry out a work they could not possibly carry out themselves. When qualified men lent their services to companies consisting of unqualified persons they were assisting in the carrying on of a business which was growing to such an extent that it had become to chemists a question of doing something to stop it or ceasing to exist. So far as chemists were concerned, that was a very serious business, and, so far as the public was concerned, it was equally serious. The protection in regard to the sale of poisons was by no means perfect, for there was no assurance that all poisons sold at stores were handled by registered persons. There was an absolute absence of protection for the public in the matter of dispensing medicines,

because it was generally done out of sight in the back premises, and it was difficult, therefore, to say whether it was dispensed by a qualified man or not. To put a stop to the evils indicated it was essential that the qualified chemists of the country should unite, and by their combined exertions bring such pressure to bear upon public opinion and the Government that some remedies might be obtained. With regard to company trading, in anything the Pharmaceutical Society did it must be supported by such a large majority of the trade that the Council of the Society might be regarded as a representative body with the force and influence of the whole trade behind it. The question was often asked, What had the Society done for the trade? Well, that was a question which involved a fallacy to begin with. It overlooked the fact that the constitution of the Society, according to its Charter, was one of absolute self-government, and if the Society only represented one-fourth of the trade, it was impossible to exercise action which could be said to be representative of the whole trade. The complaint, therefore, was really a censure upon those who entered the trade and who did not join the Society. That had operated against the Society in bringing Bills before Parliament. Added to that was the opposition which came from within, and, as appropriate to the question of company trading, he would refer to Section 16 of the Act, which provided for the continuance of a deceased chemist's business by his executors. It was of course perfectly legitimate if legally carried out, but the privilege had been so grossly abused that it had really become a basis for the construction of bogus one-man companies. Chemists who might endeavour to devise measures for dealing with company trading would probably meet with considerable opposition from persons who still desired to maintain the freedom to continue a deceased chemist's business for all time under the control of executors. That and other difficulties must be fought out within the body, as Parliament would not take much cognisance of affairs of that kind beyond recognising the absurdity of the position. If chemists asked for the suppression of trading by companies of unqualified persons they would almost certainly be met with the answer: "You must first of all provide for removing that objection which exists in Section 16 of the Pharmacy Act!"

Mr. VINCE (Lancaster), in the course of the subsequent discussion, agreed that unless chemists put the Society in a position to help them they could not hope for any benefit. It was unfair to expect the minority to fight the battles of the majority.

Mr. J. H. TAYLOR (St. Annes) believed the great obstacle to membership of the Society had been the guinea subscription. There were only two ways of crippling company trading. The Society must either obtain power to strike off the Register the name of any chemist guilty of unprofessional conduct, or join with the Medical Council in the endeavour to make it illegal for a company to carry on business as an individual. The Society had certainly done all it could to elevate the status of the trade, but he should like it to be made compulsory that every boy must pass his Preliminary examination before entering the trade. Such action would guarantee a certain education and improve the class of boys.

Mr. STUART (Preston) strongly urged the formation of an Association in Preston, and

Mr. WHITEHEAD (Morecambe) thought it might be possible to form a joint Association for Preston, Blackpool, Lytham, St. Annes, Lancaster, and Morecambe. They could then associate themselves with Blackburn, then with Manchester and Liverpool, and so on until the whole of Lancashire was united.

Ultimately, the CHAIRMAN proposed the following resolutions:—

- (1) That the use of the title "chemist" by unregistered persons trading as companies is an infringement of the Pharmacy Act, 1868, is detrimental to the interests of legally qualified persons, and that it requires to be stopped by the co-operation of all registered chemists and druggists as members of the Pharmaceutical Society.
- (2) That the support rendered by legally qualified chemists to companies trading as chemists and druggists being the only means by which companies are enabled to continue that business in defiance of the provisions of the Pharmacy Act, this meeting declares such injurious and disloyal action on the part of legally qualified persons to be deserving of the most severe condemnation of their colleagues.

Mr. WILLIAMSON (Preston) seconded, and the motions were unanimously approved.

ALBUMIN GLYCERIN FOR FIXING MICROSCOPIC SECTIONS ON THE SLIDE.—This is obtained by mixing 1 part of albumin with 1 part of glycerin. The solution is spread out thinly, and the objects fixed by warming them slightly.—*Pharm. Centr.*, xxxix., 112.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

A special meeting of the members of this Association was held at the White Bull Hotel, Blackburn, on Tuesday last, when the chair was occupied by Councillor RALPH SHORROCK, Vice-President, and there was a large attendance.

The CHAIRMAN said chemists were not satisfied with

THE PHARMACY ACT OF 1868.

The great question before them was, whether they should patch that measure up or seek for a new one. It was a very difficult question, but limited liability companies were doing an immense amount of harm to the chemists and druggists. Under the present condition of affairs it behoved chemists to be united, so that they might have more influence with the powers that be. He hoped that Association would take a strong action in bringing about a state of things that would show the country at large that it was necessary to adopt some course that would bring about a measure to their satisfaction.

Mr. WELLS (Blackburn) then moved the following resolution:—

That we are of opinion that limited liability companies owned by unqualified persons are illegal, and we urge this opinion on the Council of the Pharmaceutical Society with a view to immediate action to test the question.

They would all agree with him that the pharmacy laws were unsatisfactory, and that they ought not to rest until they had got them amended. That seven people could form a company and open as many chemists' shops as they chose was, he contended, not in accordance with the spirit of the Pharmacy Act. There was need for qualified chemists for the safety of the public, and though the unqualified companies would say that they did keep qualified assistants, it was simply to hand medicine over the counter. He trusted that some good legislation on the subject would soon be forthcoming.

Mr. J. BROWN (Burnley) briefly seconded the motion, and in the course of the subsequent discussion the meeting was addressed at great length by

Mr. R. L. GIFFORD (Blackburn), who said a monstrous state of affairs existed in the conditions of pharmacy. Though for over thirty years men had been compulsorily trained and examined, yet at the end of the century there was no regulation whatever of the practice of pharmacy. The State's treatment of chemists was both inhuman and dishonest, and the law affecting chemists had become a simple absurdity. The present unholy state of affairs was not known to the general public or to members of Parliament, or they would allow that it is incongruous, unjust, and wrong. That was no mere assertion, but a tested fact, shown to be correct in numberless instances. But reform was impossible except by unanimity, and consequent upon that came the question, "How should they become unanimous?" The first and most urgent duty of the Council of the Pharmaceutical Society was to get into touch with the great mass of chemists, more especially the younger portion. It must be driven home that it was altogether a mistake to think that the Council's interest in men ceased with the examination. As regards the Pharmacy Act, it had become so manifestly absurd and unjust that they were deeply impressed that no tinkering with it would do. They said tackle questions as they arose, as, for example, the poisons regulations and company pharmacies, but let no question whatever prevent them at once preparing to face Parliament with the statement distinctly put, that in the present state of the law the public safety was not protected in the manner intended. The opportunity was there. Public opinion was interested. The medical, dental, and veterinary professions were actively engaged in watching and preparing legislation. Illegal companies were increasing, probably in order to magnify the interests concerned. Those things considered, common sense said "Now is the time for assertion."

Mr. HAWORTH (Blackburn), endorsed everything that had been said. They could not, he observed do better than put their shoulders to the wheel, and with a long pull, a strong pull and a pull altogether make their voices heard.

Mr. COWLEY (Liverpool), Secretary of the Federation of Local Pharmaceutical Associations, also addressed the meeting, and in the course of his speech remarked that registered chemists who joined the Pharmaceutical Society had the power of delegating Councillors to Bloomsbury Square, and it lay with them to select the proper men. They must consider whether the gentlemen proposed

as Councillors were fit and proper persons to represent them, and if they found they were not they should strike their pen through the names. There were capable men in the provinces, as well as in London, and he said the provinces should wake themselves up, throw off their lethargy, and do their utmost to send to the Council gentlemen who were in touch with them.

Mr. WILKINSON (Colne) also supported the proposed resolution, and it was finally carried.

Before the meeting closed the result of the meeting held at Preston was announced (see pp. 657-8), and the CHAIRMAN read the resolutions passed at that meeting. Both the resolutions received the support of the Blackburn meeting as covering the whole situation.

FORFARSHIRE CHEMISTS' ASSOCIATION.

A meeting of this Association was held at the Queen's Hotel, Dundee, on Wednesday last, Mr. KERR, President, in the chair. There was a large attendance.

The CHAIRMAN said he was gratified by such a large attendance, showing an increased interest in pharmaceutical politics, and he congratulated those present on the improved position, the result of the Pharmacy Acts Amendment Act, 1898, which has opened the door to all those who wish to possess the privilege and advantages of membership of the Pharmaceutical Society. He hoped many would show their appreciation by now joining the Society. The chief aim of local associations should be to beat up recruits for the parent Society, the need above all things being the power of numbers. Though Dundee stood fairly well in that respect, there was room for improvement in the district.

The SECRETARY read some correspondence with a London firm of wholesale druggists regarding a complaint that they had supplied cutting grocers with capsules in boxes for retailing, bearing their trade title as "grocers." As they admitted it was the result of a mistake, and that it would not be repeated, the subject was dropped.

The CHAIRMAN said his attention had been drawn to a circular accompanying Beecham's pills, and he was shocked at its contents. He moved—

That this meeting having discovered the nature of the contents of the booklet issued with Beecham's pills, and having seen in the *Pharmaceutical Journal* that Mr. Beecham has had to alter it in order to conform to the Indecent Advertisement Act of South Australia, this meeting regrets that the circulation of such matter is permitted in this country, protests against chemists being made a medium for distributing it, and instructs the Secretary to communicate this resolution to Mr. Beecham.

This proposition was agreed to.

Mr. FERRIER then proposed—

That all chemists trading under ancient titles shall be required to use the name of the present owner in conjunction therewith.

He said this was necessary in the public interest and due to other pharmacists in business.

Mr. KERMATH seconded the proposition, and it was carried.

Mr. KERMATH then moved—

That this meeting considers that the present recommendations for the storage, etc., of poisons should become regulations subject to the provisions of the Pharmacy Act, 1868.

He thought that would strengthen the position of the Pharmaceutical Society in communications with the Privy Council, and impose no serious restrictions on modern pharmacists.

Mr. CURRIE, in seconding, said this was one of the difficult points the Society had to contend with, in needing to explain why the recommendations had not been carried out.

Mr. FERRIER thought it would be difficult to prove any fault against present arrangements to judge from the few accidents in chemists' shops, and to adopt the proposed regulations would be to put their necks in a halter. He was disposed to move an amendment. After some discussion, however, the motion was carried.

Mr. PARK proposed—

That this meeting approves the action of the Pharmaceutical Council in addressing the Lord Chancellor on company trading as affecting chemists.

and read the letter referred to, which explained the chemists' position in a satisfactory manner.

Mr. FORD (Kirriemuir) seconded, and the motion was carried.

BAILIE DOIG speaking to the question What should a new Pharmacy Bill contain? said, while it was easy to state general

wants it was difficult to formulate particulars, but discussion would ripen opinion. First, after severe examinations chemists have a better claim to protection than some other professions; secondly, their position as retailers of poison necessitated amendment of the list of poisons, which should all be under chemists' control; thirdly, they ought to have more liberty in describing the uses of domestic medicines, unfettered by Inland Revenue restrictions. The authorities should, in chemists' interests, modify their regulations. Why should ordinary compound medicines be handicapped simply because they are compound, while every simple escapes? He moved—

That this meeting considers it to be the duty of the Council to draft a Bill.

This also was agreed to.

Mr. KERMATH thought influence should be brought to bear on M.P.'s in reference to the Bill of the Lord Chancellor, and thought all associations should use such influence. A vote of thanks to the Chairman closed the meeting.

LEICESTER CHEMISTS' ASSOCIATION.

A meeting of the members of the Leicester Chemists' Association was held at the Victoria Coffee House on Wednesday night, Mr. E. H. BUTLER presiding.—The object of the meeting was to consider the proposed Pharmacy Bill and poisons regulations.

Mr. GOODNESS, Hon. Secretary, referred to the proposed amendment to the company laws brought forward by the General Medical Council, and thought that the Council of the Pharmaceutical Society had done well in asking the Lord Chancellor to grant them the same privileges as requested by the medical and dental professions. He was of opinion that the compounding and dispensing of prescriptions should be restricted to persons duly qualified under the Pharmacy Acts.

Mr. THIRLBY said he should like to see a resolution sent from that meeting supporting the action which had been taken, with a view of getting the law with respect to company trading altered. He considered the present time most opportune to take action, for it was apparent they had the sympathy of the Lord Chancellor on their side. He begged to move:—

That the members of the trade in Leicester give their unanimous support to the Pharmaceutical Society of Great Britain in their endeavour to obtain an amendment of the law in regard to company trading, whereby the word "person" in the Pharmacy Act, 1868, shall be made to include corporate companies.

Mr. HEARNshaw did not think that to desire that all persons who dispensed should be duly qualified was practical.

Mr. CLEAVER seconded the motion, which was carried unanimously.

Mr. HAMPSON next moved:—

That the members of the trade be urged to become members of the Pharmaceutical Society forthwith, and thus give it all the support in their power.

Mr. LEWIS OUGH seconded, and the motion was carried unanimously.

The meeting next proceeded to consider the storage, etc., of poisons, the resolutions passed by the Newcastle Chemists' Association and the Manchester Pharmaceutical Association being discussed. It was moved by Mr. THIRLBY—

That this meeting of Leicester chemists is of opinion that, if the Council of the Pharmaceutical Society believes that a modified measure of the regulations would improve their position under the present Acts of Parliament and conduce to the greater safety of the public and for future legislation, the case would be met by the promulgation of Parts I. and III. of the 1871 recommendations, but condemns Part II. as unworkable.

Mr. HUTTON seconded, and

Mr. GOODNESS thought it would be wise to leave the regulation of a man's pharmacy to his own judgment and to his own particular requirements. He should fall in line, however, with any scheme that would enforce some special label for all poisons.

Mr. CLEAVER and Mr. HEARNshaw were inclined to agree with Mr. Goodness, and

Mr. OUGH thought it desirable that they as an Association should take some line of action, but considered the proposed resolution as far as they could be expected to go.

On the motion being put it was carried unanimously, and this concluded the business.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

A meeting of the members of this Society was held at the Society's rooms in Surrey Street, on Wednesday evening last.—Mr. JOHN AUSTEN presided over a very good attendance. After the usual business, which included the admission of three new members and one associate,

Mr. G. SQUIRE, President, then proceeded to read a paper on

COMPANY PHARMACY: ITS CAUSE AND CURE,

which is printed in full at page 646.

The CHAIRMAN, in opening the discussion, said the chemist was a necessity, and was going to make himself a necessity, notwithstanding company pharmacy.

Mr. G. ELLINOR contended that company pharmacy was not legal. The Act of 1868 only provided for the registration of individuals who complied with its provisions. A company was not an individual, it was a thing without body, soul, conscience, or anything else except the name, and, therefore, could not register. A number of members of Parliament had told him that the President of the Board of Trade had no legal right to go beyond the Pharmacy Act when registering companies; that he did go beyond it was patent, and he was doing a villainous act in registering people who did an illegal thing. He spoke of past discussions in the ranks of the chemists and druggists, and urged that they should all unite and endeavour to obtain parliamentary representation.

Mr. NEWSHOLME said the fault was that the Companies Act was so loosely framed that the Board of Trade was practically compelled to register all applicants.

Mr. MORRISON said that if they went before Parliament they would be asked if the public would be better protected by the fact that they were trading as individuals instead of companies. What difference did it make to the public in general whether the qualified seller of a poison was at the back of his own counter or the counter of unqualified people? The speakers had been arguing for their self-preservation and not really for the preservation of the public. A Bill for the attainment of the ends of individuals would have no prospect of success in Parliament. They were all agreed as to the cause of company pharmacy, but the cure suggested by the President would, instead of aiding pharmacy, make it suspected when it was mentioned in Parliament.

Mr. PRESTON said Parliament had made certain demands upon certain people for certain qualifications, and ought now to see that the body which it had created had some protection. He urged that they should band themselves together and go to Parliament in a united body, and then they might hope to do something with regard to legislation.

Mr. EARDLEY said if anything was brought before Parliament the main thing inquired into would be how the public would be benefited, the pharmacists would not be considered in any way.

Mr. WARD looked hopefully forward to the future of pharmacy. He wanted to see the time come when the pharmacist who went into a drug store would be looked upon as a black sheep. Let the rising generation of pharmacists steer clear of drug stores and the evil would be cured. He moved:—

That this Association strongly recommends every registered chemist not already a member to, in his own interest, join the Pharmaceutical Society, and thereby add to its powers to legislate for the good of its members and the progress of pharmacy, and this Association heartily approves of the action of the Pharmaceutical Council in its communication with the Lord Chancellor.

Mr. NEWSHOLME said the Pharmaceutical Council had not been at all idle on the subject, and he was glad that the views of Mr. Squire coincided so well with what was done at the previous Wednesday's Council meeting. He believed that those who framed the Pharmacy Act never dreamt but that the proprietor of a pharmacy business was to be registered as well as the men who actually handed the poisons over the counter, and this was necessary because there was as much skill required in buying drugs as in selling them. In going to Parliament they must show that the public would be better served by individuals than by companies, and one point which showed this was the greater interest taken in the public by the individual pharmacist, who simply made himself a slave of the public night and day.

The motion was seconded by Mr. H. E. IBBITT, and carried. The meeting ended with a vote of thanks to Mr. Squire.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION,

At a meeting of this Association, held on Wednesday last, Mr. E. GASCOYNE, Vice-President, in the chair, Mr. EBERLIN, the Secretary of the Association, read a paper on

The More Important Preparations of the new B.P.,

more especially in their relation to the Food and Drugs Act. He instanced a number of articles the standard of which had undergone alteration, and urged the importance of chemists testing their supplies. Though the B.P. was not a legal standard under the Sale of Food and Drugs Act, it had been so often quoted in evidence that it had become unsafe to sell preparations which did not correspond with its requirements, unless distinctly giving the purchaser knowledge of that fact. The rulings of the Courts had of necessity, in so vaguely defined an Act, been most contradictory; they must be so until the Act was amended and a proper standard fixed under it, and a Board of Reference instituted, such as had been proposed. Whilst chemists, as a body of educated and honourable men, were desirous of always supplying the best drugs to their customers, they had a right to demand that the Sale of Food and Drugs Act should not be administered in a harsh and literal manner as against a sensible and reasonable one. It would be well, therefore, where cases of petty persecution took place, for them to unite and defend themselves vigorously; for such action, if crowned with success, would curb the tendency to over-zealousness which officialdom sometimes showed, and would render the analyst employed more careful.—A long discussion subsequently took place, after which Mr. EBERLIN briefly replied.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of the above Association was held at the rooms, Whimble Street, on Wednesday, December 14, when Mr. C. J. PARK (President) occupied the chair.

The PRESIDENT having suggested that as many chemists as possible should become members of the Conference,

Mr. J. COCKS introduced a discussion on the best means to adopt to bring before the attention of all non-members the necessity of increasing

THE MEMBERSHIP OF THE PHARMACEUTICAL SOCIETY

so as to make that body more fully representative of the entire trade. He suggested that the only effectual way of increasing the membership was by the personal canvass of all chemists by a deputation of two or three members in conjunction with the local secretaries.

The discussion was continued by Messrs. G. BREEZE and HUNT. The latter, as local secretary, concurred in the suggestion, and pointed out the small number of resident chemists in Plymouth who were not connected with the Society.

The following resolution was then proposed by Mr. COCKS, and passed:—

That this Association is of opinion that it is most important that the membership of the Pharmaceutical Society should be largely increased, so that it may more fully represent the best interest of the trade, and with that view will do its utmost by personal canvass and correspondence to induce all chemists who are non-members to unite themselves to the Society.

The CHAIRMAN then introduced the question of the

STORAGE AND SALE OF POISONS,

and it was proposed by Mr. BREEZE—

That this Association is of opinion that the time has arrived when the Pharmaceutical Society should make the regulation for the sale and storage of poisons into a compulsory Bye-law, to be enforced, if necessary, by an official appointed by the Council of the Pharmaceutical Society.

This was seconded by Mr. READE, who remarked that he had had experience of all the systems given in the recommendations. In its simplest form this consisted in attaching a strip of sand-paper to the back of the bottle, so that, on taking down the bottle the attention of the dispenser was at once called to the fact that he was handling poison. The most effectual plan, and one which he had been using for twenty-six years, was that of poison cupboards, the objection to this being the expense of providing

sufficient accommodation for all the articles containing scheduled poisons.

Mr. TURNER considered that the success of the scheme depended upon the simplicity of the means adopted.

The CHAIRMAN pointed out that it would be much better to have this matter dealt with by the Pharmaceutical Council, instead of having regulations drawn up by the Privy Council and enforced by Act of Parliament.

Mr. DAVY hoped that the particular regulations passed at the General Meeting of the Society would be in accordance with the wishes of provincial chemists.

Mr. BARGE pointed out that a certain latitude should be left to individual chemists to carry out such rules as their intelligence dictated.

Mr. HUNT expressed his approval of the views enunciated by Mr. Proctor in last week's Journal with regard to the use of distinctive labels.—The resolution was then carried unanimously.—

It was subsequently resolved to support the view of the Federation with regard to the taking of steps to empower the Pharmaceutical Society to remove from the list of qualified men any person or persons who shall act in a manner detrimental to the best interests of the profession. A hope was expressed that the Lord Chancellor would be induced to deal with the matter.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

At the monthly meeting of the above Association held on Wednesday evening, Mr. G. S. WOOLLEY presided. At the outset of the proceedings, the Chairman gave a hearty welcome to several gentlemen from Wigan, and after some other preliminary business had been disposed of,

Mr. J. RYMER YOUNG proceeded to read his paper on

The Pharmacy Act of 1868, and its Literal Interpretation.

The paper, which was well received, is printed in full at p. 638.

At the conclusion, the CHAIRMAN said their best thanks were due to Mr. Young for his able paper, which must have taken him a considerable time to compile, and showed great acquaintance with the Pharmacy Act. He thought it could be utilised very materially during the winter if it was printed *in extenso*, as he hoped it would be. On behalf of the Association he begged to thank Mr. Rymer Young for his very able paper.

Mr. J. A. GILBERT seconded the motion, and agreed that the paper should be printed.

Mr. HARRY KEMP, in supporting the motion, said that the paper dealt with an immense amount of matter which it would be impracticable, even if they had the time, to discuss satisfactorily then. He trusted it would appear in the press, so that not only the members of the Association, but chemists throughout the country, would take more than a passing interest in the matter. He urged that the various questions dealt with should be very carefully considered, and if it was possible they should press some of those matters home for decision in the courts of law.

Mr. W. KIRKBY also supported, and said he wished it to be known how thoroughly he supported the views of Mr. Young in finding out how useful that Act might be made to them. There were many points which had been touched upon by Mr. Young, which showed they had not used it as much as they ought to have done, and he hoped the Pharmaceutical Council would feel its hands strengthened by that meeting passing some resolution urging them to test some of those cases which Mr. Young had brought under their notice, with a view to ascertaining if something could not be done with regard to a curtailment of the privileges of company pharmacists.

The CHAIRMAN thought their appreciation of Mr. Young's paper quite covered the ground which Mr. Kirkby had indicated. He left them, therefore, to carry the resolution with acclamation.—This suggestion was cheerfully complied with.

Mr. RYMER YOUNG, in replying, said that what he had advanced was purely his own opinion, and must not be taken as representing that of the Pharmaceutical Council. There was no question of originality about his paper, but he had long thought they might discuss the 1868 Act. He found that different clauses were capable of different readings, and he thought they might do well to rub up an old law, having regard to the present miserable state of the Pharmacy Acts.

NEW REMEDIES.

ERYTHROL IN BUTYRIC ACID DYSPEPSIA.—Under the name of erythrol, A. Robin has prepared a double iodide of bismuth and cinchonidine, which is said to be a useful remedy in the somewhat rare form of acid dyspepsia, in which a butyric fermentation takes place. The remedy is given in doses of 1 to 5 centigrammes combined with hydrated magnesia in a cachet.—*Repert.* [3], x., 260.

ALSOL.—Under this name aluminium aceto-tartrate is introduced as an antiseptic. Having an agreeable taste, it is useful for gargles, especially when sweetened with a little sugar or glycerin. It should not be prescribed in too concentrated solutions, for most purposes from 1 to 5 per cent. is sufficient.—*Nouv. Rem.*, xiv., 228, after *Pharm. Zeit.*

QUINOLINE BISMUTH RHODAATE.— $(C_9H_7N \cdot HSCN)_2Bi(SCN)_3$ is a coarse powder, reddish-yellow in colour, with an acrid smell, insoluble in alcohol, ether, and water. It melts at 76° C. As with nearly all bismuth compounds, decomposition occurs when it is mixed with much cold water, with diluted mineral acids, and long heating with alkali. Otherwise the combination is very stable and may be kept for a long time. Forcheimer has used this preparation with advantage in treating syphilitic and other sores. Applied with a brush or tuft of wool in thin layers on wounds the rhodamate forms a yellowish paste if much secretion is formed. If the secretion is slight it only changes to a brown adherent scab, under which the ulcer in many cases closes and heals. When first used, the powder should be applied daily, but later it is better to leave the dressings a longer time.—*Théráp. Monatsh.*

EUPHTHALMINE SALTS.—Euphthalmine hydrochloride is now obtained in a definite crystalline form by repeated recrystallisation from absolute alcohol. It melts between 130° to 140° C. Euphthalmine salicylate is obtained by combining equal molecular weights of euphthalmine and salicylic acid in absolute ether-alcohol solution. It melts at 113° to 116° C., and is also readily soluble in water.—*Ztsch. d. allg. oest. Apoth. Ver.*, lii., 359.

CORONILLA VARIA AS A CARDIAC REMEDY.—V. Poulet finds that the aqueous extracts of the flowering tops and leaves of *Coronilla varia* afford an excellent remedy in the many cardiac affections in which digitalis and strophanthus are used. It possesses the great advantage over these, that it does not derange the digestive functions. In diuretic action, it is, perhaps, less energetic than digitalis, but this is easily remedied by prescribing at the same time a diuretic drug, such as theobromine. In general affect on the heart, it is to be preferred to digitalis, and has given good results where the latter has failed. The dose of the extract is 10 centigrammes, given three or four times daily, in pilular form massed with the powdered drug; as it is not cumulative in its action, the administration may be continued indefinitely.—*Nouv. Rem.*, xiv. (July 8, 1898), 239.

ORTHOFORM AS AN ANALGESIC.—Although they find that orthoform has but medium bactericidal properties, Lietwitz and Sabrazes state that as a topical application it acts very effectively, relieving pain in cases of cancer, ulcerated sores and similar states. It has proved useful in cancerous affections of the throat, where pain caused dysphagia; applied locally in these cases it gave relief which was more lasting than with other remedies, the alleviation of pain extending over twenty-four hours.—*Bull. Gen. de Therap.*, cxxxv. (May 30, 1898), 799.

INHALATION OF MENTHOL.—Jousset (*Sem. Med.*, 1898) prescribes an inhalation of menthol, 5, and ol. terebinth. rectif., 2, spirit, 100, for acute frontal headache. A teaspoonful of the mixture is used in a cup of hot water, and the vapour inhaled through the nose for several minutes and repeated every hour.—*Pharm. Central.*, xxxix., 511.

VALIDOL.—This is a solution of 30 per cent. of menthol in methyl valerianate, forming a colourless liquid with an agreeable odour, and of the consistence of glycerin. It is free from the burning taste of menthol, and is well tolerated by the stomach. In doses of 10 to 15 drops, in a little wine or on a lump of sugar, it acts as a useful analeptic in the depression of hysteria or in neurasthenia. Its powerful antiseptic properties render it useful as a surgical dressing.—*Bullet. Comm.*, xxv., 516, after *Pharm. Post.*

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE PHARMACY ACTS.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* FOWLER.

At Stonehouse County Court, on Monday, December 12, the Council of the Pharmaceutical Society brought an action to recover from Louis K. Fowler, 31, Albert Road, Morice Town, Devonport, three penalties of £5 each for infringements of the Pharmacy Act, 1868, viz., keeping open shop on two occasions for retailing poisons, and illegally using the title of "chemist."

Mr. Vaughan Williams, instructed by Messrs. Flux, Thompson, and Flux, London, appeared for the Society. He said defendant was not on the official Register of Chemists and Druggists, and was not entitled to sell poisons. Defendant bought the business from P. A. Kelly, a properly qualified chemist, and issued a handbill stating that he had removed his practice to 31, Albert Road. It also stated that he had taken into partnership J. T. Livesey, chemist and druggist, of Manchester, under whose management the business of chemist and druggist would be carried on. Defendant got an assignment of the lease and became occupier of the premises, and was, in fact, the man whose business was carried on there. Sergeant Down, a detective of Devonport, on September 28 asked for oxalic acid, and was supplied by Mr. Livesey, a qualified chemist. On the 30th Sergeant Down bought chlorodyne from Mr. Livesey. On the first purchase there was a label with the words, "Kelly, dispensing chemist," and on the second a label bearing the words, "Livesey and Co., chemists." Over the shop window was fixed the name "Livesey and Co., chemists, Albert Road Drug Stores."

Philip Alfred Kelly, chemist and druggist, said he sold his business to defendant for £170.—In cross-examination he said he did not know whether defendant wanted to carry on the business of a dentist. Defendant was not a registered dentist, but extracted teeth. Witness inferred that defendant did not want to carry on the business of a chemist, as he wished to dispose of the stock. Witness told him that only a duly qualified man, as proprietor, could carry on the business.

Mr. Vaughan Williams submitted that, even if defendant was misled by Mr. Kelly, that would not exonerate him.

Mr. G. H. E. Rundle, for the defence, admitted that defendant was not a chemist. The name over the shop showed the public there was a duly qualified chemist to dispense drugs, and the public had not been injured in the slightest degree.

His Honour said Mr. Rundle need not trouble about the paragraph alleging the use of the name of "chemist."

Mr. Williams submitted the label was sufficient proof of that paragraph.

His Honour: It is "Livesey."

Mr. Williams: If he takes an assumed name it makes the offence worse.

His Honour: I am against you on that paragraph.

Mr. Rundle submitted the cases decided showed that the defendant was not liable to penalties.

His Honour: The difficulty is this circular, where he says Livesey is a partner.

Mr. Williams contended the law was not complied with through Livesey, as a partner, being a proprietor. If that were the case, the effect of the Act would be destroyed, as anyone would be able to employ a qualified person, and so evade the Act.

J. T. Livesey, chemist and druggist, said he entered into an arrangement with defendant that he should look after the business. He took sole charge of the stock, and sold for a small salary and commission. Defendant took no part in the business, and never served a customer.—Cross-examined: Witness was Livesey, and defendant the Co.—Articles of partnership were drawn up.

His Honour said there must be judgment for plaintiffs. Very great mischief was done by unqualified persons selling poisons, and it was the duty of the Society to protect the public and bring actions of this kind. He was satisfied in this case no real harm was done. It was obvious defendant knew from the outset he could not carry on the business, and did not intend to carry it on as a chemist, and there was no reason to doubt Mr. Livesey's statement that he had sole charge of the chemist's department. But, however *bona fide* defendant's intentions, he had brought himself within the Act by keeping open shop, and however much he (his

Honour) might be of opinion that no harm had been done, there must be judgment for plaintiffs as to the first two penalties. He did not think defendant had rendered himself liable to the penalty for exhibiting the name of "chemist." There would be a verdict for the Pharmaceutical Society for £10 and costs, and he would certify for counsel's costs.

HIGH COURT OF JUSTICE.

BOGUS DEGREES IN COURT.

On Friday, December 9, before Mr. Justice North, in the Chancery Division of the High Court of Justice, in the case of the Attorney-General, at the relation of the General Medical Council, *v.* The General Council of Safe Medicine Co., Ltd., Mr. Muir Mackenzie moved that a writ of sequestration might issue against the defendant company for breach of an undertaking. The action was brought to restrain defendants from issuing or granting diplomas or degrees purporting to confer a title to practise medicine. After the statement of claim was delivered, an order was made, by consent, by which defendants undertook not to grant any further degrees or diplomas. The action was brought in consequence of a case which came before the Queen's Bench Division on the prosecution of a person named Steel for the use of the degree M.D. (B.C.).—His Lordship: What does "B.C." mean.—Mr. Muir Mackenzie said "B.C." meant "Botanic." Steel was convicted under the Medical Act for falsely using a medical title, and after the conviction an action was brought by the Attorney-General to restrain the issue of further diplomas. The objects of the defendant company, according to the memorandum, were the granting of degrees, scholarships, and awards in magnetic and botanic system of safe medicine, the highest distinction being M.D. (B.C.), which signified the rank of Doctor of Botanic Medicine. Since the order was made in 1895 it had been brought to the attention of the General Medical Council that the degrees of the defendant company were still in circulation, only with a different description. Accordingly the present motion was brought for sequestration on the ground that there had been a breach of the undertaking by granting a degree and diploma purporting to confer the right to practise medicine and surgery under the title of Fellow of the College of Safe Medicine Co. It was only right to say that Mr. Younger, the President of the defendant company, had filed an affidavit in which he denied that any degree had been granted since the undertaking was given, and, of course, if that were true it would be an answer to the motion. Before bringing the motion the Registrar of the General Medical Council wrote to Mr. Younger asking him if it was the fact that no certificate had been issued since the date of the order, but Mr. Younger declined to give any information at all. Under these circumstances he asked for an order to cross-examine Mr. Younger before the examiner. It appeared that one of the managers of the defendant company was now using the title F.C.S.M., attending patients and signing death certificates.—Mr. Vernon, for the defendant, did not object to the order for cross-examination, and his Lordship accordingly made the order and directed the motion to stand over until the examination was completed.

BEECHAM'S PILLS.—AN INJUNCTION.

On Saturday, December 10, Mr. Justice Stirling granted a perpetual injunction against the defendant in an action of Beecham *v.* Flintoff, restraining him from passing off pills not of defendant's manufacture as Beecham's pills, and ordered him to pay the costs. The plaintiff waived an inquiry as to damages. The defendant was described as carrying on business at Blackburn as a druggist and patent medicine vendor, but his name does not appear on the Register of Chemists and Druggists for 1898.

UNFAVOURABLE ACTION OF SACCHARIN.—From experiments made upon his own person Bornstein considers that saccharin cannot, with certainty, be regarded as innocuous in certain cases, such as those of diabetes. After taking 2.5 grammes of pure saccharin for several consecutive days the author found the drug to produce diarrhoea, the amount of nitrogen, of free fats, and of fatty acids in the excreta being abnormally high. It appears either to exercise a purgative action or else to hinder normal assimilation. It has been noted that diabetic patients have developed symptoms of intestinal dyspepsia while taking saccharin.—*Nouv. Rem.*, xiv., 236.

LETTERS TO THE EDITOR.

THE ADVANTAGES OF LOCAL ORGANISATION.

Sir,—In your last issue there is a report of a meeting of Preston chemists, convened to discuss the desirability of forming a local association. I am disappointed to see that it was not unanimously decided at the meeting to found one. It is, however, evidence of the healthy spirit extant in North Lancashire, and of the energy of the gentlemen connected with the Federated Associations of that district. This laudable example might be followed with advantage in other parts of the country wherever there is a town of any size, or a group of small towns, as we have in many parts of Lancashire and in other manufacturing parts of the country. Local associations, even though they are not frequently convened, form the nucleus round which the members of the trade in the neighbourhood may collect to discuss matters of importance locally, and to the members of their calling throughout the country. From a business point of view it is an advantage to meet the members of our craft who reside in the same town. It has a tendency to break down that reserve, or, I should say, trade jealousy, that often exists. It will be found, when this has rubbed off, that we have often misjudged our neighbours, and that they are at the bottom really good fellows. In these days of competition, it may be often an advantage to buy together, and it is surprising what this will do in increasing our profits if we are able to pay cash. Apart from the friendships that are sure to follow from attending such Association meetings, there is the fact that it tends to draw us out of ourselves and to bring us into touch with our fellow-men, which is essential to a business man.

Liverpool, December 12, 1898.

R. C. COWLEY,
Hon. Sec. Federation of Local
Pharmaceutical Associations.

THE USE OF NETTLES AS FOOD.

Sir,—Both *Urtica urens* and *Urtica dioica* are used extensively in some rural districts of Ulster as food for pigs and fowl. The peasantry occasionally use the young shoots of *Urtica urens* as a substitute for cabbage. The shoots are chopped finely and immersed in boiling water for a short time; the water is then poured off and the shoots subjected to pressure, after which they are cooked in a variety of ways. The preliminary treatment is said to prevent them discolouring other articles of food with which they may be served. I have known tea made with both plants to be used in the same districts as a spring medicine or "blood purifier," but in this case the preliminary steeping was omitted.

Belfast, December 12, 1898.

WM. GEO. STRATTON.

MELLIN'S EMULSION OF COD-LIVER OIL.

Sir,—I did not write my previous letter with any idea of keeping up a correspondence on this subject, but feel now, sir, with your permission, that I should like to say a word in reference to Messrs. Mellin's letter to Messrs. J. Cross and Co. in your last week's issue. One thing, I am glad Messrs. Mellin so frankly acknowledge having been guilty of such practices, but I should like to inform them they had no need in this case, as they say they had in many places where chemists refuse to stock their preparation, to get the grocer to hold a stock of the emulsion, because the three chemists in the immediate district had, for months before their representative introduced it to the grocer, held a stock of it, and as for there existing a demand from the general public, demand or no demand the grocer had never been asked for the article. Whoever heard of a medical man sending a patient to a grocer for a medicine when there are chemists in the same town? Had it been in a small country village with no chemist it would be different and quite excusable, but in my town we can muster six chemists, and if the medical men dispense their own physic, they look to the chemists for such extras, not to the grocers. Messrs. Mellin and Co. may be well astonished at any trader being so palpably dishonourable to take such a despicable advantage; but does the retailer, who knows how this firm's goods are cut without any attempt to stop or prevent it, hold the same opinion. As for the handsome profit attached to it for handling, the price now is 18s. 6d. wholesale, and sold, I am told by my customers, for 1s. 8d.? Where does the talked-of protection come in? Who is to prevent anybody getting a supply and cutting it to cost price? Could Messrs. Mellin find out where any vendor, wishing to do it, gets his supply? I doubt it under their present

protection arrangements. We country chemists have enough to contend with what with drug stores and cutting grocers in the near larger towns where so many of our people flock, and railway companies offering every facility to take the people there, without manufacturers coming and giving grocers a licence which is available for all stamped medicines, except, of course, those containing a poison, which grocers are not allowed to retail.

December 13, 1898.

DEVON (160/43).

Sir,—I cannot allow Messrs. Mellin's reply to Messrs. Cross and Co. to pass unnoticed. First, because the case referred to in Devonian's letter does not apply to the exceptional cases quoted by Mellin and Co., as their emulsion was stocked by the two nearest chemists, right and left of the shop in question. Secondly, I fail to see where the "consideration" and "handsome profit" mentioned by Mellin come in when the article is retailed at stores at 1s. 8d.—being, I believe, the minimum price fixed by Mellin, Ltd., themselves. This wonderful profit does not pay the working expenses of any business. Thirdly, to use their own words: "We are astonished at any trader being so palpably dishonest as to take such a despicable advantage," reminds one of the old metaphor of the "Pot calling the kettle smutty," because they leave a chemist's shop after offering their goods at a certain price, and immediately offer them to a grocer with an extra bonus, thereby making him a competitor with the whole of the chemists in the neighbourhood.

December 13, 1898.

ANOTHER DEVONIAN (161/5).

ARROW POISONS.

Sir,—The manchinele poison mentioned by Dr. Gordon Sharp is in all probability the milky juice of *Hippomane mancinella*, Linn., a euphorbiaceous tree, the juice of which is said to have been used by the Caribs as an arrow poison, together with other poisons derived from the Apocynaceæ. The manchinele is evidently an irritant poison, causing vomiting, diarrhoea, and all the symptoms of a powerful irritant like *Croton tiglium*, but cases of death from eating the fruit appear to be rare. The ripe fruit is eaten by goats, sheep, macaws, and land-crabs, but those who eat the crabs suffer from vomiting. It has been recommended as a diuretic in dropsy (*Therapeutical Gazette*, 1889, p. 243). An excellent figure of the plant is given in Descourtilz' 'Flore des Antilles,' tom. iii., p. 12, and a good deal of reliable information in Lunan's 'Hortus Jamaicensis,' vol. i., pp. 482-484. It is much more likely that the chief ingredient in the Carib arrow poison should have been some apocynaceous plant. One of this family, *Echites suberecta*, has long been used in Jamaica and other islands as a poison for criminal purposes, and is a most powerful heart poison. The active principles it contains were described by M. J. J. Bowrey in the *Proc. Royal Society*, 1878, vol. 27, pp. 309-332, and in the *Chem. Soc. Journ.*, 1878, vol. 33, pp. 252-269.

London, December 12, 1898.

E. M. HOLMES.

RETAIL CHEMISTS AND THE P.A.T.A.

Sir,—After reading what Mr. T. S. Wokes has to say I conclude that gentleman has not seen a full account of the history of the Dawsbury meetings, or he would not have written as he does. In reference to Mr. Broadhead's letter, he says: The P.A.T.A. is an Association which is endeavouring according to its lights to ameliorate the condition of the chemist. The only places in which the P.A.T.A. can claim that it has been able to maintain fixed prices are towns where there is no cutter, and in such places the profits would have still been about the same without the P.A.T.A. The Association has been in existence three years, and anyone who has followed the subject carefully must admit that it is an absolute failure in all towns where it has been fully tested. The P.A.T.A. was started by chemists, and I am convinced that there is now only an "insignificant minority" supporting it, and this minority is labouring under a delusion. I have before me the first six numbers of the *Anti-Cutting Record* (Grocery Section) and if any chemist will obtain these from a grocer and look through them he will find ample evidence that the P.A.T.A. is tending to draw the trade in proprietary articles from the chemist to the grocer. I learn therein that the P.A.T.A. grocery retailers think that a profit of 12½ per cent. on proprietary articles is quite sufficient, while the P.A.T.A. Chemists' Section insists on about 25 per cent. A list appears in each issue entitled "Selection of Goods from the Present Drug-List of Protected Articles in which Grocers are Interested." These comprise over eighty make-ups, while the

whole P.A.T.A. drug-lists consists of only about 170 articles, so that the P.A.T.A. Chemists' Section is making a present of half the articles to the Grocery Section of the Association. In the October issue of the grocery *Record* the Secretary writes:—

Hitherto the Chemists' Section of the Association has borne the major portion of the expense of organising the Grocery Section. This naturally cannot go on indefinitely, and the grocery trade in this matter must help itself. Grocers have nothing to lose and everything to gain by joining the movement, and we hope that we may speedily see a large influx of retailers in the ranks of the Grocery Section of the P.A.T.A.

While the Assistant-Secretary says in the November issue:—

If irreconcilable cutters are being effectively restrained in the drug trade, they can be dealt with quite as well in the grocery trade, especially as the amount of profit to be charged (12½ per cent.) is severely moderate. Though the Chemists' Section of the Association has hitherto borne the bulk of the expense of organising the Grocers' Section, this cannot be expected to go on indefinitely. There is probably ten times the wealth in the grocery trade than there is in the other, and I hope this consideration will be allowed to have full weight amongst those most concerned. Five shillings spent in this way is destined to prove a good investment, if the grocers turn out to be as far-sighted business men as chemists have been. The former are usually said to be the abler men in matters of business.

I am a chemist and I have never believed in the P.A.T.A. or its methods. That I was justified in this opinion the foregoing should convince any chemist. I read that a copy of the *Anti-Cutting Record* (Grocery Section) is sent free monthly to 5000 retail grocers. Thus, mainly at the expense of the chemists, they are teaching grocers, who now only dabble in a few patents, to stock more proprietary articles than they otherwise would have, and I venture to predict that this movement will lead to a greater number of patent medicine licences being taken out by grocers to the detriment of chemists.

Portsmouth, December 12, 1898.

HERBERT H. BAILEY.

A WARNING.

Sir,—Would you kindly insert the following warning:—A young fellow, well dressed, came to my shop a week or so ago in the evening, asking me to change a cheque for £3, stating he was a nephew of a doctor in the neighbourhood whose medicine I make up, and who had told him I would change it for him. It turned out to be an old cheque and worthless. I learn at the bank that the same trick has been played on several other chemists.

London, December 13, 1898.

ALICK MAITLAND.

MEMBERS, NON-MEMBERS AND THE PHARMACEUTICAL COUNCIL.

Sir,—If the Pharmaceutical Society wants a "lead" for company pharmacy legislation let its Council draw up and issue petitions (explaining the subject to our legislators) for chemists to sign, as suggested in the candid letter from "T. Hulme" in your last issue. Would there be apathy over doing that? I think not. No, sir, the vast majority will willingly sign. At length, too, the Pharmaceutical Society would have done something to justify its existence to the many retail chemists who now regard it with a haughty and magnificent indifference. I have been a subscriber to the Society since the day I passed the Preliminary, eighteen years ago. What real benefit has it done me in business? No doubt the local secretaries would get the provincial signatures. I will be answerable for Lowestoft.

Lowestoft, December 10, 1898.

A. H. HINDE.

Sir,—As an adherent of the Society for the last quarter of a century, permit me to express the satisfaction with which I have perused the proceedings of the Council this week. The adoption of the memorial to the Lord Chancellor and the decision to call a meeting with the view to the consideration, and as I trust the adoption, of poison regulations are both of very great significance, and I am much mistaken if both proposals do not meet with the unanimous approval of all true pharmacists. I agree with much that Mr. Hulme says in his letter to-day, but I have no doubt that he and all others likeminded will see that the time for criticism is now past, and that present duty demands the united efforts of all loyal sons of the Society in the attempt to place pharmacy once more in its proper position. The Council are truly representative of the feeling among the best pharmacists in the country, both inside and outside the Society, and I am convinced that under the guidance of our worthy, level-headed President, they will leave no stone unturned to secure the object so long aimed at and desired by us all. Doubtless, they will not be able to satisfy everyone in the way they carry out the campaign, least of all will they conciliate a jealous journalistic opposition which cannot afford to

miss an opportunity for unscrupulous "pin-pricking," but they may be assured that in the arduous fight that must now be faced, they will be backed up by the rank and file of pharmacists throughout the country.

December 10, 1898.

ONE OF THEM (160/6).

CORRECTIONS.

Sir,—The word printed "feights" (line 35, page 632) in my letter in last week's Journal should have been "fright," and the word "years" (line 22) should have been "yours."

Bury, December 9, 1898.

T. HULME.

* * The first word was printed as written; the second was a printer's error [Ed. P. J.]

ANSWERS TO QUERIES.

DENTAL PAPER.—The *British Journal of Dental Science* is probably as widely circulated as any. It is published by J. P. Segg and Co., 289, Regent Street, W. [Reply to F. C.—20/11.]

RHUBARB PETIOLE.—If the bundles be arranged as you state, it may be due to unusual development of parenchymatous tissue produced by cultivation under peculiar conditions of growth. Send a specimen if you can. [Reply to PETIOLE.—20/9.]

SAPONACEOUS SHAMPOO POWDER.—Powdered soap, 3 ozs.; dried sodium carbonate, 1½ oz.; borax, 1½ oz.; oil of *Myrcia acris*, 10 minims. [Reply to DEMETRIUS.—20/21.]

HAIR-CURLING POWDER.—Borax, 16; dried sodium carbonate, 2; powdered gum acacia, 2. Mix. Perfume if desired with a little bergamot. [Reply to DEMETRIUS.—20/21.]

MANAGER OF BRANCH.—We fear you have no remedy in the matter, unless you can prove that he is the actual proprietor. You might consult the local rate books, and so determine whether or not he is the occupier. [Reply to SALICYLAS.—20/26.]

MAKING ARTIFICIAL TEETH.—The Dentists Act, 1878, only prohibits the use by an unqualified person of the title "dentist" or "dental practitioner," or any name, title, etc., implying that he is registered under the Act, or a person specially qualified to practise dentistry. [Reply to DENS.—20/33.]

INCOMPATIBLES.—We do not know any book which treats the subject of incompatibility in medicines in the comprehensive manner you desire. The various treatises on pharmacy and materia medica for the most part contain merely a list of incompatibles under each drug or preparation. We shall be pleased to answer any query you like to send. [Reply to R. H.—20/32.]

CHEAP GINGER WINE ESSENCE.—Probably merely a mixture of burnt sugar and "gingerine," acidulated with tartaric acid, and flavoured with a few drops of lemon oil, will be what you require. Work out the proportions of those ingredients to meet the requirements of your case in price and strength. [Reply to W. W.—20/24.]

CLEANSING GLASS BEFORE SILVERING.—The most effectual way to clean glass is to rub over the surface with a piece of filter paper moistened with solution of ammonia. Care must be taken not to touch the clean surface afterwards with the bare fingers. The same method is applicable to all cases where it is requisite to have the glass absolutely clean and free from grease, as in silvering processes. [Reply to W. M.—20/20.]

MAKERS OF CHEMICALS.—For lead chloride try Typke and King, 7, Jeffrey Square, St. Mary Axe, E.C.; T. Morson and Son, 31, Southampton Row, W.C.; or Thos. Tyrer and Co., Stirling Chemical Works, West Ham. For tin oxide try Acton and Borman, 7, Shoe Lane, E.C.; and for uranium oxide apply to Johnson and Sons, Cross Street, Finsbury, E.C.; Hopkin and Williams, 16, Cross Street, Hatton Garden, E.C.; Johnson, Matthey and Co., Hatton Garden, E.C.; or Harrington Bros., Shandon Chemical Works, Cork. [Reply to POTTER.—20/14.]

Owing to pressure on our space numerous Letters and Answers to Queries are unavoidably held over.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

A New Sugar. Camille Vincent and J. Meunier have isolated from the mother liquors left on crystallising sorbite, a new sugar "octite, $C_8H_{13}O_8$," which is not itself crystalline, but yields crystalline derivatives. After converting the last traces of sorbite into sorbose by means of specific bacteria, the solution is concentrated and the new sugar isolated as its crystalline dibenzoic acetal, $C_8H_{16}H_8(C_7H_6)_2$. The crystals of this compound deposited from chloroform melt at $230^\circ C.$, but when simply washed with ether they melt at $140^\circ C.$ The specific rotation of the new sugar is $-3^\circ 42'$ at $20^\circ C.$ It does not reduce Fehling's solution. The acetic ester forms tabular crystals melting at $114^\circ C.$ —*Comptes rendus*, cxxvii., 760.

Absorption of Carbohydrates. Jules Laurent finds that plants are not only capable of absorbing carbohydrates by their roots, but, at the same time—under the influence of sunlight—of converting them into reserve material, so that carbon may be assimilated thus, as well as by the action of chlorophyll. The process, in the case of plants which are devoid of chlorophyll, is only an instance of what takes place in plants in general. Among other experiments, it was found that when the roots of plants which had previously been deprived of their starch were plunged into a solution of glucose, the whole experiment being conducted in an atmosphere deprived of carbon dioxide and exposed to sunshine, starch was detected in the leaves in a few hours. In a control experiment, where pure water alone was employed, no starch was formed.—*Comptes rendus*, cxxvii., 786.

Detection of Water. According to Brooks the double iodide of lead and potassium, $PbI_2 \cdot 2KI$, is a very delicate reagent for the presence of water, the double compound being resolved into its two constituent salts by the least trace of moisture. The double salt is prepared thus: Lead nitrate, 1 Gm., is dissolved in 10 C.c. of water, and saturated potassium iodide solution is added as long as the precipitate at first formed continues to dissolve. The solution is then allowed to crystallise, after which the white crystals of the double salt which separate are collected, washed with absolute alcohol, and kept over quicklime.—*Pharm. Zeit.*, xlii., 720.

Nicotine in Tobacco Smoke. To demonstrate the presence of nicotine in tobacco smoke, Kissling uses a bottle half full of water rendered faintly acid with sulphuric acid; two tubes pass through the stopper, one dipping into the fluid, and having a cigar inserted in the upper end; through the other, much shorter, tube the assistant draws the smoke in the ordinary way of smoking. When a portion of the cigar is consumed, a few drops of Mayer's reagent are added to the liquid, in which a copious precipitate is produced in the presence of nicotine. Further evidence of nicotine may be obtained by rendering the solution alkaline with soda and distilling. The idea that a picoline base, and not nicotine, causes the reactions described is not borne out by this experiment. Previous investigations by the author also show that tobacco smoke contains a relatively large proportion of nicotine, and never more than a very small proportion of picoline base.—*Chem. Ztg.*, lxxviii., 805.

Taka-Diastase. W. E. Stone and H. E. Wright have examined taka-diastase with a view to ascertaining its value as an analytical reagent for the determination of starch, to supersede malt diastase, which is commonly used for the purpose but possesses the disadvantage of being unstable. The result of experiments, however, on the starch of wheat, rice, and maize indicates that taka-diastase is not adapted for use in the quantitative determination of starch, in spite of its stability. Though the commencement of the action of taka-diastase on starch is more immediate than that of malt-diastase, the experiments prove that after the lapse of a few hours a considerable quantity of starch remains in presence of the former, whilst there are only traces in presence of malt diastase. After seven hours the digestion is quite complete in the case of malt diastase, but not so when taka-diastase is used.—*Journ. Amer. Chem. Soc.*, xx., 639.

Formaldehyde and Thyroid Glands. According to M. E. Lépinois a 1 per cent. solution of formaldehyde exercises a preservative action on thyroid glands, after they have been immersed in it for two or three days. He finds that this treatment does not appear to modify the chemical composition of the glands sensibly, as regards the iodised albuminoid matter; the solubility of the latter in pure or saline water is very slightly diminished. The author concludes that on subsequently extracting from the preserved glands the active principles, the latter will be found to possess better keeping qualities.—*Bull. Soc. Chim. de Paris*, xix.-xx., 932.

Enzyme of Nepenthes. S. H. Vines supplements his previous paper on the proteolytic enzyme of *Nepenthes* (see *P. J.* [4], vi., 385). Statements there made as to the great stability of this enzyme are verified by experiments relating to the action of high temperatures and of alkalies upon it. It would appear to be the most active of all known proteolytic enzymes. It is probably derived from a zymogen present in the gland-cells. Its classification is facilitated by the discovery by Ramsden of true peptone among the products of digestion; in this it resembles the tryptic ferment found by J. R. Green in germinating seeds, as also in the fact that it acts in an acid medium, thus differing from the trypsin of the pancreatic juice.—*Annals of Botany*, xlvi., 545.

Enzyme of Yeast. J. Reynolds Green has followed up his researches of last year on the alcohol-producing enzyme of yeast, with the result that he now confirms Buchner's announcement that the alcoholic fermentation of sugar is effected by the activity of an enzyme or soluble ferment which, by appropriate means, can be extracted from the yeast-cell. When so extracted it sets up fermentation in sugar solutions under conditions which prevent the activity of living yeast. The enzyme is easily decomposed; like enzymes in general it is largely thrown out of solution by the formation of an inert precipitate in the liquid in which it is contained. The secretion of the enzyme by the cell is intermittent, only taking place during actual fermentation by the yeast. It is soon decomposed when this activity ceases, so that resting yeast does not give it up to a solvent. The completeness with which it can be extracted from the yeast-cell depends upon successful disintegration of the cell. The author finds that the enormous pressure used by Buchner (500 atmospheres per square inch) is unnecessary, inasmuch as an extract obtained by a pressure of five atmospheres per square inch was more active.—*Annals of Botany*, xlvi., 491.

CRITICISM OF SOME CHEMICAL MATTERS IN THE NEW PHARMACOPŒIA.*

BY LEONARD DOBBIN, PH.D., F.R.S.E.

Some curious anomalies and inconsistencies in the 1898 B.P., when viewed from various standpoints, have already been pointed out; but, so far as I have seen, the descriptions of chemical operations and changes, the statements concerning matters of chemical fact, and the notation employed in the chemical formulæ have almost entirely escaped mention. It is the main purpose of the present paper to show that these, in numerous instances, are not what we have a right to expect in an important official publication of the kind. It will be convenient to take up the subjects to be considered in as systematic a manner as possible, but it may be stated at once that, except as regards the notation, no endeavour has been made to collect chemical matters for comment from the new Pharmacopœia as a whole, nor even from a number of successive pages in any selected part. Such of the points referred to below as do not relate to notation were simply met with during the perusal of monographs, etc., here and there at random.

(a) VAGUE OR INCOMPLETE CHEMICAL STATEMENTS.

In the monograph on potassium chlorate (p. 263) it is stated that "When heated it fuses, gives off oxygen gas," etc., but no indication whatever is given as to whether it is necessary to raise its temperature to that of boiling water (under ordinary conditions), to a red heat, or still higher. The official statement is wanting in the very desirable attribute of scientific precision, which could easily have been attained by a few additional words.

On page 257 we read, "Lead oxide, PbO, is prepared by the action of air on melted lead." This is no doubt true, but it is, nevertheless, vague, and it may even be highly misleading, for the intelligent boy who melts lead in an iron ladle and finds that a scum gathers upon the surface of the melted metal may easily arrive at the erroneous conclusion that this scum is lead oxide, B.P.

In the monograph on "Potassium Bichromate" (p. 261), we read:—"Fuses below redness; at a higher temperature is decomposed, yielding green chromium oxide and yellow potassium chromate, which may be separated," etc., but no mention is made of the oxygen which is simultaneously liberated, and is at least equal in importance to the other two substances. The official statement is here culpably incomplete.

(b) INEXACT OR INACCURATE CHEMICAL STATEMENTS.

Respecting both hyoscine hydrobromide (p. 153) and hyoscyamine sulphate (p. 154), we are told that, "heated to redness with excess of air, it leaves no residue." This statement would make it appear that these two salts can be heated, as such, to redness; but the writer of the monographs certainly did not mean to say so. The idea which it was doubtless intended should be conveyed is accurately expressed in (for example) the monograph on atropine sulphate (p. 49): "It leaves no ash when burned with free access of air."

Morphine tartrate, it is stated on p. 219, "may be prepared by the combination of morphine and tartaric acid in molecular proportions." The author of the monograph presumably meant to write "equivalent" instead of "molecular."

On p. 265 we read that potassium permanganate "may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide," and on p. 400 potassium ferrocyanide is stated to be "the yellow crystalline salt . . . prepared by fusing together potassium carbonate, nitrogenous organic matter, and iron." Both of these statements are simply

incorrect. Potassium manganate—not permanganate—is obtained by the interaction, at a dull red heat, of the substances mentioned; while potassium cyanide—not ferrocyanide—is the valuable nitrogenous product of the fusion referred to.

(c) MISCELLANEOUS CHEMICAL ANOMALIES.

We find "hydrogen borate" formally stated in heavy type (p. 7) as a synonym for boric acid, but no other acid is dealt with in an analogous manner, although "hydrogen citrate" and similar names are met with in the text. Yet the preface says, p. x: "Of synonyms, only the more important have been inserted."

It is difficult to know what to make of the statement concerning phosphorus (p. 244), where this substance is described as "a solid non-metallic element obtained from calcium phosphate." No one can seriously suppose that phosphorus obtained from the mixture of phosphates and other compounds, commonly known as bone ash, or from natural mineral phosphates other than calcium phosphate, is not phosphorus, B.P. But it is worth while to compare the above strangely narrow official statement respecting phosphorus with the corresponding one relating to sublimed sulphur (p. 318): "May be prepared, more or less directly, from native sulphur or sulphides." That is at least comprehensive, and for its purpose it is no doubt sufficient.

In view of the method given on p. 61 for preparing calcium phosphate from bone ash, it seems very inconsistent to state that this preparation should yield no characteristic reaction with the tests for magnesium. It is well known that the substance precipitated when the solution obtained by treating bone ash with dilute hydrochloric acid is mixed with dilute ammonia solution in excess contains combined magnesium in notable quantity. The B.P., moreover, does not even say that the ammonia solution, in the preparation as described, would require to be employed in excess.

No excuse can now be given for such chemical archaisms, dignified even though they may be by appearing in Latin, as acidum arseniosum and acidum chromicum in a work which has the word "hydroxide" substituted for the older word "hydrate." The substances referred to by these names are not acids in the modern acceptance of the term.

(d) THE CHEMICAL NOTATION.

The Pharmacopœia contains chemical formulæ for almost two hundred different substances. It might be supposed that the compilers would have observed some uniformity of practice in regard to the representation of kindred substances by means of formulæ, and in the use of the various signs such as a bracket, the comma, the period, and the decimal point. This, however, is in a great many instances not the case. It is very difficult to attribute to anything but carelessness or indifference the utterly haphazard manner in which the compositions of closely related substances are often represented by formulæ which differ greatly from one another. The numerous examples which follow will amply illustrate and yet not exhaust the kinds of irregularities met with.

The Pharmacopœia gives formulæ for five metal acetates. For these, three different modes of representation are adopted:—

Lead acetate	Pb(C ₂ H ₃ O ₂) ₂ , 3H ₂ O	p. 256.
Barium acetate	(CH ₃ COO) ₂ Ba	p. 394.
Potassium acetate ...	CH ₃ COOK	p. 260.
Sodium acetate	CH ₃ COONa, 3H ₂ O	p. 400.

Even potassium and sodium acetates are not represented by quite analogous formulæ.

Excluding bismuth oxycarbonate, which is perhaps scarcely comparable with the others, there are four basic carbonates mentioned in the Pharmacopœia. Three variations are met with in the mode of formulating these:—

*Read at an evening meeting of the Pharmaceutical Society in Edinburgh on December 21, 1898.

Magnesium carbonat	$3(\text{MgCO}_3), \text{Mg}_2(\text{HO})_2, 4\text{H}_2\text{O}$... p. 210.
Lead	$2\text{PbCO}_3, \text{Pb}(\text{OH})_2$ p. 256.
Zinc	$\text{ZnCO}_3, (\text{ZnH}_2\text{O}_2)_2, \text{H}_2\text{O}$	p. 386.

Acetanilide and phenacetin are closely allied substances, the latter containing the ethoxy-group, OC_2H_5 , instead of one of the hydrogen atoms of the phenyl-group, C_6H_5 , of the former. But the official formulæ are :—

Acetanilide	$\text{CH}_3 \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_5$ p. 2.
Phenacetin	$\text{C}_2\text{H}_5\text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{NHCOCH}_3$	p. 242.

There are two official sulphocarbates, and the formulæ assigned to them are :—

Sodium sulphocarbonate	$\text{C}_6\text{H}_4\text{OH} \cdot \text{SO}_2\text{ONa}, 2\text{H}_2\text{O}$	p. 301.
Zinc sulphocarbonate	$\text{Zn}(\text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3)_2, \text{H}_2\text{O}$	p. 388.

The use of the decimal point is met with in many of the formulæ (as, for example, in those of acetanilide and phenacetin, above). Its signification is not always exactly the same, but this need not be entered into. Why it should be introduced into the formula for citric acid, however, and omitted from that of gallic acid is not apparent :—

Citric acid	$\text{C}_3\text{H}_4 \cdot \text{OH} \cdot (\text{COOH})_3, \text{H}_2\text{O}$ p. 10.
Gallic acid	$\text{C}_6\text{H}_2(\text{OH})_3\text{COOH}, \text{H}_2\text{O}$ p. 11.

Neither is it clear why the period should be substituted for it in the two following cases :—

Salicin	$\text{C}_6\text{H}_{11}\text{O}_5 \cdot \text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2\text{OH}$ p. 281.
Phenol-phthalein	$\text{C}_6\text{H}_4 \cdot \text{OH}$ p. 399.
	$\text{C}_6\text{H}_4 \cdot \text{OH}$	
	$\text{C}_6\text{H}_4 \cdot \text{CO}$	
	O	

and in no others.

The above formula for phenol-phthalein is probably the most unsatisfactory of the whole two hundred. Besides the fact that the lines sloping towards the symbol for carbon on the left do not properly represent what they are designed to represent, the formula as a whole obscures in a needlessly bewildering manner, the relation of phenol-phthalein to phthalic anhydride.

The use of the comma in the formulæ for salts of alkaloids, and in those for substances represented as containing water of crystallisation, is almost quite consistent, and is in conformity with general usage. Thus (choosing an example of each kind) we have :—

Apomorphine hydrochloride	$\text{C}_{17}\text{H}_{17}\text{NO}_2, \text{HCl}$... p. 39.
Ferrous arsenate	$\text{Fe}_3(\text{AsO}_4)_2, 6\text{H}_2\text{O}$... p. 125.

but why are the following, and they alone, distinguished by the omission of the comma :—

Atropine sulphate	$(\text{C}_{17}\text{H}_{23}\text{NO}_3)_2\text{H}_2\text{SO}_4$... p. 49,
Morphine tartrate	$(\text{C}_{17}\text{H}_{19}\text{NO}_3)_2\text{C}_4\text{H}_6\text{O}_6, 3\text{H}_2\text{O}$... p. 219,
Tartarated antimony	$[\text{K}(\text{SbO})\text{C}_4\text{H}_4\text{O}_6]_2\text{H}_2\text{O}$... p. 39,
Hydrous ferrous phosphate	$\text{Fe}_3(\text{PO}_4)_2, 8\text{H}_2\text{O}$... p. 130?

And why do we find such needlessly diversified formulæ as :—

Cerium oxalate	$\text{Ce}_2(\text{C}_2\text{O}_4)_3, 9\text{H}_2\text{O}$ p. 72 and
Ammonium oxalate	$(\text{COONH}_4)_2, \text{H}_2\text{O}$ p. 393;
Sodium bichromate	$\text{Na}_2\text{B}_4\text{O}_7, 10\text{H}_2\text{O}$ p. 56 and
Potassium bichromate	$\text{K}_2\text{CrO}_4, \text{CrO}_3$ p. 261;
Calcium hydroxide	$\text{Ca}(\text{HO})_2$ p. 60 and
Barium nitrate	Ba_2NO_3 p. 394;
Ethyl acetate	$\text{CH}_3 \cdot \text{COO}(\text{C}_2\text{H}_5)$ p. 26,
Ammonium benzoate	$\text{C}_6\text{H}_5 \cdot \text{COONH}_4$ p. 31 and
Salol	$\text{C}_6\text{H}_4 \cdot \text{OH} \cdot \text{COO} \cdot \text{C}_6\text{H}_5$ p. 231?

The formulæ given for potassium permanganate and for potassium ferricyanide are incorrect :—

Potassium permanganate	$\text{K}_2\text{Mn}_2\text{O}_8$ p. 265.
Potassium ferricyanide	$\text{K}_6\text{Fe}_2\text{C}_{12}\text{N}_{12}$ p. 399.

They ought to be KMnO_4 and $\text{K}_3\text{FeC}_6\text{N}_6$ respectively. It would be of interest to learn how the correct formula for potassium permanganate of the 1885 B.P. has been displaced by an incorrect one in 1898.

THE VOLUMETRIC OPERATIONS OF THE BRITISH PHARMACOPŒIA, 1898.*

BY JOHN LOTHIAN.

The volumetric methods of the Pharmacopœia are of special interest to pharmacists owing to the ease and rapidity with which these determinations can be performed compared with gravimetric methods. While, therefore, it may be regretted that the number of volumetric solutions has not been augmented, it is gratifying to find that the scope of the volumetric analysis has been enlarged, and now embraces a number of important substances which were not previously so determined.

In the following short note I wish merely to touch on a few points suggested to me by practical work.

In the first place the requirements defined for the burette are rather vague. It is required to *hold* within the graduated portion 50 grammes of distilled water; the burette should *deliver* 50 grammes of distilled water.

"The graduated portion is divided into 50 equal parts, each of which is to be taken as corresponding to 1 C.c."

The burette should be first divided into 10 equal parts, and each division calibrated by weighing the amount of distilled water which it delivers. If equal, each division will represent 5 C.c., and can then be further sub-divided. If volumetric work is to be accurate and give concordant results too great care cannot be taken in verifying the measuring apparatus.

I now make a few remarks on the official directions for preparing the volumetric solutions.

SILVER NITRATE SOLUTION.—"Take of silver nitrate 16.869 grammes." We are not told how this quantity is to be weighed, presumably neither 1/10 of a milligramme more or less; nor supposing, on verification with sodium chloride, it should be weaker than decinormal, how the so-called strengthening of the solution is to be carried out. This could only be done by a method of "dodging," as Sutton has expressed it, which would be both tedious and impracticable.

It is better to make a stronger solution with 17 grammes AgNO_3 , which need only be roughly weighed, standardise with pure sodium chloride, and adjust by dilution to the requisite bulk. It saves trouble to have the solutions accurately normal or decinormal as the case may be, as then, with a series of factors, the determinations can be more rapidly calculated than when abnormal solutions are employed. The same remark applies to the directions for preparing iodine and potassium bichromate solutions.

SULPHURIC ACID SOLUTION.—The directions given here are not very specific. The sodium carbonate prepared by ignition of the bicarbonate should be cooled in a desiccator. No indicator is specified to be used in titrating the solution, but as the carbonic anhydride is directed to be boiled off, presumably litmus is intended. This is an unsatisfactory method, the litmus on boiling assumes a mezzotint and the point of "exact neutrality" is by no means easy to observe. I find that very concordant results are obtained by using cochineal as an indicator and titrating in the cold. Cochineal has also the advantage over litmus that the "colour change" is easily observed in gaslight.

The accurate standardisation of this solution is of the utmost importance, as it is the standard of the acidimetry, as well as the

* Read at an evening meeting of the Pharmaceutical Society in Edinburgh on December 21, 1898.

* $\text{K}_2\text{Cr}_2\text{O}_7$ occurs on p. 431 of the Pharmacopœia.

alkalimetry of the Pharmacopœia, and I find it most satisfactory to make several gravimetric determinations, precipitating the sulphuric acid solution with barium chloride, washing and igniting the resulting barium sulphate—

231.74 BaSO₄ represents 97.34 H₂SO₄ (factor 0.42004).

I think it is unfortunate that a decinormal solution of potassium permanganate has not been included in the B.P. It is undoubtedly much more convenient than potassium bichromate for the determination of ferrous salts, especially where a large number of titrations have to be performed. It is applicable to all the ferrous salts, with the exception of Ferri Carb. Sacch. Although objection may be made to its instability compared with potassium bichromate, its strength can be very rapidly determined by means of ferrous ammonium sulphate.

A number have protested against the lowering of the standard of Ferri Sulphas Exsiccatus from 97.5 per cent. to 92.5 per cent., but I think that the lower standard will be found to keep better and the analysis of five wholesale samples shows that not one even comes up to the new standard, although this should not present the slightest difficulty—

FERROUS SULPHATE EXSICCATED.		
No. 1	70.51 per cent. FeSO ₄ , H ₂ O
„ 2	80.76 „ „
„ 3	74.57 „ „
„ 4	82.11 „ „
„ 5	72.06 „ „

HYDROGEN PEROXIDE SOLUTION.—In the nitrometer determination of this solution, chlorine is evolved by the action of the sulphuric acid and nascent oxygen on the brine, and a saturated solution of sodium sulphate has been recommended instead of brine.

The strength of this solution is, however, much more expeditiously determined by diluting 1 or 2 C.c. well with water, acidulating with sulphuric acid and titrating with N/10 potassium permanganate.

1 C.c. corresponds to 0.558 C.c. available oxygen at 0° and 760 Mm. I find Fletcher's autometric stopper an accurate and convenient pipette for delivering this and other solutions.

It would have been well if a process for the preparation of this hydrogen peroxide solution had been inserted in the Pharmacopœia, so that it could be made up freshly when wanted, or at least the supply regulated to the demand, seeing its tendency to diminish in strength. I append analysis of six retail samples:—

HYDROGEN PEROXIDE DETERMINATIONS.		
No. 1	1 C.c. yields 9.3 C.c. Oxygen.
„ 2	9.0 „ „
„ 3	9.1 „ „
„ 4	8.3 „ „
„ 5	9.6 „ „
„ 6	Absolutely nil.

TARTARIC ACID.—The standard has been raised from 99 per cent. to 100 per cent. I append a very careful analysis of five samples, the best was in crystals and the lowest in powder:—

TARTARIC ACID DETERMINATIONS.		
No. 1	99.40 per cent.
„ 2	98.87 „
„ 3	98.68 „
„ 4	99.73 „
„ 5	97.60 „

POTASSIUM BICHROMATE AND POTASSIUM PERMANGANATE are determined by ferrous sulphate and oxalic acid respectively. Ferrous ammonium sulphate is better in both cases.

I give herewith a table of factors and their logarithms to five places (without indices) for the B.P. volumetric solutions, which I find useful in my own laboratory:—

Table of Factors for B.P. Volumetric Solutions.

MALIC ACID OF THE CRASSULACEÆ.—The doubt which has existed with regard to the isomeric forms of malic acid has led F. Bullenheimer to investigate the subject. He finds that malic acid may exist in three stereo-isomeric forms, two of which—the acid of crab apples and of the Crassulaceæ—are known; the third form has not yet been isolated. The form from apples occurs in a crystalline state, but that from the Crassulaceæ is amorphous. The former readily forms an acid calcium salt and a crystalline acid ammonium malate, the latter gives an acid calcium salt with difficulty and no acid ammonium salt. The former acid is lævogyre, and its salts dextrogyre, while the latter acid is itself dextrogyre, and forms lævo-rotatory salts. The chemical relations and differences of the acids are described, and the author indicates that the synthesis of crassularia malic acid will probably soon be accomplished.—*Chem. Zeit.*, xxii., 194.

NOTES ON LIME AS A PRESERVATIVE FOR CHLOROFORM.*

BY DAVID BROWN, F.C.S., F.R.S.E.

In the *Lancet* of January 23, 1897, Dr. D. Newman and Professor Ramsay published a "Note on Decomposition of Chloroform and Sickness," in which they say freshly distilled chloroform produces little or no irritation on the air passages, little excitement, and if the agent is carefully given, sickness, fainting, and irregularity of pulse and respiration seldom occur during its administration.

There is a very important qualification here which deserves careful attention when it is desired to localise the cause of disagreeable or dangerous symptoms—it is said that if the freshly distilled chloroform "is carefully given," practically no bad results follow its administration—the natural inference being that if it is not carefully given bad results will follow, which means that pure chloroform carelessly administered can produce the bad effects which are known to follow the use of an impure one. This is a very important admission, for after establishing the purity of the chloroform, we are brought very much nearer the true cause of accidents. They also say chloroform which has been exposed to air and sunlight causes excitement and sickness during and after administration. This is far too sweeping an assertion, and might more truthfully be confined to chloroform which has become decomposed by exposure. In order to prevent bad results from chloroform inhalation, distillation is recommended as a cure, and it is then put aside in favour of slaked lime treatment, which they say gives equally good results. Three cases are given in support of their statement, two of which are after lime treatment and one after distillation, the results being that sickness in a mild form follows the use of lime-treated chloroform, and that there is none when the distilled article is used, which points to distillation, not lime treatment, as the better of the two methods. The authors do not say the chloroform they were working with, and which was subjected to their treatment, was actually in a decomposed state, neither do they give any details of the effect produced on the chloroform by the treatment, they only tell us how it affected the patients. Judging, however, from the title of the paper and from the fact that they describe the action of lime on carbonyl chloride, I think they must have been under the impression they were working with decomposed chloroform, and that the treatment they recommended was intended not only to restore it to a state of purity, but also to prevent it again showing any signs of decomposition. The theory that the lime would, under the given conditions, combine with the products of decomposition as they were formed, and that there would therefore always remain a quantity of pure chloroform ready for use, is not found, however, to be true in practice.

From the results they obtained I am inclined to think their original chloroform was not decomposed, because, had it been so, neither simple distillation nor their treatment with lime would have removed the products and made it suitable for anæsthetic purposes. In reply to inquiries regarding the use of this lime treatment, I have said I could not recommend it, and have advised instead the application of the recognised tests to the chloroform, and its rejection and immediate return to the maker if it did not stand them. My experience has been that even short contact with lime hastens decomposition, and that a decomposed chloroform cannot by the treatments recommended be transformed into a pure anæsthetic, more complicated processes in which water plays a necessary and important part are required to

bring about this change. I have also found that pure chloroform of sp. gr. 1497 if properly stored may be kept for many months in a state of purity, and I know that after being so stored it has been sent to distant parts of the world, when after reaching its destination it has been found pure and was used with only beneficial results as an anæsthetic. It is also my experience that 1497 chloroform is not the delicate article some people imagine, but that it may be exposed to sunlight for many weeks without undergoing change. Some years ago I exposed a quantity for 144 days and could then find no trace of impurity in it. An exposure such as this is much longer than chloroform when properly used should ever be subjected to. In further evidence of the keeping qualities of chloroform reduced to 1497 with alcohol I have recently examined 640 samples, all now remaining, and representing part of our production for the past twenty years. I have taken the only five samples of the 1879 make, and one indiscriminately from each of the following years (twenty-four in all), and have subjected them to the zinc iodide and starch test, and to the nose, without being able to find the slightest trace of decomposition in any of them. The samples were originally drawn from finished bulks, and have been kept in white glass bottles. After standing on my table for a few days they were put into a glass case standing in a room the temperature of which is generally about 60° F., and they have been protected from light by brown paper hung up inside the case. During the time, they have been frequently exposed to light for short intervals three or four times a week, but I am unable to say how many days or weeks this exposure may represent. The fear of bad effects from the action of light and air on chloroform dates back to the time when it was made and sent out of sp. gr. 1500. It was then, and still is, a very well-founded fear so far as 1500 chloroform is concerned, but I think it has in its full force been frequently very unjustly allowed to attach itself to the alcohol-reduced article now so universally employed. In order to compare the effect of exposure to sunlight on lime-treated and ordinary chloroform, the following experiments were made with pure chloroform and slaked lime:—

1. Chloroform sp. gr. 1500 + slaked lime and exposure, decomposed in two days.
2. Chloroform sp. gr. 1497 + slaked lime and exposure, decomposed in five days.
3. Chloroform sp. gr. 1497, exposed without lime, was not decomposed after several weeks.

Nos. 1 and 2 contained carbonyl chloride, and free lime combination had not therefore, as indicated by Dr. Newman and Professor Ramsay, taken place, and the remaining chloroform contained such large quantities of carbonyl chloride that it could not possibly have been used for anæsthetic purposes. Although the results of only three experiments are given, others were made which confirmed them. Lime treatment, as a means of purifying decomposed chloroform and maintaining it in a state of purity, has been fairly tried and found wanting; it should, therefore, be abandoned in favour of alcohol, the agent which has for the past thirty-five years done its duty so well. Since its introduction I have not met with a single authentic case of decomposition, which is fairly strong evidence in its favour, and justifies the refusal to accept a substitute until it has proved its equality or superiority to it as a preservative.

STYPTICINE IN METRORRHAGIA.—Bakoffen (*Klin. Therap. Woch.*) has found stypticine (cotarnine hydrochloride) prompt and serviceable in the treatment of metrorrhagia. It is prescribed in doses of 2½ to 5 centigrammes three or four times daily, either with sugar in a cachet, or else in pills.—*Bull. Gen. de Therap.*, cxxxv., 931.

* Read at an evening meeting of the Pharmaceutical Society in Edinburgh, on December 21, 1898.

PHOTO-MICROGRAPHY.—X.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

High Power or Critical Photography.

[WITH PLATE.]

This subject commences where medium power may be said to end. I shall take specimens of several objects and describe each in detail, as it is a necessity, seeing that arrangements peculiar to each nearly always obtain. We now use our 1/6th inch objective and obtain a specimen of *Polyxenus lagurus*, the hair of the pencil-tail. This innocent-looking little hair is an excellent test for colour correction of the objective, and few lenses but the very best will show the object white. If a photograph be taken, then, with a badly corrected objective, it will look dirty, and the object, instead of standing out cleanly cut, will look as if it was steeped in mud. The N. A. 1.0 condenser must be used, and I confess to having a predilection for Powell and Lealand's new apochromatic. It is not quite free from spherical aberration, so must be centered with the greatest of care. First close the iris as small as possible, lower the condenser till the image of the hole is seen with a low eye-piece. Centre it and re-obtain critical light. Expose, about five to ten seconds; it is short, but the object is exceedingly faint. Slightly close the iris with caution and open the Davis diaphragm. The *Navicula spectabilis* may be photographed with this objective. Keep the diaphragm rather closed and widely open the Davis; the exposure about the same.

Now we come to a more difficult, in point of fact the most difficult part of the subject. I refer to the use of the larger and 1/12 immersions, and must premise my remarks upon the use of these lenses by saying that as the larger and 1/12 apochromatics both have a N.A. of 1.40, nothing save magnification is gained by the use of one power over the other. With respect to my own personal experience I find that for general work, excepting that of photographing bacilli, no lens ever made, that I have seen, and I have tested a great many in the last twenty years, can compare with the larger or 3 Mm. apochromatic made by Zeiss. A large working distance, excellent definition, and a perfection of optical centring are all combined in this lens. For photographing diatoms I know of no equal to it. It will stand a 27 eye-piece with suitable objects without producing the faintest falling-off in any respect. But for bacteria I do not find the field is so flat as we could desire, and the 1/12, especially made by Powell and Lealand for this class of work, whilst not in my estimation rendering such a good performance with diatoms, is far better for the purpose for which it was especially designed. The field is so much flatter in the Powell lens, whilst the definition of the faintest flagellum is superb. Hence for diatoms I always employ the Zeiss 3 Mm., and for bacteria the Powell and Lealand.

With these high powers it is needless to point out that only a very small portion of a specimen can be photographed at one given time; hence it has to be carefully searched for a typical place in the case of tissues, bacilli, etc., and for a well-marked and evenly-mounted specimen when dealing with diatoms. It is best to do this at some time previous to taking the photograph; in fact, to do it at one's leisure, noting the place by the verniers attached to the mechanical stage. By this means, when the actual photograph is to be taken, the verniers have only to be reset, and no search made at the time.

I say this because searching for an object when the microscope is horizontally placed on the table necessitates a continued bending of the body over it, which is certainly fatiguing. This is a fault I am aware of in my own arrangement, about which I have spoken, and it is remedied to a certain degree in the

best forms of expensive apparatus sold ready made, by having a sort of turntable to the microscope, which allows the whole instrument, with its jet and condensers, to rotate away from the camera, and permits the operator to hunt through the specimen certainly with more comfort than is afforded by the use of our own plan. This I willingly admit, but what I have found personally is that it is far better, as previously pointed out, at some other time to have searched through the slide, and not to leave it until the moment of taking the picture. Hence the lack of this arrangement, which is very expensive, is much more apparent than real.

Let us select a *Navicula rhomboides*, and, having oiled the immersion objective to the cover-glass and obtained critical light, we may for the specimen under consideration close the diaphragm a little, taking especial care to avoid diffraction effects. The attention of the photographer must be very close, or they may be very easily overlooked. The auxiliary condenser had better be used, and perhaps the faintest amount of oblique light, to sharpen up the dots. It is not an easy object to take, as the diatom itself is not flat, being as its name implies—boat-shaped. Occasionally monochromatic light—green is very good—may be employed.

It may require half to a minute's exposure with this colour, but considerably less if without. The exact time is difficult to state, for with these high magnifications the state of the lens, its quality, and the purity of the gases used, not to mention the blending of the two gases at their best illuminating power, are all such variable and yet such important factors. Of these one should be especially mentioned, it is the purity of both gases. The limes, it is true, are difficult to get good, but when a good tin is opened, and if kept well shut down when not in use, all of its contents are mostly of the same quality. But with the gases it is different. The amateur cannot test either without elaborate means, not often at his disposal. Hence he may often find that his exposures go wrong when he least expects it, entirely owing—or anyhow very largely—to his oxygen being exceedingly impure. To prevent any accident of this kind, at Brin's oxygen works the oxygen is tested almost hourly, and users need have but little fear that it is absolutely of the finest quality, which cannot be said of the producers at cheap rates, for the writer has heard of some instances where it was so very largely adulterated as to be next to useless. Another source of trouble will come from a blackening of the lime during the exposure, which lessens the brilliancy perhaps some 20 per cent. The firm to whose method of procedure I have alluded has made this an especial subject of study, and traced it to impurities in the coal-gas, which when compressed have some ill-defined chemical action on the steel of the tube itself. After much consideration and experiment they have found that it can be very largely—if not entirely cured—by coating the inside of the coal-gas cylinder with a dressing which, whilst preventing the gas attacking the metal, in no way alters its chemical properties. I have had my own coal-gas cylinder dressed this way, and so far have found it very successful.

It is interesting now to take the same diatom with a half-inch N. A. .65, using a high eye-piece or camera length to get the same magnification. It will be found that although the pictures are of the same size, one reveals the dots and the other does not, or if it does at all, most imperfectly. This is an illustration of the value of numerical aperture.

Another very good specimen to photograph is the *Coscinodiscus asteromphalus*, selecting, of course, the fine secondary markings. These require a little more oblique light than the previous, and in the Zeiss pattern microscope is easily effected by turning the screw of the oblique-light-motion just a touch more. In other

microscopes the auxiliary condenser and the light will require setting obliquely, or if using a mirror to reflect the light up the microscope it will have to be obliquely placed, and a stop added beneath the condenser with crescent-shaped stop. Focussing becomes now quite an art and the operator must not be disappointed if he has to take several negatives to get one really well in focus. The diaphragm will require careful adjustment for the object, but the Davis must be opened wide. Exposure will here vary greatly according to the amount of oblique light; and if a faint negative be obtained it is better at once to give three times the exposure to the next one. It may be better not to use any monochromatic screen or glass, but this varies very much with the ability of the operator, the amount of oblique light used, and the beauty of the specimen, for some are so much better marked than others.

Seeing we may now be using over 1000 diameters, according to the eye-piece used and the camera length, the greatest attention must be exercised in all adjustments, and the dark slide must be put into the camera in the most gentle manner possible, whilst opening the draw-slide cannot be effected with too much care. Centering the condensers and the light becomes now more than ever an act of refinement, and all movements around or about the table whilst taking the photograph must be strictly forbidden, even though it is supported on cement feet apart from the floor.

The *Pleurosigma angulatum* is another test object of much interest. It can be procured, mounted on the cover-glass, which means in air, or in a highly refractive medium such as realgar. It has two principal planes of focus, and much difference of opinion exists as to which is the correct one. For some reason, which is not very easy to discover, many microscopists find the diatom easier to photograph if mounted in air; and the easier plane of focus, the one adopted by Dr. Zeiss in his celebrated picture, where black hexagonal marking surrounds a white centre. But other authorities are equally strong in their opinion that the true focus is where the hexagonal markings are white and the centre portions dark. The last pictures taken by Dr. Van Heurck with the new Zeiss 1.6 objective and the attendant paraphernalia seem to show that after all the "black dot" is more correct than the white one. As before stated, the white one is somewhat the easier to photograph, and the dark dot seems never to be sufficiently defined to look as sharp as we should like it. It is also more often ovate, and this peculiarity I have noticed in photographs taken by others more experienced than ourselves. No arrangement that I am aware of will cure this peculiar defect, but it is not easy to notice it unless special attention be paid to the point.

When specimens are mounted in realgar another appearance may often be seen. It has been called the "pearl dot" where each white dot—which is now seen dusky around its base—seems literally elevated from its surroundings, whilst it is crowned at its summit by a very pronounced white tip, the so-called "pearl." Of course this is an optical phenomenon, but it is very beautiful in some specimens.

In photographing the white dot plane of focus—the first I mentioned—a narrow illuminating cone is required, and perhaps a touch of the faintest kind of "oblique light," too much will make the black hexagonals look elongated and distorted. With the black dot plane of focus no oblique light should be used, but the cone of light issuing through the condenser should be carefully controlled by the iris so as to get the best effects without more closure than possible. As I have before stated, it is not easy to get the definition so perfect at this plane of focus, as will be seen by inspecting pictures taken by the few who have given attention to the matter.

As regards the "pearl dot," I have never been able either to see them well or to photograph them, unless the specimen was mounted in realgar—hence I am led to suppose their presence is in some way due to the high refractive index of the mountant. A narrow cone and small amount—only a touch of oblique light is required. A somewhat peculiar point must be mentioned before we leave this specimen. To obtain a photograph of it direct, of more than 1000 diameters, is a most difficult thing, and the result has never been good, no matter what plane of focus. Neither have I ever been satisfied with the results obtained by others. The only way to get increased amplification is to re-enlarge the negative, a plan adopted by several of the best photo-micrographers, including Dr. Van Heurck. This is curious because with *Surirella gemma*, there is no difficulty of doing so, even up to 3000 diameters.

SURIRELLA GEMMA.—Oblique light is here needed, and a specimen mounted in realgar best and a narrow cone of light is wanted. The little dots are mostly square, ovate, or circular, sometimes all shapes being found in one specimen. In Dr. Van Heurck's last photographs with the new lens they appear in general ovate, but some are round. They are about 50,000 to the inch.

PODURA SCALES.—The scales of the podura are also by some considered fine tests for a good objective. If studied they will be found to exhibit curious markings—"notes of exclamation" as they are called. These simple markings should be shown easily with a 1/6th, but of what I am about to speak and what I may, for convenience of description, call "the white interior of the note," requires more magnification and a little higher N. A. Indeed, to do so perfectly an 1/8th, with fairly high N. A. and a fairly high eye-piece or much camera extension is required. I say a fairly high N. A. because I am aware that N. A. is not of so much consequence with this specimen. It is the colour correction that is of so much importance, and any failure in this respect will be readily apparent visually by showing the "white interior of the note" coloured, and photographically by failing to show it clear and well defined. Indeed, nothing but the very best of apochromatics exhibit this centre as strictly and absolutely white. Concerning definition, the white centre should in the photograph distinctly show a well-marked construction around its neck at the broadest part, and the whiteness should be prolonged, becoming narrower and narrower until almost a line for about two-thirds of the entire length of the black note itself. Good specimens are difficult to obtain; R. and J. Beck, of Cornhill, have the largest assortment.

AMPHIPLEURA PELLUCIDA, KÜTZ.—Perhaps the most difficult specimen, both to obtain as well as to photograph, is an *Amphipleura pellucida*, Kütz. None that the writer has ever seen can compare with those mounted in realgar by Dr. Van Heurck. Some considerable practice is necessary before the beginner can even see the lines, much less photograph them. It may be of service to assist him if I mention the following:—Although it is difficult to explain, still I have found that to see the lines well no auxiliary condenser is absolutely necessary; I can do so perfectly and without any difficulty, measure them with the N. A. 1.0 condenser, the F-line screen, and oblique light. But to photograph them so that the lines shall be pure and of about one-third the thickness of the white space between any two, that the auxiliary condenser, as well as the 1.30 substage condenser oiled to the slip, must be employed. It is also to be recollected that the final perfection of the image, as seen on the ground glass with the 18 or 27 eye-piece, should be attained by manœuvring the auxiliary condenser from side to side, rather than by using more and more oblique light.

This point to bear in mind is of all importance, as I have found that by so doing the lines appear finer and the exposure is enormously reduced. Without the additional condenser and not using so wide angled or so perfect a substage condenser, I failed after even an hour had been spent with the plate exposed, to obtain a good negative, and this I traced to the fact that the heat either caused the realgar to melt—if it may be so said—or it upset the focussing of the microscope itself. But after repeated trials I discovered the advantage of obtaining the perfected image by finding the suitable position for the auxiliary lens, and also the advantage of using Mr. Conrady's perfectly achromatised 1.30 condenser, for I was able to reduce the time so considerably that my son actually obtained a first-rate negative with only thirty seconds' exposure, although using the F-line screen. The closeness of the lines differs with various specimens. In my case I actually measured them and found they were about 76,000 to the inch. Hence, if an ordinary hair of the head was split into 400 strips, one strip would about fill the space between any two lines. To photograph these lines as dots is the highest record for the photo-micrographic student. According to some great authorities it can only be done with a lens which has an aperture of over 1.40, which means an expense of no small amount, seeing that a special condenser is also required, let alone slips and cover-glass cut and polished from a block of glass having the actual refractive index required for the optical combination.

Dr. Van Heurck, however, it is believed, somewhere about 1884, with some form of silvered preparation, made a photograph showing the lines resolved into beads, but in 1887 actually succeeded in photographing them by transparency, employing monochromatic solar illumination. I have never seen the photograph, but in 1889 the same renowned microscopist and photographer took with the new lens, what must be considered as his *opus magnum*, a photograph of the lines at 2000 diameters which sets any doubts at rest concerning the possibility of obtaining such resolution. Here I must pause a moment, for I know there are many authorities who entirely disagree with the reality of these pictures, believing them to be nothing but photographs of optical phenomena. I admit that the matter is very uncertain, for it is a known fact that the phenomena displayed by the *Pleurosigma angulatum* have been the subject of mathematical inquiry, and it is maintained by no less an authority than that of Professor Abbe himself, that the mathematician can accurately show what this image should be in direct accordance with the number of diffraction spectra that the objective itself has transmitted. Hence, in the case of this diatom, theory indicated the optical, but not necessarily the structural existence of the tiny markings. Dr. Eichhorn actually made the calculations of their size and shape without knowing of their existence, and when Mr. Stephenson re-examined the object with annular light he saw them, whilst Dr. Zeiss has since been able to photograph them. Why should this not apply to *Amphipleura pellucida* equally well?

Another disturbing appearance is that of a distinct image of the dots being occasionally seen outside the diatom itself, lying in space. Here we are confronted with an exhibition that nothing but optical phenomena can possibly explain. Hence I never employ oblique light unless it emphasises what can be seen without its use. If by its extreme use I can benefit my pictures, but get these "outside" effects, I reject them, and only accept photographs which may not to the eye be so elegant, but to the mind which prefers unquestionable reality, appeal all the more readily.

(To be concluded.)

BRITISH PHARMACOPŒIA, 1898.

THE PROPOSED INDIAN AND COLONIAL ADDENDUM.

The following is the list, with descriptions—continued from page 612—of drugs already proposed by Indian and Colonial Authorities for official recognition in the British Pharmacopœia, and suggestions for pharmaceutical preparations. Further suggestions are invited by the Pharmacopœia Committee of the General Medical Council from any British Dependency where the drugs of the British Pharmacopœia of 1898 are insufficient for local requirements, and comments are invited from readers of the Journal in India and the Colonies.

BUTEÆ GUMMI.

Butea Gum.

An exudation from the stem of *Butea frondosa*, *Roxb.* [Bentl. and Trim. 'Med. Pl.,' plate 79].

CHARACTERS AND TESTS.—In small angular pieces of a very dark ruby colour, opaque by reflected light, but transparent by transmitted light when in thin films. Partially soluble in *water*; in *alcohol* (90 per cent.) about 40 per cent. of the gum is soluble, the solution being scarcely coloured. It has no odour; but it has a purely astringent taste. It should be free from an admixture of corky or woody particles.

[Proposed by the Indian Government Committee for use in India as the equivalent of the official (East Indian) Kino.]

PREPARATIONS.

Pulvis Buteæ Gummi Compositus. (Formula as Pulvis Kino Compositus, 1898.)

Tinctura Buteæ Gummi. (Formula as Tinctura Kino, 1898.)

BUTEÆ SEMINA.

Butea Seeds.

The seeds of *Butea frondosa*, *Roxb.* (*Butea monosperma*, *Taub.*) [Bentl. and Trim. 'Med. Pl.,' plate 79.]

CHARACTERS.—The flat reniform seeds are from one to one and a half inches (twenty-five to thirty-eight millimetres) long, from three-quarters of an inch to one inch (sixteen to twenty-five millimetres) wide, and from one-sixteenth to one-twelfth of an inch (one and a half to two millimetres) thick. The testa is thin, glossy, veined, wrinkled, and of a dark reddish-brown colour. There is a large prominent hilum situated in the middle of the concave edge. The cotyledons are large, leafy, and of a yellow colour. The seeds have a faint odour and a slightly acrid taste.

[Proposed by the Indian Government Committee for use in India as the equivalent of *Santonin*.]

PREPARATION.

INFUSUM BUTEÆ.

Infusion of Butea.

	IMPERIAL.	METRIC.
Butea Seeds.....	¼ ounce	12.5 grammes.
Distilled Water (boiling)..	1 pint	1000 cubic centimetres.

Infuse in a covered vessel for fifteen minutes; strain.

Cambogia indica, Indian Gamboge.—[The Indian Government Committee have suggested that the Gamboge of *Garcinia Morella* might be used in India instead of the official Gamboge of *Garcinia Hanburii*.]

The product of *Garcinia Morella*, *Desr.*, appears to agree in every particular with that of *Garcinia Hanburii*. As all the specimens in this country are greatly contaminated with extraneous matters, it is desirable to know if it is possible to obtain a gum resin in commerce which contains such a small quantity of impurities as to permit of favourable comparison with the official drug. If such can be obtained it will only be necessary to include *Garcinia Morella*, *Desr.*, in the British Pharmacopœia as an additional botanical source to that already named.]

[Camphorodyne.—The word "chlorodyne" does not appear in the British Pharmacopœia, and it would not be desirable to employ the word "camphorodyne." The article, however, might be made official, if at all, under the name of "Tinctura Chloroformi et Camphoræ Composita." It is desirable, however, that any such official compound should have more than absolute local use. Information should be afforded as to whether camphorodyne is used in diarrhœa and colic over a wide area.

Suggested for use by the Principal Medical Officer, Her Majesty's Forces in India.]

CAT'CHU NIGRUM.**Black Catechu.**

An extract prepared from the wood of *Acacia Catechu*, Willd. [Bentl. and Trim. 'Med. Pl.,' plate 95].

CHARACTERS AND TESTS.—In irregular masses of a dark brown colour, brittle, having a porous, glossy, somewhat conchoidal fracture. Partially soluble in cold water, almost entirely in boiling water. Not less than 80 per cent. should be soluble in alcohol (90 per cent.) The dilute aqueous solution gives a dark green colour with test solution of ferric chloride, changing to purple when made alkaline with solution of sodium hydroxide. It is without odour; it has a sweetish, astringent taste. When incinerated it should not leave more than 6 per cent. of ash.

[The extracts of the wood of *Acacia Catechu* and of the fruit of *Areca Catechu* are suggested by the Indian Government Committee for use in India instead of the Pale Catechu from *Uncaria Gambier*. It seems doubtful if the extract of *Areca* fruit is required.]

PREPARATIONS.

Pulvis Catechu Nigri Compositum. (Formula as **Pulvis Catechu Compositus**, 1898.)

Tinctura Catechu Nigri. (Formula as **Tinctura Catechu**, 1898.)

Trochiscus Catechu Nigri. (Formula as **Trochiscus Catechu**, 1898.)

CISSAMPELOS.**Cissampelos.**

The root of *Cissampelos Pareira*, Linn. [Bentl. and Trim., 'Med. Pl.,' plate 15].

CHARACTERS.—In slightly compressed undulating pieces attaining a diameter of half an inch (twelve millimetres). It is covered with a dark brown bark, easily separable from the underlying fibrous wood, marked with broad shallow longitudinal furrows and fine transverse cracks. A transverse section exhibits a rather narrow bark surrounding a yellowish-brown woody column consisting of one ring of from ten to twenty woody wedges separated from each other by distinct narrow medullary rays; the vessels of the xylem are large and may be seen with the naked eye. The fracture is fibrous. The root has no odour; it has a very bitter taste.

[Suggested by the Indian Government Committee for use in India instead of the dried root of *Chondrodendron tomentosum*.]

PREPARATION.

Extractum Cissampelos Liquidum. (Formula as **Extractum Pareiræ Liquidum**, 1898.)

COSCINIUM.**Coscinium.**

The stem of *Coscinium fenestratum*, Colebr. [Hooker's 'Botanical Magazine,' plate 6458, contrib. III. 22, plate 28].

CHARACTERS AND TEST.—In cylindrical straight or twisted pieces of variable length and attaining a diameter of four inches (one decimetre); furrowed longitudinally and bearing occasional transverse narrow fissures. It is covered with a pale yellowish-grey cork, which is removed in many places and displays the subjacent brown cortical tissues. On transverse section it exhibits a cortex which varies considerably in thickness according to the age of the stem; this contains in the inner portion numerous semilunar masses of phloem; the wood consists of one ring of wedge-shaped bundles containing many large vessels and surrounding a small central pith. There are many well-marked expanding medullary rays of a rather lighter colour than the woody wedges. The wood breaks with a splintery fracture. The stem has no odour; it has a bitter taste. A cooled decoction gives no reaction for starch with solution of iodine.

[Suggested by the Indian Government Committee for use in India instead of *Calumba*.]

PREPARATIONS.

Infusum Coscinii. (Formula as **Infusum Calumbæ**, 1898, using boiling water.)

Liquor Coscinii Concentratus. (Formula as **Liquor Calumbæ Concentratus**, 1898.)

Tinctura Coscinii. (Formula as **Tinctura Calumbæ**, 1898.)

CRINUM.**Crinum.**

The bulb of *Crinum asiaticum*, var. *toxicarium*, Herbert [Wight, 'Icones,' plate 2021].

CHARACTERS.—The bulb consists of a lower solid fusiform portion and an upper bulbous portion composed of numerous whitish or brownish-white membranous leaves longitudinally traversed by narrow equidistant nerves. The two portions are frequently found in sections from an eighth to a quarter of an inch (three to six millimetres) thick. The solid sections have an outer, dark brown, transversely wrinkled corky layer surrounding a broad cortical portion of a brown or whitish-brown colour and marked with narrow radial wrinkles. The centre portion is of a darker colour and has a granular surface. The whole of the solid section is considerably shrunken and has a wavy margin. It has a characteristic odour somewhat resembling dried figs, but no marked taste.

[Suggested by the Indian Government Committee for use in India instead of *Squill*.]

PREPARATIONS.

Pilula Ipecacuanhæ et Crini. (Formula as **Pilula Ipecacuanhæ et Scillæ**, 1898.)

Oxymel Crini. (Formula as **Oxymel Scillæ**, 1898.)

Pilula Crini Composita. (Formula as **Pilula Scillæ Composita**, 1898.)

Syrupus Crini. (Formula as **Syrupus Scillæ**, 1898.)

Tinctura Crini. (Formula as **Tinctura Scillæ**, 1898.)

Acetum Crini. (Formula as **Acetum Scillæ**, 1898.)

CINNAMOMI LIGNUM.**Cinnamon Wood.**

[The wood of *Cinnamomum Glanduliferum*, Meiss., is suggested by the Indian Government Committee for use in India as the equivalent of *Sassafras*. A description of commercial specimens of the wood should be supplied from India, specimens in England differing widely in character.]

DATURÆ FOLIA.**Datura Leaves.**

The leaves of *Datura fastuosa*, Linn., var. *alba* Nees [Wight, 'Icones,' plate 1396], and *Datura Metel*, Linn. ['Bot. Mag.', plate 1440].

CHARACTERS.—Ovate, acuminate leaves with long petioles and sinuate-dentate margins; often unequal at the base; they attain seven or eight inches (seventeen or twenty centimetres) in length and four or five inches (ten or twelve and a half centimetres) in breadth. They have a characteristic odour and a bitter taste.

[Suggested by the Indian Government Committee as an equivalent in India of the official *Folia Belladonnæ*, and by the Authority at Hong Kong for use there in addition to *Stramonium Leaves*.]

PREPARATION.

Tinctura Daturæ. (Formula as **Tinctura Stramonii**, 1898.)

DATURÆ SEMINA.**Datura Seeds.**

The seeds of *Datura fastuosa*, Linn., var. *alba* Nees (*Datura alba*, Nees [Wight, 'Icones,' plate 1396].

CHARACTERS.—The seeds are somewhat wedge-shaped, with rounded, thickened, furrowed, wavy margins, strongly compressed latterly; from one-sixth of an inch to one-fifth of an inch (four to five millimetres) broad, and about one twenty-fifth of an inch (one millimetre) thick. The hilum is situated on one edge and extends from about the middle to the acute end of the seed. The testa is finely pitted and reticulated and is of a dull yellowish-brown colour; it is comparatively thick, and encloses a narrow translucent endosperm. The seeds are without odour; they have a rather bitter taste.

[Suggested by the Indian Government Committee for use in India instead of *Stramonium Seeds*.]

PREPARATION.

Tinctura Daturæ. (Formula as **Tinctura Stramonii**, 1898.)

DUBOISIA.**Duboisia.**

The leaves of *Duboisia myoporoides*, R. Br. []

CHARACTERS.—Shortly-petiolate, lanceolate, entire leaves; from three to four inches (seven and a half to ten centimetres) long, and from three-quarters to one inch (eighteen to twenty-five millimetres) broad; thin, smooth, narrowed at both ends; margin slightly thickened. Inodorous, but having a bitter taste.

[The Medical Society of Queensland send a small specimen of the leaves of this plant, and, together with the Queensland Pharmacy Board, recommend various preparations of the plant and of its alkaloid, duboisine, for official recognition.]

The Victorian Branch of the British Medical Association also recommend the inclusion of *Duboisia myoporoides*, R.Br., and, with the concurrence of the Pharmacy Board of Victoria and the Pharmaceutical Society of Australasia, give formulæ for *Tinctura Duboisie* and for *Unguentum Duboisine*.

The late Baron Von Mueller, the Government Botanist, supported the Victorian recommendation, and gave copious references to the chemical, pharmacological, and pharmaceutical literature of the *duboisias* up to 1884.

The subsequent literature, however, shows that as regards the alkaloid duboisine, it is sometimes hyoscyamine, and sometimes hyoscyne (Ladenburg), but never a separate distinct alkaloid, to which such a name as duboisine could properly be applied. The mother liquors of hyoscyamine sulphate, whether from hyoscyamine or from *duboisia*, yield hyoscyne sulphate (Schering). It should be remembered, too, that the alkaloid atropine probably does not exist as atropine in *belladonna*, but is a product of the alteration of, and is isomeric with, hyoscyamine, said to be the chief and often sole alkaloid in *belladonna*, and that the so-called daturine of *stramonium* is hyoscyamine.

That the official recognition of *Duboisia myoporoides* as a local medicinal substitute for *Atropa Belladonna*, Linn., or *Hyoscyamus niger*, Linn., is not considered by the Australians to be desirable by reason of any local scarcity of the latter plants, is obvious from the recommendation, by the Victorian Authorities, of the official recognition of both *belladonna* and *henbane* grown in the Colony of Victoria, where, indeed, they are stated, in the Committee's report, to flourish satisfactorily.

Considering the foregoing facts and that salts of hyoscyamine and hyoscyne are now official, the Medical and Pharmaceutical Authorities of Queensland and Victoria are invited to reconsider their recommendations in regard to *duboisia* and duboisine.

The Queensland authorities draw attention to *Anthocercis viscosa*, R. Br., and *A. Tasmanica*, Hook., as containing an active principle similar to duboisine. Probably this principle also is hyoscyamine or hyoscyne, or a mixture of these two alkaloids.

As to *Duboisia Hopwoodii*, F. Muell., the "pitury," tree of Central Australia, and its alkaloid piturine—said to be allied to but not identical with nicotine—to which the Authorities in Victoria draw attention, its pharmacology has not yet been sufficiently determined to warrant its official recognition.]

EMBELIA.

Embelia.

The fruit of *Embelia Ribes*, Burm. [Burm., 'Flor. Indic.' plate 23].

CHARACTERS.—Globular, superior fruit, about one-sixth of an inch (four millimetres) in diameter; varies in colour from a dull red with dark spots to nearly black, striated longitudinally; often attached to a five-partite calyx and surmounted by a minute beak. It contains a horny seed of a reddish colour surrounded by a delicate membrane and covered with a fine efflorescence. Taste slightly astringent and aromatic.

[Recommended by the Indian Government Committee for use in India in place of the official *Kouso* and *Male Fern*. What preparations are desired?]

Eucalypti Gummi.—*Eucalyptus Gum*.—[The Victorian Authorities recommend that official *Eucalyptus Gum* be limited to the product of *Eucalyptus rostrata*, and suggest a *Suppositoria Eucalypti Rostrate*, a *Syrupus Eucalypti Rostrate*, a *Tinctura Eucalypti Rostrate*, and a *Trochischus Eucalypti Rostrate*. Information is desired as to the special advantage of thus limiting *Eucalyptus Gum*. Is it desirable to include *Eucalypti Gummi Rostrate* in the Addendum under present circumstances? Would it be satisfactory if the preparations above mentioned were made with the gum as defined in the British Pharmacopœia of 1898? The Lozenge thus made is already official.]

Euphorbia pilulifera.—[The Victorian authorities suggest the inclusion of this drug and its preparations, but do not support their recommendation in any way. Is there sufficient evidence of the value of the drug to render its admission advisable?]

EXACUM.

Exacum.

The dried plant of *Exacum bicolor*, Roxb. [Wight, 'Icones,' vol. iv., plate 1321].

The stems are about two feet (six decimetres) in length, sharply quadrangular and narrowly winged, and about one-fifth of an inch (five millimetres) in diameter. The leaves are opposite, sessile, ovate or ovate-lanceolate, two and a half to three and a half inches (six to nine centimetres) long and three-quarters to an inch and a half (two to three and a half centimetres) broad, and furnished with five veins. The calyx is deeply four cleft into ovate-subulate segments. The corolla is large, the segments being one inch (two and a half centimetres) long and about two-fifths of an inch (one centimetre) broad; white, but tipped with purple. The inflorescence consists of cymes which are two to three times trichotomously branched.

[Recommended by the Indian Government Committee for use in India as the equivalent of *Chiretta*. Should the preparations be similar to those of *Andrographis*?

EXTRACTUM GLYCYRRHIZÆ SPIRITUOSUM.

Spirituos Extract of Liquorice.

Mix ten ounces (or five hundred grammes) of Extract of Liquorice with sufficient Distilled Water to form a liquid; add five fluid ounces (or two hundred and fifty cubic centimetres) of Alcohol (90 per cent.); then add sufficient Distilled Water to produce a well-mixed bulk of twenty fluid ounces (or one thousand cubic centimetres); filter if necessary.

[This mode of preparing a "Liquid Extract of Liquorice" is desired for local convenience in Hong Kong.]

Fœniculi Fructus—Fennel Fruit.—[The Examiner of Medical Stores in India inquires of the Indian Government Committee as to whether or not Indian fennel may be employed in making *Pulvis Glycyrrhizæ Compositus*. The Committee reply in the affirmative, but state that the powder is not issued by the medical depôts. If the official recognition of "Indian Fennel" is still desired, the name of the plant and descriptions of its fruit should be supplied from India.]

Fœniculi Fructus.—Fennel Fruit.—[A description of the fruit of *Fœniculum officinale*, *Fœniculum vulgare*, Mill., desired for official recognition, should be forwarded by the Victorian Authorities, if it differs in any important respect from the Fennel Fruit now official. In the latter case the distinctive name should be *Fœniculi Fructus Victoriae*—Victorian Fennel Fruit.]

Glycyrrhiza Radix.—[The Indian Government Committee suggest the use of the root of the *Abrus precatorius* in place of *Liquorice Root*. The seeds of this plant (Jequirity Seeds) are very poisonous, and Dymock, Warden, and Hooker ('Pharmacographia Indica,' vol. i., p. 432) consider the root bears very little resemblance to liquorice either as regards appearance or qualities. It would seem better not to recognise the root until some report of any further investigation has been published.]

GOSSYPII RADICIS CORTEX.

Cotton Root Bark.

The root bark of *Gossypium herbaceum*, Linn. [Berg. und Schmidt, 'Off. Pflanz.' plate 106.]

CHARACTERS.—In thin flexible bands or quilled pieces, covered with a thin periderm of a brownish-yellow colour and marked with fine longitudinal ridges and meshes; it is marked with small black dots or short transverse lines. Where the periderm has been removed it exhibits the underlying orange-brown tissues. The inner surface is whitish, silky, and finely striate. The liber portion is readily separated into thin fibrous laminae. It has a tough fibrous fracture. Inodorous and with a slightly acrid astringent taste.

[Recommended by the Indian Government Committee for use in India instead of *Ergot*. Suggestions from India are desired as to the most efficient preparation. A Liquid Extract is official in the 'United States Pharmacopœia' of 1890.]

GRINDELIA.

Grindelia.

The dried leaves and flowering tops of *Grindelia squarrosa* Donal, and *Grindelia robusta*, Nuttall [

The leaves of *Grindelia squarrosa* are alternate, pale green, smooth, coriaceous, brittle, oblanceolate, or elongate-oblanceolate, the lower leaves tapering considerably below, but scarcely enlarged, and at the sessile base the involucre bracts are long with reflexed subulate points. The leaves of *Grindelia robusta* are similar in colour and texture, but are shorter, more oblong, and have a cordate amphlexicaul base, are furnished with a few glandular hairs, and are sharply serrate at the margin. The

involucre in both species is about half an inch (twelve millimetres) in diameter, and the tips of the bracts are beset with short many-celled glands. Both the involucre and the leaves are more or less covered with glossy patches of exuded resin. The odour is balsamic and the taste pungently aromatic and bitter.

Grindelia Robusta.—[The Victorian authorities suggest the official recognition of this drug and its preparations, but do not support their recommendation by any data. The books allude to it as a remedy in bronchitis, asthma, and whooping-cough, and to *G. squarrosa*, Dunal, as a remedy in ague, hay-fever, and malarial diseases. The Pharmacopœia Committee of the Medical Council has therefore provisionally included both species. What preparations are desired?]

(To be concluded.)

CHEMICAL SOCIETY.

A meeting of the Chemical Society was held on Thursday, December 15, Professor DEWAR, LL.D., F.R.S., the President, in the chair.—The minutes of the previous meeting were read and confirmed, a few new Fellows signed the Register, and the preliminary business concluded with the reading of certificates of candidates for the Fellowship. Among these appeared the name of an old student in the Pharmaceutical Society's School, Mr. Thomas Anderson Henry.

The first paper, by A. W. CROSSLEY, Ph.D., dealt with the Interaction of Ethylic Sodiomalonate and Mesityl Oxide.

The author reviewed his previous work on the subject, and briefly explained how, by condensation of mesityl oxide with sodio-malonic ether, two molecules of each substance react, giving a product which by hydrolysis was found to have the formula $C_{16}H_{24}O_4$. It is an unsaturated compound, combining with bromine, its melting point is $148^\circ C.$, it yields a stable silver salt, and decolorises alkaline permanganate in the cold.

There being no discussion, the same author followed with a short résumé of his recent work on the

Interaction of Ethylic Malonate and Acetylene Tetrabromide in Presence of Sodium Ethoxide.

This paper likewise drew forth no comment, and Dr. WYNNE, Secretary, read a paper by Stanley Kipping, D.Sc., F.R.S., in the absence of the author, entitled

Derivatives of Camphoric Acid. Part III.

Recent investigations by Dr. Kipping have been directed to π -bromo-camphoric acid, which have invariably ended, on oxidation of this acid and further treatment, with the production of hydroxy-campho-tricarboxylic acid, beyond which there was difficulty in getting. The paper dealt with the bromination of π -bromo-camphoric acid, whereby the substance w - π -dibromo-camphoric acid was obtained. This body, in presence of alkalies, lost bromine, giving a bromo-lactone and the dilactone of dihydroxy-camphoric acid. By further oxidation of these derivatives the author obtained hydroxy-campho-tricarboxylic acid as before. In this substance the bromine occupies the same position as in bromo-camphoric acid.—This paper was received with the same silence as its predecessors, whereat the PRESIDENT remarked that the members seemed saturated with camphor derivatives.—After a communication by H. PERKIN, jun., F.R.S., and F. J. THORPE, Ph.D., on the

Synthesis of Trimethylglutaric Acid,

a paper was read by Dr. WYNNE on the

Hydrolysis of Methylic and Ethylic γ -Cyano-aceto-Acetates and their Derivatives, Part I.,

by W. TREVOR LAWRENCE.—This was the signal for the disappearance of the majority of the members.

The SECRETARY, in an able and succinct statement, pointed out that the investigation had resulted in the discovery of a new series of acids. The formula of one of the compounds dimethyl-keto-dicarboxylic acid obtained, however, drew forth criticism from Dr. LAPWORTH, who preferred the ketonic form—

to the enolic form—

Mr. VERNON HARCOURT then took the chair, while the PRESIDENT gave a brief account of his recent attempts to utilise liquid hydrogen in chemical research. The first scientific use to which he sought to apply

Liquid Hydrogen

was in the production of high vacua. By dipping a tube containing air in the liquid, the enclosed air rapidly condenses in the solid state. On sealing off the upper part of the tube in a blow-pipe, a vacuum is obtained, through which an electric spark passes with difficulty. The immersion lasted for no more than a minute, and the temperature attained was $35^\circ C.$ on the absolute scale. At this temperature it was incidentally mentioned that chlorine being $80^\circ C.$ below its boiling point, has no smell and no appreciable vapour pressure. It is necessary for the tubes to be chemically clean and dry, otherwise the carbonic oxide spectrum is obtained, resembling that of a substance which has been called metargon. Sir William Crookes prepared tubes containing no hydrogen and filled with dry air. These were treated as before by Professor Dewar, and showed no carbon spectrum, but one revealed the presence of hydrogen when spectroscopically examined, whilst others contained neon and helium. Some electrodeless tubes on examination by Professor Liveing gave traces of carbon, probably due to carbonates in the glass.

Speaking of the low temperatures attainable by boiling off liquid hydrogen under diminished pressure, Professor DEWAR gave his audience some insight into the extraordinary difficulties that attend low temperature research. The platinum resistance thermometer, the only variety of thermometer hitherto devised that is of any service in the work, has reached the limit of its usefulness. If its powers of registering low temperatures were limitless, then it would indicate the temperatures at which liquid hydrogen boiled under different diminished pressures, but as a matter of fact its resistance only indicated a diminution of $1^\circ C.$ in temperature when the hydrogen was boiling away at one inch pressure.

After some complimentary remarks from Mr. Harcourt, the meeting was adjourned for the Christmas vacation.

SELECTED PRACTICAL FORMULÆ.

LIQUOR HÆMALBUMINI.

Hæmalbumin, 30, is dissolved in water, 652, with heat. Simple syrup, 200; alcohol (90 per cent.), 100; aromatic saccharin solution, 10; arrack, 7; spirit of nitrous ether, 2; bitter almond oil sugar, 0.4 parts; rose oil sugar, 0.4; coumarin sugar, 0.2 (1=1000), are added and the mixture filtered. After standing, the resulting fluid is clear and brown in colour.—*Pharm. Cent.*, xxxix., 460.

FACE POWDER.

The best snow-white face powder requires for its preparation the best white talc powder, very white chalk, rice starch and zinc white, all of the highest quality. Flesh tints for blondes are obtained by using carmine alone; for brunettes burnt umber or sienna is employed. An addition of finely-powdered orris root is advisable, as imparting an agreeable odour to the powder. The following are the proportions:—Zinc white, 500; precipitated chalk, 3000; powdered talc, 500; wheat starch, 1000; white rose essence, 30; jasmine extract, 30; orange blossom extract, 30; cassie extract, 30; musk tincture, $7\frac{1}{2}$.—*Quar. Therap. Rev.*, xvi., 31, after *Pharm. Rundschau*.

LEATHER VARNISH OF VARIOUS COLOURS.

An elastic unbreakable black leather varnish may be prepared from resin, 30; thus, 30; oil of turpentine, 30; sandarach, 60; shellac, 120; alcohol (90 per cent.), 900. Mix and shake together until dissolved, then filter and mix with lampblack, 15, previously rubbed down with some of the alcohol. If another colour is desired use instead of lampblack a sufficient quantity of the desired pigment, such as kermes or zinc white, ultramarine, chrome yellow, or cinnabar (red).—*Deutsch. Amer. Apoth. Zeit.*, xix., 61.

REVIEWS AND NOTICES OF BOOKS.

COMMERCIAL ORGANIC ANALYSIS—PROTEIDS AND ALBUMINOUS PRINCIPLES, ETC. Vol. IV. By A. H. ALLEN, F.I.C., F.C.S. Second edition. Pp. 580. Price 18s. London: J. and A. Churchill. 1898.

In this volume Mr. Allen completes the second edition of 'Commercial Organic Analysis.' This edition has occupied fourteen years in its production, and his readers will learn with regret that the author now finds it to be impossible to undertake the enormous labour which would be necessary for the thorough revision of the earlier volumes, long out of print, although appendices are promised in order to maintain their standard of excellence. This part of the work deals with proteids and albuminous principles, and proteoids or albuminoids. There is a description of their general characters, with classification and analytical reactions, including colour tests and methods for their detection and determination. The proteids of eggs, of blood plasma, of urine, of plants, of milk, and of digestion; then proteoids, which include gelatin, isinglass, glue, the fibroids for silk, and keratin for hair and wool, are separately described and treated in the exhaustive manner that is characteristic of Mr. Allen's work.

There is a mass of information collected from various sources, some of it more or less contradictory, and the reader is frequently bewildered as to which authority to accept and which to reject. It is true that our knowledge of proteid matter is still very limited, and that the conception of the composition of the proteids is entirely hypothetical, for the figures "obtained by the ultimate analysis of the proteids lead to extremely complex formulæ, none of which can be said to have been fully established or even empirically correct, since the difficulty attending the study of the proteids is enhanced by their molecular complexity and tendency to change. At the same time they retain certain neutral salts with great tenacity, and hence it is almost impossible to obtain some proteids free from more or less mineral matter." It may be useful to advance theories as to "the living proteid being composed of a chain of cyanhydrins or cyan alcohols united to a benzene nucleus," but at present we know very little about the nature and composition of proteid matter. This is evident when albumin has to be expressed by the empirical formula $C_{77}H_{120}N_{20}O_{26}S$. The article on the proteids of milk consists of 178 pages, or nearly one-third of the book, and whilst it may be a matter of opinion as to including in a work on proteids a subject more adapted to a treatise on food analysis, it may certainly be said that this memoir on milk and its analysis is about the best that has been written on the subject. It treats very copiously of the various methods adopted in the analysis of milk, and what is of equal importance to the reader, of the interpretation to be placed on the analytical results. It is, of course, only to be expected that the Somerset House chemists are subjected to adverse criticism.

It seems opportune here to suggest that food analysts might now devote their abilities to other investigations, and leave for a time the consideration of the "fluid secreted by the mammary glands of female mammals." Meat preparations might well receive their attention, for it is only necessary to read Mr. Allen's article on meat and meat products to see the necessity of a systematic method of analysis being formulated for these preparations. The author truly states that while meat extracts have a true value as stimulants and restoratives, all attempts to give them characters of nutritive concentrated food can meet with but limited success, and a failure to appreciate these facts has caused

very delusive values to be placed on such preparations, and the errors have been further magnified by the discordant methods of judging the value of such articles. That this latter view is correct may be inferred from the divergent statements that have been expressed and results obtained by various authors. Stutzer, for instance, is of opinion that the only constituents of value in a meat extract are albumoses and peptones, ignoring meat fibre, gelatin, and coaguable albumin, whilst König and Bömer believe that meat extracts contain no peptone, or at most 2 to 3 per cent., and this view is confirmed by Denaeyer and by the author. On the other hand, there is given an elaborate table of analysis, in which all meat extracts are represented as containing peptones, as much, in some instances, as over 10 per cent. Some authoritative expression as to a correct method of analysis is surely necessary to prevent such contradictory statements, if only to afford the means of avoiding the exhibition of commendatory reports on valueless meat preparations, which are upheld as being highly nutritive on the basis of faulty methods of analysis, or on the result of nitrogen determinations, all the outcome of imperfect knowledge of the subject.

In about sixty pages the author deals very clearly with hæmoglobin and its allies, giving analyses of blood, tests for blood with spectra, and methods for its spectroscopic examination and for the enumeration of blood corpuscles. The section on albuminoids, which are here termed proteoids, relates to gelatin, keratin, fibroin, etc. Attention is very properly directed to the still unsolved question as to the importance of ascertaining whether gelatin, although readily digested, has a true alimentary value, in view of the practice of feeding invalids on gelatinous preparations. Analyses with practical tests are given of commercial gelatin, photographic gelatin, isinglass, glue, and kindred bodies. The section on fibroids includes silk and its detection, analysis of mixed fabrics, and the weighting of silk, whilst that on keratin contains descriptions of the constituents of horns, feathers, whalebone, hair, and wool. An addendum of twenty pages contains the latest work on proteid matter, including a criticism on the alleged synthesis of a proteid by Lilienfeld, who seems to have been premature in his claim as to the production of an artificial proteid in the absence of a substance containing sulphur, unless it is to be presumed that a pure proteid contains no sulphur.

It will be perceived how thoroughly Mr. Allen has dealt with his subject matter, and he is to be congratulated, and chemists and pharmacists in particular, on the completion of another excellent volume on commercial organic analysis.

PRESERVATIVE COMPOSITION FOR FURNITURE AND WOOD-WORK.—A composition for the preservation of wood-work and furniture has been patented in France (*Maler Zeitung*). This composition is said to possess the peculiarity of imparting to the articles upon which it is used, not only the desired gloss, but also the appearance and the brilliant colour of perfectly new articles. This distinguishes it from other preparations used for like purposes. The coating leaves no visible layer after the application. It is composed of pale resin, 10; benzene, 82; palm oil, 5; mirbane essence, $\frac{1}{2}$; and essence of peppermint, $\frac{1}{12}$ th. The mixture is prepared by the cold process and the application made as follows:—Apply a little of the composition on the furniture, floors, etc., by rubbing with an old silk rag, then finish off by wiping at once with a dry silk rag, pressing down well, an incomparable lustre is said to be produced. The objects remain in this glossy condition one to two months, according to the amount of dust developing in the rooms. The product must be kept in well-corked bottles. If used in summer it is well to add a few drops of oil.—*Sci. Amer.*, lxxix., 183.

ADMINISTRATION AND AMENDMENT OF PHARMACY LAW.

It will be convenient at the present time to direct attention to the desirability of distinguishing between procedure for effecting amendment of the Pharmacy Act and such steps as may be possible for enforcing its provisions in a manner more consistent with regard to the safety of the public and also with the claims of chemists and druggists who have complied with the requirements of the Statute. That the Pharmacy Act is defective in many respects cannot well be disputed, and experience has sufficiently demonstrated the necessity for amendment of many of its provisions. Originally a misbegotten measure, sorely crippled in its passage through Parliament, the Act has never been intelligible, but a fertile source of opposite opinions; it has been condemned by almost every Judge who has had to deal with it, as being so confused, contradictory, and obscure in its language that its meaning is inscrutable; its panic-bred provisions for public safety have fallen short of effecting their object so far that they have come to be regarded as constituting "a trade monopoly," and the ultimate result of their construction by the Judges has been to establish a state of things utterly subversive of every object the Act was intended to secure. Among other defects of importance may be mentioned the absence of any suitable definition of the chemist and druggist's business of dispensing and compounding medicine, the want of a yearly registration fee, admitting of ready detection of persons unlawfully carrying on the business; of regulations making the admission of an apprentice conditional on passing the Preliminary examination, and making the interval between that and the qualifying examination at least three years. But to obtain those desiderata would require further legislation, and on many of the points referred to there may be need for greater agreement than at present exists.

In regard to the operation of the Act as it stands, past experience has, however, shown that it has not been altogether abortive but capable of being made useful for effecting much that had not been thought possible. Even its greatest failure, in regard to the proprietary qualification of keepers of chemists' shops, has been somewhat compensated for by the judicial construction that the person who actually sells or dispenses, whether he be proprietor or servant, requires to be qualified. Though that construction turns the Act upside

down and establishes an apparent basis for a grievous abuse, it has done some good, for thus both the improper keeping of branch shops and the delegation of duties for the performance of which legal qualification is necessary, have been counteracted to a great extent. Another good effect is that the mischievous sale of poisons in the shape of secret remedies, so long thought to be consistent with the provisions of the Pharmacy Act, has, by more rational regard for the object of the Act, been declared illegal and incapable of being practised under protection of the Patent Law. In all these particulars a common-sense consideration of the main object of the Pharmacy Act 1868—regard for the safety of the public—has been in the end, sufficient to secure for its provisions judicial constructions tending partially to uphold that object. But in one important point the Act has failed to secure even that object, and it has also still more signally failed to secure to legally qualified persons—not protection in the ordinary sense, or "a trade monopoly," but the advantage that should be necessarily an incidental result of the provisions by which the main object of the Act is to be secured.

The development of the system by which combinations of unqualified persons carry on the business of chemists and druggists, has its root in the House of Lords decision in the case of the London and Provincial Association, and under present conditions it practically amounts to a repeal of the Act in every sense. The difficulties of enforcing the law, even in cases of the sale of poison at shops kept by unqualified companies, and of obtaining evidence as to its infringement, render the attainment of its object almost impossible, while the assumption of the title of "chemist" by such companies misleads the public into the belief that the shops designated "drug store" and "cash chemist" are conducted in conformity with the provisions of the Pharmacy Act. In the more important matter of dispensing there is absolutely no means of ascertaining whether it is properly conducted, by duly qualified persons, at such shops. In both cases there is no security that the conditions held to be expedient for public safety are adequately observed. But in addition to failure in that respect, there is another consideration which claims attention. According to every construction of the Act, the "person" legally entitled to dispense, or even to sell poison, or to use the title of chemist and druggist in connection with that business, has been held to mean a person who is registered and has given proof, by examination, that he has a competent practical knowledge of his business. Compliance with those conditions, imposed upon the exercise of the chemist's business and the use of the title, confers by implication upon persons who have satisfied those conditions a prescriptive right to the exercise of that business and to the use of that title which the Act declares to be otherwise unlawful. Moreover, if either of those acts be unlawful for any but qualified persons, the formation of a company to carry on business in connection with the title of "chemist" must be in itself an infringement of the Companies Act. It is this view of the matter which, at the present moment, most urgently requires attention and a united effort by legally qualified chemists and druggists, to obtain from the Law Courts as in the other instances above mentioned, a decision that would relieve them from the unjust interference with their business which they have so long had reason to complain of and one that would, at the same time, give greater effect to the main object of the Pharmacy Act, 1868—the safety of the public.

ANNOTATIONS.

LANCASHIRE CHEMISTS, while still adhering with characteristic tenacity to their conviction that, in dealing with the evils of "company pharmacy," it is the business of the Pharmaceutical Society to take the initiative, have given a very important additional significance to that proposition by recognising the fact that, in order to render the Society sufficiently strong for the purpose of taking action in the general interest of the body, it is the first duty of all persons on the Register of Chemists and Druggists to enrol themselves members of the Society. The recognition of that duty constitutes a great advance from the position of apathetic discontent which has hitherto been too prevalent. The action now being taken to give effect to it in Blackburn, Burnley, Manchester, Preston, and the neighbouring towns is such as will help to make the Society co-extensive with the Register, and to place at the disposal of the Council all the power and influence chemists and druggists are capable of exercising individually and collectively.

IN THE NEIGHBOURING COUNTY OF STAFFORD there is an equally strong conviction as to the prime necessity of a largely extended membership of the Society, for the purpose of establishing solidarity of interest and for creating a power capable either of acting in defence of the position that chemists and druggists hold under the Pharmacy Act, or of endeavouring to promote their interests by further legislation. If the action taken by chemists and druggists in those two counties is not spontaneously followed up elsewhere, their example will, at least, entitle them to call upon their brethren in other parts of the country to join in the good work they have set going. One very noticeable indication of sounder views in regard to the Pharmaceutical Society is the feeling of disgust, and even of resentment, produced by persistent attempts to excite hostility to the Society, to disparage the work of the Council, to represent it as disregarding the interests of chemists and druggists, as being animated only by a covetous desire for guineas, and the President as a mere utterer of "pious opinions," or "irresponsible after-dinner speeches." The just condemnation of such unworthy tactics is an encouraging sign of progress.

"A PARTY RENT BY SECTIONAL DISPUTES and personal interests is one which no man can consent to lead, either with credit to himself or advantage to the country." Thus wrote Sir William Harcourt in his now famous letter, published last week, and the remark is probably one of the most accurate he ever gave utterance to. Applying the words to our own affairs, they fit the situation exactly, for in the world of pharmacy sectional disputes and personal interests have predominated to a disheartening extent for many years past. They existed before the Pharmaceutical Society began its career, and they have continued in a more or less acute form ever since. At the present moment, however, an exceptional opportunity presents itself for repairing the rent in the craft, and that opportunity should be taken the fullest advantage of. It will be simply disastrous if sectional disputes and personal interests are permitted to retard the progress of pharmacy any longer, and the insidious attempts made to perpetuate differences—from a quarter whence those differences were originally suggested—ought to meet with but little support from registered chemists. In this connection, it may be observed that a member of the Pharmaceutical Society, writing to the Secretary, says he "resents the useless hypercriticisms of trade journals whose object is to live on pharmacists rather than elevate pharmacy." What another

member thinks of impertinent interference with the Society's affairs may be judged from his letter printed at page 687.

NO ABATEMENT IS SHOWN, as plainly indicated by the reports in our pages this week, in the interest taken by registered chemists throughout Great Britain in the topics suggested for their consideration by the Federation of Local Pharmaceutical Associations. There cannot now be many parts of the country from which expressions of opinion have not come, and the Council of the Pharmaceutical Society will be able, at its next meeting, to form a fair estimate of the state of feeling on the points discussed. Though the fact has not always been indicated in the reports, we are given to understand that the attendance at the various meetings has been exceptionally large in most cases. Indeed, they have generally been meetings of the whole trade in the respective districts rather than mere association meetings. That is as it should be, and we hope it may be accepted as an omen of that real union of the trade which has been lacking so long.

Mr. JOSEPH BOSISTO, C.M.G., whose death is announced as having occurred on November 8, at Richmond, Victoria, had been an honorary member of the Pharmaceutical Society of Great Britain since 1887. A letter received from him within the past fortnight afforded no indication that he was in ill-health. It has been stated that, in his early days he studied at the Leeds School of Medicine, but we are informed that, after searching the books of the Leeds Medical School, the Dean has been unable to find any record of such a person on the School lists. What is certain is that, having decided to adopt pharmacy as a calling, Mr. Bosisto came to London and studied for some time at the School of Pharmacy. Subsequently, he emigrated to Adelaide, where he established a business, and later he settled at Richmond, near Melbourne. He was a great authority on eucalyptus, and was markedly instrumental in introducing the oil of that plant into medical practice. Mr. Bosisto was also a founder of the Pharmaceutical Society of Victoria, and he took an active interest in everything pertaining to pharmacy in that Colony. At the time the Colonial and Indian Exhibition was held in London, in 1886, the Council and officers of the Pharmaceutical Society were invited by Mr. Bosisto, as President of the Victorian Commission, to inspect the exhibits from the Colony he represented. At the luncheon following the inspection, Mr. Bosisto proposed the toast of the Pharmaceutical Society, and spoke in appreciative terms of the advantage he had derived when a student at the School of Pharmacy. He helped to establish in Australia a counterpart of the institution with which his early associations were so pleasantly connected and, as remarked in the Journal at that time, he may be said to have done for pharmacy in Victoria what Jacob Bell effected for Great Britain.

THE UNIVERSITY OF LONDON and the question of its future habitation still continue to receive a considerable share of attention, the proposal to utilise the Imperial Institute for the purpose being debated with much show of warmth on both sides. The Senate of the University is reported to be divided on the subject, and Professor Karl Pearson has written to the *Times* to say he thinks that the haste with which the scheme for establishing the headquarters of the new University for London at the Imperial Institute is being pushed through is probably the best evidence that its proposers and supporters have a very bad case. In the Treasury memorandum with regard to the scheme it is stated that only three bodies are concerned in the sanction of it—namely, the Treasury, the Imperial Institute, and the present

examining University. Professor Pearson, however, thinks there are a great many other bodies which will or ought to be heard in the matter, first and foremost coming the governing body of the new University. "That body is not a new edition of the old University Senate; it is an entirely new body, representing a great variety of new and important interests. . . . But before this representative body comes into existence a deliberate attempt is being made to tie its hands by localising the centre of gravity of the new University, and by creating accommodation for various types of teaching and various types of teachers."

THE NEW UNIVERSITY, it is pointed out, will come into existence pledged to a commercial or applied science faculty in an outlying part of London. If there is to be a commercial faculty, then the City, somewhere in the neighbourhood of Gresham College, is the right and proper place for it, in Professor Pearson's opinion. If pure and applied science are to be concentrated, it should be in a district of London, not only easily reached by students from all parts, but where students can find, at a moderate rate, lodgings suited to their needs. A fashionable quarter like South Kensington hardly meets that requirement, and it is suggested that, to place the centre of gravity of the new University there, is to give its ultimate control to the teachers working on the spot, a thing which ought to be avoided, as they are not the only distinguished teachers in the metropolis, and form at best only a minority of such teachers. In conclusion, it is urged that no scheme whatever for localising the headquarters of the new University ought to be settled without consulting the corporations chiefly concerned. "As things are at present, neither future teachers nor future students are being consulted; only the Senate of a moribund University which has long ceased to inspire the public confidence."

LIQUID HYDROGEN AND ITS USES served Professor Dewar as a text at a meeting of the Royal Society last week. He showed how it could be used as a condensing agent for the production of very high vacua, the contents of a closed tube containing air being quickly condensed as solid air when one end of the tube was immersed in the liquid. Moreover, when the portion of the tube from which the air had thus been removed by condensation was sealed off with a blow-pipe, a vacuum was obtained so high that it would scarcely allow an electric discharge to pass. The rapidity with which this result was achieved was very remarkable, the immersion never lasting more than a minute, and Sir William Crookes stated that the vacuum produced in that short space of time was higher than he could obtain with the ordinary pump after working it for several hours. The lowering of temperature produced by boiling hydrogen under reduced pressure is much less than anticipated, but Professor Dewar was unable to say whether the observed results were due to the thermometer giving way, or whether liquid hydrogen does not fall in temperature like other liquids when evaporated under reduced pressure. The result may also be due in some way, he thinks, to the conduction of heat by the platinum leads. In any case further experiment is required to determine how far the platinum resistance curve can be trusted at the lowest attainable temperatures. Professor Dewar dealt with the same subject at the meeting of the Chemical Society on December 15 (see p. 675).

A LONDON DUST PROBLEM offers a fine opportunity for the many representatives of the class "inventive genius" who are to be found in the ranks of pharmacy. It has long been a matter of complaint in the Metropolis that, during the collection of house refuse, a nuisance is caused to the public by the dust being blown about the streets, and the London County Council has had under

consideration the question whether that nuisance cannot be obviated by the use of some improved form of dust cart. Inquiries have been made as to the arrangements in force in several of the principal cities and towns in England and Scotland but, so far, no form of dust-cart has been discovered which can be recommended as entirely obviating the nuisance. With the view of solving the problem the Council have decided to offer a premium of twenty-five pounds for the best design for a dust-cart and cover, and that the designs sent in shall be adjudicated by Captain Sir Douglas Galton, K.C.B., F.R.S., chairman of the Council of the Sanitary Institute.

POISONOUS CLOTHING is the latest scare, the wearing of flannelette and other fabrics weighted with zinc chloride having, not unnaturally, been followed by ill effects. The *Warehouseman* comments on a sample of flannelette received from a correspondent, who thought it had "a suspicious feel," and wished to know whether it contained "any deleterious matter prejudicial to health." On analysis the sample proved to be loaded with zinc chloride, so that if the material had been worn next the skin, without being previously washed, the consequences would probably have been serious. The effect of such adulteration is shown by a report of a recent Birmingham case, more than sixty men employed in clearing away snow in the streets having been invalided in consequence of skin irritation produced by the zinc chloride washed out from their overcoats and overalls. Half the number were still under treatment as out-patients at the hospitals a few days ago, and it was thought likely to be some time yet before they were back at work again. The zinc chloride had, as might be expected, produced a cauterising effect upon those portions of the skin with which it came into contact, and either destroyed the epidermis or created nasty sores. Imagine the effect of flannelette treated with the same chemical upon the delicate skin of women and children. The popular demand for certain goods at impossible prices is, of course, to be chiefly blamed for such things occurring, but the tradesman who touts for custom by helping to supply that demand is not free from responsibility in the matter. As for the manufacturers who produce the loaded fabrics, they are simply doing their best to ruin British trade.

ON AND AFTER CHRISTMAS DAY, the postage to be prepaid on letters from this country for the undermentioned British possessions and protectorates will be 1d. per $\frac{1}{2}$ oz., instead of 2 $\frac{1}{2}$ d. as at present:—Aden, Ascension, Bahamas, Barbados, Bermuda, British Central Africa, British East Africa, British Guiana, British Honduras, Canada, Ceylon, Cyprus, Falkland Islands, Fiji Islands, Gambia, Gibraltar, Gold Coast Colony, Hong Kong, India, Johore, Lagos, Leeward Islands, viz.: Antigua, St. Kitts, Nevis, Dominica; Montserrat and the Virgin Islands, Malay States (federated), viz.: Perak, Selangor, Negri-Sembila and Pahang; Natal, Newfoundland, Niger Coast Protectorate, Niger Territory, St. Helena, Sarawak, Seychelles, Sierra Leone, Straits Settlements, Tobago, Trinidad, Turks Islands, Uganda, Windward Islands, viz.: Grenada, St. Lucia and St. Vincent. Letters to and from her Majesty's ships abroad will be transmissible at the same rate of postage. It will be noticed, with regret, that the Australasian Colonies are not included in the list, and to that extent, as well as regards Cape Colony and Malta, the scheme of imperial penny postage is yet incomplete, as persons writing to their friends and relations in those colonies must still spend 2 $\frac{1}{2}$ d. in stamps for each $\frac{1}{2}$ oz. The postage payable on letters addressed to any foreign country, and that payable on postcards, printed papers, samples, etc., for any part of the world also remain unchanged.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

At a meeting of this Association held on Friday, December 16, Mr. A. SIDNEY CAMPKIN, J.P., delivered the presidential address for the year, his subject being

Pharmaceutical Politics.

Mr. CAMPKIN said chemists were now awaiting the result of the passing of the Pharmacy Acts Amendment Act, which he hoped would secure an enlargement of the membership of the Society. At the present time chemists were very little better off than the grocer and draper, notwithstanding the many attempts they had made to secure protection as a return for their long special training and experience. They occupied a position in which they had to encounter opposition and competition at the hands of absolutely unqualified men, to an extent almost unparalleled in any other business or profession. The public appeared to be in many respects short-sighted, and to be willing to risk the results of serious defects in the quality of their medicines and in the methods of their preparation, though they were unwilling, for the sake of a false economy, to buy food and drink and clothing at any price. Despite the spread of education and the demand for qualifications and certificates in nearly every walk of life, the public was content to buy drugs from unqualified men working in establishments having none of that seclusion and quietness necessary for the proper preparation of prescriptions. There was a growing tendency to carry on all the trade of the country by joint-stock companies. The sense of personal responsibility, of personal association in business, was being destroyed. But if chemists could bring a proper and reasonable case to bear upon the public, he thought they would see that they were all bound up in and with one another. The Pharmacy Act of 1868 had not fulfilled the anticipations of its authors, and chemists were now suffering from slight omissions and errors in the Act. Several coaches had been driven through the Pharmacy Act, and they wanted the Legislature to assist them in amending it. The present Lord Chancellor by his action last session had shown himself alive to the position, but without unity in the craft it was absolutely useless to expect adequate legislation. In order to secure unity the Society must have all the members possible, and be able to show that it was completely representative of the pharmacists of the kingdom. There were 15,000 registered chemists in the country, but not more than one-third of them were members of the Pharmaceutical Society, and yet the Society was the only body recognised by the State as acting on behalf of the chemists and druggists of the country. It was absurd for those outside the Society to sit down, fold their arms, and grumble at those who managed the Society, because unless they came into the Society it could not with any certain and definite tone speak to the Government of the country. Why did outside chemists grumble at the Society and at the same time take no steps to strengthen it, or to direct its course, by making the slight sacrifice—if it were a sacrifice—that was necessary? It was quite open for every registered and fully qualified chemist to join the Society, and then the Society might be made just what they thought fit to make it. The present Council did not, perhaps, represent the entire body of chemists and druggists, though it no doubt represented the existing members of the Society. In order to make the Council entirely representative of the trade, it was necessary that all registered chemists, or the great majority of them, should join the Society. If the 15,000 chemists of this country did but know their strength, and realise the power of association and unity, they would be able to make their mark upon any legislation affecting them, in the same way that other great organised bodies had done. He had always felt that chemists as a body had not been sufficiently united, either nationally or locally. Therefore he urged a more thorough adhesion to the Pharmaceutical Society.

Mr. W. L. WHITE thought it ought to be considered whether it would not be advisable for the Pharmaceutical Society to accept smaller subscriptions from men who did not feel justified in paying a guinea each. He would like the Society to make some endeavour to gain the allegiance of every registered chemist in the country, even were it only by a half-crown subscription. He proposed a hearty vote of thanks to Mr. Campkin for his address.

Mr. ADDISON seconded the proposition, and it was carried *nem. con.*, after which

Mr. E. SAVILLE PECK, B.A., the Cambridge delegate to the Belfast Conference and the Federation of Local Pharmaceutical Associations, said that the Belfast meetings were eminently calculated to promote a cheerful spirit among pharmacists. Neither the Conference nor the Federation was officially connected with the Pharmaceutical Society, and it would greatly help to consolidate their forces if these two bodies were more intimately connected with the Society. The Federation of Local Pharmaceutical Associations was not so much an association as a bond of union between pharmaceutical associations in different parts of the country. Nearly fifty local associations were now federated and brought in constant touch with one another, and the great usefulness of the work done by the Federation could best be understood by a perusal of the reports in the *Pharmaceutical Journal* of the discussions which had recently taken place, and the resolutions which had been passed by the various local associations throughout the kingdom. Referring to the proposed poison regulations, Mr. Peck recommended the voluntary adoption of such regulations as being more dignified than having them made compulsory by the Privy Council. The poisons question would probably occupy a prominent place in the business of the next Parliamentary Session, the adoption of regulations would indicate to the Privy Council that pharmacists were best qualified to deal with the matter. With regard to company trading, he thought it would be unwise for them to make any direct attack upon companies, but they could do much to make the way of transgressors harder. He thought that no better course could possibly have been taken at the present stage than that taken by the Pharmaceutical Council at its last meeting. He proposed:—

That this meeting of members of the Cambridge Pharmaceutical Association views with much satisfaction the recent deliberations of the Council of the Pharmaceutical Society in (1) calling a special meeting of the Society to consider and, if thought fit, adopt regulations for the improved storage and sale of poisons; and (2) endeavouring to obtain the assistance of the Lord Chancellor in prohibiting the assumption by incorporated companies of the privileges of persons qualified to practise pharmacy.

This proposition was seconded by Mr. H. F. COOK, and carried unanimously.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A conference of registered chemists was convened by the Bristol Pharmaceutical Association at the Grand Hotel, Bristol, on Thursday, December 15. Mr. B. ALLEN presided, and there was a large number of registered chemists present.

The CHAIRMAN said he thought they would all agree that it was desirable to increase the membership of the Pharmaceutical Society. Then they would see that something must be done in the direction of enforcing the intentions of the Pharmacy Act, and, as had been reported in the *Pharmaceutical Journal*, the Council had started on very good lines with a good prospect of success.

Mr. B. KEEN then proceeded to explain that the object of the meeting was to discuss the present position and prospects of the retail trade. As they calmly surveyed the situation and prospects of the trade to-day they might very justifiably be a little pessimistic about the future. An Act of Parliament had been passed providing that individuals should possess certain qualifications to carry on a certain trade; and yet there were loopholes in the Act the effect of which was that the Act was practically repealed. The medical and dental corporations were moving in the direction of preventing limited companies from doing what qualified individuals only had the right to do. The medical authorities were applying, as the Pharmaceutical Society was applying, to the Lord Chancellor and asking him to move in the matter. For years past the Pharmaceutical Council had been making attempts to get the law altered, and chemists were now beginning to feel that the thing had really become too urgent, and it was quite time that they moved themselves. The individual pharmacist was in danger of being ridden over and annihilated by limited companies, and the question was whether they would try to resist this thing, and if so, how? He thought it was quite time they threw aside all selfishness and acted with each other in some attempt to meet their difficulties. The first step should be for every registered chemist to become a member of the Pharmaceutical Society. In Bristol a large number of chemists did belong to the Society, and there were only about fourteen whom he could invite to join. The Council of the Society could do nothing without numbers behind it; but if a very large proportion of the chemists belonged to the Society, then the Council might get almost

anything it asked for in reason. The Society would then represent the whole trade, and the Council, as its executive, would do their bidding. The only way to get the help they wanted was by consolidating their ranks and making it clear that they were all working for the same thing. There was a fight before them, and they must be prepared for the struggle, simply because the House of Lords decision in the case of the London and Provincial Supply Association was to the effect that since a corporation could not be examined, or qualify as the Act provides, it was outside the Act so far as selling poisons went. He considered that was a misinterpretation of the Act, and that a combination of unqualified persons should not be allowed to keep open shop for carrying on the business of a chemist and druggist. Registered chemists were appointed by Act of Parliament to perform certain duties. The object of the 1868 Act was to compel persons who did those things to have certain qualifications. Another question for consideration dealt with the position of qualified men covering unqualified people. It should be possible to have the names of such men struck off the Register. With regard to the proposed poison regulations, he thought they ought to adopt them as a matter of expediency, if only in order to get on better terms with the Privy Council. Then, with regard to the so called "Widow's Clause," they should go in strongly for altering or modifying it. He thought they should agree to a modification of that clause so that its operation should be limited to a year.

Mr. E. W. ISAAC thought it was as palpable as the sun at noon-day that chemists must now do something to protect themselves. The Legislature with one hand had granted a Charter to the Society and with the other had opened the flood-gates to every abuse which it was the object of the Society to prevent. The first step should be the enlargement of the constituency of the Society. He thought that there was half-heartedness amongst the trade simply because so many did not belong to the Society, and for that very reason—that they did not belong to it—they had got into a habit of abusing the Society for not doing that which they ought to give it power to do.

Mr. MILTON heartily supported the views of the previous speakers. The Society had done much to elevate chemists from the low state in which they were to their present higher level. All honour to the Society and shame to registered chemists if they did not support it to the utmost of their power. As to legislation, he was afraid that too many members of Parliament were interested in the stores. But he thought they ought to go to their parliamentary representatives and say, "If you want some of our support you must give us some of yours."

Mr. VIGIS (Bath) said he had made a point of seeing every chemist in Bath, but with the exception of three they were unable for various reasons to be present at that meeting. They were, however, in sympathy with its objects. He had the honour to represent the P.A.T.A., and in twelve months he had got seventeen out of thirty-three chemists to join. They had now twenty-one members, representing thirty-nine shops, and if they could only get a like number of members for the Pharmaceutical Society it would be a great thing. He wished there was an Association at Bath, or that they could amalgamate with the Bristol Association. The present aspect of trade matters was a most serious one, and it was very necessary that something should be done.

Mr. WHISTON pointed out the necessity for ascertaining the feeling of chemists who were not in business for themselves. It was their action in many instances that was ruining the retail trade. He saw that one of the rules of the Chemists' Assistants' Union struck a blow at co-operative stores by saying that no member should sell his services to those who were not duly qualified chemists. It seemed to him that they should get into correspondence with that organisation, because, if all assistants worked on those lines, the difficulty would become a very small one.

Mr. W. PITCHFORD said he had not been in accord with the Pharmaceutical Society for many years, but if it would act up to its prerogatives and privileges he, and he thought every registered chemist in Bristol, would most cordially support it—not merely with the guinea a year, but with any other money that might be necessary for carrying on the crusade against the difficulties which the trade had to contend with. He knew something, as they did, of the action of the Society in the past, and he was not able to accept the eulogy which had been pronounced. If the Society had continued the active measures it adopted in 1870, or thereabouts, and had fought vigorously against the first stores, a large measure of success would have been ultimately gained. But apart from

that, if the Society would now really promote the interests of chemists as it should, and not simply enforce petty and absurd restrictions, the whole trade would be with it. They wanted a business-like Society, and not one that was a goose laying golden eggs for London officials. He was sure there would not then be one of the dissenting fourteen chemists in Bristol who would not subscribe to the Society.

Mr. CHANDLER suggested that chemists should abandon the so called "Widow's clause" altogether; it was of no good.

Mr. ISAAC thought there should certainly be a limit of time.

Mr. PLUMLEY said they must not make it impossible for apprentices and students to hand over pharmaceutical preparations if they were not poisons.

Mr. KEEN thought it was quite understood that was not suggested.

Eventually resolutions were passed affirming the desirability of taking action on the following points:—

- (1) The urgent necessity there was that every registered chemist should avail himself of the privilege given by the Amendment of the Pharmacy Act of becoming a member of the Pharmaceutical Society.
- (2) That legislation is much needed to enforce the Pharmacy Act, which is based upon the principle of personal proprietary of all retail chemists' shops, and the restricting to qualified persons the compounding and dispensing of medicines and the sale of pharmaceutical preparations.
- (3) That it was desirable to adopt the regulations for keeping and storing poisons.
- (4) That the so-called "Widow's clause" ought to be modified or abandoned.

It was also agreed that the operation of the "Widow's clause" in any particular case should be limited to one year.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

Members of this Association mustered strongly at the Exchange Rooms, Birmingham, on December 14, on the occasion of the second smoking concert of the season. The chair was taken by Mr. G. E. PERRY, who at the outset congratulated the Association upon its vigorous and healthy condition. Associations of older pharmacists were, he said, sometimes prone to become weak and apathetic, and it was, therefore, thought necessary, or at any rate desirable, that they should be supplemented by associations of younger men. They had energy, enthusiasm, and determination, without which no association was likely to discharge the duties for which it was formed. Their object was the advancement of pharmacy and the protection of the pharmacist. Pharmacy at present was passing through somewhat troublous times, and it would need the wisdom and experience of the older associations, as well as the energy and resoluteness of the younger men, to enable it to grapple with and overcome the difficulties that beset it. He was confident, however, that these difficulties would be overcome, and in the struggle the Midland Assistants' Association would no doubt play its part. As an older pharmacist he urged the younger men to keep steadily on in the work they were doing, to have high ideals, and to maintain the best traditions of pharmacy. He thought it was the duty of every pharmacist to endeavour to leave pharmacy a little better than he found it.—A most enjoyable musical programme followed, in which Mr. A. Cutler, Mr. Milward, Mr. Burford, Mr. Brindley Roberts, Mr. Colley, and Mr. Joe Longmore took part, the last-mentioned scoring with imitations of several of the idols of the music halls.—The artistes and Chairman were heartily thanked for their services on the proposition of Mr. W. F. COX, seconded by Mr. T. H. THOMAS.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held on Thursday, December 15, Mr. W. L. CURRIE, President, in the chair.

At the commencement of the proceedings, Mr. SUTHERLAND directed attention to a handsome bookcase which had been presented to the Association by Messrs. R. and O. Templeton. It was an article of considerable value, and the gift would be a great saving to their funds, and would enable them to purchase additional books. He proposed that the Secretary be instructed to forward the thanks of the Association to Messrs. Templeton, and the motion was carried unanimously.

The CHAIRMAN then announced that he had taken it upon himself to call a special meeting of chemists in Glasgow and the West of Scotland for Wednesday, December 21, to consider what action

should be taken regarding company trading in pharmacy, and the adoption of regulations for the keeping, dispensing, and selling of poisons as recommended by the Pharmaceutical Society. Both subjects were very important, and were receiving the attention of kindred associations throughout the country. He hoped the attendance at the special meeting would be large.

The meeting then proceeded to discuss Mr. DUNLOP's paper on

The British Pharmacopœia,

read at the previous meeting of the Association.

Mr. MACMILLAN referred to the typographical errors in the book, and said those could have been avoided had the Pharmacopœia Committee sent proofs to the local associations to be read, just as Mr. Foulis, printer to the University, put up his proof sheets for the students to criticise and revise. He thought it a pity that the Committee had not given an authoritative deliverance as to what the sign "ζi" meant. It would have been a very easy matter to say that ζi represented 480 grains, just as ζi means 60. The monograph on acetum ipecac. ought to read: "Mix, add sufficient diluted acetic acid to produce one pint, filter." Benzoic acid ought to be prepared exclusively from benzoin. The dose of hydrargyrum c. creta might be safely increased. For adults it was more commonly prescribed in Glasgow in doses of 6 to 10 grains than from 1 to 5. It was unfortunate that sanction had not been given for the use of concentrated infusions. What the concentrated liquors were introduced for was one of the things no one knew. How were fresh infusion of gentian and compound infusion of orange to be prepared in midsummer, when fresh lemons could not be obtained? The calcium hydroxide for liquor calcis sacchar. should be washed the same as for liquor calcis. He feared lotio hydrarg. nigra would be found too thick for use. The spirits would have been more miscible and probably equally efficacious if made one-quarter of the strength. Speaking of ungu. cetacei, he said that according to Boa—and he thought his experiments were conclusive—the directions for this ointment should read: "Strain and set aside to cool without further stirring." In reference to ungu. gallæ c. opio, he thought a better ointment could be prepared by melting the lard, pouring it upon the galls and opium in a heated mortar and stirring till cold.

Mr. BOYD thought the B.P. a good work on the whole, and more scientific than former publications. He advocated the publication of a condensed pocket form of the B.P. for the use of medical men.

Messrs. DUNLOP, BRODIE, and WATSON also took part in the discussion, at the conclusion of which

Mr. CURRIE exhibited an apparatus for the preparation of retail quantities of granular effervescent preparations. The apparatus had been designed by himself, and consisted of a large copper tinned plate about 1½ ft. in diameter, with turned up edges. The steam was supplied from a copper boiler with safety valve. With the apparatus from 2 ounces to 2½ lbs. could be prepared very expeditiously. A number of the usual preparations were shown. All were of a very regular granular size and were prepared without a sieve. The exhibition was a most interesting one, and the opinion was freely expressed that the apparatus was one likely to find favour among chemists who desired to meet the wishes of medical men prescribing granular preparations with medicaments of various strengths.

At the special meeting of the registered chemists of Glasgow and the West of Scotland, called by the Association and held on Wednesday, Mr. W. L. CURRIE, the President of the Association, took the chair, and there was a good attendance.—The CHAIRMAN having explained that the meeting was called to consider

Company Pharmacy and Poison Regulations,

Mr. SUTHERLAND then proceeded to deal with the proposed regulations. He did not think the recommendations which it was proposed to adopt as regulations would entail any very great hardship on retail chemists and druggists. Limited companies were held to be outside the scope of the Pharmacy Act, but if such companies were to be recognised they must be put under the same restrictions as the individual chemist. If the Pharmaceutical Society was to have any power so far as legislation was concerned, it must be supported to the fullest extent.

Mr. MACMILLAN feared limited companies had come to stay, and possibly chemists should devote their energies to minimising as much as possible the mischief those bodies might do. When once the original object of the Pharmacy Act was departed from every-

thing got into a muddle. That Act made it clear that it was intended the principal should be qualified, and that it was not necessary the assistant should be, but, according to recent decisions, limited liability companies were placed in exactly the opposite position, the assistant having to be qualified while it was not necessary that the members of the company should be. The Society had already been beaten on this point, but he thought chemists ought to support it in trying another fall. It was quite possible they might get something better; he did not think they could possibly be worse. He suggested that the poison regulations should be incorporated in a new Act, which might be an excuse for getting the Pharmacy Act altered to something like what they desired it to be. At the same time, he did not agree with the suggestions about the poison regulations. He did not see why chemists should put any more halts round their necks.

Mr. BRODIE was also of opinion that more restrictions would be more chains round the necks of chemists, and that it would be difficult to remove them.

Mr. MOIR said some restrictions on the storage and sale of poisons would have to be made, and it remained for them to say whether the Pharmaceutical Society should not do it instead of the Government. He thought the Society should do it.

Mr. FORGIE (Falkirk) could not see that there was any hardship in chemists putting their business places in order, so as to meet the requirements of the Act.

Mr. D. S. ROBERTSON (Rutherglen) said he did not see how any Government could consistently ask an educated body of men like chemists and druggists to keep their bottles in a certain way; as well define where a medical man was to keep his instruments. But if the proposed regulations would assist them in getting more legislation, then he said by all means let them agree to adopt them, though he for one would only yield under protest.

Mr. D. WATSON said the reason for adopting regulations was not so much to interfere with the handling and selling of poisons as the keeping of the chemists' business in a proper manner. It was better that the Society should carry out any regulations and so have the necessary inspections made by their own inspectors than that Government should enforce them and hand chemists over to inspection by the municipal authorities or the police. Regarding the Companies Act, they should have legislation to make it clear whether companies were within the meaning of the Pharmacy Act or not.

The CHAIRMAN said that he had made up his mind that the best thing they could do to support the Pharmaceutical Society and better their own position was to adopt as a resolution the motion which stood in the name of Mr. Robinson for the special meeting of the Pharmaceutical Society in January. Most of the speakers had looked at the matter from an individual point of view, but they should look at it as a body, and not forget that, while they as individuals might exercise every possible precaution, there were a great many individuals who did not. It would be much better if there were to be inspectors that those should be nominated by the Pharmaceutical Society than by the Government or the police. So far as the company question was concerned, the judgment of 1880 against the Pharmaceutical Society entirely reversed the order of things which they were accustomed to believe was correct, in so far that, while the Statute required a qualified master and did not require a qualified assistant, the judgment dispensed with the qualified master and sanctioned the qualified assistant. He had little doubt that if they approached Parliament and put the matter fairly before it, the justice and reasonableness of their demands would be recognised. No limited company should be entitled to call itself a chemist, as companies were not examinable bodies, and so were outside the Act.

Mr. MOIR then moved, and Mr. SUTHERLAND seconded—

That the time has arrived for the Pharmaceutical Society to adopt as regulations the recommendations issued in 1871, for the selling and dispensing of poisons, in accordance with the provisions set forth in Section 1 of the Pharmacy Act, 1868.

This was unanimously agreed to, as was also a resolution expressing satisfaction at the course the Pharmaceutical Society had adopted in relation to the Companies Act.

SASSAFRAS OIL FOR PEDICULI.—According to the *Medical Brief*, a single application of oil of sassafras will destroy all kinds of pediculi and their ova. The oil should not be allowed to come in contact with the mucous membrane. If it does so, the burning sensation it produces may be allayed by the application of olive oil.—*Mod. Med.*, vii., 187.

NORTH STAFFORD AND DISTRICT CHEMISTS' ASSOCIATION,

A well-attended monthly meeting of the above Association was held at the Copeland Arms Hotel, Stoke-on-Trent, on Thursday, December 15. There were present: Mr. John Averill, J.P. (President), Messrs. W. Marson, F. Fowke, W. Westhead (Stafford), Weston Poole (Treasurer), E. H. Croydon, C. J. Wain (Newcastle), R. Prince, Geo. Fisher (Longton), T. H. Jenkins, F. Jacks (Stone), W. Oldham, T. Charles, W. Bates, A. P. Tiley (Burslem), F. Adams (Vice-President), W. B. Allinson, W. Hemingway (Stoke), F. W. Wrench (Silverdale), W. Hartley, J. B. Blades (Leek), F. W. Goodman (Eccleshall), T. C. Cornwell, T. Bentley, and Edmund Jones, Hon. Secretary (Hanley), S. C. McKee (Tunstall). Letters and telegrams of apology for absence from Mr. Booth (Crewe), Mr. Cowley (Liverpool), Mr. G. W. Bullen (Ashby-de-la-Zouch), Mr. A. Parker, and Mr. G. R. Hankinson (Uttoxeter). Communications were read from the Secretary of the Federation of Local Pharmaceutical Associations and the Western Chemists' Association (London). Dr. B. H. Paul (London) was also present by invitation.

Mr. AVERILL addressed the meeting on the subjects of company trading in pharmacy, the illegal use of the title "chemist" by unqualified persons, and the "covering" of unqualified persons by registered chemists, concluding by moving—

1. That this meeting of the North Staffordshire and District Chemists' Association respectfully and strongly urge the necessity of the Pharmaceutical Council taking early action to secure the amendment of the Pharmacy Acts, so that companies may be prevented doing that which it is illegal for a single person to do.
2. That we consider the use of the title "chemist" by unregistered persons trading as companies is an infringement of the Pharmacy Act, 1868, is detrimental to the interests of legally qualified chemists, and that it requires to be stopped by the co-operation of all registered chemists and druggists as members of the Pharmaceutical Society.
3. That the Council be requested to represent to the Privy Council that the covering of unqualified persons in the exercise of the business of a chemist and druggist is sufficient ground for the removal of their names from the Register, as in the case of the medical profession.

Mr. W. MARSON (Stafford) seconded the propositions, to which no amendment was offered, and an active and interesting discussion followed, in which Messrs W. Poole, Hartley, Croydon, Tiley, McKee, Charles, Wain, Jacks, Allison, Jones and Cornwell took part, the resolution ultimately being unanimously carried.

Dr. PAUL was then invited by the Chairman to address the meeting, and at the conclusion of his remarks, a hearty vote of thanks was passed to Dr. Paul, on the proposition of Mr. AVERILL, seconded by Mr. E. H. CROYDON, and supported by Mr. JONES.

Mr. AVERILL also proposed the following resolution:—

That this Association hereby resolves to request the Pharmaceutical Council, for the purpose of drafting a new Pharmacy Bill, to invite delegates from all local associations, to assist in the deliberation and formation of a new Bill.

Mr. JONES seconded, and it was unanimously carried.

Mr. T. BENTLEY (Hanley) and Mr. BLADES (Leek) were admitted members of the Association. During the evening seven gentlemen expressed their intention of joining the Pharmaceutical Society in the new year. Four gentlemen promised last meeting to join the Society, making eleven new members for the Society from the North Stafford district in a month.—After the meeting the members sat down to supper.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At a meeting held on Wednesday, December 14, Mr. G. H. C. ROWLAND in the chair.

Mr. GEORGE COULL, B.Sc., dealt with

The Latinity of the New Pharmacopœia.

He had intended treating the subject fully, but pressure of other work prevented, and he only gave a few examples of things he intended to point out. In the paper he read before the Glasgow Association last year he made suggestions, several of which were embodied in the new Pharmacopœia, while others, which he still adhered to, had been disregarded. Notwithstanding what had been said by Mr. Ince, he still maintained that the genitive of "rosmarinus"

should be "rorismarini." It would also have been better Latin to adopt stibium for antimonium. No doubt ethylic alcohol was alcohol *par excellence*, but it was to have as infirmative a name as possible, and therefore alcohol ethylicum was much to be preferred to the official name, alcohol absolutum. There was no reason why such words as chloral and guaiacol should not be declined just as alcohol was. He was much disappointed to find that such words as carbonas -atis and sulphas -atis were now made masculine, and he thought Mr. Ince's remark that this was in accordance with the custom of other nations, was a particularly weak one, coming from such a classical purist. Why should we follow others if we thought them wrong? Better maintain our splendid isolation. He had failed to discover any good argument in favour of this change, and the great majority of Latin words in "as -atis" were feminine. Incidentally he remarked that he had recently compared the Latinity of forty wholesale price-lists, and found many curious discrepancies. They were mostly conspicuous for inaccuracies. Such articles as rape oil, for instance, was designated usually as ol. rapii, whereas it should be ol. rapæ, from rapa -æ, and in only one instance was it correctly so spelled.

Mr. FRASER MCDIARMID said there were some misleading names in the Pharmacopœia, such, for instance, as extractum belladonnæ viride. This extract was black and not green, and the official name was apt to cause confusion with extractum foliorum belladonnæ viride, which was of a bright green colour.

Mr. LUNAN said there were some official names which were not clear enough to obviate possible error on the part of the dispenser by misinterpreting the intention of the prescriber. There were, for instance, elaterium and its active principle elaterinum. It might result seriously if one were used by mistake for the other, and it would have been safer to have called the drug elaterium and the active principle momordicinum.

Mr. COULL, in replying, said he agreed that extractum belladonnæ viride was a misnomer. Another example was glycerinum acid borici, there was a chemical change, and the product was not really glycerin of boric acid, but glyceryl borate.

Mr. J. RUTHERFORD HILL then gave an address on "The Position and Privileges of Pharmacy and the Pharmacist," and the meeting closed with a vote of thanks to Messrs. Coull and Hill.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

A well-attended meeting of this Association was held at the Westbourne Restaurant, London, on Wednesday last, the PRESIDENT, Mr. J. F. Harrington, in the chair. After the usual preliminary business, the President proceeded to deliver his

Inaugural Address,

in the course of which he thanked the members for the honour conferred upon him in selecting him as President of the Association, and referred to his election as a member of the Council of the Pharmaceutical Society, urging all who are not already members of the Society to join, and so strengthen the hands of the Council in endeavouring to obtain legislation which will place pharmacy in a better position than is the case at present. It was his desire to see the time come when all men would join the Society on passing the Minor examination, but he was afraid that the present subscription prevents many from joining. He then referred to the question of regulations for the storage, etc., of poison, and was of opinion that some kind of regulations are absolutely necessary, and that it would be much better for pharmacists to draft their own regulations than that it should be left to the authorities, who would certainly do so if pharmacists do not. He next touched upon the question of pharmacists' "daily work and daily bread," and said that although all chemists carried on their business for the sake of making a living, they were as a body desirous of doing their best for their customers. But, with regard to companies trading as pharmacists, he thought their chief desire was to make money without studying the interests of the public at all.

Mr. MARTINDALE, in moving a vote of thanks to the President for his address, remarked that, in discussing the questions to be brought forward that evening, it was of the greatest importance that they should be considered calmly, carefully, and with discretion.

Mr. ANDREWS seconded the vote of thanks, which was carried, Mr. HARRINGTON replying.

Subsequently a discussion took place on the proposals in
The Federation Programme.

Mr. J. C. HYSLOP opened the discussion on the question whether it is desirable in the interests of pharmacy that firms trading under ancient titles should also use the names of the present proprietors in conjunction therewith. He said that although he had been selected to open the discussion on the question before the meeting he entirely disapproved of the resolution submitted by the Federation. It was so loosely worded that he did not think it would effect the purpose it was evidently intended to do. He thought it would tie the hands of some legitimate firms, whilst it would not in any way interfere with company trading.

Mr. G. S. TAYLOR pointed out that at present the Pharmaceutical Society had great difficulty in prosecuting companies, inasmuch as it is almost impossible to find out who is really responsible, and he thought if the regulations proposed were enforced it would greatly assist the Society in getting at the real offenders when the law was broken.

Mr. ANDREWS was of opinion that the public had a right to know by whom pharmacies are conducted, and he thought that such a regulation as proposed by the Federation, if carried into effect, would place many obstacles in the way of company trading. He would therefore move the adoption of the resolution as proposed.

After some considerable discussion, in which Messrs. C. B. Allen, W. Martindale, R. H. Parker, and others took part, and in which the general opinion seemed to be that the public should know who is really responsible for the conduct of pharmacies, and that it would not be detrimental to the interests of ancient firms of good reputation if the names of present proprietors were made known to the public, whilst it would materially help to check the operations of bogus companies trading as pharmacists, it was resolved—

That it is desirable, in the true interests of pharmacy, that the names of present proprietors of a pharmacy should appear in conjunction with the usual title of the firm.

Mr. F. ANDREWS next dealt with the suggestion of the Federation that, in view of the passing of the Pharmacy Acts Amendment Bill, 1898, local pharmaceutical associations should use their best efforts to induce all registered chemists to become members of the Pharmaceutical Society.

It was unanimously agreed that the suggestion of the Federation was a good one and should be adopted by all associations, Mr. Andrews suggesting that all present should use their best endeavours to get their own assistants to join the Pharmaceutical Society.

Mr. R. H. PARKER then read a paper on the question of company trading, as it affects the legitimate interests of registered chemists and the protection of the public safety—aimed at in the Pharmacy Acts, the Federation having suggested that an effort should be made to formulate some definite line of policy on which all registered chemists could agree to act.

It was decided by the meeting to consider the subject in committee, and to send copies of Mr. Parker's paper to all members of the Association, after which the discussion would be resumed on a future occasion, when it is proposed that the question should be fully considered in all its bearings.

OXFORD AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of this Association was held on Tuesday, December 13, Mr. H. MATTHEWS, President, occupied the chair, and brought forward for discussion the question of

Compulsory Regulations as to Keeping, Dispensing, and Selling Poisons.

The CHAIRMAN said he considered that the recommendations adopted at a general meeting of the Pharmaceutical Society, May, 1871, gave considerable latitude to the chemist, and would not be found irksome in any well-founded pharmacy, and as it appeared to be a matter of such great moment to the Privy Council that these recommendations should become regulations, the Council of the Pharmaceutical Society should be supported in attaining this end. He strongly urged all registered chemists to become members of the Pharmaceutical Society, and by so doing give to it that support which would enable it, with a majority at its back, to obtain from Parliament several much needed reforms. After some discussion, the following resolution was passed:—

That it is the opinion of this meeting that the present recommendations for the storage of poisons, or some modification thereof, become regulations subject to the provisions of the Pharmacy Act, 1868.

PHARMACEUTICAL SOCIETY.

EVENING MEETING IN EDINBURGH.

The second evening meeting of the session was held in the Society's house, 36, York Place, Edinburgh, on Wednesday, December 21, when Mr. J. LAIDLAW EWING took the chair. The minutes of the last meeting were read and approved. Apologies were intimated from Messrs. D. Brown, J. Lothian, Currie, Lunan, Nesbit, Stephenson, Davidson, and Duncan.

In the absence of his father, Mr. D. RAINY BROWN read the first paper,

Notes on Lime as a Preservative for Chloroform,

which is printed in full at p. 669. Mr. Brown pointed out that there is a very general but erroneous belief that chloroform is highly inflammable; it burns when brought in contact with a strong flame. He showed, however, that when he plunged a lighted taper into liquid chloroform, or introduced it into the vapour rising from boiling chloroform, it was instantly extinguished.

Mr. HILL said the appearance of Newman and Ramsay's paper in a medical journal had caused many inquiries to be made by doctors of pharmacists as to the advantages of their method. It was important that such an authority as Mr. Brown had so clearly shown that the method was quite fallacious.

The next paper, printed on page 666, was by Dr. LEONARD DOBBIN on

Criticism of Some Medical Matters in the New Pharmacopœia.

Mr. DOTT said he thought Dr. Dobbin's criticisms were in some respects hypercritical, but they were certainly very interesting.

Dr. SILLARS said there was one point he would like to ask a question about. The Pharmacopœia stated that gallic acid should give no precipitate with tartarated antimony, indicating the absence of tannic acid. He found that every sample of gallic acid he tried gave a greater precipitate with tartarated antimony than tannic acid did.

Mr. COWIE said, as a teacher, he was indebted to Dr. Dobbin, whose paper would clear away many difficulties. The old formulæ should be buried once for all.

Mr. SIMPSON asked how the true formula was determined as $K_3FeC_6N_6$. Was it by the vapour density? If it was correct, how would the graphic formula be written when iron was a pseudo-triad?

Mr. HILL said they were entitled to expect consistency in a national Pharmacopœia produced by experts. Dr. Dobbin had happily struck a new vein of criticism. The discrepancies noted caused no trouble to chemists like Mr. Dott, but they were a source of great trouble and anxiety to students, who could not know that some mysterious meaning was not involved in such variations as the author pointed out.

Dr. DOBBIN, in reply, said he was quite prepared to be called hypercritical. He had simply jotted down points as he turned over the leaves of the book, and he had not read more than fifty pages. His impression was that, taken all over, the compilers might have been more merciful to the student, whose task would have been less difficult if those discrepancies had been eliminated. As to potassium ferricyanide, the formula of such compounds was determined by the method of electric conductivity. All tribasic acids were found to act in the same way, and because hydroferrocyanic acid acted like other known tribasic acids it was classed as such.

Mr. HILL, in the absence of Mr. John Lothian, read his paper on

Volumetric Operations of the New Pharmacopœia,

which is printed full at page 667.

Mr. DOTT said this was a very interesting paper. The matter of indicators was very important. He agreed with the author as to the value of cochineal, especially in the case of ammonia titration. It was superior to litmus in the case of aromatic spirit of ammonia. He had suggested a long time ago the use of phenolphthalein, and then methyl orange, in titrating sodium and potassium hydroxides, as a means of determining the amount of carbonate, but the method had not been adopted with regard to potassium permanaganate. It was almost too delicate, owing to its ready decom-

position. Minute quantities of oxidisable substances affected the result, and led to error more than the more stable potassium bichromate. The official volumetric test for sodium sulphite was almost certain to give erroneous results from the ready oxidising of the sulphite.

Mr. HILL pointed out that some of Mr. Lothian's factors differed from those given by Lucas.

Mr. SIMPSON said the use of decinormal sulphuric acid for determining lead salts was very objectionable, because the fine precipitate would not settle, and filtration became necessary. With oxalic acid filtration was not required.

Mr. COWIE said potassium iodide solution was very useful for determining hydrogen peroxide, especially when determining small quantities. A standard hydrochloric acid would have been useful for determining alkaline carbonate.

Mr. KIDD said the Pharmacopœia stated that liq. calcis sacch. contained about 2 per cent. It only contained 1.73 per cent., and the word "about" did not cover that interval.

CONCLUDING BUSINESS.

Mr. HILL exhibited the fragments of a glass mortar sent by Mr. J. A. Gibson, which had suddenly disrupted with explosive force after being used to triturate a powder and then washed with cold water. It was suggested that those two circumstances induced the molecular disturbance which determined the explosive disruption of a badly annealed mortar.

The ASSISTANT-SECRETARY also directed attention to recent additions to the Library.

On the motion of the CHAIRMAN thanks were awarded to the authors of papers, and the meeting then closed.

NEW REMEDIES.

EUROBIN.—This is an aceto-compound of chrysarobin, which is recommended by Kromayer as a substitute for that body. Solutions of 2 to 3 per cent. are said to be as effective as the usual chrysarobin mixtures. Eurobin is perfectly free from toxic effects, is non-irritant, and does not stain.—*Pharm. Centr.*, xxxix., 476, after *Munich Med. Mod. Woch.*, 795.

OVARADENE.—Ovaradene is the name given by Knoll to an organic therapeutic preparation from ovarian tissue, which is stated to possess the active principle in an unchanged condition. It consists of a tasteless powder and has no smell. It is prepared in the form of powder and tablets; the dose is 1 to 2 grammes daily. According to Dr. Kossier this preparation is suitable in all cases of removal of the ovaries and in climacteric disorders. The remedy is also useful in cases of painful dysmenorrhœa.—*Pharm. Zeit.*, xlii., 828.

SILVER NITRATE IN INFANTILE OPHTHALMIA.—T. Bar believes in the use of iodoform, as recommended by Valude, for the systematic treatment of the eyes of new-born infants. He advocates (*Journ. de Clin. et Therap. Infant.*) the universal employment of the old-time silver nitrate remedy. He finds the instillation of a 1 per cent. solution of silver nitrate to be more successful than any other remedy as a safeguard against ophthalmia, and advocates its universal use.—*Pædiatrics*, vi., 308.

PRASOID.—Under the title "Pasoid Heckel" Dr. Poucel (*Bullet. de Therap.*, cxxxv., 81) employs a solution of globularin and globularetin; 100 drops of this solution contain 0.135 g. globularin and 0.158 g. globularetin. For a single dose Poucel gives 5 to 20 drops three times a day, or 60 drops in 24 hours. The results in gouty and rheumatic pains have been satisfactory.—*Pharm. Central.*, xxxix., 669.

MENTHOLUM VALERIANICUM.—Dr. J. R. Frieser (*Munich. med. Wchschr.*, 1898, 1121) prescribes menthyl valerianate in the form of drops, for migraine, thus: Menthyl valerianate, 5; distilled water, 20; syrup of orange flower, 30. Fifteen minims of this mixture to be taken every two hours between the attacks.—*Pharm. Cent.*, xxxix., 669.

PHENOL AFTER DENTAL EXTRACTIONS.—A Schuer advocates for the relief of pain the direct application of liquid phenol to the cavity after extraction. It is applied by wiping the cavity with a pledget of cotton dipped in the phenol. The author always employs this method to prevent pain after extractions.—*Therap. Monats.*, lē, 532.

LETTERS TO THE EDITOR.

THE USE OF NETTLES AS FOOD.

Sir,—It may interest your correspondent, D. Gair (see p. 633), to know that in Sowerby's 'English Botany' (vol. viii., p. 128, 1868), the following paragraph occurs:—"The leaves of the nettle when young, make a good potherb, and were at one time eaten largely, when green vegetables were less abundant than they now are in our gardens. In Scotland it was the practice to force the nettles for early spring kail, and we are told that nettles dressed like spinach are excellent eating. By earthing up, nettles may be blanched in the same way as seakale, and eaten in a similar manner." Several statements more interesting to agriculturists than to pharmacists are also given in detail. Of these may be briefly mentioned, that "Cattle give more milk when fed on hay containing nettles than when fed on hay alone; that the leaves chopped and mixed with other food are beneficial to young poultry." "The juice of nettles yields a beautiful and permanent green dye, which is used for woollen stuffs in Russia. The roots boiled with alum produce a yellow colour, which dyes yarn well." Campbell, complaining of the little attention paid to it in England, says, "I have eaten nettles, I have slept in nettle sheets, and I have dined off a nettle tablecloth. The stalks of the old nettle are as good as flax for making cloth." The fibre being produced in less quantities than that of flax, and being somewhat difficult to extract accounts, perhaps, for the fact that it is but little used in Britain, though in some countries it is still employed." "Medicinally, it acts as a slight astringent. It was recommended by the old writers on herbs as a styptic, and seems to be useful in arresting bleeding of the nose. With this view, a small piece of lint moistened with the juice may be placed in the nose." The plant so used is *Urtica dioica*, which has a yellow, slender, creeping perennial rhizome. *U. urens* is an annual plant with a tap root only, and is usually only about 12 or 18 inches high. The yellow colouring matter in the roots of *Urtica dioica* is very evident when the plant is pulled up. The plant has an advantage over flax in that it grows in the poorest soil and in the most stony places, whilst flax needs as rich soil as wheat. One use of the nettle that I have not seen mentioned is as a counter irritant. Flagellation with nettles for those who have the courage to use them has been known to relieve lumbago. The Roman nettle *U. pilulifera*, now an extremely rare British plant, is said by Camden to have been brought over to this country for a similar purpose. He says: "When Julius Cæsar landed at Romney the soldiers brought some of the nettle seed with them, and sowed it there for their use to rub and chafe their limbs when—through extreme cold—they should be stiff and benumbed, being told before they came from home that the climate of Britain was so cold that it was not to be endured without some friction to warm their blood." A decoction of the leaves has also been strongly recommended as a hæmostatic in metrorrhagia (*P. J.* [3], xx., p. 343), and *Urtica pilulifera* is used in the East as a galactagogue. The chemistry of this plant still needs investigation, since Reuter obtained a non-nitrogenous glucoside from all three species (*Pharm. Centralh.*, October 17, 1889, p. 609), and Oddi and Lomanaco isolated a crystalline alkaloid, fatal to frogs in the dose of 1 centigramme, but with slight general effect on mammals, but whether either of these is the source of the irritant action of the nettle, or of its galactagogue action, does not appear (*P. J.* [3], xxiii., p. 3, 1892). The peculiarities of nettle fibre have been described in *P. J.* [3], xiv., p. 786, from which it appears that nettle fibre cannot, if treated by the chemical means as yet employed, be made to yield a fibre equal to flax for technical purposes.

London, December 12, 1898.

E. M. HOLMES.

THE PHARMACEUTICAL SOCIETY AND THE TRADE.

Sir,—I regret to see that so much misapprehension exists amongst chemists in regard to the position which the Pharmaceutical Society occupies and the functions it ought to perform. This misapprehension will, unless it is removed, prove a great barrier to progress. There appears to be an idea that the Pharmaceutical Society is a kind of foreign parasite living off the pharmaceutical world; whereas the Pharmaceutical Society and the pharmaceutical world ought to be synonymous terms. The Council is looked upon as a body outside of chemists, against which only such invectives as are begotten in rare moments of inspiration are strong enough to be hurled, and yet every man in the drug trade has a right and a duty to perform in the election of the Council. Nobody

will accuse me of becoming a propagandist, I am sure, and I would not call attention to this were it not for the fact that recent events have proved conclusively that Parliament recognises the Council as the mouth-piece of the Society, and the Society, not merely as the representative of the drug world, but as the drug world-itself. We have not the faintest chance in the House of Commons unless we lay our grievances before it through the recognised official medium. It can serve no good purpose to drag up the short-comings of the Council in the past. Whatever may have been the position in days gone by, it is generally recognised that the present President is energetic and tactful, and chemists will do well to forget the past and take full advantage of the present. I do not mean by this to censure any president of the past. We have all made mistakes in the past, but I think we now see our road pretty clearly and, if we are united, pharmaceutical history ought to be made fast during the next few years. Some of the arguments brought forward against the Society are unreasonable, and others are unjust. For instance, it is unjust for a man to look back upon his student days and count up the sums he disbursed in order that he might become a chemist, and place the whole to the debit of the Pharmaceutical Society. Part may have been paid for tuition with which the Society had nothing whatever to do, part may have been paid for board and lodgings during student days, and some few pounds have been paid in the form of examination fees, but the Society does not know of a method by which it can conduct examinations free of expense. It is unreasonable to suppose that because the Society got a few pounds from a man in the shape of examination fees when he was only upon the threshold of manhood, it will protect him from his enemies, look after his interests in Parliament, and keep a protecting arm around him generally until he has reached his four-score years without further charge. I think it is rather mean for men to say they will join the Society after they see what it can do. Why, it is just in the fight that these men are needed. It is said that Napoleon cursed more at De Grouchy for coming up with fresh forces after Waterloo was lost than he did all his enemies put together. Who wants a fresh accession of strength after a battle is lost, and what would be the use of it after the battle is won? I again say that I am not acting the part of propagandist for the Pharmaceutical Society, but I am quite convinced that this fight, if it is to have any chance of success, must be waged through the medium of the Society, and if the Society is to make a strong impression on Parliament it must be able to show that it is backed up by the whole drug trade. We will do well to forget the grievances of the past, forget petty local animosities, elevate the Society to a position of impregnable strength, and present an unbreakable front to the unqualified enemy. In elevating the Society we are not doing a service to an outside body. The Society is ourselves and the Council is our servant.

Dumfries, December 12, 1898.

JAMES REID.

THE PROPOSED POISON REGULATIONS.

Sir,—As you remark in a note in this week's Journal, it is extremely desirable that the recommendations for the keeping and selling of poisons be thoroughly discussed, and if need be amended, before they become incorporated with the Pharmacy Act of 1868. It was a matter of surprise to me to find no discussion on the subject in this week's Journal, after the very elaborate article by Mr. Barnard Proctor on this subject. Whilst I most cordially agree with the desire at this time to meet our obligations to the Privy Council, and to settle a long standing grievance, I must confess that I am one of those who do not believe there is any evidence of moment to show that chemists have been negligent in this matter, and therefore I would earnestly hope that we shall not be over-regulated. Possibly there may be no inspection, but whether that be so or not, I am sure that every conscientious pharmacist would desire to be in line with the law, and I think it is the duty of the framers of the proposed regulations to bear in mind the minimum of regulation which it will be necessary and convenient to impose upon all classes of chemists for the public safety, and leave ideal regulations such as those suggested by Mr. Barnard Proctor to the free will of the ideal pharmacist. It was very well pointed out the other day by a representative pharmacist that, unless the poisons to be regulated are defined, he might as well shut his shop-door and label it "poison cupboard." In my opinion the regulations as they stand now would, in fifty per cent. of the pharmacies in the United Kingdom, mean a very large refitting order and a source of infinite worry, and in the end perhaps not answer the purpose so well as the

special means the proprietor had himself taken for his own safety. But if the poisons in Part I. of the Schedule, with such additional dangerous poisons as the Society might add, were singled out for special and strict regulations, there would be no difficulty or hardship in submitting to them. Then the minor poisons, from laudanum and nux vomica down to paregoric, surely might be sufficiently provided for in some such terms as these. That they shall be distinctly labelled with the name of the poison, and that no such poison, the maximum dose of which is, say, a drachm, shall be kept in dangerous proximity to weaker preparations. This would provide for the separation of laudanum and such poisons from black draught or tincture of rhubarb. All I plead for is that no machine-made regulations be imposed upon the arrangement of the whole pharmacy, but that very definite regulations be applied to definite and dangerous poisons, and that the remainder with some such regulation as I have suggested be left to the discretion of the qualified man. Regulations for keeping poisons are now, we believe, about to be made for the first time, and as the Society has power to make regulations from time to time should further be needed, I think we should fully meet our obligations to the Privy Council by the course I have described, coupled with further safeguards as to the selling of poisons.

London, December 17, 1898.

W. WARREN.

LIMITED COMPANIES AND MEMBERSHIP OF THE SOCIETY.

Sir,—In reading over the new Bye-Laws of the Pharmaceutical Society, confirmed and approved by the Privy Council, which I received in common with other registered chemists, they suggest to me the following questions, which I consider of vital importance:

(1) Are the registered chemists at present selling their services and qualifications for the benefit of unqualified limited companies eligible for election as members of the Pharmaceutical Society?

(2) If so could these unqualified limited companies, by means of advertisements, handbills, labels, or otherwise, make any use of the title Member of the Pharmaceutical Society in the same manner that such a company, not being a "person" according to present ruling, exhibits the title of chemist and druggist?

(3) In Section 17, Clause 2, we find words to the following effect: That if any report be made by a member of the Society that another member has been guilty of any act or conduct which is contrary to, or subversive of the interests of the Society, or a violation of its laws and regulations, the Council may—in exercise of the power conferred by the Charter—remove such member from the Society. Would the Council deem the covering of unqualified limited companies an act or conduct sufficient for removing such a person from the Register of members of the Society? A definite answer to these questions is most desirable, and if I am wrong in my surmises I feel that it is most important that the trade should know the facts. Let me also take this opportunity of expressing the pleasure afforded me in reading the admirable editorials which have recently appeared in the Journal referring to company trading; they are a distinct advance on what has gone before, are calculated to quicken the energies of the local associations and to point out the way towards which we may look for a remedy. What your carping critic at Bury meant to gain for the benefit of pharmacy by writing such a long-winded letter (*ante* p. 631), I am at a loss to understand. Methinks the energy expended would have been much better employed in appealing to his brethren to become united as members of the Pharmaceutical Society.

Blackburn, December 13, 1898.

WILLIAM HOLT.

MELLIN'S EMULSION OF COD-LIVER OIL.

Sir,—The practice which Messrs. Mellin adopt in a "few exceptional cases" of allowing something extra to their usual terms is one, I fear, too often adopted by other large firms "who cannot see their way" to assist we retailers to obtain a living profit. It is high time the local associations should inquire from such firms as A. J. White, Ltd., W. T. Owbridge, etc., whether they do or do not allow an extra bonus in one way or another to their largest customers. I have, and I know many chemists in this district who do get all their supplies from a cash chemist at the following prices: Seigel's, 11s. 6d. per dozen; Owbridge's, 8s. 6d. per dozen. There must be some inducement offered to these so-called public benefactors (?), or they would not supply the above in dozen lots so freely as they do if they do not get something in return.

December 15, 1898.

A MIDLAND CHEMIST (161/8).

INTERESTING VERSUS INTERESTED JOURNALISM.

Sir,—Just a word in praise of the *Pharmaceutical Journal*—so up-to-date in scientific matter, and withal so very practical and business-like. In fact there is no need for any pharmacist to subscribe to any other trade paper, for it is as complete as any truly progressive pharmacist can wish. The enclosed circular anent a contemporary came to hand a few days ago, and very plainly shows to what depths the reptilian press will sink, stirring up the most villainous effluvia the while. It is quite a noteworthy fact that this trade organ (as it likes to style itself) is never tired of vilifying the Pharmaceutical Society, and, if the truth was known, has been the direct cause of most of the present alienation. It is satisfactory to note, however, that the times are changing, and ere long I feel sure there will be a great influx of new members. As one of the means to this end, I would like to suggest that the papers by Messrs. Young and Squire in last week's *Journal* be printed *in extenso* and circulated to every chemist on the Register. This could easily be done if every present member would circulate, say, a dozen, to known non-members, names and addresses of whom could be got from the Register.

Nuneaton, December 19, 1898.

A. E. SLINN.

* * * Copies of the circular referred to have been sent to us by several correspondents. It is a somewhat hysterical and presumptuous appeal for half sovereigns, issued on the "worth a guinea a box" principle by the proprietors of a weekly publication which has lately distinguished itself by advocating legislative recognition of companies of unqualified persons carrying on business as chemists and druggists. Apart from that, the circular does not differ appreciably from those which tradesmen are accustomed to issue from time to time when they find business slack and their popularity passing. [Ed. P. J.]

IODINE IN THYROID GLAND.

Mr. Swinton's letter in your impression of December 10, p. 633, leaves me little to answer, as he now finds that iodine is present in the residual gland after B.P. treatment. But his statement that in my process of testing for iodine, bromine is set free, must not pass without correction. It is one of the advantages of this simple process that in the ordinary method of testing, nitro-sulphuric acid does not set free the bromine. The process would be useless for kelp testing, for which it is mostly used, if it did. I will only add that it must be difficult to get an organic substance "completely charred" in the presence of potassium nitrate.

Dalmuir, December 19, 1898.

EDW. C. C. STANFORD.

A REASONABLE REQUEST.

Sir,—May I, as an assistant, ask through your paper if the principals of all shops could not close on the Wednesday half-holiday before the Christmas and other holiday seasons, instead of keeping open, and thus making assistants pay back the time which is generally supposed to be a general holiday. It does seem hard that it cannot be given to us. If this was only done, I am sure it would be greatly appreciated by assistants generally.

December 19, 1898.

DURUS (161/30).

RETAIL CHEMISTS AND THE P.A.T.A.

Sir,—Owing to the omission of inverted commas in my letter which you printed last week it would not be clear to your readers how much of Mr. Broadhead's letter I quoted. Allow me to say it was simply the following passage: "The P.A.T.A. is an association which is endeavouring according to its lights to ameliorate the condition of the chemist."

Portsmouth, December 17, 1898.

HERBERT H. BAILEY.

Sir,—The letter of Mr. Bailey in your last week's issue was no doubt calculated by the writer to prejudice chemists against our movement. Mr. Bailey criticises our attitude towards the grocery trade as if it were a new departure on our part. He claims to speak as one having an intimate knowledge of our movement, and ought, therefore, to have information that our policy in reference to the grocers was decided upon nearly two years ago by the governing body of the Association. The subject was well discussed by the trade before. It was recognised that grocers were large distributors of articles in which chemists were interested. Indeed, they are possibly the largest distributors of such articles as meat extracts and foods. No movement could possibly have the required weight with proprietors which ignored so large a section of the distributors of their articles, hence the necessity for securing the co-operation of all traders handling these articles. It was

considered wiser rather than to court opposition from so large an interest as that represented by the grocery trade to form a basis for mutual effort in the direction of securing better profits upon articles in which both grocers and chemists are interested. It was therefore decided to form a grocery section, to control such proprietary articles as cocoas, starches, mustards, blues, and the various other peculiarly grocery proprietaries. Mr. Bailey says he hears that grocery retailers have thought a profit of 12½ per cent. on proprietary articles sufficient, but he does not go on to say that the proprietary articles referred to are of the class above-named, and not patent medicines. There are some 30,000 patent medicine licences issued; there are only 9000 chemists in business, and whilst these 9000 chemists were being kept constantly notified of the protected prices of P.A.T.A. articles through the medium of the "Anti-Cutting Record," it became absolutely necessary that those outside the drug trade, who sell these articles, should be informed as to the protected prices. Complaints were reaching the Association that grocers were cutting, and on communicating with the offenders we were invariably informed that they were ignorant of the protected prices. It became necessary, therefore, to send such grocers a list of protected articles, in which they were more or less interested, and it was found that the best means of doing that was by sending them an abridged edition of the "Record" dealing with such articles. Mr. Bailey maintains that the P.A.T.A. have made a present of half the articles to the Grocery Section. The Association has never attempted to regulate the class of traders who are to deal in certain goods. It has simply to recognise facts as they stand. Mr. Bailey will surely not deny that the list of goods he refers to is a list of articles which are not patent medicines, but are goods which are being sold by thousands of grocers, and I take it he will also admit that having protected these articles, it is our duty to inform all sellers of the protected prices. It is significant in the face of Mr. Bailey's statement, that "the only places in which the P.A.T.A. can claim that it has been able to maintain fixed prices are towns where there is no cutter," we have no information that any firm at Portsmouth is cutting P.A.T.A. articles. We have a large number of members in the town, and if there had been cutting there we should undoubtedly have heard something about it. Portsmouth can hardly be said to be a town where there is no cutter.

London, December 20, 1898.

W. S. GLYN-JONES.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

APOTHECARIES' SOCIETY.—You should address your inquiry to the Secretary of the Society, Apothecaries' Hall, Blackfriars, E.C. [Reply to APEX.—20/17.]

MIST. BISMUTH ET PEPSIN.—If the pepsin is soluble without the hydrochloric acid, omit the latter. Many samples are not soluble without acid. [Reply to W. W.—20/24.]

FIRST EXAMINATION.—The reduced fee is payable whenever a person who has failed to pass re-enters for examination. [Reply to SECUNDUS.—21/1.]

NEURALGIA POWDERS.—Exalgine, 1 grain; ammonium chloride, 10 grains. Exalgine in this dose is perfectly safe, and the small dose is stated to be as efficacious for the purpose as a larger one. [Reply to W. W.—20/24.]

APPLICATION FOR PROTECTING STONE.—The substance you send appears to be an acid fluoride of sodium. We cannot say whether alum would serve the purpose. [Reply to FLUATE.—20/27.]

RED MARROW EXTRACT.—Take the heads of young bones, disintegrate the tissue by thorough trituration, then macerate for twenty-four hours, with occasional shaking, in an equal weight of a menstruum composed of equal volumes of glycerin and chloroform water; finally express the clear red liquid.

[Reply to C. L. T.—19/29.]

COUGH MIXTURE.—Probably the following will suit you:—Fluid extract of ipecacuanha, 8 minims; fluid extract of opium, 16 minims; fluid extract of liquorice, 2 drachms; oil of aniseed, 2 minims; oxymel of squills to make 1 fluid ounce. Dose, for adults, one teaspoonful.

[Reply to W. W.—20/24.]

DYNAMICS.—You had better get an elementary text-book of mechanics, such as that published by Collins at 1s., or those issued by the University Correspondence College at 2s. per volume. If possible, also, you should join an elementary class in the subject, such as are conducted in connection with the Science and Art Department.

[Reply to S. H. E.—21/2.]

BLEACHING BROWN HOGSKIN.—This is a matter for experiment, as it all depends on the nature of the dye. Possibly a weak solution of sulphurous acid will do what you require, or salt of sorrel may answer. Try a little on an inconspicuous part of the article. It is doubtful if hydrogen peroxide will answer in this particular case.

[Reply to LEATHER.—20/2.]

PERFECT DEVELOPER.—There are a great many formulæ which would answer your purpose. Here are three: (1) Water, 1000 C.c.; sodium sulphite, 300 Gm.; hydroquinone, 7.5 Gm.; potassium carbonate, 40 Gm.; metol, 5 Gm. Dissolve in the order given. (2) Water, 1000 C.c.; glycin, 5 Gm.; metol, 1 Gm.; sodium sulphite, 300 Gm.; potassium carbonate, 125 Gm. (3) Water, 1000 C.c.; ortol, 7.5 Gm.; potassium metabisulphite, 7.5 Gm.; sodium sulphite, 150 Gm.; potassium carbonate, 30 Gm. You should be able to sell 8 ozs. for a shilling.

[Reply to STEREO.—20/25.]

VIOLETTE DE PARME PERFUME.—Try some experiments on the following lines, modifying the ingredients to suit your special requirements:—Ionone, 2 drachms; oil of bergamot, 2 drachms; anethol, 2 minims; oil of sweet orange, 10 minims; oil of neroli, 10 minims; otto of rose, 5 minims; extract of orris, 10 fl. oz.; extract of jasmín, 15 fl. oz.; extract of violet, 10 fl. oz.; extract of cassia, 3 fl. oz.; extract of abelmoschus, 3 fl. oz.; extract of rose, 5 fl. oz.; extract of musk, 2 fl. drachms; glycerin, 2 fl. drachms. You should vary the proportions until you obtain a satisfactory product.

[Reply to APPRENTICE.—19/24.]

TOILET VINEGAR.—(a) Extract of cassia, 1; extract of jasmín, 1; extract of orange, 1; dilute acetic acid, 4. Mix. Filter bright through kieselguhr. (b) Oil of neroli, 10 m; oil of ylang-ylang, 20 m; oil of rose-geranium, 10 m; oil of bergamot, 20 m; oil of sweet orange, 2 minims; glacial acetic acid, 1 oz.; alcohol (90 per cent.), 2 ozs.; distilled water, to make 10 ozs. Mix the oils with the acid, add the spirit, then the water. After standing for twenty-four hours, filter bright through kieselguhr.

[Reply to W. W.—20/24.]

ATOMIC WEIGHTS.—For all practical purposes you will find it more advantageous to use a table in which the atomic weights are given, as far as possible, in round numbers. Examiners are usually sensible men and not likely to be impressed with the pretence of absolute accuracy involved in the statement of the atomic weight of oxygen as 15.88, and that of zinc as 64.91, as given in the new Pharmacopœia.

[Reply to S. H. E.—21/3.]

PYROCATECHINE DEVELOPER.—The following formula for this developer was given in our issue for October 22, p. 446a, and it will be found quite satisfactory:—

A.	
Pyrocatechine	20 g.
Sodium Sulphite	100 g.
Water	1000 C.c.
B.	
Sodium Phosphate	188 g.
Sodium Hydrate	20 g.
Water	1000 C.c.

To make B dissolve the phosphate in 750 C.c. and the hydrate in 250 C.c. of water, and then mix. For use, mix 1 part of A, 1 part of B, and 1 part of water.

[Reply to C. J. R.—21/4.]

BOTANICAL CASES AND LABELS.—Write to Watkins and Doncaster, 36, Strand, London, W.C., stating your requirements, and asking for one of their price-lists. [Reply to J. D.—21/13.]

RESTORING PARTLY OBLITERATED PENCIL MARKS.—We are unable to help you in this matter, such experiments as we have tried having proved unsuccessful. Possibly some photographic process might give satisfactory results. [Reply to SPERO.—20/26.]

DISPENSING PROBLEMS AND NOTES.

PERCENTAGES IN PRESCRIPTIONS.

Sir,—Mr. J. C. Umney, in his excellent 'Guide' to the 1898 B.P., makes the following remark under Acid Carbolie Liquefactum:—"This acid is directed to be made by the addition of 10 parts of distilled water to 100 parts by weight of phenol, and differs (*sic*), therefore, from that of the 1885 Pharmacopœia, the monograph for which has been always understood to be 90 parts of carbolie acid and 10 parts of water." How such a misconstruction of the "monograph" could occur I cannot understand, as it distinctly states that "liquefied carbolie acid" is "carbolie acid liquefied by the addition of 10 per cent. of water"; and if any doubt existed as to what that meant reference to "carbolie acid" settles the question, as under it, it says, "At 60° F., 100 parts of the acid are liquefied by the addition of 5 to 10 parts of water." This being ancient history, I would not have referred to it had it not been that in the Journal of November 26 (p. 582), under "Dispensing Problems and Notes," in reply to a correspondent, it is said that "Adde cocain. hydrochlor., 10 per cent., implies that the finished ointment shall contain 10 per cent. of the alkaloidal salt." The reading of "liquefied carbolie acid" (1885) monograph is my conception of added percentage as against contained percentage. If I am wrong I will be glad to receive proof that added and contained percentages are synonymous expressions. Had I dispensed the recipe I would have added 96 (not 106 $\frac{2}{3}$) grains of cocain. hydrochlor. This is not a correction, it is a query, because I am anxious to have any misconception (?) I may have removed, and if I am correct (?) that others may not be misled by a wrong rendering of a term which, to my mind, has a definite meaning of its own.

PERCENTAGE (159/2).

NOTE.—"Percentage" is not labouring under any misconception. His letter shows that he appreciates the difficulty which frequently occurs in dealing with prescriptions like the one under discussion. The reply referred to was framed to comply with what was conceived to be the actual intention of the prescriber, viz., that the ointment should contain 10 per cent. of cocaine hydrochloride, and not 9 $\frac{1}{11}$ per cent. It should hardly be necessary for anyone to require to be convinced that added and contained percentages are not synonymous expressions: the ambiguity in the present case depends upon the difficulty of reconciling what appears to be the intention of the prescriber with the sense conveyed by the abbreviated form in which the prescription is written.

ICHTHYOL IN A LOTION.

Sir,—Please inform me of the best method of dispensing the following prescription:—

R Ichthyol..... 3iiss.
Zinc Oxide }
Ol. Olivæ }aa ʒi.
Aq. Calcis }
M. ft. Pasta. M. d. applic.

KILO (20/28).

NOTE.—A thick creamy product can be obtained, which shows little tendency to separate, by mixing the ichthyol with the olive oil in a mortar, adding the zinc oxide, and rubbing to a smooth paste. Finally, pour in the lime water in small portions, stirring thoroughly after each addition.

CORRECTION.

Mr. RYMER YOUNG'S PAPER.—On page 639, the sentence commencing at line 13 of column 1, should read as follows:—"That Committee, though in favour of legislating on some of the lines that had been suggested, was averse to restricting the dispensing of medicines to registered persons, and in the end its deliberations resulted in little beyond a suggestion that another Bill should be brought in by the Government." Mr. Young's letter, notifying the alterations in the sentence as printed, was not received until after the Journal had gone to press last week.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Iodine in the Blood. In a communication to the Société de Biologie, M. Gley states that iodine is found in the blood of all adult animals, and that this is the source of the iodine present in the thyroid gland, to which attention was first called by Baumann. According to Gley, the red corpuscles are the seat of the iodine compound. It is not found in the blood of new-born animals.—*Nouv. Rem.*, xiv., 418.

Reproduction in Dictyota. J. Lloyd Williams, University College, Bangor, has investigated the reproduction of *Dictyota dichotoma*, an annual which germinates during the summer, remains small during the winter, and grows rapidly in June, beginning to form reproductive cells in July. The tetraspores are produced throughout the season; the sexual cells, however, show a remarkable periodicity. The formation, maturation and liberation of each crop occupies a fortnight, the interval between two spring tides. The oospheres on liberation have no walls, attract antherozoids, become fertilised and at once start germinating. If not fertilised the eggs lose the power of attracting antherozoids and form walls, but after a few divisions the process stops and the plantlets die. At the close of the season, and in cloudy and cold summers, some sori fail to mature, and certain of the sexual cells become sterile. The author concludes that the amount of illumination probably determines the maturation and liberation of the sexual cells, and the fertilisation of the oospheres.—*Annals of Botany*, xlviii., 559.

Carbohydrates in the Yeast-cell. L. Errera, after confirming his former researches on the structure of the cells of *Saccharomyces cerevisiae*, asserts that carbohydrates are stored up in yeast in the form of glycogen, which accumulates or disappears from the vacuoles very rapidly, according to conditions of nutrition and growth.—*Annals of Botany*, xlviii., 567.

Collecting and Preserving Diatoms. F. R. Rowley gives directions for collecting and preserving diatoms. In collecting, a spoon attached to a stick may be used for skimming the brown diatomaceous ooze off the surface of the mud; a drag-net serves this purpose in the case of forms occurring at greater depths, e.g., *Surirella*. The latter should then be placed with water in shallow glass vessels sheltered from direct sunlight; after resting for about twelve hours the diatoms appear in masses on the surface of the mud, whence they are transferred by means of a pipette to the fixing fluid. Among fixing reagents, Flemming's chromo-aceto-osmic acid, and sublimate in aqueous or alcoholic solution, demonstrate the most delicate structural features of the nucleus and cytoplasm during division. Picro-sulphuric acid followed by hæmatoxylin shows up the chromatic elements of the nucleus. A 1 per cent. osmic acid solution serves, in unstained preparations, to bring out the arrangement of the cytoplasm, the chromatophores, and other inclusions in the cell. A 45 per cent. solution of iodic alcohol is recommended for the study of the so-called "red granules" of Bütschli, which stain well after fixing by the foregoing

method. Large forms are removed individually under the dissecting microscope by means of a capillary tube, and the smallest are transferred with a pipette to the fixing solution. After fifteen minutes the latter is decanted off and the preparation passed through water and alcohols of increasing strength into absolute alcohol, which extracts oil and the colouring matter of the chromatophores; a few drops of ether and moderate heat facilitate their extraction. The material is then passed through alcohols of decreasing strength into distilled water and stained. A weak solution of Delafield's hæmatoxylin is a useful stain when controlled under the microscope; alum and borax-carmin are less useful. The specimens are passed successively through 35, 70, 95 per cent., and absolute alcohol into clove oil, to clear them, and mounted in dammar. The alcohol baths must be gradually changed to avoid distortion of the protoplasm. Living diatoms live for days when stained with methylene blue solution (1 in 100,000), but the vitality of the cell wanes from the moment the nucleus takes up the stain.—*Natural Science*, xiii, 406.

Purity of Lithium Carbonate. Lyman F. Kebler has communicated the results of his researches on medicinal lithium carbonate to the Research Committee of the U.S. Pharmacopœia Revision. After reviewing the sources and various commercial methods of preparing the salt, the author compares the tests in the U.S.P. with results obtained by himself, working on eight samples. As a result he recommends the following monograph in place of that official in the U.S.P., and comparison will show how more detailed it is than that of the British Pharmacopœia: "Lithium carbonate is a light, white powder, with occasional crystalline grains, odourless, and having an alkaline taste; permanent in the air. Soluble in not less than 75 parts, and should not require more than 80 parts of water at 15° C., and in 140 parts of boiling water; much more stable in water impregnated with carbon dioxide, insoluble in alcohol. Soluble in dilute nitric, sulphuric, hydrochloric, and acetic acids, with active effervescence; fuses at a low red heat; loses carbon dioxide at a higher temperature, and is partially converted into the oxide. It imparts a crimson colour to a non-luminous flame. Its aqueous solution has an alkaline reaction upon litmus paper. One gramme dissolved in 50 C.c. of dilute acetic acid should at most leave only a trace of insoluble matter (limit of mechanical impurities). Separate portions of this solution should not be affected by hydrogen sulphide T.S. (absence of arsenic, lead, etc.); ammonium oxalate T.S. (absence of calcium); or sodium cobaltic nitrite T.S. (limit of potassium); or produce more than a faint opalescence with silver nitrate T.S. (limit of chloride); barium chloride T.S. (limit of sulphate); or more than a slight coloration with ammonium sulphide T.S. (limit of iron, manganese, etc.). If 0.5 gramme of lithium carbonate be dissolved in 2 C.c. of hydrochloric acid, and the clear solution evaporated to dryness, the dry residue should dissolve completely in 3 C.c. of absolute alcohol, and 3 C.c. of ether added to this solution should not render it turbid (limit of other alkalis). If 1 gramme of the dry salt be mixed with 25 C.c. of water, to which have been added a few drops of methyl-orange solution, it should require not less than 26.7 C.c. of normal sulphuric acid, corresponding to at least 98.61 per cent. of the pure salt." The author prefers the volumetric to the gravimetric method. He found sulphates present in six samples, chlorides in five, calcium in three, iron in two, and aluminium in one. Owing to the presence of impurities in all samples examined, he considers that the volumetric requirement of the present U.S.P. (98.98 p. c. of lithium carbonate) is too high.—*Am. Journ. Pharm.*, lxx., 600.

VISUAL OPTICS IN THEORY AND PRACTICE.—II.

BY LIONEL LAURANCE,

Instructor of Visual Optics at the Official Classes of the Worshipful Company of Spectacle Makers.

The appliances needed by the optician are not numerous, but no greater mistake can be made than that of buying inferior articles such as render the work that is to be done more difficult, longer to achieve, and not so perfect when achieved. Moreover, it should be considered, that appliances are bought for a lifetime, and, therefore, any small extra outlay on them is spread over the long number of years during which they are in use and the means of making profit for the optician. Time is almost equivalent to money, and if time be saved and errors avoided the profit on optical work is increased.

Chief and foremost is, of course, the trial case, which if complete contains almost everything that is needed. There must be in it a full range of lenses, convex and concave sphericals from 0.25 to 20° and convex and concave cylinders from 0.25 to 6°. These must all be in pairs, and should be mounted with rings and handles so that, when in use, they are kept clean and do not require constant wiping. The frequent cleaning of trial lenses when handled occupies quite a considerable time, and time that is spent uselessly, besides which, this frequent rubbing of their surfaces tends to scratch the lenses and causes them to soon lose their high polish. Unmounted lenses, moreover, are very liable to become chipped. The handles facilitate the taking of the lenses out from the case and inserting them into the trial frame, or *vice versa*, and renders easy the necessary rotation of cylinders.

The rims themselves should be made so that the lenses can be inserted into the trial frame with either face to the front, and not as some are made, so that they can only be inserted one way. They should also be made so that the lenses be secured by screws in order that if one be broken it can be easily replaced. This is not the case when the lenses are retained by bending the rims over their edges. Both rims and lenses should be as light as possible. It is also advisable to have the convexes and concaves mounted in rings which are of different colour, say, the one lot white and the other yellow, so that a mistake cannot be made between them.

The case should contain a sufficiency of prisms, the lower numbers, say from 1 to 4°, being in pairs, and in addition to these and the sphericals and cylinders, all necessary discs, such as the opaque and black disc for occluding the eye not under test, the stenopaics for testing astigmatism, the pin-hole disc for deciding as to whether a case be correctable by lenses, the Maddox rod, the double prism, etc., for testing the motor muscles, and some coloured glasses, one each red and green and others smoke and blue of different shades.

The lenses must be ground on dioptric tools, and not on those of the inch system, and numbered in diopters only, and the numbering should not be scratched on the lenses themselves, but be stamped on the handles, also the numbers should be quite distinctly marked on the divisions of the case pertaining to each lens. It goes without saying, that each lens must be true as to the power marked and which it is supposed to be, also it must be accurately centred if spherical. The axes of the cylinders must be clearly and exactly indicated. The base apex line of the prisms must be the same, in fact, everything in connection with the glasses should be of the highest grade of workmanship and as perfect as such workmanship alone can make it.

The trial frame is, perhaps, the most important part of the case,

for it is to be used on every customer, and as it is to be so used on every customer the dimensions of the faces of whom vary so very much, it is clear that, in order to fulfil what it is needed to do it must possess the many and various qualities of an ideal working tool. No non-adjustable trial frame can serve for small and big faces for adults and children. Lightness is required, and so also is perfect rigidity and strength, and it is desirable that it be made of a metal that does not easily rust. Consequently, there is nothing to compare with finely tempered steel nicked as the material from which it should be made. It must be adjustable as to interpupillary distance, as to the height of the nose, as to the set of the bridge, and as to the length of the arms, the latter being curled so as to pass over the backs of the ears, and keep the frame firmly in place. Without these qualities all the work is rendered more difficult, as the frame constantly shifts and slides forward if straight sides be on it. If the frame has no means of being advanced and retarded, lenses become smudged by contact with the lashes, and the power of the lenses is actually changed by too great a distance between them and the eyes. Accurate testing is impossible when the axes of the lenses themselves are not exactly in the lines of vision, but decentred from them as occurs when there is no adjustability for pupillary distance. Adjustability as to height is needed so as to avoid decentring, and so as to allow of the lenses being lowered for close work.

As all the adjustabilities of the frame need to be done when it is on the face they should be, therefore, achievable by means of thumbscrews, and these thumbscrews must be so placed and sufficiently large to allow of easy manipulation. Each eye-piece should have carriers for three lenses, the one for the spherical, the other for the cylinder, and the third for an extra spherical or for the opaque disc. The front carrier, which is intended for the cylinder, must be capable of revolution, so that the axis of a cylinder can be easily got into any desired meridian. The frame must be scaled for angle notation indicating the various meridians, and the numbering should be large enough and clear enough to be easily seen by the optician at a fair distance. The insertion of the lenses into the frame should be sideways and not from the top, otherwise it is necessary for a lady to remove her hat and veil, a thing not always convenient, besides which, inserting them thus relieves pressure on the nose instead of increasing it. The lenses should be retained in the carriers by means of springs, so that they cannot shake about, otherwise a cylinder after being fitted may become shifted. If the frame be also scaled for pupillary distance, height, and set of bridge, and length of arm, it is somewhat of an advantage, as it gives the optician a rough idea of what sized frame is required by the customer. The lighter the frame is, and the more securely it sets on the customer's face, thanks to the length of the arms being adjustable, the less discomfort it causes. Lightness, however, must not be sacrificed to strength and rigidity. These points about the trial frame and lenses render the optician's work easier, quicker, and more accurate.

Test types for distance should be in clear black block letters printed on white cardboard; they must be graded down to a line lower than that which represents the normal visual acuteness for the distance at which the testing is done. If the tests be made at 6 metres (20 feet), then the type must be as small as No. 4.5, or one lower than No. 6. If 4 or 5 metres (15 feet or so) only be available, there must be No. 3 type on the card. Black cards with white block letters are also good for testing purposes.

Hand-cards for testing the sight at the reading distance are better than folding books, as they can be conveniently held in one hand. All cards must be left uncovered by glass, the latter reflecting too much light, and they must be always perfectly clean.

The trial case, the test types, and a tape line scaled in centimetres or, better, a near point measure, are the only real necessities for sight testing as done by the optician.

There are a few adjuncts which are of great utility, such as a set of trial spectacles and eyeglass frames for finding that which best suits a customer; a lens measure to quickly find the power and nature of glasses previously used by customers, or to try a prescription or stock glass; a record book for entering data pertaining to each case; frame measuring cards for taking the dimensions of frames; small screwdrivers of two or three different sizes, and flat and hollow chop pliers for manipulating frames.

The distance test-card used for measuring the visual acuity and testing the refraction of the eye should be fastened to the wall six metres distant from the client and beneath it, as nearly as possible in a direct line with the eyes under test, the astigmatic chart should be placed. Six metres is considered to be the proper distance for sight testing, but, if not available, 5 or 4½ metres can serve, but no shorter distance.

Diffused sun or artificial light should fall on the test-cards but not on the client's eyes, so if artificial light be employed as the illuminant, it should be screened on the side towards the client, and this is best done by a concave reflector, which serves the double purpose of a screen and of a condenser of the light on to the cards. A light is also required behind the client for illuminating cards used for reading. It is better that this be an artificial light on an adjustable bracket, so that it can be moved into any desired position to either side, above the head or in front of it, for various purposes. Altogether, if the natural light obtainable be not good, and on account of its variability in this climate, it is preferable to depend on artificial light entirely, it being uniform and constant.

HISTORICAL POISONS, POTIONS, PRESCRIPTIONS, ETC.

BY "PHARMACIST."

The King of Korea and the leader of the Filipinos have recently had their lives attempted. The former had his coffee drugged and he and the Crown Prince nearly succumbed. There was a packet of potassium oxalate put into Aguinaldo's soup, but the cook detected it before it reached his master's table. If Shakespeare or Hamlet's father's ghost is to be believed these things were done more easily in ancient days.

(He came) "With juice of cursed hebenon in a vial,
And in the porches of my ears did pour
The leperous distilment,
And with a sudden vigour it did curd
The thin and wholesome blood."

This can only be allowed on the grounds of poetical licence or that the ghost was a deceiver, for succus hyoscyami is harmless in the ears. Perhaps the earliest recorded instance of poisoning is that which occurred when Elisha fed a host of hungry students in B.C. 891. By mistake a quantity of the cucumis colocynthus or *Momordica elaterium*, the former most likely, known as the wild gourd or bitter apple, was mixed with the pottage. The cry was raised that "death or poison was in the pot." Meal was then shed amongst the olla podrida, probably to correct the strong acrid and purgative quality of the mess. Anyhow, it rendered it innocuous.

A most deliberate and wholesale scheme of poisoning was perpetrated at the instance of Bonaparte, when he ordered all the French sick at Jaffa to be given a fatal dose of opium.

Robert Dudley, Earl of Leicester (ob. 1588), attempted through his agents to get his wife poisoned that he might thereby become a suitor for the hand of Queen Elizabeth. This was frustrated through the caution of Dr. Bailey, whom they sought to persuade

to make a medicine for her, when she was in perfect health, intending to add a deadly drug to the prescription.

Sir Francis Walsingham (ob. 1590) is said by Camden to have died "owing to the violence of the medicines administered to him." A striking testimony to the paucity of pharmaceutical preparations in that age.

Lady Frances Howard, who became the wife of Robert Earl of Essex, in the reign of James I., compassed the death of her husband and the poet Overbury. The seraphic-featured Countess was as callous and wicked in crime as Lady Macbeth. She allied herself with one Ann Turner, who supplied her with philtres, she also gave a diamond ring to Mary Wood, a Norfolk witch, for a poison warranted to kill in three days. Poisoned tarts and jellies were forwarded to Overbury, but their nature was easily discovered. These tedious intrigues having failed, Lady Frances resorted to James Franklin, an apothecary in a small shop on Tower Hill, who prepared a phial of stuff like water, which the Lieutenant of the Tower spilled. Then a French apothecary, Lobel, was called in and the poet was ultimately drugged to death.

Napoleon the Great, when he had been driven from Leipzig in defeat and disaster, culminating in his abdication at Fontainebleau, attempted to end his life by means of opium. It would appear that in the retreat from Moscow the Emperor requested his physician to provide him with the means of preventing his falling into the hands of the enemy alive. The drug was carried in a small bag slung round his neck. It is said, however, that either from the poison losing its vigour or the adamantine constitution of Bonaparte, it simply threw him into a deep slumber, from which he awakened in spasms.

That remarkable man Hannibal likewise sought retirement from his implacable enemies, the Romans; in the hollow of a ring he had long preserved some poison for the purpose. It is natural to desire that warriors should die fighting; in lieu of that we agree with old Tony Weller, "pison's the best, hangin's vulgar," when a violent exit is necessitated.

Cleopatra permitted herself to be bitten by a small serpent of the asp kind.

Socrates (who does not know it?) and Phocion drank from the hemlock cup, and Demosthenes poisoned himself in the temple of Poseidon.

Machiavelli, the acute and subtle statesman, hastened his end with his own pills, and it is of record that Oliver Goldsmith was a martyr to his own medicines.

Another author, the famous De Quincey, the "English opium-eater," suffering from neuralgia, resorted to the drug to which the present enervation of China is attributed. The dose increased until he drank 8000 drops of laudanum per diem, equal to 60 or 70 times the B.P. dose of morphia.

Cæsar tells us that Cativulus, the King of the Eburones, resolving not to survive the liberty of his country, "drank the juice of yew and so died."

Rosamond, wife of Helmichis, King of Lombardy, in 575, offered her husband poisoned wine, when he complained of thirst coming from the bath. Having drunk part of it and suspecting its nature from the unusual sensation it occasioned, he compelled her to drink the remainder, and in a few hours they both died.

Carmignola, a distinguished Italian warrior of the fifteenth century, was brought to the point of death by poison put in his food by the Duke of Milan.

King John of England, being refused as a lover by Maud Fitz-walter (Maud the Fair), whom he had imprisoned in the Tower, despatched her by means of a poisoned egg.

It is rather curious that the famous Lorenzo de Medici, who was

stabbed with a weapon said to be poisoned, recovered, while it is authoritatively asserted that the great Florentine's death was hastened by the unskillful prescriptions of his physician. "The mixture of amalgamated pearls and jewels with the most expensive potions might indeed serve to astonish the attendants and to screen the ignorance of the physician, but were not likely to be attended with any beneficial effect on the patient." In other words, it was magnificent but it was not medicine.

The above recalls the cases cited by Josephus concerning Herod, son of Antipater, "that having great pain in the back of his head, the remedies used did him no good at all, but proved contrary to the case." It is notable that when the Oriental physicians ceased their potions and "committed the disease to fortune" that Herod recovered.

The fame which attaches to the Mediæval Italians as acute and subtle discoverers of secret and deadly poisons is not perhaps based upon a very reliable foundation.

What strikes one as peculiar is that their researches in the art of medical curatives is not in the least comparable with their advances in other arts and sciences.

Princes and popes resorted to poison without a qualm when an enemy was to be removed. But so far from it being done *en camera*, Cæsar Borgia exclaimed once, "What has failed at dinner-time will succeed at supper-time." This, of a truth, was highly artistic! And surely the grossest kind of homicide appears less horrible than the overt determination and preparation of Pope Alexander VI. to poison the richest of his cardinals with a confect. It came about, however, that the Pope ate his own sweetmeat and died in great agony.

The Italian women who to-day secretly drug their husbands' food with arsenic during some time and then suddenly withdraw it, causing the victim to pine away, are but following the traditions of those who "wore the purple."

Where then is the stealthy and serpentine Italian who touches a hand, sends a gift, who strikes without fear of detection? He does not exist and never did except in the glamorous and delusive pages of the fictionist.

The "poison ring" was driven home with the effect and force of a rusty nail. It was very obliging, to be sure, of the person who was jagged not to mention it. In the novel it is an elf-like beauty who lets her fairy hand fall like a leaf into that of the victim; the tiny capillaries act, etc.

The "gloves" were gauntlets ribbed with iron and filled with a glutinous cement. The strange thing is that it should be necessary to anyone's plans to "remove" an individual who would be so idiotic as to clothe his hand in such a mess without a protest.

The ancient Arabian women were said to be expert in the preparation of love-potions which concealed a poison. The subtlety of these poisons, however, are entirely discounted by the fact that it was necessary to smuggle the powder into the food of the victim.

Naples, when it was a kingdom, had the great fortune of being ruled by a fisherman for nine days. Tyrannous taxation had driven the sea-faring population into revolt. With a fisher king at their head they demanded alleviations. The Naples rulers being deficient in strength excelled in strategy. They invited the bold usurper to a conference and a banquet, especially the latter. They drugged his wine and doctored his viands. The poison (so we are told) produced a fever in blood and brain, the unfortunate "king" went mad, plunged into the sea and was drowned. His followers dispersed and resumed their former servitude.

Thus it is seen how vast interests are affected by a prescription. Drugs are a trenchant power in the world, indeed it occurred to Mr. Perceval during the Napoleonic wars to bring the French to

their knees by prohibiting the importation to the Continent of Jesuit bark and other medicaments. This highly imaginative scheme produced the following humorous sally from the "witty Canon":—"Such a project is well worthy this statesman—to bring the French to reason by keeping them without rhubarb, and exhibit to mankind the awful spectacle of a nation deprived of neutral salts! This is not the dream of a wild apothecary indulging in his own opium, nor is it the distempered fancy of a pounder of drugs delirious from smallness of profits. What a sublime thought that no purge can be taken between the Weser and the Garonne; that the bustling pestle is still; the canorous mortar mute; and the bowels of mankind locked up for fourteen degrees of latitude!

"Without castor oil they might for some months, to be sure, have carried on a lingering war! But can they do without bark? Will the people live under a government where antimonial powders cannot be procured? Will they bear the loss of mercury? 'There's the rub.' Depend upon it, the absence of the materia medica will soon bring them to their senses, and the cry of Bourbon and Bolus burst forth from the Baltic to the Mediterranean."

Whilst in the Tower, Sir Walter Raleigh was tireless in his quest after the hidden things of science. He had an apartment, known as the still-room, fitted up with every chemical convenience. He was surrounded with vases, jars, phials, strange drugs, and potions.

It was here he pondered over the possibility of producing some specific for the cure of all diseases to which flesh is heir, the result being "the marvellous and world-famed medicine known as Raleigh's Great Cordial."

It is a blending of pearl, musk, hartshorn, benzoar stone, mint, borragé, gentian, mace, red rose, aloes, sugar, sassafras, spirits of wine, and many other ingredients. It was in high repute amongst the sovereigns of Europe, and learned physicians of that day were adulatory of its qualities.

"In ancient times (says Burke) and in all countries the profession of physic was annexed to the priesthood. . . . Medicine was always joined with magic. The use of plants and herbs in both practices was early and general. The virtues of the mistletoe may have been soon discovered. It has been fully proved against the opinion of Celsus that internal remedies were of very early use. By some modern authors the mistletoe is said to be of signal service in the cure of convulsive distempers, which have been ever considered as supernatural. The epilepsy was by the Romans called *morbus sacer*. The Druids also looked upon vervain and other plants as holy for a similar reason."

It has been asserted, however, that the art of medicine in the East chiefly consisted in external applications. Being ignorant of the manner of making decoctions and potions and of the proper doses, they trusted to oils, plasters, ointments, etc.

In the excavations at Pompeii, the chemist and his drugs were in evidence. One curious find was a large glass vase capable of holding two gallons, in which was one and a half of a reddish liquid, said to be balsam. On being opened the contents evaporated so rapidly that it had to be hermetically sealed. One inch in depth of the liquid was lost, leaving behind a sediment upon the sides of the vase. What is this ether-like balm?

Sir Gerald Portal, in his mission to Uganda in 1893, beheld abdominal pains and general soreness of the muscles removed by walking and jumping on the back, wrenching the arms, and tying the ankles of the patient tightly in a rude sort of tourniquet. Fever was cured similarly, except that the calves of the legs were gashed with knives. He thought it was murder; but it was only native medicine and massage.

PHOTO-MICROGRAPHY.—X. (*Concluded*).

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.B.C.S. ENG., F.R.A.S.

Photographing Bacteria.

Bacteria in their natural unstained state are exceedingly small, and for the most part colourless and structureless bodies of protoplasmoidal matter assuming all manner of shapes and having such a high refractive index as to be most difficult to see—even with a magnification of 1000 diameters, and still more difficult to photograph. Although these little organisms can be artificially stained by solutions of many substances, still, each variety seems to have a more or less well-marked selective power of absorbing the colouring matter of one or two special dyes in preference to that of any other. Hence, as the photo-micrographer meets with this type of work he must expect not only all varieties of shape, but all varieties of colour also.

The difficulty noticed by all photographers in obtaining a well-contrasted print of these little bodies depends solely upon the fact that the dyes with which the organisms are stained do not affect the photographic plate in the same manner and to the same extent as they do the eye. For example, a slide may be a very excellent one from a bacteriological point of view, and owing to the selective colouring of the organism as compared with that of the background, may be of a most impressive nature, yet it will not yield an equally contrasted print. On consideration, the reason for this apparent anomaly is not far to seek. Contrast visually was obtained by differentiation of colour rendering between the bacillus and the background, whereas in the photograph it must depend upon what effect each colour can cause on the plate. Put another way, contrast visually is due to duality of colour rendering, whereas in the print it alone depends upon what amount of differentiation in terms of black and white the colours employed as stains have been able chemically to produce—by deposition of silver—in the emulsion which covers the plate.

The aim, then, of the operator must be to increase the difference in these deposit rations as far as he possibly can. To understand how this can be effected, the attention of the reader must be directed to the following:—

1. Colour sensation to the eye is dependent upon the wave length of the light employed. The longest wave gives rise to the red sensation, and the shortest to the violet; intermediate lengths being productive of sensations we call yellow, yellow-green, green, greenish blue, blue and blue-violet.

2. The ordinary photograph is taken by the violet ray, because the usual emulsion is most sensitive to that particular wave length. Plates, however, can be stained so as to be extra sensitive in any one or more colours, but even then with this extra sensitiveness, the action of the violet is always the strongest, *i.e.*, more precipitation of silver—time for time—is produced with violet light than any other colour.

3. Ordinary white light consists of a blending in certain proportions of lights of all wave lengths.

4. An ideally perfect monochromatic screen is one that intercepts all other wave lengths save the one it passes. A red screen, therefore, cuts off (really converts into heat) all other rays, save the red ones; blue cuts off all but the blue, and so on. It is difficult to obtain a really monochromatic screen, and impossible to obtain a glass ideally perfect, save perhaps in the case of red glass. It must also be noted that perfection of monochromatism also depends on the strength of the illuminant, that is to say, a screen may be almost perfect with a weak light, but far from perfect with a strong one.

5. The effect of placing two monochromatic screens each ideally

perfect, and of the same intensity over one another would be to cause blackness, such blackness being the more perfect the more intense the screens or the feebler the white light—screens of differing intensity vary in their effect according to such variation, by which is meant an intense red and a feeble green will allow a residuum of red—a strong green and a thin red, a residuum of green, and so on.

6. As ideally perfect monochromatic screens are obtainable with such difficulty, so with ordinary ones another residuum may be left. Red filters often pass a little yellow; blue ones often a little red; green ones occasionally a little blue, and often red; whilst yellow ones are rarely pure at all, permitting red and green rays to pass to some considerable amount. If, now, a blue passing red be placed over a good green, but one passing a modicum of red, and provided the light be intense enough, a dark, deep red residuum is noticed instead of blackness. This is obviously caused by the green and violet causing darkness, but not sufficient to annihilate the reds from each glass. More green or more violet will often effect the production of complete darkness. In practice, owing, of course, to impurities, it is found that some colours are more antithetical than others. Red and green, for example, usually produce greater blackness than red and orange, a fact which we shall presently explain is made use of at times.

Now with these six precepts before us I hope to be able to show how the photographer can increase the contrast in his negative, and so, of course, in the print which is taken from it. Let it be assumed that he has taken an ordinary photograph of a red bacillus on a white ground, with blue-stained nuclei of cells interspersed about. He finds a flat result, a negative that produces a wretchedly poor print lacking all contrast. Now let him place a fairly strong green screen over the illuminant and use a green stained plate to shorten exposure. The resulting negative will show clear patches of glass corresponding to the red bacilli, a fairly clear deposit for the blue nuclei and an intensely black one for the background. If the bacilli are too clear, so much so that any little alteration of structure, such as segregation, seems lost, then let him use a fainter green or employ a brighter light, and the result may be good. If still not satisfactory let him try an orange screen, for as that colour is not so antithetical as green is to red, it will allow a little more light to pass. The resulting print will give of course a black bacillus, a well-defined appearance of the scattered nuclei, while both bodies are seen lying on a clear white background. The whole picture is full of contrast and pluck.

As a matter of fact pure monochromatic screens for photo-micrographing bacteria are not required, good pot glasses are amply sufficient, for be it understood it is only increase of contrast that is required, and not entire annihilation of structural details, or the rendering of minute lines visible, as in the case of diatoms. To be practical, then, in photographing bacteria, glasses of all colours must be procured, and also it is convenient to get several shades and several densities. For what may give rise to sufficient contrast to the eye with the ordinary lamp may not be sufficient, or, on the other hand, which is much more frequent, may be too great, when the photograph is taken. It would have been thought the intense limelight should always demand still greater thickness of colour, but it is usually just the reverse, for the light is reduced considerably, as seen on the ground-glass screen, when compared with that visually viewed at the eye end. The very fact that a virtual image is seen by the eye and an actual image viewed on the plate entails a loss of initial light, as the rays have to again cross. This crossing is obvious, as the image is upside down to the eye, but the right way up on the plate in the camera.

Screens may be used to increase definition when taking photographs of fine lines in diatoms, and the best method is to make these by mixing aniline or other colours with a specially-made collodion, formed by dissolving pure celloidine in equal parts of ether and alcohol. Float the collodion over very thin glass plates—cover-glass type of glass preferable, especially flat ones—allow to dry, and cover with another protective glass, as when covering ordinary lantern slides. Malachite green, methyl green, blue and violet aniline, fuchsine, naphthol yellow, chrysoidine, all of differing quantities and densities, may be made; they may be of service. There is no special difficulty otherwise than to obtain sufficient contrast in taking photo-micrographs of bacteria when they are stained. Hydroquinone produces dense pictures which are always necessary, especially when lantern slides are required, for no background, unless it be of some specific nature, is needed, and the bacteria on clear glass look much better on the screen than when they are shown on a dirty white background.

When taking a photograph of living bacteria, such as the clumping of the typhoid germs in Widal's method of diagnosis, much difficulty may be experienced in getting a photograph at all. It is best then to take advantage of diffraction effects and to close the iris, which would be otherwise considered an undue amount. By this means a faint "standing-out" effect is produced which enables the bacteria to show sufficiently for the purpose, provided the exposure be short enough to prevent choking effects, and yet long enough to give a sufficiently dense background. I have found about ten seconds sufficient with a subdued light and using a 1/6th-inch apochromatic objective. A vertical apparatus must be used. It should be distinctly remembered that when photographing bacteria at any time the iris diaphragm should never be closed, and a full-sized cone of light always employed, otherwise white diffraction lines will appear around the organisms. At times I have thought that a 1.35 substage condenser gave better results, especially when photographing bacteria with flagella.

Photographing Opaque Objects.

The next step is to explain the method of taking a photo-micrograph of an opaque object. It is obvious that transmitted light will be of no service, so the only available source of illumination is by placing the limelight in such a position that it may shine obliquely upon the object. To make the illumination equal, one light should be placed on each side, hence this double form of obliquely illuminating an object has been termed photographing by "double oblique light," a name which it is a mistake to use, as it might lead anyone not well versed in the subject to think it a modification of the "oblique light" which has been already explained, and with which of course it has nothing whatever to do.

As the form of illumination by reflection is of such a feeble nature, so the strongest limelight mixed jet must be utilised, and each should be augmented by the use of a condenser, and the safety of the specimen secured by the addition of a water-bath. The great difficulty in employing double oblique light is to prevent the objective getting in the way of the rays coming from the limes, and so casting a shadow in one or more directions. With the planar or Dallmeyer lenses this is not so apparent, on account of their long focal distance from the specimen, but, when employing a half-inch apochromatic, to avoid such a fault becomes exceedingly difficult, and with some specimens a positive impossibility. With a planar lens of 50 Mm. focus the exposure is usually about three to five minutes at F/22.

Zeiss and other manufacturers, notably the old-established firm of Powell and Lealand, whose instruments are so nearly brought to absolute perfection, make a special form of illuminator which fits onto the objective between it and the nose-piece of the

microscope, and which by reflection throws a light from an illuminant on one side of the microscope down the objective onto the specimen, the rays passing back again onto the lens and so onto the photographic plate. I must confess that I have experienced much difficulty in using the arrangement, just as much as I have also experienced when employing a Lieberkuhn, which is a parabolic reflector placed on the nose of the objective itself. This latter plan, however, answers well with some specimens, but not by any means always. It is designed to reflect back on to the specimen all the rays that pass outside the opaque object (transmitted light being used) and so back again into the objective. This frequent reflection, however, adds considerably to the exposure.

Dark Ground Illumination.

Dark ground illumination is yet another conventional term, by which is meant that although the object is mounted transparently, yet it is supplied in the resulting photograph with a dark ground produced by optical means entirely. There are two methods: one is by placing a piece of black paper as a central stop in the centre of the condenser, and by a suitable movement of it up and down to produce the required effect. The field is black and the object brilliantly illuminated. As to how this is optically formed the reader must refer to books on the microscope, and the photographer may find the information at times useful. The arrangement is often called the spot lens method of dark ground illumination. A "central" diaphragm or stop on an ordinary condenser may also be used. I have had but little experience with the spot lens, always preferring the second method, that of employing what is called a Wenham's paraboloid.

The paraboloid is practically another form of substage condenser which is placed in the substage in the usual manner. It is supplied with a central black disc of metal capable of being moved up or down independently of the condenser, that is to say, nearer to or farther from the specimen without the position of the condenser itself being disturbed. This is of great importance. Considerable experience is required before a complete mastery is obtained in the use of this arrangement, but it is worth the time, as it is an instrument of great optical elegance and produces effects which are of exceeding beauty. The theory of its action will be found in all text-books on the microscope. The photographer will find the darkness of the field is more easily obtained when the Davis diaphragm is slightly closed, and old-fashioned objectives were always supplied with a special stop to be placed over the objective, between it and the eye-piece, for this reason. Too great darkness in the field is not desirable when a lantern slide is to be produced, but in a print one cannot have it too pronounced. Some difficulty may be experienced in obtaining a thoroughly uniform dark field with ordinary lantern plates—it often appears brown and flat, so I prefer to use an Edwards' isochromatic medium-plate, with an exposure at a foot from the gas burner of one second, and developed in the ordinary way. The exposure when using a paraboloid requires to be increased about one-third. Plenty of bromide is a necessity we have mostly found to keep the background as near as possible to clear glass.

The Upright Apparatus.

There are certain specimens, notably such as cultures and living typhoid germs, that necessitate the use of an upright apparatus. Of these there are several forms, which may be seen in any of the opticians' catalogues, but the best is either that designed by Dr. van Heurck or that lately brought out by Zeiss. The former is like a camera on legs, and is placed over the microscope, the gap between the eye-piece of the microscope and the camera front being filled by a velvet bag. The head is placed

inside the camera to focus with primarily, and this being done the door is closed and the image viewed on the ground glass placed on the top of the apparatus. Final focussing is then made, the operator having to stand on a stool to gain sufficient height. The objection I find to this vertical apparatus is that all magnification of a high order must be effected by the use of eye-pieces, or by subsequent enlargement of the negative, to both of which with some specimens there is an objection. Then, again, stooping over the machine to focus is much more fatiguing than when sitting in a chair to perform the same operation, as usual with the horizontal form. I say this, notwithstanding the opinion of Dr. van Heurck, who thinks his own plan is so much more convenient that he has entirely dispensed with the horizontal form, and all his high-power work, which is the admiration of all photo-micrographers, has been done in the manner described.

The second form of apparatus is that adopted by many firms, a camera suitably suspended by one or more pillars being made to slide from above downwards on to the microscope. The intervening gap between microscope and camera is filled by a velvet bag, into which the eye-end of the microscope as well as the tube from the camera front fit, and the camera can be extended several inches. Zeiss has lately brought out a magnificent form of this arrangement which enables the photographer to use the apparatus vertically, horizontally, and at an angle of 45° to the vertical. I can recommend this arrangement with all possible confidence, and think it has a great future before it. It is needless to state, however, that the same objection as above holds good when this apparatus is used vertically, namely, that it is more fatiguing, and that eye-pieces must be employed for extremes of amplification, not in this case, because the camera will not extend, for it does so to an immense length, but because the operator cannot reach the fine adjustment screw to focus if it be drawn up vertically beyond a limited extent to gain magnification.

Another objection to all forms of upright apparatus is that a mirror must be used with the microscope. At times this is very inconvenient, and especially so if the glass of the mirror be thick, when double images of the illuminant may arise which spoil the finest of definition. In conclusion, I am led by experience to the belief that it is far better to employ, whenever possible, one of the horizontal forms of camera—in which camera extension to any amount may be resorted to, provided the "long arm" in the shape of the focussing rod is sufficiently long—but that, when necessity demands, the upright arrangement may be used in its stead without great disadvantage.

STRUCTURE OF STARCH-GRAINS.—According to J. H. Salter the starch-grain is, in all stages of its growth, sharply differentiated from the plastid in which it is formed. Its substance is excreted, and is not formed by gradual transformation of successive layers of protoplasm. Staining experiments show that the stratified appearance of starch-grains is the result of variations in density, that is, in the capacity of different layers for absorbing water. All growing starch-grains appear to have a denser margin, which is not stratified. The lamellæ attain their final differentiation only when they are covered by others formed later. A progressive, but not a uniform, decrease in density may be detected, advancing from the margin to the nucleus of the grain. Observation of starch-grains in the process of solution renders it probable that changes may in some cases take place in the surface of the grain from the action of a ferment. As regards the inner structure of starch-grains, all the phenomena lead to the conclusion that each lamella, or at least each watery lamella, consists of a series of elements deposited radially.—*Pringsheim's Jahrbücher*, vol. xxxii.

BRITISH PHARMACOPŒIA, 1898.

THE PROPOSED INDIAN AND COLONIAL ADDENDUM.

The following is the list, with descriptions—concluded from page 675—of drugs already proposed by Indian and Colonial Authorities for official recognition in the British Pharmacopœia, and suggestions for pharmaceutical preparations. Further suggestions are invited by the Pharmacopœia Committee of the General Medical Council from any British Dependency where the drugs of the British Pharmacopœia of 1898 are insufficient for local requirements, and comments are invited from readers of the Journal in India and the Colonies.

GUMMI INDICUM.

Indian Gum.

A gummy exudation from *Anogeissus latifolia*, *Wall.* []

CHARACTERS AND TESTS.—In vermiform or rounded tears of varying size, pale amber or yellowish white in colour, translucent, with a rather dull surface and breaking with a bright glassy fracture. It has a faint odour; taste insipid and mucilaginous. Entirely soluble in water, forming a viscid, adhesive mucilage. Insoluble in alcohol (90 per cent.). The aqueous solution is gelatinised by the addition of alcohol (90 per cent.), solution of borax, or solution of lead subacetate; but it is unaffected by the addition of test solution of ferric chloride (distinction from Amrad and other gums (or of solution of lead acetate. It is not coloured blue or brown by a small quantity of solution of iodine (absence of starch or commercial dextrin). On incineration it should not yield more than 4 per cent. of ash.

PREPARATION.

MUCILAGO GUMMI INDICI.

Mucilage of Indian Gum.

(Formula as that of Mucilago Acaciæ, British Pharmacopœia, 1898, using twice the quantity of water.) Half the quantity of Indian Gum may be used in other preparations, in India, instead of Acaciæ Gummi.

ISPAGHULA.

Ispaghula.

The seeds of *Plantago ovata*, *Forsk.* (*Plantago Ispaghula*, *Roxb.*) [Bentl. and Trim. 'Med. Pl.,' plate 211].

CHARACTERS.—The seeds are boat shaped and rather acute at one end, from one-tenth to one-eighth of an inch (two to three millimetres) long; from one-twenty fifth to one-sixteenth of an inch (one to one and a half millimetres) wide. They are pale pinkish grey in colour, with a darker elongated spot on the convex side; the concave side contains the hilum covered with the remains of a thin white membrane. When placed in water the testa swells and produces a viscous mucilage. They possess neither odour nor taste.

[The Indian Government Committee recommended official recognition of the seeds of *Plantago ovata* for use, in India, in making demulcent drinks equivalent to the (now unofficial) *Infusum Lini* and *Decoctum Hordei*.]

JASMINUM.

Jasmine.

Synonym.—Mogra.

The flowers of *Jasminum Sambac*, *Ait.* [

[Proposed by the Indian Government Committee for use in India. A description of the flowers should be supplied from India. It appears to be well recognised in India as a lactifuge.]

KINO EUCALYPTI.

Eucalyptus Kino.

The varieties of Eucalyptus Gum which have the characters and respond to the tests of Kino may be used in the Australasian parts of the Empire.

MUDAR.

Mudar.

The root bark of *Calotropis procera*, *R. Brown* (*Calotropis Hamiltonii*, *Wight*) [Bentl. and Trim., 'Med. Pl.,' plate 176], and of *Calotropis gigantea*, *R. Brown* (*Asclepias gigantea*, *Willd.*) [Wight, 'Illustr.,' plate 155].

CHARACTERS AND TEST.—In more or less quilled pieces having a thickness of from one-tenth to one-fifth of an inch (two to five

millimetres), and attaining a width of one and a half inches (thirty-seven millimetres). It is covered with a soft, greyish buff, strongly furrowed and reticulated periderm, having a thickness of from one-twentyfifth to one-twelfth of an inch (one to two millimetres); the periderm is easily separable from the underlying yellowish-white tissues. The inner liber portion exhibits, on transverse section, narrow pale brown indistinct phloem rays. The inner surface of the bark is rather granular and of a pale brown colour. It has a short farinaceous fracture, a slightly disagreeable odour, and a mucilaginous bitter acrid taste. A cooled decoction gives the characteristic reaction for starch with *solution of iodine*.

[Recommended by the Indian Government Committee as remedy, in India, in place of *Ipecacuanha*. Is the name "Mudar" satisfactory? What preparations are desired?]

MYLABRIS.

Mylabris.

The dried beetle *Mylabris phalerata*, Pallas [Brandt and Ratz., 'Med. Zool.,' vol. ii., tab. xviii., fig. 18].

CHARACTERS.—About an inch or rather more (twenty-five millimetres) long and three-eighths of an inch (nine millimetres) broad; with two long elytra, each three times as long as broad, black with two broad wavy transverse orange-coloured bands and a large orange-coloured spot at the base of each; one pair of brown membranous wings. Odour rather disagreeable.

[The Indian Government Committee recommend the *Mylabris Cichorii* for recognition. Commercial specimens of *Mylabris* contain both *M. Cichorii* and *M. phalerata*; the latter being the larger is selected for recognition. It is not well to have two species recognised if one is sufficient. A preparation of *Mylabris* should not be called by the name of *Cantharides*.]

PREPARATIONS.

Unguentum Mylabridis. (Formula as Unguentum Cantharidis, 1898.)

Emplastrum Mylabridis. (Formula as Emplastrum Cantharidis, 1898.)

Tinctura Mylabridis. (Formula as Tinctura Cantharidis, 1898.)

Acetum Mylabridis. (Formula as Acetum Cantharidis, 1898.)

This beetle might also replace *Cantharides* in the preparation of *Liquor Epispasticus* and *Emplastrum Calefaciens*, in India.

MYROBALANUM.

Myrobalans.

The immature fruits of *Terminalia Chebula*, Retz. [Roxb., 'Coroman. Pl.,' plate 197].

CHARACTERS.—Ovoid or fusiform fruits from one-third to three-quarters of an inch (eight to eighteen millimetres) long and attaining a width of three-eighths of an inch (nine millimetres); strongly shrivelled longitudinally, black, solid, brittle, having a somewhat shining fracture, which is a little paler than the exterior of the fruit. No odour; taste very astringent.

[The Indian Government Committee recommend *Myrobalans* for use in India instead of *Galls*.]

PREPARATIONS.

Unguentum Myrobalani. (Formula as Unguentum Gallæ, 1898.)

Unguentum Myrobalani cum Opio. (Formula as Unguentum Gallæ cum Opio, 1898.)

OLEUM AJOWAN.

Ajowan Oil.

The oil distilled from the fruit of *Carum Copticum*, Benth. and Hook. [Bentl. and Trim., 'Med. Pl.,' plate 120].

CHARACTERS.—Colourless, with an odour and taste resembling thyme. Specific gravity 0.917 to 0.930. It turns a ray of polarised light to the right from 1.0° to 1.5°. If a portion of the oil be cooled to 32° F. (0° C.) it should yield from 30 to 36 per cent. of crystalline thymol.

[Recommended by the Indian Government Committee for use in India instead of *Olea Carui*, *Anethi*, *Anisi*, and *Mentha Piperita*. It should be noted that the constituents of *Oleum Ajowan* (Thymol and Cymol) are quite unlike the constituents of *Oleum Carui* (Carvone and Limonene). It is very desirable that specimens of Indian drawn oil should be forwarded from India for comparison, as the authentic specimens of the Indian oil in this country are old and useless for the purpose.]

OLEUM ARACHIDIS.

Earth-nut Oil.

The oil expressed from the seeds of *Arachis hypogæa*, Linn. [Bentl. and Trim., 'Med. Pl.,' plate 75].

CHARACTERS AND TESTS.—Pale yellow or greenish yellow in colour, with a faint nutlike odour and a bland nutty taste. Specific gravity 0.916 to 0.918. It becomes turbid at 37.4° F. (3° C.) and solidifies at 23° F. (5° C.).

Arachis oil may be employed in Indian Pharmacy whenever olive oil is ordered in official preparations.

[Information is wanted as to whether the substitution of Earth-nut Oil for Olive Oil has been found, in India, to require any modification in the quantity of oil employed in order to produce preparations practically identical with those made with Olive Oil.]

OLEUM GRAMINIS CITRATI.

Oil of Lemon Grass.

Synonym.—Indian Oil of Verbena.

The oil distilled from *Andropogon citratus*, DC. [Wallich, 'Plant. Asiat. Rar.,' plate 280].

CHARACTERS.—A dark yellow oil having an odour resembling that of verbena. Specific gravity 0.895 to 0.905. It should not rotate the plane of polarised light more than 3° in either direction. Soluble in alcohol (70 per cent.). If 10 cubic centimetres be well shaken with 50 cubic centimetres of a boiling 30 per cent. solution of sodium hydrogen sulphite, an oily layer separates, which, when cooled to 60° F. (15.5° C.), should not measure more than 3.5 cubic centimetres (absence of more than 35 per cent. of constituents other than aldehydes).

[The Indian Government Committee recommend the use of this oil in India instead of Oil of Cajuput in *Linimentum Crotonis* and instead of Oil of Lavender in *Linimentum Camphoræ Compositum*. It seems doubtful if such substitution should be officially recognised, since the oil of verbena differs notably from the oils for which it is proposed to substitute it. The oil might, however, be recognised for its own sake.]

OLEUM SESAMI.

Sesame Oil.

The oil expressed from the seeds of *Sesamum indicum*, DC. [Bentl. and Trim., 'Med. Pl.,' plate 198].

CHARACTERS AND TESTS.—A limpid oil of a pale yellow colour, with a faint odour and a bland taste. Specific gravity 0.921 to 0.924. It congeals at a temperature of 23° F. (−5° C.). If 10 cubic centimetres be treated with 10 cubic centimetres of hydrochloric acid containing 0.6 grammes of pyrogallol and the mixture be shaken vigorously and then set aside for one minute, two layers will be formed. The upper oily layer is to be carefully removed by means of a pipette; the lower acid layer is to be boiled for five minutes, when it will gradually assume a colour purple by transmitted light and blue by reflected light.

[The Indian Government Committee recommend this oil as a substitute for Olive Oil in *Linimenta Ammoniac* and *Calcis*, and in *Unguenta Cantharidis*, *Hydrargyri Compositum*, and *Hydrargyri Nitratis*. It does not appear to be as useful as *Oleum Arachidis* for the preparation of the *Emplastra*. For *Linimentum Ammoniac* it seems to be well suited.]

SAMADERA.

Samadera.

The wood and bark of *Samadera indica*, Gärtn. [Wight, 'Icones,' plate 68.]

CHARACTERS.—The wood is of a pale yellow colour, tough and dense. On transverse section it shows, when viewed with a lens, numerous very faint narrow concentric rings traversed by faint narrow medullary rays. It is inodorous, but has an intensely bitter taste. The bark is in quills attaining an inch (twenty-five millimetres) in width and a twelfth of an inch (two millimetres) in thickness. It is of a dull brown colour marked with numerous patches of silvery grey lichen; the periderm is minutely reticulated. Internally it varies in colour from pale yellow to reddish brown. On section it exhibits the dark brown periderm surrounding the yellow cortical tissues which sometimes become slightly darker in the inner portions. It is inodorous, and has an intensely bitter taste.

[Recommended for official recognition by the Indian Government Committee to take the place of *Quassia*, in India. Is it desirable that preparations should be made indifferently from the wood and the bark? It should be noted that the preparation of the one will be of a different colour from that of the other. Reports on these preparations are desired.]

SAPPAN.**Sappan.**

The heartwood of *Cæsalpinia Sappan*, *Linn.* [Roxburgh, 'Coroman. Pl.,' i., 17, plate 16].

CHARACTERS AND TEST.—In hard, heavy sections of variable size, or in the form of chips, of a fine orange-red colour. A transverse section exhibits well-marked concentric rings, numerous narrow medullary rays, and large vessels which are readily seen with a pocket-lens. It is cut with difficulty transversely, but is easily split longitudinally, showing distinctly the grain due to the medullary rays. The wood has no odour, and only a slightly astringent taste. It communicates a red colour to alcohol (90 per cent.) and water, which becomes a carmine red, and not purple, upon the addition of solution of potassium hydroxide.

[Recommended by the Indian Government Committee for use in India instead of *Logwood*.]

PREPARATION.

Decoctum Sappan. (Formula as Decoctum *Hæmatoxyli*, 1898.)

WERTIA.**Swertia.**

The dried plants of *Swertia affinis*, *Clarke* [Wight, 'Icones,' plate 1331], and *Swertia corymbosa*, *Wight* [Wight, 'Icones,' plate 1329].

CHARACTERS.—*Swertia affinis* has a quadrangular stem; leaves lanceolate-acuminate three-veined, the upper narrower, one and three-quarter inches long (four and a half centimetres) and one-third of an inch (eight millimetres) broad. The corolla is white with bluish veins; petals a quarter of an inch (six millimetres) long and an eighth of an inch (three millimetres) broad; cymes forming an elongated panicle. Taste very bitter. *Swertia corymbosa* has a quadrangular stem; leaves oblanceolate, obtuse, slightly mucronate, the lower three-quarters of an inch (eighteen millimetres) long and one-third of an inch (eight millimetres) wide. The corolla is white with bluish veins; petals half an inch (twelve millimetres) long and one-third of an inch (eight millimetres) wide. The cymes form a level-topped corymb. Taste very bitter.

[Recommended by the Indian Government Committee for use in India as the equivalent of *Chiritta*. Should the preparations be similar to those of *Andrographis*?]

THUS INDICUM.**Indian Frankincense.**

The semi-solid oleo-resin of *Pinus longifolia*, *Roeb.* [Royle's 'Illustr.,' plate 85].

CHARACTERS.—A dirty white opaque semi-solid substance which separates upon standing into a larger dense opaque layer and an upper opalescent essential oil. It has a strong aromatic terebinthinate odour, in some degree recalling that of fennel.

[Suggested by the Indian Government Committee for use in India instead of the official (American) *Frankincense*. An Indian *Frankincense* appears to be softer than the official *Frankincense*, the formula for *Emplastrum Pieis* would probably need readjustment.]

TINOSPORA.**Tinospora.**

The stem of *Tinospora cordifolia*, *Miers* (*Cocculus cordifolius* DC.) [Bentl. and Trim., 'Med. Pl.,' plate 12].

CHARACTERS AND TEST.—In cylindrical straight or twisted pieces or in transverse sections, having a diameter of from a quarter of an inch to two inches (six to fifty millimetres), covered with a strongly shrunken bark with deep longitudinal furrows and bearing numerous round elevated scars. The bark is somewhat smooth and wax-like and is of a greenish-brown or brown colour; it is easily separable from the very porous woody cylinder, which is of a pale yellowish-grey colour. The transverse section exhibits one

loose ring of xylem bundles containing large vessels; the bundles are separated by distinct starchy medullary rays. Fracture is tough and fibrous. There is no marked odour; taste bitter. The cooled decoction gives the characteristic reaction for starch with solution of iodine.

PREPARATIONS.

Infusum *Tinosporæ*. (Formula as Infusum *Calumbæ*, 1898.)

Liquor *Tinosporæ* Concentratus. (Formula as Liquor *Calumbæ* Concentratus, 1898.)

Tinctura *Tinosporæ*. (Formula as Tinctura *Calumbæ*, 1898.)

[Recommended by the Indian Government Committee for use in India instead of *Calumba*.]

TODDALIA.**Toddalia.**

The root bark of *Toddalia aculeata*, *Pers.* [Bentl. and Trim., 'Med. Pl.,' plate 49].

CHARACTERS AND TEST.—In quilled pieces having a thickness of from one-twelfth to one-ninth of an inch (two to three millimetres), covered with a soft yellowish periderm fissured longitudinally and exhibiting a subjacent bright yellow layer and a deeper brown layer. The transverse section shows an outer yellowish periderm, a narrow bright yellow intermediate layer, and an inner broad radiate layer of brown phloem in which are situated numerous oleo-resin receptacles. The inner surface of the bark is somewhat granular and brown in colour. It has a short, close fracture, a faint aromatic odour, and an aromatic pungent bitter taste. The cooled decoction does not give the characteristic reaction for starch with solution of iodine.

PREPARATIONS.

Infusum *Toddaliæ*. (Formula as Infusum *Cuspariæ*, 1898.)

Liquor *Toddaliæ* Concentratus. (Formula as Liquor *Cuspariæ* Concentratus, 1898.)

[Recommended by the Indian Government Committee for use in India instead of *Cortex Cuspariæ*.]

TYLOPHORÆ FOLIA.**Tylophora Leaves.**

The leaves of *Tylophora asthmatica*, *Wight et Arnott* [Bentl. and Trim. 'Med. Pl.,' plate 177].

CHARACTERS.—Petiolate, entire, from two to five inches (five to twelve and a half centimetres) long and from three-quarters of an inch to two and a half inches (eighteen to sixty-five millimetres) broad, lanceolate-ovate, ovate or sub-rotund in outline, somewhat cordate at the base, abruptly acuminate; rather leathery in texture, glabrous on the upper surface and finely downy on the lower one; brownish-green colour, which is paler on the lower surface. Odour slightly aromatic; almost devoid of taste.

[Recommended by the Indian Government Committee for use in India instead of *Ipecacuanha*. As the leaves appear to be more certain in their action than the root, and are more easily obtainable, there seems no reason for making the root official also. What preparations are desired?]

VALERIANÆ RHIZOMA INDICUM.**Indian Valerian.**

[The Indian Government Committee recommend that the rhizome and rootlets of *Valeriana Leschenaultii*, DC., var. *Brunoviana*, *Wight and Arn.*, should be made official in India. Specimens of this are not in the museums in Great Britain. A description, therefore, should be furnished. Is an ammoniated tincture, or other preparation, desired?]

MAMMARY GLAND FOR UTERINE FIBROIDS.—J. B. Shober confirms the facts recorded by Bell, indicating the value of extract of mammary gland in the treatment of fibroid tumours of the uterus. Since 1897 he has employed the remedy in four cases, in the form of extract or of dry powder, and in all marked benefit has been shown. Without the aid of any other form of treatment, the tumours are decreasing in size and the general health improving. Even if after prolonged treatment the tumours do not entirely disappear, the necessity for surgical intervention has, at least, been delayed.—*Med. Chron.*, x., 53.

THE STUDENTS' PAGE.

EXPLANATORY NOTES ON THE B.P. 1898.

Jalapæ Resina.—This is composed of two resins in the proportion of about 1:10. The one constituting the main portion is insoluble in ether, which is somewhat exceptional for bodies of this class. The ether-soluble portion is identical with the resin obtained from Tampico jalap, and very closely allied, if not identical, with scammony resin.

Linimenta.—Only one liniment has been omitted from the list official in the 1885 Pharmacopœia, viz., Linimentum Iodi. A preparation of almost the same composition has been introduced under the name of Liquor Iodi Fortis. The other changes in this group may be summarised as follows:—

Linimentum Ammonia.—Olive oil has been partly replaced by almond oil, the resulting creamy emulsion, formed by the addition of ammonia, being less apt to solidify than when it is made with olive oil alone.

Linimentum Belladonna.—Now made by diluting the standardised liquid extract to twice its volume with a mixture of water and 90 per cent. alcohol. It will contain, therefore, 0.375 part of belladonna alkaloids in 100 fluid parts.

Linimentum Camphoræ Ammoniatum.—This is the name for the preparation known formerly as Linimentum Camphoræ Compositum. The proportions of camphor, oil of lavender, and strong solution of ammonia remain unaltered, but the official formula is now made to measure exactly 20 fluid ounces instead of a little over a pint.

Linimentum Terebinthinæ.—The proportion of soft soap has been reduced and the water increased, both changes tending to make the preparation thinner. It is now a thick creamy fluid instead of a gelatinous solid as heretofore.

Liquores.—This important group of preparations has undergone numerous alterations. The changes comprise the omission of seventeen liquors official in the 1885 Pharmacopœia, the addition of formulæ for nineteen new liquors, and alteration in name, strength, details of manufacture, or some other point of minor importance for the greater number of the remaining members of the group, which now contains fifty-three preparations.

Omissions.

Liquor Calcii Chloridi.
 „ Chlori.
 „ Sodæ.
 „ Iodi.

These four liquors have been relegated to, or replaced by solutions in Appendix II. They are used chiefly for testing, and are hardly ever required for direct use in medicine.

Liquor Ferri Dialysatus.
 „ Magnesii Citratis.
 „ Morphina Bimeconatis.
 „ Morphina Sulphatis.

These liquors are found to be seldom used, and have been omitted for this reason.

Liquor Gutta Percha.
 „ Cocainæ Hydrochloratis.

The first of these has been replaced by a solution of india-rubber, and the second has been transferred to another part of the Pharmacopœia under the name of Injectio Cocainæ Hypodermica.

Liquor Ammonii Acetatis Fortior.
 „ „ Citratis „
 „ Ferri Acetatis Fortior.

The weaker liquors of these substances, in which form they are always prescribed, are now directed to be made from the necessary materials instead of by the dilution of a stronger liquor. Formulæ for these latter are, therefore, no longer required.

Liquor Lithiæ Effervescens.
 „ Potassæ „
 „ Sodæ „

Lithia, potash, and soda water are used chiefly as beverages, and the formulæ under the above names in the 1885 Pharmacopœia were too strong to be agreeable to most persons.

Liquor Antimonii Chloridi.

This was only included for the purpose of making antimony oxide. Since the present Pharmacopœia only describes the origin of the oxide in general terms there is no need for the inclusion of a definite solution of the chloride.

Additions.

Of the nineteen new "liquors," ten are prepared from vegetable drugs, and are intended to provide uniform preparations to replace the so-called concentrated infusions and decoctions found in trade. In the absence of official formulæ, these have hitherto been prepared by each manufacturer according to his own formulæ, and the resulting preparations obtained from different sources have been found to be very variable in physical characters and potency. As a remedy for this undesirable state of affairs, and in deference to the demand which undoubtedly exists for preparations of this nature, the official formulæ have been introduced. The name "concentrated liquor," as applied to them, is open to criticism, since the official liquors have hitherto included (with the exception of Liquor Epispasticus) only solutions of definite chemical substances, and not complex and variable fluids obtained by the selective solvent action of menstrua upon crude vegetable drugs. Unofficially, however, the extension of the term to include such vegetable preparations has been recognised, and it is difficult to see into which other of the existing official classes of galenic preparations they could have been introduced. The term concentrated infusion is not applicable, because preparations obtained by actually concentrating the official infusions are lacking in the aroma and other distinctive physical characters associated with preparations of this class. For this reason quite different processes have been adopted for the new concentrated liquors—in most cases slow percolation with dilute alcohol. Another course open to the compilers of the Pharmacopœia would have been to coin a new title for them, but apparently this has not been deemed desirable.

Liquor Chirata Concentratus	} These are prepared by slowly percolating the powdered drug with 20 per cent. alcohol until two fluid parts of percolate have been collected from one part by weight of drug.
„ Cusparia „	
„ Krameria „	
„ Rhei „	
„ Serpentaria „	

Liquor Senegæ Concentratus	... } Prepared in the same manner as the foregoing, but with slightly stronger alcohol (about 28 per cent.)
----------------------------	---

Liquor Quassia Concentratus	... } Prepared like the first group, with 20 per cent. alcohol, but ten parts of percolate are collected from one part of drug.
-----------------------------	---

Liquor Sennæ Concentratus } Prepared with water in place of dilute alcohol, senna (1 in 1) by repercolation, and calumbæ (1 in 2) by two successive macerations, followed by expression. The finished fluids are preserved by the addition of alcohol to calumba, and alcohol and tincture of ginger to senna.
„ Calumbæ „ }

Liquor Sarsæ Compositus Concentratus } This contains the same constituents as the old compound decoction. The sarsaparilla is infused and the other constituents boiled with water. The infusion and decoction are concentrated by evaporation, mixed, and preserved by addition of alcohol.
--------------------------------------	---

The drugs are used in No. 40 powder, with the exception of calumba, rhubarb, and senna in No. 5 powder, and the constituents of the sarsaparilla. In all cases except the last-mentioned cold processes are employed, hence it is desirable to facilitate the exhaustion by using a fine powder. The three drugs mentioned as being used in No. 5 powder form, however, when used in finer powder, thick mucilaginous fluids with water or weak alcoholic menstrua, which are percolated and filtered with extreme difficulty. The practicability of several of these formulæ is questionable, but it is rather early to offer a definite opinion. It is somewhat curious that no concentrated liquor representing the most frequently used "concentrated infusion," viz., compound infusion of gentian, should have been provided for,

PHARMACEUTICAL JOURNAL.

THE "WIDOW'S CLAUSE."

THAT legislative regulations relating to the practice of pharmacy should comprise provision for the continuance of a business after the death of the proprietor, appears to be such a natural necessity as to require little argument in its favour. Even in the case of there being no successor to the business, having the necessary qualification for carrying it on, an abrupt termination does not appear to be requisite in the public interest, or indeed on any other account. As regards the relatives of a deceased chemist and druggist, on the other hand, it may be a matter of considerable importance that opportunity should be afforded for continuing the business, at least for a time that would allow for the qualification of a son or other intended successor, or admit of the business being disposed of without incurring the disadvantage of a forced sale. It was probably from that point of view the provision was made in the 16th Section of the Pharmacy Act, 1868, that upon the decease of a chemist and druggist, actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such chemist and druggist to continue such business if and so long as such business shall be *bonâ fide* conducted by a duly qualified assistant. This provision is consistent with the general principle of the Act that persons selling poisons or keeping open shop for retailing, dispensing, or compounding poison under the designation of chemists and druggists or any equivalent title, should possess a legal qualification affording evidence that they have a competent practical knowledge of their business. That is really the case, whether it be held that the legal qualification established as necessary in the public interest is to be understood as a qualification requisite for the proprietor of a business, or for the person who actually keeps the shop, in the sense of being there and attending to the business, though not the real proprietor. That is also shown by the subsequent provision that the duly qualified assistant referred to in the 16th Section of the Act as being competent, in the position of assistant or manager, to continue the business of a deceased chemist and druggist shall be a person possessing the same legal qualification that would be required for keeping open shop on his own account. So far as concerns the object of the Act—the safety of the public—and the condition deemed to be expedient on that account, viz., competent practical knowledge of the business, every requirement would thus be satisfied by the duly qualified assistant acting as manager, as much as if he were carrying on business as a chemist and druggist on his own account.

Reasonable as the provision above mentioned may appear in principle, and unobjectionable as its application in the interest of a widow might be under appropriate conditions, it has certainly been much abused in practice. It has also had the mischievous effect of being regarded as evidence that legal qualification of the proprietor or proprietors of a chemist and druggist's business was not intended by the framers of the Pharmacy Act, 1868, to be indispensably necessary, provided that there was in the business a person duly qualified within the meaning of the Act, acting as manager or assistant. In the case of the London and Provincial Supply Association that view contributed to influence the House of Lords in its decision that the meaning and application of the word

"person" in the Act should not be extended so as to include a corporation. But it must be remembered that the so-called "widow's clause" was not alone the means of bringing about that result. The consideration that the actual seller, whether master or servant, would, in either case, be liable for infringement of the Act, had by far the greatest influence in leading to the conclusion that the object of the Act did not require the larger construction which would exclude a company of unqualified persons. Hence the assumption that, for the public purpose of the Act, qualification of the person actually selling—whether he be the ultimate vendor or not—is of more importance than qualification of the proprietor of a business. As to the meaning of the word "person" counsel for the appellants argued that since a corporation could not be examined, therefore it could not lawfully perform the acts prohibited to any but duly qualified persons; while the other side argued that, for the same reason, a corporation was free to do what individual persons were prohibited from doing. But this latter argument was not accepted by the judges any more than the opposite argument. On the contrary, Lord WATSON was inclined to think considerations of policy rather preponderated in favour of the appellant's argument. Lord BLACKBURN distinctly held that a corporation is not entirely out of the Act, and Lord SELBORNE expressed himself still more decidedly of that opinion by stating in his judgment that he thought "the argument against a company being permitted to carry on the business of a chemist and druggist would have been extremely strong" if there were not—besides the qualification of the proprietor of such a business—"other safeguards against the sale of poisonous drugs in a manner contrary to the provisions of the Act." Having regard to the mischief which the Act was intended to prevent, the liability of the person who conducts a sale was thought to be such a safeguard as would suffice, in the interest of the public, without extending the application of the word "person" beyond its natural meaning.

The decision of the House of Lords in the case of the London and Provincial Association—going no further than the "act of selling"—may be attributed partly to the provision of the Pharmacy Act, 1868, making the minor qualification required for an assistant under the Act of 1852, the qualification entitling a person to sell poison, also partly to the provision for continuing the business of a deceased chemist and druggist. But even in so far as the latter provision may be taken as affording evidence that the Act—either in wording or intention—admits of the keeping open shop by persons who are not qualified, there are still good reasons for maintaining that there is a very great difference between continuing the business of a deceased chemist and druggist, under the management of a duly qualified assistant, and a drug department attached to a general store carried on by a limited liability company. In the one case the arrangements for carrying on the practice of pharmacy being the chief object to consider, they would have been provided for accordingly by the principal, so that the continuation of the business after his death would be a mere matter of routine work. In the case of the store drug department, on the contrary, pharmaceutical work would be of minor importance as compared with general trade operations, and in the absence of a principal skilled in pharmacy it might be expected that even with legally qualified assistants the pharmaceutical business would not command such care and attention as in a shop directed by a qualified proprietor.

ANNOTATIONS.

THE YEAR JUST EXPIRING will be remarkable in the annals of pharmacy as one in which the value of organisation was more clearly recognised by registered chemists than at any former period in their history. The stress of circumstances has caused local associations to spring into existence on every hand, and it is hard to say whether the newer or older associations have been most active in promoting the cause of pharmaceutical reform. The success of the Pharmacy Acts Amendment Bill and the defeat of the Poisonous Substances Bill served to show that chemists are capable of making their influence felt in Parliament and, better still, those two important events emphasised the necessity of a permanent union of the craft rather than a merely temporary combination to meet some pressing danger. The opportunity for such a permanent union, upon the best possible terms, is now afforded by the Pharmacy Act of 1898, and it seems extremely probable that the fulfilment of the dreams of the founders of the Pharmaceutical Society and the accomplishment of the reasonable desires of the chemist and druggist of to-day may be secured almost at one and the same time. Strenuous efforts to perpetuate the existing disunion amongst registered chemists have been made, and continue to be made, by parties who appear always to have acted as though their private interests would best be served by the continuance of the unfortunate conditions that have prevailed so long, but there are signs that chemists throughout Great Britain are awaking to the fact that their future is in their own hands and not dependent upon the vagaries of those who would sacrifice the future of the craft to their own selfish ends. That such may prove to be the case every true friend of pharmacy must cordially wish.

THE ADOPTION OF POISON REGULATIONS is arousing but languid interest, probably because of the fact that matters of the most serious importance fail to receive the attention they deserve at holiday times and particularly at the great festival of the year. Nevertheless, a few communications on the subject have come to hand and are printed in the present issue of the Journal. Mr. Richard Reynolds, who was one of the most influential opponents of the proposed regulations in 1871, returns to the charge again, and states many reasons why the matter should not be decided without the most careful consideration. Briefly, his view appears to be that there is no pressing necessity for the hasty adoption of regulations at the present moment, and that it would be wiser to have the matter dealt with in a new Act of Parliament. In other words, he contends that no imposition of penal regulations, such as are suggested, will be satisfactory to the persons most concerned, unless those regulations form part of a general revision of legislation for pharmacy. Mr. Morrison and Mr. Taplin also suggest food for thought in this connection, and the views put forward by an anonymous correspondent are perhaps none the less weighty because they appear to be written in a spirit of sarcasm. We must reiterate that the subject is one of the gravest importance, not to be dealt with lightly or from the view of personal convenience only, but with a due sense of responsibility and proper regard for the position the registered chemist occupies in relation to the State.

THE BRITISH PHARMACEUTICAL CONFERENCE, as briefly announced in last week's Journal, will have its headquarters at Plymouth during the week commencing Monday, July 24, next year, and already newspapers in the West of England are beginning to devote space to anticipations of the meeting. A

Bristol paper, which begins by falling into the old error of assuming identity between the Pharmaceutical Society and the Conference, prints the not very relevant remark that "there will no doubt be a very pleasant gathering, but whether there will be any permanent benefit to pharmacists is very doubtful." It must not, of course, be inferred from this that Bristol newspaper men think pharmacists hold conferences for the good of their health. A vague clue to what the writer means to convey may be gleaned from his subsequent statement, that for some years now chemists have passed the good old days (if they ever existed) when they could sell a bottle of medicine for half-a-crown, though the medicine did not cost them quite so much as did the bottle containing it. The Limited Liability Acts, it is quite correctly remarked, have brought "company pharmacy," and that has brought about a revolution in the trade. But it will be news to our readers to learn that the Council of the Pharmaceutical Society has been struggling to get an amendment of the law in the hope that it will help chemists against companies, though many wish that the Council would do so.

A WILFUL MISREPRESENTATION of facts appears in the *Sporting Express*, a Liverpool paper, of the 17th inst., where it is alleged that the Pharmaceutical Society discriminates unfairly between registered and unregistered persons in its administration of the Pharmacy Act of 1868. The writer of the notes referred to asserts that, whereas a well-known local photographic dealer was heavily fined some time ago for illegally selling a scheduled poison, a case has recently come under his notice of a chemist having three shops, one of which is being conducted by an unqualified assistant, while another is often left in charge of an apprentice. Both the unqualified assistant and the apprentice are said to sell poisons, and it is urged that it is an anomaly that the Pharmaceutical Society does not prosecute the proprietor. In reply we can only say that it is the duty of any person who knows the law is being broken in the manner suggested to report the facts to the Registrar of the Society. If the facts be confirmed on inquiry the informant may depend upon proceedings being taken against the offenders in due course, whether the proprietor of the shop be a registered chemist or not. The suggestion in the Liverpool paper, that the Pharmaceutical Society does not take action when offences against the Pharmacy Act are committed on the premises of registered chemists, because it is supported by the voluntary contributions of those chemists and the college and examination fees of their assistants is, of course, as baseless as it is malicious.

POISONING CASES reported of late have varied greatly in their details, though carelessness continues to be the chief characteristic of most accidental cases, and suicides show, as they have ever done, how difficult it is to prevent a man bent on terminating his existence from accomplishing his purpose. At Lancaster a child has found death before its time as the result of neglect to shake the bottle containing its medicine. The mixture contained bromoform suspended by the aid of mucilage, but as the bottle was not regularly shaken, most of the bromoform was administered in the last dose, with a fatal result. At Camberwell, liquid ammonia contained in a bottle labelled "Children's Cough Syrup," has been administered to an infant under the impression that it was aniseed water. Death from suffocation was the result. At Blackheath, a chemist's assistant has died from the effects of an overdose of prussic acid, with which he had been treating himself, and at Walworth a tailor's cutter has found a dose of three ounces or more of chlorodyne incompatible with continued existence on this mundane sphere. This last-mentioned case was also attributed

by a coroner's jury to misadventure. The coroner, by the way, commented on the fact that the label on the bottle stated that the chlorodyne was "perfectly safe but poison." A fatality at Flushing, resulting from an overdose of cocaine, taken to relieve pain, presents no remarkable features; neither do cases of poisoning by overdoses of laudanum at Bury and Canning Town. Suicides by carbolic and sulphuric acids are also reported, and the moral to be drawn from the week's record is the old and well-established one, that the restriction of the sale of all poisonous substances to properly trained and duly registered persons is the best safeguard the State can adopt.

THE PREVENTION OF TUBERCULOSIS is now known to be well within the bounds of possibility, and as mentioned in the Journal a few weeks ago (see p. 495) an influential association has been formed to deal with the subject in this country as effectually as it has been dealt with abroad. The existence of that Association may fairly be attributed to the efforts made by the editor of the *Practitioner* to bring public opinion to bear on the question, and he is to be congratulated on the speedy success that has crowned his efforts, for the Association includes the leading medical practitioners of the day as members, and its operations are supported by the Prince of Wales and other prominent persons. At a meeting held at Marlborough House last week, in furtherance of the objects of the recently-formed Association, the Prince presided, and Sir William Broadbent explained the nature and means of prevention of tuberculous disease. The objects of the Association, as defined by him, are to educate the public as to the means of preventing the spread of consumption from those already suffering from the disease; to extinguish tuberculosis in cattle; and to promote the erection of sanatoria for the open-air treatment of tuberculous disease. Subsequently, on the motion of Lord Salisbury, the meeting expressed its approval of the effort which is being made to check the spread of diseases due to tubercle, and to promote the recovery of those suffering from consumption and tuberculous disease generally. It also commended the method adopted by the Association of instructing public opinion and stimulating public interest rather than the advocacy of measures of compulsion. An interesting announcement was made at the meeting, to the effect that the London partners of Messrs. Werner and Beit have undertaken to erect and equip a sanatorium for tuberculous patients at an estimated expense of twenty thousand pounds. The construction and management of the sanatorium will be under the guidance of the Association, branches of which are being formed at York, Norwich, Ipswich, Huddersfield, and other towns.

IN GERMANY, a central committee was constituted three years ago with the object of promoting the establishment of a sufficient number of sanatoria for consumptives throughout the German Empire. The *Times*, quoting a few days ago from the official organ of the Prussian Ministry of the Interior, in which an account is given of the work accomplished during the existence of the Committee, states that the efforts made have been most successful, owing to the co-operation of wide circles of the public and more particularly owing to the measures taken by the Imperial German Working People's Insurance Office in providing hospitals and convalescent homes for those of the insured who are attacked by illness and prevented from earning their living. A large number of sanatoria, which are already receiving patients, have demonstrated that Germans who suffer from tuberculous diseases do not require to go abroad in search of health, but can secure the best medical treatment in the immediate neighbourhood

of the places where they have to live and work. Before long there will be some fifty sanatoria in Germany for persons in straitened circumstances. The central committee has co-operated in various degrees in the development of those institutions by placing at their disposal information and, where requisite, by making grants for their support. It has thus been found possible, while consulting in every case the special nature of local necessities, to establish the institution of sanatoria for consumptives in Germany on a sound and permanent basis.

THE LONDON UNIVERSITY MUDDLE is not being allowed freedom from attack during the holidays, the *Daily News* referring to the curious fact that, though the Government has appointed a Commission to deal with the university problem, it has also announced that it is prepared to make the financial arrangements necessary to enable the Imperial Institute to become the headquarters of the organisation of the new university. According to *Nature*, a very considerable discussion of an informal character is going on among many interested in the various institutions which may form part of the new university, and regret is expressed at the evident probability of the work of the Commission being hampered by the fact that many of the suggestions now being made are more inspired by the local interests concerned than by the desire to help on the educational question in the abstract. The Commission has to deal with an area defined by a radius of thirty miles, a population which may be roughly estimated at seven millions, and a large number of existing institutions. The amount of good the Commission will ultimately produce along new lines may be expected to be capable of measurement by the success it will achieve in co-ordinating the old forces which are already at work, by working on the principle of organic growth and regarding what exists from the most general standpoint. It is from this point of view that *Nature* deprecates some of the suggestions now being made, "because, if accepted, they will harm existing institutions, because the new university must not commence by localising itself, however high any local bid may be, and because again no good work will be achieved if any new suggestions be accepted before the actual condition is fairly grappled with, mastered and legislated for."

OBJECTION IS TAKEN in the *Times*, by the Surgeon of St. Mary's Hospital, to the idea of University College becoming the future home of the new university of London. No bait, he thinks, of buildings or endowments, however large, could overcome the objections of many of the constituent colleges to such a scheme. It is pointed out that there are a dozen medical schools in London, all in varying degrees equipped for the work of medical education with hospitals of their own, and each in equal degree looking forward to affiliation with the university. Were the University of London to be planted in Gower Street, Dr. Page feels that University College, having a new hospital—the best in construction and in arrangements for teaching, as it may be expected to be, in the kingdom—would attract medical students in such large numbers that some of the other medical schools less favourably situated "would inevitably be starved to death, unless, indeed, a happy despatch should reveal that it was thought hardly worth while to continue the unequal contest." Dr. Page does not especially advocate the claims of the Imperial Institute—although he is of opinion that, on the whole, it is the best site to be found—but he is anxious to show how essential it is for the peaceful progress of the new university that impartiality shall govern the choice of a site for its academic home. The university spirit, he urges, as distinguished from the collegiate

spirit, has hitherto had no existence in London; many, indeed, have had no notion what it is. "The birth, development, and continued vitality of such a spirit will depend in no small degree on the place of habitation of the university itself, where the several institutions, corporations, and schools, with their diverse interests and healthy rivalries, may flourish under the common and equal care of one *Alma Mater*, which is over and above them all."

THE TYPHOID BACILLUS has been shown by Dr. Sidney Martin to be capable of maintaining its existence for four hundred and fifty-six days in soil that has been sterilised and subsequently polluted with organic matter. Towards the end of that period a "soil culture" of the bacillus was dried and powdered, but it still yielded the microbe in viable condition and, presumably, in virulent phase. The record of Dr. Martin's experiments is published in a supplement to the latest annual report of the Local Government Board. His more difficult task of testing the ability of the typhoid bacillus to maintain itself in soil in which it is brought in competition with other bacteria is as yet in its initial stages, but the investigation has yielded an interesting result in one instance, in which the typhoid bacillus survived for fifty days in competition with other micro-organisms, though it had not multiplied.

SIR RICHARD THORNE THORNE, in the same supplementary report, states that there is no doubt bacteriology affords a ready means of detecting contaminating matters in waters which, from the point of view of the chemist, would be classed as "of high degree of purity." Examples are given of the delicacy of bacterioscopic tests, as compared with chemical tests, in detecting undesirable, if not dangerous, organisms in water, the facts being derived from a paper recording certain joint experiments by Drs. Klein and Houston. Those observers added to a number of separate samples of sterile distilled water various "minimal" quantities of raw sewage, obtaining thereby sewage dilutions ranging between one in a hundred and one in twenty thousand, which they proceeded to test severally, both chemically and bacterioscopically. As a result they ascertained that while the majority of their sewage dilutions would be classed chemically as at least organically safe drinking water, they had no difficulty in detecting in each and all of them certain objectionable bacilli. They were able to identify one particular organism in liquid made up of only one part of crude sewage in each half million parts of distilled water. Similarly, they succeeded in obtaining the same objectionable bacilli from a sample of Thames water collected below Staines.

POSTAL REFORMS are coming thick and fast this holiday time. It is now possible to send a letter to most British Colonies and Dependencies at a cost of one penny; on and after January 1, the postal rates will be reduced to one simple classification for parcels sent to any of the following places:—Antigua, Ascension, Bahamas, Barbados, British East Africa, British Honduras, Beyrout, Ceylon, Constantinople (by direct steamer), Cyprus, Dominica, Falkland Islands, Gambia, Gibraltar, Gold Coast Colony, Grenada, Johore (*via* Singapore), Lagos (Africa), Malta (by direct steamer), Montserrat, Nevis, Newfoundland, Niger Coast Protectorate, Niger Territory, St. Helena, St. Kitts, St. Lucia, St. Vincent (West Indies), Sarawak, Seychelles, Sierra Leone, Smyrna (by direct steamer), Straits Settlements, Tobago, Tortola, Trinidad. If the weight of the parcel does not exceed 3 lb. the postage will be 1s.; over 3 lb. but not over 7 lb., the cost will be 2s.; over 7 lb. but not over 11 lb., it will be 3s. Another order

of the Postmaster-General provides for the insurance of letters to and from places abroad. The places covered by those important regulations are nearly fifty in number, including all other European countries and many of their colonies. Letters thus insured—at fees which range from 5*d.* in respect to £12 compensation up to 2*s.* 3½*d.* in respect to £120—will have all the safeguards of the registration system.

CO-OPERATION IN SCIENCE was the burden of Professor Michael Foster's recent address to the members of the Yorkshire Naturalist Union at Scarborough, in which he endeavoured to impress upon his hearers the great necessity of co-operation in science. He also pointed out that all the earlier naturalists sought to solve the problems which every form of life possessed; that Nature is the naturalist's teacher, and the field his laboratory. The method of teaching science in schools was described as being open to serious objection, and the examinations often held as prejudicial to the development of science, the minds of students being very often pushed on by compulsion and drawn on by rewards, without any encouragement being given to study Nature in the fields and receive from her lips the catholic teaching which she alone can give. Naturalists, properly so-called, must be reared apart from the schools.

IN TABLES OF ATOMIC WEIGHTS hydrogen (=1.00) is usually taken as the standard, though many chemists have contended that it would be more convenient to take oxygen (=16.00) as the standard, and it is worthy of note that a commission consisting of Professors Landolt, Ostwald and Seubert—appointed by the Council of the German Chemical Society to draw up a table of atomic weights for use in calculations incident to the practice of analytical chemistry—has decided to take oxygen as 16.00, and to select atomic weights for other elements in direct or indirect comparison with that value. In the table as printed in the *Berichte* the atomic weights are not given beyond the last trustworthy figure, and in no case beyond the second decimal place. The table is practically the same as that issued in America by Professor F. W. Clarke on behalf of the Atomic Weight Commission of the United States. Hydrogen becomes 1.01, carbon 12.00, chlorine 35.45, sodium 23.05, potassium 39.15, and so forth, the figures not differing appreciably from those to which practical chemists have been accustomed for many years past. It is proposed to print the table annually in the *Berichte*, with any revision that may be found necessary, and the wish is expressed by the Commission that there should be some international understanding on the subject of the atomic weights used in analytical chemistry.

A NOVEL PRODUCTION OF VORTEX MOTION is described by C. S. Stanford Webster in the *Chemical News*. When the freshly-gathered leaves of *Eucalyptus globulus*, produced at San Remo, were ignited, they projected vortex rings in considerable numbers in succession, accompanied by a spluttering noise. The best results were obtained by holding the scythe-shaped leaf vertically and igniting the apex—that being the part where the greatest number of translations were obtained. It is suggested that possibly in the production of the vortex rings blisters are first formed by the extrusion of the cuticular tissues and, on the blisters bursting, air or aqueous vapour is spontaneously liberated, the rings being rendered visible on their contact with the smoke from the burning external portion of the leaf. The leaves of the small English variety of *Eucalyptus* are said to possess similar properties but in a lesser degree, the rings projected being insignificant in size, comparatively speaking.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

'THE TREATMENT OF DISEASE BY PHYSICAL METHODS,' by Dr. T. S. Dowse (Bristol: J. Wright and Co. Pp. 412. Price 7s. 6d. net), is a new edition of that author's 'Lectures on Massage and Electricity in the Treatment of Disease' under a new name. Though the general style of the book has not undergone any material change, new and important matter has been added to bring it up to date, and the work remains an authoritative one on the subjects of which it treats. The greater portion of it deals with massage—its principles, method of application, and detailed particulars regarding its use in special cases. The Nauheim or Schott treatment, electro-physics, and electro-therapeutics are also fully described, and the book is illustrated throughout.

'THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1899' (London: Greenwood and Co. Pp. 1508. Price 1s. net.), is a wonderful production, in which the scientific, practical, and trade aspects of photography—as they present themselves at the present moment—are satisfactorily summarised. The principal literary contents include an exhaustive article on "Colour Photography," by the editor—Thomas Bedding, F.R.P.S.; a large number of contributions on practical subjects by prominent photographers; a series of "Practical Notes and Suggestions of the Year"; an "Epitome of Progress during 1898"; miscellaneous information, and "the completest collection of photographic formulæ and recipes ever gathered together in one volume," thus constituting the Almanac of the greatest possible use to all photographers. In addition there can be but few manufacturers and large dealers in photographic specialties who do not advertise their wares in the book, so that it is a veritable trade compendium of the greatest possible use to all chemists who do a photographic trade.

'ROUSE'S SYNONYMS FOR THE USE OF CHEMISTS, THEIR ASSISTANTS AND APPRENTICES' (London: Rouse Bros. Pp. 218. Price 1s.), is a work of modest appearance, but it ought to be found on the bookshelf in every pharmacy in English-speaking countries. It contains between four and five thousand references, and covers a wider area, beside being more complete, than any similar collection of synonymous terms yet published. An enormous amount of labour must have been involved in preparing this compilation. Amongst other points of interest are many useful criticisms of, or comments on, statements in the British Pharmacopœia, 1898. Every registered chemist, every assistant, and every apprentice should hasten to procure a copy forthwith.

THE 'FORMULAIRE DES MÉDICAMENTS NOUVEAUX POUR 1899,' by H. BOUQUILLON-LIMOUSIN (Paris: J. B. Baillière et fils. Pp. 332. Price 3 francs), has come to hand as promptly as its predecessors, and like each of those includes particulars of a number of novel medicaments, amongst others being benzeucaine, cearin, eigon, erythrol, ingestol, protargol, quinochloral, salitannol, thiocol, validol, and others too numerous to mention here. As usual, a separate monograph is devoted to each substance, and the name of each is followed by the synonym, description, composition, therapeutic properties, method of use and dose. For those who can read French there is no handier little guide to the therapeutics, etc., of mushroom-like synthetics.

THE 'DIGEST OF CRITICISMS ON THE UNITED STATES PHARMACOPŒIA, Part II. (New York Committee of Revision and Publication of the U.S.P. Pp. 146), is a continuation of the first part, which brought the record up to the end of June, 1896, and

contains abstracts from all accessible sources from that date down to the end of December, 1897. The idea underlying the issue of this publication is, of course, that of arranging systematically every suggestion and criticism of the U.S.P. which seems worthy of note, and the Committee of Revision is to be congratulated upon the thoroughness with which the work has been done.

'HOW TO MAKE LANTERN SLIDES,' by S. L. Coulthurst (London: Dawbarn and Ward, Ltd. Price 1s), is a practical little book, in which the gelatino-bromide and gelatino-chloride processes are given special prominence. The formulæ given are few but well-tried ones, and beginners at lantern slide making should find here all they require in the way of information.

'FALLOWFIELD'S PHOTOGRAPHIC ANNUAL FOR 1898-9' (London: Jonathan Fallowfield. Pp. 852. Price 1s. 6d., post free) is another bulky production, containing particulars—usually with illustrations—of nearly every form of apparatus and accessory used by professional and amateur photographers. If only as a guide to what is on the market, all retail photographic dealers should possess copies of this book, which is now issued for the fortieth year.

'VITALITY: AN APPEAL, AN APOLOGY, AND A CHALLENGE,' by Professor Lionel S. Beale (London: J. and A. Churchill. Pp. 75. Price 6d. post free) is a reprint from the *Lancet* of a series of papers in which the author considers the part played by vitality in various departures from the healthy state in some of the most important tissues and organs. Thus, he treats of the living matter of man, physical and chemical doctrines, the nature of growth, and a variety of other more or less controversial topics.

'PRESCRIPTION READING: A TEXT-BOOK FOR PHARMACEUTICAL STUDENTS,' by William Watson Will (London: Metropolitan College of Pharmacy. Pp. 139. Price 12s. 6d. net.) is a collection of materials to be used for instructing the student in the technicalities and conventionalities associated with physicians' prescriptions. It is to be regretted that the conditions under which pharmacy is now carried on renders necessary the academic study of a subject which under more favourable circumstances should be learnt as part of the routine duties of the student during his apprenticeship. For it cannot be doubted that the supply of materials, in the form of prescriptions actually dispensed, available for the instruction of the apprentice, in many cases falls far below the amount and variety necessary for his education in prescription reading. Hence, in order to meet the requirements of the examining Board and to equip himself with the knowledge necessary for his possible position as a principal in keeping a pharmacy, the aspirant for the diploma of a chemist and druggist is often obliged to supply the deficiencies of his apprenticeship training by resorting to a compilation of prescriptions prepared for him. The book which Mr. Will has produced contains a copious collection of abbreviated prescriptions for all manner of medicinal preparations, with a dictionary and tables of terms and abbreviations employed. The student is directed to look out for incompatibilities, excessive doses, mistakes in construction, etc., but no notes or explanations are supplied to indicate where those occur, and that omission distinctly limits the utility of the book for those students who are unable to refer continually to a coach or teacher. The employment of different type or asterisks at those places where errors or ambiguities occur, even if full explanations were not supplied,

would have prevented the student missing many useful points. As it is there is a danger that the beginner using the book may perpetuate many of the errors which he is unable to detect. Posological tables and extracts from the Pharmacy Act complete the volume, which is printed on quarto pages with very open type, making cross reference very easy. The book contains abundance of material representative of modern prescribing as well as the old prescriptions written in former times, when the physician was accustomed to write his directions for the patient almost entirely in Latin.

NOTES OF PHOTOGRAPHIC NOVELTIES.

"Busch" Photographic Lenses.

MR. HENRY F. PURSER, of 33, Hatton Garden, E.C., the wholesale London agent of the Rathenow Optical Manufacturing Company, late Emil Busch, has placed in our hands for trial some specimens of the productions of the firm he represents and their catalogue. From the latter we find that they make a specialty of rapid, portrait, and detective aplanats, but also supply wide-angle lenses giving an angle of from 100° to 110° . Portrait lenses of the Petzval form and Projection lenses. The lens to which we applied the practical test of making a negative with it was the No. 2 of the "Rapid Aplanat" series, working at F/8. The lens was 8 inches focus, and at the full aperture it covered a half-plate well. Owing to the unusual shortness of the tube for this type of lens, which is claimed as one of the good points of the series, the circle of illumination was found to be a large one, and, employing a smaller stop, an $8\frac{1}{2} \times 6\frac{1}{2}$ plate was well covered, and a considerable rise of the camera front was possible. The field of the lens just covered a 10×8 plate. With a plate of this size, of course, it was working at quite a wide angle, and in buying a lens this power is worth considering. The lenses are priced very moderately for good instruments. The retail price of that we have referred to, with iris diaphragm, being quoted at £1 13s. All lenses for the English market are fitted with stops according to the Royal Photographic Society's standard.

Ross Enlarging Lantern.

This lantern, made by Ross, Ltd., 111, New Bond Street, W., bears a general resemblance to other instruments for the same purpose. Improvements have, however, been introduced in

matters of detail which make it worthy of notice. A special feature is the fitting for the illuminant. This may be an oil lamp, or, where gas is available, an incandescent gas-burner may be used, or a limelight jet may be employed. Any or all these forms of illuminant can be supplied, and may be used with the same lantern at discretion. The body of the lantern is another feature. This, as shown in the illustration, is capable of being raised and fixed in its raised position, so that the light may be got at at any time. The

slide for the insertion of the negative to be enlarged is open on three sides, so that there is no difficulty in adjusting the negative in any desired position, and, if required, a portion of a larger negative may be arranged before the condenser, a clamping screw holding the negative in position. When a smaller negative or a part of a negative smaller than the full size the apparatus is constructed to enlarge is used, the condenser may be drawn backwards, as it is mounted on a sliding base, and a metal disc inserted of the same diameter as the condenser, but having a 3 or 4 inch opening eccentrically placed, so that it is not necessary when part of a large negative is to be used that the part required should be placed centrally in front of the condenser. All the sliding parts are of metal and work with extreme smoothness. The bellows may be removed, and the lantern is then available for any purpose to which an optical lantern of the kind can be applied. The workmanship is admirable, and the price reasonable for a first-class instrument. With $5\frac{1}{2}$ inch condenser, for $4\frac{1}{2}$ by $3\frac{1}{2}$ negative, £6 10s. With 6 inch condenser, £7 10s. With 8 inch condenser £9 10s. The apparatus is made to 16 inches.

Lumière's Rigid Vitrose Films.

These films are the manufacture of Messrs. A. Lumière et ses fils, of Lyons. It is claimed that the Vitrose composition, upon which the emulsion is coated, is superior to celluloid, both in transparency and rigidity, and that it is free from any volatile or odorous matter likely to have an injurious effect upon the emulsion. The film is about $\frac{2}{10}$ th Mm. in thickness, and the weight is approximately $\frac{1}{12}$ th that of a glass-plate of the same size. It is absolutely waterproof, and does not expand. The cut films are sold packed in the usual way. They are also sold with film inserted in a neat and ingeniously-made sheath ready for insertion in the dark slide, and requiring no further backing. The sheath consists of a black cardboard, surrounded with a metal rim, with an opening at one end for the insertion of the film. The metal rim, besides fulfilling the purpose of holding the films to the backing, also serves to stiffen the whole, and it is perhaps as neat and efficient a film carrier as any we have seen. The sheaths are of course charged for, but they are moderate in price, $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$ plate sheaths being respectively 10d., 1s. 10d., and 2s. 8d. a dozen. The sheaths can, of course, be used over and over again. The Vitrose composition is also made in the thin and flexible form, and coated for rollable and kinematograph films. The emulsion with which the films are coated is, unless specially ordered, an extremely rapid one of the ordinary kind, but films coated with ortho-chromatic or colour-sensitive emulsions of three kinds are also supplied. A is sensitive to yellow and green, B to yellow and red, and C to yellow, red, and green. The price of the films per dozen is: $\frac{1}{4}$ -plate, extra rapid, 2s. 6d.; ortho-chromatic, A, B, or C, 2s. 9d.; $\frac{1}{2}$ -plate, extra rapid, 4s. 10d.; ortho-chromatic, 5s. 4d.; $\frac{3}{4}$ -plate, extra rapid, 8s. 10d.; ortho-chromatic, 9s. 9d.

"Albuminate" Emulsion Paper.

We have some samples of this paper from C. A. Rudowsky, of 22, Coleman Street, E.C., who is the London agent for it. We understand that it is claimed for it that it has all the good qualities of albuminised paper, sensitised in the ordinary way upon a silver bath, but being manufactured by an emulsion process it may be relied upon as being all alike, and not liable to the various ills which arise from the variation of the bath and its deterioration as successive sheets of paper are sensitised on it. From the directions for use we gather that the procedure is practically the same as for ordinary albuminised paper, and formulæ are given for an acetate and gold bath, a sulphocyanide and gold bath for separate toning and fixing, and a combined toning and fixing bath. We have only had opportunity to make a hurried and, therefore, unfair experiment on a couple of prints, and we must say the results we obtained were admirable, and better than we should have expected from gelatino-chloride paper under the same circumstances. The price is rather high, 18s. a quire. If that could be reduced to meet the present demand for cheapness it would probably come into extensive use. We should recommend those who study quality rather than price to try it. It is also made up in packets of the usual plate sizes.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 16, Bloomsbury Square, on Thursday, December 22. Present:—Mr. WALTER HILLS (Vice-President) in the chair, Mr. J. C. Umney (Hon. Treasurer), Prof. Greenish, Messrs. Bird, Collier, Druce and White; Messrs. Naylor and Ransom (Hon. Gen. Secs.) and Mr. J. C. Nightingale (Asst. Sec.).

Letters were read from Mr. J. C. C. Payne (President) and Messrs. Atkins, Atkinson, Downes, Martin, McKnight, Moss, Park, Symes, and Wright regretting their inability to be present.

The minutes of the previous meeting were read and confirmed.

Mr. Louis Siebold, F.I.C., F.C.S., was unanimously appointed editor of the Year-Book for 1899.

After some discussion the following gentlemen were appointed as a Sub-Committee to inquire as to the best method of increasing the membership of the Conference, and to report to a future meeting of the Executive—Professor Greenish, Messrs. Bird, White, Wright, J. C. Umney, Naylor, and Ransom.

It was unanimously resolved to request the following gentlemen to allow their names to be added to the list of honorary members of the Conference—Dr. Charles Rice (New York), Mr. A. Petit (Paris), and Professor A. Tschirch (Bern).

On the recommendation of the Local Committee it was resolved that the sessions of the Plymouth meeting should commence on July 25, 1899, the reception being held the previous evening.

Sixteen gentlemen having been duly nominated were elected to membership.

EXTRACTS FROM CONSULAR REPORTS.

THE QUANTITY OF SULPHUR EXPORTED from Licata (Sicily) to foreign countries during 1897 was 85,741 tons, and to Italy 9106 tons, making a total of 94,847 tons, value £331,964; an increase of 20,808 tons, and £124,875 on the preceding year. Of the 85,741 tons shipped for foreign countries France took 31,813 tons; the United States of America, 30,828; Norway and Sweden, 4085 tons; Spain, 2367 tons; Austria, 2339 tons; the United Kingdom, 2232 tons; Germany, 1983 tons, and to other countries 10,094 tons. The quantity of sulphur exported from Catania was 90,590 tons as against 95,678 tons in 1896. The operations of the "Anglo-Sicilian Sulphur Company, Ltd.," Vice-Consul Elford reports, have been a boon to the mine proprietors who are now able to earn a good profit on their industry, with the result that several millions of lire remain in the island to their and the miner's benefit, whilst before the advent of the company the industry was at the mercy of speculators.

THE BRITISH IMPORT TRADE in chemicals, dye-stuffs, and tanning substances for the month of November this year compares very favourably with that of the same period in 1897, there being an increase in value of £21,994, the total figures being £372,609 for November, 1897, and £394,603 last month. There is a decrease of £500,524, however, on the value of imports for the eleven months ending November 30, £5,591,546 representing the value for that period in 1897, as against £5,091,022 in 1898. The exports of manufactured chemicals and chemical and medicinal preparations also show a decrease for both periods; goods to the value of £753,840 having been exported in November last year, and £690,973 this year, a reduction of £62,867. For the longer period the figures are £7,959,214 in 1897, compared with £7,678,009 in 1898, showing a decrease of £281,205.

THE PRODUCTION AND EXPORT OF BEER at Hamburg is the subject of a report by Consul-General Ward, in which he gives some very interesting figures. At present there are fifteen large breweries in and near Hamburg, the aggregate capital of which amounts to about £1,000,000. It has been estimated that these breweries together produce annually something over 22,000,000 gallons of beer, which if required could be increased by eight or nine million gallons per annum. The larger portion of the beer is consumed in the district itself, only a comparatively small proportion of the Hamburg beer being exported to foreign countries by sea, or by land to the interior of Germany. All the Hamburg breweries are said to be fitted with the newest and best brewing machinery, the beer, which is of a light colour and medium strength, being brewed upon the same principles as other good German beers. That made for exportation is of a stronger quality

than that consumed on the spot, and when destined for hot climates is subjected to "Pasteurisation."

THE QUANTITY OF BEER annually exported, by land and by sea, from all parts of Germany has been gradually diminishing during recent years. In 1897 the total value of exportations was about £950,000, whilst in 1885 their value is stated to have largely exceeded that figure. The value of the Hamburg exportations by sea alone fell from £748,061 in the year 1889 to £498,310 in 1897. This decline is attributed, amongst other causes, partly to the gradual falling off of the demand in France, which has always been and still is the best customer for German beer. But during the last ten years its own production has been largely increased by the introduction of improved brewing methods. With regard to the United Kingdom, the quantity of beer shipped from Hamburg to this country in 1880 was no less than 1,100,000 gallons, whilst in 1897 only 120,824 gallons were received here. The development of direct steam communication between Hamburg and the various oversea countries of the world is held to be responsible, in great measure, for the falling off of the exports to Great Britain, as the beer was and is mostly transhipped from here to other countries.

NEW REMEDIES.

IODOLMENTHOL.—This is a mixture of iodol with one per cent. of menthol, an addition which covers the odour of the iodol, while the mixture is stated to be even more active than iodol alone.—*Pharm. Zeit.*, xliii., 668.

PULVIS CUTICULOR.—This term is applied by Unna (*Monats. fur Derm.*) to the following powder, used for scborrhoea:—Zinc oxide, 2; magnesium carbonate, 3; white bole, 3; Armenian bole, 2; rice starch, 10.—*Pharm. Zeit.*, xliii., 668.

ANALGENE IN CHOREA.—Moncorvo has found antipyrine, exalgine, asaprol, and analgene all valuable remedies in the treatment of chorea in young children, and of these drugs analgene gave the best results. Several cases are recorded which were cured by treatment with this remedy. The initial dose was generally 2 grammes in twenty-four hours, gradually increased. In many cases improvement was noted in a few days after commencing the treatment, and, in some, a cure was effected in less than a month.—*Pediatrics*, vi., 353.

JELLOIDS OF LYMPH GLAND EXTRACT IN THE TREATMENT OF CANCER.—Dr. Herbert Snow calls attention to the possible value of lymph gland extract in the treatment of cancer. He records a case which was much ameliorated by the administration of the extract in the form of jelloids, each containing 4 grains of the extract. Of these from one to three were taken twice or thrice daily after meals. There was marked improvement in the general health, and it is considered that the extract added at least three months to the patient's life. The treatment included the administration of opium and cocaine, as well as lymph gland extract. Other cases are now under observation.—*Med. Press*, new ser., lxvi., 482.

CHINOSOL AS AN ANTISEPTIC IN VETERINARY SURGERY.—In the *Veterinary Record*, xi., 187, E. R. Edwards publishes a case which illustrates the value of chinisol as an antiseptic in veterinary practice. A horse, in attempting to jump a fence, became impaled upon a stake and received a severe abdominal wound, from which the bowel protruded. This stake was covered with filth, and the horse when first seen was lying in a very ill-drained, dirty stable; yet, after thoroughly washing the wound and protruding intestines—which were in a filthy condition—with chinisol solution, 1 in 600, the necessary surgical operations were performed and a satisfactory recovery obtained, without a trace of peritonitis or septic symptoms.

HEXAMETHYLENETETRAMINE IN GOUTY DIATHESIS.—Walter recommends the use of hexamethylenetetramine (termed urotropine by Nicolaiew, or aminoform by Lederer) as a prophylactic in gouty diathesis in doses of a teaspoonful every morning, taken in a glass of water. Taken in this manner it will ward off an attack of gout.—*Nouv. Rem.*, xiv., 456, after *Munich. Med. Woch.*

LETTERS TO THE EDITOR.

THE PROPOSED POISON REGULATIONS.

Sir,—If the special general meeting of the Society convened for January 11, 1899, is to produce results beneficial to the members it is very desirable that it should avoid the attitude historically described by “’Ang hargiment; let’s ’ave a show of ’ands.” The tribunal of such a meeting is not ideal, and if it were suggested that the governing body of the Society should be so elected, provincial members would find their allegiance seriously weakened. I might, from personal knowledge, claim to say something of what occurred in 1871, but ancient history will help us little towards a solution of present difficulties. We ought, however, to bear in mind that the alleged private bargain dates back to the “unreformed” period of the Society’s history, when reporters were not admitted to meetings of the Council, and neither by information vouchsafed to the members nor by the minutes of the Council has any confirmation of a bargain been produced. On one occasion the irony of the situation was manifested by the party for the exclusion of reporters, issuing by post an *ex parte* statement of its case. We know enough from the past history of legislation for pharmacy to appreciate that we should carefully forecast the effects of any enactments. If not doing so, we shall still further confound a condition which at present is one of absolute topsy-turvydom, there being several hundreds of drug shops where the only legal qualification is held by servants. I have, therefore, put to the highest pharmaceutical authority the question, “How will any regulations for the storage, etc., of poisons affect ‘stores’ and ‘cash chemists’?” The answer I have received is, “I am unable to tell you.” Any need for penal regulations for the storage, etc., of poisons has diminished steadily during the thirty years that have elapsed since the Pharmacy Act was passed, now that registered chemists have generally proved their qualification by examination. On the other hand, time has produced, outside the legitimate body, the mongrel traders having no scrap of qualification, whose right to defy the Pharmacy Act is about to be challenged. Are these men to be permitted to steal the horse whilst we are arranging the penalties upon any legitimate chemist who looks over a fence? We shall probably be told that the moral effect of our self-imposed mortification would be so grand that we might get friends who would be useful when the larger question comes up. Have we amongst our rulers no public men accustomed to negotiate delicate questions for municipalities, county councils, and the like? Would they give away the interests of their constituents, as a preliminary act, in the hope that such generous actions would meet their reward, or would they make these interests a part of the whole question? It is unfortunate that this subject has ever been the special field for “intellectual insincerity.” The promise that regulations would carry no inspection used to be freely made, but there can hardly be anyone unwise enough to believe this now. Unfortunately, the despairing mood of our members gives too much justification for readiness to catch at any straw. But it is safe to say that salvation will not be found by this road. To some of us it is inexplicable why our Council has made no communication on the subject to Sir John Gorst, M.P., the Vice-President of the Committee of Council. His department is supposed to have “views” as to our past engagements and to hold an I.O.U. given thirty years ago. We also have “views,” and, as citizens of a free state, have the right to state those to the existing authorities. Recently, our elected chiefs have acted as Le Bon described the Latin races “who feel the incurable need of being governed.” Last year our reticence would have done a great injustice to the Duke of Devonshire, had we been previously aware of the course he would take, for his lamentable ignorance of the question was too apparent. If our Council is dissatisfied with the consequent manifestation of our Parliamentary strength for defence, it must be difficult to please. The fact of ranging Ireland in line with us on this question has removed all real danger. Surely someone will put before the general meeting an amendment declaring the opinion that no imposition upon registered chemists and druggists of penal regulations for the keeping, selling, etc., of poisons will be satisfactory unless forming part of a general revision of legislation for pharmacy.

Leeds, December 27, 1898.

RICHARD REYNOLDS.

Sir,—I am pleased to see from this day’s issue that at least one member of the Council views the notice of motion to be discussed at the special general meeting on the 11th prox. from a practical and common-sense position, and doubtless many chemists will do likewise. The worthy members of that admirable debating Society, the Western Chemists’ Association, seem to have been carried away by the flow of oratory that permeates their periodic reunions. What does this motion mean? To my mind this, “that although we have been examined by a board of examiners who have found and declared us qualified to act as chemists and druggists, the Western Chemists’ Association in solemn conclave has discovered that the examiners are wrong, and we are not qualified to manage our own pharmacies.” This is a serious matter, and what individual member of that Association would accept this statement as applied to himself? Poisons, I take it, are those defined by the Poisons Schedule, and if this motion became law it would be necessary for a chemist to have two establishments, one for dealing in poisons and the other for non-poisons. Nostrums containing poisons which can only be sold by chemists must be kept in one and those that do not in the other. Homœopathic tincture of aconite, 3^x is either a preparation of aconite (Schedule I.) or it is not. If it is it must be kept and sold as a poison, if it is not, the seller is liable to prosecution under the Sale of Food and Drugs Act. Tincture of rhubarb and crude carbolic acid (not a poison within the meaning of the Act) may stand side by side and be accidentally transposed by a chemist whose olfactory organs are deficient. Is it not necessary to be cautious with non-poisons as well as poisons? Or does it not matter whether we give a patient ext. cascara liquid. or tincture of catechu? I hope before the Society agrees to any hard and fast motherly care of its “unqualified qualified members” it will quietly consider the advisability of trammelling the liberty of the subject with impracticable fetters, and thereby rendering itself unpopular.

Tring, Herts, December 24, 1898.

JOHN W. T. MORRISON.

Sir,—At the special general meeting of the Pharmaceutical Society, on January 11 next, a topic of great moment will be discussed. In the interim all chemists should bestow their serious attention upon this measure. In all probability a chain will be forged wherewith to bind us, and it behoves everyone to see that all the links are so fashioned that the least galling takes place. The second clause of recommendations directs that poisons be kept on one of three systems—A, B, or C. I would suggest a combination of the three. It would render the storage of poisons much more amenable and be equally safe and a more convenient plan than to adopt one only of the three systems, especially as pharmacies exist. I would like a fourth clause added, somewhat as follows: “That in the sale of scheduled and unscheduled poisons, liquid poisons, except medicines for internal use, be sent out in the aforesaid distinguishable bottles, mentioned in Clause 3, with labels attached, as directed in Part II. of the Poisons Schedule.” As to what an unscheduled poison is, it would have to be left to the discretion of the seller, but there could be no two opinions as to the poisonous nature of the corrosive acids in their concentrated state and several other potent poisons not in the Schedule. It would be in these cases that I would make it compulsory the poison bottle only should be used.

Harlesden, N. W., December 26, 1898.

J. W. TAPLIN.

Sir,—It is a source of great satisfaction to a conscienceless person to find little or nothing which could in the most remote degree be considered to indicate any anxiety regarding the public safety in all that has recently been said or written by registered chemists on the question of poison regulations. Rather more than twenty-seven years ago we declined to adopt compulsory poison regulations, because it was felt that hard and fast rules would be less in the interest of the public safety than the fact of the registered chemist being a properly trained individual with a due sense of his own responsibility in the matter of keeping and dispensing poisons. Doubtless it would also have been most inconvenient to many of us to have our business arrangements regulated in any way at that time, but there is no occasion to talk much about that. Why should we give ourselves away unnecessarily? Because, as we are told, the Privy Council regards our non-adoption of regulations as a breach of faith, and the permanent officials who speak in the name of that august body have been careful to remind us of the fact from time to time, whilst also interposing obstacles in the way of extending the list of scheduled poisons

and even threatening to seek powers to draft and enforce regulations themselves. More than that, the Privy Council actually drafted a Bill on the subject last session, and though we promptly blocked that, there is not the least doubt that we are somewhat in a hole, the more especially as the company pharmacy difficulty tends to increase rather than diminish. It is a happy thought, therefore, that has occurred to some of us—to adopt poison regulations forthwith, so as to secure the benevolent neutrality, if not the active sympathy, of the Privy Council, with the possibility in the background of Government support for a Bill dealing with the company pharmacy difficulty. The more especially is the idea a brilliant one, since the regulations adopted need not bind us to anything new or compel us to make any difference in our present practice. The object is simply to persuade the Privy Council that we are carrying out the intentions of the Pharmacy Act of 1868, according to the Government official's view of the matter, and whilst carefully avoiding the appearance of hoodwinking the Society's mentors, we must be equally careful not to incommode ourselves in the least. For it must be borne in mind that it is within our power to draft and adopt really effective regulations bearing on the keeping of poisons, such in fact as might prove exceedingly inconvenient to ourselves, though the Privy Council, acting in the public interest, would willingly confirm and approve of them. There is an opinion prevalent, for example, that there is no power under the Act to appoint inspectors, whose duty should be to see that any regulations adopted are properly conformed to. But, as a matter of fact, all we have to do is to adopt a regulation stipulating that the arrangements for keeping poisons shall at all times be open for inspection by officials appointed by the Privy Council or by the Council of the Pharmaceutical Society, and the trick would be done. Why, however, should we be so foolish as to take steps to bring more trouble and worry on our own heads? Such a regulation might, of course, be to the public interest, but think of the inconvenience of it! The recommendations which we are to be advised to adopt as regulations are free from that drawback, and we have it on the authority of Mr. R. A. Robinson and other prominent individuals that their adoption will involve us in no inconvenience whatever. Some people (say, for example, Privy Council officials) might even consider them absurdly insufficient and not worth the trouble of adopting. We need not even trouble to conform to them, as it is only in the extremely improbable event of an accident occurring that we could be compelled to say whether we had done so or not. And though we may have scruples, on ethical grounds, as to the straightforwardness of such a course, why should we worry if our high-minded leaders say that what is must be right? If the adoption of unobjectionable regulations, say they, will ingratiate us with the Privy Council and possibly gain Government sympathy if not active support for a Bill dealing with the company pharmacy difficulty, let us forget that we think qualification superior to regulations and conclude our bargain with Mephisto forthwith. The position is not free from complications, but by doing as we are shortly to be asked to do we shall "appear" to be caring for the safety of the public whether we actually do care for it or not, and the position is therefore one that thoroughly commends itself to

Christmas, 1898.

A CONSCIENCELESS M.P.S. (162/45).

THE ASSAY OF OPIUM.

Sir,—Referring to the short discussion at a meeting of the Liverpool Chemists' Association, reported in your issue of December 17 (p. 653), as to the best method of separating the ethereal liquid from the aqueous in the official process for the assay of opium, I beg to suggest that the following is less troublesome and more accurate than that mentioned by Messrs. Cowley and Hornblower, especially in the hands of students or of men who have not had considerable practice in the use of a pipette. Instead of filtering the aqueous alkaline liquor into a wide-mouth bottle, I filter direct into a short-stemmed, stoppered glass separator—either pear-shaped or cylindrical, preferably the latter—marked at 52 C.c. or 104 C.c., according to the quantity of crude opium I am operating upon. After the addition of the ether, S.V.R., and ammonium chloride, and subsequent separation of the two layers, I draw off the aqueous one into a 100 C.c. graduated measure. Much of the crystallised alkaloid is removed, and the last drop of aqueous liquid is with ease run out. Now decant the ether upon the double filter papers, return the contents of the measure to the separator, rinsing round the last portion so as to include practically all the

morphine. Wash the measure and the contents of the separator with the second portion of ether and repeat the separation in the same way. Finally, after drying the filter papers in the air in the usual manner, run the liquid from the separator into the filter, wash out any adherent crystals of morphine from the beaker with a few C.c. morphinated water, using the washings to rinse out the separator in turn. Of course, in using a syringe or pipette, any aqueous fluid which may be drawn up with the ether can be easily returned to the bottle, but I have found this trifling deviation from the official directions, just mentioned, to be in every way satisfactory and expeditious.

Newcastle-on-Tyne, December 21, 1898.

GEO. E. F. MERSON.

Sir,—The separation of the ethereal layer in the assay of opium was the subject of a note recently read before the Liverpool Chemists' Association by Mr. R. C. Cowley (*ante* p. 653). The method suggested involves the use of an ordinary male syringe, with an india-rubber band covering the cotton packing so as to fit the bore accurately and prevent the adherence of morphine crystals. In the subsequent discussion Mr. Hornblower recommended an ordinary pipette with an india-rubber teat attached, while Mr. A. C. Abraham got over the difficulty attending the separation of the ethereal layer by a liberal use of ether. A device which will be found to be useful in performing the operation, without possessing the disadvantages of the above-mentioned methods, consists simply of an ordinary wash-bottle, slightly modified. In place of a flask a wide-mouth glass bottle should be taken and fitted with an india-rubber cork perforated with two holes, through one of which passes the usual bent glass tube, slightly drawn out to a point, and having the longer arm of such a length that it may be slid up or down to the required level. The second glass tube, bent like the ordinary mouth-piece tube of a wash-bottle, is provided at the end terminating within the bottle with an ordinary slit rubber valve. In use it is only necessary to slide the exit tube to the bottom of the ethereal layer and blow through the other tube. The increased pressure in the bottle forces the liquid through the exit tube, and it may be caught directly on the filter. By arranging the apparatus on blocks at a suitable height the liquids are not disturbed by shaking; as is often the case when a pipette or other instrument is inserted into the liquid by hand. Among other advantages of this device may be mentioned its cheapness and permanence, as well as the speed and thoroughness with which the ethereal layer is removed.

School of Pharmacy, London,

December 23, 1898.

F. A. UPSHER SMITH.

RETAIL CHEMISTS AND THE P.A.T.A.

Sir,—Mr. Glyn-Jones informs your readers that the P.A.T.A. has been considering for two years how best to gather the grocers into the fold. During that time it is strange it did not occur to the Committee what damage they were doing to the chemists. It is all nonsense his now talking of "peculiarly grocery preparations" when he invited them all to stock half the P.A.T.A. drug list. The mischief is now done, and the grocers have been awakened to the fact that it is a simple matter for them to give space to the most saleable patents. To prove what I say is right, let any chemist get a *Grocery Gazette* of December 10, and read the editorial remarks on "Proprietary Articles," as follows:—

As is well known, the grocer's trade in proprietary articles of the character to which particular attention is now drawn in these columns has been very considerably reduced by the action of the Pharmaceutical Society and the decisions that patent medicines and other articles containing poisons may only be sold by a duly qualified chemist, and in drawing attention to a number of articles which do not come within the legal restrictions mentioned above our readers will doubtless find it to their advantage to make themselves acquainted with, and to stock various of the articles.

In looking through this grocer's paper I thought it in keeping with my argument to find the only pill advertisement was the P.A.T.A. Dr. Scott's. I have no *Anti-Cutting Record* (grocery section) for December, and cannot find anyone who has received a copy, and I am very pleased to hear that the P.A.T.A. does not intend bringing this out again, as the grocers have not been sending in the desired subscriptions. I wonder Mr. Glyn-Jones did not give you this good news last week. I have, however, the *Anti-Cutting Record*, which throws such a wonderfully one-sided light on the P.A.T.A. business, and I notice, in comparing this and last month's protected lists, that although there is no reference to their withdrawal, Hall's Wine and Keystone Brand Beef Wine do not now appear. (Is this pending the arrangement of the

grocery list, which was the reason why Mr. Glyn-Jones advised Liebig's Extract to come off?) In regard to this *Record*, I maintain that any chemist who looks at this matter through the spectacles of its editor can do justice neither to himself nor to the public. Their minds must become warped, as some of your correspondents show. In the whole of the paper any reference to the grocers is carefully avoided. As regards Portsmouth, permit me to complete the paragraph that Mr. Glyn-Jones partly quotes, by adding: "and in such places the profits would still have been about the same without the P.A.T.A." An extreme cutter might start here any day, and then this would be added to "the hundred towns" in which Mr. Glyn-Jones has admitted the P.A.T.A. is a failure.

Portsmouth, December 27, 1898.

HERBERT H. BAILEY.

THE EFFECT OF VISITS TO LOCAL ASSOCIATIONS.

Sir,—Referring to your recent visit to Blackburn, I have been conferring with my fellow-chemists here, and have come to the conclusion that if it could be arranged that members of the Pharmaceutical Council could go out frequently and address the various local associations, it would be the means of bringing more members to the Pharmaceutical Society, for we noticed particularly that your visit here proved an attraction and brought together the chemists (as nothing else would except a dinner). Coming together they have become more friendly to each other, and more disposed to co operate to mutual interest. Your visit has been the means of a large increase of members to the Pharmaceutical Society, not only in Blackburn, but also in the neighbouring towns of North-East Lancashire. I wish to express my own pleasure at seeing you amongst us, and it is needless to say that you (or any member of the Council) will be always a welcome visitor at our meetings.

Blackburn, December 21, 1898.

THOMAS CRITCHLEY,
Local Secretary and President
of the N.E.L. Association.

A WARNING.

Sir,—I wish to warn the trade against an individual who appears to be carrying on a systematic swindle. He applied for a situation as assistant in reply to my advertisement at the end of October, and I engaged him early in November. In a most despicable way he got my confidence and sympathy to the extent of my advancing him £3. Though I wanted an assistant as soon as possible, I waited and kept the situation open for him, first, under excuse of his spraining his ankle, and then, that he had to wait and settle affairs connected with his father's business. He said his father was a chemist and had recently died, but I have since heard that he never had anything to do with this business. I found him out about five days ago through a chemist in Bolton and another in Lincolnshire who he obtained money from. His exceptionally lying letters to them disagreed in everything except that he wanted to borrow money to come to me.

Sidcup, Kent, December 21, 1898.

J. R. ROADNIGHT.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

ETYMOLOGY OF BOTANICAL NAMES.—Hooker's 'Student's Flora' and kindred works give the etymology of such names as you refer to. [Reply to A. A.—21/15.]

WALNUT STAIN.—You will probably get the desired colour by mixing Bismarck brown and spirit-soluble aniline black in suitable proportions, but you can buy a walnut spirit stain more cheaply from Williams Bros., of Hounslow. We do not know of any book on the subject. [Reply to GENTIAN.—21/20.]

JURY SERVICE.—No. The exemption only applies to pharmaceutical chemists. [Reply to GENTIAN.—21/21]

USE OF FIRM'S NAME.—Unless you were bound down by any stipulation to the contrary, there appears to be nothing to prevent you doing as you think proper in the matter, but it hardly seems reasonable so to use the name of a firm with whom you only stayed three months. [Reply to AN ANXIOUS ONE.—21/14]

RED BOTTLE.—This Lancashire liniment is composed of ol. origani, 4 drachms; tinct. lavand. co, 2 drachms; ol. tereb., 5 drachms; rectified spirit, 1 pint. Another form, known as Whitworth bottle, is: Camphor, 6 drachms; ol. origani, 6 drachms; rad. anchusæ, 1 drachm; rectified spirit, 20 fl. oz. Macerate four days and filter. [Reply to SPERO.—20/30.]

VINUM COCÆ FROM THE FLUID EXTRACT.—Probably the troublesome precipitate you find is due to your wine being very astringent. Port is not well suited for making coca wine for this reason. Malaga answers better, since it contains less tannin. You can get rid of the tannin contained in the wine by first macerating it for fourteen days with an ounce of gelatin to each gallon, and then filtering it. [Reply to G. E. F.—21/3.]

LABELLING SEIDLITZ POWDERS.—If you label them "Seidlitz Powders" and do not make it clear to each customer that they are not made according to the formula which custom has established as the recognised one, you will incur the risk of a fine if you should be proceeded against under the Sale of Food and Drugs Act. It matters not that the name is not a B.P. synonym. If your labels read: "Improved Seidlitz Powders; not according to the British Pharmacopœia," you would minimise the risk, but even then you would do well not to supply them when "Seidlitz Powders" are asked for. [Reply to FORTIOR.—162/2.]

TOMATO SAUCE.—Take 2½ lbs. of ripe tomatoes, place them in a covered vessel, and digest in the water bath until quite soft. Meanwhile, heat vinegar, 1 pint, to boiling, and pour it on capsicums, ½ oz. When cold, decant. Mash the tomatoes; add to them the decanted vinegar; shallots, bruised, 1 oz.; garlic, bruised, ½ oz.; sugar, 8 ounces; soy, 2 ounces; one anchovy, and salt to taste. Boil the mixture gently, until the garlic and shallots are quite soft, then pulp through a hair sieve. If too thick, thin down with a little vinegar. Some like the addition of a little tarragon vinegar instead of the plain article, but this is a matter of taste. A sliced lemon cooked with the tomatoes may also be considered an improvement. The sauce is fit for use immediately and will keep indefinitely. [Reply to A. R. J.—21/10.]

GINGER WINE.—Loaf sugar, 28 lbs.; soluble essence of ginger, 1 pint; soluble essence of lemon, 10 fl. ozs.; raisins stoned and bruised, 2 lbs.; compressed yeast, q.s.; water, 12 gallons. Boil the water and dissolve the sugar in it while hot; pour out into an open vessel, and when cooled to about 96° F. add the other ingredients, including the yeast. Let stand 24 hours, then transfer to a clean cask and allow to ferment. Agitate once a day for fourteen days, then bung down and bottle off in about six weeks. Another formula is: Bruised unbleached ginger, 1 lb.; loaf sugar, 28 lbs.; 12 lemons; raisins, 8 lbs.; water, 12 gallons. Peel the lemons, boil the ginger, sugar, and lemon-peel with the water for thirty minutes, and pour the hot liquor on to the raisins previously stoned. When cool, add the juice of the lemons and the yeast, then ferment as above. It may be fined with a little isinglass before bottling, and is improved by the addition of a pint of brandy. [Reply to W. A. S.—21/9.]

INFORMATION WANTED.

CASSARITE.—An article bearing the name of "Cassarite" is made by a firm called Beardall and Metcalf. The address of the firm is required.—(J.A.—21/16.)

STAINS.—Particulars are wanted regarding the composition of Stirling's aniline gentian violet stain and Austin's fuchsine stain. Can any reader oblige?—(X. S.—21/17.)

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

JUNE 30, 1898.

Business has again been exceedingly quiet during the past week the near approach of the turn of the half-year, combined with continued dulness of trade having tended to reduce transactions to a minimum. The changes in value which have taken place have also been comparatively unimportant. Opium is dearer. Quinine after being active, has again relapsed slightly. Bromides have been reduced in price. Quick-silver and Mercurials, Iodine and Iodides, Bismuth and Salts are firm. Cod-liver Oil very quiet. Glycerin firm. Cocaine rather easier. Acetanilide, Phenacetin, and Sulphonal unchanged. Morphia and Codeia quiet. Borax and Acid Boracic without change. Acid Citric and Acid Tartaric firm. Cream of Tartar steady. The following are prices ruling for articles of chief interest:—

ACETANILIDE.—Second hand sellers appear to be getting cleared out. Makers' price remains at 1s. 2d. to 1s. 3d. per lb.

ACID BORACIC.—Unchanged at 23s. per cwt. for crystals and 25s. per cwt. for powder.

ACID CARBOLIC.—Is steady, the best make being still quoted 7d. per lb., for 35 to 36° C. *ice crystals* in 2½ cwt. drums and overcasks. 39 to 40° C. ditto 7½d., and 39 to 40° C. *detached crystals* 8½d. per lb. *Crude* 60° F. 2s. 1d. per gallon; 75° F. 2s. 6d. per gallon. Liquid 95 per cent. of pale straw colour 1s. 2d. to 1s. 3d. per gallon, in 40 gallon casks.

ACID CITRIC.—Is firm at 1s. 1d. per lb. on the spot for crystals in large bulk.

ACID OXALIC.—Steady at 3½d. per lb. for quantity delivered free in London.

ACID TARTARIC.—Continues firm at 1s. 1d. for *English* crystals on the spot; *foreign*, 12½d. per lb.

AMMONIA COMPOUNDS.—*Bromide* lower at 2s. 1d. per lb. *Iodide* steady at 14s. 6d. per lb. *Oxalate* unchanged at 6d. per lb. *Sulphate*, £9 10s. per ton for grey 24 per cent. *Carbonate*, 3d. to 3½d. per lb., according to package. *Sal Ammoniac*: Sublimed firsts, 35s. per cwt.; seconds, 33s. per cwt. *Muriate*: Refined white, chemically pure, B.P., 30s. per cwt.; 98 per cent., 26s. per cwt.; ditto, large crystals for batteries, 27s. 6d. per cwt. *Sulphocyanide*, 1s. 1d. to 1s. 2d. per lb.

ATROPINE.—Firm at 17s. 10d. per oz. for the *pure*, and 15s. 6d. per oz. for the *Sulphate*.

BALSAM COPAIBÆ.—1s. 7d. to 1s. 9d. per lb. is asked for good *Maracaibo*.

BALSAM PERU.—Holders ask 9s. 3d. to 9s. 6d. per lb.

BALSAM TOLU.—1s. 8d. is the price asked.

BISMUTH.—Without change at 5s. per lb. for the *metal* and 4s. 10d. per lb. for the *Subnitrate* in 5-cwt. lots.

BLEACHING POWDER.—Steady at £7 5s. per ton on the spot.

BORAX.—Is very quiet, and *crystals* can be had at 13s. 6d. per cwt., and *powder* at 14s. per cwt.

BROMIDES.—A rearrangement of European prices has been made in order to equalise the quotations of each country, and from to-day the following will be the new prices: Potass. bromide, 1s. 9½d. per lb. Sodii bromide, 2s. 0½d. per lb. Ammon. bromide, 2s. 1d. per lb. for ordinary small quantities,

with the usual reductions for larger lots. Our readers will note from the odd halfpennies how closely the new quotations have been calculated.

BUCHU LEAVES.—There has been some inquiry this week, but holders are asking long prices, which, for the moment, prevents business. Good green rounds are held for 5½d. to 6d. per lb.; yellowish, 4½d. to 5d. per lb.

CAMPHOR.—Market is very quiet at unchanged prices both for *crude* and *refined*.

CASCARA SAGRADA.—Is quiet but firm at about late prices, the anticipated rise having so far not taken place, owing, it is believed, more or less to the fact that there has been so little business doing in the article during past week or two. For old bark 25s. to 27s. 6d. per cwt. is asked, and even 30s. for fine, but last year's bark could be obtained in limited quantity at 22s. 6d. to 24s. per cwt., according to quality and quantity.

CLOVES.—Privately the market for *Zanzibar* is stronger; spot business done at 3½d., and buyers October to December delivery at 3¾d. At auction 465 bales *Zanzibar* bought in at 3¼d. to 3½d., except 25 bales ordinary mixed, which were sold at 2½d. 6 cases dull *Ceylon* bought in at 5d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol* commercial 1s. 5d.; pure, 3s. per gallon. *Benzole*: 50 per cent., 1s. 2d.; 90 per cent., 1s. 1d. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 6d. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 8d.; 90 per cent. at 160° C., 1s. 4d.; 90 per cent. at 190° C., 1s. 3d. per gallon.

COCAINE.—Market is quiet but steady at 9s. 3d. to 9s. 9d. per oz., according to quantity and brand.

CODEIA.—Firm at 11s. 3d. to 11s. 9d. per oz., for *pure*; the *salts* being 1s. per oz. less.

COD-LIVER OIL.—Very quiet, price for best new non-congealing *Norwegian* oil in tin-lined barrels is nominally 82s. 6d. to 90s. per barrel. In *Newfoundland* oil there is nothing doing.

COLOCYNTH.—Further arrivals have taken place, mainly of small *Turkish* apple which are being sold in a retail way at 11d. to 11½d. per lb. Good bold pale apple is held for 1s. 1d. to 1s. 2d. per lb.

CREAM OF TARTAR.—Is fairly steady with, however, but little business passing. First white French *crystals* are quoted 71s. 6d. per cwt.; *powder*, 73s. 6d. to 74s. per cwt. The higher strengths, now in more inquiry in order to comply with the requirements of the new B.P., are firm at 82s. per cwt. for *crystals*, and 82s. 6d. per cwt. for *powder*.

CUTCH.—Holders are firm but business has been on a very small scale. *ACL* held for 24s. 6d. per cwt.

ERGOT OF RYE.—Really good sound Spanish is scarce, and holders ask high prices up to 1s. 4d. per lb., while for sound *Russian* price is 10d. per lb.

ESERINE (PHYSOSTIGMINE).—Price of the *pure* is 4s. per gramme, and of the *Sulphate* and *Salicylate* 3s. per gramme.

GLYCERIN.—Is firm at 53s. to 65s. per cwt. for *German* white double-distilled chemically pure 1260° quality in tins and cases, according to quantity and brand, *English* being obtainable at rather less money.

GINGER.—*Cochin* continues flat, and 566 bags rough were mostly bought in; washed at 22s. to 25s., only 95 bags washed rough being sold at easy rates; ordinary dull, 21s.; fair, 23s. Of cut kinds 17 cases sold; medium and small limed native half-cut at 44s.; 200 bags limed *Japan* sold at 15s. 6d. to 16s.; 1 barrel *Jamaica* sold at 79s.

GOLDEN SEAL ROOT.—The bale reported as being sold at 1s. 3d. per lb. last week "without reserve" should have been stated as heavily sea damaged. Sound root on the spot is worth 2s. per lb.

GUM TRAGACANTH.—The market is firm with, however, but a small trade doing. Such business has been mainly in fourths and lower qualities at £9 10s. per cwt. downwards.

IODIDES—Firm at unchanged prices, viz., 9s. 9d. to 10s. 3d. per lb. for *Potass. Iodide*, 13s. 4d. to 13s. 7d. for *Iodoform*, and 7½d. per oz. for *Iodine*.

IPECACUANHA.—A new arrival of 87 bales from Brazil comes to strong hands, and no reduction in the quotation has taken place. So far nothing can be got under 9s. per lb., and for good bold 9s. 2d. to 9s. 3d. per lb. is asked. *Carthagera* is quiet at about 5s. per lb.

JALAP—Is inquired for. Holders ask 6d. per lb. for fair heavy, but small root.

JAPAN WAX—Continues in very slow demand with a small business in good pale squares at 34s. per cwt.

LITHIA—Is firm at 10s. 8d. per lb. for the *Carbonate* in 2 cwt. lots; 6s. 8d. per lb. for *Citrate crystals*, and 7s. 2d. per lb. for the *Citrate powder*.

MENTHOL—August to September shipment by steamer is held for 6s. 6d. per lb. *c.i.f.* There are buyers at 6s. 3d. Spot price, 6s. 10½d. to 7s. per lb.

MERCURIALS—Firm at 2s. 9d. per lb. for *Calomel* and 2s. 5d. per lb. for *Corrosive sublimate* in quantity.

MORPHIA—Is steady, makers still quoting 4s. 6d. per oz. for the *Hydrochlorate powder* in quantity and in bulk, although in face of the continued rise in value of *Opium* price of *Morphia* should certainly be dearer.

NITRATE OF SILVER.—Price ranges from 1s. 5d. to 1s. 5½d. for *crystals*, according to quantity, the sticks being dearer in proportion.

NITRATE OF SODA—Steady at £7 12s. 6d. to £7 15s. per ton for commercial, and £7 17s. 6d. to £8 per ton for refined.

OILS (ESSENTIAL).—*Star Aniseed*: Very little doing, quotation 6s. 9d. per lb. *Cassia*: For 75 to 80 per cent. cinnamic aldehyde 4s. 7d. per lb. has been paid. *Citronelle*: Quoted 1s. 2d. per lb. *Peppermint*: American slow of sale. HGH has been done at 5s. 6d. per lb. in large lots. Wayne County quoted 3s. 6d. to 3s. 9d. per lb., according to quantity in bulk packing. Japan dull at 3s. per lb. for dementholised and 4s. per lb. for 40 per cent. menthol contents. *Lemongrass* remains quiet but steady.

OILS (FIXED) AND SPIRITS.—*Linseed*: The market has again fallen during the week, but closes steadier at £16 7s. 6d. for spot pipes, and £16 17s. 6d. for barrels, Hull dealer at £16. *Rape*: Dull and rather easier at £22 for ordinary brown on the spot, with refined at £23 10s. *Cotton* dearer, and closes firm at £13 17s. 6d. for London crude spot, and £15 10s. to £16 for refined, according to make. *Olive*: Ordinary green oils steady at £33. *Coconut* quiet at £24 10s. for Ceylon pipes, hogsheads £25 10s. *Cochin*: Spot nominally worth £29 10s. *Palm* lower at £23 *Turpentine* lower at 21s. 3d. per cwt. for American spot, July to December 20s. per cwt. *Petroleum Oil* dull, Russian spot 4½d. per gallon, American 5½d. per gallon. *Petroleum Spirit*: American 5½d.; deodorised 6d. per gallon.

OPIMUM.—Market is very firm, price in *Smyrna* being about 6d. per lb. higher than parity on this side. Here we quote fair *Druggists* 10s. 6d. to 11s. 6d., fair to good *soft shipping* 11s. to 12s. 6d. *Persian* 11s. 3d. to 12s. 3d. per lb., while everything would appear to point in the direction of possible higher prices in the autumn.

PHENACETIN—Quiet at 3s. 9d. to 4s. 3d. per lb., according to make, Bayer's *phenacetin* being still held for the fancy price of 14s. 3d. per lb. in bulk packing.

PERMANGANATE OF POTASH—Continues in demand, price being unchanged at 62s. 6d. per cwt. for *small crystals*, and 67s. 6d. per cwt. for *large crystals*, large lots being obtainable at rather less money.

PILOCARPINE.—Makers still quote 33s. per oz. for 1 oz. lots, price for larger quantity being cheaper.

POTASH COMPOUNDS.—*Chlorate*: Price for early delivery, 3½d. per lb. *Bichromate*: 4d. per lb. *Prussiate*: *Yellow* firm at 6¾d. to 7d. per lb., *Red* 1s. 2d. per lb. *Bicarbonate* unchanged at 30s. per cwt. for crystals or powder. *Bromide* is slightly lower at 1s. 9½d. per lb. *Iodide* steady at 9s. 9d. to 10s. 3d. per lb. according to quantity. *Carbonate*: Pure B.P. 55s. to 60s. per cwt., refined 80 to 82 per cent. 17s. per cwt. *Cyanide* is scarce on the spot at 1s. 2d. per lb. for the 98-100 per cent. cake. *Permanganate* steady at 62s. 6d. to 67s. 6d. per cwt. for small and large crystals respectively.

QUICKSILVER—Is firm at £7 12s. 6d. per bottle from importers and £7 12s. from second hands.

QUININE.—Market, after being somewhat active, 10d. per oz. having been paid for good second-hand *German* brands in 100-oz. tins and cases and for 1000-oz. lots, has since quieted down. There are, however, few sellers below above price. Makers still quote

10d. per oz.; decline, however, to sell to speculators, or, in fact, to anyone except to their regular wholesale customers.

SANTONIN—Unchanged at 4s. 5½d. per lb. in 3 cwt. lots.

SHELLAC.—There is a small but steady demand for spot goods at full rates. For arrival the market is firm, with buyers of *T N* orange, April to June steamer, at 66s. 6d. cwt.

SODA COMPOUNDS—*Crystals* remain firm at 55s. to 57s. 6d. per ton ex ship "Thames." *Ash* is dearer at £5 5s. to £5 15s. per ton according to strength and package. *Bicarbonate*: The commercial 98 per cent. is steady at £7 5s. to £7 10s. per ton, whilst the chemically pure free from mono-carbonate is unchanged at 18s. 6d. per cwt. *Caustic*, 70 per cent., £8 5s. per ton; 60 per cent., £1 per ton less. *Bromide* lower at 2s. 0½d. *Iodide* unchanged at 11s. 7d. per lb. *Sulphide*, for tanners' use, £7 5s. per ton.

SPICES (VARIOUS).—*Black Pepper*: 29 bags Malabar sold at 4½d. to 4¾d. *White Pepper*: Penang bought in at 7¾d., and Siam at 8d. Of Singapore 50 bags sold, fair 7¾d., good bold bright, 8½d. *Chillies*: 5 cases good Japan sold without reserve at 34s. 6d. *Cinnamom Chips*: 16 bags Ceylon sold at 4¾d. *Mace*: 32 cases Penang bought in, pickings 1s. 5d., low middling red 1s. 9d. 7 boxes Singapore bought in at 1s. 9d., 1 box West Indian sold at 1s. 5d. *Nutmegs*: dull, 38 cases Penang bought in, 65's at 2s. 5d., 80's at 1s. 10d., 108's at 1s. 3d.; 84 boxes Singapore sold, 114's at 1s. 2½d., 150's partly shrivelled 9½d., shrivelled 6d.

SUGAR OF LEAD.—*Foreign* is very firm at the late advance to 27s. 6d. per cwt. *English* 30s. to 31s. per cwt.

SULPHATE OF COPPER—Is very dull of sale, and quotations on the spot are easier at £15 to £16 per ton, according to brand.

SULPHONAL—makers continue to supply in limited quantities at 7s. 3d. per lb. for bulk packing.

SULPHUR—Is firm. *Foreign* roll 6s. 6d. per cwt., *Foreign* flowers 7s. per cwt., *English* roll 7s. 6d., per cwt., *English* flowers 9s. per cwt.

TURMERIC.—Whilst business is limited, holders continue very firm, and for *Bengal* finger 17s. 6d. per cwt. has been paid, 23s. per cwt. for fair *Madras* finger, and 19s. 6d. per cwt. for fair pale *Madras* bulb. *Cochin* split bulbs are held for 9s. 6d. to 10s. per cwt.

Newcastle Chemical Report.

JUNE 29, 1898.

Whilst prices are stationary, a shade more business found to be passing, but principally against shipping orders. Soda Crystals for the Channel ports are in more request, and Sulphur moving with a better tone. Prices are:—Soda Crystals: 45s. to 52s. 6d. Bleaching Powder: £6 5s. to £6 10s. Caustic Soda: 70 per cent., basis, £7 5s. to £7 10s. Soda Ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. Sulphur: £5 per ton.

Liverpool Market Report.

JUNE 29, 1898.

During the week large sales of Chilian Honey have taken place at fully recent rates, besides miscellaneous transactions in West African Ginger, Chillies, and South American Beeswax at satisfactory prices. The indication of higher rates for Calcutta Castor Oil mentioned a short time since has been confirmed, and at present a very steady tone characterises the market. Cottonseed Oil and Spirits of Turpentine are both lower in price, but Spanish Olive Oil has advanced 7s. 6d. per tun. The trade in heavy chemicals from Liverpool is very depressed, and prices generally may be regarded as nearly nominal.

AMMONIA SULPHATE—Is a turn firmer; £9 3s. 9d. to £9 5s. per ton.

BEESWAX.—Peruvian has been sold at £7 2s. 6d. to £7 7s. 6d. per cwt.

CANARYSEED.—Turkish is quoted at 25s. to 26s. 6d. per 464 lbs., but the demand is very circumscribed. A parcel of Spanish seed sold at 35s. per 464 lbs.

CHILLIES.—Sierra Leone fruit has found buyers at 40s. per cwt.

CREAM OF TARTAR—Is in quiet demand at 78s. 6d. per cwt. for "finest white."

GINGER.—32 bags of Sierra Leone brought 17s. 6d. per cwt.

HONEY.—Good sales of Chilian are reported—some 200 barrels in all—at 27s. to 28s. per cwt. for Pile X, 24s. for Pile 1, 22s. for Pile 2, and 21s. for Pile 3.

LINSEED.—No sales are reported, though buyers might have Calcutta out of store on easier rates than those obtained of late.

OILS.—*Castor* has commanded a good share of attention, and Calcutta "good seconds" cannot be had here under 3½d. per lb. French 1st pressure is quoted at 3½d. to 3¾d., and Madras at 3½d. per lb. *Olive*: Early in the week Spanish oils ranged from £28 10s. to £29 10s. per tun, but an advance of 7s. 6d. per tun has since taken place. *Linseed*: Liverpool pressed is steady at 18s. to 18s. 6d. per cwt. *Cottonseed* is extremely slow of sale at 15s. 9d. to 16s. 3d. per cwt. *Spirits of Turpentine* has rapidly subsided to 22s. per cwt., owing to recent large arrivals in port.

POTASH AND SODA SALTS—Unchanged since last report.

Manchester Chemical Report.

JUNE 29, 1898.

There is again a poor report concerning heavy chemicals, except perhaps Ammonia, Alkali and Soda Crystals, which are firm. Bleaching Powder is quotably 2s. 6d. lower, and ranges from £5 2s. 6d. to £5 7s. 6d. per ton soft-wood casks on rails. Bicarbonate of Soda is steady. Owing to a reduction in freights, and a better supply, American Brown Acetate is lower at £5 5s. per ton *c.i.f.* Welsh varies from £5 5s. to £5 10s. at station, Manchester, 2s. 6d. less delivered by canal. Benzols are unchanged, but Naphthas are scarce, Miscible being scarcely obtainable at even 4s. 3d. per gallon. Sulphate of Copper is dull at £16 10s. to £16 15s. per ton best brands here. Green Copperas rules firm and is in good inquiry at late rates. Yellow Prussiate scarce at 7d. per lb. for best Lancashire make.

News in Brief.

EDINBURGH DISTRICT CHEMISTS' GOLF CLUB.—The third competition this season for the Gibson Handicap Medal was played last week over the Braids course, with the following results:—1st, A. C. Kirkpatrick, 93 (scratch); 2nd, W. C. Baker, 107 less 12 equals 95; 3rd, Jas. Stott, 95 plus 6 equals 101.

APPLICATIONS are invited from pharmaceutical chemists for the post of Senior Dispenser at University College Hospital. The salary is £150 per annum and half the fees paid by dispensing pupils. Further particulars may be obtained from the advertisement which appears in this issue.

PHOSPHORUS POISONING.—At Gloucester last week Messrs. Moreland & Sons, match manufacturers, were summoned by the local Inspector of Factories for failing to notify a case of necrosis and one of phosphorus poisoning which had occurred at their works. The first summons was dismissed, it being shown that the defendants had not been made aware of the fact. On the second a technical offence was admitted, and a fine of 10s. and costs £2 6s. 6d. was imposed.

THE NEW VOLUME of the Badminton Library on "Rowing," by R. P. P. Rowe and C. M. Pitman, contains an additional chapter on "Punting" by P. W. Squire.

OWENS COLLEGE, MANCHESTER, has now a separate library building and an adequate college hall, two things, which until Wednesday, June 22, it lacked. The Duke of Devonshire opened the new buildings, which have been presented to the college by Mr. R. C. Christie.

MANCHESTER COLLEGE OF PHARMACY.—On Saturday last the students of this College paid a visit to the Botanical Section of the Manchester Museum, where an interesting lecture on the life-history of the principal cryptogams was delivered by Mr. F. Pilkington Sargeant, Ph.C. The party afterwards proceeded to the Royal Botanical Gardens, Old Trafford, where the various medicinal plants were described in detail, and an examination was made of the splendid collection of orchids. The natural order

beds, which abounded with specimens of interest to the pharmacist, were then reviewed, a hearty vote of thanks to Mr. Sargeant concluding a very pleasant and instructive afternoon.

BIRMINGHAM DRUGS TESTED.—The City Analyst for Birmingham has issued a report dealing with the first quarter of the year, in which he states that of nine samples of compound tincture of benzoin submitted, three were found to be adulterated. One was deficient in solid ingredients to the extent of 23 per cent., and the vendor was cautioned. Another was adulterated with 20 per cent. of water and 25 per cent. of glycerin, as well as being deficient in solid ingredients to the extent of 65 per cent. In this case the vendor was fined £1 and 9s. costs. In the third case there was a deficiency of 16 per cent. of solid ingredients, and a caution was administered. Four of five samples of tincture of iodine were of the correct composition. The fifth contained 17 per cent. of iodine in excess of the proper quantity. No action was taken, as the vendor was prosecuted in respect of one of the samples of benzoin already referred to. Of eight samples of tincture of rhubarb analysed, seven were of satisfactory quality. One contained a little suspended vegetable matter, but was otherwise of the correct composition.

IRISH PHARMACY ACT CASES.—On June 23, a Petty Sessions Court, consisting of Mr. H. Turner, R.M., Mr. Chesterton, and Mr. R. Garstin, sat at Castle Bellingham, County Louth, to hear summonses at the suit of Police Sergeant M'Donagh, Inspector of Weights and Measures for the police district of Castle Bellingham, against two traders of the town—Mr. James Gannon and Mr. Stephen Butterly—for "keeping open shop for retailing and dispensing poisonous compounds within the meaning of the Poisons Act of 1870, and selling and retailing and dispensing a poison contrary to the Pharmacy Act (Ireland), 1875, defendants not being properly qualified to do so." The first-named defendant had sold a bottle of "Calvert's carbolic acid" and a bottle of "M'Dougall's sheep dip" to complainant; and Mr. Butterly had sold a tin of "Medcalf's cough syrup and elixir" to a police-constable named David Coughlan. In the first case it was urged for the defence that for twenty-seven years after the passing of the Act carbolic acid was not considered to be a poison under the Act, and it was only last year that it was made so by being scheduled in the *Gazette*, which was never seen by country shopkeepers. As a matter of fact, the sale of the bottle was quite unintentional, as it was only intended for Mrs. Gannon. An assistant in the shop of Mr. Gannon said he had given the bottle to Sergeant M'Donagh by mistake, thinking it was on the premises for sale, while in reality it was for Mrs. Gannon's private use. The Bench imposed a fine of £5 for this offence. The other summons with reference to M'Dougall's sheep dip was withdrawn by Mr. Day. The summons against Mr. Butterly was then gone into in reference to the selling of "Medcalf's cough syrup and elixir," and the offence being held proved, a fine of £5 was inflicted on defendant.

MESSRS. C. J. HEWLETT & SON'S staff and employes held their annual excursion on Saturday, June 25, when a large party went to Eastbourne. Several of the staff in the morning paid a visit to Beachy Head, where lunch was provided. Dinner was served at the Pier Hotel in first-class style; the toast of the firm was proposed by Mr. S. Hale, and responded to by Mr. E. J. Tucker, Chairman. In the afternoon arrangements were made to visit Pevensey Castle. After tea the return journey was safely accomplished and London reached by 11.30. Thanks to the splendid weather and the liberal arrangement, a most enjoyable day was spent.

ACCIDENT TO A BIRMINGHAM CHEMIST.—An unfortunate accident happened on Saturday to Mr. Wm. Adams, chemist, Dudley Road, Birmingham. Whilst engaged in the cellar, Mr. Adams handled a bottle containing spirits of collodion, when it suddenly burst and the contents ignited. Mr. Adams was severely burned about the hands and arms, and the flames quickly got hold of the goods stored in the cellar. A number of policemen were quickly on the spot, and succeeded in extinguishing the flames. Being members of the St. John Ambulance Association, they were also able to render Mr. Adams first aid.

EXCHANGE

Offers & Wants

OFFERED.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

Books.

'Year-Books of Pharmacy,' 1879 to 1897. Nest of 66 Drawers (painted), 13 ft. by 3. Wanted, Safe.—J. E. Allenby, Hemsley.

Two vols. 'History Scotland,' 2s.; 4 vols. Boyle's Works, 15s.; 1 vol. Humfrey Davy's Works, 5s.; 'Billiards' (Captain Hawley), 1s.; Wat Tyler, Pierce Egan, 5s.; 'Guide to Soap-making,' 1s. 6d.; Sykes' 'Hydromotor,' 30s.—Garforth, Chemist, Sheffield.

Miscellaneous.

Magic Lanterns, second-hand; triples and binoculars; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

Complete Fittings for Chemists' Shop, new and good, sell whole or part.—Apply, Business, 64, Linthorpe Road, N.

WANTED.

Upright Case for front of desk on counter, about 25 by 25 in.; need not be plate glass; must be cheap. Particulars to—"Chemist," 1, Archer Street, Bayswater.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Trade Notes.

SOUTHALL BROS. AND BARCLAY, LTD.—We learn that the shares in this company have been applied for several times over, and that letters of allotment and regret will be issued on Monday next.

MESSRS. BARCLAY & SONS, LTD., of Farringdon Street, have introduced, under the name of "The Komphy," a useful appliance for lady cyclists. It consists of two inflated rubber pads, joined by a band, and to be attached to the corset. This appliance, which retails at 7s. 6d., has been devised by a lady cyclist for comfort in riding and to prevent undue pressure.

THE "VALTINE" MEAT GLOBULES, referred to last week, are, it should be stated, the invention of Mr. Charles R. Valentine, who has for some years been connected with the manufacture and handling of extract of meat in bulk from our Australian colonies, and who delivered an important lecture on "The Preparation of Meat Extracts" before the Society of Arts in March last.

MESSRS. BURROUGHS, WELLCOME AND Co. submit specimens of their bismuth subgallate tabloids, each of which contains 35 grains. The internal administration of bismuth subgallate has lately received considerable attention, the compound having been favourably reported on in various forms of diarrhoea and in fermentative dyspepsia. Bismuth subgallate is insoluble in water or alcohol, and it is best administered compressed and in a dry state. The rapid disintegrating property of bismuth subgallate in tabloid form, and its great convenience especially when, as in chronic cases, it is necessary that the doses be taken regularly and for a considerable period, render it a reliable and acceptable form for the administration of the drug.

Receiving Orders in Bankruptcy.

(From the London Gazette.)

Alfred Howell Atkin, physician and surgeon, Theobald House, Rochester, Kent.

Joseph Dallaway, drysalter, 54, Hereford Street, Sheffield.

Owen Mills, drug dealer, 46, High Street, Bethesda, Carnarvonshire.

(Received too late for Classification.)

NORTH OF ENGLAND HEALTH RESORT.—Light Retail and Dispensing BUSINESS for sale. About 3000 prescriptions yearly at good prices. Corner shop, well fitted and fully stocked. House attached. Satisfactory reason for disposal. Price £800. No reasonable offer refused. Must sell soon. Address, STATIM, "Pharm. Journal" Office, 5, Serle St., London, W.C.

Partnerships Dissolved.

(From the London Gazette.)

Joseph Parkin and Allen Roberts, manufacturing chemists Union Mills, Beck Lane, Heckmondwike (trading as Joseph Parkin & Co.). Debts will be received and paid by Allen Roberts.

Frank Flood and George Robert Fisher, chemists, Leamington (trading as Fisher & Flood). Debts will be received and paid by George Robert Fisher.

Frederic William Skrimshire and Arthur Brumell, surgeons, Morpeth.

Charles Edward Oakeley and Reginald Frederick Tencken, physicians and surgeons, 200, Ivydale Road, Nunhead, London, S.E.

John Senior Boothroyd and Henry Brunton Kitchin, general medical practitioners, Deptford.

Charles Armstrong Sharp and Charles Joseph Allan, trading as chemists and druggists at 36, Newcomen Street, Coatham, Redcar, under style of Sharp and Allan. Debts will be received and paid by C. J. Allan.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Barrett, Baylis, Bott, Brown, Campkin, Chambers, Clarke, Cockburn, Gifford, Goldby, Hacking, Howlett, Hill, Hirst, Hooper, Jackson, Kershaw, Kirkby, Kluge, McKellar, Morgan, Perréds, Pickering, Reynolds, Russell, Suddaby, Thomas, Wavell, Wood, Young.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the price quoted and those of the wholesale drug trade.

JULY 7, 1898.

Past week has been characterised by extreme quietness in the Drug and Chemical Trades. Transactions have been limited, while the changes which have taken place are of quite minor importance. Quinine is steady at makers' prices. Quicksilver and Mercurials, Bromine and Bromides, Iodine and Iodides unchanged. Cocaine firmer and expected to be dearer. Acetanilide, Phenacetine and Sulphonal quiet. Eserine (Physostigmine) lower. Borax and Boracic Acid quiet, Acid Citric firm, with higher prices expected. Acid Tartaric and Cream of Tartar steady. Glycerin firm. Cod-liver Oil inactive. Opium firm. Morphia and Codeia steady at unchanged prices, an advance in price being confidently predicted, especially for the former. Cocoa Butter decidedly dearer. Sulphate of Ammonia dull and lower. Following are values of articles of principal interest:—

ACID BORACIC—Steady at 23s. to 24s. per cwt. for *crystals*, and 25s. to 26s. per cwt. for *powder*.

ACETANILIDE.—Makers' price is 1s. 2d. to 1s. 3d. per lb., while there are sellers from second hand at something below these figures.

ACID CARBOLIC.—Best makers still firm at 7d. per lb. for 35-36° C. *ice crystals* in bulk packing, other qualities in proportion. *Crude and Liquid* unchanged from last week.

ACID CITRIC—Very firm at the advance, to 1s. 2d. per lb. for *crystal*.

ACID TARTARIC—Is steady, *English* on the spot 1s. 1d. per lb. for *crystals* and *Foreign crystals* at 12½d.

ACID TANNIC.—Price of the *leviss.* B.P. quality varies from 1s. 7½d. to 1s. 8½d. per lb. in 1-cwt. cases according to quantity and make.

ACID OXALIC—Firm at 3¼d. to 4d. per lb., according to quantity.

AMMONIA COMPOUNDS.—*Bromide* steady at the late reduction to 2s. 1d. per lb. *Iodide* unchanged at 14s. 6d. per lb. *Oxalate* firm at 6d. per lb. *Sulphate* dull and lower at £9 6s. 3d. per ton, for grey prompt 24 per cent. London. *Carbonate* 3¼d. to 4d. per lb., according to package. *Sal ammoniac*: Sublimed firsts 35s. per cwt.; seconds 33s. per cwt. *Muriate*: Refined white chemically pure 30s. per cwt.; 98 per cent. 26s. per cwt.; ditto large crystals for batteries 27s. 6d. per cwt. *Sulphocyanide* 1s. 1d. to 1s. 2d. per lb.

BLEACHING POWDER—Weak at £7 per ton on the spot.

BORAX—Quiet, *lump* at 13s. 6d. to 14s. per cwt., with *powder* 6d. per cwt. more.

BROMIDES—Unchanged from last week at 1s. 9½d. per lb. for *Potass. Bromide*, *Bromine* being still quoted 1s. 11d. per lb. in 20 case lots.

CLOVES.—Privately *Zanzibar* are steady on spot, but rather easier for delivery. Spot business done at 3½d., August to October delivery quoted 3½d., and October to December 3½d.

At auction 309 bales *Zanzibar* bought in at 4d., also 18 cases picked *Penang* at 11d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 5d.; pure, 2s. 9d. per gallon. *Benzole*: Fifty per cent, 1s. 1d.; 90 per cent, 1s. *Crude Naphtha*: Thirty per cent at 120°C., 5d. *Solvent Naphtha*: Ninety-five per cent. at 160°C., 1s. 8d. per gallon.

COCAINE.—While makers' prices are nominally unchanged at 9s. 3d. to 9s. 6d. for the *Hydrochlorate* in 100-oz. lots, in 25-oz. tins, there is a decided feeling that higher prices will prevail ere long, looking at the actual low price. Buyers will probably do well to cover their future requirements before the anticipated rise takes place.

COCOA BUTTER.—On Tuesday 400 cases (40 tons), Cadbury's sold at an average price of 10½d. per lb, a rise of 1d. per lb. on the June auctions.

CODEIA—Steady at 11s. 3d. to 11s. 9d. per oz. in bulk packing, according to quantity.

COD-LIVER OIL—Is at the moment practically a dead letter, although the time is gradually drawing near when buyers will be thinking of laying in their stock for the coming autumn, winter, and spring. Nominal quotations for the best new non-congealing *Norwegian* oil remain at 85s. to 92s. 6d. per barrel, *f.o.b.*, in 25-gallon, tin-lined barrels.

CREAM OF TARTAR—Is quiet, but very firm at 71s. 6d. per cwt. for *First White crystals* on the spot; *B.P.* quality is strong at 82s. 6d. per cwt. for *crystals*, and 85s. per cwt. for *powder*.

ESERINE (PHYSOSTIGMINE).—The three makers who had agreed amongst themselves to advance the price to 3s. per gramme for the *Sulphate* and *Salicylate*, and 4s. per gramme for the *Pure*, have as suddenly reduced their price to 2s. and 3s. per gramme respectively. No reason is given for this reduction, which may, however, be fairly assumed to be due to the fact that the previous high prices were hardly justified by the cost of the raw material and of manufacture. It remains to be seen how long present prices will be maintained.

GINGER—*Cochin* continues dull, and of rough kinds only 240 bags sold at easier rates; cuttings 12s. 6d., rough ends 15s., common washed rough 19s. 6d., fair washed rough 21s. to 22s. Of cut kinds, 34 cases ordinary B cut sold, without reserve, at 60s. *Jamaica* also sold at lower rates, low middling dull to middling 73s. to 78s., good middling to good 80s. to 84s., fine in half-barrels 92s.

GLYCERIN—Is very firm at 55s. to 65s. per cwt., according to brand. *German* white, double distilled, chemically pure 1260° quality in 2-cwt. cases, 4 by 56-lb. tins in a case. *English* being obtainable at rather less money.

GUM TRAGACANTH.—For medium and lower grades the demand is very good, and fair sales have been made at full values. Quotations range from £13 10s. for firsts down to £7 10s. for yellow.

IODIDE.—Without change at 10s. 3d. per lb. for *Potass. Iodide* and 13s. 7d. per lb. for *Iodoform*. *Iodine* is still quoted 7½d. per oz.

JAPAN WAX—Quiet at 34s. per cwt., but no buyers thereat.

MERCURIALS—Unchanged at prices quoted last week, viz., 2s. 5d. per lb. for *Corrosive Sublimite*, and 2s. 9d. per lb. for *Calomel*.

MORPHIA—Still without change at 4s. 6d. for the *Hydrochlorate salt* in powder.

OILS (ESSENTIAL).—*Peppermint* very quiet, American *H G H* slow of sale at 5s. 6d. to 5s. 7½d. per lb. *Wayne County*, 3s. 8d. to 3s. 9d. per lb. *Star Aniseed* slow of sale, 6s. 9d. per lb. *Cassia*, 4s. 7d. to 4s. 8d. per lb. for 75 to 80 per cent. *Cinnamic Aldehyde*. *Lemongrass* firmer at 4½d. per oz. on the spot. *Citronelle* steady at 1s. 1d. per lb. for drums and 1s. 2d. per lb. for tins,

OILS (FIXED) AND SPIRITS.—*Linsced* quiet and shade easier. On the spot, pipes, London, £16 17s. 6d. ; barrels £16 15s. *Rape* very dull, and rather lower at £21 10s. for ordinary brown on spot ; refined spot, £23. *Cotton* quiet, London crude spot £13 15s. Refined spot £15 10s. to £16, according to make. *Olive* : Green oils unchanged at £33 per ton. Eating oils quiet at 5s. to 6s. 6d. per gallon. *Coconut* lower at £24, for *Ceylon* in pipes on the spot. *Cochin* spot nominal £29. *Palm* again lower at £22 10s. for Lagos on the spot. *Turpentine* lower at 21s. per cwt. on the spot. *Petroleum* : The oil is quiet at 4½d. per gallon for Russian on the spot and 5½d. per gallon for American. *Spirit* : American 5¼d. per gallon.

OPIUM—Market is firm, prices being a shade harder than last week, a further advance being considered not improbable.

PERMANGANATE OF POTASH.—Quiet at 62s. 6d. and 67s. 6d. per cwt. respectively for *small* and *large* crystals in 1-cwt. kegs.

PHENACETIN—Is quiet at 3s. 9d. to 4s. 3d. per lb. for *cryst.* and *powder*.

PHENAZONE.—Is again being offered at very low prices, down to 14s. per lb. in quantity and bulk for both *powder* and *crystal*. *Antipyrine Knorr* is still firmly held by makers at 2s. 1½d. per oz. in 1-oz. tins.

POTASH COMPOUNDS.—*Chlorate* is steady at 3½d. per lb. on the spot. *Bichromate* : 4d. to 4½d. per lb. *Prussiate* : Yellow dearer at 7d. to 7½d. per lb. ; red 1s. 2d. per lb. *Bromide* firm at 1s. 9½d. per lb. *Iodide* unchanged at 9s. 9d. to 10s. 3d. per lb. *Cyanide* continues scarce on the spot at 1s. 2d. per lb. for the 98 to 100 per cent. cake. *Permanganate* quiet at 62s. 6d. for small and 67s. 6d. for large crystals. *Bicarbonate* : 30s. per cwt. for crystals or powder.

QUICKSILVER.—First hands continue firm at £7 12s. 6d., second hands taking orders at 6d. less.

QUININE—Is quiet with, however, a firm undertone. Makers' price remains nominally 10d. per oz., for the *Sulphate* in 100 oz. tins for 1000 lots, while second-hand holders are firm at this figure, very little being obtainable below 10d., and that not of brands most in favour.

SARSAPARILLA.—*Mexican* is scarce on the spot, but further arrivals are expected ; 5d. to 6d. per lb. is asked on the spot.

SHELLAC.—Demand has not improved since our last ; holders, however, are very firm and prices are well maintained. At the fortnightly sales on Tuesday out of the 281 cases offered only 86 cases sold. *TN* remains unchanged at 64s. per cwt.

SODA COMPOUNDS.—*Crystals* firm at 57s. 6d. per ton ex ship London. *Ash* firm at £5 5s. to £5 15s. per ton, according to strength and package. *Bicarbonate* firm at £7 10s. per ton for the commercial 98 per cent. ; the chemically pure, free from monocarbonate, 18s. 6d. per cwt. *Bromide*, 2s. 0½d. per lb. *Iodide*, 11s. 7d. per lb. *Sulphide* : £7 10s. per ton.

SPICES (VARIOUS).—*Black Pepper* : Lampong bought in at 4¼d., and Tellicherry at 4½d. ; 55 bags good clean Wynaad sold at 4½d. *White Pepper* : 58 bags Penang sold at 7½d. *Chillies* : 20 bales second-class damaged Zanzibar sold at 27s. *Mace* : 7 cases Penang pickings bought in at 1s. 5d. ; 15 packages West India sold at 1s. 4d. to 1s. 6d. *Nutmegs* firm at about previous rates. *Pimento* : 71 bags sold, ordinary grey to fair at 4¼d. to 4½d.

SUGAR OF LEAD.—*Foreign* is very firm at 27s. 6d. per cwt. *English*, 30s. to 31s. per cwt.

SULPHATE OF COPPER—Firm at £15 10s. to £16 10s. per ton, according to brand and quantity.

SULPHUR—Firm. *Foreign* roll, 6s. 6d. per cwt. ; *flowers*, 7s. per cwt. *English* roll, 7s. 6d. per cwt. ; *flowers*, 9s. per cwt.

SULPHONAL—Is still obtainable in limited quantity at 7s. 3d. per lb. in bulk packing.

To DAY'S drug auctions passed off extremely quiet, a very considerable number of the lots offered being bought in, while the changes in price which took place were of practically very little importance, although some were chiefly rather in a downward direction.

AMBERGRIS—Is in good demand, and fine quality is becoming scarce. In the auctions 5 tins together, about 24 ozs., sold subject to owner's approval at 5s. per oz. for black heavy, with sandy coat and of very weak flavour.

ANTIMONY.—40 cases crude *Japan* held for 24s. per cwt.

ANATTO SEED.—3 bags dark sold very cheaply at 1d. per lb.

ASAFETIDA.—29 cases of nicer quality than seen for some time past sold in part at 70s. per cwt. for fine soft pinky almondly block, part loose, being a very cheap lot.

BALSAM COPAIBA.—3 cases fair *Maranham* but rather cloudy were held for 1s. 11d. per lb.

BALSAM TOLU.—7 cases held for 1s. 7d. for good flavour but rather softish.

BIRD LIME.—8 cases *Japanese* sold at 3½d. per lb.

BUCHU LEAVES.—18 bales of good green sold at 4½d. per lb., marking no alteration in value.

CARDAMOMS.—About 250 cases were offered, and sold at irregular but, on the whole, steady prices. Fine bold pale *Mysore* sold at 3s. 10d. per lb. ; good ditto, 3s. 1d. to 3s. 4d. per lb. ; small, 2s. 5d. to 2s. 9d. per lb. ; decorticated, 2s. 8d. to 2s. 10d. per lb.

CASTORUM.—2 small boxes sold at 21s. per lb. for fair thirds.

CINCHONA BARK.—32 bales cultivated flat *yellow bark* sold at 8d. per lb. for sound, down to 3½d. for badly damaged ; 3 bales *Mara-caibo*, small to medium, bought in at 7d. per lb. ; 5 bales, fair, bright chips, *Ceylon Cinchona*, sold at 2d. to 2½d. per lb.

COLOCYNTH.—6 cases Turkish, fair apple, part small and broken, and slightly brownish held for 1s. per lb.

COLOMBO ROOT.—19 bags bought in at 50s. per cwt. for good bold picked washed, 191 bags dark stalky, slightly mouldy, part sold at 16s. per cwt.

COCA LEAVES—4 bales fair green *Truxillo* sold cheaply without reserve at 4d. per lb.

CROTON SEEDS.—1 bag bought in at 75s. per cwt.

CUBEBS—62 bags fair quality, slightly dark, bought in at 30s. per cwt.

CUTTLEFISH.—3 cases sold at 1¼d. per lb. for medium, slightly dark, part small, and 2½d. for fair bold, part broken.

DILL SEED.—56 bags fair quality sold cheaply without reserve at 15s. per cwt.

DRAGON'S BLOOD.—Stocks of this article have fallen very low, and in auction only 1 case dark slabs rather damp was offered, but no one wanted it, at £5—the price asked. *Reed* has been sold privately at £9.

ESSENTIAL OILS.—6 cases *Nutmeg* bought in at 3d. per oz. 14 cases *Cajeput* held for 3s. 7½d. per bottle, part having been sold previously at price which did not transpire. 2 cases *James B. Horner's Oil of Wintergreen* bought in at 5s. 6d. per lb.

GAMBOGE—Is in demand, and privately sales have been made at full rates. In the auctions 10 cases ricey Saigon was held for £5 10s. Good bright broken pipe, but soft and slightly drossy, being held for £8 per cwt.

GENTIAN ROOT.—15 bales held for 19s. 6d. per cwt. for fair small dry part rather dark root.

GUM ARABIC.—Good white grain was bought in at £6 10s. to £7 per cwt. ; fair white picked at £14. 12 bags and 2 cases low *East Indian* gum held for 25s. per cwt.

GUM ELEMI—25 cases fair pale sold at 25s. 6d. per cwt.

GUM BENJAMIN—32 cases low to medium seconds *Sumatra*, bought in at £5 5s. to £6 10s. ; 11 cases *Siam*, sold at 57s. 6d. per cwt. for common blocky siftings.

GUM AMMONIACUM—8 cases good clean blocky, part loose, held for 50s. per cwt.

GUM MYRRH.—Medium to fair sorts held for 50s. to 65s. per cwt., down to 20s. for low and inferior.

HONEY—45 packages *Jamaica*, part sold at 19s. to 20s. per cwt. for a medium quality ; fair *New Zealand* realised 25s. per cwt. ; and fair *Queensland* 21s. per cwt.

IPECACUANHA.—Notwithstanding late arrivals holders of *Rio* continue to demand full prices, seeing which a certain amount of buying took place—6 bales sold at 9s. per lb., and 5 bales at 8s. 11d., being very slightly lower than last auctions. *Carthage* : 11 bales sold at 4s. 9d., 1 bale 4s. 10d. per lb., being slightly easier. Other lots held for 5s. per lb.

KAMALA.—4 cases fair bright bought in at 7d. per lb.

KOLA NUTS.—24 bags bought in at 3d. per lb.

LIQUORICE ROOT.—5 bags each nett about 1 cwt. good cut decorticated bought in at 40s. per cwt.

MENTHOL.—2 cases good white dry crystals, *Kobayashi* brand, were taken out at 7s. per lb.

MUSK.—2 caddies, good pile 3, thin skin, blue, and grey and brown *Tonquin* held for 42s. 6d. per oz. ; 4 caddies ditto low, unsightly, and damp sold at 11s. 6d. to 12s. per oz.

NUX VOMICA—For 114 bags good bold pale *Cochin*, a bid of 9s. 6d. per cwt. was refused, 10s. 6d. per cwt. being asked.

ORANGE PEEL.—22 packages bought in, prices being 5d. per lb. for thick cut, and 8d. per lb. for thin cut.

PATCHOULI LEAVES.—12 bales of fair quality, but slightly musty, were bought in at 4d. per lb.

PODOPHYLLIN RESIN.—36 tins, brand McKesson and Robbins, New York, sold at 7s. to 7s. 3d. per lb.

QUINCE SEEDS.—Good red Cape are firmly held at 1s. 6d. per lb., but this price was not obtainable at the auctions.

RHATANIA ROOT.—6 bales bought in at 6½d. per lb.

RHUBARB.—Good bold round *Canton* held for 1s. 4d. per lb.; ditto second size for 1s. 1d.; good grey trimming root for 1s. 3d.; ditto small part trimming root for 1s. 5d.; 1 case rough pickings round and flat sold for 10d. per lb.; bold flat *Canton* dull coat held for 1s. 8d. per lb.; ditto medium size for 1s. 3d. per lb.; 1 box flat *Shensi* high-dried sold at 11d.; dull coated flat high-dried half grey and dark mixed size held for 1s. per lb., a bid of 9d. being refused: common rough wormy round high-dried held for 6½d. to 8d. per lb., a bid of 6d. per lb. for one lot being declined; fine bold round *Shensi* held for 3s. 3d. per lb.; medium ditto for 1s. 9d. down to 1s. 4d.; bold flat ditto ¾ good, ¼ dark, for 2s. 4d. per lb.

SARSAPARILLA.—2 bales fair *Jamaica* sold at 1s. 8d. per lb.; 3 bales ditto 1CCD at 1s. 6d. per lb.; 7 bales good ditto, part rather coarse, held for 1s. 10d. per lb.; 1 bale red native for 1s. 2d. per lb. 22 bales *Lima* held for 1s. 2d. to 1s. 3d. per lb. 1 bale very rough, catalogued as *Lima*, held for 1s. 1d. per lb. 4 serons good *Honduras* held for 1s. 8d. per lb.

SENA.—Very little *Tinnevelly* from first hands was offered, such as there was being small spotty leaf, which sold at 2d. to 2½d. per lb.; pods, 1½d. per lb. A further arrival of about 150 bales is expected to arrive next week. *Alexandrian*: Siftings of dark colour sold at 2½d. per lb., being cheap.

SENEKA ROOT.—3 bales, very chumpy, being practically all chumps, sold at 11½d. per lb.

SQUILLS.—15 bales bought in at 2½d. for fair pale seconds up to 4d. per lb. for good bold.

STROPHANTHUS SEEDS.—2 bags, fair *Kombé*, bought in at 3s. 3d. per lb.

TONQUIN BEANS.—8 cases *Para*, held for 1s. 9d. per lb., for fair frosted.

VANILLA.—Was in small supply which sold in part at rather firmer rates.

WAX.—50 cases fair *Japan* in squares sold cheaply without reserve at 32s. to 32s. 6d. per cwt. 12 packages *Jamaica* sold at £6 15s. to £7 for fair to good quality. Fair *Australian* bought in at £7 5s. per cwt.

Newcastle Chemical Report.

JULY 6, 1898.

With the exception of more shipping orders passing for new goods there is little new business to report. Sulphur is somewhat scarce, and very firm at quotation. Prices are:—Bleaching Powder, according to market, £6 5s. to £6 10s. Soda Crystals: basis, 45s. to 52s. 6d. Caustic Soda: 70 per cent. basis, £7 5s. to £7 10s. Soda Ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. Sulphur: £5 per ton.

Liverpool Market Report.

JULY 6, 1898.

Business has been of a steady character during the week, though there has not been much variety in the goods handled. Good sales of Ginger have been effected, and two lots of dried Kola Nuts changed hands at recent rates. In Heavy Chemicals there is an improved inquiry, with better tone as regards Sulphates of Copper and Ammonia.

AMMONIA SALTS.—*Carbonate*: 3d. per lb. *Sal Ammoniac*: 33s. to 35s. per cwt. *Sulphate* again dearer at £9 7s. 6d. to £9 8s. 9d. per ton.

BLEACHING POWDER.—Is quiet at £5 10s. to £6 per ton.

CANARYSEED.—Turkish is rather more inquired after, and 250 bags sold for 25s. 6d. per 464 lbs.

COPPERAS.—38s. per ton Lancashire; 36s. Welsh.

COPPER SULPHATE.—£15 17s. 6d. per ton.

GINGER.—Fifty bags good *Cochin* found a buyer of 23s. per cwt., and 720 bags of *Sierra Leone* made 18s. per cwt. in transit.

KOLA NUTS.—Twenty bags dried sold for 1½d. per lb. and 19 packages for 1¼d., both in store.

OILS (FIXED) AND SPIRITS.—*Castor* is very steady; *Calcutta* at 3¾d. per lb., *French 1st pressure* at 3½d. to 3¾d., and *Madras* at 3¾d. per lb. *Olive*: Spanish oils are now subject to an export

duty of 2¼ per cent., which is equal to a rise in price of about 12s. 6d. per tun. *Linseed* is quiet at 18s. to 18s. 6d. per cwt. *Cottonseed* is unchanged in price, and still slow of sale at 15s. 9d. to 16s. 3d. per cwt. *Spirits of Turpentine* is again a turn lower and may be had for 21s. 9d. per cwt.

POTASH SALTS.—*Bichromate*: 3¼d. per lb. *Chlorate*: 3¼d. to 3½d. per lb. *Cream of Tartar*: 78s. 6d. per cwt. *Potashes* are only nominal and very slow of sale at 20s. to 20s. 3d. per cwt. *Pearl-ash* is very slack, both in inquiry and sale, and is quoted at 35s. per cwt. *Saltpetre*: 21s. 6d. per cwt.

SODA SALTS.—*Bicarbonate*: £6 15s. per ton. *Borax*: £12 15s. to £13 per ton. *Caustic*: 70 per cent., £7 5s. per ton; 60 per cent., £6 5s. *Crystals*: £3 per ton. *Nitrate* is steady at 7s. 6d. to 7s. 9d. per cwt.

Manchester Chemical Report.

JULY 5, 1898.

It is almost impossible to accentuate the dulness which prevails in heavy chemicals, for the reports on all hands are that transactions are of a hand-to-mouth character, and in drysalteries only a moderate business is passing. In miscellaneous articles there is a general reduction on last week's prices. Brown Acetate of Lime varies from £5 2s. 6d. to £5 5s. delivered Manchester. Salt Cake is easier at 24s in bulk on rails. Carboic Acid is in better request. Naphthas continue firm and unchanged. Benzols are a trifle lower—90's being quoted 10d., and 50's to 90's 10½d. to 11d. Creosote is moving well at 2½d. Sulphur is scarce, and varies from £4 10s. to £5 per ton, according to delivery. White Powdered Arsenic is dull at £16 10s. per ton ex-ship Garston. Aniline Oil higher at 5½d., and Salt at 5d. Pitch firmer at 17s. 6d. to 18s. *f.a.s.* Manchester Ship Canal. Lancashire Yellow Prussiate firm at 7d. per lb. Green Copperas in fair inquiry at late rates.

Trade Notes.

MESSRS. BURROUGHS, WELLCOME & Co. point out a printer's error in the note referring to their bismuth subgallate tabloids in last week's issue page 24d. Each tabloid contains 5 grains and not 35 grains as printed.

THE WELL-KNOWN BUSINESS of Mr. James Burrough, of the Cale Street Distillery, Chelsea, has been converted into a limited company for family reasons. No shares are being offered to the public.

MESSRS. R. MORRISON & Co., 2, Fen Court, Fenchurch Street, London, E.C., have been appointed the sole agents for the United Kingdom for the old-established and well-known firm of Messrs. Gehe & Co., wholesale druggists and manufacturers of fine chemicals and pharmaceutical preparations, Dresden, Germany.

MESSRS. GEORGE HOUGHTON AND SON, 88 and 89, High Holborn, W.C., send a copy of their 1898 price list of photographic apparatus and materials. It contains nearly 700 pages with a comprehensive index, and is a book of reference that no photographic dealer should be without. The price is 6d. or 10d. post free, but a copy is sent free to professional photographers or dealers on receipt of trade card. The same firm also send specimens of their mounts in various sizes and artistic designs. No daintier mounts could be desired, and chemists interested in the photographic trade should take care to see them.

Partnerships Dissolved.

(From the London Gazette).

J. S. Turner, J. H. Galton, and Donald F. Shearer, Surgeons and Apothecaries, Upper Norwood, so far as regards Donald F. Shearer, who retires. Debts will be received and paid by J. S. Turner and J. H. Galton.

G. H. Ward Humphreys and H. Boyd Cardew, Physicians and Surgeons, Cheltenham. Debts will be received and paid by H. Boyd Cardew.

John P. Little and David Coulthard, Chemists, Druggists, and Drysalterers, The Crescent, Douglas, Isle of Man. Debts will be

received and paid by David Coulthard, who will continue the business in his own name.

B. E. Fordyce and A. F. Wilson, Physicians and Surgeons, Chesterton Road, Cambridge. Debts will be received and paid by B. E. Fordyce.

E. A. Elkington and C. E. Baddeley, Surgeons, etc., Newport, Salop. Debts will be received and paid by E. A. Elkington.

S. Locke and J. W. Ingram, Veterinary Surgeons, 100 and 102, Grosvenor Street, Chorlton-on-Medlock, Manchester. Debts will be received and paid by S. Locke.

Receiving Orders in Bankruptcy.

(From the London Gazette.)

A. J. Grossman, photographer, 18, Effingham Crescent, Dover, and carrying on business at 20, Biggin Street, Dover.

John Lowes, mineral water manufacturer, 6, Oaks Place, Tenterden, Kent.

W. D. Clark, chemist, The Stockhill Drug Stores, Holbeck, Leeds.

News in Brief.

MR. G. S. WEST, A.R.C.S., Scholar of St. John's College, Cambridge, the younger son of Mr. Wm. West, chemist, Bradford, obtained a First Class in the second part of the recent University examination for the Natural Sciences Tripos at Cambridge at the end of his third year of residence. This examination is usually taken at the end of the fourth year.

A TONIC AS A PUNISHMENT.—At Richmond, on June 30, a chemist was fined twenty shillings for making a boy drink water out of a quassia cup. The boy was very much frightened, thought he had been poisoned, and even complained of great pain, though it was shown in evidence that the water was perfectly harmless and could have no other effect but that of a mild tonic. It was administered to the boy as a punishment for swinging on the shop-blind.

THE COURT OF THE PATTERNMAKERS' COMPANY has inaugurated a fund for the purchase and presentation of a badge and chain of office to Lieutenant-Colonel Clifford Probyn upon his election as sheriff of London. Friends of the sheriff-elect are invited to forward their subscription either to Mr. Harry S. Foster, M.P., 46, Finsbury Circus, Hon. Treasurer, or Mr. W. H. Pannell, 13, Basinghall Street, Hon. Secretary of the fund.

CRICKET.—At a match played on Saturday, July 2, between Burgoyne Burbridges C. C. and Allenburys C. C., the latter were victorious by 37 runs, the scoring being 52 against 89.

SILVER WEDDING PRESENTATION.—On Saturday morning, at the Camden Town Works of Messrs. Idris & Co., Ltd., an interesting ceremony was witnessed in the presentation by the employes of a pair of handsome silver candelabra to Mr. and Mrs. Idris in recognition of their silver wedding. The function took place in the yard, where, on their appearance, the assembled employes greeted their chief and his wife with unbounded enthusiasm. Miss White, on behalf of the young ladies of the establishment, having presented Mrs. Idris with a handsome bouquet, Mr. Griffith explained that the presentation had only been suggested on Monday last, but so heartily and unanimously had the idea been taken up that it was easily evident how greatly the staff admired Mr. Idris's sound commercial knowledge, his sense of justice, and his uniform kindness. It was a happy circumstance that the founding of the firm had been almost synchronous with the event they were now celebrating. The workpeople were proud of the public honours their chief had gained, and should he be returned to Parliament, it was no more than his merits warranted. Mr. Simpson and Mr. Hussey then made the presentation, and begged its acceptance as a token of affection and respect, and they trusted the recipients would, for a great many years to come, live to enjoy the great success of the firm during the past quarter of a century. Mr. Idris, on coming forward to reply, was greeted with loud cheers. He confessed that the gift had completely taken him by surprise, although he guessed there was something in the wind when he was asked to bring his wife with him that morning. He did not know

how he deserved their kindness, as his chief function in that building was to act as fault-finder. He was proud of that mark of their kindness to them, and next to the esteem of his own family, he valued that of his fellow-workpeople. Mr. Idris, who spoke with visible emotion, said he had endeavoured under all circumstances to do his duty, and he thanked them from the bottom of his heart for their appreciation. Mrs. Idris, in an eloquent speech, also acknowledged the gift, which she prized more highly than any she had ever received, because it showed that Mr. Idris and herself had undoubtedly found a place in their hearts, and she trusted that the bond of sympathy between them would grow and deepen and not be lightly broken. They would never forget that morning, whether their years were few or many. Not only was the gift subscribed for by the employes of the firm in London, but all the provincial establishments of Messrs. Idris and Co., Ltd., took part in the presentation. During the morning telegrams conveying heartiest congratulations and best wishes were received from the workpeople at the factories in Liverpool, Southampton, etc. The wedding of Mr. and Mrs. Idris took place at Pembroke Dock, in Pembrokeshire, twenty-five years ago, and it is interesting to note that Mr. Adpar Jones, a director of Idris's, who has been associated with the firm from its infancy, was "best man" on that occasion.

MR. A. NICHOLSON, chemist and druggist, of Tunbridge Wells, has been called to give evidence before the Select Committee of the House of Commons on the question of telephonic control. Mr. Nicholson has been in business in Tunbridge Wells for over thirty-five years, and was one of the original subscribers of the Tunbridge Wells Telephone Exchange, and appeared before the Committee as Chairman of the Tunbridge Wells Telephone Subscribers' Committee, as well as on behalf of other local bodies. The Subscribers' Committee was formed in 1895, four chemists being members.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

Miscellaneous.

Magic Lanterns, second-hand; triples and binoculars; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s. —Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

WANTED.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Perkin and Kipping's 'Organic Chemistry'; Green's 'Botany,' second volume; Benthams and Hooker's 'Flora'; Cross and Cole's 'Modern Microscopy.' State edition, condition, and price. "Chemist," 6, Long Causeway, Peterborough.

Martindale's Extra Pharmacopoeia, eighth edition, in good condition. Lowest price to "Chemist," 147, Holdenhurst Road, Bournemouth.

Will give 4s. 6d. for 'Chemist and Druggist,' posted free for year (Mondays), or exchange 'Pharmaceutical Journal,'—Chemist, Mossley Hill, Liverpool.

Formulae suiting any good toilet specialty; liberal price. Particulars privately to W. Lewis, 15, Shelden Street, Bishop's Road, London, W.

Students' and Chemists' Books wanted for cash. Please supply following particulars:—Edition, date of publication, condition, and price required.—Gower, Publisher, Waterloo, Liverpool.

Advertisements.

(Received too late for Classification.)

SEASIDE engagement wanted, for few weeks, in high-class dispensing business. Qualified. 23. H. J. S., Abbey Villas, Wellowgate, Grimsby.

WANTED, a Qualified Junior ASSISTANT (out-door) accustomed to good-class trade. Apply to JOHN H. MATHER, Pharmacist, Godalming.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Arnott, Attenburrow, Blackburn, Bradbury, Brooks, Brunt, Burrell, Catkin, Clark, Currie, Davy, Elsdon, Fraser, Gardner, Gifford, Gray, Gregory, Hanbury, Hancock, Hill, Hyslop, Ireland, Jennings, Lake, Lambert, Mason, Morrison, Mumbray, Poole, Reynolds, Taylor, Turner, West, Whysall, Williams, Wilson.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

JULY 14, 1893.

Business has been somewhat more active during past week, although many complaints are still heard of the dulness of trade in drugs and chemicals. Quinine is fairly steady. Acid Citric and Tartaric and Cream of Tartar firm. Sulphate of Ammonia again lower. Opium, Morphia, and Codeia very firm. Sulphonal and Phenactin steady. Acetanilide weak. Glycerin quiet but firm. Acid Carbolic in good demand at steady prices. Phenazone again lower. Acid Oxalic steady. Borax and Acid Boracic very quiet. Thymol dearer and expected to further advance. The same applies to Orris. Quicksilver and Mercurials, Bismuth and Salts unchanged. Balsam Peru dearer. Ipecacuanha firm. The following are prices actually ruling for articles of chief interest:—

ACETANILIDE—Is very quiet at 1s. 1d. to 1s. 2d. per lb., according to quantity, for bulk packing.

ACID BORACIC—Quiet at 23s. to 24s. per cwt. for *crystal* and 25s. to 26s. for *powder*.

ACID CARBOLIC—Steady at 6¾d. to 7d. per lb. according to make for 35-36° C. *ice crystals* in bulk, other qualities and packing in proportion. *Crude* 60° F. 2s. 1d., 75° F. 2s. 7d. per gallon. *Liquid*: 95 per cent. of pale straw colour 1s. 1d. to 1s. 2d. per gallon, in 40 gallon casks.

ACID CITRIC—Is very firm, and the price of *Lemon juice* justifies a further advance. At present 1s. 2d. per lb. remains the quotation.

ACID TARTARIC—Firm at 1s. 1d. per lb. for *English*, and 1s. 0¼d. per lb. for *foreign*.

AMMONIA COMPOUNDS.—*Bromide* firm at 2s. 1d. per lb. *Iodide* quiet at 14s. 6d. per lb. *Oxalate* unchanged at 6d. per lb. *Sulphocyanide* firm at 1s. 1d. to 1s. 2d. per lb. *Sulphate* again lower at £9 3s. 9d. for grey prompt, 24 per cent., London. *Sol ammoniac*: Sublimed firsts, 35s. per cwt.; seconds 33s. per cwt. *Carbonate*, 3¾d. to 4d. per lb., according to package.

ATROPINE Is firm at 17s. 10d. per oz. for the *pure*, and 15s. 6d. per oz. for the *Sulphate P. B.*

BALSAM CANADA—Steady at 1s. 3d. per lb.

BALSAM COPAIBA—Quiet and tending easier at 2s. per lb.

BALSAM TOLU—Dull and lower at 1s. 9d. to 1s. 10d. per lb.

BALSAM PERU—Is scarce and held for high prices—9s. 6d. to 10s. per lb.

BISMUTH—Unchanged at 5s. per lb. for the *metal*, and 4s. 10d. for the *Subnitrate* in 5-cwt. lots.

BLEACHING POWDER.—Dull of sale at £6 15s. to £7 per ton, according to quantity.

BORAX—Steady but with very little doing. Quotations remain unchanged at 13s. 6d. to 14s. per cwt. for *lump, powder* 6d. per cwt. more.

BROMIDES—Makers quote 1s. 9½d. to *Potass Bromide*, 2s. 1d. for *Ammon.*, and 2s. 0¼d. for *Soda Bromide*. *Bromine* 1s. 11d. per lb. in 20-case lots.

BUCHU LEAVES.—There has been some inquiry this week for fair round green leaves, but the article seems concentrated in few hands, and holders are firm at 5d. to 6d. per lb.

CAMPHOR.—Crude continues dull with easier values. Refiners have therefore reduced their prices 1d. per lb., as follows:—bells, 1s. 2½d. per lb.; blocks, 1-lb., ½-lb., or ¼-lb., 1s. 2½d. per lb.; other sizes at proportionate prices. Flowers in 5 or 10-lb. boxes, 1s. 2½d. per lb.; ditto in 1-lb. boxes, 1s. 3½d. per lb.

CASCARA SAGRADA—Is in better demand and inclined to be dearer, owing to advices that supplies are likely to be small. New bark is held for 22s. 6d. per cwt., whilst for old bark 25s. to 27s. 6d. per cwt., according to quantity, is required.

CLOVES.—Privately *Zanzibar* quiet but firm, spot 3¾d., Oct.-Dec. delivery 3¾d. At auction 80 bales *Zanzibar* sold without reserve, at 3¾d. to 3¾d.; 10 cases *Penang* bought in at 8¾d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 4½d.; pure, 2s. 9d. per gallon. *Benzole*: 50 per cent., 1s. 1d.; 90 per cent., 1s. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 5d. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 9d. per gallon.

COCAINE—Is quiet but steady at 9s. 3d. to 9s. 9d. per oz., according to brand, for the *Hydrochlorate* in 25-oz. tins.

CODEIA.—Makers quote 11s. 6d. to 11s. 9d. per oz., according to quantity. It would appear likely, however, that price will be advanced in the autumn, if not at an earlier date.

COD LIVER OIL.—Slow of sale at 85s. to 90s., *f.o.b.*, for best new non-congealing *Norwegian* oil in 25-gallon tin-lined barrels. For *Newfoundland* oil there is at present no demand.

COLOCYNTH—Market is very quiet, and holders are anxious to make sales. Prices nominally 1s. to 1s. 2d. per lb. according to quality.

CREAM OF TARTAR—Dearer at 73s. per cwt. for white French *Crystals* on the spot. *Powder* 75s. to 76s. per cwt. High strength *Crystals* are very firm at 82s. 6d. per cwt. *Powder* 85s. per cwt.

DRAGON'S BLOOD.—The one case offered in last week's auctions has since been sold at £5 per cwt.

GALLS.—*China* continue very quiet, with a few sales of fair at 54s. per cwt. *Persian* in better demand, with sales of Blues at 54s. per cwt. and Greens at 50s. for fine.

GINGER.—*Cochin* continues flat. Of rough kinds 425 bags sold at easy rates. *Calicut* without reserve at 23s.; fair rough, 22s. 6d. Of 83 cases only 23 cases small native, partly cut, sold at 32s. 6d.; the remainder, native half cut, bought in at 48s. to 50s. *Jamaica* steady; 104 barrels sold; good common, 72s. 6d.; middling to good middling washed, 75s. to 78s.; 12 half-barrels good plump sold at 88s.

GLYCERIN—Quiet but firm at 52s. 6d. to 65s. per cwt. according to brand; for *German* white double distilled chemically pure 1260° quality in 2 cwt. cases and 56 lb. tins. *English* being obtainable at rather less money.

GOLDEN SEAL ROOT—Is lower at 1s. 10d. per lb. to come forward.

IPECACUANHA—*Rio* continues very firm and except for damages it does not appear possible to buy below 9s. per lb., whilst for picked 9s. 6d. per lb. is required. *Carthagena* is also very firm at 5s. per lb. with a rather better inquiry.

IODIDES—Continue in good demand at 9s. 9d. to 10s. 3d. for *Potass. Iodide*, and 13s. 4d. per lb. for *Iodoform*. Price of *Iodine* is 7½d. per oz.

JALAP.—Supplies are stated to be small this season, so that an improvement in values is anticipated, present price is 6d. per lb. for good, but demand is slow.

JUNIPER BERRIES—Continue very dear, and the near approach of the new crop does not appear to make holders of the old any less firm. Sales this week have been made at 10s. 3d. per cwt. *c.i.f.* terms.

MENTHOL—Is rather better at 7s. per lb. on spot and 6s. 6d. to 6s. 9d. per lb., *c.i.f.*

The stocks of camphor, oils of aniseed and cassia are incomplete, some warehouses not making returns.

MERCURIALS.—Makers' prices are unchanged at 2s. 9d. and 2s. 5d. per lb. for *Calomel* and *Corrosive sublimate* respectively in $\frac{1}{2}$ -cwt. lots.

MORPHIA.—Makers now quote 4s. 9d. to 5s. per oz. for the *Hydrochlorate Salt* in powder, stating that the present cost of *Opium* would fully justify a further advance.

NITRATE OF SILVER.—Rather higher in sympathy with higher price of the metal, crystals being quoted 1s. 5 $\frac{1}{2}$ d. per oz. in quantity, the sticks being proportionately dearer.

NITRATE OF SODA.—Quiet at £7 12s. 6d. to £7 15s. per ton for *Commercial*, and £7 17s. 6d. to £8 for *refined*.

OILS (ESSENTIAL).—*Peppermint*: *H. G. H.* is steady at 5s. 6d. to 5s. 8d. per lb., according to quantity. *Wayne County* of good quality held for 3s. 9d. to 3s. 10d. per lb. *Sassafras* lower at 1s. 7d. to 1s. 8d. per lb. *Sandalwood*: Logs are scarce, and the prices of the oil are therefore advancing; English drawn is quoted 12s. 6d. to 13s. per lb., as to quantity. *Star Aniseed* quiet at 7s. per lb. on the spot. *Cassia* in rather better demand, with sales of fine quality at 5s. 6d. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed*: Lower but closing firm; on the spot, pipes £16 7s. 6d., barrels £16 15s. *Rape*: firmer, ordinary brown on the spot £21 15s., refined spot £23 5s. *Cotton*: Quiet, London crude spot £13 15s., refined spot £15 10s. to £16, according to make. *Coconut*: Ceylon on the spot £24, for pipes; *Cochin* nominally £28 10s. *Palm* unchanged at £22 10s. for Lagos on the spot. *Turpentine*: There is more doing, and the market is firmer, American spot 21s. 3d. per cwt. *Petroleum Oil*: Quiet Russian spot 4 $\frac{1}{2}$ d. per gallon, American 5 $\frac{1}{2}$ d. per gallon, water white 6 $\frac{1}{4}$ d. per gallon. *Petroleum Spirit*: American 5 $\frac{1}{2}$ d., deodorised 6d. per gallon.

OPIUM.—Market is firm. In Smyrna sales have been made up to 10s. 9d. per lb. for new *tale quale*, while price of good *manufacturing* stuff ranges here from 10s. 9d. to 11s. 3d. per lb. *Druggists'* is worth 11s. to 12s. 6d. for fair to fine quality. *Soft shipping*, 11s. 3d. to 12s. 6d. *Persian*, 11s. 3d. to 12s. 3d. per lb.

ORRIS ROOT.—Reports from Leghorn state that the new crop promises to be very bad, both as to quality and quantity, the latter being, it is said, not more than two-thirds of that of last year. *Florentine* sorts are quoted 36s. per cwt., and picked, 40s. per cwt., *c. i. f.* terms.

PERMANGANATE OF POTASH.—Quiet at 62s. 6d. for small crystals and 67s. 6d. per cwt. for large crystals in 1-cwt. kegs.

PHENAZONE.—The competition between the various makers has led to a further reduction in price down to 12s. per lb. for quantity in bulk packing; there is, however, now a slightly better feeling in the article, the idea being that we may possibly now see a reaction. *Dr. Knorr's Antipyrine* is maintained at 2s. 1 $\frac{1}{2}$ d. per oz. in 1 oz. tins.

PHENACETIN.—A good article is still obtainable at 3s. 9d. to 4s. 3d. per lb. for *crystals* or *powder*, according to quantity. It is rumoured that *Bayer's* article, which has been maintained at the fancy figure of 14s. 3d. per lb. for bulk, will shortly be reduced in price, while it is believed that one of the other best brands, viz., *Riedel's*, will be offered in original packing at a higher price than

that at which it has lately been selling as a commercial article in ordinary bulk packing.

POTASH COMPOUNDS.—*Chlorate* is firm at 3 $\frac{1}{2}$ d. per lb. *Cyanide* continues comparatively scarce on the spot, and some considerable business has been done for export at 1s. 1 $\frac{1}{2}$ d. per lb. for the 98 to 100 per cent. cake. *Bromide* steady at 1s. 9 $\frac{1}{2}$ d. per lb. *Iodide* firm at 9s. 9d. to 10s. 3d. per lb., according to quantity. *Bichromate*: 4d. to 4 $\frac{1}{2}$ d. per lb. in large bulk. *Prussiate*: Yellow steady at 7d. per lb.; red firm at 1s. 2d. per lb. *Permanganate* quiet at 62s. 6d. and 67s. 6d. for small and large crystals respectively. *Bicarbonate*: 30s. per cwt. for crystals or powder.

QUICKSILVER.—Unchanged at £7 12s. 6d. from first hands, second hands 6d. less.

QUININE.—Market has been quiet, with, however, a fairly firm undertone. Maker's price remains 10d. per oz. for the *Sulphate*, with very little obtainable from second hand below this figure.

SALICYLATES.—Makers have advanced the prices of these 2 $\frac{1}{2}$ d. per lb., quotations for small lots being now:—*Salicylic Acid*: Powder, 1s. 10d. per lb.; crystals, 2s. per lb.; physiologically-pure crystals, 3s. 10d. per lb. *Salicylate of Soda*: Powder, 2s. per lb.; crystals, 2s. 6d. per lb.; physiologically-pure crystals, 3s. 6d. per lb. Above prices referring to 1-lb. paper parcels, the usual extra charges being made for boxes, bottles, or tins. For contracts for 2, 8, and 20 cwt. over six and twelve months the usual reductions are made.

SANTONINE.—Is unchanged at 4s. 5 $\frac{1}{2}$ d. per lb. for 3-cwt. lots.

SENEGA ROOT.—Good Western is offered at 1s. per lb. *c. i. f.*, and at 1s. 2d. per lb. on the spot.

SHELLAC.—A very quiet market with small transactions. Prices are, however, fairly steady. *TN Orange* being quoted on the spot at 64s. to 65s. basis fair.

SODA COMPOUNDS.—*Crystals* quiet at 57s. 6d. per ton in barrels. *Bicarbonate* steady at £7 10s. per ton for the 98 per cent. commercial quality, and 18s. 6d. per cwt. for the chemically pure, free from monocarbonate. *Ash* firm at £5 5s. to £5 15s. per ton, according to strength. *Bromide* firm at 2s. 0 $\frac{1}{2}$ d. per lb. *Iodide* steady at 11s. 7d. per lb. *Caustic*: 70 per cent. white, £7 15s. per ton.

SPERMACEIN.—Is lower at 1s. 2d. to 1s. 3d. per lb., according to quantity.

SPICES (VARIOUS).—*Black Pepper*: 65 bags Singapore sold at 4 $\frac{1}{2}$ d. to 4 $\frac{3}{4}$ d.; 10 bags Tellicherry sold at 4 $\frac{1}{4}$ d. to 4 $\frac{3}{4}$ d.; Wynaad bought in at 4 $\frac{3}{4}$ d. *White Pepper*: Singapore bought in good to fine at 8 $\frac{1}{2}$ d. to 10d. *Chillies*: 20 bags Zanzibar sold at 30s.; 28 bags fine red Japan bought in at 43s. *Cinnamon Chips*: 12 bags good Ceylon sold at 4 $\frac{1}{2}$ d. *Mace*: 7 packages West India sold at 1s. 6d. to 1s. 8d. *Nutmegs* steady: 4 cases Penang sold 66's at 2s. 4d.; 10 boxes Singapore sold 80's at 1s. 9d.; 90's at 1s. 5d.; 112's at 1s. 2d.; 8 packages West India sold, 98's at 1s. 3d.; 126's at 11d.

SULPHATE OF COPPER.—Dearer at £15 15s. to £16 15s. per ton according to brand.

SUGAR OF LEAD.—*Foreign* firm at 27s. 6d. per cwt. *English*, 0s. to 31s. per cwt.

SULPHONAL—Unchanged. Makers still executing orders for limited quantity and to regular customers only at 7s. 3d. per lb. in bulk packing, for both *crystal* and *powder*.

THYMOL.—Owing to the increase of the plague in India the prices for *Ajowan* seed are advancing rapidly. *Thymol* is quoted 7s. 6d. per lb., but higher values are likely to rule.

TURMERIC—Supplies continue scarce and quotations consequently rule high. *Bengal*, 20s. per cwt.; *Madras*, fair finger 23s. per cwt., fine quality obtaining excessive figures. *Cochin*, 17s. 6d. per cwt. for finger, 10s. per cwt. for split bulbs.

Newcastle Chemical Report.

JULY 13, 1898.

Not much new business passing, but shipping orders for heavy goods keep matters moving. Sulphur if anything is the turn scarcer but unchanged in value. General quotations are: Bleaching powder: £6 5s. to £6. 10s. Soda crystals: 45s. to £52 6s. Caustic soda: 70 per cent. basis, £7 5s. to £7 10s. Soda ash: 52 per cent., £4 5s. Alkali. 52 per cent., £5 5s. Sulphur: £5 per ton.

Liverpool Market Report.

JULY 13, 1898.

Transactions in goods of interest to druggists have been remarkably few during the week. In Seeds the only movements have been retail sales of Turkish Canaryseed at last week's rates. Oils generally are quoted as last week, Castor Oils having receded somewhat, and Spirits of Turpentine advanced about 3d. per cwt.

AMMONIA SALTS.—*Carbonate*, 3d. per lb. *Sal ammoniac*, 33s. to 35s. per cwt. *Suphate* is quieter and a shade lower at £9 7s. 6d. per ton.

BLEACHING POWDER—Is only selling slowly at £5 7s. 6d. to £5 15s. per ton, or 2s. 6d. per ton less than last week.

CANARYSEED.—Business has been confined to retail transactions in *Turkish* at 25s. to 26s. per 464 lbs.

CARNAUBA WAX.—About 70 bags have changed hands at 55s. to 57s. 6d. per cwt. for good yellow, and 34s. for grey.

COPPERAS—Is in good demand and firm at 38s. per ton for Lancashire, and 36s. for Welsh.

COPPER SULPHATE—Has advanced 7s. 6d. to 10s. per ton on last week's quotations, and now is held for £16 5s. to £16 7s. 6d. per ton.

OILS.—*Castor* are selling well at easier prices, Calcutta "good seconds" is at 3½d. per lb., French 1st pressure at 3d. to 3¼d., and Madras at 3¾d. *Olive* is dull and sales are few; *Spanish* oils rule from £28 to £30 per tun. *Linseed* of Liverpool make sells steadily at 18s. to 18s. 6d. per cwt. *Cottonseed*: Liverpool refined maintains its price of 15s. 9d. to 16s. 3d. per cwt. *Spirits of Turpentine* has risen 3d. per cwt. and holders ask 22s. per cwt.

POTASH SALTS.—*Bicarbonate* 30s. per cwt. *Bichromate* 3¼d. per lb. *Chlorate* 3¼d. per lb. *Cream of Tartar* is still quoted at 78s. 6d. per cwt. for finest white, both to arrive and on the spot. *Pearlashes* are nominal at 35s. per cwt. *Potashes* are in fair demand at 20s. to 20s. 3d. per cwt. *Prassiate* quiet at 6¼d. to 7d. *Saltpetre* 21s. 6d. per cwt.

SODA SALTS.—*Bicarbonate*: £6 15s. per ton. *Borax*: £12 15s. per ton. *Caustic*: 76 to 77 per cent., £8 5s.; 70 per cent., £7 5s. per ton. *Crystals* firm at £3 per ton. *Nitrate* is in quiet demand at 7s. 6d. to 7s. 9d. per cwt.

Manchester Chemical Report.

JULY 13, 1898.

There seems to be again a weakening tendency in heavy chemicals, and in the drysaltery department things are generally dull. The Board of Trade returns are again depressed, Bleaching Powder being the only article that shows any stiffening in price. Sulphate of Copper and Glycerin are perhaps the only articles locally which show any advance. In the first-named, dealers here are firm at £17 to £17 5s. per ton for best brands. delivered Manchester, though they cannot account for it at this season of the year, when it is usually at its lowest. Brown Acetate of Lime has again declined, and varies from £5 2s. 6d. to £5 5s. for America, *c.i.f.*, although £5 would be taken for a fair quantity with firm order. Glycerin is quoted £54 to £56, according to package on rails or *f.o.b.*, Manchester Ship Canal. Yellow Prus-

siate is a shade easier, although unchanged at 7d. White Powdered Arsenic varies from £16 to £16 5s. ex-ship Garston. Naphthas are steady at 4s. 1½d. to 4s. 3d. for miscible, and 2s. 7d. to 2s. 9d. per gallon for solvent wood (white colourless), with little offering. Benzols are dull and unchanged. Aniline Oil is firmer at 5¼d., and Salt, 5d. Alum dull.

News in Brief.

TRADE OUTING.—The employes of Messrs. Evans, Gadd & Co., of Exeter and Bristol, held their annual wayzgoose in delightful weather. The Bristol staff went to Dawlish, a popular seaside resort in South Devon, for their trip. A visit was subsequently paid to Teignmouth. Dinner was partaken of at the Royal Hotel at Dawlish, where the party had the pleasure of meeting Alderman H. Gadd, J.P., who presided. Mr. H. E. Boorne, the Bristol manager, was in the vice-chair. The day passed all too quickly, and the homeward journey was commenced after an enjoyable day's outing. The Exeter employes, to the number of about seventy, selected Dartmoor for a visit. They left Queen Street Station in special carriages, and proceeded by the London and South-Western Railway Company's picturesque route through Dartmoor to Tavistock, where an hour's stay was made, after which they left Backwell's "Cornish Arms" in well-appointed brakes for a twenty-mile drive across the moor. On returning to Tavistock a capital dinner was awaiting the party. Mr. W. J. Wippell occupied the chair and Mr. H. W. Gadd the vice-chair. The party left Tavistock by the 7.55 train, arriving in the "Ever Faithful" city at half-past nine, all voting the outing one of the most successful that had been arranged.

THE NEWCASTLE-ON-TYNE AND DISTRICT CHEMISTS' ASSOCIATION has made arrangements for a half-day excursion to Hexham on Wednesday next, July 20. The party will meet in the main area of the Central Station, Newcastle-on-Tyne, to travel by the 1.15 west express, on which special accommodation (saloon or otherwise) will be reserved. On arrival at Hexham, the party will proceed by way of the woods to Swallowship, where the earlier part of the afternoon will be spent in rambling, photography, etc. At 4.40 p.m. the visitors will leave Swallowship for Hexham, where tea will be served in the Royal Hotel, Priestpopple Street, at 5.30 p.m. Subsequently a visit will be paid to the Abbey at Hexham, under the guidance of Mr. J. P. Gibson, after which the evening will be spent according to individual inclination. The return train will leave Hexham Station at 10.10 p.m., reaching Newcastle Central at 10 48 p.m.

PRESENTATION TO MR. W. B. COWIE.—In Aitchison's Rooms, Queen Street, Edinburgh, on Wednesday, July 6, at a social meeting of past and present pupils of the Edinburgh Central School of Pharmacy, Clyde Street, the Principal, Mr. W. B. Cowie, was presented with a handsome timepiece and side ornaments on the occasion of his marriage. Mr. A. J. Dey occupied the chair, and at the request of the students the presentation was made by Mr. J. Rutherford Hill. Mr. Cowie expressed his high appreciation of this mark of their goodwill. It was quite a pleasure to him to teach such students, and he congratulated them on their success at recent examinations. They must not give him too much credit for the results. It was largely due to the devotion and ability of his assistants, Messrs. Senter and Scobie, and most of all to their own diligence and hard work. For himself and his future partner he desired to thank them most heartily for their kindness and good wishes.

THE CAMBRIDGE PHARMACEUTICAL ASSOCIATION held their annual summer outing on Thursday, July 7. A trip for the half-day being taken to Hunstanton, where the members and friends indulged in a substantial meat tea, after which Mr. E. Saville Peck photographed the group, when parties were made up for drives, sea trips, and walks. Mr. Harry Spencer, Mr. H. F. Cook and others entertained the company on the homeward journey with humorous songs and sketches. Mr. E. Saville Peck proposed a vote of thanks to the Secretary for the manner in which all the arrangements had been made and carried out. This was seconded by Mr. W. L. White in a humorous speech, and suitably responded to by Mr. B. Sidney Campkin. The party reached Cambridge shortly after 11 p.m., having had a most enjoyable trip.

THE COUNCIL OF THE PHARMACEUTICAL SOCIETY OF IRELAND invites applications for the post of Examiner to conduct the Pharmaceutical and General Chemistry Division of the Pharmaceutical Licence Examination, subject to the approval of His Excellency the Lord-Lieutenant and the Privy Council of Ireland. Full particulars can be obtained from the Registrar, Mr. Arthur T. Ferrall, 67, Lower Mount Street, Dublin, with whom applications should be lodged not later than the 27th inst.

MESSRS. JAMES TOWNSEND AND SON'S employes held their annual waygoose on Saturday, July 9, a portion of the party leaving St. David's, Exeter, at 5.45 a.m. for Bristol, while another portion left for Bath at 6.15 a.m., afterwards proceeding to Bristol in time for the annual dinner held at Stuckey's Hotel, Bristol. The chair was taken by Mr. James Townsend, the vice-chairs being occupied by Messrs. W. Townsend and T. J. Tayler. Beautiful weather prevailed, and the united party, numbering nearly 130, thoroughly enjoyed the day's outing. A train leaving Bristol at 10.35 p.m. conveyed the majority of the party back.

FREEMASONRY.—The installation meeting of the Apollo Lodge took place in the Town Hall, Beccles, on Thursday, when Bro. Walter Plumbly was duly installed W.M. The following brethren are the officers for the year:—Bro. A. McQueen, S.W.; Bro. Youngs, J.W.; Bro. Copeman, S.D.; Bro. Godfrey, J.D.; Bro. White, I.G.; Bro. Norman, Tyler (for the forty-eighth time); Bro. Yarnall, organist; Bro. Nobbs, treasurer; Bro. Scott, secretary. The banquet took place at the Bell Hotel, St. Olaves, and during the evening a centenary jewel was presented to Bro. Jolly, the I.P.M., in recognition of his earnestness and zeal for the good of the lodge during his year of office, and in the cause of the masonic charities. The installation ceremony was very impressively performed by Bro. Woodroffe, P.M., P.P.G.S. of W.

EDINBURGH DISTRICT CHEMISTS' GOLF CLUB.—The sixth and final round of the Hole and Hole competition, which began in March, was played over the Braids course last Saturday. Mr. A. C. Kirkpatrick, allowing Mr. D. N. Wylie one hole, beat him after a close game by two holes.

Trade Notes.

MR. J. F. SHOREY'S business as manufacturer of Peterman's Cockroach and Beetle Food and other vermin destroyers, carried on at 67, Farringdon Road, E.C., has been taken over by Messrs. F. Newbery and Sons, King Edward Street, Newgate Street, E.C., who will continue to attend to the yearly contracts, etc.

MESSRS. F. NEWBERY AND SONS, 1 and 3, King Edward Street, Newgate Street, E.C. announce that the proprietors of Cuticura remedies have notified advanced rates for Cuticura Resolvent, and Cuticura Soap, which have just taken effect. They also intimate that the sole agency in this country for the sale of the following preparations has been taken over by the firm, prices hitherto prevailing remaining in force, viz:—Fels's Tuna, Richter's Pain Expeller, Congo Pills, etc., and Peterman's Cockroach and Beetle Poison and other vermin killers.

THYROID GLANDS are in increasing demand, and inquiries are occasionally received as to where they may best be obtained. Mr. T. Williams, 2, Trowbridge Street, Liverpool, announces that he is open to supply sheep's thyroid glands (Scotch) in any quantity to suit purchasers. He also supplies kidney glands and ovaries.

MESSRS. BURROUGHS, WELLCOME & Co. send samples of their "Tabloid" Hypophosphites Compound, in which the full therapeutic activity of all the constituents is retained without any danger of an overdose of strychnine either through a mistake in measurement or through precipitation. Two strengths are issued, each in bottles of 25 and 100. "Tabloid" Hypophosphites Compound, gr. 1-1/2, contains gr. 1/128 of strychnine hypophosphite, together with the combined hypophosphites of calcium, potassium, manganese, iron and quinine, and is equivalent to dr. 1/2 of standard compound syrup of hypophosphites. "Tabloid" Hypophosphites Compound, gr. 3, contains gr. 1/64 of strychnine hypophosphite, together with the combined hypophosphites of calcium, potassium, manganese, iron and quinine, and is equivalent to dr. 1 of standard compound syrup of hypophosphites.

Advertisements.

(Received too late for Classification.)

FOR SALE.—High-class DISPENSING BUSINESS in good suburb. Large house and handsomely-fitted shop. Apply by letter for interview with trade and banker's reference. REES, Chemist, 5, Queen's Parade, Muswell Hill, N.

SITUATION wanted as LOCUM-TENENS. Qualified. Age 53. Disengaged latter part August and after. JONES, at Mr. Mumford's, 40, Castle Rd., Cardiff.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Miscellaneous.

Magic Lanterns, second-hand; triples and binoculars; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

Major, scientific, requires situation, not in retail; excellent references. Apply—"Ajax," Pharm. Journ. Office, 5, Serle Street, W.C.

One each 5s. and 10s. 6d. Arcma Atomiser, with 15 bottles assorted Inhalants for £1.—"Cascara," Pharm. Journ. Office, 5, Serle Street, W.C.

Ovaline soap, large surplus stock; 36 boxes Breidenbach's soaps; stereotype block to print homoeopathic cards; what offers? Any quantity carriage paid.—Gibson Dixon, Chemist, Halifax.

Complete Fittings for Chemists' Shop, new and good, cheap.—Apply, Business, 64, Linthorpe Road, N.

For Sale.—11s. Rooke's Elixir, 6s. 6d.; 4s. 6d. Crosby's, 3s.; 4s. 6d. Sequah's Oil, 3s.; Snook's Pills, 8d.; Frampton's, 8d.; Nurse Powell's, 7d.; 2s. 9d. ditto, 1s. 6d.; 2s. 9d. Johnson's Syrup, 2s.; Herrmann's Helmet Metal Polish, black or red, per gross, 1d. size, 3s. 9d.; 2d., 6s. 6d.; 3d., 11s.; 4d., 16s.; "Nanon" white, 1d., 6s.; 2d., 10s.; 4d., 18s.; Winch. Acetic Ether, 2s. 10d. per lb.; 1s. 1 1/2. Barrow Evan's Peppermint, 7d.; 2s. 9d. ditto, 1s. 8d.—Percy, Chemist, Truro.

For Sale.—Four 2-gal. swan necked, one 1-gal. pear-shaped Carboys; black and gold Dispensing Screen and Desk Case.—Carveth, Chemist, Plymouth.

Twelve Tooth Forceps, 10s.; 'Extra Pharmacopoeia,' 6th edition, 'Minor Ailments,' Remsen's 'Organic Chemistry,' Pereira's 'Selecta,' Bentley's 'Botany,' 4th edition. What offers?—Lee, Chemist, Derby.

Soda-water Trolley, light and strong, on which your boy can easily convey 3 dozen syphons, 37s., carriage paid. Further particulars of Arthur and Co., Cambridge.

Books.

Wills' 'Pharmacy,' latest, 3s. 6d.; 'Elementary Materia,' latest, 3s.; Squire, latest, 4s. 6d.; Martindale, 1892, 3s. 6d.; Atfield, latest, 7s. 6d.; B. P., 1885, 3s. All excellent condition, some new. Carriage free. Gower, Waterloo, Liverpool.

Perkin and Kipping's 'Organic Chemistry'; Green's 'Botany,' second volume; Bentham and Hooker's 'Flora'; Cross and Cole's 'Modern Microscopy.' State edition, condition, and price. "Chemist," 6, Long Causeway, Peterborough.

WANTED.

Proctor's 'Pharmacy,' third edition, state price and if quite clean.—E. S. Peck, Trumpington Street, Cambridge.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Sponge Case—Similar to Maw's Fig. 3 preferred. State condition and lowest price.—Gare, Chemist, Lymington, Hants.

Dandelion roots (dried), by the cwt.; Rennets (dried), by the gross.—Percy, Chemist, Truro.

Old metal mortars, in any condition; also old apothecaries' jars; send description and lowest price.—Chemist, 157a, Lodge Lane, Liverpool.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Bullivant, Campkin, Cracknell, Cresswell, Eberlin, Ellis, Frank, Gillard, Guiler, Hawthorn, Hewlett, Hill, James, Jamison, Jones, Keen, Kirkby, Kirkpatrick, McKnight, Merson, Naylor, Peck, Plumbly, Richmond, Roberts, Rowland, Savage, Smith, Thompson, Tucker, Wells, White, Wyatt.

London Report.

JULY 21, 1898.

As might have been anticipated, business has been very quiet during the past week, and a revival of trade can now hardly be expected before the advent of cooler weather. Quinine is quiet. Opium has advanced in consequence of a report of an even more reduced crop than had been previously prognosticated. This, if confirmed, will mean also higher prices for Morphia and Codeia. Acid Citric extremely firm. Cream of Tartar and Acid Tartaric steady. Quicksilver and Mercurials unchanged. Borax and Acid Boracic quiet. Cod-liver Oil dull. Glycerin dearer. Cocaine steady. Sulphonal and Phenacetin quiet. Acetanilid lower. Sulphate of Ammonia rather dearer. Iodides and Bromides unchanged. The following prices are actually ruling for articles of principal interest:—

ACETANILIDE—Lower, there being sellers at 1s. per lb. for quantity and in bulk.

ACID BORACIC—Quiet at 23s. 6d. per cwt. for *crystals* and 25s. 6d. per cwt. for *powder*.

ACID CARBOLIC—Quiet but steady at 6¼d. for 35-36° C. *ice crystals* in bulk packing, other qualities and packing in proportion. *Crude* 60° F. 2s. 1d., 75° F. 2s. 6d. per gallon. *Liquid*: 95 per cent. of pale straw colour 1s. 1d. to 1s. 2d. per gallon, in 40 gallon casks.

ACID CITRIC—Continues very firm at 1s. 2d. per lb., with a probability of an early rise, juice being firm at £16 10s.

ACID OXALIC—Steady at 3¼d. per lb. for bulk packing.

ACID TARTARIC—Very firm at 1s. 1d. per lb. for English *crystals*, and 12¼d. per lb. for foreign.

AMMONIA COMPOUNDS.—*Bromide* firm at 2s. 1d. per lb. *Iodide* steady at 14s. 6d. per lb. *Sulphate* dearer £9 6s. 3d. for grey prompt, 24 per cent., London. *Sal ammoniac* unchanged at 35s. and 33s. for first and second sublimed respectively. *Sulpho-cyanide* steady at 1s. 2d. per lb. *Carbonate*, 3¼d. to 4d. per lb., according to package.

ARSENIC.—*Powder*, 19s. per cwt. *Lump*, 34s. per cwt.

BLEACHING POWDER—Quiet at £6 15s. to £7 per ton.

BORAX.—Unchanged at 14s. per cwt. for *crystals* and 14s. 6d. per cwt. for *powder*.

BROMIDES AND BROMINE—In good demand at unchanged price.

CINCHONA BARK.—The auctions on Tuesday comprised smaller offerings than usual, amounting to 1160 packages as against 2700 at the previous sales. The bulk was disposed of at dearer rates. *Ceylon*: 356 bales offered and 266 bales sold, according to analysis; *Succirubra*, stem chips and shavings at 2¼d. to 2½d., broken quill at 3d., renewed chips at 2¾d. to 2½d. *East Indian*: Of 254 bales offered 211 bales sold, Red, stem chips, fair 2½d. to 3d., ordinary renewed ditto at 2¼d.; *Officinalis*, chips and shavings, fair to good 2½d. to 4¼d., renewed ditto 4¼d. to 4½d. *Java*: Of 310 bags and 40 bales 310 bags sold, Ledger stem chips, good at 4¼d. to 5¼d. *African*: 200 bales offered and sold, ordinary to fair quill at 2¼d. to 3½d., quilly chips 3¼d., with one lot at 4d.

CLOVES.—Privately *Zanzibar* have been in good demand, and prices have improved. Sales include spot, 3½d.; August to October delivery, 3½d. to 4d.; and October to December at 4¼d. At auction no *Zanzibar* offered; 1 barrel *Grenada* sold at 3½d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 2d. per gallon. *Benzole*: 50 per cent., 1s. 1d.; 90 per cent., 11d. *Crude Naphtha*: 30 per cent. at 120° C., 5d. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 8d. per gallon.

COCAINE—Quiet but with a general feeling that the next move will probably be in an upward direction, price remains meantime

unchanged at 9s. 3d. to 9s. 6d. per oz. for the *Hydrochlorate* in 100-oz. lots.

CODEIA—Nominally unchanged at 11s. 6d. to 11s. 9d. per oz. for the *pure* and 1s. per oz. less for the *salts*.

COD-LIVER OIL—Remains almost a dead letter, price being nominally 85s. to 90s., *f.o.b.*, per barrel for best new non-congealing *Norwegian* oil in tin-lined barrels of 25 gallons.

CREAM OF TARTAR.—A good business has been done this week at rising rates, closing quiet but steady at 73s. 6d. for first white *crystals* on the spot, and 76s. for *powder*. *B.P. crystals*, 83s. per cwt.; *powder*, 86s. per cwt.

DAMIANA LEAVES.—San Francisco and Lower Californian correspondents report a scarcity, and prices are firm at 9d. per lb. to come forward.

GINGER.—*Cochin* continues in poor demand. Of 652 bags rough kinds only 135 bags sold at easy rates; low shrivelled 11s., ordinary ends 14s., small dull washed 19s. to 19s. 6d. Of 731 cases only 42 sold, bold limered Calicut 77s. 6d. to 80s., medium and small 39s., small 29s. to 33s. *Jamaica* is quiet at about previous rates, common to good common Rhatoon 65s. to 71s. 6d., small and low middling washed to good middling bright 72s. to 80s., good bright plump 81s. to 84s. 6d.

GLYCERIN—Has been advanced in price, one of the good *German* brands, which was previously quoted £53 per ton in ton lots, being now unobtainable from the makers below £54 for 1260° quality in tins and cases. A further advance is considered not improbable.

HENBANE LEAVES.—English dried leaves of second year's growth are very scarce, and as much as 12s. per lb. is asked, but even at this high figure very little could be got.

IODIDES AND IODINE—Are without change.

ISINGLASS.—The monthly auctions were held on Tuesday, the offerings being smaller than of late. About one-half sold at rather easier rates. The smaller supply of *Bombay* and *Kurrachee* was firmly held and mostly withdrawn, the few lots finding buyers showing full to slightly higher prices. The large supply of *Penang* was mostly sold at again lower prices for both leaf and tongue. *Saigon* leaf met little demand, and was all bought in. Moderate supplies of *Para* went off slowly at a decline of 1d. to 2d. *Maranham* also sold at easier rates. *West India* showed an average decline of 1d. per lb.

JAPAN WAX—Quiet at 32s. per cwt. for good squares.

KAVA KAVA—Is very scarce, and only small lots are to be had on the spot at 1s. per lb. American reports state that there are no stocks on the coast and none expected from Hawaii.

MERCURIALS—Unchanged at prices given last week.

MORPHIA.—Makers' price is nominally 4s. 10d. per oz. for the *Hydrochlorate* powder, but, should the advance in value of *Opium* be maintained, we shall certainly see higher prices in the near future.

NITRATE OF SODA—Quiet at £7 15s. for *commercial* and £8 per ton for *refined*.

OILS (ESSENTIAL).—*Star Aniseed* is dearer at 7s. 3d. per lb. *Cassia* in good enquiry and firm at 5s. 6d. per lb. for 80 to 85 per cent. *Peppermint*: Fine *Wayne County* is in better enquiry owing to continued reports of short acreage; 3s. 10d. to 4s. per lb. is quoted. *Citronelle* firm at 1s. 2d. per lb. *Lemongrass* 4¼d. per oz.

OILS (FIXED) AND SPIRITS.—*Linsced* dearer, but closes easy at £16 17s. 6d. for spot pipes, London, and £17 7s. 6d. for barrels. *Rape* dearer at £22 for ordinary brown on spot and £23 10s. for refined. *Cotton* steady at £13 15s. for London crude and £15 10s. to £16 for refined, according to make. *Olive* steady at £33 for green oils and up to 6s. per gallon for eating oils. *Coconut* lower at £23 10s. for Ceylon on the spot; *Cochin* unchanged at £28 10s. *Palm* lower at £22 5s. for Lagos on the spot. *Turpentine* dearer at 21s. 9d. per cwt. for American on the spot. *Petroleum Oil* firmer

at 4½d. per gallon for Russian and 5½d. per gallon for American. *Petroleum Spirit*: American 5½d. per gallon, deodorised 6d. per gallon.

OPIUM.—Market is exceedingly firm on the report just to hand from Smyrna that 11s. 6d. per lb. has been paid there, and that holders now ask 12s. per lb., cause being stated to be that the new crop is reported not likely to exceed 2500-3000 cases. Holders here have meantime withdrawn their quotations.

PERMANGANATE OF POTASH—Steady at unchanged prices.

PHENACETINE.—*Bayer's* article which was hitherto held at the fancy price of 14s. 3d. per lb. for bulk packing has been reduced to 5s. 6d. per lb.; people will, however hardly be willing to pay even this reduced price in view of the fact that a good and reliable article can be purchased at 3s. 9d. to 4s. 3d. per lb., according to quantity.

PHENAZONE.—There is not quite so much pressure to sell, price remaining nominally unchanged. It now remains to be seen what will be the result of the expected increased competition in the article, consequent on the expiry of the German patent for *Antipyrine* which takes place in a few days.

PODOPHYLLIN—Is slow of sale. A fully soluble article is offering at 12s. 6d. per lb.

POTASH COMPOUNDS.—*Chlorate* is steady at 3½d. per lb. *Bichromate* firm at 4d. per lb. in large bulk. *Prussiate*: English is firm at 7d. per lb. for yellow; red is held for 1s. 2d. per lb. *Bromide* unchanged at 1s. 9½d. per lb. *Iodide* quiet at 9s. 9d. to 10s. 3d. per lb., according to quantity. *Permanganate* quiet but unchanged at 62s. 6d. per cwt. for small, and 67s. 6d. per cwt. for large crystals. *Cyanide* continues scarce for immediate delivery at 1s. 1½d. to 1s. 2½d. per lb. for the 98 to 100 per cent. cake. *Bicarbonate* unchanged at 30s. per cwt. for crystals or powder.

QUICKSILVER—Quiet but firm at £7 12s. 6d. per bottle from first hands.

QUININE—Remains quiet at 10d. per oz. for good *German* brands from the makers for *Sulphate* in 100-oz. tins and 1000-oz. lots, there being but little offering from second hand below this figure.

SALTPETRE.—*English* refined 20s. per cwt. in large bulk.

SCAMMONY.—*Virgin*: Firsts have been sold at 30s. per lb., and good seconds at 23s. per lb. Supply is now running short. *Roots* are in good supply, but business is prevented by holders asking long prices. *Resin*, 6s. 9d. to 7s. per lb.

SENEGA ROOT—Is inquired for, but appears scarce on the spot at 1s. 2d. per lb.

SHELLAC.—This market continues very quiet, and at the fortnightly auctions on Tuesday, whilst demand was good, sales were only made by giving way slightly in values. A total of 885 cases were offered and 577 cases sold. *Second Orange*: Of 679 cases 426 sold, chiefly without reserve, fine pale (2 cases) at 79s., fair bright flat free at 63s. to 64s., ordinary red at 61s., ordinary reddish livery at 50s. to 60s., more or less cakey and blocky, fair to good bright at 58s. to 62s., claret colour, part hard block at 52s. to 54s. *Garnet*: Of 76 cases 56 sold, flat ruby free at 56s., ditto part hard block at 54s., blocky G at 55s. *Button*: Of 130 cases 93 sold, pure firsts at 95s., ditto seconds at 88s. to 89s., very low resinous dark at 16s. to 20s.

SODA COMPOUNDS.—*Crystals* steady at 57s. 6d. per ton in barrels. *Bicarbonate* firm at £7 10s. per ton for the 97 per cent. commercial quality, and 18s. 6d. per cwt. for the free from monocarbonate quality. *Ash* firm at £5 5s. to £5 15s. per ton, according to strength. *Bromide* firm at 2s. 0½d. per lb. *Iodide* quiet at 11s. 7d. per lb. *Caustic*: 70 per cent. white, £7 15s. per ton., 60 per cent. £6 15s. per ton.

SPICES (VARIOUS).—*Black Pepper*: *Aleppy* bought in at 4½d. *White Pepper* also all bought in, Singapore at 8½d. and Siam at 8¼d. *Chillies*: 95 bags bought in at 32s. to 42s. *Macé*: 10 cases Penang bought in, pickings 1s. 4d. to 1s. 5d., good red 2s.; 60 packages West India sold well, mostly at 1s. 6d. to 1s. 8d., low 1s. 4d. to 1s. 5d., a few lots good to fine palish 1s. 10d. to 2s. 4d. *Nutmegs* steady at full previous prices. *Pimento* firm: 140 bags sold at 4¾d. to 4¼d.

SUGAR OF LEAD.—*Foreign* is very firm at the advance to 27s. 6d. per cwt. *English* 31s. per cwt.

SULPHATE COPPER—Dearer at £16 to £17 5s. per ton according to brand.

SULPHONAL.—Makers are still selling in restricted quantities at 7s. 3d. per lb. in bulk.

SULPHUR.—A firm market. *Foreign* roll 6s. 6d. per cwt., flower 7s. per cwt.; *English* roll 7s. 6d. per cwt.

To-day's Drug Auction passed off quietly, chief point of interest being an advance in Buchu Leaves and a fall in value of Colombo Root, of which latter, however, the offerings consisted chiefly of the lower qualities.

ACONITE ROOT.—3 bags *Japan* bought in at 27s. 6d. per cwt.

ALOES.—Good bright livery *Curacoa* sold at 34s. 6d. per cwt. down to 28s. for less desirable quality. *Zanzibar* of fair quality in monkey skins bought in at 90s. per cwt., ditto good part softish selling at 59s. per cwt. 4 cases soft and drossy cape held for 17s. per cwt.

AMBERGRIS.—2 tins together, only 5¼ oz. of not very special quality, sold at 85s. per oz.; 1 tin 2¾ oz. nett. of really fine quality held for 100s. per oz., only 90s. being bid.

ANISEED.—10 bags good *Spanish* bought in at 25s. per cwt.

ANNATTO SEEDS.—33 bags of fair quality chiefly bought in, 1 bag *ICSD* selling without reserve at 2½d. per lb.

BALSAM PERU.—Good genuine quality was held for 9s. per lb.

BALSAM TOLU.—18 cases were bought in at 1s. 8d. per lb.

BIRD LIME.—2 cases *Japan* bought in. 6d. would probably be the price, a bid of 3d. per lb. not being entertained.

BUCHU LEAVES.—18 bales fair to good green rounds sold at an advance of fully 1½d. per lb., medium green selling at 6d. per lb.

CAMOMILES.—15 packages bought in at 50s. per cwt.

CARDAMOMS.—In only moderate supply, and very few sold. Medium *Mysore* sold at 2s. 3d. per lb., other qualities being bought in.

CASCARILLA BARK.—Fair thin bright sold at 36s. per cwt., down to 25s. per cwt. for siftings.

CINCHONA BARK.—8 bales *Guayaquil* crown bark bought in at 9d. per lb. 1 case fair quills *Red* bark at 5s. per lb.

COLOCYNTH.—5 cases *Turkey* bought in at 1s. per lb. for small apple.

COLOMBO ROOT.—Price is decidedly lower while quality of the offerings left much to be desired. Fair sorts for which 25s. was asked not long ago were sold at 15s. per cwt., while 156 bags of dull sorts only realised 13s. down to 10s. 6d. per cwt.; good sort sold at 17s. 6d. to 18s. per cwt.

CORIANDER SEED.—85 bags fair *Morocco* sold without reserve at 5s. 3d. per cwt.

COTTON SEED OIL.—1 barrel sold without reserve at 12s. 6d. per cwt.

CROTON SEEDS.—1 bag of fair quality bought in at 75s. per cwt.

CUBEBS.—73 bags of fair quality held for 25s. per cwt.

CUMIN SEED.—11 serons country damaged sold cheaply without reserve at 6s. per cwt. Good *Malta* was held for 28s. per cwt.

CUS CUS ROOT.—15 bales cleaned bought in at 50s. per cwt.

CUTTLE FISH.—16 packages mostly sold at 4d. for fair medium down to 3d. per lb. for smaller.

DRAGON'S BLOOD.—4 cases *Zanzibar* drop, of fair colour but woody, held for £7 10s. per cwt.

ESSENTIAL OILS.—2 tins *Lime Oil* bought in at 4s. per lb. 4 cases *Cinnamon Oil* at 9d. per oz., 6d. per oz. being, however, the price which would have been accepted. *Oil of Lemon* bought in at 3s. 3d. to 4s. per lb. *Eucalyptus*: Fair commercial was held for 11d. to 1s. per lb. 5 cases *Hale and Parshall's Oil of Peppermint* for 4s. 6d. per lb. 2 cases *Cinnamon-bark oil* bought in, 4 ditto held for 1s. 6d. per oz.

ERGOT OF RYE.—Good *Spanish* was bought in at 9d. per lb. weevily ditto at 7d.

GALANGAL ROOT.—20 bales sold without reserve at 23s. per cwt.

GUM ACCROIDES.—12 bags taken out at 20s. per cwt.

GUM ARABIC.—7 bales fair *Turkish* sorts held for 75s. per cwt., good pale grain for £7.

GUM BENJAMIN.—Medium seconds *Sumatra*, part sold at £6 5s. to £6 15s. per cwt., rest being taken out at higher prices. *Palem-bang* fetched 35s. per cwt. Medium *Siam* bought in at £13, lower quality at £7 10s. per cwt.

GUM ELEMI.—9 cases fair pale were held for 26s. per cwt.

GUM GUAIAACUM.—40 cases sold at 2½d. per lb. for common block, up to 4d. per lb. for somewhat better quality. Good glassy block fetched 2s. per lb., down to 12½d. per lb. for somewhat inferior, while for low drossy only 1d. per lb. was offered.

GUM KINO.—3 cases *African* bought in at 3s. per lb. for fair down to 2s. for dark block, and 1s. for woody; while for genuine *Cochin* 12s. per lb. was required.

HONEY.—5 packages *Jamaica* realised 21s. per cwt., down to 16s. for inferior quality. 100 barrels *Chilian* part sold at 21s.,

down to 18s. per cwt. 15 cases fair *Californian* were all bought in at 30s. per cwt.

IPECACUANHA.—For *Rio* there was no demand, but holders decline to sell under 9s. per lb. *Carthagenia*: A few bags sold at 4s. 10d. to 5s. per lb., being firm.

JALAP.—57 bales fair small heavy tubers held for 5d. per lb.

KAMALA.—6 cases bought in at 11d. per lb. for fair bright, and 5d. per lb. for dull.

KOLA NUTS.—6 bags of fair quality were taken out at 4½d. per lb.; 3½d. would, however, probably have been accepted. 14 bags bright cut sold cheaply without reserve at 2d. per lb.

MUSK.—1 tin low *Touquin* dark and damp sold cheaply at 26s. per oz.

NUX VOMICA.—114 bags good bright *Cochin* bought in at 10s. 6d. per cwt., 25 bags fair ditto selling at 8s.

ORANGE PEEL.—7d. to 8d. per lb. was price required for fair to good thin cut.

ORRIS ROOT.—7 serons *Mogador* sold without reserve at 20s. 6d. per cwt. for good, down to 10s. 6d. for ordinary. 25 bags fair *Florentine* held for 40s. per cwt.

QUINCE SEEDS.—1 bag fair *Cape* sold at 1s. 6d. per lb.

RHATANIA ROOT.—6 bales were taken out at 7d., a bid of 5d. per lb. being refused.

RHUBARB.—Good flat *high-dried*, two-thirds good colour, was held for 1s. 2d., ditto second size, of better colour for 1s. 1d. per lb.; round *Shensi* bought in at 3s. for small trimming root of fine colour, and at 1s. 7d. for ditto not so good in colour; 2 cases bold round but very wormy sold without reserve at 9½d. per lb. Four cases medium round *Canton* were bought in at 1s. per lb. Common flat *high-dried* sold at 8¼d. to 9¼d. per lb.

SARSAPARILLA.—8 bales fair red to grey native *Jamaica* held for 1s. 2d. per lb., a bid of 1s. being declined. 19 bales *Lima* part sold at 11½d. to 1s. 2d. per lb. 3 bales fair *Jamaica* sold at 1s. 10d. per lb., fair *Honduras* held for 1s. 7d. per lb., and *Mexican* for 4½d. per lb.

SENNA.—About 140 bales *Tinnevelly* from first hands, all of low quality, sold at fully last sales' rates at 1½d. to 2½d. for small spotty to medium leaf. *Jungle* sold at 1d. per lb. *Alexandria* kinds in no demand, all being bought in; good leaf at 7d. per lb.

SQUILLS.—12 bags fair bought in, 3d. per lb. being price required.

TAMARINDS.—30 barrels fair *West Indian* realised from 9s. 6d. to 10s. per cwt., 1 cask good wild *Barbados* taken out at 14s. per cwt.

TURMERIC.—13 bags *China* taken out at 17s. per cwt.

VANILLOES.—53 tins black *Mauritius* sold at 25s. per lb. for 8 to 8½ inch down to 16s. per lb. for 4 to 5½ inch.; *Seychelles* realised 19s. 6d. per lb. for 7 to 8 inch down to 16s. for 4 to 5½ inch.

WAX.—2 packages fair *Jamaica* sold at £6 15s. per cwt.; 26 packages *Morocco* bought in at £6; *Madagascar* at £6 to £6 7s. 6d.; *Zanzibar* at £6 per cwt.

Liverpool Market Report.

JULY 20, 1898.

A brisker tone has been noticeable during the week's business, sales have been more numerous, and several slight increases have taken place in the price of certain staple articles. Good sales of West African produce have been reported, chiefly in Ginger, Chillies, Kola nuts, and Beeswax. No very considerable alteration has occurred in the prices of oils with the exception of a rise in Spirits of Turpentine.

AMMONIA SALTS.—*Carbonate* scarce at 3d. per lb. *Sulphate* is also scarce at £9 7s. 6d. to £9 10s. per ton, but quiet.

BEESWAX.—45 sacks of *Chilian* made from £6 17s. 6d. to £7 10s. per cwt., and small amounts of *Gambia* sold for £6 15s. per cwt.

BLEACHING POWDER.—Is quiet at £5 7s. 6d. to £5 15s. per ton.

CANARY SEED.—Is quite neglected, and the price merely nominal at 25s. to 26s. per 464 lbs. 50 bags of *Turkish* sold at 25s. 6d.

CHILLIES.—Small amounts of fine *Sierra Leone* fruit changed hands at 40s. per cwt. in store.

COPPERAS.—Continues firm at 36s. and 38s. per ton.

COPPER SULPHATE.—Is very firm at £16 10s. per ton, higher rates are looked for when the season commences.

GINGER.—Sales of *Sierra Leone Rhizome* have been effected a 18s. 6d. in store, and 18s. per cwt ex-quay.

HONEY.—30 barrels of *Chilian* were disposed of at 24s. 6d. per cwt. for Pile 1, and 27s. 6d. to 28s. per cwt. for Pile X.

KOLA NUTS.—30 packages of dried fetched 1½d. per lb.

LINSEED.—Sellers quote 35s. 4½d. per 416 lbs. for *Calcutta* seed and 32s. for *River Plate*, July to August, but buyers evidently expect lower rates, as no business has been concluded.

OILS (FIXED) AND SPIRITS.—*Castor* is firmly held for 3¼d. per lb. *Calcutta* "good seconds," 3d. to 3½d. French 1st pressure, and 3½d. per lb. for *Madras*. The demand is steady and good, but supplies are somewhat short. *Olive* is dull and sales only retail in quantity. Holders would accept rather lower than late rates in order to clear the quays. *Linseed* of *Liverpool* make still commands a fair trade at 18s. to 18s. 6d. per cwt. *Cottonseed*: *Liverpool* refined in export barrels is selling steadily at 15s. 9d. to 16s. 3d. per cwt. *Spirits of turpentine* is in fair demand at the higher rate of 22s. 6d. per cwt.

POTASH SALTS.—*Bicarbonate* (*Montreal*): 30s. per cwt. *Bichromate*: 3¼d. per lb. *Chlorate* firm at 3½d. to 3¾d. per lb. *Cream of Tartar* does not command much attention at 78s. 6d. per cwt. *Pearlashes* continue nominal at 35s. per cwt. *Potashes* are in improved demand at 20s. 3d. to 20s. 6d. per cwt. *Saltpetre*: 21s. 6d. per cwt.

SODA SALTS.—*Bicarbonate*: £6 15s. per ton. *Borax*: £12 15s. to £13 10s. per ton. *Caustic*: 76 to 77 per cent., £8 5s. per ton; 60 per cent., £6 5s. *Crystals* steady at £3 per ton. *Nitrate* is not very brisk and is a turn easier in price, 7s. 4½d. to 7s. 7½d. per cwt.

Newcastle Chemical Report.

JULY 20, 1898.

More orders for heavy chemicals are moving in the hands of shippers, but still not to the extent of stating that a busy tone exists. Sulphur is a trifle scarce, otherwise the market is unchanged, and late prices rule thus: Bleaching powder, £6 5s. to £6 10s. Soda crystals, basis, price, 45s. to 52s. 6d. Caustic soda: 70 per cent. basis, price, £7 5s. to £7 10s. Soda ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. Sulphur: £5 per ton.

Manchester Chemical Report.

JULY 20, 1878.

The dull state of things noted for two or three weeks past continues. In heavy chemicals there has been no material change, either on home or foreign account. Bleaching Powder is weak at £5 per ton, soft-wood casks, on rails. Sulphate of Copper continues to advance, and now ranges from £17 5s. to £17 10s. per ton for best brands, delivered Manchester. Brown Acetate is dull at £5 to £5 5s. per ton, *c.i.f.*, Manchester or at station, both Welsh and American. Chlorate of Potash is rather dearer at 3½d. per lb. Salt Cake ranges from 24s. to 25s. per ton in bulk on rails. Yellow Prussiate is firm at 6¼d. to 7d., and there is an upward tendency. Benzols are a shade lower, although 11d. is asked for 90's, July-December delivery. Naphthas, especially miscible, are scarce, and makers are well sold forwards. Green Copperas of Lancashire make is fairly firm.

Partnerships Dissolved.

(From the London Gazette.)

E. R. B. Reynolds, Highcroft, Shepherd's Hill, Highgate, R. A. Ironside, 8, Highbury New Park, N., and A. E. Reynolds, 81, Hornsey Rise, N., Surgeons carrying on a medical practice at the above addresses. Debts will be received and paid by the late partners at their respective addresses.

Wm. Parker and Wm. Walker (trading as Walker and Parker), Mineral Water Manufacturers, Crown Works, London Road, Coventry. Debts will be received and paid by Wm. Walker.

Henry J. Stokes and Henry F. Stokes, Surgeons, etc.

J. H. Kirk and Geo. J. Sershall (trading as the Coloured Ivoryide Photo Co.), Photographic Artists, 62, Soho Hill, Handsworth, Stafford. Debts will be received and paid by Geo. J. Sershall, who will continue the business under the old style.

G. W. Blomfield and E. E. Blomfield, Physicians and Surgeons, Knottingley and Pontefract. Debts will be received and paid by G. W. Blomfield.

Eliza Abbott and J. J. Anning, Chemists and Druggists, 145, Woodhouse Lane, Leeds.

PHARMACY ACTS AMENDMENT BILL.

In the House of Lords on Thursday afternoon the Pharmacy Acts Amendment Bill was set down for third reading, and notice of amendment had been given by the Lord Chancellor as follows:—

A company may carry on the business of a pharmaceutical chemist or chemist and druggist if and so long as the business is *bona fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, but, subject as aforesaid, Sections 1 and 15 of the Pharmacy Act, 1868, shall apply in the case of a company in like manner as they apply in the case of an individual.

The Earl of Hardwicke having formally moved the third reading of the measure,

The Lord Chancellor, referring to the amendment which stood in his name on the paper, said: "Undoubtedly the state of the law as disclosed in the inquiry before the Standing Committee is extremely unsatisfactory, and it appeared to me under the circumstances that some amendment of the law was required. I do not think this amendment of mine would hurt the Bill; still, the Bill, on the other hand, really and truly only affects the internal economy of the Pharmaceutical Society. I have received a number of complaints in respect of companies carrying on the business of chemists and druggists, but most of the complaints came from Ireland, and therefore would not be touched. However, the question is a very important and serious one. I know that after the Bill was introduced in the House of Commons an agreement was come to that it should be taken as an unopposed Bill, but I have received a very considerable body of correspondence on both sides with reference to this question discussing whether or not such an amendment ought or ought not to be introduced into the existing law. Well, my Lords, I have considered the matter very carefully, and it appears to me that the amendment would be inoperative unless there was a very considerable amount of machinery introduced in the measure in the way of registration. I have therefore come to the conclusion—though I still adhere to the opinion I expressed in the Standing Committee—that unless such additional provisions were made it would be better for me not to move the amendment now standing in my name."

The amendment having been withdrawn, the Bill was then read a third time and passed.

News in Brief.

MR. J. KENN ROBERTS, A.P.S., who has been in business in Swansea for twenty-five years, has removed to new premises in Marlborough Road, Rhydding, Swansea, but still retains the old title of the St. Helen's Pharmacy.

MR. HAROLD WILSON, who for the past two years has held the post of Demonstrator in Pharmacy and Materia Medica in the Society's School has been appointed Pharmacist to University College Hospital, London.

MR. SIDEBOTHAM (Hyde) will on Friday, 22nd inst., ask leave to introduce a Bill to regulate the use of University Degrees in the British Isles. This belated Bill is not expected to make much disturbance this session. Mr. Sidebotham is a graduate of Owens College and a Bachelor of Music of Oxford, but his political judgment in introducing a private measure after Mr. Balfour has announced the suspension of the 12 o'clock rule for the remainder of the session may be somewhat questioned by the mere layman.

A FELLOW-FEELING FOR JURORS distinguishes Mr. Pickersgill (Bethnal Green) above his Parliamentary colleagues. The honourable gentleman's sensitiveness to the sufferings of criminals is well known, but it is gratifying to learn that he has a compassionate thought for the juries which try them. He asked the Home Secretary to direct his special attention to the present-day jury box, and see if its capabilities of inflicting physical pain could not be modified. Replying to Mr. Pickersgill, Sir M. W. Ridley said he had received no complaints, but now that the subject had been mentioned he would see what could be done. This information is of little interest to the pharmaceutical chemist, but the as yet unemancipated chemist and druggist will be glad of the prospect of being comfortable when he is called upon to discharge that highest act of citizenship—service on juries.

MR. THOMAS MABEN, pharmaceutical chemist, Hawick, was induced to give 15s. to John Irving, clerk, of Galashiels, who represented that he required the money to bail his brother out of prison. The statement was false, and in consequence of the deception, on July 18 he received a sentence of fourteen days' imprisonment.

IRISH PAUPERS' MEDICINES will be prepared according to the new B.P. in due course, but for the present they will be supplied as heretofore. One very well-known firm of union drug contractors in Ireland was recently asked by one of its union customers whether it is supplying the medicines in conformity with the Pharmacopœia of 1898 or that of thirteen years ago, and the reply was that the firm proposed to continue to use the older work until their contract expires, as that would give them time to study the new work. In the opinion of the *Medical Press* that statement indicates admirable discretion.

ACCIDENTAL POISONING CASES.

CARBOLIC ACID kept in a medicine bottle caused the death of Alice Mary Evans (34), of Cathless Road, Balham, on Tuesday, July 12. She appears to have mistaken the poison for medicine which she had been taking regularly for some time. The jury returned a verdict of "Death by misadventure."

CARELESS STORAGE OF LIQUID WEED-KILLER appears to have been responsible for the death of the Rev. James Thomson, minister of Arbroath Parish Church. On Tuesday, July 19, he and his wife cycled from Comrie to Drummond Castle, arriving at their destination thirsty and fatigued. Whilst passing through the estate, observing what he thought was a barrel of water near the road, he drank some of the contents, but discovered when too late that it was arsenical weed-killer. Assistance being obtained he was conveyed to Crieff, where he died the following day.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Miscellaneous.

Magic Lanterns, second-hand; triples and binoculars; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

One dozen each Ashton and Parsons' Pilules, Sulphur, Nux Vomica, Chamomile, Aconite, Belladonna, Phosph., Ipecac.; new and clean; what offers?—Houston, Chemist, Chesterfield.

R.R. Facile Hand-Camera and Canvas Case, cost £5 12s. 6d., good as new, £3 10s. or offers.—T. B. Rowell, Haydon Bridge.

Books.

"Dispensatory," latest, complete, quite new; cost 35s., take 27s. 6d.—M., 22, Society Place, Derby.

WANTED.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Perkin and Kipping's 'Organic Chemistry'; Green's 'Botany,' second volume; Bentham and Hooker's 'Flora'; Cross and Cole's 'Modern Microscopy.' State edition, condition, and price. "Chemist," 6, Long Causeway, Peterborough.

Old Chemists' Pots, Jars, and Bottles. Particulars and price to "Antique," Pharmaceutical Journal Office, 5, Serle Street, London, W.C.

Students' and Chemists' Books wanted for cash or exchange. Please supply following particulars:—Edition, date of publication, condition, and price required.—Gower, Publisher, Waterloo, Liverpool.

Offers Wanted.—1 oz. Piperazin; 3 × 1 oz. Guaiacol Carb.; ½ lb. Guaiacol; 1 oz. Chinosol; 2 ozs. Cocain Hydrochlor.; 1 oz. Zymine (Fairchild); 1 lb. Bismuth Carb.; 3ss. Homatropin Hydrobrom.—Chemist, 156, Green Lanes, Stoke Newington, N.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Alcock, Atkinson, Austen, Brierley, Clegg, Downes, Evans, Forrest, Freeman, Gifford, Glyn-Jones, Goldby, Griffith, Hewlett, Hill, Hogg, Johnston, Lake, Lawrence, MacNaught, Plumbly, Reynolds, Ross, Southall, Swainson, Symes, Thompson, Winship.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

JULY 28, 1898.

The Markets have again been very quiet during the past week, with, however, a somewhat more hopeful feeling as to the future of trade in Drugs and Chemicals after the summer holidays are over. There has been a further advance in Acid Citric, which closes quite firm. The same may also be said of Acid Tartaric and Cream of Tartar. Opium is again dearer, which has had its effect on Morphia and Codeia. Quicksilver and Mercurials, Iodine and Iodides, Bromine and Bromides, Bismuth and Salts, are all unchanged. Cod-liver Oil very quiet. Glycerin firm. Quinine quiet and unchanged. Sulphate of Ammonia dearer. Cocaine rather firmer, as also is Phenacetin. Sulphonal unchanged. Acetanilide weak. Borax and Acid Boracic very quiet. Acid Oxalic lower. Ipecacuanha steady. The following are the actual prices of articles of chief interest:—

ACETANILIDE.—Weak at 1s. to 1s. 1d. per lb., according to quantity.

ACID BORACIC.—Quiet at 23s. per cwt. for *crystals*, and 25s. per cwt. for *powder*.

ACID CARBOLIC.—Is quiet but steady at 6½d. to 6¾d. per lb. for 35-36° C. *ice crystals* in 2½-cwt. drums and overcasks; other qualities and packing in proportion. *Crude*: 60° F., 2s. 1d.; 75° F., 2s. 6d. per gallon. *Liquid*: 95 per cent., of pale straw colour, 1s. 1d. to 1s. 2d. per gallon in 40 gallon casks.

ACID CITRIC.—Is again dearer at 1s. 2½d. per lb. for *Crystal*. Market is very firm, and a further rise is expected in view of the relatively higher values of juice.

ACID OXALIC.—Steady at late reduction to 3½d. to 3¾d. per lb. on the spot.

ACID TANNIC.—The *leviss B.P.* quality is quoted 1s. 8d. to 1s. 9d. per lb. in cwt. cases.

ACID TARTARIC.—Exceedingly firm at 1s. 1d. per lb. for *English crystal* and 12¼d. per lb. for *foreign*. An early advance is anticipated.

AMMONIA COMPOUNDS.—*Sulphate* dearer, with a very firm market. Grey prompt, 24 per cent., London, £9 10s. per ton; Hull, prompt, £9 8s. 9d.; Leith, prompt, £9 10s. per ton. *Carbonate* firm at 3¾d. to 4d. per lb., according to package. *Bromide* steady at 2s. 1d. per lb. *Iodide* unchanged at 14s. 6d. per lb. *Sulpho-cyanide* firm and scarce on the spot; 1s. 2d. per lb. quoted. *Sal ammoniac* steady at 35s. per cwt. for sublimed firsts, and 33s. per cwt. for seconds.

APOMORPHIA.—One maker advanced his price to 17s. per oz., while a further advance in value would appear to be practically certain.

BISMUTH.—There is no change in price either of the *metal* or of the *salts*.

BLEACHING POWDER.—Firm at £6 15s. to £7 10s. per ton, according to package.

BORAX.—Is steady, although quiet, at 13s. 6d. per cwt. for *lump*, and 14s. per cwt. for *powder*.

BROMIDES.—Without change at prices quoted last week.

CAMPHOR.—The position of *crude* shows no improvement, and quotations in the absence of business are quite nominal. *China* at 78s. 6d. per cwt., and *Japan*, 87s. per cwt., *c.i.f.* terms. *Refined* is quiet at late reduction.

CARDAMOMS.—There has been more enquiry privately, and a moderate business has been done at some improvement on the prices realised in last auctions.

CLOVES.—Privately *Zanzibar* have been strong, and good business has passed, including spot, 4¼d.; August to October delivery, 4¾d. to 4½d.; October to December, 4¾d. to 4½d.; January to March, 4½d. At auction of 125 bales *Zanzibar* 25 bales middling sold at 4d.; 8 cases good picked *Penang* bought in at 10d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 4d., pure 2s. 3d. per gallon. *Benzole*: 50 per cent., 11d.; 90 per cent., 10d. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 5d. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 7½d. per gallon.

COCAINE.—There is a decidedly better feeling in this article, prompted first by the fact that buyers are now rigorously insisting on having an article which quite fully answers all the B.P. tests (which fact has tended to throw into the shade one or two of the makes which have lately been offering at comparatively reduced prices), and, secondly, owing to the limited supply of *crude*. The best brands of the article can, however, still be bought from the makers at 9s. 3d. to 9s. 6d. per oz. for the *Hydrochlorate* in 25-oz. tins and 100-oz. lots.

COD LIVER OIL.—Very quiet, nominal price being 85s. to 90s., according to brand *f.o.b.* for best new non-congealing *Norwegian* oil in tin lined barrels of 25 gallons each.

CODEIA.—Makers lately advanced their price to 12s. 6d. per oz., at which figure the article remains very firm.

CREAM OF TARTAR.—Is again dearer, first white *crystals* on the spot having been done at 74s. per cwt., and at 76s. 6d. to 77s. per cwt. for *powder*. Good B.P. *crystals* firm at 83s. per cwt.: *powder*, 86s. per cwt.

DAMIANA LEAVES.—Are again reported dearer from the other side, and 10d. per lb. here is quoted.

GALLS.—*Persian* are very firm, but little business has been done owing to the firmness of holders.

GOLDEN SEAL ROOT.—Comes dearer from New York at 1s. 8d. to 1s. 9d. per lb. *c.i.f.*

GINGER.—*Cochin* remains flat; of 587 bags, rough kinds, only 190 bags sold, cuttings 13s., sea damaged washed rough 18s. 6d. to 19s., the remainder bought in washed rough 22s., brown 26s.; 98 cases, medium and small native, part cut, bought in at 42s. to 50s. *Jamaica* steady but quiet, of 279 barrels only 100 sold, common *Rhatoon* 65s. to 65s. 6d., middling to good middling washed 73s. to 77s.; 36 half-barrels, good bright plump, sold at 86s. 6d. to 88s.

GLYCERIN.—Is firm at 52s. 6d. per cwt. for *English* and 55s. to 65s. according to brand for *German* white double-distilled chemically pure 1260 quality in tins and cases.

IODIDES.—In good demand at unchanged prices.

IPECACUANHA.—Since last week's auctions a few bales of *Rio* have changed hands at 9s. per lb., and a certain quantity of *Carthagena* at 5s. per lb.

JAPAN WAX.—Is very quiet. Good squares quoted 32s. 6d. per cwt.

LAVENDER FLOWERS.—*New* are offering at 25s. to 27s. 6d. per cwt., *c.i.f.*, according to quantity.

MERCURIALS.—Are firm at unchanged prices.

MORPHIA.—Makers' prices are 5s. per oz. for powdered salts, and 2d. per oz. more for *crystals*, at which figures the article is very firm, in face of the continued rise in value of opium.

NITRATE OF SODA—Is quoted £7 12s. 6d. per ton for *commercial*, and £7 17s. 6d. per ton for *refined*.

NITRATE OF SILVER—Has continued to fluctuate slightly in sympathy with price of the *metal*, price being 1s. 5½d. to 1s. 6½d. per oz., according to quantity, for *crystals*, *sticks* costing more in proportion.

OILS (ESSENTIAL).—*Star Aniseed* is quieter, with sellers on the spot at 7s. 1½d. per lb. *Peppermint*: American H.G.H. is quoted 5s. 6d. to 5s. 9d. per lb., according to quantity. *Wayne County*: New York advices report a firm market. Here on the spot 4s. per lb. is quoted. *Cassia* firm and dearer, 70 to 75 per cent. 5s. 1½d. to 5s. 3d. per lb., 75 to 80 per cent. 5s. 6d. per lb. *Citronelle* is firm, but quotations are nominal. *Eucalyptus*: Good ordinary quality 1s. per lb.; medicinal oil 2s. 6d. to 2s. 9d. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed* lower at £16 12s. 6d. for spot pipes, and £16 17s. 6d. for barrels. *Rape* is lower at £21 10s. for ordinary brown on the spot, refined spot £23. *Cotton* rather easier at £13 12s. 6d. for London crude on the spot, refined spot £15 15s. to £16, according to make. *Olive* quiet for green oils, Spanish lower, owing to exchange, at £31; French, Levant and Mogador £32 10s. *Coconut* firm; Ceylon in pipes on the spot, £23 10s.; hogsheads, £24 10s.; Cochin, spot, £28 10s. *Palm* slightly dearer at £22 10s. for Lagos on the spot. *Turpentine* dearer, but closing quiet at 22s. per cwt. for American on the spot. *Petroleum Oil* very firm at 4½d. per gallon for Russian, and 5½d. per gallon for American.

OPIUM.—The demand for both "druggists" and "manufacturing" kinds continues, and a large business has been done at advancing prices. Stocks have been considerably reduced, and a further advance may be safely anticipated. Most holders ask exorbitant figures; others have withdrawn their stocks from the market. Full rates have been paid for *soft shipping*. Nominal quotations on the spot are:—Ordinary to good *soft shipping*, 11s. 6d. to 13s. 6d. per lb.; good to fine *druggists*, 11s. to 12s. 6d. per lb.; *Persian*, 11s. 6d. to 12s. 6d. per lb.

PHENACETIN.—Market is rather firmer at 3s. 9d. to 4s. 3d. per lb. for good quality *crystal* or *powder* in quantity and bulk packing.

OTTO OF ROSE.—Mr. H. A. Holstein, of Constantinople, estimates this year's crop at about 48,000 Turkish ounces, as against 70,000 Turkish ounces in 1897, and an average of 71,000 Turkish ounces for the previous nine years. It is anticipated that in consequence of the small yield this season that higher prices will have to be paid.

PERMANGANATE OF POTASH—Is quoted 60s. to 62s. 6d. per cwt., according to quantity, for small crystals in 1 cwt. kegs, the large crystals costing 5s. per cwt. more.

PHENAZONE.—Dr. Knorr's *Antipyrine* was reduced late last week by nearly 50 per cent. from the comparatively high price at which it had been previously held, while the chemical equivalent of *Antipyrine*, *Phenazone* to wit, was also further reduced, there being sellers as low as 9s. per lb. in quantity and in large bulk packing.

POTASH COMPOUNDS.—*Chlorate* firm at 3½d. per lb. on the spot for both crystal and powder. *Bichromate* lower at 2¼d. to 3d. per lb. according to quantity. *Prussiate*: *Yellow* firm at 7d. per lb. *Red* unchanged at 1s. 2d. per lb. *Bicarbonate* steady at 30s. per cwt. for crystals and powder. *Iodide* unchanged at 9s. 9d. to 10s. 3d. per lb., according to quantity. *Bromide* very firm at 1s. 9½d. per lb. *Permanganate* is in fair demand at 62s. 6d. per cwt. for small and 67s. 6d. per cwt. for large crystals. *Cyanide*: Spot goods continue scarce, and realise readily 1s. 2d. to 1s. 2½d. per lb. for the 98 to 100 per cent. cake.

QUICKSILVER—Is very firm at £7 12s. 6d. per flask from first hands, and £7 12s. from second-hand holders.

QUININE.—Market has been very quiet this week, makers' price being unchanged at 10d. per oz. for *German* brands of the *Sulphate* in 100 oz. tins and 1000 oz. lots.

SARSAPARILLA.—*Jamaica* is scarce, and 1s. 10d. per lb. is asked. *Native* is held for 1s. per lb. for fair grey to red, and 1s. 2d. per lb. for all red.

SENA.—There is some enquiry for *Tinnevely*, and business has been done at 2d. per lb. for small spotty leaves, and 3½d. to 4d. per lb. for fair medium leaves. Pods have been done at 1½d. per lb. for fair pale.

SENEGA ROOT—Is scarce on the spot, 1s. 2d. per lb. being asked for the little that is available. Price in the United States is firmer with a good demand.

SHELLAC.—The market is extremely quiet, and only a few hundred cases of *Second Orange* have been done this week at steady prices. For August delivery TN is quoted 64s. 6d. per cwt.

SODA COMPOUNDS.—*Crystals* remain firm at 57s. 6d. per ton in barrels. *Bicarbonate* unchanged at £7 5s. to £7 10s. per ton for the 97 to 98 per cent. commercial quality, and 18s. 6d. per cwt. for the fully bicarbonated chemically pure article. *Ash* steady at £5 5s. to £5 15s. per ton, according to strength. *Bromide* firm at 2s. 0½d. per lb. *Iodide* steady at 11s. 7d. per lb. *Caustic*: 70 per cent. white, £7 15s. per ton, 60 per cent. £1 per ton less.

SPICES (VARIOUS).—*Black Pepper*: 39 bags good Coorg and 73 bags Wynaad sold at 4½d. *White Pepper* privately firm, Penang 7¼d. to 8d., Siam and Singapore 8½d. to 9d., according to position. *Chillies*: 36 bales Zanzibar brought in at 32s., and 5 bales sea-damaged sold at 30s. 36 cases Japan sold, without reserve, at 32s. to 32s. 6d. *Cinnamon Chips*: 35 bags good Ceylon sold at 4¼d. *Mace*: 11 packages West India sold at 1s. 5d. to 1s. 11d. *Nutmegs* quiet but steady. *Pimento* firm: 100 bags good sold at 4½d.

SUGAR OF LEAD.—*Foreign* is firm at 27s. 6d. per cwt. *English*: 31s. per cwt.

SULPHATE OF COPPER—Is dearer at £16 to £17 5s. per ton, according to brand.

SULPHONAL.—Remains in *statu quo*, being still obtainable from the makers in limited quantity and to regular customers only at 7s. 3d. per lb. for bulk.

SULPHUR.—Is firm. *Foreign* roll 6s. 6d. per cwt. Flowers 7s. per cwt. *English* roll 7s. 6d. per cwt.

TURMERIC—Continues very firm, but scarcity restricts business. *Bengal* finger of dark fracture sold at 21s. per cwt. *Cochin* finger quoted at 21s. per cwt.; split bulbs, 10s. per cwt. *Madras* is very scarce, and extreme rates are asked.

Newcastle Chemical Report.

JULY 27, 1898.

Sulphur is scarce on this market, and very firmly held at price quoted. With the exception of new shipping orders in circulation against contracts, new business for forward is slow. Prices are: Sulphur: £5 to £5 5s. Bleaching powder, £6 5s. to £6 10s. Soda crystals, basis, 45s. to 52s. 6d. Caustic soda: 70 per cent. basis, £7 5s. to £7 10s. Soda ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. per ton.

Manchester Chemical Report.

JULY 27, 1898.

In heavy chemicals Ammonia Alkali, Soda Ash, and Crystals are fairly firm at late rates, but Caustic Soda and Bleaching Powder remain inactive. The price for the last-named article ranges from £5 2s. 6d. to £5 7s. 6d. per ton on rails, prompt delivery. Some contract business over next year has been put through, it is reported, at £5, an extraordinarily low figure under the circumstances. Sulphate of Copper is firm at from £17 to £17 10s. per ton, according to brand, delivered Manchester. It is evident there is little second-hand stuff on the market. Brown acetate continues to droop, and is rather neglected at even £5 per ton for American or Welsh ex-ship. Pitch has improved a little, but prices are still low. Locally, Green Copperas is in fair demand for best Lancashire make, but is suffering somewhat from the competition of the Welsh article. Aniline oil and salt are unchanged on last week.

Liverpool Market Report.

JULY 27, 1898.

AMMONIA SALTS.—*Carbonate*: 3d. per lb. *Sulphate*: £9 7s. 6d. to £9 10s. per ton.

BEE SWAX.—Gambia, 10 bales, at £6 15s. to £6 17s. 6d. per cwt.

BLEACHING POWDER—£5 7s. 6d. to £5 15s. per ton.

CANARY SEED—Continues dull and neglected at 25s. to 26s. per 464 lbs.

COPPERAS—Is very firm at 38s. per ton for Lancashire and 36s. for Welsh.

COPPER SULPHATE—Is firmly held for £16 10s. to £16 15s. per ton.

GINGER.—200 bags of Sierra Leone sold, ex-quay, at 18s. per cwt.

OILS (FIXED) AND SPIRITS.—*Castor* is somewhat quiet, but

Prices are steadily maintained at 3¼d. per lb. for Calcutta, 3d. to 3½d. for French, first pressure, and 3½d. per lb. for Madras. *Olive*: Spanish was offering early in the week at £28 15s. per tun. for Malaga for shipment, cost, and freight, and £27 15s. for Seville ditto; Malaga is now quoted on same terms at £28 5s. to £28 15s. *Linseed* of Liverpool make is priced at 18s. to 18s. 6d. per cwt. *Cottonseed*: Liverpool refined, 15s. 9d. to 16s. 3d. per cwt. *Spirits of turpentine* is again a shade higher at 22s. 9d. per cwt.

POTASH SALTS.—*Chlorate* is dearer; crystal, 3¼d. per lb.; and powder, 3½d. to 3½d. per lb. *Chromate (Bi)*, 3¼d. per lb. *Pearlash* quiet at 35s. per cwt. *Potashes* have dropped a little, owing to arrivals, 20s. to 20s. 3d. per cwt. *Tartar* is steady at 78s. 6d. per cwt.

SODA SALTS.—*Borax*, £13 to £14 per ton. *Bicarbonate*, £6 15s. per ton. *Caustic*: 70 per cent., £8 5s. per ton; 60 per cent., £6 5s. *Crystals* firm at £2 17s. 6d. to £3 per ton. *Nitrate*, 7s. 6d. to 7s. 9d. per cwt.

News in Brief.

THE HUNLEY LECTURE on "Recent Advances in Science and their Bearing on Medicine and Surgery," will be delivered next October at the Charing Cross Medical School by Professor Virchow.

AN OVERDOSE OF LAUDANUM taken by Charlotte Smith (49), of Wrelton, caused her death on July 2. It was shown at the inquest that the woman was an inveterate laudanum drinker, and the Coroner, in reviewing the evidence, commented strongly upon alleged defects of the law in regard to the sale of poisons. The jury condemned the action of the chemist who supplied the poison, on the ground that there was reason to believe he knew the purpose for which it was required. They also recommended alterations in the Act of Parliament relating to the sale of poisons.

MR. CHARLES E. TURNER, jun., eldest son of Mr. C. E. Turner, pharmaceutical chemist, Bury Street, Bloomsbury, W.C., has successfully passed the final examination of the Conjoint Board of the Royal Colleges of Physicians and Surgeons.

AN OVERDOSE OF MORPHINE has caused the death of the Medical Officer of Health for Montrose, Dr. Greatbatch, who suffered greatly from sleeplessness. Efforts were made to overcome the effects of the drug, but without success.

EDINBURGH PHARMACY ATHLETIC CLUB (Swimming Section).—The second of the series of summer handicaps (50 yards) was brought off in Dalry Baths on July 18, with the following result:—1, J. Grieve, 12 sec.; 2, L. S. Lamb, 6 sec.; 3, A. G. Paterson, 6 sec.; 4, G. H. C. Rowland, 8 sec.; 5, J. Lockerbie, scratch. A very close finish.

NEWCASTLE-ON-TYNE AND DISTRICT CHEMISTS' ASSOCIATION.—The second annual excursion was held on Wednesday, July 20, when a large company of members and their friends visited the ancient and picturesque borough of Hexham. On arrival at the town the party proceeded by way of the woods to Swallowship, where the time was spent in rambling, photography, etc. On returning to Hexham an excellent meat tea was provided at the Royal Hotel, the party doing full justice to the meal, afterwards inspecting the Abbey under the guidance of Mr. J. P. Gibson. The party included Mr. J. Maltby Clague, President of the Association; Mr. C. Ridley and party, Newcastle; Mr. and Mrs. J. D. Rose, Jarrow; Mr. W. Kerse, Newcastle; Mr. J. P. Gibson, Mr. John, and the Misses Gibson, Hexham; Mr. and Mrs. Brand, Wallsend; Mr. F. R. Dudderidge, Principal of the North of England School of Chemistry, Newcastle; Mr. Gelderdale, F.C.S., Mr. Ismay, Mr. Pescod, Newcastle, and many others. Mr. G. F. Merson, F.C.S., Hon. Secretary, was responsible for the arrangements for what proved to be a most delightful and enjoyable outing.

A COUNTY COUNCIL'S RESPONSIBILITIES.—The Warwickshire County Council has had its attention called by Mr. Hollick, chemist and druggist, Birmingham, to the important changes made in the B.P. Mr. Hollick expressed a hope that no prosecution would be instituted until the trade and the public had been allowed sufficient time to become acquainted with the new standard. He said the changes applied specially to

tincture of rhubarb, milk of sulphur, and chlorodyne, and, referring to the last mentioned, said it became a question in making up prescriptions whether chemists should disobey the law or kill the patient.—After thanking Mr. Hollick for his valuable statement, the Chairman suggested the addition of Mr. Hollick's name to the Committee, remarking that his practical experience was likely to be valuable. He added that as a public body they had only to carry out the law, and if in so doing they killed a patient, he could only say he was sorry for the patient.

CRICKET.—In the match played at Wadham Lodge, Walthamstow, on Saturday, July 23, between "Allenburys" C.C. and the City Mills, C.C., the former scored 101 for six wickets, and the latter 71 for five wickets.

MR. PELHAM C. MAITLAND, of Great Portland Street, W., formerly of Stonehouse, Plymouth, has obtained the diploma of the Royal College of Physicians of London. This is in addition to the Royal College of Surgeons (Eng.) and a triple qualification obtained before.

ARSENIC was the cause of death in the case of W. G. Nash (36), landlord of the Original Pack Horse Inn, Winchcombe, on July 5. He had been drinking and took what he supposed was a dose of Epsom salts, but which proved to be a white powder containing arsenic. "Misadventure," the jury thought.

POISONING BY LIQUID WEED-KILLER.—In connection with the death of the Rev. James Thompson, of Arbroath, mentioned last week, it appears that the barrel containing the weed-killer was placed on supports, covered by a tarpaulin, near the inner court of Drummond Castle, and hanging on the spigot was a tin jug. It is stated that the word "Poison" was marked on the barrel, but the tarpaulin cover hid it from view.

INLAND REVENUE PROSECUTION.—At Stalybridge Police Court, on July 13, Frederick William Jackson, "patent" medicine vendor, was summoned for exposing for sale medicines without a licence, and also for not having them stamped. Mr. Hawkins, who prosecuted, said defendant sold for one shilling a number of recipes, and presented each purchaser with a box of pills. That, he contended, amounted to a sale of the pills. Each box should have upon it a three halfpenny stamp, but they were all unstamped. The defendant pleaded that he thought it was not a sale when he gave away the pills with the recipes, but he was nevertheless fined.

LITTLE MISS LOGIC.

Little Dot (to Eminent Professor of Chemistry): Are you a chemist?

Eminent Professor: Yes, my dear.

L. D.: Have you got a shop with lovely large coloured bottles in the window?

E. P.: No, my dear, I don't keep a shop.

L. D.: Don't you? Then I suppose you don't sell Jones' Jubilee Cough Jujubes?

E. P.: No, my dear, I certainly do not.

L. D. (decidedly): I don't think I ought to talk to you any more. You can't be a respectable chemist.

E. P.: Why not, my dear?

L. D.: 'Cos it says on the box, "Sold by all respectable chemists."—*Punch*.

Marriages.

MASKEW—SMITH.—On July 19, at St. Mary's Parish Church, Scarborough, by the Right Rev. the Lord Bishop of Hull, William Maskew, pharmaceutical chemist, of 285, Oxford Street, Manchester, to Agnes Annie, eldest daughter of Richard Smith, jeweller, of 5, Newboro' Street, and 13, Albemarle Crescent, Scarborough.

COWIE—SINGER.—At Rothmaise Inch, Aberdeenshire, on the 26th inst., by the Rev. Wm. Masson E. C. Culsalmond, William Beverly Cowie, pharmaceutical chemist, Edinburgh, to Mary Barbara, third daughter of the late Adam Singer.

Publications Received.

THE VALUE OF CERTAIN DRUGS IN THE TREATMENT OF GOUT. By ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P. (Lond.). Pp. 16. Being a reprint from the *Lancet*. From the Author.

PRACTICAL ORGANIC CHEMISTRY. By GEORGE GEORGE, F.C.S. Pp. 96. Price 1s. 6d. London: W. B. Clive. University Correspondence College Press. 1898. From the Publishers.

A COURSE OF PRACTICAL CHEMISTRY OR QUALITATIVE CHEMICAL ANALYSIS. By the late W. G. VALENTIN, F.C.S. Edited and revised by W. R. Hodgkinson. Ninth edition. Pp. xii. + 403. Price 9s. London: J. & A. Churchill. 1898. From the Publishers.

DIE OXYMETHYLANTHRACHINONE UND IHRE BEDENTUNG FÜR EINIGE ORGANISCHE ABFÜHRMITTEL. By A. TSCHIRCH. Reprinted from *Berichten der Deutschen Pharmaceutischen Gesellschaft*, Jahrgang 1898, Heft 5. Berlin: Verlag von Gebrüder Borntraeger. From the Author.

VERSUCH EINER THEORIE DER ORGANISCHEN ABFÜHRMITTEL, WELCHE OXYMETHYLANTHRACHINONE ENTHALTEN. By A. TSCHIRCH. Reprinted from *Schweiz Wochenschrift für Chemie und Pharmacie*, 1898, No. 23. From the Author.

Advertisement.

(Received too late for Classification).

LABORATORY. Vacancies for two or three hands with some manufacturing experience, especially in chemicals. Apply by letter, with full particulars of age, experience, and wages required, to LABORATORY, c/o Street & Co., 30, Cornhill, E.C.

Partnerships Dissolved.

(From the London Gazette.)

John M. Owen, H. L. Swcte, and Joseph Hammond, Surgeons, Castle Hill, Fishguard, Pembroke. Debts will be received and paid by Joseph Hammond, Public Accountant, Duffryn Chambers, Pontypridd.

Wm. D. James and Hugh Rhodes, Surgeons, Sheffield.

Receiving Orders in Bankruptcy.

(From the London Gazette.)

Arthur Skand, Perfumer, 71, Leyspring Road, Leytonstone, and trading in co-partnership at 103, Bishopsgate Street Within.

Peter Craven, Ankle Strap Manufacturer, 10, Musgrave Fold, The Bank, and 19, Ellerby Road, Leeds.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Books.

First 3 Parts Quain's 'Dictionary of Medicine'; first 8 parts each of Cassell's 'History of England' and 'Family Physician.' First reasonable offer gets them.—Postlethwaite, Chemist, Barrow-in-Furness.

Miscellaneous.

Magic Lanterns, second-hand; triples and binials; oxyhydrogen microscope; marvellous pamphengos. oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

Photographic mounts, Bristol cartes, 3s.; G.B.E., 10s.; cabinets, 10s.; G.B.E., 15s.; quarter-plates, 6s.; half-plates, 12s. 1000; plate-sunk mounts, 12 by 10, 40s. 1000. Samples free.—Edward Peck, East Dereham, Norfolk.

Soda-Water Trolley, will carry 2 or 3 dozen easily, 37s., carriage paid.—Particulars of Arthur & Co., Cambridge.

WANTED.

Formulae suiting any good toilet specialty; liberal price. Particulars privately to W. Lewis, 15, Shelden Street, Bishop's Road, London, W.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Bell, Bennett, Butcher, Evans, Ffoulkes, Gauber, Harvie, Hill, Johnson, Johnston, Long, Lunan, McKnight, McNaught, Matthews, Moore, Narami, Plumbly, Siviter, Thresh, Wild.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

AUGUST 4, 1898.

As might have been expected, business has been extremely quiet during past week, comparatively few transactions having taken place, while the changes in value worthy of record are practically *nil*. Acid Citric remains extremely firm, one maker having advanced his price. Quinine steady. Cocaine, Opium, Morphia, and Codeia very firm. Glycerin is also firm. Same may be said of Quicksilver and Mercurials. Bromides and Iodides without change. Ipecacuanha steady. We give below the actual prices, some of which must, however, be considered as in so far nominal, in that there has been no business passing:—

ACETANILIDE.—There are sellers in half-ton lots at 1s. per lb. in bulk packing.

ACID CARBOLIC.—Quiet but steady at 6½d. to 6¾d. per lb. for 35 to 36° C. *ice crystal* in bulk packing according to quantity and brand. *Crude*: 60° F. 2s. 1d.; 75° F. 2s. 7d. per gallon. *Liquid*: 95 per cent. of pale straw colour 1s. 1d. to 1s. 2d. per gallon in 40-gallon casks.

ACID BORACIC.—Steady but quiet at 23s. per cwt. for *crystals*, and 25s. per cwt. for *powder*.

ACID CITRIC.—Is very firm at 1s. 2½d. per lb. on the spot, it being reported that one maker has advanced his price to 1s. 3d. per lb.

ACID TARTARIC.—Unchanged at 1s. 1d. per lb. for *English crystals* and 12¼d. per lb. for *Foreign*.

ACID OXALIC.—Is steady at 3½d. to 3¾d. per lb., according to package.

ALUM.—Loose lump £5 10s. per ton, ground in bags, £6 per ton.

AMMONIA COMPOUNDS.—*Sulphate* quiet at £9 10s. per ton for grey 24 per cent. *Carbonate* firm at 3¾d. to 4d. per lb., according to package. *Bromide* unchanged at 2s. 1d. per lb. *Iodide* quiet at 14s. 6d. per lb. *Sulpho-cyanide* very firm at 1s. 2d. per lb. *Sal ammoniac*: Sublimed firsts 35s. per cwt.; seconds 33s. per cwt. *Muriate*: 25s. per cwt. for white.

ARSENIC.—Firm at 19s. per cwt. for *powder*; *lump*, 34s. per cwt.

BISMUTH AND SALTS.—Unchanged.

BLEACHING POWDER.—Steady at £6 15s. to £7 per ton, according to package.

BORAX.—But little doing, price, however, firm at 13s. 6d. per cwt. for *lump*, and 14s. for *powder*.

BROMIDES.—Are firm at prices hitherto ruling.

BUCHU LEAVES.—This article has firmed up since the drug auctions, and a few small lots still to be had at 6d. per lb. have been secured, and in view of the small stocks and falling off in shipments from the Cape, no leaves of fair green colour can be had to-day under, it is said, 9d. per lb.

CAMPHOR.—*Crude* is very quiet, quotations are as follows:—China August to September steamer 78s.; and Japan 87s. per cwt. *c.i.f.*; *Refined* steady at 1s. 2d. to 1s. 2½d. per lb. for bells or flowers, and 1s. 3½d. to 1s. 6d. per lb. for tablets according to size.

CLOVES.—*Zanzibar* have been in active demand, and large sales

have resulted at advancing prices, comprising spot 4¾d., Aug.-Oct. delivery 4½d., and Oct.-Dec. 4¼d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 4d., pure 2s. 6d. per gallon. *Benzole*: 50 per cent., 11d.; 90 per cent., 10½d. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 5d. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 6d. per gallon.

CODEIA.—Is firm. at 12s. 6d. per oz. for the *pure*, the price of the *salts* being 1s. per oz. less.

COCAINE.—Market is firm at 9s. 3d. to 9s. 6d. per oz. for 100 oz. lots in 25 oz. tins, the tendency of price being in an upward direction, due partly to the reported scarcity of raw material, and partly to the fact that the increasing tendency to insist that the article fully answers all the requirements of the B.P. has had the effect of increasing demand for those brands which are known to fully answer such requirements.

COD-LIVER OIL.—Very little doing, price being nominally unchanged.

CREAM OF TARTAR.—Is a shade easier; first white *crystals* on the spot 73s. 6d. per cwt., and 76s. to 77s. per cwt. for powder. High strength quality is firm at 83s. and 86s. per cwt. for crystals and powder respectively.

DAMIANA LEAVES.—This article is reported from New York to be in a very strong position, 10d. per lb. is wanted on the spot here.

DRAGON'S BLOOD.—Stocks have fallen to 8 packages but a further arrival of 8 cases is just announced. Fine is much wanted.

GENTIAN ROOT.—Is rather easier at 19s. 6d. per cwt., to come forward.

GLYCERIN.—Remains firm at about last week's prices. It is, thought however, that with the advent of the increased demand for autumn and winter consumption we may very likely see a further advance in value.

GUM MASTIC.—Good clean pale tear is held for 1s. 11d. per lb., but demand is slow.

IODIDES.—Are in fair demand at unchanged prices.

IPECACUANHA.—Business has been done since our last at 9s. per lb. for fair *Rio* root and at 5s. per lb. for *Carthagenia*, the supply of the latter being small.

JAPAN WAX.—Quiet but steady at 33s. per cwt. for good squares.

MENTHOL.—Is firm, with fairly good inquiry, at 7s. 1½d. to 7s. 3d. per lb.

MERCURIALS.—Are firm at unchanged prices, viz., 2s. 5d. per lb. for *Corrosive Sublimate*, and 2s. 9d. per lb. for *Calomel* in 56-lb. lots.

MORPHIA.—Makers' prices remain firm at 5s. per oz. for the *powdered salts* and 5s. 2d. for *crystals*, in quantity and bulk packing.

NITRATE OF SODA.—*Commercial* is quoted at £7 12s. 6d. to £7 15s., and *refined* £7 17s. 6d. to £8 per ton.

OILS (ESSENTIAL).—*Star Aniseed* is firm at 7s. 1½d. per lb. on the spot, but demand is less active this week. *Cassia* is firm at 5s. 3d. to 5s. 6d. per lb. for 70 to 75 per cent., and 5s. 6d. to 5s. 9d. per lb. for 75 to 80 per cent. *Peppermint*: American firm; H.G.H. quoted 5s. 7½d. per lb.; Wayne County, 3s. 9d. per lb. It is stated that this year's Mitcham crop will be late, and a crop rather less than the average may be expected. *Lavender*: The Mitcham crop promises well, and should give a good yield. *Cloves*: English, 3s. per lb. *Santal Flav. Eng.*, 12s. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed* quiet at £16 12s. 6d. for spot pipes, and £17 for barrels. *Rape* a shade easier at £21 10s. for ordinary brown on the spot, and £23 for refined on the spot. *Cotton* lower at £13 10s. for London crude spot; refined, £15 5s. to £16, according to make; Hull naked, refined spot, £13 5s. *Olive*: Green oils are firm at £32 per ton; feeding oils are also firm at 5s. 6d. to 6s. 6d. per gallon, according to quality. *Coconut* a shade lower at £23 5s. for Ceylon pipes on the spot: Cochin, spot,

The stocks of camphor, oils of aniseed and cassia are incomplete, some warehouses not making returns.

£28 10s. *Palm* firm at £22 10s. for Lagos on the spot. *Turpentine* firm at 22s. per cwt. for American on the spot. *Petroleum Oil* quiet at 4½d. to 4¾d. per gallon for Russian on the spot, and 5½d. per gallon for American; water white, 6¾d. per gallon. *Petroleum Spirit*: American, 5¾d.; deodorised, 6d. per gallon.

OPIUM—Is firm, prices being nominally about the same as last week.

PERMANGANATE OF POTASH.—Small crystals are quoted 62s. 6d. per cwt., and large crystals 67s. 6d. per cwt.

PHENACETIN—Is slightly firmer, price remaining, however, nominally unaltered, a good article being still obtainable at 3s. 9d. to 4s. 3d. per lb. in bulk packing, according to quantity.

PHENAZONE.—The price of this article is being still further cut. Buyers will, however, do well to be careful that they get a reliable product, it being reported that there are inferior makes in the market.

POTASH COMPOUNDS.—*Bromide* steady at 1s. 9½d. per lb. *Iodide* firm at 9s. 9d. to 10s. 3d. according to quantity. *Bicarbonate, Foreign*, crystal or powder, 30s. per cwt. *English* 35s. per cwt. *Chlorate* steady at 3¾d. per lb. *Bichromate* steady at 3¾d. per lb. *Prussiate* firm at 7d. per lb. for *Yellow*, and 1s. 2d. per lb. for *Red*. *Cyanide*: Cake, 1s. 2d. per lb.; Stick 1s. 7d. per lb. *Permanganate* steady at 62s. 6d. per cwt. for small, and 67s. 6d. per cwt. for large crystals.

QUICKSILVER—Continues strong at £7 12s. 6d. for flask from importers, with second-hand sellers at £7 12s.

QUININE.—Market is very quiet, with few sellers of German *sulphate* below makers' price, which remains 10d. per oz. for 1000-oz. lots in 100-oz. tins.

SENNA.—Stock of all grades remains abnormally low. *Alexandrian*: Market quiet, with demand for good leaf only, which is scarce. *Tinnevelly*: Business has been done this week at 3¾d. to 4d. per lb. for medium green leaf.

SHELLAC.—This article is exceedingly dull in all positions, and prices are quite nominal. According to telegraphic advices from Calcutta, the shipments to the United Kingdom during July amount to 3800 cwt., as against 8300 cwt. same time last year, to the United States 6500 cwt., against 1700 cwt. last year, and to the Continent 2600 cwt., as against 1900 cwt. last year.

SCAMMONY.—*Virgin*: Supply very short; firsts are held for 30s. per lb.; seconds 20s. to 25s. per lb. *Roots* are firmly held at 28s. to 30s. per cwt. *Resin* firm at 6s. 9d. to 7s. per lb.

SODA COMPOUNDS.—*Crystals* are steady at 57s. 6d. per ton in barrels. *Bicarbonate* steady at £7 5s. to £7 10s. per ton for the 97 per cent. commercial article, and 18s. 6d. per cwt. for the fully bicarbonated quality. *Ash* firm at £5 5s. to £5 15s. per ton, according to strength. *Bromide* unchanged at 2s. 0½d. per lb. *Iodide* quite at 11s. 7d. per lb. *Caustic*: 70 per cent. £8 per ton, 60 per cent. £7 per ton.

SUGAR OF LEAD.—*Foreign* continues very firm at 27s. 6d. to 28s. per cwt. *English* steady at 31s. per cwt.

SULPHONAL—Unchanged, the two makers still accepting orders from regular customers only, and for limited quality at 7s. 3d. per lb. in bulk.

SULPHUR—Firm. *Foreign roll*, 6s. 6d. per cwt. *Flowers*, 7s. per cwt. *English roll*, 7s. 6d. per cwt. *Flowers*, 9s. per cwt.

SULPHATE OF COPPER.—Very firm at £16 10s. to £17 per ton, according to brand and delivery.

TURMERIC—Continues exceedingly firm. *Bengal*, 21s. per cwt. *Madras* is in very small supply and high prices are asked. *Cochin*, finger, 20s. per cwt. for fair, bulbs 10s. per cwt.

Newcastle Chemical Report.

AUGUST 3, 1898.

Rather more is doing in heavy chemicals for the Baltic ports. Bleaching powder moves slowly at slightly easier figures. Sulphur still keeps scarce. Prices are: Bleaching powder, £6 to £6 10s. Soda crystals, 45s. to 52s. 6d. Caustic soda: 70 per cent. £7 5s. to £7 10s. Soda ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. per ton. Sulphur: £5 per ton.

Liverpool Market Report.

AUGUST 3, 1898.

AMMONIA SALTS.—*Carbonate*, 3d. per lb. *Sal ammoniac*, 33s. to 35s. per cwt. *Sulphate* is slightly dearer; £9 10s. to £9 12s. 6d. per ton.

BLEACHING POWDER—Is quiet at £5 7s. 6d. to £6 15s. per ton. CANARY SEED—Is not much inquired for, and rules steady at 25s. to 26s. per 464 lbs. for *Turkish*.

COPPERAS—Continues firm at 36s. and 38s. per ton.

COPPER SULPHATE—Is firm at £16 10s. to £16 15s. per ton.

HONEY.—*Chilian* has been in good demand for export, and 170 barrels, nearly all of Pile 3, sold at 21s. per cwt.

OILS (FIXED) AND SPIRITS.—*Castor* is quiet, Calcutta, 3¾d. per lb. *French*, 3d. per lb., *Madras* 3d. to 3¾d. per lb. *Olive*: Fine Spanish are in good demand, but supply is short. *Malaga* for shipment is quoted at £29 (cost and freight) per tun. *Linseed*: Liverpool pressure is unchanged at 18s. to 18s. 6d. per cwt. *Cottonseed*: Liverpool refined, is selling quietly at 15s. 9d. to 16s. 3d. per cwt. *Spirits of turpentine* is quoted at 22s. 6d. per cwt., for which it is firmly held.

POTASH SALTS.—*Bichromate* is quiet at 3¾d. per lb., a slight drop in price. *Chlorate* firm at 3¾d. to 3¾d. per lb. *Cream of Tartar* 78s. 6d. per cwt., both on the spot and to arrive. *Pearlashes* nominal at 35s. per cwt. *Potashes* are a turn firmer 21s. to 22s. per cwt.

SODA SALTS.—*Bicarbonate*, £6 15s., *Borax* firm, £13 to £14 per cwt. *Caustic*: 76 to 77 per cent., £8 2s. 6d. to £8 5s. per ton. *Crystals* £2 17s. 6d. to £3 per ton. *Nitrate*, steady 7s. 6d. to 7s. 9d. per cwt.

Manchester Chemical Report.

AUGUST 3, 1898.

There is little or nothing new to report in heavy chemicals, except perhaps that prices are somewhat easier, except for Ammonia Alkali, which remains firm at £4 2s. 6d. to £4 7s. 6d. per ton, according to quantity, on rails. Recovered Sulphur is firm at £4 10s. to £5 per ton, according to point of delivery. Sulphate of Copper is in less request at £17 per ton, best brands, delivered Manchester. Brown Acetate of Lime is higher, and may be quoted at £5 2s. 6d. to £5 5s., Welsh and American, delivered Manchester. Naphthas are still scarce, especially Miscible and Solvent Wood (white colourless), the latter being about 1d. higher than last week. Benzols are unchanged at 10d. for 90's and 50's to 90's. Creosote is higher, 2½d. to 2¾d. Pitch is slow of sale at low prices, and Anthracene is also low, being quoted 4½d. for A, and 3¾d. for B quality. Saltcake rather dearer at 24s. to 25s. per ton. Arsenic is dull at £15 to £15 5s., ex ship Garston. Acetate of Soda somewhat dearer.

News in Brief.

MR. J. W. KNAPMAN, the Pharmaceutical Society's Librarian, is to be congratulated on his eldest son having won, at Rugby School, a leaving exhibition of £30 per annum, tenable for four years.

A BOTTLE OF CARBOLIC ACID, kept in a washstand cupboard, at Sheffield, was discovered by Charles Fenn, a boy of six years, who administered a teaspoonful of the poison to his young brother, aged three. Afterwards he told the nurse that he had been giving him some medicine. The dose proved fatal.

A BOTTLE OF LINIMENT which stood on a chest of drawers was espied by Lawrance Oliver Withington (2½), living with his parents at Gosberton. He climbed on to a chair, obtained the bottle, drank a portion of the liniment, and died in a few hours from belladonna poisoning.

MISS LIZZIE BUCHANAN, daughter of Mr. David Buchanan, chemist and druggist, Kirriemuir, was successful, at a recent examination, in gaining the St. Andrew's L.L.A. Diploma. The young lady is an apprentice chemist and druggist, and also holds the Art Teacher's Certificate, South Kensington.

THE LORD MAYORALTY OF MANCHESTER.—At an informal private meeting of the Manchester City Council held on Wednesday afternoon a resolution was unanimously adopted, requesting Alderman R. Gibson, Ph.C., to allow himself to be nominated to the office for the ensuing year. A deputation was appointed to wait upon his Lordship and to report to another meeting to be held that day fortnight.

DROYLSDEN PRUSSIATE WORKS, MANCHESTER.—Messrs. R. H. Pickles and Co., chemical manufacturers and drysalters, announce that they have purchased the above works, and that all the patented products which were worked at the Ardwick Chemical Works will be carried on by them. Mr. R. H. Pickles and Mr. Hartley Pickles, who have been connected with the late firm of Robert Rumney and Mellor and Pickles for the last twenty years, will have the management.

DR. TANNER IS IN FORM this week. He has a number of questions on the paper and seems consumed with a thirst for knowledge. Amongst the posers for various Ministers he proposes to ask Mr. Long (Board of Agriculture) next Monday whether he has any evidence of the physiological action of the worm called *Solerostomum tetracanthum*, and whether he is aware that thymol is of great service as a "nematocide" in cases of severe "epizootic attacks" set up by the interesting organism above alluded to. This question makes a brave show on the notice paper and may make a sensation at the Board of Agriculture.

THE DIRECTOR-GENERAL of the Medical Department of the Navy is inviting applications from dispensers, who must be legally

qualified, for temporary service in the Royal Naval Hospitals, but a correspondent who has had much experience in the service expresses the hope that men will not be induced to apply for the positions offered, as there is positively no inducement whatever for a man in the service, promotion being a thing unknown. There is little reason to doubt that the position of pharmacists in the public service is far from satisfactory, and the authorities should not be surprised, therefore, if they experience difficulty in filling up vacancies with dispensers of the best type.

MR. H. E. ELLIS, Ph.C., late Demonstrator at the Northern School of Pharmacy, Manchester, has, on the recommendation of the Aberdeen Pharmaceutical Association, been appointed Pharmacy teacher at Robert Gordon's College, Aberdeen.

FOOD AND DRUGS ACT PROSECUTION.

Isaac Baron, shopkeeper, of Abbey Village, Withnell, was charged at the Chorley Petty Sessions on Tuesday, July 26, with selling a drug which was not of the nature and quality demanded.—P.S. Jackson said he visited defendant's shop on Thursday, May 19. He saw Mr. Baron, and asked what kind of drugs he sold, and he replied "Compound tincture of Turkey rhubarb." He asked to be supplied with eight ounces, and defendant took it from a three-pound bottle. Witness told defendant he had purchased it for the purpose of analysis, and made the usual offer as to the division of the article, and he left a third portion. The following day he took the sample to the public analyst. The latter reported that he had examined the sample, and found that it was composed of 47.0 per cent. of water, 50.1 of alcohol, 2.9 of total solids or extractives, of which 2.4 per cent. was soluble in water, and 0.4 per cent. was insoluble in water. The sample contained only about one-half the usual quantity of extractives in which were included the active ingredients of tincture of rhubarb. In the opinion of Mr. Collingwood Williams, the analyst, the sample had not been prepared by the method of the British Pharmacopœia, a copy of which was produced.—Cross-examined: He did not know that the B.P. only came into operation in June.—In defence, Mr. Evans, barrister-at-law, said they were charged with selling compound tincture of rhubarb to the prejudice of the purchaser and not being the quality demanded. He would be able to show that in the 1885 edition of the Pharmacopœia there was no such heading of any preparation as compound tincture of rhubarb. The British Pharmacopœia, 1898, was not published until May, and it was recognised in the trade that it only came into operation in June. The purchaser was notified that the preparation was a compound. He did not ask for a simple preparation at all, and there was no such thing in the British Pharmacopœia of 1885 as a compound. He suggested that the article demanded was supplied, and if it were not so, there was nothing done to the prejudice of the purchaser, because if the wrong article was sold, the prosecution must go further and show that the substances sold were to the prejudice of the purchaser.—The Bench retired, and on their return the Chairman said they had carefully considered the case, and had decided to convict. Defendant would be fined 40s. and costs.

Marriages.

KIRBY—ELLIOT.—On July 28 at St. Catherine's Church, Abercromby Square, Liverpool, by the Rev. T. W. M. Lund, M.A., Samuel Collier, son of the late Rev. Canon Kirby, Vicar of Haverthwaite, North Lanes, to Mary Louisa, eldest daughter of Robt. J. Elliot, Ph.D., of Liverpool.

KELLY—JOHNSTON.—On July 28, at Greyfriars Parish Church, Aberdeen, by the Rev. Gordon J. Murray, B.D., Francis Kelly, M.D., to Annie, youngest daughter of John Johnston, member of the Council of the Pharmaceutical Society.

MARTIN—MARTIN. On July 28, at Lamesley Parish Church, by the Rev. E. Sydney Savage, M.A., vicar designate of Hexham, assisted by the Rev. J. Crott, vicar of the parish, William Martin, M.A., M.D., fourth son of James Martin, Restronguet, Cornwall, to Ellen Renfree, eldest daughter of N. H. Martin, J.P., Pharmaceutical Chemist, Ravenswood, Low Fell.

Advertisements.

(Received too late for Classification).

WANTED.—Qualified ASSISTANT (out-doors), aged about 24. Good dispenser. Off one night weekly at 5. State height, experience, &c., to STARKIE, 7, Grand Hotel Bldgs., Charing Cross.

DISENGAGED August 30th. Qualified. LOCUM or permanent to hospital or private practice. Age 30. Present locum, Bromley Hospital, E. Previous locum, South Western Hospital, Stockwell, S.W. Highest testimonials. Thoroughly trustworthy. Address, DISPENSER, Poplar and Stepney Sick Asylum, Bromley, London, E.

PARIS.—Wanted, immediately, by a first-class chemist, a qualified ASSISTANT. Must be expert salesman, competent prescriber, and of good address, with knowledge of French preferred. For particulars, write, enclosing photo (will be returned), J. DELOUCHE, 2, Place Vendôme, Paris.

CLIFTON.—Wanted, an ASSISTANT for August 22nd, or soon after. One accustomed to good-class dispensing and retail, with knowledge of photography. Not necessarily qualified. Apply, with full particulars and photo, to COMPACT, "Pharm. Journal" Office, 5, Serle St., London, W.C.

APOTHEKER, 29, with German qualification, and also Dr. Zil. of Basle, desires situation in high-class pharmacy. Speaks French and German fluently. Reply, Dr. PAUL SCHNEIDER, 6, Bedford Place, Russell Square, London.

John H. Atherton, Chemist and Druggist, 46, Market Street, Wigan.

OBITUARY.

JENKINS.—On July 25, Jabez Jenkins, Chemist and Druggist, Llysyfrann. Aged 62.

TAYLOR.—On July 27, Joseph Edward Taylor, Chemist and Druggist, Manchester. Aged 35.

SHEARING.—On July 28, Robert Shearing, Chemist and Druggist. Aged 85.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Books.

Pharmaceutical Journal, 7 vols., from July, 1879, to July, 1886, bound, clean, perfect, 1s. 6d. per vol., 1, Cemetery Road, Burry, Suffolk.

Brunton's Text-book, 'Pharmacology, Therapeutics, and Materia Medica,' and Lescher's 'Recent Materia Medica,' new, 22s. cash.—Westwood, 14, Thomas Street, Grimsby.

Whitla's 'Materia Medica, Pharmacy, and Therapeutics,' Brunton's ditto; Martindale's, 1885, 1888, 1891, 1892; Squire's 'Companion,' 1882, 1890, 1894; 'Vet. Counter Practice'; Canning's 'Formulae.' What offers?—Tansley, Chemist, Kingsgrove, Staffs.

Miscellaneous.

Photographic mounts, Bristol cartes, 3s.; G.B.E., 10s.; cabinets, 10s.; G.B.E., 15s.; quarter-plates, 6s.; half-plates, 12s. 1000; plate-sunk mounts, 12 by 10, 40s. 1000. Samples free.—Edward Peck, East Dereham, Norfolk.

Magic Lanterns, second-hand; triples and binoculars; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

Three 6-gall. pear-shape carboys, cut stoppers; offers.—Scanlan, 436, Borough Road, Birkenhead.

Moulds.—Suppository, Pessary, Bougie, Capsule, Fumigating Pastille, all Maw's patterns, some new; particulars free.—Warnes, Chemist, 333, Gray's Inⁿ Road, W.C.

A few gross Iolanthe Hair-curling Fluid, 3d. size, 18s. gross, carriage paid; Camwal Shares wanted.—S. Sugden, Pharmacist, Waterfoot, Manchester.

Dispensing Screen for sale, by Maw, nearly new, 5 ft. 3 in. x 6 ft.—Apply by letter only, 64, Linthorpe Road, N.

WANTED.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Bell, Buchanan, Cannon, Deed, Donald, Elliot, Elsdon, Ferrall, Hackforth, Hill, McKnight, Moss, Plumbly, Reid, Stephenson, Warrell.

NOTES ON EXPOSURE IN PHOTOGRAPHY.*

Of all subjects connected with photography, probably the most difficult to the tyro is the estimation of the correct exposure for the various subjects which he may wish to take. It is possible, by long experience and working under practically fixed conditions, to mentally estimate the correct exposure, a well-known instance being the studio work of a professional photographer, but when it comes to the taking of all classes of subjects, under varying conditions of light, the task is by no means so easy, and it is with the hope that the following exposure tables may be of some assistance that they are included in this work.

There are certain factors which govern the duration of exposure which must be thoroughly grasped before starting practical work. They are:—

- 1.—The sensitiveness of the plate.
- 2.—The ratio aperture of the lens.
- 3.—The character of the subject.
- 4.—The chemical activity of the light illuminating the object.

1.—THE SENSITIVENESS OF THE PLATE.

There is not, unfortunately, absolute agreement as to the best method of estimating plate speeds or sensitiveness. Briefly, we may say that there are four methods: (a) "times"; (b) Warnerke's system; (c) Hurter and Driffield's system; (d) no system.

(a) "Times."—It is well known that the present gelatine dry plate has supplanted for general work the old wet collodion process, which is now only used for particular kinds of work, and in the early days of dry plates their speed was reckoned as so many "times" a wet plate. Unfortunately, the sensitiveness of a wet plate was by no means a fixed quantity, but varied considerably with certain conditions, which we need not enter into. This method is, therefore, about as unreliable as it can be, though it is still sometimes used, and a plate is described as "15 times," "30 times," and so on.

(b) Warnerke's system.—This consisted in exposing a plate behind a numbered screen to the light emitted from a phosphorescent tablet under given conditions, and a plate was said to be 18, 22, or 25, according to the number that could be read on development. The numbers on the screen ranged from 1 to 25. Notwithstanding the many grave defects existent in this method it is still sometimes used.

(c) Hurter and Driffield's system.—This is now the most generally accepted, and, briefly, a plate is exposed to a standard light developed for a standard time, the deposit measured in a photometer, and the speed calculated from the reading. The numbers are frequently expressed as "X, H, and D," and this is the system that has been chosen for these exposure tables.

(d) No System.—It is possibly an open question whether a method of denominating plate speeds from no system can be called a method at all, but the fact remains that there are many plates on the market which are merely called "ordinary," "landscape," "rapid," "extra rapid," "special rapid," "instantaneous," "snapshot," and so on. The actual definition, as regards speed, of these words being left entirely to the manufacturer, so that there can be no common agreement as to what these terms mean.

2.—THE RATIO APERTURE OF THE LENS.

There is, fortunately, more agreement as to this factor in photographic circles, and the result is that the leading opticians now designate the aperture of the diaphragms or stops of the lens in terms of the focal length. Thus a stop which has a diameter of aperture that is one-eighth of the focal length of the lens, no matter whether that focus be 3 or 300 inches, always requires the same exposure *ceteris paribus*. This is hardly the place to define "ratio aperture," "focal length," etc., because they are treated of in all elementary text-books on photography. The usual apertures of stops are 1/8, 1/11.31, 1/16, 1/22.62, 1/32, 1/45, 1/64 of the focus, and are written as F8, F16, etc., or f/8, f/16, etc. The ratio of exposure with the above, or any other stops, is readily found by squaring the F number, thus:—

S	×	S	=	64	—	1	—	1/4
11.31	×	11.31	=	128	—	2	—	1/8
16	×	16	=	256	—	4	—	1/16
22.62	×	22.62	=	512	—	8	—	1/32
32	×	32	=	1024	—	16	—	1/64
45	×	45	=	2048	—	32	—	1/128
64	×	64	=	4096	—	64	—	1/256

So that if the exposure with F/8 was two seconds, the exposure for any other stop may be found by increasing it in the ratio of

the square of the second stop to F/8; to facilitate matters this ratio is shown in the third column above. Thus the exposure would be with F/45, $2 \times 32 = 64$ secs. For the purpose of these tables, however, F/16 has been taken as the unit, for this aperture is far more general than F/8 in ordinary work.

3.—THE CHARACTER OF THE SUBJECT.

By this factor we mean practically the colour of the object or its light-reflecting powers; thus it is obvious that a white cloud lit by the sun will reflect far more light than a piece of black velvet lit by the same sun. Subjects may therefore be divided into the following classes:—

Sea and sky	1/16
Snow scenes, white objects, and black and white objects	1/8
Ordinary landscape	1
Heavy foreground or close objects	3
Portraits outdoors in diffused light	7
" in sitting rooms	150
Interiors, well lighted	300

4.—THE CHEMICAL ACTIVITY OF THE LIGHT.

It has been proved by several eminent chemists that the actinic power of the light is constant for any given hour, on any given day, in any given month, provided always that meteorological

" 30	—	—	3 1/2	1 1/2	2 1/2	1 1/2

influences do not come into play. For our purposes we have taken four meteorological conditions—very bright, bright, ordinary, dull. There will be no difficulty in estimating the light after a little practice. "Very bright" may be defined as what one would naturally call a brilliant day; "bright" would mean not so brilliant, and yet sunny; whilst "ordinary" means a bright day, and yet no sun, whereas "dull" means a heavy, lowering day.

Each month has been divided into three divisions, that is, the exposures have been calculated for the 10th, 20th, and 30th of each month, and the days have been divided into equally active hours; thus from 11 a.m. to 1 p.m., 10 a.m. and 2 p.m., 9 a.m. and 3 p.m., 8 a.m. and 4 p.m., 7 a.m. and 5 p.m., 6 a.m., and 6 p.m., 5 a.m. and 7 p.m.

In all cases a plate speed of 60 H and D, which is a normal,

Reprinted from the 'Photographic Tourists' Guide,' published at the Pharmaceutical Journal Office, 5, Serle Street, Lincoln's Inn, W.C.

ordinary, or landscape-plate speed, has been taken as the unit, and the advantage of Messrs. Hurter and Driffield's speed system is that the plate speeds are directly proportional, and the exposures consequently inversely proportional—that is to say, a plate marked 30 H and D is just half the speed of one marked 60, and would require double the exposure, and one marked 120 double the speed of the 60, and would require half the exposure.

The unit aperture has been taken as F/16; the unit subject as an ordinary landscape; the unit light has been taken as "ordinary."

Now the factors for the various lights are as follows:—

Ordinary	1
Bright	$\frac{3}{4}$
Very bright	$\frac{1}{2}$
Dull	2

Now to explain the working of the various factors we have laid down, let us take an example.

Required the exposure with a lens working at F/22 with a plate marked H and D 60, for ordinary landscape, on June 25, at 11 a.m. On turning to the table of exposures we find the exposure to be 1/10 second with F/16, and by the table on p. 65, we see that F/22 requires twice the exposure.

$$\therefore 1/10 \times 2 = 1/5 \text{ sec.}$$

Taking precisely the same conditions, but with a very dull day, we simply give double the exposure found above, which will be $2/5$ sec.

Suppose we take the same conditions as in the last, but wish to take a portrait outdoors, then we have $2/5 \times 7 = 3$ sec. practically.

FOREIGN DARK-ROOMS.*

The addresses in the following list are those on the Continent and in other parts of the world at which dark rooms are available for the use of tourists. Many of them belong to dealers from whom photographic materials may be obtained, others are attached to hotels, public institutions, and private houses.

Trade Notes.

MESSRS. REYNOLDS & BRANSON, LTD., direct attention to a dish designed by Mr. H. de Paiva B. Veale, L.S.A. (Lond.), for the reception of flexible catheters in daily use. It consists of an elongated narrow vessel furnished with an overlapping lid, and it is sufficiently long to admit a catheter of ordinary length without flexion being necessary. The catheter rests on two transverse ridges attached to the bottom of the dish, so that the antiseptic solution with which the dish is filled surrounds the instrument. A flexible catheter once having been used has to be bent to place in most of the receptacles as used at present, and this frequently produced "kinking" or injury at the eye. In this dish the catheter can be kept

perfectly straight, and a minimum amount of solution is required to keep it submerged. The vessel being long and flat it may be kept by a patient's bedside without fear of upsetting it, and the shallow depth, combined with the absence of angles, renders the dish very easily cleaned and sterilised. A label may be attached to the handle, or the patient's name may be written directly in ink or pencil on the lid. The dishes will serve for all forms of flexible catheters or bougies, and may also be used for drainage tubes. They are manufactured of iron, enamel ware, glass, or porcelain, and may be obtained from Messrs. Reynolds & Branson, Limited, of Leeds, at a small cost.

MESSRS. BURROUGHS, WELLCOME & Co. send specimens of zinc oxide tabloids, for which it is anticipated there will be a demand. The therapeutic uses of zinc oxide are many, and it is thought there is little doubt that the imperfect solubility of pills of this drug has discouraged its use for internal administration. The rapid disintegration of zinc oxide tabloids when dropped into water should remove this objection, and enable so useful a therapeutic agent to be more generally prescribed. They are issued in bottles containing 100.

MESSRS. JEWsbury AND BROWN, of Manchester, have produced a daintily-bound little volume for the waistcoat pocket, in which the doses and strengths of substances official in the British Pharmacopœia, 1898, are compared with those of the 1885 volume. Nothing better of the kind has yet been produced, and the volume is commended to the notice of readers of the Journal.

MESSRS. BURGoyNE, BURBIDGES & Co., of 16, Coleman Street, have submitted samples of Chlorobrom. This preparation, which is a combination of bromide of potassium and chloralamide, was the outcome of a suggestion by the late Dr. Charteris, Professor of Materia Medica and Therapeutics at Glasgow University, who since its introduction made a series of further experiments with it. It appears that it had been the professor's habit in his lectures to speak of the climatic treatment of disease, and notably of the magic effect produced by sea voyages, which in many cases was, unfortunately, discounted by the patient's liability to seasickness, and in order that this disadvantage might be removed he recommended the use of chlorobrom, which from personal experience he knew in many cases cures, and in all cases alleviates, seasickness. Numerous testimonials from ships' surgeons speak of chlorobrom as a most valuable preventive, both in long and short voyages, of this distressing ailment. Chlorobrom has also proved a most valuable remedy in insomnia. Messrs. Burgoyne & Co. will be glad to hear from chemists issuing price-lists and almanacks with a view to the insertion of advertisements of this preparation.

ENAMEL FOR DENTAL PLATES.—In order to overcome the inconvenience and concurrent pain and discomfort due to the shrinkage of the gums after teeth have been extracted, a Dr. Clarke has invented a rubber oil enamel, which is applied to the dental plates, and provides an elastic medium or buffer for the gums. Messrs. May, Roberts & Co., of Clerkenwell Road, are the wholesale agents for the sale of this ingenious invention.

MESSRS. W. R. WARNER & Co., of Philadelphia, have sent us (through their London agents, Messrs. F. Newbery & Sons) samples of their soluble preparations. Amongst them are compressed lentiforms of cascara sagrada, sugar coated, a convenient form for the administration of this aperient. Lithia water lentiforms each containing five grains of citrate of lithia, and affording an accurate method of administering a definite quantity of soluble lithia. Pil. sumbul comp. and pil. sumbul aperient are preparations of sumbul, which is a stimulant and tonic to the nervous system. Another preparation in liquid form of this drug is tono-sumbul cordial, in which the potency is increased by the addition of iron and cinchona. It is free from the disagreeable flavour of many bitter tonics.

MESSRS. NEWBERY & SONS have also forwarded samples of various toilet articles, &c. The St. Paul's Carbolic Tooth Powder bears no proprietor's name, and is supplied in quantities with labels bearing customer's name and address. Other articles similarly supplied are Almond Shaving Cream and Areca Nut Tooth Paste. "Papyroles" is the registered title given to the toilet roll papers issued by this firm in various sizes and prices from 6d. to 1s. The Old London Dalmatian Insect Killing Powder supplied in tin boxes should find a ready sale at this season.

MESSRS. MARION & Co., of Bury Street, Chelsea, call attention to their system of protected profits for chemists who undertake the sale of their Royal Court Hair Dyes.

OFFICE APPLIANCES.—In every business it is of the utmost importance to be able to refer to invoices, orders, and letters without delay or difficulty. The Globe Ideal File, which is supplied by Thomas Turner, Ltd., of Leicester, whose London office is 44, Holborn Viaduct, was introduced some twelve years since for this purpose, and from time to time repeated improvements have been made, such as have been suggested by experience in its use. The Ideal File is in the form of a drawer with open back to give easy access to its contents, which with the index are held in by an automatic spring. When the files are filled the contents can be removed to transfer cases, and there is an ingenious system of indexing, so that the contents can be readily referred to. The same firm supplies desks with roll tops in various forms of sizes, catalogues of which can be had on application to the manufacturers.

A NEW TRUSS PAD.—Mr. Vincent Wood, of Albion Place, Blackfriars, has forwarded for our inspection one of his new moulded truss-heads, which, it is claimed, is prepared chemically and specially moulded, and will not be affected by heat or cold. These truss pads have been subjected to a hydraulic power pressure of nearly 50 tons without bursting. Trusses with these pads will be supplied at a very slight advance on the price of ordinary trusses, and an excellent sample has been shown us which will be sold to the trade at 30s. per dozen.

AMIRAL SOAP FOR THE CURE OF OBESITY.—It is claimed for this soap that it will remove an excess of adipose tissue wherever applied. Testimonials emanating from medical men giving results of their experience appear to show that this soap when applied is absorbed by the pores of the skin, and has the effect of dispersing the local deposits of fatty tissue. The soap is green in colour, possesses a pleasant aromatic odour, and will doubtless meet with a ready sale amongst those who suffer discomfort through corpulence, many of whom have tried various internal remedies without success, and often with harmful results. Some of the leading medical journals testify to its freedom from injurious substances. The active agent is an extract of animal bile. The Amiral Soap Syndicate, Ltd., of 28A, Basinghall Street, have acquired the sole right of sale throughout the world, France and her Colonies and the Argentine Republic excepted.

THE BUSINESS OF MR. H. W. COX, of Cursitor-street, the maker of X-ray coils and apparatus, has recently been converted into a limited company. We have previously mentioned that Mr. Cox's work is to be relied on, and we are informed that he will continue to supervise the manufacture of all the apparatus made by the firm.

London Report.

AUGUST 11, 1898.

As might have been expected, the drug and chemical markets have been exceedingly quiet during the past few days, while the actual changes in value have been more or less unimportant. At the same time there is certainly a better feeling as to the prospects of business during the coming autumn, winter, and spring, and buyers, who have been hitherto holding off, and as far as possible only buying from hand to month, appear to be seriously considering the apparent advisability of securing supplies while prices remain, as is still the case with many articles, at a comparatively cheap level; and in view of the hope of a speedy termination of the Spanish-American war, combined with the prospects of a bounteous harvest, it is to be hoped that we may ere long see a satisfactory state of trade generally prevailing. Opium, Morphia, and Codeia remain very firm. Quinine steady. Iodides and Bromides in fair demand. Quicksilver and Mercurials firm. Saffron dearer, in consequence of the progress made in the negotiations for peace and consequent advance in Spanish rate of exchange, combined with actual good position of the article. Cod Liver Oil quiet. Glycerine firm. Cocaine likely to be dearer. Sulphonal unchanged. Phenacetin steady. Acetanilide dull and weak. Acid Carbolic in fair demand at steady prices. Sulphate of Ammonia rather firmer. Borax and Acid Boracic quiet. Acid Citric dearer. Cream of Tartar quiet. Acid Tartaric firm. Ipecacuanha very firm. Cacao Butter much dearer. The following are the prices actually ruling for articles of chief interest:—

ACETANILIDE—Can be bought at 1s. per lb. in half-ton lots. The article is, however, somewhat slow of sale.

ACID ACETIC is firm; 1 to 7 is quoted 14s. 3d. per cwt., B.P. 15s. 6d. per cwt., 50 per cent. 21s. 6d. per cwt., 74 per cent. 30s. per cwt., 85 per cent. 34s. per cwt., and Glacial 39s. 6d. per cwt.

ACID BORACIC unchanged at 23s. per cwt. for crystals, and 25s. per cwt. for powder.

ACID CARBOLIC.—Market remains steady at 6½d. to 6¾d. per lb. according to make for 35 to 36° C. *ice crystal* in large bulk, other qualities and packing in proportion. *Crude*: 60° F. 2s. 1d.; 75° F. 2s. 7d. per gallon. *Liquid*: 95 per cent. of pale straw colour 1s. 2d. per gallon in 40-gallon casks.

ACID CHRYSOPHANIC steady but quiet at 11s. 6d. to 13s. 6d. per lb.

ACID CITRIC is quiet but firm at 1s. 2½d. to 1s. 3d. per lb. for English crystals. Makers ask the latter figure.

ACID OXALIC firm at 3½d. per lb. on the spot.

ACID TANNIC is firm at 1s. 9½d. per lb. for light crystals, and 1s. 3d. per lb. for pure powder.

ACID TARTARIC.—English on the spot firm at 1s. 1d. per lb. for Crystals Foreign unchanged at 12¾d. per lb.

ALUM.—Loose lump is quoted £5 10s. per ton, ground in bags £6 per ton.

AMMONIA COMPOUNDS.—*Sulphate* rather firmer at £9 11s. 3d. per ton for grey prompt 24 per cent. *Carbonate* unchanged at 3¾d. to 4d. per lb. according to package. *Bromide* steady at 2s. 1d. per lb. *Iodide* firm at 14s. 6d. per lb. *Sulpho-cyanide* in good request at 1s. 2d. per lb. *Sal ammoniac*: Sublimed, "firsts," 35s. per cwt.; seconds, 33s. per cwt.

APOMORPHIA—Is firm in sympathy with *morphia*, at 17s. to 18s. per oz.

ARSENIC—Steady at 19s. per cwt. for powder, and 34s. per cwt. for lump.

ASAFETIDA.—There are some inquiries on the market, part for fine quality, which is exceedingly scarce, and part at prices which holders will not accept.

ATROPINE.—Remains firm at 17s. per oz. for the *pure* and 15s. 6d. per oz. for the *Sulphate P.B.*

BALSAM CANADA—Is steady at 1s. 3d. to 1s. 4d. per lb. in cases of 2 + 45-lb. tins.

BALSAM CAPIVI is easier at 1s. 11d. per lb. on the spot.

BALSAM TOLU is steady at 1s. 8d. to 1s. 9d. per lb. in large tins.

BISMUTH—Unchanged at 6s. per lb. for the *metal* and 4s. 10d. per lb. for the *subnitrate*.

BLEACHING POWDER—Is unchanged at £6 15s. to £7 15s. per ton, according to brand, quantity, and packing.

BORAX steady at 14s. per cwt. for lump and 14s. 6d. per cwt. for powder.

BROMIDES in good demand at 1s. 10d. per lb. for *Pot. Bromide*.

BUCHU LEAVES.—These continue scarce, and 9d. per lb. is asked for fair green round, and the same price is required for long leaves.

CALABAR BEANS—Are quiet but steady at 3d. per lb.

CAMPHOR.—Both *crude* and refined are quiet at unchanged prices.

CASCARA SAGRADA.—This bark is decidedly firmer, and higher prices are looked for in the autumn, when the smallness of this year's crop will be more evident. New bark is quoted 21s. per cwt., whilst for three-year-old bark 25s. per cwt. is asked, this quality being scarce.

CHLORAL HYDRATE remains in good demand at 3s. 11d. to 4s. 6½d. per lb., according to packages.

CINCHONA BARK.—7503 packages are advertised for the Amsterdam auctions on the 25th inst. The shipments from Java for July were 1,172,000 Amsterdam lbs. against 900,000 last year; and the total shipments from January to July were 6,089,000 lbs. as against 4,234,000 lbs. for the corresponding period last year.

CLOVES.—Privately the market for *Zanzibar* has been quiet and is rather easier. Business has passed at 4¾d. for October to December delivery, and there are further sellers at this figure, and buyers of January to March at the same price. At auction of 128 bales *Zanzibar* only 21 bales sold at 4¾d. to 4¾d.; 50 bags *Ambonya* bought in at 5½d. Of 44 cases *Penang* 8 cases dull, of old import, sold without reserve at 7¾d. to 7¾d. 1 box *Ceylon* sold at 7d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 3d.; pure, 2s. 3d. per gallon. *Benzole*: 50 per cent., 1s. 1d.; 90 per cent., 10½d. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 5d. per gallon. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 8d. per gallon.

COCAINE—Is firmer. There is, however, so far, no change in price, which remains at 9s. 3d. to 9s. 6d. per oz. for the *Hydrochlorate* in 25-oz. tins and 100-oz. lots.

COCA LEAVES.—Green *Truxillo* are firm at 7d. per lb. *Bolivian* are offered to arrive at 8½d. per lb.

COCOA BUTTER.—In the monthly auctions on Tuesday, 300 cases sold with active competition at a decided advance in values. Average price works out at 1s. 2½d. per lb., as against 10¾d. in July, and 9¾d. per lb. in June.

CODEIA.—Makers are firm at the advanced price of 12s. 6d. per oz. for the *pure*, and 1s. per oz. less for the *salts*.

COD LIVER OIL is quiet but firm. Fine quality *Norwegian* is offered at 85s. per barrel on the spot.

COLOCYNTH.—The demand for these apples is very quiet, and quotations of 1s. to 1s. 2d. per lb. are therefore nominal.

COUMARINE is quiet at 2s. 3d. per oz. in bottles of 1 oz., or in large bulk at less.

CREAM OF TARTAR is quiet. First white crystals on the spot, 74s. per cwt.; powder, 76s. to 77s. per cwt. High strength B.P. crystals, 80s. per cwt.; powder, 82s. 6d. per cwt.

DAMIANA LEAVES are tending upwards, and 10d. per lb. is asked on the spot.

ESERINE (PHYSOSTIGMINE) quiet at the reduced price of 2s. per gramme for the *sulphate* and 3s. per gramme for the *pure*.

GENTIAN ROOT—Is quiet but steady at 18s. 6d. to 19s. 6d. per cwt. *f.o.b.* for good dry red root.

GINGER.—*Cochin* continues dull, 875 bags rough kinds being mostly bought in, washed 23s., brown 25s. to 26s., only 80 bags being sold, cuttings 12s., dull washed rough 20s. to 22s. 6d. Of 89 cases only 17 cases limed A cut sold at 80s. *Jamaica* went off slowly; of 229 barrels and 41 half-barrels only 40 packages sold at 69s. to 75s.

GLYCERIN—Is firm at 55s. to 65s. per cwt., according to quantity and brand, for *German* best white double distilled chemically pure 1260 quality in tins and cases, *English* being obtainable at somewhat lower figures.

GUM ACACIA.—Market is very quiet for picked *Trieste*, for which consumption is limited. Quotations range from £7 to £13 per cwt. For *Soudan* sorts 80s. to 85s. per cwt. is asked, at which small sales have been made.

GUM TRAGACANTH.—Values of all grades remain steady, although the business this week has been confined to the lower qualities. Firsts are quoted £13 10s. to £14 per cwt.; seconds, £13; thirds, £10 10s. to £11.

GUARANA.—Is very slow of sale, although quotations are low at 1s. 6d. per lb.

HELIOTROPINE.—In bottles of 1 oz. this is quoted at 1s. 7d. per oz. inclusive.

HYDRASTIS CANADENSIS.—This root is reported to be in good demand in America, causing higher prices to be asked. Quotations come 1s. 9d. to 1s. 10d. per lb. for early shipment.

INSECT FLOWERS.—Quotations are now at a very low level, and new crop are quoted as follows:—Open flowers, 49s. 6d. per cwt.; half open, 68s. per cwt.; and closed at 100s. per cwt.

IODIDES steady at 9s. 9d. to 10s. 3d. per lb. for *Pot. Iodide*, and 13s. 4d. to 13s. 7d. per lb. for *Iodoform*.

IPECACUANHA continues to be firmly held at 9s. per lb. for fair *Rio* and 5s. per lb. for *Carthagena*, at which prices small sales have been made.

JALAP is a shade firmer and holders will not sell good small V.C. tubers below 6d. per lb. Arrivals of new crop have been small.

JAPAN WAX—Is very quiet, and good squares can be had at 33s. to 34s. per cwt., according to quantity.

LITHIA is firm at 10s. 8d. per lb. for the carbonate in 2 cwt. lots, the other salts being quoted in proportion.

LOBELIA HERB—Loose in bags is quoted at 4½d. per lb. on the spot, and pressed packets at 6d. per lb.

MENTHOL.—Good dry crystals continue firm at 7s. 1½d. to 7s. 3d. per lb. on the spot, and the article is quoted dearer for arrival.

MERCURIALS.—Firm at 2s. 5d. per lb. for *Corrosive sublimate* and 2s. 9d. per lb. for *Calomel* in 56-lb. lots.

MORPHIA is very firm at 5s. per oz. for the *Hydrochlorate powder*, and 2d. per oz. more for the *crystals*.

NITRATE OF SILVER—Continues to fluctuate in sympathy with price of the *metal*; *crystals* being quoted 1s. 5d. to 1s. 6d. per oz., according to quantity; *sticks* being quoted at the proportionate difference.

NITRATE OF SODA quiet at £7 12s. 6d. per ton for commercial and £8 per ton for refined.

OILS (ESSENTIAL).—*Peppermint*: American is dearer owing to frosts on the 10th of last month, which did much damage, although not so much as was first expected. In some places it is said crops will be very small owing to this and dry weather, and choice Wayne County will be in short supply. New crop is quoted at 4s. 3d. per lb. *c.i.f.*, whilst old crop on the spot is to be had still at 3s. 10d. to 3s. 11d. per lb. H.G.H. is very firm at 5s. 7½d. to 5s. 9d. per lb. *Japanese* very slow of sale; dementholised on the spot at 3s. per lb.; 40 per cent. at 4s. 3d. per lb. *Star aniseed* remains quiet, although quotation is firm at 7s. 1½d. per lb. on the spot. *Cassia* rather easier at 4s. 9d. to 5s. per lb. for spot, 70 to 75 per cent.

Citronelle is quiet at 1s. 1½d. per lb in tins. *Clove*: English is 3d. per lb. dearer at 3s. 3d. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed* dearer, and closes firm at £16 17s. 6d. for spot pipes, whilst barrels are quoted £17 5s.—same position. *Rape* steady at last week's prices of £22 10s. for ordinary brown on the spot, and £23 for refined. *Cotton* firm at £13 10s. for London crude on the spot, and £15 5s. to £16 for refined, according to make. *Cocunut* steady at £23 5s. for Ceylon pipes on the spot; *Cochin* spot, £28 10s. *Palm*: Lagos on spot, £22 10s. *Turpentine* quiet at 22s. per cwt. on the spot for American. *Petroleum oil* steady at 4½d. per gallon for Russian on the spot; American, 5½d. per gallon; Water White, 6¼d. per gallon. *Petroleum spirit*: American, 5½d. per gallon; deodorised, 6d. per gallon.

OPIUM—Remains very firm. Quotations, which are, however, somewhat nominal, are as follows:—*Soft shipping*, ordinary to good, 11s. 6d. to 14s. per lb.; good to fine *Druggists*, 11s. 6d. to 13s. per lb.; *Persian*, 11s. 6d. to 12s. 9d. per lb.

ORRIS' ROOT.—Favourable reports have been received from Italy respecting the new crop, at the same time it is not considered probable that we shall see any reduction on present quotations of 36s. per cwt. *c.i.f.* for *Florentine* sorts, and 40s. to 42s. 6d. for picked *Florentine*.

PERMANGANATE OF POTASH—Is quiet at 62s. 6d. per cwt. for *small crystals* in 1-cwt. kegs and 5s. per cwt. more for *large crystals*.

PILOCARPINE—Is quiet at 33s. per oz. for the *Hydrochlorate* and *Nitrate salts*.

PHENACETIN.—Firm at 3s. 9d. to 4s. 3d. per lb. according to quantity and make. Bayer's make is in limited demand at the reduced price of 5s. 6d. per lb.

PHENZONE (*Antipyrine*) weak, at 9s. per lb., in quantity and bulk packing. *Dr. Knorr's Antipyrine* remains steady at the late reduction, the sale of same being, however, restricted by the fact that its chemical equivalent, *Phenazone*, to wit, is obtainable, as stated above, at about 30 per cent. less money.

PODOPHYLLIN is steady at 12s. 6d. per lb. for B.P. quality. Good autumn dug *Mandrake Root* is firm at 25s. 6d. per cwt., summer dug being quoted at 2s. per cwt. less.

POTASH COMPOUNDS.—*Bicarbonate* steady at 30s. per cwt. for foreign crystal or powder, and 35s. per cwt. for English. *Bromide* steady at 1s. 9½d. per lb. *Chlorate* firm at 3½d. per lb. on the spot. *Iodide* quiet but firm at 9s. 9d. to 10s. 3d. per lb. *Bichromate* unchanged at 3½d. to 3¾d. per lb. *Prussiate* firm at 7d. per lb. for yellow, and 1s. 2d. per lb. for red. *Cyanide* firm for spot delivery at 1s. 2d. per lb. for cake; sticks 1s. 7d. per lb. *Permanganate* steady at 62s. 6d. per cwt. for small, and 67s. 6d. per cwt. for large crystals.

QUICKSILVER continues without change at £7 12s. 6d. per flask from importers and 6d. less from second hands.

QUININE—Remains in an inactive condition, and whilst nothing is to be had under makers' price of 10d. per oz., very little if any business has been doing in the article during the past few days.

SAFFRON—Has had a sharp advance this week, and with peace in sight and a consequent improvement in the exchange, a further important advance is very probable. *Valencia* is quoted 35s. to 40s. per lb., according to quality.

SALICINE—Is firm at 10s. to 10s. 6d. per lb., according to quantity.

SANTONINE—Is steady at 4s. 5½d. per lb. in 3 cwt. lots.

SALICYLATES are firm at the late advance of 2¼d. per lb., to 1s. 10d. per lb. for the *Acid Powder*, and 2s. per lb. for the *Acid Crystals*, and 2s. per lb. for the *Soda Powder*, and 2s. 6d. per lb. for the soda crystals, and to 3s. 10d. per lb. for the physiologically pure acid crystals, and 3s. 6d. per lb. for the physiologically pure soda crystals.

SCAMMONY.—*Virgin* is in short supply. "Firsts" quoted 30s. per lb. *Resin* steady at 6s. 6d. to 6s. 9d. per lb. as to quantity.

SENEGA ROOT is dearer and stock here is small. From New York higher prices are quoted, being equal to about 1s. 2½d. per lb., London terms.

SENNA.—By the steamer Egypt from Bombay 236 bales *Tinnevelly* have arrived. This, however, is thought to be old crop, but probably samples will be up in time for the next drug sales. A few sales of fair small leaf quality have been made at 2d. per lb. this week. *Alexandrian* leaves are dull of sale. Fine leaf is scarce; broken leaf is quoted at 4d. to 4½d. per lb.; siftings, 2¾d. to 3d. per lb.; and "sorts" have been sold in a retail way at 3d. per lb.

SHELLAC.—The supplies at the auctions were on an unusually

small scale, notwithstanding an interval of three weeks. 123 cases second orange offered, and 103 cases sold at steady rates; dull palish free flat at 63s. per cwt. The speculative market is dearer, with more business passing. *TIN* sold at 62s. to 64s. per cwt., closing buyers at latter price.

SNAKE ROOT is rather easier at 1s. 1½d. per lb. on the spot; demand, however, is slack.

SODA COMPOUNDS.—*Crystals* continue firm at 57s. 6d. per ton in barrels. *Bicarbonate* firm at £7 5s. to £7 10s. per ton for the 97 per cent. commercial article, and 18s. 6d. per cwt. for the fully bicarbonated quality. *Ash* steady at £5 5s. to £5 15s. per ton as to strength. *Bromide* quiet at 2s. 0½d. per lb. *Iodide* quiet at 11s. 7d. per lb. *Caustic*: 70 per cent. £8 per ton, 60 per cent. £7 per ton.

SPERMACEYL.—American is lower at 1s. 2d. per lb., packed in 60 lb. boxes.

SPICES (VARIOUS).—*Black Pepper*: 52 bags Singapore bought in, 3 bags Perak sold at 4½d., 180 bags Tellicherry bought in at 4½d. 5 bags Ceylon sold at 4½d. *White Pepper*: Only 124 bags offered and bought in, Siam at 8½d, Singapore 9d. to 9½d. *Chillies*: 45 bales dull Japan sold at 31s. 6d. *Capsicums*: 2 bales Natal sold at 75s. *Cassia Lignea*: 348 boxes bought in at 55s.; of 156 bales broken, 16 bales sold at 32s. *Mace*: 13 cases Penang broken pickings bought in at 1s. 4d., and 4 cases Bombay at 1s. 7d.; 42 packages West India sold at 1s. 5d. to 1s. 8d., pickings 1s. 2d. to 1s. 3d. *Pimento* in better demand, 126 bags sold at 4½d. to 5d.

STAR ANISEED—Is very firm at 120s. per cwt. on the spot.

STROPHANTHUS SEEDS.—Green *Kombé* are firm at 3s. 3d. per lb. Brown seeds have been done this week at 10d. per lb. for weevily.

STRYCHNINE—Firm at 2s. 1d. per oz. for pure crystals, 2s. for precipitated, and 1s. 9d. for sulphate or nitrate.

SULPHATE OF COPPER is firm at £16 to £17 5s. per ton on the spot, according to brand.

SUGAR OF LEAD—Firm at 27s. 6d. to 28s. per cwt. for *foreign* and 31s. to 32s. 6d. per cwt. for *English*.

SULPHONAL quiet, makers still accepting orders for limited quantities at 7s. 3d. per lb. in bulk packing.

VANILLINE—Is quoted as low as 3s. 4d. per oz. for large quantity, this being, of course, for the *synthetic* product.

Manchester Chemical Report.

AUGUST 10, 1898.

There is a fair amount of business passing locally, but the export returns for the past month are still far from encouraging. So far as what may be termed chemical and pharmaceutical preparations are concerned there is a very small increase, but heavy chemicals are still a diminishing quantity, especially to the United States. All round Alkali shows a decline of 24·1 per cent., and bleaching materials an increase of 12·0 per cent, but this is more than counterbalanced by a decrease in value of 28·1 in the one and 6·3 in the other. So far as this market is concerned, caustic soda is decidedly dull, but ammonia alkali and soda crystals are fairly active. Brown acetate of lime has declined to £4 15s. and £5 *c.i.f.*, Welsh and American, and sulphate of copper is weaker at £17 per ton best brands, delivered. Manchester Glycerine is very firm at £54 per ton, local make on rails or *f.o.b.*, and £50 maker. Green Copperas is in good demand locally, but prices are unchanged. In Yellow Prussiate makers are well sold, and generally the figure is 7d. per lb., reports to the contrary notwithstanding. Prussiate of Soda is, on the other hand, easy at 5¼d. to 5½d. Bichromate of Potash is about a farthing lower. Chlorate of Potash unchanged. Aniline oil and Salt are firm at 5½d. and 5d. respectively. Benzols continue to decline, and the phenomenal figure of 9d. and 9½d for 50's and 50's—90's has been touched. Naphthas are firm all round, solvent wood (white colourless) being quoted 3s. per gallon.

Liverpool Market Report.

AUGUST 10, 1898.

With the passing of the holiday season the general tone of the market has improved considerably, and prices generally have become more settled. Several good sales of Linseed from the River Plate are reported, and Canaryseed, after a considerable period of neglect, gives indications of both improved demand and better prices. Stocks of several staples have fallen rather low, and with

a better demand prices have gone up considerably; this has been most observable in Potashes, Quillaya Bark, and Olive Oil.

AMMONIA SALTS.—*Carbonate*: 3d. per lb. *Sal ammoniac*: 33s. to 35s. per cwt. *Sulphate*: £9 10s. per ton.

BEE SWAX.—Some 45 sacks of Chilian and packages of Gambia sold for £7 per cwt. and £6 13s. 9d. per cwt respectively.

BLEACHING POWDER—Is unchanged and slow of sale at £5 7s. 6d. to £5 15s. per ton.

CANARY SEED—Is very firm and much improved in inquiry. 100 bags of Turkish sold at 26s. per 464 lbs., and 300 bags at 27s.

COPPERAS—38s. per ton for Lancashire, and 36s. per ton for Welsh.

COPPER SULPHATE—Is a little dearer, £16 12s. 6d. to £16 15s. per ton.

GINGER.—Cochin has been selling from store in small lots at 25s. per cwt.

LINSEED.—3000 bags of River Plate sold at 31s. 9d. per 416 lbs., and 700 bags at 32s.

OILS (FIXED) AND SPIRITS.—*Castor*: Calcutta is firmly held for the improved price of 3¼d. per lb.; French, 3d., and Madras 3d. per lb. *Olive* is advancing; Malaga on the spot is quoted at £29 10s. to £30 10s. per tun. *Linseed* of Liverpool pressure is in steady demand at 17s. 9d. to 18s. 6d. per cwt. *Cottonseed*: Liverpool refined is still quoted at 15s. 9d. to 16s. 3d. per cwt. *Spirits of Turpentine* is selling quietly at 22s. 6d. per cwt.

POTASH SALTS.—*Bicarbonate*, 30s. per cwt.; bichromate, 3½d. per lb. Chlorate is firm at 3¾d. per lb. Cream of tartar is still quoted at 78s. 6d. per cwt. Pearlashes nominal at 35s. per cwt. Potashes, owing to small supply, are 22s. per cwt. Saltpetre, 21s. 6d. per cwt.

SODA SALTS.—*Bicarbonate*: £6 15s. per ton. *Caustic*: 76 to 77 per cent., £8 2s. 6d. to £8 5s.; 70 per cent., £7 3s. 9d. per ton. *Borax*: £13 10s. to £14 per ton. *Nitrate*: 7s. 6d. to 7s. 9d. per cwt.

QUILLAYA BARK.—5 tons sold at £18; owing to short supply £19 to £20 is now asked.

Newcastle Chemical Report.

AUGUST 10, 1898.

More orders are passing for heavy goods, yet on the whole now business is slow. The Alkali Syndicate has reduced export prices of caustic soda by 5s. per ton, otherwise late values rule as follows:—Bleaching powder: £6 to £6 5s. Soda crystals: basis price, 45s. Caustic soda: 70 per cent., £7. Alkali: 52 per cent., £5 5s. Soda ash: 52 per cent., £4 5s. Sulphur: £5 per ton.

News in Brief.

THE LAST ACT OF THE SESSION, namely, the prorogation, is fixed for Friday, the 12th. The House will practically have finished business on Thursday, and probably very few commoners will be found in the Upper House when Her Majesty's Commissioners formally put up the parliamentary shutters until next spring.

THE NOBLE AND SELECT COMMITTEEMEN who are charged with the consideration of the Companies Bill (House of Lords), re-assembled for a few minutes on Monday last after a long period of profound rest. The object of the meeting was the purely formal one of agreeing to a report of the usual character for presentation to the Lords in accordance with the procedure of the House. That presentation duly took place on Monday evening, and, all things having thus been regularly accomplished, the purification of companies was comfortably postponed for another year.

MR. THOMAS TICKLE'S NAME appears in the first division of the list of successful candidates at the recent examination for the Intermediate Examination in Science at the London University. Mr. Tickle is the present holder of the Salters' Research Fellowship in the Pharmaceutical Society's Research Laboratory, and has had a distinguished pharmaceutical career in the Society's School. He was Bell Scholar in 1892, and carried off the Pereira Medal in 1893.

THE LORD MAYORALTY OF MANCHESTER.—The deputation appointed at the informal meeting of the Manchester City Council on Wednesday, August 3, interviewed Alderman R. Gibson, the Lord Mayor, on Tuesday last, and presented the unanimous request of the council that he should accept the nomination to the Lord Mayoralty for the ensuing year. The Lord Mayor stated that, feeling very much honoured by the request, and much gratified by the kind feeling entertained towards him by the City Council, he nevertheless was unable to comply with the desire which had been communicated to him.

MR. JOHN HENRY RHODES, second son of Mr. Edmund Rhodes, of Kendal, who served his apprenticeship as chemist with Messrs. Severs and Bateson, and then entered Edinburgh University as medical student, has passed his examinations with distinguished honours. At the recent graduation ceremonial at Edinburgh University, he received the degree of Bachelor of Medicine and Bachelor of Surgery, with first-class honours, and gained the Beane Prize as the most distinguished student in anatomy and surgery, and was awarded also the Buchanan Scholarship. The young student strove hard for the first position in the year, and came out a good second, an Oxford man being in the leading.

THE SPECTACLE MAKERS' COMPANY.—The Court of Assistants to this Company has voted £100 for the purchase of optical instruction instruments to be used at the Technical Classes for Opticians, which are to be held at the Northampton Institute, Clerkenwell, commencing next month. A revised list of regulations with syllabus of examinations held in London next November when diplomas will be granted to capable opticians who become members of the Company, will be sent on application to Colonel Davies Sewell, the Clerk, whose office is at the Guildhall, E.C. Dr. H. Trentham Maw, of Aldersgate Street, has recently been nominated to serve on the Optical Committee. It is the object of the Spectacle Makers' Company to advance the status and knowledge of opticians, and chemists who cultivate this branch of business will do well to acquaint themselves with the facilities offered.

BRIGHTON ASSOCIATION OF PHARMACY.—The annual excursion of the above Association has been fixed for Wednesday, August 24. The arrangements are to visit Horsham, leaving Brighton by 10.15 train, looking over the church and park, dine at "Black Horse" Hotel, drive by Christ Church School and Denne Park to Knepp Castle and Park, afterwards to West Grinstead, tea at the "Burrell Arms," thence to Cowfold, returning to Brighton by the 9 p.m. train. All chemists and friends are invited. Tickets, 10s. 6d. each (inclusive), can be obtained of Mr. J. R. Gwatkin, 49, Grand Parade; Mr. W. H. Gibson, King's Road; Mr. Padwick, Preston Street; or Mr. G. B. Savage, 109, St. James's Street, Brighton.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.—The botanical class of this Association had a most enjoyable outing on Wednesday, August 3. The party journeyed to Mount Edgcumbe Park, where, by kind permission, the orangery, fernery, Italian and tropical gardens were visited. Amongst other plants seen were a very fine specimen of *Dicksonia arborescens* (tree fern); large cedar of Lebanon, 10 feet in circumference; *Magnolia grandifolia*; myrtle and mandarin oranges growing in the open, bearing flower and fruit on the same tree; also some very fine eucalyptus trees. The party then proceeded to Picklecombe Cottage, where (through the kindness of Mr. Jas. Cocks, President) tea was provided.—Mr. O. A. Reade moved a vote of thanks to Mr. Cocks for his kindness in entertaining the party.—Mr. J. D. Turney seconded.—Dr. Smith, R.N. (as one of the visitors), supported.—Mr. Cocks suitably responded.—The party having been photographed, they started for home at 8 p.m., after a most instructive and enjoyable afternoon.

GREAT NORTHERN CENTRAL HOSPITAL.—Sir John Dickson Poynder, Bart., M.P., has been elected Chairman of the Committee of Management of the Great Northern Central Hospital, in succession to the late Mr. C. T. Murdoch, M.P.

MESSRS. AYRTON & SAUNDERS, of Duke Street, Liverpool, have recently fitted up a handsome pharmacy at High Street, Bangor, North Wales, for Mr. John Bowen.

Partnerships Dissolved.

(From the London Gazette.)

S. G. Watson and Alfred M. S. Turner, Surgeons, 1, York Road and San Remo, Hove Park Villas, Hove, Sussex.

John Burton and W. J. Richardson, Aërated Water Manufacturers, etc., Amble, Northumberland. Debts will be received and paid by John Burton, who will continue the business in his own name.

John Girling and J. I. Waite, Physicians and Surgeons, 66, Micklegate, York. Debts will be received and paid by J. I. Waite, who will continue the practice.

Receiving Order in Bankruptcy.

(From the London Gazette.)

George Shears, Photographer and Photographic Printer, residing at Gloucester House, Hexham Road, New Barnet, and carrying on business at Torrington Villa, Bulwer Road, New Barnet.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Miscellaneous.

Photographic mounts, Bristol cartes, 3s.; G.B.E., 10s.; cabinets, 10s.; G.B.E., 15s.; quarter-plates, 6s.; half-plates, 12s. 1000; plate-sunk mounts, 12 by 10, 40s. 1000. Samples free.—Edward Peck, East Dereham, Norfolk.

Magic Lanterns, second-hand; triples and binials; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 52, Mortimer Road, Kingsland, N.

A few gross Iolanthe Hair-curling Fluid, 3d. size, 18s. gross, carriage paid; Camwal Shares wanted.—S. Sugden, Pharmacist, Waterfoot, Manchester.

Moulds.—Suppository, Pessary, Bougie, Capsule, Fumigating Pastille, all Maw's patterns, some new; particulars free.—Warnes, Chemist, 333, Gray's Inn Road, W.C.

Cameras.—Pocket Kodak, new model, 15s.; old model, 10s.; 63s. folding Kodak, 42s.; Griffith's guinea, 14s.; Tylar's stereoscopic, 17s. 6d.; all new.—Griffiths Richards, Hastings.

Overstocked.—2×10 lb. Coppers Superfine Oil of Lemon, 27s. 6d. copper; 1 lb. sample free by post 3s., postal order.—Moss, 34, Avondale Road, Chorley.

Curiosities.—Old china and earthenware syrup jars, ointment pots and vases, or any pharmaceutical antiquities. Good prices given for above by John Austen, Dore, nr. Sheffield.

What offers for 2 lb. Formalin Schering, 1 lb. Menthol, 1 oz. Piperazin, ¼ lb. Battle's Bromidia, 1 oz. Orthoform, 1 oz. Zymaine Fairchild.—Chemist, 156, Green Lanes, Stoke Newington, N.

Stramonium plants, suitable for botanical specimens, 2s. doz.—Williams, 213, High Street, Poole.

WANTED.

Muter's 'Practical Chemistry,' Newth's 'Inorganic Chemistry,' Perkin and Kipping's 'Organic' or Turpin's 'Organic,' Ince's 'Latin Grammar,' Green's 'Botany.'—State lowest cash price, latest editions only, to W. B. Marshall, 203, Edge Lane, Liverpool.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Students' and Chemists' Books wanted for cash or exchange. Please supply following particulars:—Edition, year of publication, condition, and price required.—Gower, Publisher, Waterloo, Liverpool.

Wanted.—Complete set of Shop Rounds and Pots, Recess Labels. Full particulars to—Mr. Hogg, Eagle Pharmacy, York Street, Belfast.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Andrews, Bott, Bryant, Center, Cherry, Clarke, Fielden, Forrester, Gadd, Glass, Harrison, Hitchen, Holtan, Johnston, Jowett, Marchant, Nash, Nicholls, Owen, Parry, Peck, Picken, Pickering, Reeve, Renworth, Reynolds, Smith, Thomas, Tredaway, White, Woodman.

1. *JUNCUS LAMPROCARPUS*. T.S. Rhizome x 10.

6. *PILOCARPUS JABORANDI*.—T.S. Leaf x 50. Zeiss
Apochromatic 24 Mm.

7. *DROSEROTA ROTUNDIFOLIA*.—Leaf x 6. Unstained
Specimen. Planar 50 Mm.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

AUGUST 18, 1898.

THE past week has resulted in but few changes of importance in the Drug and Chemical Markets. Quinine remains very quiet. Opium, Morphia, and Codeia firm. Sulphate of Ammonia dearer. Acid Tartaric and Cream of Tartar quiet. Acid citric firm. Iodides and Bromides without change. Quicksilver and Mercurials very firm. Acetanilide and Phenacetin steady. Phenazone weaker. Glycerine and Cod-liver Oil quiet. Cascara Sagrada very firm, and likely to be dearer. Cocaine firm. The following prices rule for articles of chief interest:—

ACETANILIDE—Is, if anything, a trifle firmer at 1s. to 1s. 1d. per lb. for quantity.

ACID BORACIC—Quiet at 23s. per cwt. for *Crystals*, and 25s. per cwt. for *Powder*.

ACID CARBOLIC.—Is rather firmer at 6½d. to 6¾d. per lb., according to quantity and brand for 35 to 36° C. *ice crystal* in large bulk packing. Other qualities in proportion. *Liquid*: 95 per cent. of pale straw colour 1s. 2d. to 1s. 3d. per gallon, according to quantity, in 40-gallon casks.

ACID CITRIC—Is quiet, but makers are strong at 1s. 2¼d. to 1s. 3d. per lb. for *English crystals*.

ACID OXALIC—Firm at 3¾d. per lb. on the spot.

ACID TARTARIC.—English on the spot remains steady at 1s. 1d. per lb., Foreign being a shade weaker at 12¾d. per lb.

ALUM.—Loose lump steady at £5 10s. per ton; ground in bags £6 per ton.

AMMONIA COMPOUNDS.—*Sulphate* has advanced rapidly during the week, grey prompt 24 per cent. London being now £10 per ton, Hull prompt £9 17s. 6d. *Carbonate* firm at 3¾d. to 4d. per lb. according to package. *Bromide* firm at 2s. 1d. per lb. *Iodide* steady at 14s. 6d. per lb. *Sulphocyanide* firm at 1s. 2d. per lb. *Sal ammoniac*: Sublimed, "firsts," 35s. per cwt.; seconds, 33s. per cwt.

BLEACHING POWDER—Is fairly active at £6 15s. to £7 15s. per ton, according to brand, packing and quantity.

BORAX—Steady at 14s. per cwt. for lump, and 14s. 6d. per cwt. for *powder*.

BROMIDES—Are unchanged at last week's prices.

CASCARA SAGRADA.—Very firm, with a small business doing at 21s. 6d. per cwt. for new, and 25s. for old bark.

CINCHONA BARK.—At Tuesday's London auctions the supplies were on a small scale, amounting to 1819 packages of all descriptions, as against 1160 packages at the July auctions. The bulk sold at fully the average of last sales rates with good demand. *Ceylon*: 117 bales offered and 86 bales sold, according to analysis: *Succirubra*, stem chips, ordinary to fair 1¾d. to 2¼d., renewed ditto at 2¼d. to 3d. *East India*: Of 812 bales and 16 cases offered 481 bales and 1 case sold: Red stem chips and shavings, fair at 2¼d. to 2¾d.; renewed ditto, fair at 2¼d. to 2¾d., good root at 4¾d., broken quill at 2¾d. to 3¾d. *Officinalis*, chips and shavings,

ordinary to fair at 1½d. to 2¼d.; renewed ditto, fair to good at 2¼d. to 4½d. Ledger, natural stem chips, fair to good rich at 3¾d. to 5d., Ledger branch at 2¾d. 155 bales *Neilgherry* offered and sold, *Officinalis*, renewed quilly chips at 4¾d. to 5¼d. *Java*: 135 bags offered and sold, Ledger stem chips at 3¾d., stem chips and root at 2¾d. to 2¼d., branch at 2¼d. to 2¾d. *South American*: Of 348 bales *Bolivian cultivated Calisaya* 248 bales sold, fair to good quill at 4¼d. to 6d., and flat (country damaged) at 5d. 134 bales soft *Columbian* bought in. *African*: 102 bales offered and sold, broken quill and chips at 3¾d. to 4d.

CLOVES.—Privately *Zanibar* are firm, although quiet; business done comprises spot at 4¾d., October-December delivery 4½d., and January-March delivery at 4¾d. At auction only 8 cases dull *Penang* offered and sold at 8d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial, 1s. 4d.; pure, 2s. 4d. per gallon. *Benzole*: 50 per cent., 1s. 1d.; 90 per cent., 11d. per gallon. *Solvent Naphtha*: 95 per cent., at 160° C., 1s. 10d. per gallon.

COCAINE—Is firm without any change in price, good brands being still obtainable in 25 oz. tins, and for 100 oz. lots at 9s. 3d. per oz.

CODEIA—Unchanged at 12s. 6d. per oz.

COD-LIVER OIL—Very little doing, price of best new non-congealing *Norwegian* oil remaining nominally 85s. per barrel *f.o.b.*

COLOCYNTH.—Has been in better inquiry and more money is now asked for the better qualities.

CREAM OF TARTAR—Quiet and rather easier. First white *crystals* on the spot, 73s. per cwt.; *powder*, 75s. to 76s. per cwt. High strengths in accordance with the new B.P. requirements; 78s. for *crystals*; *powder*, 81s. per cwt.

GINGER.—*Cochin* continues dull. Of 738 bags rough offered 120 bags *calicut* sold, without reserve, at 23s.; and 239 bags washed rough, the bulk slightly mouldy, at 21s.; 40 cases medium and small limed native, part cut, bought in at 44s. to 46s. Of *Jamaica* 29 barrels sold, common lean 63s. 6d., low middling 68s. to 70s., middling 73s. to 75s.

GLYCERIN—Quiet at 55s. to 65s. per cwt. according to quantity and brand for *German* best white double distilled chemically pure 1.260 quality in tins and cases. *English* being obtainable at rather less money.

GOLDEN SEAL ROOT.—This is reported to be much firmer from the United States, and 1s. 10d. per lb. *c.i.f.* is now the lowest quotation, equal to about 2s. per lb. London terms.

GUM MASTIC.—Supply is now practically exhausted, sales having taken place at 1s. 10d. to 1s. 11d. per lb. for pale drops.

IODIDES.—Without change and in fair demand.

MERCURIALS—Firm at prices quoted last week.

MENTHOL.—Good dry crystals are firm at 7s. 1½d. to 7s. 3d. per lb.

MORPHIA—Without change at 5s. per oz. for the *Hydrochlorate powders* for large quantities and in bulk packing.

OILS (ESSENTIAL).—*Peppermint*: American H.G.H. firm at 5s. 7½d. to 5s. 9d. per lb. Wayne County dealer at 3s. 9d. to 4s. 3d. per lb. *Star Aniseed* steady at 7s. 1¼d. per lb. on the spot. *Cassia* quiet, 70 to 75 per cent. 5s. per lb. *Clove* continues very firm at 3s. 3d. per lb. *Lemongrass* lower, sellers on the spot 3¾d. per ounce. *Citronelle* quiet with small sales on the spot at 1s. 1½d. per lb. in tins, drums 1s. 1d. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed* quiet and the shade easier at £16 15s. for spot, London, pipes, and £17 5s. for barrels. *Rape* lower; ordinary brown on the spot, £21 10s.; refined spot, £23. *Cotton* firm; London crude spot, £13 12s. 6d.; refined spot, £15 5s. to £16, according to make. *Olive*: Green oils rather easier at £30 to £32. *Coconut* quiet, Ceylon on the spot, pipes, £23 5s.; *Cochin* spot, nominal, £28. *Palm*: Lagos on the spot, £22 10s. *Turpentine* dull at 21s. 9d. for American on the spot. *Petroleum Oil* steady; Russian spot, 4¾d. per gallon; American, 5¾d. per gallon; water

white, 6¼d. per gallon. *Petroleum Spirit*: American, 5½d. per gallon; deodorised, 6d. per gallon.

OPIUM—Without change from last week, with but very little doing.

PHENACETIN—Steady at 3s. 9d. to 4s. 3d. per lb. in bulk packing, according to quantity and make.

PHENAZONE—Is quiet with a continued weakening tendency in price. *Antipyrine Knorr* unchanged.

POTASH COMPOUNDS.—*Chlorate* is steady at 3¼d. per lb. on the spot. *Bicarbonate* firm at 30s. per cwt. for foreign crystal or powder, and 35s. for English. *Bromide* unchanged at 1s. 9¼d. per lb. *Iodide* firm at 9s. 9d. to 10s. 3d. per lb. according to quantity. *Bichromate* unchanged at 3¼d. to 3½d. per lb. *Prussiate* quiet at 7d. per lb. on the spot for yellow and 1s. 2d. per lb. for red. *Cyanide* still scarce for spot delivery, and firm in that position at 1s. 2d. per lb. for cake, 98 to 100 per cent. *Permanganate* dull at 62s. 6d. per cwt. for small and 67s. 6d. per cwt. for large crystals.

QUICKSILVER—Very firm at £7 12s. 6d. per bottle from importers, and 6d. less from second hand.

QUININE—Is very sick, and although second hand sellers are a shade easier buyers do not respond. Makers' price remains at 10d. per oz. in bulk packing.

SENEGA ROOT—Comes dearer from New York, and 1s. 3d. per lb. is now asked on the spot.

SHELLAC—Is very quiet, and whilst prices are steady at last quotations, but few transactions have taken place.

SODA COMPOUNDS.—*Crystals* 57s. 6d. per ton in barrels *Bicarbonate* in fair demand at £7 5s. to £7 10s. per ton, according to packing and quantity, for the 97 to 98 per cent., the fully-bicarbonated quality being still quoted 18s. 6d. per cwt. *Ash* steady at £5 5s. to £5 15s. per ton as to strength. *Bromide* unchanged at 2s. 0¼d. per lb. *Iodide* steady, 11s. 7d. per lb. *Caustic* 70 per cent. white £8 per ton.

SPICES (VARIOUS).—*Black Pepper*: Only 25 bags *Tellicherry* offered and sold at 4¼d. *White Pepper*: Only 54 bags offered and mostly sold; *Singapore*, 8¼d. to 9¼d.; *Penang*, 7½d.; *Ceylon* bought in at 9d. *Cinnamon chips*: 9 bags sold at 3½d. *Mace*: 4 cases *Penang* sold; good middling, partly wormy, 1s. 11d. to 2s.; good bold, 2s. 4d. to 2s. 5d.; 19 packages *West India* sold; common mixed to middling, 1s. 3d. to 1s. 6d.; good middling to good, 1s. 8d. to 1s. 11d.; fine bright, 2s. 4d. *Nutmegs* dull; 48 cases *Penang* all bought in; 133 packages *West India* all sold; 76's to 73's, 1s. 10d.; 80's, 1s. 9d.; 87's, 1s. 7d.; 98's to 90's, 1s. 3d. to 1s. 4d. *Pimento*: Of 348 bags only 78 bags sold at 5d.

SULPHATE OF COPPER—Is firm at £16 to £17 per ton, according to brand.

SULPHONAL—Still obtainable from the makers in limited quantity at 7s. 3d. per lb. in bulk.

TURMERIC—Continues very firm but quiet in consequence of high prices asked. *Bengal* quoted 21s. per cwt. *Madras* is very scarce and prices are nominal. *Cochin*: *Split bulbs* are dearer at 10s. 3d. to 10s. 6d. per cwt.

The quantities offered in to-day's drug sales were considerable, and for the season of the year a fair number of sales were effected, the following being the particulars as far as it was possible to give same at time of going to press:—

ACONITE ROOT.—10 bags *Japan* of fair quality were taken out at 27s. 6d. per cwt.

AMBERGRIS—1 tin weighing nett about 11 oz. of good grey spicy avour was held for 98s. per oz.

ANISEED.—50 bags fair *Italian* bought in at 24s. per cwt.

ANTIMONY.—20 cases *Japan* crude held for £23 10s. per ton.

ARGOL.—25 bags *Cape* sold at 50s. 6d. to 53s. per cwt. down to 42s. for low inferior quality.

BALSAM COPAIBA.—55 cases of fair quality part sold at 1s. 4d. per lb. 6 cases good *Maranham* being bought in 1s. 11d. per lb.

BALSAM PERU.—10 cases held for 8s. 6d., which shows a slight decline in value.

BALSAM TOLU.—18 cases, some of which were stated to contain, in addition to their legitimate contents, up to 8 lbs. of stones, sold at 1s. 2d. to 1s. 3d. per lb.

BUCHU LEAVES.—4 bales green rounds sold at 6¼d. per lb. being again dearer—the other lots offering are said to be held for much more than this price. Yellow leaves held for 4¼d. per lb.

CACTUS FLOWERS.—Four bags *Grandiflora* were taken out at 8d. per lb.

CAMPHOR OIL.—60 cases "pure" bought in at 20s. per cwt.

CARDAMOMS.—Fair greyish *Mysore* part rather brown sold at 2s. 3d. to 2s. 6d. per lb. down to 2s. for slightly splitting, fine bold plump ditto realising up to 4s. 1d. per lb. Small brown *Malabars* part sold at 2s. per lb. As a whole prices generally show a reduction of about 2d. per lb. on those previously ruling.

CINCHONA BARK.—28 bales flat *Calisaya* held for 8d. per lb.

CIVET.—5 horns of fair quality and flavour were taken out at 13s. 6d. per oz.

COCA LEAVES.—11 cases *Ceylon* sold without reserve at 9¼d. per lb. for good green part broken.

COLOCYNTH.—Small apple *Turkish*, fairly pale, bought in at 11d. to 1s. 2d., very seedy ditto being held for 11d. per lb. 5 cases selling at 10¼d. per lb. subject to approval.

COLOMBO ROOT.—11 bags picked washed were held at 35s. per cwt., 379 bags fair to good sorts sold freely at 16s. down to 8s. per cwt. for very inferior.

CROTON SEEDS.—7 bags part sold at 90s. per cwt. for good bright fair; darkish being bought in at 65s. per cwt.

CUBEBS.—52 bags somewhat stalky sold at 24s. per cwt.

CUSCUS ROOT.—14 bales of good quality, but more or less weighted with sand, sold at 12s. per cwt.; 3 bales cleaned held for 25s., which shows lower value.

CUTTLE FISH—Good bold pale sold at 5¼d. per lb. down to 4d. for rather darkish, and 3¼d. for small to medium.

DILL SEED.—85 bags good bright sold cheaply at 14s. per cwt.

DRAGON'S BLOOD.—4 cases fair thin *reed* sold at £8 17s. 6d. per cwt.

ERGOT OF RYE.—14 cases fair *Spanish*, slightly weevily held for 8d. per lb.; good sound ditto for 10d. Six bags fair greyish *Russian* sold at 7¼d. per lb., subject to approval.

GAMBOGE.—One case fair pipe sold at £7 5s. per cwt.

GENTIAN ROOT.—Seven bags sound old root were bought in at 22s. per cwt.

GUARANA.—5 cases of fair quality were held for 1s. 4d. per lb., a very low figure, there was, however, no demand.

GUINEA GRAINS.—Four bags [of fair quality] sold at 45s. per cwt.

GUM AMMONIACUM.—1 case dark and blocky sold at 10s. per cwt.

GUM ARABIC.—2 cases sorts were held for 62s. 6d. per cwt.

GUM BENJAMIN.—16 cases low *Siam* part sold at 52s. 6d. per cwt. Fine *Sumatra* was held for £10, medium to fair ditto for £6 to £6 5s. per cwt.

GUM GALBANUM.—15 packages bought in at 1s. 3d. per lb. down to 9d. for low inferior part blocky.

GUM GUAIAIACUM.—Ten cases broken block fair to drossy bought in at 9d. per lb.—6d. would, however, probably have been accepted. Fine glossy block sold at 1s. 10d. down to 11d. for more or less inferior and drossy.

GUM MYRRH.—7 casks good native picked held for 95s. per cwt., rough sorts for 55s.

GUM OLIBANUM.—3 cases siftings held for 15s. per cwt.

HONEY.—74 cases pale to brown crystallising *Honolulu* sold without reserve at 16s. 6d. per cwt., which may be regarded as decidedly cheap; 20 cases fair white *Peruvian* sold also without reserve at 18s. 6d. per cwt.

IPECACUANHA.—Good *Rio* sold at 9s. 2d. down to 8s. 11d. for slightly damaged. Four bales *Carthagena* sold at 4s. 8d. and 4s. 10d. per lb. for 1 and 2 *CCD* respectively.

KAMALA.—4 cases fair bright held for 6d. per lb., which is a decidedly moderate figure.

LIQUORICE ROOT.—50 bales rough *Syrian* bought in at 9s. 6d. per cwt.

MUSK.—Fine thin skin blue *Tonquin*, fair to bold, fairly dry, fine flavour sold at 70s. per oz.; ditto pile 3 pasty pods, few broken, bought in at 42s. 6d.; low, old-fashioned, unsightly and damp at 22s.

NUX VOMICA.—71 bags *Cochin* chiefly bought in at 10s. for good bright; dull selling at 6s. per cwt.

OILS (ESSENTIAL).—10 cases *Cajaputa* held for 3s. 9d. per bottle. 9 cases dementholised *Japan Peppermint Oil* part sold at 3s. 3d. per lb. 2 cases fine *Cinnamon Oil* bought in at 1s. 6d. per oz. 8 cases ditto leaf held for 3¼d. to 4¼d. per oz. 1 case *West Indian Oil of Limes* bought in at 4s., a bid of 3s. 7d. per lb. being refused. 2 cases *West Indian Bay Oil* sold at 5s. 9d. per lb. 23 cases *Cassia Oil* bought in at 5s. 2d. to 5s. 9d. per lb.

ORANGE PEEL.—Four cases good thin cut part sold at 8d., remainder only realising 7d. per lb.

ORRIS ROOT.—58 bales *East Indian* bought in at 10s. per cwt., a bid of 2s. 6d. per cwt. being declined.

OTTO OF ROSES.—4 vases bought in at 21s. per oz.

RHUBARB.—10 chests good bold flat high dried bought in at 1s. 3d. per lb., common selling at 9d. 2 cases fine trimming *Shensi* realised 2s. 10d. per lb., fine small round ditto being held for 3s., good bold round *Canton* held for 1s. 6d. per lb., good small fetching 1s. 5d., and second size rather roughish 1s. 2d. per lb., small flat sold at 1s. 2d. per lb.

SARSAPARILLA.—Fair *Jamaica* sold at 1s. 7d. to 1s. 8d. per lb., fair *Lima* at 1s. to 1s. 1d.; 2 bales 3 *CSD* selling at 11d. per lb., 7 bales good *Honduras* sold at 1s. 6d. per lb.

SENNA.—*Tinnevely* was in fair supply, the bulk being, however, of low quality, which sold well at 1½d. to 2¼d. for low spotty small, and 3d. to 3½d. for a few bales of new crop, the first of the season. In the next auctions it is said about 500 bales will be offered—mainly of new crop. *Alexandrian* variety was as usual mainly bought in, a few bales of siftings selling at 2¼d. per lb. *Mecca*: 47 bales bought in.

SERPENTARY ROOT.—Two bales fair bright part dark held for 1s. 2d. per lb.

TAMARINDS.—59 barrels fair *Antigua* sold at 10s. per cwt.

TONQUIN BEANS.—14 casks dampish *Angostura* were taken out at 5s. per lb., a bid of 3s. 6d. being declined. Fairly crystallised *Paras* were held for 1s. 9d. per lb.

VANILLA.—Rather over 150 tins were offered, the bulk being disposed of at late rates, one fine lot fetching 24s. per lb.

VERMILION.—4 cases *China* bought in at 2s. 1d. per lb.

WAX.—Fair *Madagascar* was brought in at £6 to £6 10s. per cwt., part selling at £5 12s. 6d. to £5 15s.; fair *Jamaica* sold at £6 15s.; 11 cases *Bombay* bought in at £5 10s.; 30 cases *Japan* fair squares held for 32s. per cwt.

Newcastle Chemical Report.

AUGUST 17, 1898.

New business in heavy goods keeps slow. Perhaps the only special feature of moment is the reduced make of Crystal Soda through the warm weather, prices, however, are unchanged all round. Such are: Soda crystals: 45s. to 52s. 6d. Bleaching Powder: £6 to £6 5s. Caustic Soda: 70 per cent., £7 5s. Soda ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. Sulphur: £5 per ton.

Liverpool Market Report.

AUGUST 17, 1898.

The only alterations since last report are in oils, several of which have advanced a shade in price, amongst others being Linseed and Cottonseed Oils and Spirits of Turpentine. Good sales of Ginger, Beeswax, and Cochineal have been effected at fair rates.

BEESWAX.—3 cases of Peruvian sold at auction for £7 7s. 6d. per cwt.

CANARY SEED.—Turkish continues firm at the improvement noted last week. 350 bags sold on private terms, and the nearest rate now is 28s. to 30s. per 464 lbs.

COCHINEAL.—10 bags of Teneriffe grey-black fetched 8½d. per lb.

GINGER.—175 bags sold—Sierra Leone at 18s. 6d., and Monrovia at 16s. 6d. per cwt.

OILS (FIXED) AND SPIRITS.—*Castor* is firm, but not quite so active; Calcutta 3¼d. per lb., Madras 3d., French 1st pressure 3½d., to arrive 5 tons, sold at £25 per ton, *f.o.b.* Brazilian has changed hands at 3½d. per lb. *Olive* maintains its recent advance, but no transactions have been reported in it. *Linseed* of Liverpool make has advanced slightly, and holders demand 18s. 3d. to 18s. 6d. per cwt. *Cottonseed* has also risen a shade, 16s. to 16s. 3d. per cwt. *Spirits of Turpentine* enjoy a fair demand at 22s. 6d. to 22s. 9d. per cwt.

POTASH SALTS.—*Bicarbonate*: 30s. per cwt. *Bichromate*: 3½d. per lb. *Chlorate*: 3½d. to 3¾d. per lb. *Cream of Tartar* is in slow demand at 78s. 6d. per cwt. for finest white. *Pearlashes* only nominal at 35s. per cwt. *Potashes* steady at the full rate of 22s. per cwt. *Saltpetre*: 21s. 6d. per cwt.

SODA SALTS.—*Bicarbonate*: £6 15s. per ton. *Borax*: £13 10s. to £14 per ton. *Caustic*: 76 to 77 per cent., £8 2s. 6d. to £8 5s. per ton. *Crystals*: £2 17s. 6d. to £3. *Nitrate* easier in price and slow in demand at 7s. 6d. to 7s. 7½d. per cwt.

Manchester Chemical Report.

AUGUST 17, 1898.

There is little now to report on home accounts, heavy chemicals being fairly firm, and it is reported that things have taken a turn for the better in regard to the States. It is sincerely to be hoped this is the case, as the margin of profit has for some time past been exceedingly small. Soda Crystals and Ammonia Alkali are still firm, but Bleaching Powder is dull at £5 per ton for soft wood casks on rails. Sulphate of Ammonia is variable, but makers here report a full order book forward, and do not seem disposed to offer. Brown Acetate, notwithstanding reports to the contrary, is dull, and low figures rule for firm orders. Ordinarily £4 17s. 6d. to £5 is the price. Sulphate of Copper is practically stationary at £17 per ton for best brands delivered Manchester. Benzols are, perhaps, a trifle firmer at 9½d. for 50's, 90's, and Naphthas are unchanged. Arsenic is very low comparatively, ranging from £14 to £14 10s. per ton, ex ship, Graston. Pitch is improving. Yellow Prussiate is still scarce and firm at 6¼d. to 7d. In Green Copperas local makers are fully booked for some time. Both Glauber and Epsom Salts are scarce owing to the hot weather, and there is an upward tendency. Epsoms are quoted 55s. and Glaubers 40s., in bags, on rails.

News in Brief.

MISS MARIAN J. NEWBIGIN, daughter of Mr. L. J. Newbigin, of Alnwick, and Lecturer in Zoology in the Edinburgh College of Medicine for Women, has recently obtained the degree of Doctor of Science from London University. Her subject was zoology, the title of her thesis being "On Certain Green (Chlorophylloid) Pigments in Invertebrates."

A MANUFACTURER'S MISTAKE.—Three Birmingham shopkeepers were summoned on the 6th inst. for selling adulterated borax. In two cases the samples contained 35 per cent. of sodium bicarbonate and in the third case the percentage was 25. Defendants informed the Bench that they sold the borax in the same state as it was received from the manufacturer, Mr. Josiah Austin, Excelsior Chemical Works, Nechells. It was pointed out that, finding a mistake had been made, Mr. Austin had sent circulars out to his customers asking for the return of all recent consignments of borax. Defendants were fined 5s. and costs each, and Mr. Austin undertook to pay the money.

FIRE AT A CHEMIST'S.—On Thursday morning, August 4, about one o'clock, a fire was discovered at the rear of the branch establishment of Mr. D. Davison, pharmaceutical chemist, Fakenham. The fire originated in a carpenter's shop adjoining Mr. Davison's premises, and spread to his warehouses, which were stored with very inflammable material. The contents of one warehouse and part of another were destroyed, and also some of the private belongings of the manager, Mr. J. C. Holton. The local fire brigade was summoned, and quickly got the flames under control. Everything was covered by insurance.

A NEW EDITION is announced for September of 'King's American Eclectic Dispensatory' in two volumes royal 8vo. It is entirely re-written and enlarged by Dr. Harvey W. Felter and Professor J. Uri Lloyd, the talented author of 'Etidorhpa.' Messrs. Potter & Clarke, of Artillery Lane, will be the British agents for the book.

WE UNDERSTAND that the projected amalgamation of several firms in the mineral water trade—comprising H. D. Rawlings, Ltd., Ray & Son, Ltd., Fleet & Co., Hooper, Struve & Co., and others—is indefinitely postponed. The share and debenture capital were fixed at £600,000, but the recent disclosures anent company promotion have probably convinced the promoters that the present time is scarcely opportune for the proposed flotation.

DEFICIENT GREGORY'S POWDER.—At Lambeth, on August 4, Thomas Tijou, of Upper Kennington Lane, was summoned at the instance of the Lambeth Vestry for selling a drug which was not of the nature, substance, and quality of the article demanded by the purchaser. Mr. W. J. Perrin, an inspector in the service of

the Vestry, said he purchased some Gregory's powder at the defendant's shop and submitted it to the public analyst, who certified the constituents to be rhubarb and ginger, 33'4; official carbonate of magnesia, 66'6. The analyst added the following note to his certificate:—"This article has been made with official carbonate of magnesia instead of the more expensive light magnesia required by the British Pharmacopœia." Mr. Hopkins remarked that it was most important that drugs should be kept pure, and ordered the defendant to pay a penalty of 40s. and 12s. 6d. costs.

MR. THOMAS STUART BARRIE, pharmaceutical chemist, enters the Glasgow and West of Scotland School of Pharmacy on September 1, as Lecturer in Chemistry and Pharmacy.

ACCIDENTAL POISONING CASES.

CARBOLIC ACID.—Emma Whale (50), of Stoke Newington, died on Friday, August 12, from the effects of carbolic acid poisoning. It appeared from the evidence at the inquest that she complained to her husband of the intense heat, and while he was gone for some supper beer, she evidently drank from a bottle containing carbolic acid, which stood on a table together with several others. A verdict of "death by misadventure" was returned.

LAUDANUM.—Bernard Beville Gilpin, of Sheerness, *locum tenens* for one of the regular staff of the Royal Naval Hospital, Yarmouth, was found at the Victoria Hotel, Yarmouth, on Monday, August 15, suffering from narcotic poisoning. A bottle containing whisky and an empty six-ounce laudanum bottle were found by his side. It was stated at the inquest that he was troubled with internal pain. The jury thought he had taken the laudanum to lull pain or to produce sleep, and that he inadvertently took an over-dose.

THE EXMOUTH CORONER AND THE CHEMIST.—Just before going to press a correspondent informs us that he has learnt from an authoritative source that Mr. Coroner Cox on Wednesday afternoon waited upon Mr. Bickford and apologised to him for making use of the remarks he made at the inquest, also expressing regret that he should have overlooked the provisions of the Pharmacy Act of 1869. Mr. Cox further undertook that at the next inquest held at Exmouth he would publicly repeat the apology to the jury summoned on that occasion.

OPIUM.—An inquiry was held at Bethnal Green on Saturday, August 6, respecting the death of Annie Parker, 40, domestic servant, of Cambridge Heath. From the evidence it appears that she suffered from diarrhoea, and applied to the parish doctor for medicine. He prescribed an opium mixture, which was supplied by the dispenser in a pint and a half bottle, with directions to take two tablespoonfuls as a dose. Shortly afterwards twelve doses had disappeared from the bottle, and the woman died from the effects of an overdose of opium. The jury thought it was a case of misadventure, and added to the verdict as a rider "That the authorities should not supply such powerful medicines in such large bottles."

A DOSE OF EMBROCATION was given to a young child at Brighton on Thursday, August 4, by its father, who got out of bed "half asleep" to give it medicine, but took up the wrong bottle. The embrocation contained in the bottle, which was not labelled "poison," had been procured at a local chemist's. The jury subsequently returned a verdict of "Death by misadventure," with a rider that chemists should be more careful in supplying embrocation.

Partnerships Dissolved.

(From the London Gazette.)

Edward A. Hearn and Sidney H. R. Wright (trading as Hearn, Wright & Co.), Glass Bottle Manufacturers, Eclipse Glass Works, Chatsworth Road, Lower Clapton. Debts will be received and paid by Edward A. Hearn.

E. Downes and A. Harper, Medical Practitioners, Mollerstein, Eastbourne. Debts will be received and paid by A. Harper.

S. B. Fairley and J. C. S. Matthews, Physicians and Surgeons, 159, Lichfield Road, Aston, Warwickshire.

Receiving Orders in Bankruptcy.

(From the London Gazette.)

Joseph H. J. Frye, Surgeon, 78, Camden Road, London, N. W.
R. J. Whitehead and John Cox (trading as Whitehead & Cox),
Camera Makers, 54, Irving Street, Birmingham.
James Cooke, Herbalist, etc., 71, Mill Road, Battley Carr,
Dewsbury.

Photographic Notes.

THE DOUBLE TRANSFER PROCESS is often thrown over in disgust, because of the trouble workers experience in getting the final support to leave the temporary. If only after the former has been squeegeed on to the latter, the two supports be placed on the rack of the kitchener, the finished print will peel off by itself very speedily, and with the utmost readiness, without a flaw, provided the heat from the fire be not too fierce.—M. E. M. D., in *Photo News*.

A VARNISH FOR WET NEGATIVES can be made as follows:—Dissolve 120 grains of borax and 30 grains of carbonate of soda in 5 ounces of warm water; add 480 grains of broken gum lac, and shake till dissolved; filter, and then add about 20 minims of glycerin, and water to make a total bulk of 10½ ounces. Stand aside for a few hours; filter, and varnish is ready for use. Varnish by soaking negative in liquid, the coating of gum being afterwards removed from glass side with a rag wetted with alcohol.—G. E. B., in *Photo News*.

EXCHANGE.

Prepaid Notices not exceeding thirty words are inserted at a fee of Sixpence, if they do not partake of the nature of ordinary advertisements. For every twelve words (or less) extra, the charge is Sixpence. A price, or two initials, count as one word. The fee for use of Serle Street address is Sixpence. All communications should reach "PHARMACEUTICAL JOURNAL" Office, 5, Serle Street, Lincoln's Inn, W.C., not later than 10 a.m. on Thursdays.

OFFERED.

Miscellaneous.

Photographic mounts, Bristol cartes, 3s.; G.B.E., 10s.; cabinets, 10s.; G.B.E., 15s.; quarter-plates, 6s.; half-plates, 12s. 1000; plate-sunk mounts, 12 by 10, 40s. 1000. Samples free.—Edward Peck, East Dereham, Norfolk.

Magic Lanterns, second-hand; triples and binials; oxyhydrogen microscope; marvellous pamphengos oil; lantern gives 14-ft. picture; 60,000 slides and effects; 4-in. 4-wick lanterns, 18s. 6d. each, bargains; illustrated list post free, 2d. Animated photographs: A splendid machine for £9 9s.—Hughes, Brewster House, 82, Mortimer Road, Kingsland, N.

A few gross Iolanthe Hair-curling Fluid, 3d. size, 18s. gross, carriage paid; Camwal Shares wanted.—S. Sugden, Pharmacist, Waterfoot, Manchester.

Overstocked.—2×10 lb. Coppers Superfine Oil of Lemon, 27s. 6d. copper; 1 lb. sample free by post 3s., postal order.—Moss, 34, Avondale Road, Chorley.

Moulds.—Suppository, Pessary, Bougie, Capsule, Fumigating Pastille, all Maw's patterns, some new; particulars free.—Warnes, Chemist, 333, Gray's Inn Road, W.C.

WANTED.

Old Platinum Utensils or Scrap, also Old Electric Lamps wanted for prompt cash by P. Rowsell, 14, Walcot Square, London, S.E.

Advertisement.

(Received too late for Classification.)

ENGAGEMENT wanted as **MANAGER**. Age 28. Good general experience. Highest references. **CHEMIST**, 5, Geddes Rd., New Wandsworth, S.W.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Culmer, Dewhurst, Farr, Forret, Haigh, Herbert, Hill, Hollick, Hyslop, Jack, Jowett, Kirkby, Lake, Matthews, Miller, Napier, Newbiggin, Owen, Sharp, Smyth, Spooner, Stamp, Stewart, Symes, Umney, Wardleworth, Warrell, Wells, Whitby, Wilkinson.

London Report.

The quotations here given are in all cases the lowest cash prices for bulk quantities, and often the articles quoted have to be sorted in order to suit the requirements of the retail pharmacist. The cost of freightage from the chemical and drug works to the various distributing centres must also be considered. It is important that these conditions should be borne in mind in making any comparison between the prices quoted and those of the wholesale drug trade.

AUGUST 25, 1898.

As might be expected at the season of the year, and partly also in consequence of the excessive heat of the weather, business has been very dull during the past week, and this applies more especially to the drug trade, while chemicals have also been decidedly quiet. There have also been practically no changes of importance to record. Quinine dull. Opium, morphia and codeia unchanged. Quicksilver and mercurials firm. Bleaching powder very firm. Bromides and Iodides steady. Sulphate of Ammonia again dearer. Acid Citric firm. Tartaric steady. Borax and Acid Boracic quiet. Acid Carbolic in good demand and steady. Cascara Sagrada very firm and expected to further advance. Cocaine firm. Acetanilide, Phenacetin, and Sulphonal unchanged. Glycerin firm. Cod-Liver Oil very quiet. Phenazone weak. Ipecacuanha firm. The following are the ruling prices for articles of chief interest:—

ACETANILIDE—Steady at 1s. per lb. for ton lots.

ACETIC ACID—Is unchanged. 1 to 7, 14s. 3d. per cwt.; *B.P.*, 15s. 6d. per cwt.; 50 per cent., 21s. 6d. per cwt.; 74 per cent., 30s. per cwt.; 85 per cent., 34s. per cwt.; *Glacial* 39s. 6d. per cwt.

ACID BORACIC.—A fair business passing at 23s. per cwt. for *Crystals*, and 25s. per cwt. for *Powder*.

ACID CARBOLIC—Is steady at 6½d. to 6¾d. per lb. for 35° to 36° C. *ice crystals* in large drums and overcasks. *Liquid*: 95 per cent. of pale straw colour, 1s. 2d. per gallon in 40-gallon casks.

ACID CITRIC.—Makers are firm at 1s. 3d. per lb. for *Crystals*, from second-hand round lots can be obtained at rather below this figure.

ACID OXALIC—Steady at 3½d. per lb. on the spot.

ACID TANNIC—Is steady at 1s. 9½d. per lb. for light *Crystals*, and 1s. 3½d. per lb. for *Powder*.

ACID TARTARIC—Steady at 1s. 1d. per lb. for English *Crystals*, and 12¾d. per lb. for foreign.

ALUM.—Loose lump is firm at £5 10s. per ton; ground, in bags, £6 per ton.

AMMONIA COMPOUNDS.—*Sulphate* is again dearer at £10 5s. per ton for grey prompt 24 per cent. London. Hull prompt £10 2s. 6d. per ton. *Carbonate* firm at 3½d. to 4d. per lb. according to package. *Bromide* steady at 2s. 1d. per lb. *Iodide* unchanged at 14s. 6d. per lb. *Sulpho-cyanide* in good demand at 1s. 2d. per lb. *Sal ammoniac*: Sublimed firsts 35s. per cwt., seconds 33s. per cwt.

ARSENIC—Firm at 19s. per cwt. for *powder*, and 34s. per cwt. for *lump*.

BALSAM CAPIVI.—Since last week's auctions, sales have been made of fair Central American, rather mixed in colour, at 1s. 3½d. to 1s. 4d. per lb.

BALSAM PERU—Remains quiet at 8s. 6d. per lb.

BLEACHING POWDER—Very firm at £6 15s. to £7 15s. per ton, according to brand, quantity, and packing.

BORAX—Steady at 14s. per cwt. for *lump*, and 14s. 6d. per cwt. for *powder*.

BROMIDES—Are without change at 1s. 9½d. per lb. for *Potass Bromide*.

CASCARA SAGRADA.—Reports from San Francisco state that very little has been gathered this season, and prices are sure to be considerably above present rates. Very little is offering for shipment. On the spot two year old bark is offered at 22s. 6d. per cwt., and four year old bark at 25s. 6d. per cwt.

CENTAURY HERB.—Ordinary is offered at 30s. per cwt., finest 42s. 6d. per cwt.

CHAULMOOGRA Oil—Is inquired for, and 2s. to 2s. 3d. per lb. is the general quotation for bulk packing.

CLOVES.—Privately the market for *Zanzibar* is flat, with little business doing; quotation for October to December delivery 4¼d. At auction 100 bales *Zanzibar* bought in; of 10 cases good picked *Penang*, 2 cases sold at 11d.

COAL TAR DISTILLATION PRODUCTS.—*Toluol*: Commercial 1s. 5d., pure 2s. 4d. per gallon. *Beuzole*: 50 per cent., 1s. 1d.; 90 per cent., 1s. per gallon. *Crude Naphtha*: 30 per cent. at 120° C., 5d. per gallon. *Solvent Naphtha*: 95 per cent. at 160° C., 1s. 9d. per gallon.

COCAINE.—Makers' price for best brands is 9s. 3d. per oz. for 100 oz. lots in 25-oz. tins, there being practically nothing available from second hand below this figure.

CODEIA—Without change and firm at 12s. 6d. per oz. for the *pure* and 1s. per oz. less for the salts.

COD-LIVER OIL.—Market is exceedingly quiet at nominally 85s. per barrel, *f.o.b.*, for best new non-freezing *Norwegian* oil in tin lined barrels of 25 gallons.

COLCHICUM SEEDS—Are very firm, 45s. per cwt. being asked on the spot.

GENTIAN ROOT—Is firm at 22s. per cwt. on the spot for good dry red root.

GINGER.—With an improved demand rather better prices ruled for *Cochin*. Of 901 bags rough about 650 bags sold, low shrivelled pickings, 12s.; cuttings, 14s.; ordinary small rough, 19s. 6d. to 20s.; small and lean brown rough, 23s.; fair to good washed rough, 24s. 6d. to 26s. Of 143 cases about 40 cases sold, medium and small native limes, partly cut, 42s. 6d. to 43s. 6d. 60 bags *Japan* bought in at 20s. *Jamaica* in fair demand and firm. Of 190 barrels about 130 barrels sold, middling to good middling washed at 72s. 6d. to 76s.; good to fine, 79s. to 90s.

GLYCERIN.—It is reported that an arrangement has been come to between the English makers of the refined article not to unduly cut the price; they would, however, still sell at 52s. 6d. per cwt., while 55s. to 65s. per cwt. according to quantity and brand, is quoted for the best *German* white double distilled chemically pure, 1260 quality, in tins and cases.

GUM MASTIC—Only inferior offering, clean pale tear wanted, nominal value 1s. 10d. to 2s. per lb.

HONEY.—*Californian* crop is reported to be short, and decidedly higher prices are anticipated. Good white is quoted 40s. per cwt.

IODIDES—Firm at 9s. 9d. to 10s. 3d. per lb. for *Potass. Iodide*, and 13s. 4d. for *Iodoform*.

IPECACUANHA.—*Rio* is very firmly held at 9s. per lb. for ordinary, whilst *Carthagena* is becoming scarce, and 5s. to 5s. 3d. per lb. is asked, according to quality.

JAPAN WAX—Is difficult of sale, although holders of good squares would be prepared to take 33s. per cwt.

MENTHOL—Firm at 7s. 1½d. to 7s. 3d. per lb. on the spot.

MERCURIALS—Are steady at 2s. 5d. per lb. for *Corrosive sublimate*

MORPHINE—Makers quote the *Hydrochlorate powder* 5s. per oz. for quantity and bulk packing, *crystal* being 2d. per oz. higher. and 2s. 10d. per lb. for *Calomet* in ½-cwt. lots.

OILS ESSENTIAL.—*Star Aniseed* is in good demand at 7s. 1½d. to 7s. 3d. per lb. *Cassia* quiet at 5s. to 5s. 9d. per lb., as to quality. *Lemongrass* quiet at 3¾d. per oz. *Citronelle* steady at 1s. 2d. per lb. *Peppermint*: *American* is steady; H.G.H. 5s. 7½d. to 5s. 9d. per lb. *Wayne County* 3s. 9d. to 4s. per lb., as to quality. *Japanese* is dearer in all positions; quotations from the other side come at 3s. 11d. per lb. *c.i.f.* for dementholised, and 4s. 11d. per lb. *c.i.f.* for 40 per cent. On the spot dementholised has been done at 3s. 3d. and 40 per cent. at 5s. per lb.

OILS (FIXED) AND SPIRITS.—*Linseed* dearer, closing firm at £17 for pipes, London; barrels, £17 7s. 6d. *Rape* firm at higher rates; ordinary brown on the spot £22 to £22 10s.; Refined £23 10s. to £24. *Cotton* slightly dearer at £15 15s. for London Crude spot; refined £15 7s. 6d. to £16, according to make. *Olive* steady at £29 to £32 for green oils and 5s. 6d. to 6s. 6d. per gallon for feeding oils. *Coco-nut* dearer at £23 10s. for Ceylon on the spot. *Cochin* being still quoted £28 nominally. *Palm Lagos* on the spot £22 10s. *Turpentine* quiet at 22s. per cwt. for spot American. *Petroleum Oil* firm. Russian spot 4¾d. per gallon; American 5¾d. per gallon; water white 6¾d. per gallon. *Petroleum Spirit*: American 5¾d. per gallon; deodorised 6¾d. per gallon.

OPIUM—Practically nothing doing, prices remaining nominally unchanged.

ORRIS ROOT—Is steady, best picked *Florentine* being quoted 42s. 6d. per cwt. *t.o.b.*

PHENACETIN—Without change at 3s. 9d. to 4s. 3d. per lb. according to quantity, for both *crystals* and *powder*.

PIHENAZONE—Quiet with a weak tendency at 9s. per lb. for *crystals* and *powder* for quantity and bulk packing. *Dr. Knorr's antipyrine* remains unchanged.

PODOPHYLLUM—Is in fair inquiry at 12s. 6d. per lb. for B.P. quality.

POTASH COMPOUNDS.—*Chlorate* unchanged at 3½d. per lb. on the spot. *Bromide* steady at 1s. 9½d. per lb. *Bicarbonate* steady at 30s. per cwt., for Foreign, 35s. per cwt. for English in crystal or powder. *Prussiate* quiet at 7d. per lb. for yellow 1s. 2d. for red. *Bichromate* firm at 3½d. to 3¾d. per lb. *Iodide* quiet at 9s. 9d. to 10s. 3d. per lb., according to quantity. *Cyanide* the spot at 1s. 2d. per lb. for cake, 98-100 per cent. *Permanganate* very dull at 62s. 6d. per cwt. for small, and 5s. per cwt. more for large crystals.

QUICKSILVER—Firm at unchanged values, first hand £7 12s. 6d. per flask, secondhand £7 12s.

QUININE.—Very quiet, makers' price remaining unchanged at 10d. per oz. for best *German* brands of sulphate in 100-oz. tins and 1000-oz. lots.

SALICINE—Remains firm at 10s. 6d. per lb. for fair lots.

SENNA.—There has been a fair demand for *Tinnevelly* since last week's sales, and several lots bought thereat have been resold. It is anticipated that prices for new crop will remain steady.

SHELLAC.—At the auctions on Tuesday only small supplies were offered, but, notwithstanding this, demand was very slow, and only about one-fourth found buyers at about previous rates. Of a total of 426 cases 102 cases sold. *Second Orange*: Ordinary red flat free sold 61s. per cwt., dark red Rangoon hard block at 50s. to 53s. per cwt. *Garnet*: Hard block Rangoon sold 52s. to 53s. per cwt. *Button*: Genuine sold at 89s. to 92s. per cwt. Privately the demand is slow, and sales are quite unimportant. *TN Orange* basis fair quoted 63s. per cwt.

SODA COMPOUNDS.—*Crystals*, 57s. 6d. per ton in barrels. *Bicarbonate* steady at £7 5s. to £7 10s., according to quantity and packing. *Bichromate*, 2¾d. to 3d. per lb. *Bromide* unchanged at 2s. per half pound. *Ash* firm at £5 5s. to £5 15s. per ton, according to strength. *Caustic*: 70 per cent. white, £8 per ton; 60 per cent., £7 per ton. *Nitrate*: Refined, £8 per ton; ordinary, £7 12s. 6d. per ton.

SPICES.—*Black Pepper*: nearly all bought in, Penang at 4¾d. to 5d., Lampong 4¾d., Singapore 4¾d. to 4½d., Aleppy 4¾d., and Wynaad at 5d., 8 bags Malabar sold at 4¾d. *White Pepper*: also almost all bought in; 54 bags Singapore sold at 8¾d. to 9½d., and 5 cases extra fine bold at 10½d. *Cassia Lignea*: of 390 boxes 140 sold at 54s. to 54s. 6d. *Cassia Buds*: 18 bags wild Bombay bought in at 35s. *Mace*: Of 6 cases Penang only 1 case pickings sold at 1s. 4d.; 13 packages West India sold at 1s. 4d. to 1s. 6d. *Nutmegs*: Quiet at about previous rates. *Pimento*: Quiet but steady; of 522 bags only 75 bags sold at 4¾d. to 5d.

STAR ANISEED.—*China* continues very firm on the spot at £6 per cwt.

STRYCHNINE—Steady at 2s. 1d. per oz. for pure crystals, 2s. for precipitated, and 1s. 9d. for sulphate or nitrate.

SULPHATE OF COPPER—Steady at £16 to £17 per ton according to brand.

SULPHONAL.—Makers still quote 7s. 3d. per lb. in bulk for limited quantity for immediate delivery, declining, however, to book for later delivery.

TURMERIC—Is quiet but mainly owing to the scarcity of offers. *Bengal* quoted 20s. per cwt. *Cochin*: Split bulbs 10s. 6d. per cwt. *Madras*: None offering.

Newcastle Chemical Report.

AUGUST 24, 1898.

Steadiness prevails on this market, but mostly for heavy goods. Shipments to the Baltic are on a larger scale; but the weather preventing the making of Soda Crystals is causing that article to be slightly scarce. General prices go unchanged. Such are: Soda Crystals: 45s. to 52s. 6d. Bleaching powder: £6 to £6 5s. Caustic Soda: 70 per cent., £7 5s. to £7 10s. Soda ash: 52 per cent., £4 5s. Alkali: 52 per cent., £5 5s. Sulphur: £5 per ton.

Manchester Chemical Report.

AUGUST 24, 1898.

There is little activity in heavy chemicals, although a certain amount of contract business over next year is being put through. Bleaching Powder is quoted at £5 per ton, soft wood casks, on rails, for home consumption, but for export there is a great falling off in values. The new processes in Caustic Soda and Soda Ash are evidently telling a tale, and it is evident that great changes are impending. Values, however, cannot fall much lower, or even under improved methods of production the margin will be unremunerative. For prompt delivery Sulphate of Copper remains at £17 per ton best brands here, but for spring delivery much higher figures are quoted, and at these makers are not inclined to sell great quantities. Brown Acetate of Lime is dull, but without material change, at £4 17s. 6d. to £5 2s. 6d. per ton *c.i.f.* Ship Canal or station, Manchester. Benzols are firmer, and it is thought that a syndicate to regulate production in the future may have some effect in improving prices. Anthracene values are low, but the outlook for Pitch is better. Naphthas continue firm. In Saltcreek a considerable business over next year is reported at 25s. to 26s. per ton in bulk on rails. Yellow Prussiate is well sold for local make at 6¾d. to 7d. per lb.

Liverpool Market Report.

AUGUST 24, 1898.

The only special point about this week's market is that the spot price for Spanish Olive Oils is below that asked at present in Spain, a state of things brought about by the prospect of shortage in the Spanish olive harvest, due to the young fruit dropping off with the extreme heat. Chilian Honey and Spermaceiti have been selling in some quantity at fair rates.

AMMONIA SALTS.—*Carbonate*: 3d. per lb. *Sal ammoniac*: 33s. to 35s. per cwt. *Sulphate* is firm and dearer, £10 to £10 12s. 6d. per ton.

CANARYSEED.—Turkish commands more attention, and 800 bags of old crop seed sold at 28s. 6d. per 464 lbs.

COPPERAS.—Lancashire, 39s. per ton. Welsh, 37s. per ton, has risen considerably.

COPPER SULPHATE—Closes very firm at £17 to £17 10s. per ton.

HONEY.—250 barrels of Chilian found buyers at 22s. per cwt. for Pile 1, 22s. for Pile 2, and 21s. for Pile 3. Lots of Pile 3 have since sold for 21s. 6d.

LINSEED.—Transactions have been limited, owing to extreme figures asked by holders. 100 bags of Calcutta sold, ex-quay, at 36s. 6d. per 416 lbs., and 30 tons of River Plate at 33s.

OILS (FIXED) AND SPIRITS.—*Castor* is unchanged in price from last week. Calcutta, 3¾d. per lb., French 1st pressure, 3½d. per lb.; Madras, 3d. to 3½d. per lb. *Olive* has been selling here at £30 10s. to £31 10s. per tun for Malaga, and £30 to £30 10s. for Seville. The price in Spain for shipment is, Malaga £32 to £34 10s.

per tun and Seville £31 10s. to £32 10s. Holders here having disposed of the cheaper lots are withdrawing their stocks in anticipation of higher prices. *Linseed* of Liverpool pressure is steady at 18s. to 18s. 6d. per cwt. *Cottonseed* continues at 16s. to 16s. 3d. per cwt. with fair demand. *Spirits of Turpentine* are again at 22s. 6d. to 22s. 9d. per cwt., after dropping 3d. per cwt. early in the week.

POTASH SALTS.—*Bichromate*, 3½d. per lb. *Chlorate*, 3¾d. to 3¼d. per lb. *Cream of Tartar* is unchanged. *Pearlashes* are slow of sale at 35s. per cwt. *Potashes*, 22s. per cwt. *Prussiate* quiet, 6½d. to 6¼d. per lb.

SODA SALTS.—*Bicarbonate*, £6 15s. per ton. *Borax*, £13 10s. to £14 per ton. *Caustic*: 76 to 77 per cent., £8 per ton. *Crystals*, £2 17s. 6d. to £3 per ton. *Hyposulphite*, £4 17s. 6d. per ton. *Nitrate*, 7s. 7½d. to 7s. 9d. per cwt.—a slight improvement.

SPERMACEYL.—20 cases of Chilian refined changed hands at 1s. 1d. per lb.

THE BRITISH ASSOCIATION.

The President of the Association at the Bristol meeting, which commences next week, will be Sir William Crookes, under whose supervision arrangements for the meeting are steadily progressing, and in many of the sections the programme is practically complete. The President of the Geological Section is Mr. W. H. Hudleston, F.R.S., and in his presidential address he is expected to deal mainly with certain points in the geology of the south-west of England east of Dartmoor. In the Chemical Section Professor F. R. Japp, F.R.S., will preside, and it is expected that his address will deal principally with stereo-chemistry and vitalism.

A joint meeting of Sections A and B will be held on Monday, September 12, to discuss the results of the recent eclipse expeditions, when Captain Abney and Dr. T. E. Thorpe will probably be present to represent the chemists. Professor W. Ramsay and Dr. Morris Fraser are to communicate an account of their recent discoveries in a paper entitled "On the Extraction of Argon and on Neon." The spectra of those new constituents of the atmosphere will be exhibited at the *soirée* at Clifton College. Dr. W. J. Russell will read a paper on his recent photographic work, which deals with peculiar radiations emanating from metallic surfaces, and which are capable of affecting a photographic plate. "Some Researches on the Thermal Properties of Gases and Liquids" is the title of a paper by Professor Sydney Young, which will include, among other points of interest, an account of his work on practical distillation and its application to the separation of pure hydrocarbons from American petroleum. Mr. Wertheimer is to read a paper on "The Influence of Examinations on the Teaching of Chemistry." Several other papers of a technical character have also been accepted, which, together with the reports of Committees, give promise of good and plentiful work for the section.

The President of the Anthropological Section is Mr. E. W. Brabrook, C.B., F.S.A. He will deliver his address on Friday, instead of on Thursday, so that it shall not clash with those of the other sections. The section will, however, meet on Thursday, September 8, to discuss papers on subjects relating to China and Eastern Asia generally. The Botanical Section will be presided over by Professor F. O. Bower, F.R.S., whose address will probably be devoted to discussing present views as to the classification of the members of plants. There will also be a discussion on alternation of generations, which will be opened by Dr. W. H. Lowé. In the Economic Science Section the President is Professor Bonar, LL.D. He will deliver his address on Thursday, Sept. 8. One of the most important meetings of world-wide interest to experts will be that of the International Conference on Terrestrial Magnetism. To attend this Conference delegates from a great number of foreign countries are expected.

Partnerships Dissolved.

(From the London Gazette.)

Robert Chase and Robert W. Chase (trading as Robert Chase & Son), Brush Manufacturers, Upper Dean Street, and 9, Spiceal Street, Birmingham. Debts will be received and paid by Robert W. Chase, who will continue the business under the old style.

Carlton H. Riches and Herbert C. Riches, Dentists, 24, Dumfries Place, Cardiff, 22, Windsor Terrace, Penarth, and at Bridgend.

Trade Notes.

A NOVEL HAND LAMP.

THE SIMPLEX-SALUS LAMP Co., 13, Walness Road, Lower Broughton, Manchester, sends a specimen of the "Simplex-Salus" hand lamp. As the name implies, it is simple in construction, but at the same time perfectly safe. The metal container, which is packed with absorbent material, is filled with petroleum oil and then inverted so as to allow the oil to drain away, after the style of the old-fashioned benzoline lamps. A round spirit wick (¼ in. diameter) is used, the flame being protected by a metal reflector. Thus there is nothing to break, to spill, or to explode, and the lamp can be employed for reading or as a night lamp. It should be very useful for all purposes where candles have formerly been used, while the cost is exceedingly small.

NOTICE OF REMOVAL.

MESSRS. AYRTON & SAUNDERS, of LIVERPOOL, in consequence of increased business, have vacated their warehouse in Duke Street, and have removed to larger and more centrally situated premises in Hanover Street and Campbell Street, which have been specially designed and built to suit the requirements of their business. Messrs. Ayrton & Saunders employ nearly 400 hands and manufacture on their own premises such articles as boxes, menthol cones, abdominal belts and trusses. We have received from them an advance copy of their new illustrated price current, which contains nearly 400 pages and more than 2000 illustrations. It is of convenient size, cloth bound, with rounded edges, and it certainly is one of the most useful and comprehensive price-lists of druggists' sundries that we have yet seen. To afford some idea of the profuse way in which it is illustrated, there are 169 illustrations of bottles, forty-six patterns of baby comforters, 114 patterns of forceps, sixty illustrations of pessaries, forty-three specimens of burnt-in pots for cold cream, etc., and many other interesting features, but as Messrs. Ayrton & Saunders will forward a copy to any of our readers who may write for one, there is no need for us to particularise further.

News in Brief.

THE STUDENTS' NUMBER.—The usual annual students' number of the Journal will be published on September 10 next. Secretaries of technical schools and principals of schools of pharmacy are therefore invited to send particulars of courses of instruction suitable for pharmaceutical students. Such particulars should be summarised on the lines of what was published in the Journal of September 11, last year, and should reach the Editor, 17, Bloomsbury Square, W.C., as early as possible next week. The Editor will also be pleased to receive any other information that may prove useful to students.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.—The monthly botanical ramble on Wednesday, August 31, is to Bickleigh, Shargh, and Wickford Down. Train leaves Millbay, at 3.5 p.m.

BORACIC ACID IN FOOD.—The prosecutions recently instituted by the Birmingham Health Committee in respect of boracic acid used as a food preservative have given rise to a good deal of anxiety amongst members of the grocery trade. The local Grocers' Association met on Monday evening and passed a resolution deploring any such action, whilst the subject of food adulteration is still under the consideration of the Government, and requesting the Members of Parliament for the district to impress upon the Government the urgent necessity of setting up a national standard of the percentage of boracic acid that may be used by traders without fear of a conviction for adulteration.

THE LOCAL GOVERNMENT BOARD FOR IRELAND has directed the attention of the Irish Boards of Guardians to the issue of a new British Pharmacopœia, and to the fact that contractors for medicine are obliged by the terms of their bond to supply all drugs in accordance with the standard prescribed by the latest edition of the Pharmacopœia. The Local Government Board considers that the Guardians should instruct the clerks of the unions to com-
